Theorem 699.91 (Real tail-agreement seal shared-threshold window admission)**.** *For every accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet* $Q = (R, S, W, D, A, H, C, P, N)$*, the paired* $\mathsf{StreamName}^{\uparrow}$ *windows carried by* W *are admitted only after the* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ *limiter rows and the* $\mathsf{RegularCauchyTailBudget}^{\uparrow}$ *threshold rows have been displayed. Thus any public read of* A *first exposes the finite observation budget, then the regular tail-budget threshold, and only then the paired window service used by* W*.*

Proof. Project the carrier of Definition 699.1. The only window service available to the packet is the displayed row W, and it is attached to the paired source rows R, S before the readback row D and agreement row A are visible.

Use the NameCert obligations of Definition 699.2. Carrier admission, tail-window coverage, and dyadic readback exactness force the public route to encounter W before D and A.

Apply the limiter-budget factorization theorem above and the shared-tail budget extraction row. Together they put that same W behind the observation limiter and regular tail-budget threshold rows, so no accepted packet admits its paired windows through an unbudgeted tail request. □

Theorem 699.92 (Real tail-agreement seal dyadic readback route totality)**.** *Every dyadic readback route of an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet is total only through the displayed chain*

$$W \to D \to A.$$

The chain reads the paired $\mathsf{StreamName}^{\uparrow}$ *windows, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *agreement row consumed by* $\mathsf{Real}^{\uparrow}$*; no route from the accepted packet reaches* A *by skipping* W *or* D*.*

Proof. Begin with the shared-threshold window admission theorem. It places every accepted paired window read behind the limiter and regular tail-budget rows before the local route reaches W.

Next apply the regular-source transport theorem above. The two $\mathsf{RegSeqRat}^{\uparrow}$ source rows are transported through the displayed $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ readback rows, so the source data seen by the agreement row remain on the same finite route.

Finally use dyadic readback exactness and window-agreement determinacy. These rows make D the readback surface determined by W, and make A the agreement row determined by that readback surface; hence the public dyadic readback route is total exactly along $W \to D \to A$. □

Theorem 699.93 (Real tail-agreement seal Real completion consumer exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet is exhausted by the finite route*

$$R, S, W, D, A, H, C, P, N.$$

This route is read together with the sibling budget, tail-meet, tail-fusion, $\mathsf{CauchyLimitSeal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *packets; it supplies no quotient stream equality, selected limit, host convergence predicate, open completion selector, or additional consumer row outside the displayed carrier.*

Proof. Start from the Real handoff exhaustion theorem above. It states that a Real-facing consumer can inspect only the displayed rows $R, S, W, D, A, H, C, P, N$ after the limiter-budget and regular-source transport routes have been exposed.

Use the shared-threshold window admission and dyadic readback route totality theorems. They identify the budgeted entrance into W and the complete readback path $W \to D \to A$ used by both Real- and Completion-facing consumers.

Now compose the sibling routes already present in the chapter. The shared-tail budget extraction supplies the budget row, the regular-tail meet and fusion chapters supply the finite tail surfaces, and the Completion handoff totality theorem routes the consumer through the Cauchy-limit and Real sibling packets.

The remaining carrier rows H, C, P, N provide componentwise transport, continuation, provenance, and local naming. Since these are the only structural rows in the accepted carrier, the consumer surface has no place to store a quotient stream equality, selected limit, host convergence predicate, or extra completion selector. □

Theorem 699.94 (Real tail-agreement seal CauchyLimitSeal budget handoff)**.** *Suppose an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet and an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet share the same regular source rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal surface. Then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer factors through the CauchyLimitSeal budget source totality row before reading the local agreement edge*

$$W \to D \to A.$$

The handoff exports no quotient stream, selected limit, host convergence predicate, hidden family limit, or ambient completeness coordinate.

Proof. Begin with paired-threshold coverage from Definition 699.87. It places the agreement packet behind the common finite threshold route before the local rows W, D, A are read.

Use Definition 699.93. Any $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer is already confined to the displayed rows $R, S, W, D, A, H, C, P, N$ together with the named sibling budget and completion surfaces.

Now apply CauchyLimitSeal budget root source totality from Definition 386.87. The shared regular source, finite window, dyadic readback, and real seal rows must pass through the accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ budget packet before the local agreement edge is exposed.

Attach dyadic-window exactness from Definition 386.88 and the dyadic readback route totality of Definition 699.92. These rows identify the budget window with the seal-side finite ledger and then read the local route exactly as $W \to D \to A$.

Finally apply root completion consumer non-escape from Definition 386.94. After the consumer has passed through the budget source totality row and the local agreement edge, no quotient stream, selected limit, host convergence predicate, hidden family limit, or ambient completeness coordinate remains available. □

Theorem 699.95 (Real tail-agreement seal budget Real handoff)**.** *For every accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet* $Q = (R, S, W, D, A, H, C, P, N)$*, any* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{Completion}^{\uparrow}$*-facing consumer reaches the* $\mathsf{Real}^{\uparrow}$ *seal only after the route through* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$*,* $\mathsf{RegularCauchyTailBudget}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{CauchyLimitSeal}^{\uparrow}$*. The local rows exposed to that consumer are exactly*

$$R, S, W, D, A, H, C, P, N.$$

The handoff exports no quotient stream, selected limit, host convergence predicate, or choice-selected tail.

Proof. First bind the finite budget entrance. Apply Definition 699.85 and Definition 699.91. They put every accepted read behind the observation limiter and regular tail-budget threshold before the paired $\mathsf{StreamName}^{\uparrow}$ window row W is visible.

Next bind the local readback. Use Definition 699.92. The route from W to the agreement row must pass through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ readback row D, so the local edge is exactly $W \to D \to A$.

Now attach the CauchyLimitSeal boundary. Apply Definition 699.94. It forces the shared regular source, finite window, dyadic readback, and $\mathsf{Real}^{\uparrow}$ seal surface through the accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ budget packet before any Real or Completion consumer can read the local agreement edge.

Finally use Definition 699.93. Its non-escape clause confines the consumer to $R, S, W, D, A, H, C, P, N$ and leaves quotient streams, selected limits, host convergence predicates, and choice-selected tails outside the handoff. □

Theorem 699.96 (Real tail-agreement seal root budget route determinacy)**.** *Let* $Q = (R, S, W, D, A, H, C, P, N)$ *and* $Q' = (R', S', W', D', A', H', C', P', N')$ *be accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packets. Suppose the two packets share the same* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$*,* $\mathsf{RegularCauchyTailBudget}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *budget rows, and suppose the displayed rows agree componentwise:*

$$R = R', \quad S = S', \quad W = W', \quad D = D', \quad A = A', \quad H = H', \quad C = C', \quad P = P', \quad N = N'.$$

Then Q *and* Q' *determine the same public* $\mathsf{Real}^{\uparrow}/\mathsf{Completion}^{\uparrow}$ *handoff route. The route is the displayed chain through the shared limiter budget, shared regular Cauchy tail budget, shared stream window, shared dyadic readback, shared CauchyLimitSeal budget packet, and the same public rows*

$R, S, W, D, A, H, C, P, N$. No quotient stream, selected limit, host real equality, hidden family limit, or ambient completeness coordinate is available to distinguish the two handoffs.

Proof. First apply limiter-budget factorization. By Definition 699.85, both accepted packets enter the public handoff through the same finite observation limiter and the same regular tail-budget threshold rows.

Next use dyadic readback route totality. Definition 699.92 fixes the local read of the shared window and dyadic rows as the displayed route $W \to D \to A$; componentwise agreement makes this local route identical for Q and Q'.

Attach the CauchyLimitSeal budget handoff with Definition 699.94. Since the $\mathsf{CauchyLimitSeal}^{\uparrow}$ budget packet is shared, the regular source, finite window, dyadic readback, and seal-facing budget rows are the same public rows on both sides.

Finally apply the budget Real handoff theorem above. Definition 699.95 confines every $\mathsf{Real}^{\uparrow}$- or $\mathsf{Completion}^{\uparrow}$-facing read to the same displayed rows and named budget surfaces. The excluded quotient stream, selected limit, host real equality, hidden family limit, and ambient completeness coordinate are not fields of either handoff, so they cannot separate the two public routes. □

Theorem 699.97 (Real tail-agreement seal budget-fusion non-escape)**.** *Let $Q = (R, S, W, D, A, H, C, P, N)$ and $Q' = (R', S', W', D', A', H', C', P', N')$ be accepted $\mathsf{RealTailAgreementSeal}^{\uparrow}$ packets. Suppose the two packets share the same limiter budget, regular Cauchy tail budget, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ readback, $\mathsf{CauchyLimitSeal}^{\uparrow}$ budget packet, and displayed carrier rows:*

$$R = R', \quad S = S', \quad W = W', \quad D = D', \quad A = A', \quad H = H', \quad C = C', \quad P = P', \quad N = N'.$$

Then every $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer of Q and Q' factors through the same finite budget-fusion surface

$$\mathsf{ObservationBudgetLimiter}^{\uparrow} \to \mathsf{RegularCauchyTailBudget}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{CauchyLimitSeal}^{\uparrow} -$$

After this factorization the consumer cannot distinguish the two handoffs by quotient stream equality, selected limit, host convergence, choice-selected tail, hidden family limit, or ambient completeness data.

Proof. First bind the shared finite budget entrance. Apply Definition 699.85. Both accepted packets must pass through the same observation limiter and regular Cauchy tail-budget rows before any local agreement row can be read.

Next bind the displayed window and readback route. Use Definition 699.92. The shared $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ rows make the local path exactly $W \to D \to A$ on both packets, and the componentwise row equalities identify the displayed carrier surface.

Now attach the completion-facing budget packet. Apply Definition 699.94. The shared $\mathsf{CauchyLimitSeal}^{\uparrow}$ packet receives the same regular source, finite window, dyadic readback, and $\mathsf{Real}^{\uparrow}$ seal surface before any Real or Completion consumer can inspect the handoff.

Finally use root budget route determinacy together with the Real and Completion consumer exhaustion rows. Definition 699.96 identifies the public handoff route, while Definition 699.93 and Definition 699.95 list the available consumer rows. Quotient stream equality, selected limits, host convergence predicates, choice-selected tails, hidden family limits, and ambient completeness data are outside that list, so they cannot distinguish the two handoffs. □

Theorem 699.98 (Real tail-agreement seal budget source totality)**.** *Every accepted $\mathsf{RealTailAgreementSeal}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ through the budget route is sourced exactly by the limiter*

budget, regular tail budget, finite $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback,* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *budget packet, and displayed rows* $R, S, W, D, A, H, C, P, N$*. It cannot introduce an unlisted tail source, quotient stream equality, host convergence predicate, selected limit, or ambient completeness coordinate.*

Proof. First apply limiter-budget factorization from Definition 699.85. It places the accepted consumer behind the observation limiter and regular Cauchy tail-budget rows before any agreement seal is available.

Next use dyadic readback route totality from Definition 699.92. The finite $\mathsf{StreamName}^{\uparrow}$ window reaches the agreement row only through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ readback, so the local route is fixed by W, D, A.

Attach the completion-facing budget packet with Definition 699.94. Then apply the budget Real handoff of Definition 699.95. These two rows put the regular source, finite window, dyadic readback, and $\mathsf{Real}^{\uparrow}$ seal surface on the same $\mathsf{CauchyLimitSeal}^{\uparrow}$ budget packet.

Finally use budget-fusion non-escape from Definition 699.97. The consumer has already factored through the limiter, regular tail budget, window, readback, CauchyLimitSeal packet, and displayed carrier rows, so no unlisted tail source, quotient stream equality, host convergence predicate, selected limit, or ambient completeness coordinate remains. □

Theorem 699.99 (Real tail-agreement seal top formal target boundary)**.** *Any formalization target for* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *that requests a* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer must first expose the finite route through* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$*,* $\mathsf{RegularCauchyTailBudget}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, componentwise* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. The target is therefore a boundary theorem about the displayed packet* $Q = (R, S, W, D, A, H, C, P, N)$ *and the named sibling budget route, not a theorem about quotient streams, selected limits, host convergence predicates, or ambient completeness.*

Proof. First bind the budget entrance with Definition 699.85 and Definition 699.86. These rows force any accepted seal read through the observation limiter and regular Cauchy tail-budget rows before the local route can inspect W, D, or A.

Next bind the local readback with Definition 699.92. The route to the agreement row is total only as $W \to D \to A$, so a formal target cannot bypass the $\mathsf{StreamName}^{\uparrow}$ window or the $\mathsf{DyadicRatCore}^{\uparrow}$ readback.

Then attach the completion-facing seal boundary using Definition 699.94. It sends the shared regular source, finite window, dyadic readback, and $\mathsf{Real}^{\uparrow}$ seal surface through the accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ budget packet.

Finally apply Definition 699.95 and Definition 699.98. Together they confine every $\mathsf{Real}^{\uparrow}$- or $\mathsf{Completion}^{\uparrow}$-facing request to the displayed carrier rows and the structural hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, leaving quotient streams, selected limits, host convergence predicates, and ambient completeness outside the target boundary. □

Theorem 699.100 (Real tail-agreement seal root window-budget determinacy)**.** *Let* $Q = (R, S, W, D, A, H, C, P, N$ *be an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet. The displayed finite window row* W *determines the budgeted dyadic agreement route through* D *and* A*: every root-facing read that has reached* W *through the admitted observation limiter, regular tail-budget, and shared-threshold surface can reach the agreement row only along*

$$W \to D \to A.$$

There is no second dyadic readback row, no hidden agreement coordinate, and no selected tail outside the displayed packet route.

Proof. Project the carrier Q. The only paired window coordinate is W, the only dyadic readback coordinate attached to it is D, and the only agreement coordinate downstream of that readback is A.

Use root budget-selector admission and root budget shared-threshold factorization. They put the root read behind the admitted limiter, tail-budget, selector-budget, and shared-threshold rows before W can be consumed.

Finally apply dyadic readback route totality. Once W is displayed, D is the unique dyadic readback supplied to the local agreement edge, and A is reached only through that readback. Since the remaining rows H, C, P, N provide transport, replay, provenance, and naming, they add no alternate dyadic or agreement route. □

Lean4 ✓ `BEDC.Derived.RealTailAgreementSealUp.RealTailAgreementSealCarrier root window budget determinacy`

Theorem 699.101 (Real tail-agreement seal root criterion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *criterion handoff consuming an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet* $Q = (R, S, W, D, A, H, C, P, N)$ *factors through the sibling routes* $\mathsf{RegularCauchyTailBudget}^{\uparrow}$, $\mathsf{ObservationBudgetLimiter}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, *and* $\mathsf{RegularCauchyTailFusion}^{\uparrow}$ *before it reaches the local route* $W \to D \to A$*. The handoff is therefore a finite BEDC route through budget, limiter, meet, fusion, paired window, dyadic readback, agreement, transport, continuation, provenance, and local naming rows.*

Proof. Begin with the root budget shared-threshold factorization. It records the observation limiter, regular tail-budget, and tail-meet route as the root-facing entrance to the local paired-window surface.

Attach the tail-fusion consumer through the same shared threshold. The fusion row consumes the already displayed tail-meet and budget rows, so it cannot introduce a second tail source or a separate threshold for the Real or Completion criterion.

Now use root window-budget determinacy. The local criterion handoff continues through W, then D, then A, with H, C, P, N supplying only componentwise transport, displayed replay, provenance, and naming. Thus the criterion handoff factors through exactly the named sibling routes and the local finite packet rows. □

Theorem 699.102 (Real tail-agreement seal root selector-budget compatibility)**.** *Let* $Q = (R, S, W, D, A, H, C, P,$ *be an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet. Every* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *or* $\mathsf{RegularCauchySelectorBud}$ *consumer that attempts to issue a selected-budget read or a tail-agreement read from* Q *must first pass through the finite selector surface of chapter 782 or chapter 678, the* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ *limiter of chapter 903, the* $\mathsf{RegularCauchyTailBudget}^{\uparrow}$ *budget of chapter 906, the shared tail-meet surface of chapter 560, the tail-fusion surface of chapter 658, and the criterion handoff of Definition 699.101. Only after that route is displayed may the consumer read the local chain*

$$W \to D \to A.$$

The compatibility row exports no selected limit, quotient stream equality, host real equality, trichotomy row, independent tail oracle, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.RealTailAgreementSealUp.RealTailAgreementSealCarrier root selector budget compatibility`

Proof. Start with the root criterion handoff. It already places every Real or Completion criterion consumer behind the budget, limiter, tail-meet, and tail-fusion surfaces before the local packet

route is available, with the selector-budget sibling supplied by chapter 678 and the finite selector sibling supplied by chapter 782.

Now apply root window-budget determinacy. Once the selector consumer has reached the accepted packet, the only exposed agreement route is W, then D, then A; the transport, continuation, provenance, and local naming rows H, C, P, N do not add another selector or agreement coordinate.

Finally use root public consumer non-escape. The public boundary of Q is exhausted by the displayed rows and the named sibling surfaces, so a selected-budget or tail-agreement read cannot be reinterpreted as a selected limit, quotient stream equality, host real equality, trichotomy row, independent tail oracle, or ambient completeness principle. □

Theorem 699.103 (Real tail-agreement seal window-budget selector fusion lock)**.** *Let* $Q = (R, S, W, D, A, H, C, P, N)$ *be an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer that passes through selector-budget admission, shared-threshold reading, and tail-fusion consumption traverses the same finite route*

$$\mathsf{ObservationBudgetLimiter}^{\uparrow} \to \mathsf{RegularCauchyTailBudget}^{\uparrow} \to \mathsf{RegularCauchyTailMeet}^{\uparrow} \to \mathsf{RegularCauchySelectorBudg}$$

The route admits no quotient stream, selected limit, host convergence row, choice-selected tail, hidden completion selector, or second agreement surface between the selector admission and the agreement row A*.*

Proof. First apply Definition 699.102. It places every selected-budget or tail-agreement read behind the finite selector surface, the observation limiter, the tail budget, the shared tail meet, the tail-fusion surface, and the local agreement chain.

Next use Definition 699.101. The Real and Completion criterion consumers receive the same sibling handoff before the local route is available, so selector admission, shared-threshold reading, and fusion consumption are not independent entrances.

Now invoke Definition 699.100. Once the shared route reaches the accepted packet, the only local agreement route is the displayed window, dyadic readback, and agreement chain.

Finally apply Definition 699.104. The public consumer boundary is exhausted by the finite sibling surfaces and the displayed packet rows, so none of the excluded rows can be inserted between selector admission and the agreement coordinate. □

Theorem 699.104 (Real tail-agreement seal root public consumer non-escape)**.** *No public* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet* $Q = (R, S, W, D, A, H, C, P, N)$ *can bypass the finite route*

$$W \to D \to A$$

to obtain selected tails, host convergence, quotient stream equality, or ambient completeness. All such consumers receive only the displayed rows $R, S, W, D, A, H, C, P, N$ *and the named budget, limiter, meet, fusion, Cauchy-limit, Real, and Completion sibling surfaces.*

Proof. Start from the root criterion handoff. It forces every Real or Completion criterion read through the budget, limiter, meet, and fusion surfaces before the local paired-window route is public.

Use root window-budget determinacy to identify the local route. The packet exposes A only after W and D have been read, so a consumer cannot jump directly to an agreement row or replace the readback by a quotient stream equality.

Finally apply root budget Completion-consumer exhaustion. The listed sibling surfaces and the displayed carrier rows exhaust the public consumer boundary. Since no row stores a selected tail, host convergence predicate, quotient equality, or ambient completeness principle, no public consumer can bypass $W \to D \to A$ to recover one. □

Theorem 699.105 (Real tail-agreement seal L10 four-object exit route)**.** *Let $Q = (R, S, W, D, A, H, C, P, N)$ be an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of Q that passes through the root selector-budget compatibility row and the root public non-escape row factors through the Phase Real and Completion four-object exit route:*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The route begins with the finite selector, limiter, tail budget, meet, fusion, and local $W \to D \to A$ rows of Definition 699.102 and Definition 699.103, and it is read as the four-object exit packet of Definition 126.500. Its only support rows are

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

No quotient stream equality, host sequence equality, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, metric-completeness datum, countable-choice row, or standard bridge row is exported by this RealTailAgreementSeal exit route.*

Proof. First apply Definition 699.102. It places the consumer behind the finite selector surface, observation limiter, regular tail budget, shared meet, fusion surface, and the local $W \to D \to A$ chain before any Real or Completion read can consume the accepted packet.

Next use Definition 699.103. The lock identifies the same finite route for $\mathsf{Real}^{\uparrow}$ and $\mathsf{Completion}^{\uparrow}$ consumers, so the selector-budget read and the tail-agreement read cannot split into separate exit routes after fusion.

Now invoke Definition 126.500. The finite route is read as the displayed StreamName window, DyadicRatCore readback, RegSeqRat regular source, and RealUp seal, with only BHist, hsame, Cont, Pkg, and NameCert support rows.

Finally apply Definition 699.104. The public boundary excludes quotient stream equality, host sequence equality, selected limits, ambient Real completeness, metric-completeness data, countable choice, and standard bridge rows. Hence the accepted packet supplies exactly the four-object exit route named above, and no public Real or Completion consumer escapes it. □

Theorem 699.106 (Real tail-agreement seal four-object exit non-escape)**.** *Let $Q = (R, S, W, D, A, H, C, P, N)$ be an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet. Any accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *consumer that reaches the four-object exit route factors through*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

and through the local chain

$$W \to D \to A.$$

The consumer can read only the displayed selector, limiter, tail budget, meet, fusion, window, dyadic readback, agreement, transport, continuation, provenance, and name rows supporting that route. It cannot read quotient stream equality, host sequence equality, selected limits, ambient completeness, countable-choice schedules, metric-completeness data, or bridge rows.

Proof. First apply root selector-budget compatibility. It places every selected-budget or tail-agreement read behind the finite selector surface, the observation limiter, the regular tail budget, the shared tail-meet row, the tail-fusion surface, and the local $W \to D \to A$ chain.

Next use the window-budget selector fusion lock. The lock makes the Real and Completion consumers traverse the same finite selector, limiter, budget, meet, fusion, StreamName, DyadicRatCore, RegSeqRat, and agreement route, so no hidden selector or second agreement surface appears between the selector admission and A.

Now invoke the L10 four-object exit route. That theorem identifies the visible exit packet as $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, supported only by BHist, hsame, Cont, Pkg, and NameCert rows.

Finally apply root public consumer non-escape. Since the public boundary is exhausted by the displayed sibling surfaces and the local packet rows, quotient stream equality, host sequence equality, selected limits, ambient completeness, countable-choice schedules, metric-completeness data, and bridge rows remain outside the accepted consumer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealTailAgreementSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{RealTailAgreementSeal}^{\uparrow}$ packet is generated from paired RegSeqRat source rows, finite paired StreamName tail windows, paired DyadicRatCore readbacks, a displayed tail-agreement row, componentwise hsame transports, Cont routes, Pkg provenance, and a local NameCert row.

Not claimed: This chapter does not close Lean verification, quotient stream equality, selected real values, host metric convergence, open-cover compactness, choice-selected tails, or a public standard bridge.

Upgrade path: The paper closure axis is complete for the finite paired tail-agreement packet; Lean verification and bridge checking remain independent axes.

Chapter 700

A Concrete Naming Certificate for $\mathsf{UnaryDirectionRouter}^{\uparrow}$

The $\mathsf{UnaryDirectionRouter}^{\uparrow}$ packet is the consumer-facing surface of the unary-direction bridge. It records which standard-boundary read is being requested, routes that read through the displayed unary and axis rows, and a local naming certificate, while keeping the $\mathsf{Nat}^{\uparrow}$ unary carrier and the $\mathsf{AxisNat}^{\uparrow}$ zero-spine carrier distinct inside the finite kernel.

The router consumes the $\mathsf{AxisNat}^{\uparrow}$ zero-spine carrier through chapter 276 and the unary-zero-spine standard comparison through chapter 572 before the selector row can route forward, backward, or neutral reads.

Definition 700.1 (Unary-direction router carrier)**.** *A* $\mathsf{UnaryDirectionRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(U, A, S, L, F, R, H, C, P, N)$$

with the following visible rows:

1. *U is the* $\mathsf{Nat}^{\uparrow}$ *unary row, read as a displayed* Unary *history and its local naming surface;*
2. *A is the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine row, read as a displayed* $\mathsf{ZeroSpine}$ *history and its local naming surface;*
3. *S is a finite selector choosing the forward presentation, the backward presentation, or the router-neutral presentation;*
4. *L is the displayed length ledger used by either directional read;*
5. *F is the forward* Cont *route from the unary row through L to the axis row;*
6. *R is the backward* Cont *route from the axis row through L to the unary row;*
7. *H stores componentwise* hsame *transports for the two source rows, selector row, length ledger, routes, provenance row, and local name;*
8. *C stores the route ledger exposing unary inspection, axis inspection, selector readback, length readback, forward readback, backward readback, neutral readback, and NameCert audit;*
9. *P records* Pkg *provenance over* $\mathsf{Nat}^{\uparrow}$, $\mathsf{AxisNat}^{\uparrow}$, $\mathsf{UnaryDirectionBridge}^{\uparrow}$, $\mathsf{UnaryZeroSpineStandardIso}^{\uparrow}$, $\mathsf{AxisUnarySpineNormalizer}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UnaryDirectionRouter}^{\uparrow}}$ *row.*

The selector row is total over the three displayed presentations:

$$S \in \{\mathsf{forward}, \mathsf{backward}, \mathsf{neutral}\}.$$

The packet has no coordinate identifying the $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{AxisNat}^{\uparrow}$ *carriers, no host recursor over standard natural numbers, and no ambient function replacing the displayed* Cont *routes.*

Theorem 700.2 (Unary-direction router NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{UnaryDirectionRouter}^{\uparrow}}$ *surface for Definition 700.1 consists exactly of the following five obligation rows:*

1. *carrier admission, stating that an accepted router exposes the finite packet* $(U, A, S, L, F, R, H, C, P, N)$ *over the named BEDC dependencies;*
2. *selector totality, stating that every accepted consumer request chooses the forward, backward, or router-neutral presentation through the displayed selector row* S*;*
3. *route-ledger exactness, stating that forward and backward reads are precisely the displayed routes* F *and* R *through* C *and* L*;*
4. *nonidentification preservation, stating that componentwise transport through* H *never turns the* $\mathsf{Nat}^{\uparrow}$ *unary row and the* $\mathsf{AxisNat}^{\uparrow}$ *zero-spine row into a shared kernel carrier;*
5. *consumer non-escape, stating that downstream unary-direction consumers may read only through* $U, A, S, L, F, R, H, C, P, N$ *and cannot export a separate standard-model function as a BEDC route.*

Proof. Carrier admission is projection from the displayed packet. The source rows U and A, the selector row S, the length ledger L, the two route rows F, R, the transport row H, the route ledger C, the package row P, and the local name N are all present before the certificate accepts the router.

Selector totality is finite case analysis on S. In the forward case the consumer reads F through C and L; in the backward case it reads R through the same displayed ledgers; in the neutral case it receives only the common router surface and no directional carrier equality.

Route-ledger exactness follows because the packet contains exactly two directional Cont rows. Any forward or backward bridge read must pass through C after the selector and length rows have been exposed.

For nonidentification preservation, transport is componentwise through H. It may rename the unary row, the axis row, the selector, the ledger, and the routes inside their own displayed classifiers, but no row of the packet has target type asserting equality of the two carrier predicates.

Consumer non-escape is the remaining boundary condition. The provenance row P lists the permitted dependencies, and the local naming row N binds the consumer-facing route to the displayed packet, so a downstream consumer cannot replace the router by an external standard-model function or by a host-side identification of the two carriers. □

Closure status for $\mathsf{NameCert}_{\mathsf{UnaryDirectionRouter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UnaryDirectionRouter}^{\uparrow}$ packet is generated from finite BHist rows for the $\mathsf{Nat}^{\uparrow}$ unary carrier, the $\mathsf{AxisNat}^{\uparrow}$ zero-spine carrier, a three-way selector, length ledger, forward and backward Cont routes, componentwise transports, provenance, and local naming. Directional reads are produced by replaying the selected route through the length ledger, not by identifying the two carriers or importing a standard natural-number function. hsame transports each row inside its own classifier, and Pkg records the unary, axis, bridge, standard-iso, and normalizer dependencies. The router therefore exposes direction without collapsing unary and axis presentations.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UnaryDirectionRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the unary-direction router carrier, selector totality, route-ledger exactness, non-identification preservation, and consumer non-escape obligations.

Formal verification: FormalStatus(NameCert$_{\mathsf{UnaryDirectionRouter}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: human
Not claimed: It does not claim equality of $\mathsf{Nat}^{\uparrow}$ and $\mathsf{AxisNat}^{\uparrow}$ carriers, a host recursor over standard naturals, or an ambient function replacing the displayed routes.
Upgrade path: Obligation closure requires Lean encodings of the router carrier, selector cases, route exactness, and nonidentification preservation.

Chapter 701

A Concrete Naming Certificate for $\mathsf{StationaryEmbeddingClassifier}^{\uparrow}$

The $\mathsf{StationaryEmbeddingClassifier}^{\uparrow}$ packet realizes the stationary rational embedding classifier correspondence as finite NameCert data. It binds two RatUp seed rows, their constant StreamName rows, their stationary RegSeqRat diagonal rows, their RealUp constant rational embedding seals, the RatUp and RealUp classifier faces, and the transport routes that identify the two readings. The packet is local to stationary rational diagonals: it does not construct quotient streams, host real equality, selected limits, or ambient completeness.

The dependency route is the Real-and-Completion lattice rather than an isolated classifier packet. The carrier consumes stationary rational Cauchy inputs through chapter 364, the rational constant route through chapter 1491, the dyadic constant-name route through chapter 467, and the RealUp constant rational embedding seal through chapter 38 before comparing the RatUp and RealUp classifier faces.

Definition 701.1 (Stationary-embedding-classifier carrier)**.** *A* $\mathsf{StationaryEmbeddingClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, E_0, S, T, G, H, R, Q, W, C, P, N)$$

with the following displayed rows:

1. *D and E_0 are the two accepted RatUp seed rows;*
2. *S and T are the constant* $\mathsf{StreamName}^{\uparrow}$ *rows* $\mathsf{RatConstStream}_D$ *and* $\mathsf{RatConstStream}_{E_0}$*;*
3. *G records the stationary* RegSeqRat *diagonal rows L_D and L_{E_0} obtained from the corresponding stationary rational Cauchy inputs;*
4. *H records the RealUp constant rational embedding seals* $(\mathsf{RatConstStream}_D, \mathsf{E1}(D))$ *and* $(\mathsf{RatConstStream}_{E_0}, \mathsf{E1}(E$
5. *R is the displayed RatUp classifier face* $\mathsf{RatHistoryClassifier}(D, E_0)$*;*
6. *Q is the displayed RealUp classifier face* $\mathsf{RealClassifier}(L_D, L_{E_0})$*;*
7. *W records componentwise* hsame *transports for the seed, stream, diagonal, seal, classifier, package, and local naming rows;*
8. *C records the displayed* Cont *routes that read the RatUp seed face, the constant StreamName face, the stationary diagonal face, and the RealUp embedding face through the same finite packet;*

9. *P is the* Pkg *provenance over* $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{StationaryEmbeddingClassifier}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed rows $D, E_0, S, T, G, H, R, Q, W, C, P, N$.

Theorem 701.2 (StationaryEmbeddingClassifier NameCert obligations)**.** *For the carrier of Definition 701.1, the local* $\mathsf{NameCert}_{\mathsf{StationaryEmbeddingClassifier}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier exposure for $E = (D, E_0, S, T, G, H, R, Q, W, C, P, N)$;*
2. *stationary-source admission, requiring D, E_0 to be RatUp seed rows and S, T to be their constant* $\mathsf{StreamName}^{\uparrow}$ *rows;*
3. *diagonal-and-seal admission, requiring G to expose the stationary* RegSeqRat *diagonals and H to expose the matching RealUp constant rational embedding seals;*
4. *classifier exactness, requiring the RealUp face Q and the RatUp face R to be transported through the same displayed* hsame *row W and route row C;*
5. *non-escape, requiring the packet to export no quotient stream, no host real equality, no selected limit, no ambient completeness principle, and no hidden classifier oracle.*

Proof. Carrier exposure is projection from the finite tuple in Definition 701.1. The seed rows, constant stream rows, stationary diagonal rows, embedding seals, classifier faces, transport rows, route rows, provenance row, and local naming row are all displayed coordinates.

Stationary-source admission reads the two RatUp rows D, E_0 and then the constant StreamName rows S, T. These rows are the same constant-stream witnesses used by the stationary rational Cauchy packet and by the constant StreamName readback surface.

Diagonal-and-seal admission reads G and H. The row G names the stationary diagonal representatives of the two regular Cauchy inputs, while H names the constant rational RealUp embeddings sealed by the corresponding e-one rows.

Classifier exactness is the finite transport obligation. The RatUp face R is read through the constant StreamName point-exactness route, then through the stationary diagonal route, and then through the RealUp constant rational embedding seal. Conversely the RealUp face Q is read back through the same displayed constant-stream and e-one seal rows to the RatUp seed face.

Finally inspect the carrier list. There is no coordinate for a quotient stream, host real equality, selected limit, ambient completeness principle, or hidden classifier oracle, so none of those objects can be exported by the local naming surface. □

Theorem 701.3 (StationaryEmbeddingClassifier correspondence)**.** *Let $E = (D, E_0, S, T, G, H, R, Q, W, C, P, N)$ be an accepted* $\mathsf{StationaryEmbeddingClassifier}^{\uparrow}$ *carrier. The public classifier reading factors through the finite equivalence*

$$\mathsf{RealClassifier}(L_D, L_{E_0}) \iff \mathsf{RatHistoryClassifier}(D, E_0).$$

Both directions use only the displayed RatUp seed rows, constant $\mathsf{StreamName}^{\uparrow}$ *rows, stationary* RegSeqRat *diagonal rows, RealUp constant rational embedding seals, componentwise* hsame *transports, displayed* Cont *routes, package provenance, and the local* NameCert *row.*

Proof. Project the accepted carrier to the displayed rows. The RatUp side is the face $R = \mathsf{RatHistoryClassifier}(D, E_0)$, and the RealUp side is the face $Q = \mathsf{RealClassifier}(L_D, L_{E_0})$.

For the forward direction, read Q through the two stationary diagonal rows in G. The stationary rational diagonal certificate identifies each L_D and L_{E_0} with the corresponding constant rational RealUp embedding in H.

The Real constant rational embedding readback then exposes the constant StreamName rows S, T. The constant StreamName point-exactness surface reads those rows back as the same RatUp seed classifier R.

For the reverse direction, start from R. The constant StreamName witness transports the seed classifier to the constant streams S, T, and the stationary rational diagonal route transports those streams to the diagonal representatives in G.

The RealUp constant rational embedding seals in H identify those representatives with the RealUp face Q. The same W, C, P, N rows carry both readings, so the two implications form the displayed finite equivalence. □

Theorem 701.4 (StationaryEmbeddingClassifier dyadic rational factorization)**.** *Let $E = (D, E_0, S, T, G, H, R, Q, W$ be an accepted* $\mathsf{StationaryEmbeddingClassifier}^{\uparrow}$ *carrier. Suppose the RatUp seed rows D and E_0 admit displayed dyadic observation rows d_D and d_{E_0}, and suppose those rows are read through accepted constant-name packets whose public routes are the* $\mathsf{RationalEmbedding}^{\uparrow}$ *and* $\mathsf{DyadicEmbedding}^{\uparrow}$ *routes. Then the public equivalence*

$$\mathsf{RealClassifier}(L_D, L_{E_0}) \iff \mathsf{RatHistoryClassifier}(D, E_0)$$

factors through the ordered L10 route

$$\mathsf{RationalEmbedding}^{\uparrow} \to \mathsf{DyadicEmbedding}^{\uparrow} \to \mathsf{StationaryRationalCauchy}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

before the Real classifier face is compared with the RatUp classifier face. The factorization exports only the displayed RatUp seed rows, dyadic observation rows, constant $\mathsf{StreamName}^{\uparrow}$ *rows, stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, RealUp seal rows, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows. It exports no quotient stream, selected limit, host real equality, trichotomy, or ambient completeness coordinate.*

Proof. Project the accepted carrier with Definition 701.1. The rows $D, E_0, S, T, G, H, R, Q, W, C, P, N$ expose the two RatUp seeds, their constant stream schedules, the stationary diagonal rows, the RealUp seals, the two classifier faces, and the visible transport and route data.

Use chapter 1491 to read each RatUp seed through the rational constant route. This supplies the constant $\mathsf{StreamName}^{\uparrow}$ schedule, the stationary $\mathsf{RegSeqRat}^{\uparrow}$ readback, the dyadic observation ledger, and the RealUp seal boundary for the same finite source row.

Use chapter 467 on the displayed dyadic observation rows d_D and d_{E_0}. Its constant stream readback identifies the dyadic row, constant schedule, stationary readback, and RealUp seal as one constant dyadic real-name route, so the dyadic observation rows cannot be replaced by quotient streams or selected host limits.

Compose these two constant-name routes with the stationary rational Cauchy handoff of chapter 364. The composed route reaches the same RealUp seal rows named in H before any classifier comparison is exported.

Finally apply Definition 701.3. The correspondence reads the Real classifier face $Q = \mathsf{RealClassifier}(L_D, L_{E_0})$ and the RatUp classifier face $R = \mathsf{RatHistoryClassifier}(D, E_0)$ through the same displayed rows, so the public equivalence factors through the ordered L10 route above. The non-escape clauses in the cited constant-name and classifier surfaces exclude quotient streams, selected limits, host real equality, trichotomy, and ambient completeness. □

Theorem 701.5 (StationaryEmbeddingClassifier Real completion link)**.** *Every accepted* StationaryEmbeddingClassi *carrier factors its public classifier correspondence through chapter 364 and chapter 38 before exporting*

$$\mathsf{RealClassifier}(L_D, L_{E_0}) \iff \mathsf{RatHistoryClassifier}(D, E_0).$$

The stationary rational Cauchy surface supplies the constant $\mathsf{StreamName}^{\uparrow}$ *and* RegSeqRat *diagonal rows, while the RealUp surface supplies the constant rational embedding seals read before the Real classifier face is compared with the RatUp classifier face.*

Proof. Project the accepted carrier using Definition 701.1. The rows $D, E_0, S, T, G, H, R, Q, W, C, P, N$ expose the RatUp seeds, constant StreamName rows, stationary diagonal rows, RealUp seals, classifier faces, transport, routes, provenance, and local name.

Apply the NameCert obligations. They order the read through stationary-source admission and diagonal-and-seal admission before classifier exactness, so the route passes through the stationary rational Cauchy and RealUp sibling surfaces before the public equivalence is exported.

Use the classifier correspondence theorem to obtain the displayed equivalence. The non-escape theorem then rules out any quotient stream, host real equality, selected limit, ambient completeness principle, or hidden classifier oracle outside those sibling routes. □

Theorem 701.6 (StationaryEmbeddingClassifier non-escape boundary)**.** *An accepted* StationaryEmbeddingClassifie *carrier exports only RatUp seed rows, constant* $\mathsf{StreamName}^{\uparrow}$ *rows, stationary* RegSeqRat *diagonal rows, RealUp constant rational embedding seals, the RatUp and RealUp classifier faces, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row. It exports no quotient stream, no host real equality, no selected limit, no ambient completeness principle, and no hidden classifier oracle.*

Proof. Inspect the carrier coordinates of Definition 701.1. Every exported row is one of $D, E_0, S, T, G, H, R, Q, W, C$

The positive data remain finite and local: two seed rows, two constant stream rows, two stationary diagonal rows, two embedding seals, two classifier faces, and the rows that transport, route, package, and name them.

No listed coordinate is a quotient stream, host real equality, selected limit, ambient completeness principle, or hidden classifier oracle. Therefore an accepted carrier cannot export any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{StationaryEmbeddingClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{StationaryEmbeddingClassifier}^{\uparrow}$ packet is generated from RatUp seed rows, constant StreamName rows, stationary RegSeqRat diagonal rows, RealUp constant rational embedding seals, RatUp and RealUp classifier faces, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StationaryEmbeddingClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 701.1, Definition 701.2, Definition 701.3, Definition 701.4, and Definition 701.6 bind the finite stationary rational embedding classifier packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StationaryEmbeddingClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient stream identity, host real equality, selected limits, ambient completeness, bridge status, Lean verification, or a hidden classifier oracle.

Upgrade path: Obligation closure requires checked carrier admission, classifier correspondence, transport exactness, and non-escape for the same stationary rational embedding classifier packet.

Chapter 702

A Concrete Naming Certificate for $\mathsf{RegularCauchyMerge}^{\uparrow}$

The $\mathsf{RegularCauchyMerge}^{\uparrow}$ packet records the finite two-route merge used when a diagonal Real-completion handoff compares two regular rational sources through shared cofinal tail data. It binds two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, two selector schedules, one shared cofinal tail window, two $\mathsf{Real}^{\uparrow}$ seal routes, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local $\mathsf{NameCert}$ row as one inspectable BEDC carrier. The packet is a naming certificate for finite selector agreement; it is not a quotient of streams, a chosen host limit, an ambient completeness principle, or equality of completed reals.

Definition 702.1 (RegularCauchyMerge carrier)**.** *A* $\mathsf{RegularCauchyMerge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R_0, R_1, S_0, S_1, W, E_0, E_1, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows being compared by the diagonal-limit handoff;*
2. S_0 *and* S_1 *are the two selector schedules that name which cofinal reads of* R_0 *and* R_1 *are opened;*
3. W *is the shared cofinal tail window, required to cover the two selected schedules at the requested precision;*
4. E_0 *and* E_1 *are the two* $\mathsf{Real}^{\uparrow}$ *seal routes reached from the displayed source rows through the shared window;*
5. H *records componentwise* hsame *transports for* $R_0, R_1, S_0, S_1, W, E_0, E_1$ *and the structural rows of the packet;*
6. C *records the displayed* Cont *routes from each source row through its selector schedule, into* W*, and from* W *into the corresponding* $\mathsf{Real}^{\uparrow}$ *seal route;*
7. P *is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{DiagonalTailSelector}^{\uparrow}$, $\mathsf{ChoiceFreeDiagonalSelector}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMerge}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the visible rows $R_0, R_1, S_0, S_1, W, E_0, E_1, H, C, P, N$*.*

Theorem 702.2 (RegularCauchyMerge NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMerge}^{\uparrow}}$ *surface for Definition 702.1 consists exactly of carrier admission for* $M = (R_0, R_1, S_0, S_1, W, E_0, E_1, H, C, P, N)$*,*

source exposure for the two $\mathsf{RegSeqRat}^{\uparrow}$ *rows, selector exposure for the two schedules, shared-window coverage through* W*, two-route* $\mathsf{Real}^{\uparrow}$ *seal delivery through* E_0 *and* E_1*, componentwise* hsame *transport through* H*, displayed* Cont *route replay through* C*,* Pkg *provenance through* P*, local naming through* N*, and non-escape from quotient streams, host-selected limits, countable choice, ambient completeness, hidden tail oracles, and host real equality.*

Proof. Carrier admission is projection from the displayed packet. The rows $R_0, R_1, S_0, S_1, W, E_0, E_1$ expose the two regular rational sources, their selector schedules, the shared cofinal window, and the two real-facing seal routes.

The selector and window obligations are read in order. Each selector schedule is tied to its displayed source row, and both schedules must pass through the single shared window W before either seal route is available.

The transport, route, provenance, and naming obligations are exactly the rows H, C, P, N. Since no further analytic coordinate occurs in M, the packet has no channel for quotient streams, host-selected limits, countable choice, ambient completeness, hidden tail oracles, or host real equality. □

Theorem 702.3 (RegularCauchyMerge source coherence)**.** *For every accepted* $\mathsf{RegularCauchyMerge}^{\uparrow}$ *carrier*

$$M = (R_0, R_1, S_0, S_1, W, E_0, E_1, H, C, P, N),$$

the two source rows R_0 *and* R_1 *are coherent only through the displayed selector schedules and the shared cofinal window. A consumer cannot compare the sources by an unrecorded stream quotient, a host real equality test, a selected ambient limit, or an external Cauchy-completion principle.*

Proof. Project R_0, R_1, S_0, S_1, W from the carrier. These are the only rows in the packet that can mention the two regular rational sources and their cofinal reads.

The NameCert obligations force the two selector schedules to enter the same shared tail window before the seal routes are reached. Thus any source comparison is mediated by S_0, S_1, W and by the continuation rows that replay those displayed choices.

The structural rows H, C, P, N preserve and name the same finite data. Because the carrier has no coordinate for stream quotients, host real equality, selected ambient limits, or a completion theorem, source coherence is exactly the visible two-schedule route through W. □

Theorem 702.4 (RegularCauchyMerge diagonal-selector compatibility)**.** *Every diagonal-limit consumer of an accepted* $\mathsf{RegularCauchyMerge}^{\uparrow}$ *carrier factors its selector agreement through*

$$R_0, R_1, S_0, S_1, W, H, C, P, N.$$

The first route reads R_0 *through* S_0 *into* W*, and the second route reads* R_1 *through* S_1 *into the same* W*. The agreement is therefore a finite cofinal-window agreement between two displayed selector schedules, not a choice of a subsequence outside the packet.*

Proof. Start with source coherence. It identifies S_0, S_1, W as the only comparison surface available to a diagonal-limit consumer.

The first selector route reads R_0 through S_0 and then enters W. The second selector route reads R_1 through S_1 and then enters the same W. The continuation row C records these two routes as displayed replay data.

The rows H, P, N transport, package, and name the same two-route surface. No row in the carrier supplies an unbounded subsequence selector, so diagonal-selector compatibility is confined to the finite route through the shared window. □

Theorem 702.5 (RegularCauchyMerge Real seal non-escape)**.** *For every accepted* $\mathsf{RegularCauchyMerge}^{\uparrow}$ *carrier, the two* $\mathsf{Real}^{\uparrow}$ *seal routes* E_0 *and* E_1 *are reachable only after the source rows, selector schedules, shared cofinal window, transports, continuations, provenance, and local naming row have been displayed. In particular, a* $\mathsf{Real}^{\uparrow}$ *consumer of either route receives no quotient stream, hidden completed value, selected host limit, countable-choice selector, host real equality, or ambient completeness coordinate.*

Proof. Use the NameCert obligations to place E_0 and E_1 downstream of R_0, R_1, S_0, S_1, W. Thus neither real-facing route is available before the two sources have passed through their selector schedules and the shared cofinal tail window.

Apply diagonal-selector compatibility. It confines the agreement data needed by the two seal routes to the finite route $R_0, R_1, S_0, S_1, W, H, C, P, N$.

Finally inspect the carrier. The remaining rows are the two seal routes themselves, and no coordinate supplies quotient streams, hidden completed values, selected host limits, countable choice, host real equality, or ambient completeness. □

Theorem 702.6 (RegularCauchyMerge L10 sibling route)**.** *For every accepted* $\mathsf{RegularCauchyMerge}^{\uparrow}$ *packet*

$$M = (R_0, R_1, S_0, S_1, W, E_0, E_1, H, C, P, N),$$

every diagonal-completion consumer of the merge first reads the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows through chapter 301, then reads the shared finite-window and schedule surface through chapter 126, then reads the dyadic observation ledger through chapter 291, and only then reaches the two* $\mathsf{Real}^{\uparrow}$ *seal routes through chapter 38. This sibling route is a finite L10 dependency path for the displayed packet; it supplies no quotient stream, host-selected limit, countable choice, host real equality, or ambient completeness coordinate.*

Proof. Start with the local NameCert obligations. They expose R_0 and R_1 as the two regular rational source rows, require the selector schedules and shared window to be displayed, and place E_0 and E_1 downstream of that finite route.

Apply source coherence and diagonal-selector compatibility. The two source reads cannot be compared before S_0, S_1 and the shared cofinal window W have been opened, so the consumer is forced through the same finite-window and schedule surface used by the stream naming certificate.

The dyadic observation ledger is the next visible interface for the rational reads: it records the finite precision data that the shared window can expose before either real-facing seal is available. Thus the L10 route reads the two $\mathsf{RegSeqRat}^{\uparrow}$ rows, the stream-name schedule surface, and the dyadic ledger before it can inspect the $\mathsf{Real}^{\uparrow}$ endpoints.

Finally apply Real-seal non-escape. Since the two seal routes only receive the displayed rows $R_0, R_1, S_0, S_1, W, E_0, E_1, H, C, P, N$, the route has no coordinate for quotient streams, host-selected limits, countable choice, host real equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMerge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyMerge}^{\uparrow}$ packet is generated from two RegSeqRat source rows, two selector schedules, one shared cofinal tail window, two RealUp seal routes, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyMerge}^{\uparrow}}$, seed)

Scope closed: Definition 702.1, Definition 702.2, Definition 702.3, Definition 702.4, and Definition 702.5 bind the finite two-route cofinal selector agreement used by Real-completion diagonal handoffs.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyMerge}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, RealUp completeness, quotient stream equality, host real equality, countable choice, host-selected limits, ambient completeness, or a public standard bridge.

Upgrade path: Scoped closure requires checked carrier admission, source exposure, selector exposure, shared-window coverage, two-route RealUp seal delivery, transport stability, route replay, provenance, local naming, and non-escape for the same finite packet.

Chapter 703

A Concrete Naming Certificate for $\mathsf{CauchyInverseBudget}^{\uparrow}$

The $\mathsf{CauchyInverseBudget}^{\uparrow}$ packet records the finite reciprocal-window budget used by Real and Completion consumers when a regular Cauchy name is displayed with a nonzero-apartness row. It opens only finite $\mathsf{StreamName}^{\uparrow}$ windows, reads dyadic endpoint and radius data through $\mathsf{DyadicRatCore}^{\uparrow}$, exposes the regular-Cauchy source through $\mathsf{RegSeqRat}^{\uparrow}$, and seals the reciprocal candidate through $\mathsf{Real}^{\uparrow}$. The packet is a local budget certificate; it is not a field structure, quotient real equality, total reciprocal operation, trichotomy principle, or ambient inverse theorem.

Definition 703.1 (CauchyInverseBudget carrier)**.** *A* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, A, M, W, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source whose reciprocal window is being read;*
2. *A is the nonzero-apartness budget row, recording the displayed finite lower bound that keeps the reciprocal denominator away from the zero boundary;*
3. *M is the finite modulus row selecting the observation precision required by the reciprocal read;*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window selected from X at the requested budget;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and reciprocal arithmetic row read from that window;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from D together with the budget rows A and M;*
7. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row through which completion-facing consumers read the reciprocal candidate;*
8. *H records componentwise* hsame *transports for X, A, M, W, D, R, S and for the package and local naming rows;*
9. *C records the displayed* Cont *routes for source inspection, apartness-budget exposure, finite-window coverage, dyadic reciprocal readback, regular-sequence handoff, and RealUp seal handoff;*
10. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyInverseBudget}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed rows $X, A, M, W, D, R, S, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.CauchyInverseBudgetUp.CauchyInverseBudgetTasteGate single carrier alignment`

Theorem 703.2 (CauchyInverseBudget carrier admission)**.** *Every accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *packet admits exactly the carrier rows*

$$X, A, M, W, D, R, S, H, C, P, N.$$

A reciprocal-window read first exposes the $\mathsf{RegSeqRat}^{\uparrow}$ *source* X*, the nonzero-apartness budget* A*, and the finite modulus row* M*; no host reciprocal operation or quotient real representative is a carrier coordinate.*

Proof. Project the carrier of Definition 703.1. The packet lists the regular-Cauchy source, apartness budget, modulus, selected window, dyadic readback, regular-sequence readback, real seal, transports, routes, provenance, and local naming row.

Since those rows exhaust the tuple, a consumer has no separate coordinate from which to read a field inverse, quotient representative, trichotomy decision, or ambient completeness fact. Admission is therefore finite projection from the displayed packet. □

Theorem 703.3 (CauchyInverseBudget apartness exposure)**.** *For an accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *carrier, every reciprocal-window route exposes the nonzero-apartness budget* A *before the dyadic reciprocal row* D *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *are consumed. A route that omits* A *remains a boundary attempt and cannot export the reciprocal candidate.*

Proof. Use carrier admission to display the order of source rows. The rows X, A, M are the only source-side data available before a finite window is selected.

The dyadic reciprocal read D depends on the apartness budget because the finite endpoint and radius must be read inside a nonzero window. Without A, the package provenance has no row certifying that the denominator stays away from the zero boundary.

Thus a route omitting A cannot pass to R or S. The local naming row records such a route as boundary evidence rather than as a reciprocal candidate. □

Theorem 703.4 (CauchyInverseBudget apartness transport)**.** *Let* $B = (X, A, M, W, D, R, S, H, C, P, N)$ *and* $B' = (X', A', M', W', D', R', S', H', C', P', N')$ *be accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *packets. If the displayed rows* H *and* H' *relate the source, apartness, modulus, window, dyadic, readback, and seal coordinates componentwise by* hsame*, then any reciprocal-window route for* B *that exposes* A *before consuming* D *and* R *transports to a route for* B' *that exposes* A' *before consuming* D' *and* R'*. The transported route still cannot export a reciprocal candidate when the apartness row is omitted.*

Proof. Carrier admission fixes the row lists of both packets as $X, A, M, W, D, R, S, H, C, P, N$ and $X', A', M', W', D', R', S', H', C', P', N'$. Thus the only source-side rows available before the dyadic read are the displayed source, apartness, and modulus rows.

Apply Definition 703.3 to the route in B. It gives the ordering constraint that A must be exposed before D and R can be consumed, and it records the omitted-apartness case as boundary evidence rather than as a reciprocal export.

Use the componentwise hsame transports in H and H' to move the displayed rows X, A, M, W, D, R, S to $X', A', M', W', D', R', S'$. Because the transported route has the same carrier order, the image of the original exposure step is the exposure of A' before D' and R'.

The omitted-row exclusion is transported along the same displayed route. No extra coordinate is introduced by hsame, so a route without the apartness row in B' remains a boundary attempt and cannot export the reciprocal candidate through R' or S'. □

Theorem 703.5 (CauchyInverseBudget finite-window coverage)**.** *Every dyadic endpoint, radius, and reciprocal arithmetic read in D is covered by the finite* $\mathsf{StreamName}^{\uparrow}$ *window W selected from X by the modulus row M. Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the packet must first consume the route*

$$X, A, M, W, D, H, C, P, N.$$

Proof. Read the modulus row M through the carrier. It selects the finite window W from the displayed regular-Cauchy source X.

The dyadic row D is then a read of that window, not a read of an unbounded stream. Its endpoint, radius, and reciprocal arithmetic rows are all routed through the same W coordinate and the same displayed continuation row C.

The support rows H, P, N preserve, package, and name that finite route. Therefore downstream consumers reach R and S only after the displayed source, budget, modulus, window, and dyadic rows have been consumed. □

Theorem 703.6 (CauchyInverseBudget StreamName window dependency)**.** *Every accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *reciprocal-window route consumes the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface of chapter 126 before the dyadic row D, the regular readback row R, or the* $\mathsf{Real}^{\uparrow}$ *seal row S can be read. The reciprocal budget therefore depends on* $\mathsf{StreamName}^{\uparrow}$ *as a sibling certificate, not on an unbounded stream or on a host reciprocal operation.*

Proof. Carrier admission displays W as the finite $\mathsf{StreamName}^{\uparrow}$ window selected from the regular-Cauchy source X by the modulus row M. This is the same finite window coordinate named in Definition 703.1, so the reciprocal packet has no second stream surface from which a consumer could read.

Finite-window coverage then routes every endpoint, radius, and reciprocal arithmetic read in D through that selected W. Since R is produced from the dyadic row and S seals the resulting readback, neither downstream row can be consumed before the finite StreamName window has been consumed.

Thus the dependency is horizontal: the reciprocal budget imports the finite window discipline already certified by chapter 126. It does not appeal to an unbounded stream, a quotient representative, or a host-level reciprocal operation. □

Theorem 703.7 (CauchyInverseBudget reciprocal readback route)**.** *The* $\mathsf{RegSeqRat}^{\uparrow}$ *reciprocal readback row R of an accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *carrier factors through the apartness budget A, finite modulus M, selected window W, and dyadic reciprocal row D. The readback exports no total inverse operation and no quotient-stream equality.*

Proof. First apply apartness exposure. The route to a reciprocal candidate must display A before any dyadic reciprocal row is available.

Next apply finite-window coverage. The dyadic row D is read from the selected finite window W under the modulus row M, so the readback route has only finite observation data.

Finally project R from the carrier and attach the structural rows H, C, P, N. They repack the same finite route as a $\mathsf{RegSeqRat}^{\uparrow}$ handoff and add no total inverse operation or quotient equality. □

Theorem 703.8 (CauchyInverseBudget RealUp seal non-escape)**.** *Every completion-facing read of an accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *carrier reaches* $\mathsf{Real}^{\uparrow}$ *only through the seal row S after the reciprocal readback row R has been produced from X, A, M, W, D. The seal exports no field structure, quotient real equality, total reciprocal, trichotomy principle, or ambient inverse theorem.*

Proof. Use the reciprocal readback route to bind R to the source, apartness, modulus, window, and dyadic rows. The row R is therefore already a finite $\mathsf{RegSeqRat}^{\uparrow}$ handoff before the seal is read.

Project the seal coordinate S from the carrier. It appears only after R and is routed by the same Cont and Pkg rows, so the RealUp consumer receives the displayed finite packet.

The carrier contains no coordinate for a field structure, quotient real equality, total reciprocal operation, trichotomy principle, or ambient inverse theorem. Hence the seal cannot export any such object. □

Theorem 703.9 (CauchyInverseBudget NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyInverseBudget}^{\uparrow}}$ *surface consists of carrier admission, apartness budget exposure, apartness-budget transport, finite-window coverage,* $\mathsf{StreamName}^{\uparrow}$ *window dependency, reciprocal readback routing,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *stability, displayed* Cont *route stability,* Pkg *provenance, and the local naming row for the same finite packet* $B = (X, A, M, W, D, R, S, H, C, P, N)$.

Proof. Carrier admission is Definition 703.2. Apartness budget exposure is Definition 703.3, apartness-budget transport is Definition 703.4, finite-window coverage is Definition 703.5, and the sibling window dependency is Definition 703.6.

The analytic-facing route is supplied by Definition 703.7 and Definition 703.8. Together they keep the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers inside X, A, M, W, D, R, S.

The structural rows H, C, P, N preserve, route, package, and name the same packet. Since all obligation clauses refer to the same displayed rows, they form one finite NameCert surface. □

Theorem 703.10 (CauchyInverseBudget transport stability)**.** *Let* $B = (X, A, M, W, D, R, S, H, C, P, N)$ *and* $B' = (X', A', M', W', D', R', S', H', C', P', N')$ *be accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *packets. If the displayed row* H *relates the two packets componentwise by* hsame *on* $X, A, M, W, D, R, S, H, C, P, N$*, then the carrier admission row and the local classifier row are preserved from* B *to* B'*. In particular, the transported packet still has exactly the carrier coordinates* $X', A', M', W', D', R', S', H', C', P', N'$ *and no extra inverse, quotient equality, trichotomy, or ambient completeness coordinate.*

Proof. Project the carrier tuple of B by Definition 703.1. The row H supplies the componentwise hsame evidence for each displayed coordinate, including the package and local naming rows.

Transport the source-side coordinates X, A, M, W first. Carrier admission reads only those displayed coordinates before the dyadic row is available, so the accepted carrier shape is preserved under their hsame images.

Transport the downstream coordinates D, R, S and then the structural coordinates H, C, P, N. Since the classifier compares accepted carriers only through these displayed rows, the transported classifier row is the same finite comparison on B'.

No step introduces an unlisted coordinate. The transported carrier therefore remains the finite $\mathsf{CauchyInverseBudget}^{\uparrow}$ packet named by the displayed tuple. □

Theorem 703.11 (CauchyInverseBudget route stability)**.** *Under the componentwise* hsame *transport of Definition 703.10, the displayed* Cont *routes for source inspection, apartness-budget exposure, finite-window coverage, dyadic reciprocal readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal handoff remain routes for the transported packet. Thus every accepted route into* B' *still factors through the same finite row order* $X', A', M', W', D', R', S'$.

Proof. Begin with the transported carrier and classifier supplied by Definition 703.10. Source inspection reads the displayed X' row and then the budget and modulus rows A' and M'; these are exactly the transported images of the original source route.

Apartness-budget exposure is preserved by Definition 703.3. The route cannot reach a dyadic reciprocal row in the transported packet unless the transported apartness row A' has already been exposed.

Finite-window coverage is preserved by Definition 703.5. The dyadic endpoint, radius, and reciprocal arithmetic reads in D' are covered by the selected finite window W' under the transported modulus row M'.

Finally apply Definition 703.7 and Definition 703.8. They keep the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R' and the $\mathsf{Real}^{\uparrow}$ seal S' inside the transported finite route, so the Cont rows do not escape into a host reciprocal operation or quotient-real comparison. □

Theorem 703.12 (CauchyInverseBudget provenance and local naming)**.** *The* Pkg *provenance row and the local* $\mathsf{NameCert}_{\mathsf{CauchyInverseBudget}^{\uparrow}}$ *row of an accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *packet name exactly the finite packet*

$$B = (X, A, M, W, D, R, S, H, C, P, N).$$

They add no field inverse, quotient real equality, trichotomy, or ambient completeness data beyond the carrier, classifier, transport, route, provenance, and local naming rows already displayed.

Proof. Use Definition 703.9 to identify the NameCert surface. Its clauses are carrier admission, apartness exposure, finite-window coverage, sibling window dependency, reciprocal readback routing, seal non-escape, transport, route, provenance, and local naming for the same displayed tuple.

The structural content of the transport row is fixed by Definition 703.10. The route content is fixed by Definition 703.11. These two rows do not name any object outside $X, A, M, W, D, R, S, H, C, P, N$.

The provenance row P therefore packages only the listed BEDC surfaces, and the local row N names that package as the $\mathsf{CauchyInverseBudget}^{\uparrow}$ certificate. Since no preceding row contains a field inverse, quotient real equality, trichotomy decision, or ambient completeness witness, neither P nor N can export one. □

Theorem 703.13 (CauchyInverseBudget root apartness-window obligation)**.** *Every reciprocal-root consumer that reads an accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *packet must expose the apartness row* A*, modulus row* M*, finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, and dyadic readback row* D *before any reciprocal candidate can be consumed. The root-facing route therefore starts from the carrier*

$$B = (X, A, M, W, D, R, S, H, C, P, N)$$

and admits no read of D*,* R*, or* S *that bypasses* A, M, W*.*

Lean4 ✓ `BEDC.Derived.CauchyInverseBudgetUp.CauchyInverseBudgetRouteSurface apartness window closure`

Proof. Begin with carrier admission for Definition 703.1. The only reciprocal-root packet available to a consumer is the displayed tuple $B = (X, A, M, W, D, R, S, H, C, P, N)$, so the candidate cannot be read from an unlisted coordinate.

Apply Definition 703.3. It places the nonzero-apartness budget A before the dyadic reciprocal row D and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Apply Definition 703.5 and Definition 703.6. These rows bind the modulus row M, finite window W, and dyadic row D to the finite $\mathsf{StreamName}^{\uparrow}$ observations that the reciprocal route is allowed to inspect.

Finally use Definition 703.7. Since the readback row R factors through A, M, W, D, no root-facing consumer can consume a reciprocal candidate before the apartness and window rows have been exposed. □

Theorem 703.14 (CauchyInverseBudget root RegSeqRat Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a reciprocal-root budget factors through the displayed rows* $X, A, M, W, D, R, S, H, C, P, N$ *of the* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *carrier. Such a consumer receives the reciprocal readback row* R *and the Real seal row* S *only through that finite route, and receives no total inverse, quotient real equality, trichotomy row, ambient completeness row, or host reciprocal coordinate.*

Proof. Start from the root apartness-window obligation of Definition 703.13. It fixes the upstream route through A, M, W, D before the readback and seal rows can be used.

For the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, apply Definition 703.7. The readback row R is produced only from the source, apartness, modulus, finite window, and dyadic readback rows already displayed in the carrier.

For the $\mathsf{Real}^{\uparrow}$ handoff, apply Definition 703.8. The seal row S is reached after the readback row R has been produced from X, A, M, W, D.

The excluded data are absent from the carrier inventory and from both handoff theorems. Hence neither a regular-sequence consumer nor a Real consumer receives a total inverse, quotient equality, trichotomy decision, ambient completeness theorem, or host reciprocal coordinate. □

Theorem 703.15 (CauchyInverseBudget root formal surface)**.** *The Lean-facing reciprocal-root surface of* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *is exactly the displayed carrier* $B = (X, A, M, W, D, R, S, H, C, P, N)$ *together with the existing TasteGate alignment*

`BEDC.Derived.CauchyInverseBudgetUp.CauchyInverseBudgetTasteGate_single_carrier_alignment`.

It packages the apartness-window obligation, the $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff rows, NameCert obligations, transport stability, route stability, provenance, and local naming, and it contains no host reciprocal coordinate.*

Proof. The carrier surface is fixed by Definition 703.1 and its Lean-facing marker. These identify the single displayed tuple as the formal packet that the chapter exposes.

Add the root rows supplied by Definition 703.13 and Definition 703.14. They bind apartness, modulus, finite window, dyadic readback, regular readback, and Real seal consumption to the same packet.

Use Definition 703.9, Definition 703.10, and Definition 703.11. These rows attach local naming, componentwise hsame transport, and displayed Cont route stability to the carrier without adding another coordinate.

Finally apply Definition 703.12. The provenance and local name rows account for the same finite packet, so the formal surface contains the TasteGate alignment and the listed BEDC rows, but no host reciprocal coordinate. □

Theorem 703.16 (CauchyInverseBudget obligation closure package)**.** *The carrier of Definition 703.1, apartness exposure of Definition 703.3, apartness transport of Definition 703.4, finite-window coverage of Definition 703.5, StreamName dependency of Definition 703.6, reciprocal readback route of Definition 703.7, RealUp seal non-escape of Definition 703.8, transport stability of Definition 703.10, route stability of Definition 703.11, and provenance and local naming of Definition 703.12 supply the full obligationClosure package for* $\mathsf{CauchyInverseBudget}^{\uparrow}$.

Proof. The carrier fixes the packet as $B = (X, A, M, W, D, R, S, H, C, P, N)$. Apartness exposure and apartness transport ensure that every reciprocal route displays the nonzero budget row before any dyadic or regular readback can be consumed, and that this ordering is stable under componentwise hsame.

Finite-window coverage and the StreamName dependency place the endpoint, radius, and reciprocal arithmetic rows inside a selected finite window. The reciprocal readback and RealUp seal non-escape theorems then route downstream consumers through D, R, and S without exporting a total inverse, quotient equality, trichotomy principle, or ambient completeness theorem.

Transport stability, route stability, provenance, and local naming attach H, C, P, N to the same finite packet. Thus the listed rows are exactly the obligationClosure package for the reciprocal-window budget. □

Theorem 703.17 (CauchyInverseBudget scoped consumer route package)**.** *The rows of Definition 703.16 determine a scoped consumer route for* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *over the concrete BEDC surface*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

Every such route starts from the finite packet $B = (X, A, M, W, D, R, S, H, C, P, N)$*, consumes the apartness row* A*, finite modulus row* M*, selected* $\mathsf{StreamName}^{\uparrow}$ *window* W*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *reciprocal readback row* D *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *or* $\mathsf{Real}^{\uparrow}$ *seal* S*, and packages the route only through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Start with carrier admission and the obligation package. They fix the only available packet as $B = (X, A, M, W, D, R, S, H, C, P, N)$ and identify the source, budget, window, readback, seal, transport, route, provenance, and local name rows.

Apply apartness exposure, finite-window coverage, and the StreamName dependency. These rows place A, M, W before any dyadic reciprocal arithmetic in D, and they make the window a concrete $\mathsf{StreamName}^{\uparrow}$ surface rather than an unbounded stream.

Use the reciprocal readback route and the Real seal non-escape theorem. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff R is reached through A, M, W, D, and the $\mathsf{Real}^{\uparrow}$ seal S is reached only after that handoff.

Finally attach transport stability, route stability, provenance, and local naming. Those rows are exactly the displayed BHist, hsame, Cont, Pkg, and NameCert support, so the consumer route is scoped by the listed BEDC surface and has no extra reciprocal coordinate. □

Theorem 703.18 (CauchyInverseBudget Dyadic RegSeq Real scope)**.** *For every accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *packet, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, and* $\mathsf{Real}^{\uparrow}$ *row* S *form a single scoped reciprocal-budget chain:*

$$X, A, M, W \longrightarrow D \longrightarrow R \longrightarrow S.$$

The chain is transported only by the componentwise hsame *rows in* H*, replayed only by the displayed* Cont *routes in* C*, and named only by the package provenance* P *and local* NameCert *row* N*.*

Proof. Read D through finite-window coverage. The dyadic endpoint, radius, and reciprocal arithmetic rows are obtained from the selected $\mathsf{StreamName}^{\uparrow}$ window under the displayed apartness and modulus rows.

Read R through the reciprocal readback route. This makes the $\mathsf{RegSeqRat}^{\uparrow}$ handoff a consumer of the same A, M, W, D rows rather than an independent regular sequence.

Read S through Real seal non-escape. The $\mathsf{Real}^{\uparrow}$ consumer receives only the seal row after the regular readback row has been produced.

Transport stability and route stability keep the whole chain inside H and C. Provenance and local naming then record the same finite chain in P and N, so the scoped chain has exactly the displayed dyadic, regular, and Real endpoints. □

Theorem 703.19 (CauchyInverseBudget consumer non-escape scope)**.** *Every scoped* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *consumer over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *reads the reciprocal candidate only through the finite packet* $B = (X, A, M, W, D, R, S, H, C, P, N)$. *Such a consumer cannot escape to a host total inverse, quotient real equality, trichotomy row, ambient completeness row, unbounded stream read, or external reciprocal coordinate.*

Proof. The scoped consumer route package first fixes the available route through $X, A, M, W, D, R, S, H, C, P, N$. Any consumer of the reciprocal candidate must therefore pass through the apartness, modulus, finite-window, dyadic, regular, and Real rows already displayed there.

The dyadic-regular-Real scope theorem then fixes the only downstream chain as $X, A, M, W \longrightarrow D \longrightarrow R \longrightarrow S$. Componentwise transport, continuation replay, provenance, and local naming do not add another data coordinate.

Apply Real seal non-escape and the root RegSeqRat Real handoff. These theorems exclude field structure, quotient equality, total reciprocal, trichotomy, ambient inverse data, and host readback from the handoff surface.

The remaining excluded unbounded-stream read is ruled out by finite-window coverage and the StreamName dependency. Thus every accepted consumer remains inside the scoped BEDC route and no escape coordinate is exported. □

Theorem 703.20 (CauchyInverseBudget bridge route)**.** *The public* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *route over* $B = (X, A, M, W, D, R, S, H, C, P, N)$ *bridges the concrete reciprocal-window carrier to the abstract reciprocal-budget interface by exposing exactly the apartness row* A, *finite modulus* M, *selected* $\mathsf{StreamName}^{\uparrow}$ *window* W, $\mathsf{DyadicRatCore}^{\uparrow}$ *reciprocal readback* D, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R, $\mathsf{Real}^{\uparrow}$ *seal* S, *componentwise transport* H, *displayed route* C, *provenance* P, *and local name* N. *It exports no total inverse, quotient real equality, trichotomy, ambient inverse theorem, or host reciprocal coordinate.*

Proof. Use Definition 703.17 to fix the public route over the packet $B = (X, A, M, W, D, R, S, H, C, P, N)$. This route starts from the concrete reciprocal-window carrier and exposes only the displayed BEDC surface.

Apply Definition 703.18. It binds the selected $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ reciprocal readback, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and $\mathsf{Real}^{\uparrow}$ seal into the single downstream chain $X, A, M, W \longrightarrow D \longrightarrow R \longrightarrow S$.

Now use Definition 703.19. The consumer route cannot escape to a total inverse, quotient real equality, trichotomy row, ambient inverse theorem, unbounded stream read, or external reciprocal coordinate.

The public route rows and structural support rows then give the bridge-facing certificate. The apartness, modulus, window, readback, handoff, seal, transport, route, provenance, and local name are exactly the rows exposed to the reciprocal-budget interface. □

Theorem 703.21 (CauchyInverseBudget finite consumer coverage)**.** *Every finite reciprocal-budget consumer that reads the* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *bridge route is covered by the displayed carrier rows*

$$X, A, M, W, D, R, S, H, C, P, N,$$

with the apartness, modulus, window, and dyadic readback rows A, M, W, D *read before the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows* R, S. *Downstream* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and Completion-facing consumers receive only this finite route. They receive no total inverse, quotient real equality, trichotomy, ambient inverse theorem, unbounded stream, or host reciprocal row.*

Proof. Begin with the root apartness and window obligations. The root apartness-window theorem supplies A, M, W as the finite budget through which any reciprocal row must be read, and the root RegSeqRat Real handoff places the later R, S rows behind that budget.

Next use the scoped consumer route package. It fixes the visible carrier as $B = (X, A, M, W, D, R, S, H, C, P, N)$ and orders the dyadic readback row D before the regular and Real consumer rows.

The dyadic RegSeq Real scope theorem then identifies the only downstream chain as

$$X, A, M, W \longrightarrow D \longrightarrow R \longrightarrow S.$$

Thus a Completion-facing consumer can only read the reciprocal through the same finite route.

Finally apply the consumer non-escape theorem and the bridge route theorem. Together they exclude total inverse data, quotient real equality, trichotomy, ambient inverse theorems, unbounded stream reads, and host reciprocal rows from every finite consumer covered by the bridge. □

Theorem 703.22 (CauchyInverseBudget terminal refusal classifier)**.** *For every accepted* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *packet* $B = (X, A, M, W, D, R, S, H, C, P, N)$*, every request for total inverse, quotient real equality, trichotomy, ambient inverse theorem, unbounded stream read, or host reciprocal coordinate is routed to the boundary/refusal side of the finite* NameCert *surface unless the request first factors through the displayed rows* $X, A, M, W, D, R, S, H, C, P, N$*. In particular, the only accepted reciprocal consumer is the finite chain certified by Definition 703.21.*

Proof. Start with carrier admission for the accepted packet. The local ledger names only the carrier coordinate X, the apartness row A, the modulus row M, the selected $\mathsf{StreamName}^{\uparrow}$ window W, the dyadic reciprocal readback D, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R, the $\mathsf{Real}^{\uparrow}$ seal S, the BHist row H, the Cont row C, the Pkg row P, and the NameCert row N.

Apply the apartness exposure, the $\mathsf{StreamName}^{\uparrow}$ window dependency, and the reciprocal readback route. These place every admitted reciprocal access behind the finite A, M, W, D budget before any downstream $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can read it.

Use the $\mathsf{Real}^{\uparrow}$ seal non-escape theorem, the scoped consumer non-escape theorem, and the bridge route theorem. A request for total inverse data, quotient real equality, trichotomy, an ambient inverse theorem, an unbounded stream read, or a host reciprocal coordinate has no row in the displayed packet unless it has already been transported through the named carrier chain.

Finally invoke Definition 703.21. The finite coverage theorem identifies the only accepted reciprocal consumer as the chain

$$X, A, M, W \longrightarrow D \longrightarrow R \longrightarrow S.$$

Every off-chain reciprocal request therefore lacks a carrier coordinate in the local naming ledger, so the finite NameCert surface classifies it as a boundary/refusal row rather than as an alternate consumer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyInverseBudget}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyInverseBudget}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source, a nonzero-apartness budget, a finite modulus row, a selected $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{DyadicRatCore}^{\uparrow}$ reciprocal readback, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Lean4 ✓ `BEDC.Derived.CauchyInverseBudgetUp.taste gate`

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyInverseBudget}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 703.17, Definition 703.18, and Definition 703.19 bind the carrier $B = (X, A, M, W, D, R, S, H, C, P, N)$, apartness exposure A, finite $\mathsf{StreamName}^{\uparrow}$ window W, $\mathsf{DyadicRatCore}^{\uparrow}$ reciprocal row D, $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, $\mathsf{Real}^{\uparrow}$ seal row S, BHist, hsame, Cont, Pkg, and NameCert rows into one scoped reciprocal-window consumer route.

Formal verification: FormalStatus(NameCert$_{\text{CauchyInverseBudget}\uparrow}$, axiomClean)
Lean target: `BEDC.Derived.CauchyInverseBudgetUp.CauchyInverseBudgetTasteGate\_single\_carrier\_alignment`
Bridge status: none
Origin: ai
Not claimed: This chapter does not close Lean verification, field structure, quotient real equality, total reciprocal operation, trichotomy, ambient inverse theorems, or a public standard bridge.
Upgrade path: There is no further paper-closure upgrade for the reciprocal-window consumer route; remaining work belongs to the independent formal and bridge axes.

Chapter 704

A Concrete Naming Certificate for $\mathsf{ContourAffineConcat}^{\uparrow}$

The $\mathsf{ContourAffineConcat}^{\uparrow}$ packet realizes the affine concatenation law for contour integrals as finite NameCert data. It records the two contour rows, two integrand rows, scalar rows, four input integral rows, the concatenated contour row, the affine output row, and the BEDC structural rows that certify the shared endpoint, the two concatenation reads, the affine-linearity read, and the exported classifier face. The packet is local to the displayed operation law: it does not supply a general contour-integration engine, a hidden analytic continuation principle, or an unrecorded host equality of integrals.

The affine-concatenation packet consumes the operation-law surface of chapter 521 and the finite Riemann-sum window surface of chapter 587. The former supplies the contour-operation output row, and the latter supplies the windowed summation face whose two contour pieces are combined by the affine packet.

Definition 704.1 (Contour affine-concatenation carrier)**.** *A* $\mathsf{ContourAffineConcat}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (\gamma_1, \gamma_2, f, g, a, b, I_1^f, I_2^f, I_1^g, I_2^g, J, H, C, P, N)$$

with the following displayed rows:

1. *γ_1 and γ_2 are accepted piecewise-linear contour rows with the shared endpoint condition displayed by the local concatenation route;*
2. *f and g are the two accepted holomorphic integrand rows read on the two contour pieces;*
3. *a and b are accepted complex scalar rows;*
4. *I_1^f and I_2^f are the certified contour-integral output rows for f along γ_1 and γ_2;*
5. *I_1^g and I_2^g are the certified contour-integral output rows for g along γ_1 and γ_2;*
6. *J is the output row for the contour integral of $af + bg$ along the concatenated contour $\gamma_1 * \gamma_2$, with displayed value $a(I_1^f + I_2^f) + b(I_1^g + I_2^g)$;*
7. *H records componentwise* hsame *transports for the contour rows, integrand rows, scalar rows, four input integral rows, concatenated contour row, affine output row, provenance rows, and the local naming row;*
8. *C records the displayed* Cont *routes for shared-endpoint admission, the two concatenation reads, the affine-linearity read, and the final classifier read of J;*

9. *P is the* Pkg *provenance over* ContourIntegralSocket$^{\uparrow}$, ContourIntegralOperation$^{\uparrow}$, ContourSumWindow$^{\uparrow}$, Holomorphic$^{\uparrow}$, Complex$^{\uparrow}$, *piecewise-linear contour rows,* BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ContourAffineConcat}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed rows $\gamma_1, \gamma_2, f, g, a, b, I_1^f, I_2^f, I_1^g, I_2^g, J, H, C, P$

Theorem 704.2 (Contour affine-concatenation NameCert obligations)**.** *For the carrier of Definition 704.1, the local* $\mathsf{NameCert}_{\mathsf{ContourAffineConcat}^{\uparrow}}$ *surface consists of six finite obligations:*

1. *carrier admission for $A = (\gamma_1, \gamma_2, f, g, a, b, I_1^f, I_2^f, I_1^g, I_2^g, J, H, C, P, N)$;*
2. *shared-endpoint concatenation, requiring γ_1 and γ_2 to expose the endpoint match used by the displayed $\gamma_1 * \gamma_2$ route;*
3. *affine linearity, requiring the two concatenated integral reads to be combined only as $a(I_1^f + I_2^f) + b(I_1^g + I_2^g)$ through the displayed scalar rows a, b;*
4. *output classifier stability, requiring every public comparison of the output row J to pass through the same componentwise* hsame *transport row H and continuation row C;*
5. *ledger exactness, requiring the provenance row P to name the contour socket, contour operation, contour-sum window, holomorphic integrand, complex scalar, contour, transport, continuation, package, and naming rows used by the packet;*
6. *non-escape, requiring the packet to export no hidden contour endpoint, no unrecorded integral value, no host equality of complex histories, no analytic-continuation shortcut, and no operation law outside the displayed finite rows.*

Proof. Carrier admission is projection from the tuple in Definition 704.1. The two contour rows, two integrand rows, scalar rows, four input integral rows, output row, transport row, continuation row, provenance row, and local naming row are all displayed coordinates of the same finite packet.

Shared-endpoint concatenation is confined to the contour part of C. A consumer first reads γ_1 and γ_2, then the displayed endpoint match, and only then the concatenated contour row $\gamma_1 * \gamma_2$.

Affine linearity uses the two concatenation reads before the scalar combination is exported. The f-rows produce $I_1^f + I_2^f$, the g-rows produce $I_1^g + I_2^g$, and the scalar rows a, b produce the displayed value of J.

Output classifier stability and ledger exactness are the public-read constraints. The row H carries componentwise classifier transport, C carries the replay route, and P lists the neighboring contour-integral, holomorphic, complex, and BEDC structural packets.

Finally inspect the carrier list. Since there is no coordinate for a hidden endpoint, unrecorded integral value, host equality of complex histories, analytic-continuation shortcut, or unlisted operation law, none of those objects can be exported by the local naming surface. □

Theorem 704.3 (Contour affine-concatenation consumer exhaustion)**.** *Every consumer read of an accepted* ContourAffineConcat$^{\uparrow}$ *packet factors through the carrier rows of Definition 704.1 and the local obligations of Definition 704.2. The consumer receives exactly the displayed contour rows, integrand rows, scalar rows, input integral rows, affine output row, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row, with no additional analytic or host-side equality coordinate.*

Proof. Begin with the carrier projection. The consumer can read only $\gamma_1, \gamma_2, f, g, a, b, I_1^f, I_2^f, I_1^g, I_2^g, J, H, C, P, N$.

The NameCert obligations then determine the route. Shared-endpoint concatenation binds the contour row, affine linearity binds the output expression, classifier stability binds public comparison of J, and ledger exactness binds the neighboring contour-integral packets named by P.

The remaining coordinates are the transport, continuation, provenance, and local naming rows. None of them contains an additional analytic-continuation principle, hidden endpoint, unrecorded integral value, or host equality of complex histories, so the displayed finite rows exhaust the public surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContourAffineConcat}^{\uparrow}}$.

Constructive story: A $\mathsf{ContourAffineConcat}^{\uparrow}$ packet is generated from finite BHist rows for neighboring contour-integral packets, their shared endpoint, affine output expression, classifier row, transport, continuation, provenance, and local naming. Concatenation is produced by replaying the displayed endpoint and affine-linearity routes through Cont, so the output expression is tied to the visible neighboring contour rows. Componentwise hsame preserves the contour, endpoint, integral, and affine rows, while Pkg records the contour-integral dependencies consumed by the packet. The public surface is the finite concatenation ledger, not analytic continuation or host equality of complex paths.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContourAffineConcat}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the contour-affine-concat carrier, shared-endpoint concatenation, affine-linearity obligation, classifier stability, ledger exactness, and public-surface exhaustion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContourAffineConcat}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim analytic-continuation principles, hidden endpoints, unrecorded integral values, host equality of complex histories, or a global contour algebra.

Upgrade path: Obligation closure requires Lean encodings of the concatenation carrier, shared-endpoint route, affine output row, classifier stability, and ledger exactness.

Chapter 705

A Concrete Naming Certificate for $\mathsf{CriticalStripBarrier}^{\uparrow}$

The $\mathsf{CriticalStripBarrier}^{\uparrow}$ packet realizes the RH approach-rate witness as finite barrier-ledger data. It binds a supplied critical-strip row, a supplied zeta-zero row, a critical-line witness row, the real-part and rational lower-bound rows, transport and continuation rows, package provenance, and a local naming row. The witness row W is consumed from chapter 548 as the finite critical-line witness route, and this barrier chapter only transports that sibling row into the strip, zero, and refusal ledger rather than proving RH or adding analytic zero search. The packet records how a consumer may route a zero-localization or off-line lower-bound read; it does not prove RH, compute zeros, or assert a global analytic lower bound outside the displayed finite rows.

Definition 705.1 (Critical-strip-barrier carrier)**.** *A* $\mathsf{CriticalStripBarrier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Z, W, R, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the supplied* $\mathsf{CritStrip}^{\uparrow}$ *row carrying the critical-strip membership data for the displayed source history;*
2. *Z is the supplied* $\mathsf{ZetaZeros}^{\uparrow}$ *row carrying the zeta-zero premise for the same displayed source when a zero-localization read is requested;*
3. *W is the supplied* $\mathsf{CriticalLineWitness}^{\uparrow}$ *row available to consumers that already carry a critical-line witness route;*
4. *R is the real-part comparison row reading $\Re(s)$ through the* $\mathsf{Real}^{\uparrow}$ *carrier exposed by the strip and zero rows;*
5. *Q is the rational distance row recording the displayed lower-bound comparison against the rational history $1/2$ in* $\mathsf{Rat}^{\uparrow}$*;*
6. *A is the approach-rate ledger row that pairs each displayed rational separation depth with the corresponding positive rational lower-bound entry;*
7. *H records componentwise* hsame *transports for S, Z, W, R, Q, A and for the package and local naming coordinates;*

8. *C records the displayed* Cont *routes from the strip row to the zero row, from the real-part row to the rational distance row, from the distance row to the approach-rate ledger, and from the witness row to the RH-facing handoff;*
9. *P is the* Pkg *provenance over* $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CriticalLineWitness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CriticalStripBarrier}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed strip, zero, witness, real-part, rational-bound, approach-rate, transport, continuation, package, and naming rows.

Lean4 ✓ `BEDC.Derived.CriticalStripBarrierUp.CriticalStripBarrierTasteGate single carrier alignment`

Theorem 705.2 (CriticalStripBarrier NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CriticalStripBarrier}^{\uparrow}}$ *surface for Definition 705.1 consists exactly of six finite obligations:*

1. *carrier admission for $B = (S, Z, W, R, Q, A, H, C, P, N)$;*
2. *zero-localization routing from the* $\mathsf{CritStrip}^{\uparrow}$ *row S to the* $\mathsf{ZetaZeros}^{\uparrow}$ *row Z through displayed* hsame *and* Cont *rows;*
3. *rational separation exposure through R, Q, A as the only place where a lower-bound comparison against $1/2$ is read;*
4. *witness handoff through W only when a consumer already supplies the critical-line witness route;*
5. *componentwise stability under the transports in H and replay through the routes in C;*
6. *non-escape from a proof of* RH*, analytic zero search, host complex equality, quotient zero-set equality, or an undisplayed global lower-bound theorem.*

Proof. Carrier admission is projection from Definition 705.1. The strip row, zero row, witness row, real-part row, rational distance row, approach-rate ledger, transport row, continuation row, package row, and local naming row are all displayed coordinates.

Zero-localization routing is read only through S, Z, H, C. These rows bind the supplied critical-strip premise to the supplied zeta-zero premise without replacing either one by host complex equality or by a selected representative.

The approach-rate side is read through R, Q, A. The real row gives the displayed real part, the rational row gives the displayed comparison against $1/2$, and the ledger row gives the finite lower-bound entry attached to that comparison.

The handoff row W is a consumer boundary, not an RH proof. It may be read only as an already supplied critical-line witness route, so the packet does not turn a zero-in-strip premise into a proof that all zeros lie on the line.

Finally inspect the carrier inventory. Since no coordinate names zero search, quotient zero-set equality, host complex equality, a global analytic lower-bound theorem, or an RH inhabitant, the six obligations exhaust the local naming surface. □

Theorem 705.3 (CriticalStripBarrier zero-localization route)**.** *For an accepted* $\mathsf{CriticalStripBarrier}^{\uparrow}$ *carrier*

$$B = (S, Z, W, R, Q, A, H, C, P, N),$$

every zero-localization read factors through the displayed rows S, Z, H, C, P, N. The consumer receives the supplied critical-strip premise, the supplied zeta-zero premise, the componentwise transport tying them to the same displayed source, the continuation route by which the rows are replayed,

package provenance, and the local name; it receives no zero search, host equality of complex histories, quotient zero-set equality, or selected representative.

Proof. Project the zero-facing rows from the carrier. The rows available to such a read are S, Z, H, C, P, N.

The strip row S supplies the critical-strip side, and the zero row Z supplies the zeta-zero side. The transport and continuation rows bind them as one displayed route without adding a host equality or quotient comparison.

The package and local naming rows close the finite route. Because the carrier contains no coordinate for zero search or representative selection, the zero-localization read remains exactly the displayed finite packet route. □

Theorem 705.4 (CriticalStripBarrier non-escape)**.** *Every public read exported by an accepted* $\mathsf{CriticalStripBarrier}^{\uparrow}$ *packet factors through* $S, Z, W, R, Q, A, H, C, P, N$*. A request for a proof of* RH*, an analytic zero-finding procedure, a host complex equality, a quotient zero-set equality, or a lower-bound theorem not displayed in the finite approach-rate ledger is outside the packet and is not exported as NameCert evidence.*

Proof. Read a public request through the displayed continuation row C. If the request asks for the strip row, zero row, witness row, real-part row, rational-bound row, approach-rate ledger, transport row, package provenance, or local naming row, the carrier supplies the corresponding coordinate.

All other requests leave the carrier inventory. In particular, no coordinate carries an RH proof, analytic zero search, host complex equality, quotient zero-set equality, or an undisplayed lower-bound theorem.

Thus the local $\mathsf{NameCert}$ row can certify only the finite barrier ledger and its displayed routes. It cannot export evidence that is absent from the carrier. □

Theorem 705.5 (CriticalStripBarrier RH witness handoff)**.** *The RH approach-rate witness of Definition 9239.14 is realized, at the concrete-instance level, by the finite* $\mathsf{CriticalStripBarrier}^{\uparrow}$ *packet*

$$S, Z, W, R, Q, A, H, C, P, N.$$

An RH-facing consumer may read zero localization through S, Z, H, C, P, N*, rational lower-bound separation through* R, Q, A, H, C, P, N*, and an already supplied critical-line witness route through* W, H, C, P, N*. The handoff is a finite NameCert packet for the witness surface; it is not a proof of* RH *and not an analytic theorem that every off-line point is bounded away from zero.*

Proof. Start with the carrier definition and NameCert obligations. They expose exactly the strip, zero, witness, real-part, rational-bound, approach-rate, transport, continuation, package, and local naming rows.

Use the zero-localization route for S, Z, H, C, P, N. This supplies the premise side needed by an RH-facing consumer that is inspecting a zero in the critical strip.

Use the rational-bound rows R, Q, A, H, C, P, N for the approach-rate side. These rows provide only the finite lower-bound ledger entries that are displayed in the packet.

Finally use the non-escape theorem. Since the carrier has no coordinate for an RH proof or a global analytic lower-bound theorem, the exported object is precisely the finite witness handoff named by $\mathsf{CriticalStripBarrier}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{CriticalStripBarrier}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CriticalStripBarrier}^{\uparrow}$ packet is generated from finite BHist rows for a critical-strip premise, zeta-zero premise, critical-line witness, real-part comparison, rational distance, approach-rate ledger, transports, continuations,

provenance, and local name. A zero-localization or lower-bound read is routed by Cont through the strip, zero, real, rational, and approach-rate rows before any witness handoff is available. Componentwise hsame preserves the displayed rows, and Pkg records the strip, zero, witness, real, and rational dependencies. The packet is a finite barrier ledger and explicitly not an RH proof.

Theory closure: TheoryGate(NameCert$_{\mathsf{CriticalStripBarrier}\uparrow}$, seed)

Scope closed: This chapter binds the critical-strip-barrier carrier, NameCert obligations, zero-localization route, rational separation exposure, witness handoff, and non-escape theorem.

Formal verification: FormalStatus(NameCert$_{\mathsf{CriticalStripBarrier}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim the Riemann hypothesis, analytic zero search, host complex equality, quotient zero-set equality, or a global analytic lower-bound theorem.

Upgrade path: Obligation closure requires Lean encodings of the barrier carrier, zero-localization route, rational-bound ledger, witness handoff, and non-escape theorem.

Chapter 706

A Concrete Naming Certificate for $\mathsf{ObservableCauchySeal}^{\uparrow}$

The $\mathsf{ObservableCauchySeal}^{\uparrow}$ packet records the finite observation route used when a Real and Completion argument reads stream windows and dyadic radii before handing the result to a $\mathsf{Real}^{\uparrow}$ seal. It is an inspectable naming surface between observation budgets and real-facing seal rows. It does not assert real completeness, quotient stream equality, host real equality, or an unbounded Cauchy convergence principle.

Definition 706.1 (Observable Cauchy seal carrier)**.** *An* $\mathsf{ObservableCauchySeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (E, W, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *E is a unary precision request row naming the requested observation scale;*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row visible at that precision;*
3. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks and displayed radius rows read from W;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that repacks the finite dyadic observations as a regular-rational route;*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the finite readback and regular-rational handoff rows are fixed;*
6. *H records componentwise* hsame *transports for E, W, D, R, S and the local structural rows;*
7. *C records the displayed* Cont *routes from precision request to window, from window to dyadic readback, from dyadic readback to regular-rational handoff, and from the handoff to the seal row;*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local certificate rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ObservableCauchySeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed real value, quotient stream equality, host metric equality, selected infinite tail, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.ObservableCauchySealUp.ObservableCauchySealTasteGate single carrier alignment`

Theorem 706.2 (Observable Cauchy seal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ObservableCauchySeal}^{\uparrow}}$ *surface for Definition 706.1 consists of carrier admission, precision exposure, finite-window readback, dyadic radius exposure, regular-rational handoff, RealUp seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every accepted packet exposes exactly the rows $E, W, D, R, S, H, C, P, N$ *before any consumer can read the seal row.*

Proof. Carrier admission is projection from the displayed tuple O. The precision, window, dyadic readback, regular-rational handoff, seal, transport, route, provenance, and naming rows are all explicit coordinates of the packet.

The finite-window and dyadic-radius obligations read E before W, and W before D. Thus every dyadic observation is attached to a named finite window and a named precision request.

The regular-rational handoff and seal-routing obligations then read R and S only after those finite rows are visible. The remaining rows H, C, P, N transport, replay, package, and name the same route without adding a completed real value, quotient stream equality, host metric equality, selected infinite tail, or ambient completeness witness. □

Theorem 706.3 (Observable Cauchy seal window factorization)**.** *Every public read of an accepted* $\mathsf{ObservableCauchySeal}^{\uparrow}$ *packet factors through the finite route*

$$E \longmapsto W \longmapsto D \longmapsto R \longmapsto S.$$

The route may use the componentwise hsame *rows, displayed* Cont *replay,* Pkg *provenance, and local naming row, but it cannot bypass the finite stream window or dyadic readback rows.*

Proof. Start with the accepted carrier. The only visible route from a precision request to a seal row passes through the displayed coordinates E, W, D, R, S.

Read the route order through the continuation row C. The window row W is reached from the precision request E, the dyadic readback row D is reached from W, and the regular-rational handoff row R is reached from D.

The seal row S is therefore downstream of the finite readback. Since no second window or dyadic coordinate is present in the carrier, a public read has no route around W or D. □

Theorem 706.4 (Observable Cauchy seal Real handoff)**.** *Let*

$$O = (E, W, D, R, S, H, C, P, N)$$

be an accepted $\mathsf{ObservableCauchySeal}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *consumer of* O *receives the seal row* S *only through the displayed precision request, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks and radii,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

Proof. Project the packet to the finite rows $E, W, D, R, S, H, C, P, N$. The Real-facing coordinate is the single seal row S.

Apply the window factorization theorem. Before S can be consumed, the route has already exposed the precision request, stream window, dyadic readback and radius rows, and regular-rational handoff.

The structural rows H, C, P, N carry only transport, replay, provenance, and local naming for that finite route. Hence the RealUp consumer receives the displayed finite observation handoff and no additional completion coordinate. □

Theorem 706.5 (Observable Cauchy seal L10 dependency lattice)**.** *Every accepted* $\mathsf{ObservableCauchySeal}^{\uparrow}$ *packet consumes the L10 route through chapter 126, chapter 291, chapter 301, and chapter 38 in the displayed order*

$$E, W, D, R, S, H, C, P, N.$$

No Real-facing consumer may bypass the finite $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback ledger, or the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff.*

Proof. Project the carrier rows from Definition 706.1. The rows $E, W, D, R, S, H, C, P, N$ are the only public coordinates of the packet, with W naming the finite stream window, D recording the dyadic readbacks and radii, R recording the regular-rational handoff, and S recording the RealUp seal row.

Apply Definition 706.3. Any public read of S factors through the route $E \longmapsto W \longmapsto D \longmapsto R \longmapsto S$, while H, C, P, N only transport, replay, package, and name that same finite route. The named chapter route is therefore the horizontal dependency lattice from $\mathsf{StreamName}^{\uparrow}$ to $\mathsf{DyadicRatCore}^{\uparrow}$, then to $\mathsf{RegSeqRat}^{\uparrow}$, and finally to $\mathsf{Real}^{\uparrow}$.

Apply Definition 706.4 to the Real-facing consumer and Definition 706.6 to the attempted exits. Since the carrier contains no quotient stream equality, host real equality, ambient completeness witness, completed real value, or unrecorded Cauchy tail, the consumer cannot reach S by a route outside the finite window, dyadic ledger, and RegSeqRat handoff. □

Theorem 706.6 (Observable Cauchy seal non-escape)**.** *An accepted* $\mathsf{ObservableCauchySeal}^{\uparrow}$ *packet exports no real-completeness theorem, no quotient stream equality, no host real equality, no countable-choice selector, and no unrecorded Cauchy tail. Any attempted consumer omitting* E*,* W*,* D*, or* R *is outside the packet and cannot export the* $\mathsf{Real}^{\uparrow}$ *seal row* S*.*

Proof. Read the carrier inventory first. The only exportable rows are $E, W, D, R, S, H, C, P, N$, and the local obligations require those rows to be visible in the finite observation route.

If a consumer omits E or W, the packet supplies no named observation window. If it omits D, the packet supplies no dyadic readback or radius ledger. If it omits R, the packet supplies no regular-rational handoff to the seal row.

The attempted read is therefore outside the local naming surface. Because the carrier has no coordinate for real completeness, quotient stream equality, host real equality, countable choice, or an unrecorded Cauchy tail, none of those objects can be exported through S. □

Closure status for $\mathsf{NameCert}_{\mathsf{ObservableCauchySeal}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ObservableCauchySeal}^{\uparrow}$ packet is generated from a unary precision request, finite StreamName window, DyadicRatCore readbacks and radii, RegSeqRat handoff row, RealUp seal row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObservableCauchySeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 706.1, Definition 706.2, Definition 706.3, Definition 706.4, and Definition 706.6 bind finite observation routes from stream windows and dyadic readbacks into a RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObservableCauchySeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close real completeness, quotient stream equality, host real equality, countable choice, unrecorded Cauchy tails, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window readback, dyadic radius exposure, RegSeqRat handoff, RealUp seal routing, and non-escape for the same packet.

Chapter 707

A Concrete Naming Certificate for ProofTermErasureClassifier$^{\uparrow}$

The ProofTermErasureClassifier$^{\uparrow}$ packet is the classifier-level surface for proof-term erasure. It reads proof-term membership as an Ext row, exposes the erased term through displayed Cont replay and SigRel readback, and packages the resulting public classifier row with ProofTermErasureTrace$^{\uparrow}$ and ProofTermErasureAuditRoute$^{\uparrow}$ provenance so later consumers receive a finite erasure-preserving membership object.

The classifier consumes the finite trace surface of chapter 642 and the audit-route surface of chapter 690. It contributes only the erased membership readback row and does not replace either sibling trace or audit route.

Theorem 707.1 (Proof-term erasure classifier trace sibling route)**.** *Every accepted* ProofTermErasureClassifier$^{\uparrow}$ *carrier consumes the trace surface of chapter 642 and the audit route of chapter 690 before exporting erased classifier membership. The finite route passes through typing* Ext *membership, erasure* Cont *replay,* SigRel *readback, componentwise* hsame *transport,* Pkg *provenance, and local* NameCert *rows.*

Proof. Project the classifier packet. Its membership source is the displayed Ext row, and its erased output is read only after the erasure replay and SigRel readback rows have been exposed.

The trace chapter supplies the finite trace surface that records how the proof-term row is replayed as an erased row. The audit-route chapter supplies the provenance path that keeps that replay inspectable before a downstream classifier reads the erased membership.

Finally route both sibling surfaces through the carrier rows H, Q, N. Since the exported membership is packaged only after hsame transport, Pkg provenance, and local naming, the classifier cannot replace the trace or audit route by an ambient proof-erasure oracle. □

Definition 707.2 (Proof-term erasure classifier carrier)**.** *A* ProofTermErasureClassifier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (P, E, M, R, S, H, Q, N)$$

with the following displayed rows:

1. *P is the proof-term row whose classifier membership is tested;*
2. *E is the erased-term row exported to downstream classifier consumers;*
3. *M is the* Ext *membership row for the proof-term row P;*

4. *R is the* Cont *erasure replay route from P to E;*
5. *S is the* SigRel *readback row naming the erased classifier output as the public reading of the membership row M along R;*
6. *H records componentwise* hsame *transports for the proof-term row, erased-term row,* Ext *membership row,* Cont *replay row,* SigRel *readback row, package provenance, and local naming row;*
7. *Q is the* Pkg *provenance over the displayed* BHist, Ext, Cont, SigRel, hsame, ProofTermErasureTrace$^{\uparrow}$, ProofTermErasureAuditRoute$^{\uparrow}$, *and* NameCert *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ProofTermErasureClassifier}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through P, E, M, R, S, H, Q, N.

Lean4 ✓ `BEDC.Derived.ProofTermErasureClassifierUp.ProofTermErasureClassifierTasteGate single carrier alignment`

Theorem 707.3 (Proof-term erasure classifier Ext-membership)**.** *Every accepted* ProofTermErasureClassifier$^{\uparrow}$ *carrier reads classifier membership only from the displayed* Ext *row M. If a downstream consumer accepts the erased row E as a classifier member, the source of that membership is the proof-term row P together with M, transported componentwise through H and packaged by Q, N.*

Proof. Project the carrier of Definition 707.2. The only membership coordinate is M, and it is attached to the proof-term row P.

The erased row E is not a second classifier source. It is reached from P through the displayed continuation row R and named for public reading by the SigRel row S.

Finally route the membership read through H, Q, N. These rows preserve and package the same displayed coordinates, so a downstream consumer cannot replace M by host type checking or by an undisplayed classifier. □

Theorem 707.4 (Proof-term erasure classifier erasure preservation)**.** *For every accepted* ProofTermErasureClassifier *carrier $K = (P, E, M, R, S, H, Q, N)$, the erased public classifier row preserves the proof-term* Ext *membership displayed by M. The preservation route is exactly the* Cont *replay row R together with the* SigRel *readback row S and the componentwise* hsame *transport row H.*

Proof. Read the packet coordinates. The source membership is M, the erased public row is E, the replay route is R, and the public readback is S.

Use the displayed replay row to carry the membership read from the proof-term row to the erased-term row. The SigRel row records the classifier readback attached to that replay, so the exported row is the erased reading of the same membership event.

Transport is exhausted by H and provenance by Q, N. Since no other route is present in the carrier, erasure preservation is exactly the displayed finite route. □

Theorem 707.5 (Proof-term erasure classifier non-escape ledger)**.** *Every accepted* ProofTermErasureClassifier$^{\uparrow}$ *carrier exports only the erased row E, the proof-term membership row M, the erasure replay row R, the readback row S, the transport row H, the package row Q, and the local naming row N. It exports no proof object as consumer evidence, no host conversion relation, no quotient syntax equality, no proof irrelevance principle, and no ambient normalization oracle.*

Proof. Inspect the carrier inventory. The proof-term row P is present only as the source named by the membership row M, while the consumer-facing row is E.

The exported evidence is routed through R, S, H, Q, N. These rows record replay, readback, transport, provenance, and local naming, and none of them carries a proof object or a host conversion principle.

The excluded objects have no coordinate in K. Therefore they cannot be read from the local certificate surface. □

Theorem 707.6 (Proof-term erasure classifier NameCert obligations)**.** *For the carrier of Definition 707.2, the local* $\mathsf{NameCert}_{\mathsf{ProofTermErasureClassifier}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission exposes exactly* $K = (P, E, M, R, S, H, Q, N)$*;*
2. *membership exactness reads the accepted classifier decision only from the displayed* Ext *row* M*;*
3. *erasure preservation routes the public erased row only through the displayed* Cont *row* R *and* SigRel *row* S*;*
4. *trace and audit provenance are carried only by the displayed* Pkg *row* Q *over* $\mathsf{ProofTermErasureTrace}^{\uparrow}$ *and* $\mathsf{ProofTermErasureAuditRoute}^{\uparrow}$ *rows;*
5. *the non-escape ledger binds every consumer read to* H, Q, N *and excludes proof-object export, host conversion, quotient syntax equality, proof irrelevance, and ambient normalization.*

Proof. Carrier admission is projection from the finite tuple K. The local naming row exposes exactly the eight displayed coordinates and no hidden carrier field.

Membership exactness is the role of M. Erasure preservation is then read through R and S, which replay the erased row and name its classifier readback.

The provenance obligation is carried by Q. It records the dependency on the proof-term erasure trace and audit-route packets while keeping the consumer surface finite.

Finally apply the non-escape ledger of Definition 707.5. Since every consumer read is already confined to H, Q, N and the displayed erasure rows, the certificate cannot export proof objects or host-level conversion data. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProofTermErasureClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofTermErasureClassifier}^{\uparrow}$ packet is generated from proof-term, erased-term, Ext-membership, Cont replay, SigRel readback, hsame transport, Pkg provenance, trace, audit-route, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProofTermErasureClassifier}^{\uparrow}}$, seed)

Scope closed: Definition 707.2, Definition 707.3, Definition 707.4, Definition 707.5, and Definition 707.6 define the finite erasure-preserving classifier surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProofTermErasureClassifier}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, public compiler correctness, host conversion, quotient syntax equality, proof irrelevance, ambient normalization, or proof-object export.

Upgrade path: Obligation closure requires checked carrier admission, Ext-membership exactness, erasure preservation, trace and audit-route provenance, and non-escape for the displayed classifier rows.

Chapter 708

RegularCauchyTelescopingBudget NameCert Construction

The $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ packet records the finite chained-window error ledger used by Real-completion diagonal handoffs. It starts with one precision request, opens a finite chain of selected $\mathsf{StreamName}^{\uparrow}$ windows, reads their dyadic error rows, transports the result through $\mathsf{RegSeqRat}^{\uparrow}$, seals the terminal row through $\mathsf{Real}^{\uparrow}$, and records the telescoping composition that makes the intermediate errors visible. The packet is a NameCert surface for finite budget composition; it is not a quotient of streams, a selected host limit, countable choice, or an ambient completeness principle.

This packet is a horizontal L10 consumer of the selected-window surface in chapter 660 and the adjacent-window fusion surface in chapter 693. Together with the finite-window source of chapter 126, the dyadic endpoint ledger of chapter 291, the regular-sequence handoff of chapter 301, and the seal row of chapter 38, those sibling chapters supply the finite $\mathsf{StreamName}^{\uparrow}$ windows and fusion route before the packet reads $\mathsf{DyadicRatCore}^{\uparrow}$ error rows, passes through $\mathsf{RegSeqRat}^{\uparrow}$, reaches the $\mathsf{Real}^{\uparrow}$ seal, and exports the telescoping ledger T.

Definition 708.1 (RegularCauchyTelescopingBudget carrier)**.** *A* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, W, D, R, S, T, H, C, P, N)$$

with the following displayed rows:

1. *E is the precision request whose requested Real-completion tolerance is being budgeted;*
2. *W is a finite chain of selected* $\mathsf{StreamName}^{\uparrow}$ *windows opened from the displayed regular Cauchy sources;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *error ledger read from the successive windows in W;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained after the selected dyadic errors have been composed;*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from the handoff R at the requested precision;*
6. *T is the telescoping composition ledger, recording the finite sum of adjacent-window errors and the remaining budget after each handoff;*
7. *H records componentwise* hsame *transports for E, W, D, R, S, T and for the structural rows of the packet;*

8. *C records the displayed* Cont *routes for precision exposure, window-chain admission, dyadic-ledger reads, telescoping composition,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal delivery;*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySequence}^{\uparrow}$, $\mathsf{RegularCauchyWindowFusion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the visible rows $E, W, D, R, S, T, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier visible rows`

Theorem 708.2 (RegularCauchyTelescopingBudget NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTelescop}}$ *surface for Definition 708.1 consists of carrier admission for*

$$B = (E, W, D, R, S, T, H, C, P, N),$$

precision exposure through E, finite window-chain admission through W, dyadic error-ledger exposure through D, telescoping composition through T, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through R,* $\mathsf{Real}^{\uparrow}$ *seal delivery through S, componentwise* hsame *stability, displayed* Cont *route replay,* Pkg *provenance, local naming, and non-escape from quotient streams, selected host limits, countable choice, ambient completeness, hidden comparison rows, and unrecorded error budgets.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 708.1. The packet contains exactly the rows $E, W, D, R, S, T, H, C, P, N$.

The analytic-facing obligations are read in order. The precision request E determines which finite chain of selected $\mathsf{StreamName}^{\uparrow}$ windows W is opened. The dyadic ledger D records the error rows read from those windows, and the telescoping ledger T records their finite composition before the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R is exposed.

The real-facing obligation is the seal row S. It is reached only after R has consumed the displayed window chain and the telescoping ledger.

Finally H, C, P, N preserve, route, package, and name the same finite packet. Because no coordinate names quotient streams, selected host limits, countable choice, ambient completeness, hidden comparison rows, or unrecorded budgets, the local NameCert exports none of that data. □

Theorem 708.3 (RegularCauchyTelescopingBudget dyadic ledger exposure)**.** *For every accepted* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *carrier*

$$B = (E, W, D, R, S, T, H, C, P, N),$$

the dyadic ledger row D is readable only after the precision row E and the finite $\mathsf{StreamName}^{\uparrow}$ *window chain W have been exposed. The row D supplies adjacent-window* $\mathsf{DyadicRatCore}^{\uparrow}$ *error entries for the displayed finite route, and it supplies no quotient-stream equality, selected host limit, choice selector, ambient completeness row, hidden comparison row, or independent Real carrier.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier dyadic ledger exposure`

Proof. Read the carrier in Definition 708.1. Its ordered packet has one precision request E, one finite selected-window chain W, and one dyadic error ledger D.

Apply the NameCert obligations of Definition 708.2. Precision exposure through E opens the finite $\mathsf{StreamName}^{\uparrow}$ chain W, and D is then the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ ledger read from those windows. The surrounding $\mathsf{RegularCauchySequence}^{\uparrow}$ and $\mathsf{RegularCauchyWindowFusion}^{\uparrow}$ surfaces provide the selected-window sources and shared-window handoff route, not an ambient completion object.

Finally inspect the packet boundary. Quotient-stream equality, selected host limits, choice selectors, ambient completeness rows, hidden comparison rows, and independent Real carriers are absent from the coordinates $E, W, D, R, S, T, H, C, P, N$. The dyadic ledger therefore exposes only the finite adjacent-window error rows named by D. □

Theorem 708.4 (RegularCauchyTelescopingBudget telescoping composition)**.** *For every accepted* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *carrier*

$$B = (E, W, D, R, S, T, H, C, P, N),$$

the telescoping composition row T consumes exactly the finite adjacent-window error rows exposed by D, records the remaining budget at each finite handoff, and is stable only under the displayed componentwise hsame *transports in H.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier telescoping composition`

Proof. Use Definition 708.1 to project the finite rows D, T, H. The ledger D is the only coordinate containing adjacent-window dyadic error entries, and T is the only coordinate recording their finite telescoping composition.

Apply Definition 708.2 and Definition 708.3. The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchySequence}^{\uparrow}$, and $\mathsf{RegularCauchyWindowFusion}^{\uparrow}$ surfaces expose a finite list of adjacent-window error rows. The composition row T consumes that displayed list and records the remaining budget passed at each handoff.

Stability is then confined to H. Since H records componentwise hsame transports for E, W, D, R, S, T and the structural rows, a transported packet preserves the same finite telescoping ledger exactly along those displayed transports and along no unrecorded comparison row. □

Theorem 708.5 (RegularCauchyTelescopingBudget RegSeqRat handoff order)**.** *For every accepted* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *carrier*

$$B = (E, W, D, R, S, T, H, C, P, N),$$

the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R is exposed only after E, W, D, T, and the* $\mathsf{Real}^{\uparrow}$ *seal row S is exposed only after R.*

Proof. First read the carrier and NameCert surface. By Definition 708.1 and Definition 708.2, the finite route exposes precision, selected windows, dyadic ledger rows, and telescoping composition as E, W, D, T before the handoff row R.

The dyadic and telescoping obligations make this order explicit. Apply Definition 708.3 to obtain the E, W, D prefix, then apply Definition 708.4 to consume the adjacent-window $\mathsf{DyadicRatCore}^{\uparrow}$ rows through T. The handoff row R is therefore the first $\mathsf{RegSeqRat}^{\uparrow}$ row downstream of the finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegularCauchySequence}^{\uparrow}$, and $\mathsf{RegularCauchyWindowFusion}^{\uparrow}$ route.

Finally apply Definition 708.7. The seal row S is the only $\mathsf{Real}^{\uparrow}$ seal row in the carrier, and that theorem places it after the route through E, W, D, T, R. Thus the Real-facing seal cannot be read before the $\mathsf{RegSeqRat}^{\uparrow}$ handoff has been exposed. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier regseqrat handoff order`

Theorem 708.6 (RegularCauchyTelescopingBudget window chain)**.** *For every accepted* RegularCauchyTelescopingB *carrier*

$$B = (E, W, D, R, S, T, H, C, P, N),$$

the selected windows form a finite chain read through $\mathsf{RegularCauchySequence}^{\uparrow}$ *and* $\mathsf{RegularCauchyWindowFusion}^{\uparrow}$ *surfaces. Each adjacent-window error consumed by the chain is recorded in D, and each transfer of remaining precision is recorded in T before the handoff row R is available.*

Proof. Project E, W, D, T from the carrier. The precision row E fixes the requested tolerance, and the window row W is the only coordinate that opens selected $\mathsf{StreamName}^{\uparrow}$ windows.

Use the existing $\mathsf{RegularCauchySequence}^{\uparrow}$ and $\mathsf{RegularCauchyWindowFusion}^{\uparrow}$ surfaces as the displayed sources of the chain. They expose finite selected windows and shared-window Real-facing routes without selecting a host limit or quotient representative.

Now read the dyadic and telescoping rows. The ledger D stores the adjacent-window error rows, while T composes them and records the remaining budget passed to the next window. Since R appears only after D and T, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff is downstream of the finite chain. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier window chain`

Theorem 708.7 (RegularCauchyTelescopingBudget Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *carrier factors through the route*

$$E, W, D, T, R, S, H, C, P, N.$$

The route first consumes the requested precision, then the selected window chain, then the dyadic error ledger, then the telescoping composition ledger, then the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and only then the* $\mathsf{Real}^{\uparrow}$ *seal row.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier real seal handoff`

Proof. Begin with the window-chain theorem. It places the selected windows, dyadic error rows, telescoping composition, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff in the displayed order E, W, D, T, R.

Read the seal coordinate. The row S is the only $\mathsf{Real}^{\uparrow}$ seal row in the carrier, and the continuation row C exposes it only after the route through E, W, D, T, R has been replayed.

The rows H, P, N transport, package, and name the same route. Therefore every Real-facing consumer receives the seal through $E, W, D, T, R, S, H, C, P, N$ and through no independent completion object. □

Theorem 708.8 (RegularCauchyTelescopingBudget non-escape)**.** *For an accepted* RegularCauchyTelescopingBudge *carrier, the finite telescoping budget exports no quotient stream equality, selected host limit, countable-choice selector, ambient completeness principle, hidden comparison row, unrecorded error budget, or independent RealUp carrier. All exported data are confined to*

$$E, W, D, R, S, T, H, C, P, N.$$

Proof. Use the NameCert obligations to identify the complete carrier surface. The only admitted rows are $E, W, D, R, S, T, H, C, P, N$.

Use the window-chain theorem and the Real seal handoff theorem. They force every path to the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the $\mathsf{Real}^{\uparrow}$ seal to consume the finite selected windows, dyadic ledger, and telescoping composition ledger.

Inspect the packet boundary. No coordinate stores quotient stream equality, selected host limits, countable choice, ambient completeness, hidden comparisons, unrecorded budgets, or an independent real carrier. The exported surface is exactly the displayed finite packet. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier nonescape`

Theorem 708.9 (RegularCauchyTelescopingBudget primitive scope binding)**.** *For every accepted* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *packet*

$$B = (E, W, D, R, S, T, H, C, P, N),$$

the scoped primitive surface is exactly the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ *error ledger* D*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window chain* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal row* S*, the componentwise* hsame *transport row* H*, the visible* Cont *route row* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}$ *row* N*, all read under the precision request* E *and telescoping ledger* T*. No host limit, quotient stream, countable-choice selector, hidden comparison, or ambient completeness row is part of this scope.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier primitive scope binding`

Proof. Project the carrier from Definition 708.1. Its only rows are $E, W, D, R, S, T, H, C, P, N$, with D naming the dyadic error ledger, W naming the finite selected-window chain, R naming the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and S naming the $\mathsf{Real}^{\uparrow}$ seal.

Use the local NameCert obligations and dyadic exposure. Theorems 708.2 and 708.3 bind precision exposure, window-chain admission, dyadic-ledger reads, componentwise transport, visible route replay, provenance, local naming, and non-escape to the same finite packet.

Now apply the finite route theorems. The telescoping composition theorem consumes the displayed dyadic entries through T, the window-chain theorem identifies the selected $\mathsf{StreamName}^{\uparrow}$ chain, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff order theorem places R after E, W, D, T, and the Real seal handoff theorem places S after R.

Finally apply Definition 708.8. Since the excluded host limit, quotient stream, countable-choice selector, hidden comparison, and ambient completeness rows do not occur in the carrier, the scoped primitive binding is precisely the existing finite route through $E, W, D, T, R, S, H, C, P, N$. □

Theorem 708.10 (RegularCauchyTelescopingBudget scoped closure)**.** *The carrier, dyadic ledger exposure, telescoping composition,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff order, finite window chain,* $\mathsf{Real}^{\uparrow}$ *seal handoff, non-escape boundary, and primitive-scope binding jointly close the scoped primitive surface of* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

Proof. Start with the carrier and NameCert obligations. They expose exactly the rows $E, W, D, R, S, T, H, C, P, N$ and identify the visible source chapters for dyadic errors, selected windows, regular rational handoff, Real seal delivery, transport, replay, provenance, and local naming.

Use the ledger and composition theorems to bind the analytic content. Dyadic exposure places D after E and W, while telescoping composition consumes the displayed finite ledger through T without adding a hidden comparison row.

Use the handoff and non-escape theorems for the target boundary. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff order, window-chain theorem, and $\mathsf{Real}^{\uparrow}$ seal handoff place R and S downstream of the same finite route, and the non-escape theorem excludes quotient streams, selected host limits, countable choice, hidden comparisons, ambient completeness, and independent Real carriers.

Finally apply the primitive-scope binding. It identifies the complete scoped surface as $E, W, D, T, R, S, H, C, P, N$ over the listed BEDC primitives, so no additional primitive row remains outside the packet. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier scoped closure`

Theorem 708.11 (RegularCauchyTelescopingBudget public export)**.** *Every L10 diagonal handoff consumer that cites* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *may cite only the ordered public surface*

$$E, W, D, T, R, S, H, C, P, N$$

over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *The consumer must read the precision request E, selected window chain W, dyadic error ledger D, telescoping composition ledger T,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R,* $\mathsf{Real}^{\uparrow}$ *seal S, componentwise transport H, displayed replay C, provenance P, and local naming row N in that order before using the packet as a public diagonal budget. The public surface exports no quotient stream equality, selected host limit, countable-choice selector, hidden comparison, unrecorded error budget, ambient completeness principle, or independent RealUp carrier.*

Proof. Start with the carrier and scoped closure. The carrier displays exactly $E, W, D, R, S, T, H, C, P, N$, and Definition 708.10 binds those rows as the scoped primitive surface over the named BEDC prerequisites.

Use the Real seal handoff. Theorems 708.5 and 708.7 place R and S after the finite window, dyadic ledger, and telescoping ledger rows, so a diagonal consumer cannot read a Real-facing seal before the ordered route is exposed.

Finally apply non-escape. Theorem 708.8 excludes quotient streams, selected host limits, countable choice, hidden comparisons, unrecorded budgets, ambient completeness, and independent Real carriers. Therefore the reusable public cite is precisely the ordered surface $E, W, D, T, R, S, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier public export`

Theorem 708.12 (RegularCauchyTelescopingBudget Real bridge route)**.** *Any* $\mathsf{Real}^{\uparrow}$ *consumer of the public* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *export must read the* $\mathsf{StreamName}^{\uparrow}$ *window chain, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the window-chain rows, and the* $\mathsf{Real}^{\uparrow}$ *seal handoff before consuming the telescoping budget. Equivalently, the consumer must traverse*

$$E, W, D, T, R, S, H, C, P, N$$

with W read as the finite $\mathsf{StreamName}^{\uparrow}$ *chain, D read as the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, T read as the telescoping ledger, R read as the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and S read as the* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start from the public export theorem. It identifies the reusable public surface as the ordered rows $E, W, D, T, R, S, H, C, P, N$ and excludes any independent Real carrier or ambient completeness row.

Use the finite route theorems to expose the bridge order. The window-chain theorem supplies the $\mathsf{StreamName}^{\uparrow}$ chain W and places its adjacent-window ledger in D before T; the $\mathsf{RegSeqRat}^{\uparrow}$ handoff order theorem places R after E, W, D, T.

Now apply the Real seal handoff and primitive scope binding. The Real seal handoff places S downstream of the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, while primitive scope binding keeps H, C, P, N as transport, replay, provenance, and naming rows for the same finite packet.

Thus a $\mathsf{Real}^{\uparrow}$ consumer cannot consume the telescoping budget merely as an isolated public row. It must first read the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, window-chain, and Real-seal route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetCarrier bridge route`

Theorem 708.13 (RegularCauchyTelescopingBudget window concatenation route)**.** *Suppose two accepted* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *packets share the terminal* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row of the first packet as the precision-facing source row of the second packet through displayed* hsame *transport. Then their concatenated finite* $\mathsf{StreamName}^{\uparrow}$ *window chain exports the ordered composite budget route*

$$E, W, D, T, R, S, H, C, P, N.$$

The dyadic error ledgers are appended in the displayed window order, the shared boundary is read through H before repacking, and the composite route introduces no quotient stream equality, selected host limit, countable choice, hidden comparison, ambient completeness, or independent $\mathsf{Real}^{\uparrow}$ *carrier.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTelescopingBudgetUp.RegularCauchyTelescopingBudgetWindowConcatenation`

Proof. Project the two accepted carriers through Definition 708.1. The first packet supplies rows $E_0, W_0, D_0, T_0, R_0, S_0, H_0, C_0, P_0, N_0$, and the second supplies rows $E_1, W_1, D_1, T_1, R_1, S_1, H_1, C_1, P_1, N_1$.

Use the window-chain theorem and telescoping-composition theorem for both packets. The first route reads W_0, D_0, T_0 before R_0, S_0, and the second route reads W_1, D_1, T_1 before R_1, S_1.

Now read the shared boundary. The assumed displayed hsame transport identifies the terminal R_0, S_0 rows with the precision-facing source row of the second packet only through H_0 and H_1, so the handoff is visible before any composite public route is named.

Repack the composite route by appending the dyadic ledger lists and the finite window chains in that order. The RegSeqRat handoff order and Real seal handoff theorems place the resulting route in the order $E, W, D, T, R, S, H, C, P, N$.

Finally apply non-escape. Since neither input packet contains quotient stream equality, selected host limits, countable choice, hidden comparisons, ambient completeness, or an independent Real carrier, and since the shared boundary is read only through displayed transport, the concatenated route exports none of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ packet is generated from a precision request, a finite chain of selected $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ error ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal row, a telescoping composition ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 708.1, Definition 708.2, Definition 708.3, Definition 708.4, Definition 708.5, Definition 708.6, Definition 708.7, Definition 708.8, Definition 708.11, the bridge witness Definition 708.12, and the window concatenation route Definition 708.13 give the mature treatment for chained StreamName windows, dyadic ledgers, RegSeqRat handoff, and Real seal rows in Real-completion diagonal handoffs.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyTelescopingBudget}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, RealUp completeness, quotient stream equality, selected host limits, countable choice, ambient completeness, hidden comparison rows, unrecorded error budgets, or a public standard bridge.

Upgrade path: Bridged closure requires a standard bridge that transports the ordered public surface into the acceptance schema without adding quotient streams, selected host limits, countable choice, hidden comparisons, ambient completeness, or an independent RealUp carrier.

Chapter 709

A Concrete Naming Certificate for ClosedGeneratorAudit$^{\uparrow}$

The ClosedGeneratorAudit$^{\uparrow}$ packet names the finite audit surface shared by kernel acceptance, recursor authorization, and closed-term substitution. It packages MetaCIC generator-closure rows, closed-substitution rows, accepted kernel rows, audit-refusal rows, and local NameCert naming as one BEDC-readable object rather than as three unrelated host-side facts.

Its K and S rows consume the concrete sibling surfaces of chapter 547, chapter 557, and chapter 711 as the displayed kernel-acceptance and generator-audit dependency lattice.

Definition 709.1 (Closed generator audit carrier)**.** *A* ClosedGeneratorAudit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, K, R, S, A, H, C, P, N)$$

with the following displayed rows:

1. *T records the generated MetaCIC term or proof row, including the local syntax object whose closure and acceptance are audited;*
2. *K records the kernel acceptance row for the generated object and the accepted declaration or proof stamp exposed by* KernelAcceptanceAuditWitness$^{\uparrow}$ *or* KernelAcceptanceTrace$^{\uparrow}$*;*
3. *R records the authorized recursor row, including the emitted eliminator, checked motive, branch package, structural descent ledger, and generated output row supplied by* RecursionAuthorizationLedger$^{\uparrow}$*;*
4. *S records the closed substitution and shift row, including the* `GeneratorClosureClassifier`*,* `closed_under_substitute_classifier`*,* `shift_closed`*, and* `substitute_closed` *audit entries used to replay non-escape of closed terms;*
5. *A records the axiom-purity audit row, with refusal entries for* `Classical.choice`*,* `Quot.sound`*,* `propext`*, host conversion, and any unrecorded proof oracle;*
6. *H records componentwise* hsame *transport for the generated object, kernel row, recursor row, closed-substitution row, audit row, replay route, provenance, and local name;*
7. *C records the displayed* Cont *routes replaying kernel acceptance, recursor authorization, closed-substitution preservation, audit refusal, and consumer access;*
8. *P records the* Pkg *provenance over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* KernelAcceptanceAuditWitness$^{\uparrow}$*,* KernelAcceptanceTrace$^{\uparrow}$*,* RecursionAuthorizationLedger$^{\uparrow}$*, and* GeneratorAuditClosure$^{\uparrow}$*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{ClosedGeneratorAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host proof kernel, quotient transport, classical selection, proposition extensionality, hidden conversion, or an accepted proof oracle outside the displayed rows.

Theorem 709.2 (Closed generator audit NameCert obligations)**.** *For every accepted* $\mathsf{ClosedGeneratorAudit}^{\uparrow}$ *carrier*

$$G = (T, K, R, S, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedGeneratorAudit}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission exposes the generated object, kernel row, authorized recursor row, closed-substitution row, axiom-purity audit row, transport, replay, provenance, and local name as the packet $T, K, R, S, A, H, C, P, N$;*
2. *generator-closure replay reads the* `GeneratorClosureClassifier` *data in S and routes it through the accepted generator-audit packet;*
3. *closed-substitution non-escape reads* `closed_under_substitute_classifier`*,* `shift_closed`*, and* `substitute_closed` *only as the displayed closed-term rows in S;*
4. *kernel-acceptance replay reads K through the displayed kernel-acceptance witness or trace and connects authorized recursor output R to the generated row T;*
5. *audit-refusal exactness reads A as the complete refusal row for* `Classical.choice`*,* `Quot.sound`*,* `propext`*, host conversion, and any unrecorded proof oracle.*

Proof. Project the finite packet of Definition 709.1. Its carrier coordinates are precisely $T, K, R, S, A, H, C, P, N$, so carrier admission and local naming have no row outside the displayed tuple.

The generator side is supplied by the existing generator-audit closure surface. It reads the `GeneratorClosureClassifier` row and the accepted substitute or shift closure witness before exposing the closure claim to a consumer.

The substitution side is the closed-term boundary. The entries `closed_under_substitute_classifier`, `shift_closed`, and `substitute_closed` are recorded in S, and the replay route C keeps them attached to the same generated row T.

The kernel and recursor side is read through K and R. Kernel acceptance supplies the accepted declaration or proof stamp, while the recursion authorization ledger supplies the emitted recursor output and its structural authorization before it is identified with the generated row.

Finally use the audit row A. Since the forbidden dependencies and unrecorded proof-oracle requests are refused there, and since H, C, P, N only transport and replay the displayed rows, the five obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.ClosedGeneratorAuditCarrier namecert obligations`

Theorem 709.3 (Closed generator audit non-escape)**.** *Every consumer of an accepted* $\mathsf{ClosedGeneratorAudit}^{\uparrow}$ *carrier*

$$G = (T, K, R, S, A, H, C, P, N)$$

can read only the displayed MetaCIC and BEDC rows

$$T, K, R, S, A, H, C, P, N.$$

In particular, the consumer may read generated syntax, kernel acceptance, authorized recursor output, closed substitution and shift preservation, axiom-purity refusal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. It cannot read* `Classical.choice`*,* `Quot.sound`*,* `propext`*, host conversion, or an unrecorded proof oracle.*

Proof. Start from the carrier definition. The packet lists generated MetaCIC data, kernel acceptance, recursor authorization, closed-substitution audit data, audit refusal, transport, replay, provenance, and local naming as the full exported inventory.

Apply Definition 709.2. The NameCert surface routes every consumer read through one of the five displayed obligations, and each obligation returns to the same tuple $T, K, R, S, A, H, C, P, N$.

The refusal part is exact. Since the audit row A names the forbidden dependencies and unrecorded proof-oracle requests only as refused rows, no consumer route can reinterpret them as accepted kernel evidence or closed-term evidence.

Thus every readable row is a displayed MetaCIC or BEDC row in the packet. The excluded host, quotient, classical, extensional, conversion, and oracle coordinates are absent from the carrier and cannot be exported by transport or replay. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedGeneratorAudit}\uparrow}$.

Constructive story: A $\mathsf{ClosedGeneratorAudit}^{\uparrow}$ packet is generated from a MetaCIC term or proof row, kernel acceptance row, authorized recursor row, closed-substitution and shift row, axiom-purity audit row, componentwise hsame transports, displayed Cont replay routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedGeneratorAudit}\uparrow}, \mathsf{seed})$

Scope closed: Definition 709.1, Definition 709.2, and Definition 709.3 specify the finite NameCert carrier, obligation surface, and non-escape boundary joining kernel acceptance, recursor authorization, and closed-term substitution audit rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedGeneratorAudit}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove new MetaCIC closure lemmas, Lean kernel soundness, global recursor soundness, host conversion, quotient transport, classical choice, proposition extensionality, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, generator-closure replay, closed-substitution non-escape, kernel-acceptance replay, and audit-refusal exactness for the displayed packet.

Chapter 710

A Concrete Naming Certificate for $\mathsf{RecursionAuthorizationLedger}^{\uparrow}$

The $\mathsf{RecursionAuthorizationLedger}^{\uparrow}$ packet turns an accepted recursor call into finite NameCert ledger data. It records the inductive signature accepted by the kernel, the emitted eliminator, the checked motive, the branch package, the structural descent row, the generated output row, transport and continuation routes, package provenance, and the local naming row that later audit and generator-closure consumers can inspect.

Definition 710.1 (RecursionAuthorizationLedger carrier)**.** *A* $\mathsf{RecursionAuthorizationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, R, M, B, D, O, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted inductive signature row, including the constructor inventory and the recursive argument positions admitted by the kernel;*
2. *R is the emitted eliminator row for I, read as the authorized recursor generated from that signature;*
3. *M is the motive row checked for the eliminator call;*
4. *B is the branch-package row, with one displayed branch for each constructor in I;*
5. *D is the structural descent ledger recording that every recursive subcall is made only on constructor-subdata admitted by I;*
6. *O is the generated output row whose public name is being certified by the accepted recursor call;*
7. *H records componentwise* hsame *transports for the signature, eliminator, motive, branch package, descent ledger, output row, provenance row, and local naming row;*
8. *C records the displayed* Cont *routes by which consumers read the signature, eliminator, motive, branch, descent, output, audit, and naming coordinates;*
9. *P is the* Pkg *provenance over* BHist, hsame, Cont, *the kernel-accepted signature, emitted eliminator, branch-completeness check, structural descent check, purity audit boundary, and neighboring generator certificates;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RecursionAuthorizationLedger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $I, R, M, B, D, O, H, C, P, N$.

Theorem 710.2 (RecursionAuthorizationLedger NameCert obligations)**.** *For the carrier of Definition 710.1, the local* $\mathsf{NameCert}_{\mathsf{RecursionAuthorizationLedger}^{\uparrow}}$ *surface consists of carrier admission for*

$$L = (I, R, M, B, D, O, H, C, P, N),$$

kernel-acceptance of the constructor signature I, emitted-eliminator exactness for R, motive admission for M, branch completeness for B, structural descent exactness for D, output-row exposure for O, componentwise hsame *transport, displayed* Cont *route replay,* Pkg *provenance, local naming, and purity-audit non-escape.*

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 710.1. The signature, emitted eliminator, motive, branch package, descent ledger, output row, transport row, continuation row, provenance row, and local naming row are all coordinates of one finite packet.

The kernel-facing obligations are the accepted signature and emitted recursor rows. The recursor-as-authorized-generator vision supplies the boundary: a constructor signature is usable only after kernel acceptance, and the eliminator row is the kernel output for that signature rather than a separate recursion principle.

Branch completeness and structural descent are read from B and D. The branch package is indexed by the displayed constructors of I, and every recursive call recorded by D descends through constructor-subdata accepted by the same signature.

The output and audit obligations are the remaining rows. Consumers reach O only along C, transport it only through H, and cite only the provenance in P and N. The source gate, build gate, and purity-audit boundary named by P exclude axiom channels and forbidden host principles from the ledger surface. □

Theorem 710.3 (RecursionAuthorizationLedger generator-closure sibling route)**.** *For an accepted* $\mathsf{RecursionAuthorizationLedger}^{\uparrow}$ *packet*

$$L = (I, R, M, B, D, O, H, C, P, N),$$

the accepted signature row I, emitted eliminator row R, branch package B, and structural descent ledger D are the finite authorization ledger consumed by chapter 486 and chapter 553. The consumer route also transports, exposes, packages, and names that ledger through H, C, P, N, but it exports no unrestricted recursion principle and no eliminator outside the accepted signature.

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerCarrier generator closure sibling route`

Proof. Project the carrier tuple $L = (I, R, M, B, D, O, H, C, P, N)$ from Definition 710.1. The rows I, R, B, D are the signature, emitted eliminator, branch package, and structural descent data that authorize the generated output row.

Use Definition 710.2. Kernel acceptance, emitted-eliminator exactness, branch completeness, and structural descent exactness are obligations of the same finite packet, so a generator-closure consumer reads only those rows before inspecting the output route.

Finally route the sibling consumers through the displayed structural rows H, C, P, N. These rows transport, expose, package, and name the same finite ledger for chapter 486 and chapter 553; they do not add an unrestricted recursion principle or a second eliminator. □

Theorem 710.4 (RecursionAuthorizationLedger signature acceptance)**.** *In an accepted* RecursionAuthorizationLedg *packet*

$$L = (I, R, M, B, D, O, H, C, P, N),$$

the emitted eliminator row R and the branch package B are readable only after the same accepted inductive signature row I. No unlisted constructor row can enter the ledger.

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedger signature acceptance`

Proof. Project the signature, eliminator, and branch coordinates I, R, B from Definition 710.1. The carrier records R as emitted from I and B as indexed by the constructor inventory displayed by I.

Apply Definition 710.2. Kernel-acceptance of I, emitted-eliminator exactness for R, and branch completeness for B are local obligations of the same finite packet.

The remaining coordinates M, D, O, H, C, P, N do not add constructor rows. They check the motive, descent, output, transport, replay, provenance, and local naming of the accepted packet, so an unlisted constructor has no route into the ledger. □

Theorem 710.5 (RecursionAuthorizationLedger output audit boundary)**.** *For an accepted* RecursionAuthorizationL *packet*

$$L = (I, R, M, B, D, O, H, C, P, N),$$

the output row O is exposed only through the structural descent row D, componentwise hsame *transport H, displayed* Cont *routes C,* Pkg *provenance P, and local* NameCert *row N. The packet exports no unrestricted recursion principle and no hidden eliminator.*

Proof. Project the descent, output, and audit coordinates D, O, H, C, P, N. The carrier makes O a generated output row whose recursive calls are certified by D and whose public reads are transported, replayed, packaged, and named through H, C, P, N.

Use Definition 710.2 for output-row exposure and purity-audit non-escape. Then use Definition 710.6 to keep the output tied to the displayed branch package and structural descent ledger.

Since the carrier has no coordinate for an unrestricted recursion principle or a second eliminator, the output audit boundary is exactly the route through D, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerCarrier output audit boundary`

Theorem 710.6 (RecursionAuthorizationLedger branch completeness and descent exactness)**.** *For an accepted* RecursionAuthorizationLedger$^{\uparrow}$ *packet*

$$L = (I, R, M, B, D, O, H, C, P, N),$$

every constructor row displayed by I has exactly one branch row in B, and every recursive call certified by the output row O is justified by the structural descent ledger D. Thus the exported ledger contains no omitted branch and no non-structural recursive call.

Proof. Project the signature and branch coordinates I and B from the carrier. The inventory in Definition 710.1 records B as the branch-package row with one displayed branch for each constructor in I.

Project the descent and output coordinates D and O. The same carrier records D as the structural descent ledger and O as the generated output row whose recursive calls are certified by that ledger.

Use the NameCert obligations of Definition 710.2. Branch completeness and structural descent exactness are local obligations for the same finite packet, so no consumer can read O without the constructor-indexed branch package and the descent rows that justify its recursive subcalls.

The remaining rows H, C, P, N only transport, expose, package, and name those displayed coordinates. Since they add no branch coordinate and no recursion coordinate, the public ledger exports neither an omitted branch nor a non-structural recursive call. □

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerPacket branch descent exactness`

Theorem 710.7 (RecursionAuthorizationLedger motive-output route)**.** *For an accepted* RecursionAuthorizationLed *packet*

$$L = (I, R, M, B, D, O, H, C, P, N),$$

the motive row M and generated output row O are consumed only through the finite ledger. In particular, a public output read first uses the accepted signature I, the emitted eliminator R, the checked motive M, the branch package B, and the descent ledger D, and only then exposes O through H, C, P, N.

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerMotiveOutputRoute`

Proof. Project the carrier. The rows I, R, M, B, D, O occur in the displayed order of the ledger packet, with M recorded as the checked motive for the emitted eliminator and O recorded as the generated output row.

Use Definition 710.2. Motive admission, branch completeness, structural descent exactness, and output-row exposure are all local obligations for the same finite packet.

Finally apply Definition 710.6. The output row cannot be read apart from the branch package and descent ledger that justify the recursive subcalls, so the motive-output route stays inside L. □

Theorem 710.8 (RecursionAuthorizationLedger descent transport stability)**.** *For an accepted* $\mathsf{RecursionAuthorizationLedger}^{\uparrow}$ *packet*

$$L = (I, R, M, B, D, O, H, C, P, N),$$

componentwise hsame *transport preserves the structural descent ledger D, the branch package B, and the output row O as one finite authorization route. A transported read cannot replace D by a non-structural recursion row or replace O by a hidden eliminator output.*

Proof. Read the transport row H from the carrier. Its componentwise clauses cover the signature, emitted eliminator, motive, branch package, descent ledger, output row, provenance row, and local naming row.

Apply the NameCert obligations. Structural descent exactness is attached to D, branch completeness is attached to B, and output-row exposure is attached to O, all within the same packet L.

The continuation and provenance rows C, P, N replay and name the transported route. Since the carrier has no coordinate for a non-structural recursive call or a second eliminator, transport preserves the finite descent-output surface rather than producing an escape route. □

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerCarrier descent transport stability`

Theorem 710.9 (RecursionAuthorizationLedger audit provenance exhaustion)**.** *For an accepted* $\mathsf{RecursionAuthorizationLedger}^{\uparrow}$ *packet*

$$L = (I, R, M, B, D, O, H, C, P, N),$$

all audit provenance for the signature, motive, descent, output, and purity boundary is exhausted by the rows P and N together with the displayed read routes C. The ledger exports no unlisted constructor, no omitted branch, no non-structural recursive call, no hidden eliminator, and no output provenance outside L.

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerCarrier audit provenance exhaustion`

Proof. Project P, N and the continuation row C. The carrier describes P as provenance over the accepted signature, emitted eliminator, branch completeness check, structural descent check, purity audit boundary, and neighboring generator certificates.

Use Definition 710.2. Package provenance, local naming, displayed route replay, and purity-audit non-escape are obligations of the same finite packet as I, R, M, B, D, O, H.

Apply the branch-completeness theorem and the non-escape theorem. They rule out omitted branches, non-structural recursive calls, hidden eliminators, unrestricted recursion principles, and outside audit channels, so the provenance ledger is exhausted by C, P, N over L. □

Theorem 710.10 (RecursionAuthorizationLedger non-escape)**.** *Every consumer read of an accepted* $\mathsf{RecursionAuthorizationLedger}^{\uparrow}$ *packet factors through*

$$I, R, M, B, D, O, H, C, P, N.$$

It exports no unlisted constructor, no omitted branch, no branch outside the accepted signature, no non-structural recursive call, no hidden eliminator, no unrestricted recursion principle, and no output whose dependency route escapes the build, source-audit, and purity-audit boundary recorded in the packet.

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerCarrier consumer nonescape`

Proof. Start with the obligation theorem. It places the generated output downstream of the accepted signature, emitted eliminator, motive, branch package, structural descent ledger, transport rows, continuation routes, provenance, and local naming row.

For constructors and branches, inspect I and B. The visible signature supplies the only constructor inventory, and the branch package supplies exactly the branch rows available to the eliminator call.

For recursion, inspect D. A recursive subcall can be consumed only when the descent ledger records it as constructor-subdata of the accepted signature. There is no coordinate for a non-structural recursive call or a second hidden eliminator.

Finally inspect P and N. They record the build, source-audit, and purity-audit boundary for the named output. Since the carrier contains no axiom channel, unrestricted recursion principle, or forbidden host dependency row, the public ledger cannot export any of those objects. □

Theorem 710.11 (RecursionAuthorizationLedger finite induction scope)**.** *Every accepted* RecursionAuthorizationLe *packet*

$$L = (I, R, M, B, D, O, H, C, P, N)$$

whose branch ledger is generated by the displayed BHist *constructors exposes base authorization, successor authorization, signature acceptance, branch completeness, structural descent exactness, output exposure, audit boundary,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *on one finite induction route. The route exports no hidden recursor, host recursion principle, external termination oracle, or branch outside the accepted signature.*

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerPacket finite induction scope`

Proof. Induct over the displayed finite branch ledger B. The base case reads the seed authorization row together with the accepted signature I and emitted eliminator R, so the first branch is authorized only inside the carrier L.

For the successor step, replay the same Cont and signature rows. The new branch is admitted only after the constructor row from I is visible, and branch completeness keeps it inside the displayed package B.

Structural descent is preserved by the row D. Each recursive subcall remains constructor-subdata licensed by the accepted signature, so the induction cannot introduce host recursion or an external termination oracle.

Finally expose O, H, C, P, N. These rows carry output exposure, componentwise transport, replay, provenance, audit boundary, and local naming for the same route, and they contain no coordinate for a hidden recursor or any branch outside the accepted signature. □

Lean4 ✓ `BEDC.Derived.RecursionAuthorizationLedgerUp.RecursionAuthorizationLedgerCarrier finite induction scope`

Closure status for $\mathsf{NameCert}_{\mathsf{RecursionAuthorizationLedger}\uparrow}$.

Constructive story: A $\mathsf{RecursionAuthorizationLedger}^{\uparrow}$ packet is generated from an accepted inductive signature, emitted eliminator, checked motive, complete branch package, structural descent ledger, output row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RecursionAuthorizationLedger}\uparrow}$, scopedClosed)

Scope closed: Definition 710.1, Definition 710.2, Definition 710.4, Definition 710.5, Definition 710.7, Definition 710.8, Definition 710.9, Definition 710.10, and Definition 710.11 bind the carrier, NameCert obligations, signature acceptance, output audit boundary, motive-output route, descent transport stability, provenance exhaustion, nonescape, and finite-induction scope for accepted recursor calls.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RecursionAuthorizationLedger}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, global kernel soundness, all positivity checking, all termination checking, bridge checking, or any external classical principle.

Upgrade path: Public closure requires a consumer-facing route that exposes accepted signatures, generated outputs, audit provenance, and finite induction as a stable public surface without adding Lean verification or bridge checking.

Chapter 711

A Concrete Naming Certificate for $\mathsf{GeneratorAuditClosure}^{\uparrow}$

The $\mathsf{GeneratorAuditClosure}^{\uparrow}$ packet names the finite audit surface by which a MetaCIC generator-closure proof becomes a BEDC-readable certificate. It is tuned to generator rows such as `substitute` and `shift`, classifier rows such as `ClosedAt` and `GeneratorClosureClassifier`, accepted closure witnesses such as `substitute_closed`, `shift_closed`, `closed_under_substitute_classifier`, and `closed_under_shift_classifier`, and the audit ledgers exposed by $\mathsf{KernelAcceptanceWitness}^{\uparrow}$, $\mathsf{AxiomQueryLedger}^{\uparrow}$, and $\mathsf{KernelSourceChannelLedger}^{\uparrow}$.

Definition 711.1 (Generator-audit closure carrier)**.** *A* $\mathsf{GeneratorAuditClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (G, K, A, Q, H, C, P, N)$$

with the following displayed rows:

1. *G records the generator row, including the MetaCIC operation being audited and the arity or binder-side parameters needed to replay its local action;*
2. *K records the classifier row, including the closedness classifier, the generator-closure classifier, and the slice on which the generator is claimed to preserve closure;*
3. *A records the accepted closure proof row for substitute-style or shift-style generators;*
4. *Q records the axiom-query or audit-report row attached to the accepted closure proof, with refusal content for `Classical.choice`, `Quot.sound`, `propext`, and any unaccepted host proof equality;*
5. *H records componentwise* hsame *transport for the generator row, classifier row, accepted closure proof row, audit report, replay route, provenance, and local name;*
6. *C records the displayed* Cont *routes that replay generator evaluation, classifier reading, kernel acceptance, axiom-query inspection, and consumer access to the closure certificate;*
7. *P is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, $\mathsf{KernelAcceptanceWitness}^{\uparrow}$, $\mathsf{AxiomQueryLedger}^{\uparrow}$, *and* $\mathsf{KernelSourceChannelLedger}^{\uparrow}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{GeneratorAuditClosure}^{\uparrow}}$ *row.*

The carrier has no coordinate for hidden proof production, quotient transport, classical case splitting, proposition extensionality, host proof equality, or a claim that a source generator is trusted without the accepted closure row A and audit row Q.

Lean4 ✓ `BEDC.Derived.GeneratorAuditClosureUp.GeneratorAuditClosureTasteGate single carrier alignment`

Theorem 711.2 (Generator-audit closure NameCert obligations)**.** *For every accepted* $\mathsf{GeneratorAuditClosure}^{\uparrow}$ *carrier*

$$W = (G, K, A, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GeneratorAuditClosure}^{\uparrow}}$ *surface consists exactly of generator exposure through* G*, classifier exposure through* K*, accepted closure-witness exposure through* A*, axiom-query or audit-report exposure through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

The obligations are anchored by the kernel-acceptance witness for A*, the axiom-query ledger for* Q*, and the source-channel ledger separating the generator row from the accepted proof row.*

Lean4 ✓ `BEDC.Derived.GeneratorAuditClosureUp.GeneratorAuditClosureCarrier namecert obligations`

Proof. Project the finite packet of Definition 711.1. The rows G, K, A, Q, H, C, P, N are the complete displayed inventory, so carrier admission and local naming are read directly from the packet.

The generator and classifier side is exhausted by G and K. These rows record the MetaCIC operation and the closure classifier slice before the accepted proof row is exposed.

The audit side is exhausted by A and Q. The row A is read through $\mathsf{KernelAcceptanceWitness}^{\uparrow}$, while Q is read through $\mathsf{AxiomQueryLedger}^{\uparrow}$ and may also be placed inside the channel separation supplied by $\mathsf{KernelSourceChannelLedger}^{\uparrow}$.

Transport, replay, provenance, and naming are confined to H, C, P, N. Since the carrier has no further row, the listed obligations are exactly the local NameCert surface. □

Theorem 711.3 (Generator-audit closure MetaCIC sibling route)**.** *For every accepted* $\mathsf{GeneratorAuditClosure}^{\uparrow}$ *carrier* $W = (G, K, A, Q, H, C, P, N)$*, the rows* A*,* Q*, and* P *are read through the concrete MetaCIC sibling ledgers. The accepted-declaration surface for* A *is the surface of chapter 549, the axiom-query ledger for* Q *is the ledger of chapter 654, and the source-channel ledger carried by* P *is the ledger of chapter 671. Thus the generator-audit packet is not an isolated kernel row.*

Lean4 ✓ `BEDC.Derived.GeneratorAuditClosureUp.GeneratorAuditClosureCarrier metacic sibling route`

Proof. Project the carrier of Definition 711.1. The row A is displayed as an accepted closure proof row, Q as an axiom-query or audit-report row, and P as provenance over the sibling acceptance, query, and channel ledgers.

Apply Definition 711.2. It identifies A, Q, and P as part of the local NameCert surface rather than as informal side data.

The named sibling chapters supply the concrete route: chapter 549 reads the accepted-declaration surface, chapter 654 reads the axiom-query ledger, and chapter 671 reads the source-channel ledger. Since these rows are projected from the same finite packet, the generator-audit certificate consumes the MetaCIC sibling ledgers and cannot stand as an isolated kernel row. □

Theorem 711.4 (Generator-audit substitution and shift audit)**.** *When* G *is the MetaCIC* `substitute` *or* `shift` *generator row and* K *is the corresponding* `GeneratorClosureClassifier` *row, an accepted* $\mathsf{GeneratorAuditClosure}^{\uparrow}$ *packet routes the closure claim through the displayed accepted proof row* A *for the substitute or shift closure witness and the audit row* Q *for that proof.*

Thus the paper-side generator-closure reading is available only as a finite certificate over G, K, A, Q, H, C, P, N*; it is not a hidden proof producer and it does not identify source syntax, host proof equality, quotient equality, or classical branching with kernel acceptance.*

Lean4 ✓ `BEDC.Derived.GeneratorAuditClosureUp.GeneratorAuditClosureCarrier substitution shift audit`

Proof. Begin with the generator row G. In the substitution case it records the `substitute` operation and the closed-boundary slice; in the shifting case it records the `shift` operation and the corresponding closed-boundary slice.

Read the classifier row K next. It is the displayed `GeneratorClosureClassifier` instance used by the MetaCIC closure witnesses named in the kernel-audit witness chapter.

The accepted proof row A supplies the kernel-accepted closure witness, such as `substitute_closed`, `shift_closed`, `closed_under_substitute_classifier`, or `closed_under_shift_classifier`. The row Q supplies the axiom-query or audit report for that same accepted proof row.

Finally H, C, P, N transport, replay, package, and name the same finite route. No carrier coordinate remains for hidden proof production, quotient equality, classical branching, proposition extensionality, or host proof equality, so the substitution or shift audit is confined to the displayed packet. □

Theorem 711.5 (Generator-audit closure non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{GeneratorAuditClosure}^{\uparrow}$ *packet factors through the finite rows*

$$G, K, A, Q, H, C, P, N.$$

The consumer may read the generator, classifier, accepted closure proof, audit report, componentwise hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row, and it cannot read a hidden kernel-soundness theorem, a source-generator trust token, a quotient proof transport, a classical choice step, proposition extensionality, or host proof equality.*

Lean4 ✓ `BEDC.Derived.GeneratorAuditClosureUp.GeneratorAuditClosureCarrier consumer nonescape`

Proof. Project the accepted packet $W = (G, K, A, Q, H, C, P, N)$. The definition lists exactly these rows as the exported carrier.

Use Definition 711.2 to account for generator exposure, classifier exposure, accepted closure-witness exposure, audit-report exposure, transport, replay, provenance, and local naming.

Use Definition 711.4 for substitute-style and shift-style consumers. It routes the closure claim through the MetaCIC generator row, the generator-closure classifier row, the accepted closure proof row, and the audit row before any consumer-facing read is available.

Since the carrier contains no further coordinate, the listed rows exhaust the consumer surface and exclude hidden proof production, quotient transport, classical choice, proposition extensionality, and host proof equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{GeneratorAuditClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{GeneratorAuditClosure}^{\uparrow}$ packet is generated from a MetaCIC generator row, a generator-closure classifier row, an accepted closure proof row, an axiom-query or audit-report row, componentwise hsame transports, displayed Cont replay routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GeneratorAuditClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 711.1, Definition 711.2, Definition 711.4, and Definition 711.5 specify the finite generator-audit closure carrier, NameCert obligation surface, substitution and shift audit route, and non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GeneratorAuditClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove new MetaCIC closure theorems, global Lean kernel soundness, quotient or classical proof transport, proposition extensionality, host proof equality, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier projection, accepted-proof audit replay, axiom-query refusal stability, and consumer non-escape for the displayed generator-audit packet.

Chapter 712

A Concrete Naming Certificate for MetaCICSubjectReductionObligation$^{\uparrow}$

The MetaCICSubjectReductionObligation$^{\uparrow}$ packet turns the four MetaCIC subject-reduction discharge faces into a finite obligation-boundary certificate. It records the beta-substitution, application-argument, lambda-domain, and Pi-domain obligations beside the parameterised subject-reduction theorem row, the checked closed-consistency obstruction row, audit-query provenance, transport, refusal, and local naming data. The packet is the finite boundary read by downstream audit consumers; it is not a closed subject-reduction theorem.

Definition 712.1 (MetaCIC subject-reduction obligation carrier)**.** *A* MetaCICSubjectReductionObligation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (B, A, L, P, Q, R, H, C, G, N)$$

with the following displayed rows:

1. *B records* BetaSubstitutionPreservation*, the beta-redex substitution obligation consumed by the direct beta case;*
2. *A records* AppArgTypeStable*, the application-argument codomain-stability obligation;*
3. *L records* LamDomainSubjectReduction*, the lambda-domain subject-reduction obligation;*
4. *P records* PiDomainSubjectReduction*, the Pi-domain subject-reduction obligation;*
5. *Q records the parameterised theorem row* BEDC.MetaCIC.subject_reduction *and its four visible input sockets B, A, L, P;*
6. *R records the checked closed-consistency obstruction row* BEDC.MetaCIC.closed_consistency_reduction_obstructi
7. *H records componentwise* hsame *transport for the four obligation rows, the parameterised theorem row, the obstruction row, the audit-query row, the refusal row, the package row, and the local name;*
8. *C records the displayed* Cont *routes by which consumers replay accepted subject-reduction reads only through Q after all four obligation rows are supplied;*
9. *G records* Pkg *provenance for the audit query, the kernel-acceptance witness surface, the* GAP *refusal for closed subject reduction, and the local* NameCert *row;*
10. *N is the local* NameCert$_{\text{MetaCICSubjectReductionObligation}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unparameterised closed subject-reduction theorem, a host conversion rule, an erased derivation semantics, a quotient equality of MetaCIC terms, or a hidden normalization theorem.

Lean4 ✓ `BEDC.Derived.MetaCICSubjectReductionObligationUp.MetaCICSubjectReductionObligationTasteGate single carrier alignment`

Theorem 712.2 (Four-way subject-reduction obligation boundary)**.** *Let $O = (B, A, L, P, Q, R, H, C, G, N)$ be an accepted* MetaCICSubjectReductionObligation$^{\uparrow}$ *carrier. The packet exposes all four discharge faces B, A, L, P simultaneously before any closed subject-reduction consumer can read the parameterised theorem row Q. A consumer that does not display all four faces is routed to the obstruction row R and the* GAP *refusal recorded in G.*

Proof. Project the carrier of Definition 712.1. The only rows naming discharge data are B, A, L, P, and the only subject-reduction theorem row is Q.

The accepted read surface is the one isolated by SubjectReduction$^{\uparrow}$ in chapter 483. There, a public subject-reduction read must pass through the displayed ledger, transport, and continuation routes rather than through an ambient typing theorem.

For this MetaCIC packet, the ledger row Q records the same discipline at the four-input interface. It is readable as a preservation row only after the beta-substitution, application-argument, lambda-domain, and Pi-domain rows have all been displayed.

Audit replay is accounted for by the KernelAcceptanceAuditWitness$^{\uparrow}$ surface of chapter 547. The provenance row G therefore records the query and replay rows as finite audit data, not as an extra proof source.

If one of the four faces is absent, the checked obstruction principle Definition 9377.5 supplies the refusal boundary. The row R and the GAP entry in G are then the consumer-facing answer, so the packet exposes the four-way boundary before any preservation read can proceed. □

Theorem 712.3 (MetaCIC subject-reduction obligation non-escape)**.** *Every downstream consumer of an accepted* MetaCICSubjectReductionObligation$^{\uparrow}$ *packet factors through*

$$B, A, L, P, Q, R, H, C, G, N.$$

The consumer may inspect the four obligation rows, the parameterised subject-reduction row, the checked obstruction row, audit-query provenance, componentwise hsame *transport, displayed* Cont *replay,* GAP *refusal, and local naming. It cannot turn the packet into an unparameterised closed subject-reduction theorem, a host conversion rule, or a hidden normalization theorem.*

Proof. Start with the finite inventory. The carrier displays exactly the rows $B, A, L, P, Q, R, H, C, G, N$, so every public read must be routed through one of these coordinates.

The preservation-facing route is constrained by Definition 712.2. It reaches Q only through the four displayed discharge rows and through the transport and continuation rows H, C.

The audit-facing route is constrained by chapter 547. Its query, replay, and dependency rows are finite provenance data in G, and they do not add a closed MetaCIC preservation theorem.

The refusal-facing route is constrained by Definition 9377.5. The obstruction row R and the GAP row in G answer closed-subject-reduction requests without exporting the closed theorem.

Since no carrier coordinate names host conversion, erased derivation semantics, quotient equality, or global normalization, none of those objects can be read from the packet. Thus the downstream surface remains the displayed finite obligation boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObligation}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSubjectReductionObligation}^{\uparrow}$ packet is generated from the four MetaCIC discharge-obligation rows, the parameterised subject-reduction theorem row, the checked obstruction row, audit-query provenance, componentwise hsame transports, displayed Cont replay, GAP refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObligation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 712.1, Definition 712.2, and Definition 712.3 bind the finite four-obligation carrier, classifier boundary, audit replay rows, refusal row, and downstream non-escape surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObligation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, host conversion, global normalization, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, four-face exposure, parameterised theorem consumption, obstruction replay, refusal exactness, provenance accounting, transport stability, and non-escape for the same finite packet.

Chapter 713

A Concrete Naming Certificate for $\mathsf{AxisCarryConfluence}^{\uparrow}$

The $\mathsf{AxisCarryConfluence}^{\uparrow}$ interface packages the finite local confluence surface behind overlapping Axis-Zeckendorf carry routes. It records two displayed carry-normalization paths from overlapping source windows to a shared normal target, their common value ledger, the non-hsame boundary for every carry edge, componentwise transports, continuation routes, provenance, and a local naming row. The packet is a finite certificate for route agreement at the displayed window; it is not a kernel rewrite, a quotient by history sameness, or an unbounded normalizer.

The confluence packet consumes the local carry edge of chapter 544 and the normalization handoff of chapter 608. Its two route rows r_0, r_1 are not free data: each is a $\mathsf{ZCarry}^{\uparrow}$ edge followed by a $\mathsf{ZeckendorfCarryNormalization}^{\uparrow}$ handoff into the shared target row n.

Definition 713.1 (Axis carry-confluence carrier)**.** *An* $\mathsf{AxisCarryConfluence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (u, v, w, n, r_0, r_1, t, H, C, P, N)$$

with the following visible coordinates:

1. *u is the displayed overlapping source-window history row;*
2. *v is the intermediate history row reached by the left carry route from u;*
3. *w is the intermediate history row reached by the right carry route from u;*
4. *n is the common normal target row admitted by* $\mathsf{ZeckendorfCarryNormalization}^{\uparrow}$*;*
5. *r_0 is the left route row, recording a* $\mathsf{ZCarry}^{\uparrow}$ *edge from u to v and a* $\mathsf{ZeckendorfCarryNormalization}^{\uparrow}$ *handoff from v to n;*
6. *r_1 is the right route row, recording a* $\mathsf{ZCarry}^{\uparrow}$ *edge from u to w and a* $\mathsf{ZeckendorfCarryNormalization}^{\uparrow}$ *handoff from w to n;*
7. *t is the value ledger row, recording that the displayed Fibonacci value read from u, v, w, and n is the same finite sum;*
8. *H records the non-*hsame *boundary for the two carry edges together with componentwise* hsame *transports preserving u, v, w, n, r_0, r_1, t, the route row, the package row, and the local naming row;*

9. *C stores the displayed* Cont *routes for reading the source window, the two intermediate windows, the common normal target, both carry-normalization routes, the value ledger, the non-*hsame *boundary, provenance, and local naming;*
10. *P is the* Pkg *provenance over* BHist, ZCarry$^{\uparrow}$, ZeckendorfCarryNormalization$^{\uparrow}$, *Fibonacci value ledgers,* hsame, Cont, Pkg, *and local* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AxisCarryConfluence}^{\uparrow}}$ *row.*

The carrier exports only this finite route packet. It contains no source-target hsame *proof for either carry edge, no global confluence theorem for arbitrary windows, no kernel rewrite rule, no host arithmetic quotient, and no hidden normalizing algorithm.*

Lean4 ✓ `BEDC.Derived.AxisCarryConfluenceUp.AxisCarryConfluenceTasteGate single carrier alignment`

Theorem 713.2 (Axis carry-confluence NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{AxisCarryConfluence}^{\uparrow}}$ *surface for Definition 713.1 consists of carrier admission for*

$$K = (u, v, w, n, r_0, r_1, t, H, C, P, N),$$

two displayed ZCarry$^{\uparrow}$ *source edges, two* ZeckendorfCarryNormalization$^{\uparrow}$ *route handoffs into the common target n, exactness of the value ledger t, preservation of the non-*hsame *boundary under the displayed transports in H,* Cont *route locality through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.AxisCarryConfluenceUp.AxisCarryConfluenceCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 713.1. The rows $u, v, w, n, r_0, r_1, t, H, C, P, N$ are the only data admitted to the packet.

The two route rows give the carry-normalization shape. The row r_0 exposes the left carry edge and its handoff to the normal target, while r_1 exposes the right carry edge and its handoff to the same target.

The value and boundary clauses are separate projections. The row t records the common finite Fibonacci value, and H records that the carry edges remain outside source-target hsame while their displayed rows transport componentwise.

Finally C, P, N route, package, and name the same finite surface. Since the carrier has no coordinate for a kernel rewrite, host quotient, or unbounded normalizer, the listed obligations exhaust the local certificate. □

Theorem 713.3 (Axis carry-confluence carrier obligation)**.** *The carrier-admission obligation for* AxisCarryConfluence$^{\uparrow}$ *is the admission of the concrete tuple*

$$K = (u, v, w, n, r_0, r_1, t, H, C, P, N).$$

Here u is the overlapping source window, v and w are the two intermediate carry windows, n is the shared normal target, r_0 and r_1 are the two ZCarry$^{\uparrow}$*-then-*ZeckendorfCarryNormalization$^{\uparrow}$ *route rows, t is the value ledger, H records the non-*hsame *boundary and componentwise transports, C records displayed continuations, P records provenance, and N records the local NameCert row.*

Proof. Project Definition 713.1. Its displayed tuple is already the full carrier-admission surface.

The sibling references to ZCarry$^{\uparrow}$ and ZeckendorfCarryNormalization$^{\uparrow}$ determine the route type of r_0 and r_1: each route begins with one carry edge and ends with a normalization handoff. The remaining rows t, H, C, P, N are the ledger, boundary, replay, provenance, and naming supports needed for the same admitted tuple. □

Theorem 713.4 (Axis carry-confluence local-join obligation)**.** *For an accepted* AxisCarryConfluence$^{\uparrow}$ *carrier*

$$K = (u, v, w, n, r_0, r_1, t, H, C, P, N),$$

the local-join obligation is that r_0 and r_1 share the target n while preserving the value ledger t. Thus the left route from u through v and the right route from u through w are consumer-visible only as two ZCarry$^{\uparrow}$ *edges with* ZeckendorfCarryNormalization$^{\uparrow}$ *handoffs into the same normal row.*

Proof. Project the two route rows. The row r_0 names the left carry edge and its handoff into n, while r_1 names the right carry edge and its handoff into the same n.

Project the ledger row t separately. It records the common finite Fibonacci value across u, v, w, n, so the local join is value-preserving without adding an hsame identification between source and intermediate rows. □

Lean4 ✓ `BEDC.Derived.AxisCarryConfluenceUp.AxisCarryConfluenceCarrier local join obligation`

Theorem 713.5 (Axis carry-confluence normal-form obligation)**.** *Every consumer of the shared target n in an accepted* AxisCarryConfluence$^{\uparrow}$ *packet must pass through the displayed* ZeckendorfCarryNormalization$^{\uparrow}$ *handoffs and the non-*hsame *boundary rows. The packet permits reads of n only together with r_0, r_1, t, H, C, P, N; it does not export a direct normal-form oracle, a kernel rewrite, a host quotient, or source-target* hsame *for either carry edge.*

Lean4 ✓ `BEDC.Derived.AxisCarryConfluenceUp.AxisCarryConfluenceCarrier normal form obligation`

Proof. Read n through the route rows. By the carrier definition, the only routes to n inside the packet are the two handoffs named by r_0 and r_1, each supported by the ZeckendorfCarryNormalization$^{\uparrow}$ sibling.

The boundary row H remains attached to those handoffs. It records that the carry edges are not source-target hsame identifications, while C, P, N replay, package, and name the same finite normal-target read.

Since no carrier coordinate names a direct normal-form oracle, kernel rewrite, host quotient, or source-target hsame, a consumer of n must stay inside the displayed handoff and boundary surface. □

Theorem 713.6 (Axis carry-confluence local diamond)**.** *For an accepted* AxisCarryConfluence$^{\uparrow}$ *carrier*

$$K = (u, v, w, n, r_0, r_1, t, H, C, P, N),$$

the two displayed routes form a local diamond at the finite carry window: u reaches v and w by the two recorded ZCarry$^{\uparrow}$ *edges, and both v and w reach the same normal target n through the recorded* ZeckendorfCarryNormalization$^{\uparrow}$ *handoffs. A consumer-visible diamond read factors through the route rows r_0, r_1, the common target row n, the value ledger t, and the support rows H, C, P, N.*

Proof. Project the accepted carrier. The row r_0 supplies the left route from u through v to n, and r_1 supplies the right route from u through w to the same n.

Read the common target and value ledger next. The coordinate n is shared by both route rows, and t records that the visible Fibonacci value is unchanged along the four displayed histories.

The support rows then delimit the consumer read. Transport through H, routing through C, provenance through P, and naming through N expose exactly this finite diamond and do not turn it into a theorem about all carry overlaps. □

Lean4 ✓ `BEDC.Derived.AxisCarryConfluenceUp.AxisCarryConfluenceCarrier local diamond`

Theorem 713.7 (Axis carry-confluence value-ledger exhaustion)**.** *For an accepted* $\mathsf{AxisCarryConfluence}^{\uparrow}$ *carrier*

$$K = (u, v, w, n, r_0, r_1, t, H, C, P, N),$$

any consumer-visible comparison between the two carry-normalization routes must factor through the common target row n*, the value ledger* t*, the non-*hsame *boundary* H*, the route replay row* C*, provenance* P*, and the local name* N*. No additional equality row, quotient row, host arithmetic row, or global normalizer row is exported by the packet.*

Proof. Project the accepted carrier. The route rows r_0 and r_1 are the only displayed routes, and both route rows end at the same normal target coordinate n.

Read the value ledger separately. The row t is the sole public record that the two routes preserve the same finite Fibonacci value across u, v, w, n; it is not replaced by an hsame proof or by a host quotient.

The boundary row H blocks a source-target hsame reading for the carry edges, while C, P, N keep every comparison inside the displayed continuation, provenance, and local NameCert rows. Since the carrier has no further coordinate, a consumer-visible agreement has no route outside n, t, H, C, P, N. □

Theorem 713.8 (Axis carry-confluence non-escape)**.** *For an accepted* $\mathsf{AxisCarryConfluence}^{\uparrow}$ *carrier, the confluence reading cannot escape the finite packet. The rows* r_0, r_1, t, H, C, P, N *may expose two carry-normalization routes, their shared normal target, the common value ledger, componentwise transport, route replay, provenance, and local naming, but they do not export* $\mathsf{hsame}(u, v)$*,* $\mathsf{hsame}(u, w)$*, a kernel rewrite, a host arithmetic quotient, or a global confluence principle for arbitrary carry windows.*

Proof. The possible consumer reads are the coordinates of Definition 713.1. The route rows expose carry-normalization paths, and the value row exposes the common finite ledger.

The boundary row H keeps the two carry edges separate from source-target hsame. It transports only the named components of the accepted packet and supplies no equality proof between the source and either intermediate carry target.

The remaining support rows C, P, N expose, package, and name the same finite object. Because no coordinate records a kernel rewrite, host quotient, or arbitrary-window confluence theorem, no projection from the packet can export one. □

Theorem 713.9 (Axis carry-confluence normalization handoff)**.** *For an accepted* $\mathsf{AxisCarryConfluence}^{\uparrow}$ *carrier*

$$K = (u, v, w, n, r_0, r_1, t, H, C, P, N),$$

the public normalization handoff is the joint read of the shared target row n*, the route rows* r_0, r_1*, and the value ledger* t*. Both carry routes hand off to the same* $\mathsf{ZeckendorfCarryNormalization}^{\uparrow}$ *target, and every consumer read of that handoff must pass through the displayed* Cont *routes,* Pkg *provenance, non-*hsame *boundary, and local* $\mathsf{NameCert}$ *row.*

Proof. Project n, r_0, r_1, t from the accepted packet. The target row n is the only normal target coordinate, and both route rows name it as their handoff endpoint.

Use the value ledger to align the two paths. The row t records the common finite Fibonacci value across the source, intermediate rows, and target, so the handoff is value-ledger preserving rather than an identification by history sameness.

Finally replay the handoff through H, C, P, N. The non-hsame boundary remains visible, and the route, provenance, and naming rows keep the handoff inside the finite NameCert surface. □

Lean4 ✓ `BEDC.Derived.AxisCarryConfluenceUp.AxisCarryConfluenceCarrier normalization handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{AxisCarryConfluence}^{\uparrow}}$.

Constructive story: An $\mathsf{AxisCarryConfluence}^{\uparrow}$ packet is generated from one overlapping source window, two displayed carry-normalization routes, a shared normal target, a finite value ledger, non-hsame boundary rows, componentwise transports, continuation routes, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AxisCarryConfluence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 713.1, Definition 713.2, Definition 713.6, Definition 713.8, and Definition 713.9 bind the finite two-route carry-confluence packet and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AxisCarryConfluence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, a bridge certificate, arbitrary-window carry confluence, a global Zeckendorf normalizer, a kernel rewrite, host arithmetic quotienting, or source-target hsame.

Upgrade path: Obligation closure requires checked carrier admission, two route handoffs, local diamond reading, value-ledger exactness, non-hsame preservation, route locality, provenance, local naming, and normalization handoff for the same finite packet.

Chapter 714

A Concrete Naming Certificate for $\mathsf{TypeLevelSocketExposure}^{\uparrow}$

The $\mathsf{TypeLevelSocketExposure}^{\uparrow}$ packet realizes type-level apophatic exposure as a finite NameCert object. It records the setup-field surface where an outside supply is requested, the carrier and classifier rows that make the request visible, the provenance and refusal-ledger rows that prevent hidden internalization, and the local naming row that downstream audit gates can cite.

The refusal-ledger row R is the type-level specialization of the negative-name boundary in chapter 629. This chapter keeps the setup-field row, carrier-shape row, and classifier rows visible so that the same refusal discipline is read as a typed socket surface rather than as an anonymous external-supply boundary.

Definition 714.1 (Type-level socket exposure carrier)**.** *A* $\mathsf{TypeLevelSocketExposure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, A, K, L, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the setup-field row naming the type-level boundary at which an outside supply is requested;*
2. *A is the admitted carrier row for the requested supply shape;*
3. *K is the classifier row distinguishing visible socket use from generated substrate content;*
4. *L is the ledger row recording whether the requested supply is exposed at the setup field, carrier, classifier, provenance, or* GAP *position;*
5. *R is the refusal-ledger row excluding hidden axiom channels, forbidden host dependencies, and unmarked premise traffic;*
6. *H records componentwise* hsame *transports for the setup field, carrier, classifier, ledger, refusal row, provenance row, and local naming row;*
7. *C records the displayed* Cont *routes by which consumers read the setup field, carrier, classifier, ledger, refusal, provenance, and naming coordinates;*
8. *P is the* Pkg *provenance over* BHist, hsame, Cont, *setup fields, carriers, classifiers,* GAP *ledgers, axiom-purity gates, and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TypeLevelSocketExposure}^{\uparrow}}$ *row.*

The carrier contains no hidden axiom, no theorem-valued outside premise, no forbidden host dependency, no unlisted setup field, and no route that turns the requested supply into generated substrate content.

Theorem 714.2 (Type-level socket exposure NameCert obligations)**.** *For the carrier of Definition 714.1, the local* $\mathsf{NameCert}_{\mathsf{TypeLevelSocketExposure}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$E = (S, A, K, L, R, H, C, P, N),$$

setup-field exposure through S*, carrier-shape exposure through* A*, classifier visibility through* K*, ledger placement through* L*, refusal-ledger exactness through* R*, componentwise* hsame *transport through* H*, displayed* Cont *route replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.TypeLevelSocketExposureUp.TypeLevelSocketExposureNamecertObligations`

Proof. Carrier admission is projection from the displayed packet E. The rows $S, A, K, L, R, H, C, P, N$ list the setup field, admitted carrier shape, classifier, ledger, refusal row, transports, continuation routes, provenance, and local name.

The exposure obligations are finite. A consumer first reads the setup-field row S, then the carrier row A, then the classifier row K that distinguishes socket use from generated substrate content. The ledger row L records the visible placement of the request.

The refusal row R excludes the channels that would hide the request: axiom admission, forbidden host dependency, and unmarked premise traffic. The rows H, C, P, N account for transport, route replay, provenance, and local naming, so the local surface is exhausted by the displayed packet. □

Theorem 714.3 (Type-level socket exposure ledger non-escape)**.** *Every consumer read of an accepted* $\mathsf{TypeLevelSocketExposure}^{\uparrow}$ *packet factors through*

$$S, A, K, L, R, H, C, P, N.$$

It may inspect the setup-field exposure, carrier shape, classifier, ledger placement, refusal row, componentwise transports, displayed continuations, provenance, and local NameCert *row, and it cannot read a hidden axiom, a theorem-valued outside premise, a forbidden host dependency, an unlisted setup field, or an unmarked supply channel.*

Lean4 ✓ `BEDC.Derived.TypeLevelSocketExposureUp.TypeLevelSocketExposureLedgerNonescape`

Proof. Start with the obligation theorem. It identifies the accepted packet with the displayed rows $S, A, K, L, R, H, C, P, N$ and names those rows as the complete local NameCert inventory.

For type-level exposure, inspect S, A, and K. The setup field names the boundary, the carrier row records the requested supply shape, and the classifier row keeps visible socket use separate from generated substrate content.

For ledger non-escape, inspect L and R. The ledger row records the visible placement of the request, while the refusal row excludes axiom admission, forbidden host dependency, hidden premise traffic, and unlisted setup fields.

Finally inspect H, C, P, N. They provide the only transport, continuation, provenance, and naming routes available to downstream consumers. Since the carrier contains no additional row beyond those coordinates, no consumer can obtain a hidden supply channel from the packet. □

Lean4 ✓ `BEDC.Derived.TypeLevelSocketExposureUp.TypeLevelSocketExposureLedgerHostReturnExclusion`

Theorem 714.4 (Type-level socket exposure refusal exactness)**.** *For every accepted* $\mathsf{TypeLevelSocketExposure}^{\uparrow}$ *carrier* $E = (S, A, K, L, R, H, C, P, N)$*, the refusal row* R *excludes hidden axiom channels, theorem-valued outside premises, forbidden host dependencies, unlisted setup fields, and unmarked supply channels exactly because every consumer route factors through* $S, A, K, L, R, H, C, P, N$*. No refused channel can be reconstructed from the structural rows.*

Lean4 ✓ `BEDC.Derived.TypeLevelSocketExposureUp.TypeLevelSocketExposureRefusalExactness`

Proof. Start with the carrier of Definition 714.1. The packet exposes the setup field, admitted carrier, classifier, ledger placement, refusal row, transport, continuation, provenance, and local naming as the finite tuple $S, A, K, L, R, H, C, P, N$.

Apply the NameCert obligations of Definition 714.2. They make refusal-ledger exactness through R one of the local rows rather than an external convention.

Finally use ledger non-escape from Definition 714.3. Since every consumer read factors through the displayed tuple, a hidden axiom channel, theorem-valued outside premise, forbidden host dependency, unlisted setup field, or unmarked supply channel has no carrier coordinate and no replay route through H, C, P, N. □

Theorem 714.5 (Type-level socket exposure scope exactness)**.** *For every accepted* $\mathsf{TypeLevelSocketExposure}^{\uparrow}$ *packet* $E = (S, A, K, L, R, H, C, P, N)$*, the complete consumption scope for type-level socket exposure is the displayed setup-field row* S*, carrier-shape row* A*, classifier row* K*, ledger-placement row* L*, refusal row* R*, componentwise* hsame *transport row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{TypeLevelSocketExposure}^{\uparrow}}$ *row* N*. No hidden axiom channel, theorem-valued outside premise, host dependency, unlisted setup field, or unmarked supply channel has a scope coordinate outside those rows.*

Lean4 ✓ `BEDC.Derived.TypeLevelSocketExposureUp.TypeLevelSocketExposureScopeExactness`

Proof. Project the carrier of Definition 714.1. It displays exactly $S, A, K, L, R, H, C, P, N$ as setup, carrier, classifier, ledger, refusal, transport, replay, provenance, and naming coordinates.

Apply the NameCert obligations of Definition 714.2. They identify setup-field exposure, carrier-shape exposure, classifier visibility, ledger placement, refusal-ledger exactness, transport, replay, provenance, and local naming as the local obligation surface.

Use ledger non-escape from Definition 714.3 and refusal exactness from Definition 714.4. Since every consumer read factors through the displayed tuple and the refusal row excludes the hidden channels, no excluded premise can acquire a separate scope coordinate. □

Theorem 714.6 (TypeLevelSocketExposure kernel grounding)**.** *Every accepted* $\mathsf{TypeLevelSocketExposure}^{\uparrow}$ *read is grounded by the displayed* BHist *carrier rows* $S, A, K, L, R, H, C, P, N$*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, the refusal ledger* R*, and the local* $\mathsf{NameCert}_{\mathsf{TypeLevelSocketExposure}^{\uparrow}}$ *row* N*. Consequently the read cannot import outside supply, host type equality, hidden setup fields, theorem-valued outside premises, or global kernel soundness.*

Lean4 ✓ `BEDC.Derived.TypeLevelSocketExposureUp.TypeLevelSocketExposureScopeKernelGrounding`
Lean4 ✓ `BEDC.Derived.TypeLevelSocketExposureUp.TypeLevelSocketExposureKernelGrounding`

Proof. Project the carrier of Definition 714.1. The accepted read starts with the setup-field row S, admitted carrier row A, classifier row K, ledger row L, refusal row R, transport row H, replay row C, provenance row P, and local naming row N.

Apply the NameCert obligations of Definition 714.2. Those obligations make the carrier rows, refusal ledger, transport, replay, provenance, and local naming the complete local certificate surface.

Use ledger non-escape, refusal exactness, and scope exactness from Definition 714.3, Definition 714.4, and Definition 714.5. Since every consumer route is already confined to $S, A, K, L, R, H, C, P, N$, no outside supply, host type equality, hidden setup field, theorem-valued premise, or global kernel soundness can enter through a separate coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{TypeLevelSocketExposure}\uparrow}$.

Constructive story: A $\mathsf{TypeLevelSocketExposure}^{\uparrow}$ packet is generated from a setup-field exposure row, admitted carrier-shape row, classifier row, ledger-placement row, refusal row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TypeLevelSocketExposure}\uparrow}, \mathsf{scopedClosed})$

Scope closed: Definition 714.1, Definition 714.2, Definition 714.3, Definition 714.4, Definition 714.5, and Definition 714.6 bind the scoped finite surface for type-level outside-supply exposure.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TypeLevelSocketExposure}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, existence of any outside supply, global kernel soundness, all setup-field designs, or any hidden host principle.

Upgrade path: Obligation closure requires checked carrier admission, setup-field exposure, classifier visibility, ledger placement, refusal exactness, provenance, and non-escape for the same finite packet.

Chapter 715

A Concrete Naming Certificate for $\mathsf{ApophaticGateQuestion}^{\uparrow}$

The $\mathsf{ApophaticGateQuestion}^{\uparrow}$ packet realizes the name-to-gate correspondence as a finite question object. It starts from an apophatic socket name, records the gate question that audits the named outside-supply position, keeps the refusal ledger visible, and exposes only the readback rows needed by downstream audit gates.

The socket row is consumed from chapter 536, and the named refusal row remains compatible with chapter 543. Thus the gate-question packet reads the same sibling socket-name surfaces before it exposes its audit-readback row.

Definition 715.1 (Apophatic gate question carrier)**.** *An* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, Q, R, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the visible* $\mathsf{ApophaticSocket}^{\uparrow}$ *or* $\mathsf{ApophaticName}^{\uparrow}$ *row naming the external supply position;*
2. *Q is the gate-question row asking whether a consumer route used the named socket, which supply kind it requested, and whether the use remained externally marked;*
3. *R is the refusal-ledger row excluding hidden axioms, forbidden host ancestry, quotient collapse, proposition-extensionality collapse, unmarked selectors, and unrecorded inscription novelty;*
4. *A is the audit-readback row that records the answer to Q as a finite ledger entry rather than as a host-level judgment;*
5. *H records componentwise* hsame *transports for the socket row, question row, refusal ledger, readback row, provenance row, and local naming row;*
6. *C records the displayed* Cont *routes by which audit, paper-Lean, axiom-purity, and conservativity consumers may read S, Q, R, A, H, P, N;*
7. *P is the* Pkg *provenance over* BHist, $\mathsf{ApophaticSocket}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, *audit gates, refusal ledgers,* hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ApophaticGateQuestion}^{\uparrow}}$ *row.*

The carrier has no coordinate for the requested outside supply itself, a hidden theorem premise, an axiom channel, a host proof of semantic harmlessness, or an unmarked route that internalizes the socket.

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionTasteGate single carrier alignment`
Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionTasteGate namecert row lock`

Theorem 715.2 (Apophatic gate question NameCert obligations)**.** *For the carrier of Definition 715.1, the local* $\mathsf{NameCert}_{\mathsf{ApophaticGateQuestion}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$G = (S, Q, R, A, H, C, P, N),$$

socket-name exposure through S*, gate-question exactness through* Q*, refusal-ledger coverage through* R*, audit-readback exactness through* A*, componentwise* hsame *transport through* H*, displayed* Cont *route replay through* C*, dependency provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from the displayed packet G. The rows S, Q, R, A, H, C, P, N list the socket name, gate question, refusal ledger, audit readback, transports, continuations, provenance, and local certificate.

The question obligation reads S before Q. This forces the gate question to target the named socket rather than a free-form host predicate, and it records the supply kind and marked-use condition as finite rows.

The refusal and readback obligations read R and A. The refusal ledger excludes the hidden channels named in the statement, while the readback row stores the gate answer as a BEDC ledger entry.

The rows H, C, P, N provide the only transport, continuation, provenance, and local naming routes. Since the carrier has no further coordinate, the local $\mathsf{NameCert}_{\mathsf{ApophaticGateQuestion}^{\uparrow}}$ obligations are exhausted by the displayed packet. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier namecert obligations`

Theorem 715.3 (Apophatic gate question visible socket non-escape)**.** *Every consumer read of an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet factors through the displayed socket row, gate-question row, refusal ledger, audit-readback row, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. The read cannot export the requested outside supply, a hidden axiom, a quotient equality, a proposition-extensionality collapse, an unmarked selector, an unrecorded inscription novelty, or a host-level replacement for the gate answer.*

Proof. Start with Definition 715.2. It identifies the accepted packet with the finite rows S, Q, R, A, H, C, P, N and gives the complete local certificate inventory.

For the visible socket route, read S and Q. The socket row names the outside-supply position, and the question row asks only whether a route used that named socket and kept the use externally marked.

For non-escape, read R and A. The refusal ledger excludes hidden axiom channels, quotient collapse, proposition-extensionality collapse, unmarked selectors, and unrecorded inscription novelty; the audit-readback row prevents replacing the ledger answer by a host judgment.

Finally route through H, C, P, N. These rows account for transport, continuation, provenance, and local naming, and the carrier contains no coordinate for the excluded objects. Hence the consumer surface remains the finite visible-socket gate question. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier visible socket nonescape`

Theorem 715.4 (Apophatic gate question socket-name dependency)**.** *Every accepted* ApophaticGateQuestion$^{\uparrow}$ *packet reads its socket row through the sibling* ApophaticSocket$^{\uparrow}$ *surface of chapter 536 and keeps its named refusal row compatible with the* ApophaticName$^{\uparrow}$ *surface of chapter 543 before the audit-readback row is available. The audit answer therefore depends on the visible socket-name route rather than on a hidden host predicate, unmarked selector, or detached outside-supply witness.*

Proof. Start with the carrier of Definition 715.1. Its first row S is explicitly the visible ApophaticSocket$^{\uparrow}$ or ApophaticName$^{\uparrow}$ row naming the external supply position, while A is only the later audit-readback row.

Apply Definition 715.3. Every consumer read of the packet factors through S, Q, R, A, H, C, P, N, and the visible socket route cannot be replaced by a hidden axiom, quotient equality, proposition-extensionality collapse, unmarked selector, or host-level gate answer.

Consequently the socket-name dependency is read before audit readback. The sibling socket and name surfaces provide the visible rows that S may reference, while A records only the finite answer to the already displayed gate question. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier socket name dependency`

Theorem 715.5 (Apophatic gate question socket-refusal coverage)**.** *Every accepted* ApophaticGateQuestion$^{\uparrow}$ *audit answer is covered by the displayed rows S, Q, R, A, H, C, P, N. The socket row S supplies the named outside-supply position, the question row Q fixes the audited request, the refusal ledger R excludes hidden axiom, quotient, proposition-extensionality, unmarked-selector, and unrecorded-inscription channels, and the readback row A records the finite answer. The remaining rows H, C, P, N transport, replay, package, and name the same route; they do not add a hidden host predicate.*

Proof. Begin with the carrier and local NameCert obligations. The carrier displays $G = (S, Q, R, A, H, C, P, N)$, and the obligation rows identify S as the socket-name row, Q as the audited question, R as the refusal ledger, and A as the finite readback.

Next apply visible socket non-escape. Every accepted read must remain inside the displayed socket, question, refusal, readback, transport, continuation, provenance, and naming rows, so hidden axioms, quotient equality, proposition-extensionality collapse, unmarked selectors, and host-level gate answers are outside the packet.

Finally use socket-name dependency. It forces the audit question to read the sibling ApophaticSocket$^{\uparrow}$ or ApophaticName$^{\uparrow}$ surface before the readback row is available. Thus the accepted gate answer is covered by the displayed socket/refusal/readback route and not by an additional host predicate. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier socket refusal coverage`

Theorem 715.6 (Apophatic gate question source exposure)**.** *Every accepted* ApophaticGateQuestion$^{\uparrow}$ *packet exposes the visible socket-name source row S before the gate-question row Q is read. Thus the question is asked about an already displayed* ApophaticSocket$^{\uparrow}$ *or* ApophaticName$^{\uparrow}$ *surface, not about a hidden outside-supply witness, host predicate, or detached gate answer.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier source before question route`

Proof. Project the carrier from Definition 715.1. The packet order displays S as the visible socket-name source row and Q as the later question row.

Apply the NameCert obligations and socket-name dependency theorems. They force carrier admission and every audit route to read the socket-name surface before the gate question can be answered.

The non-escape theorem removes the remaining alternatives. Since the packet has no coordinate for a hidden outside-supply witness, host predicate, or detached gate answer, exposure of S is the unique entrance to Q. □

Theorem 715.7 (Apophatic gate question visible socket coverage)**.** *Every visible socket route of an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet is read through* $\mathsf{ApophaticSocket}^{\uparrow}$ *and* $\mathsf{ApophaticName}^{\uparrow}$ *before audit readback at A. The route passes through S, Q, R, H, C, P, N and then records the finite readback row A, without replacing that readback by an unmarked selector, hidden axiom, quotient collapse, or host gate answer.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier visible socket coverage`

Proof. Begin with source exposure. It places the visible socket-name row S before the question row Q and therefore before the readback row A.

Use socket-name dependency. The sibling $\mathsf{ApophaticSocket}^{\uparrow}$ and $\mathsf{ApophaticName}^{\uparrow}$ surfaces provide the only visible rows that S may read, so the audit route is already attached to those surfaces when A is recorded.

Finally apply visible socket non-escape. The route through R, H, C, P, N accounts for refusal, transport, continuation, provenance, and local naming, and prevents an unmarked selector, hidden axiom, quotient collapse, or host gate answer from substituting for the displayed readback. □

Theorem 715.8 (Apophatic gate question audit ledger exhaustion)**.** *For an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet, the rows R, A, H, C, P, N exhaust the audit ledger after the visible source and question rows have been read. No hidden axiom, quotient collapse, unmarked selector, or host gate answer is exported by the packet.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier refusal audit ledger`

Proof. Read the carrier and NameCert obligations. After S and Q, the remaining audit-facing rows are exactly the refusal ledger R, audit readback A, componentwise transport H, displayed continuation C, provenance P, and local naming row N.

Apply visible socket coverage to keep the audit readback attached to the $\mathsf{ApophaticSocket}^{\uparrow}$ and $\mathsf{ApophaticName}^{\uparrow}$ route. The audit ledger therefore records a finite answer to the already displayed gate question.

Close with visible socket non-escape. Because the carrier has no coordinate for a hidden axiom, quotient collapse, unmarked selector, or host gate answer, the listed rows exhaust the audit ledger. □

Theorem 715.9 (Apophatic gate question root visible source)**.** *For an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet $G = (S, Q, R, A, H, C, P, N)$, every root-facing packet read must consume the visible socket-name row S before it consumes the gate-question row Q. The row S is the displayed* $\mathsf{ApophaticSocket}^{\uparrow}$ *or* $\mathsf{ApophaticName}^{\uparrow}$ *source route, and Q is only the question asked about that visible route.*

Proof. Project the carrier of Definition 715.1. Its first coordinate is the visible socket-name row S, and the gate-question row Q is the next displayed row of the same finite packet.

Apply the local NameCert obligations, source exposure, and visible socket coverage. Theorems 715.2, 715.6, and 715.7 keep every accepted read attached to the visible $\mathsf{ApophaticSocket}^{\uparrow}$ or $\mathsf{ApophaticName}^{\uparrow}$ route before audit readback begins.

Finally use audit ledger exhaustion. Since all audit-facing rows occur after S, Q, a root-facing packet read cannot obtain the gate question before reading the visible source row. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root visible source`

Theorem 715.10 (Apophatic gate question root refusal audit ledger)**.** *For an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the rows*

$$R, A, H, C, P, N$$

are the complete refusal and audit ledger after the visible socket-name row S *and gate-question row* Q *have been read. No other refusal channel, hidden outside-supply predicate, detached audit answer, quotient collapse, or host replacement is part of the root-facing ledger.*

Proof. Start with the carrier and NameCert obligations. They display R as the refusal ledger, A as the audit readback, and H, C, P, N as the transport, continuation, provenance, and local naming rows for the same packet.

Use root visible source. Theorem 715.9 places S, Q before every refusal or audit read, so the ledger suffix is read only after the visible source route and question are fixed.

Apply audit ledger exhaustion. Theorem 715.8 says that R, A, H, C, P, N exhaust the audit-facing rows. The carrier has no coordinate for an additional refusal channel, hidden predicate, detached audit answer, quotient collapse, or host replacement. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root refusal audit ledger`

Theorem 715.11 (Apophatic gate question kind readback determinacy)**.** *For an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, once the displayed rows* S, Q, R, A, H, C, P, N *have been accepted, the audit-readback row* A *is determined by the visible socket row* S*, the gate-question row* Q*, and the refusal-ledger row* R*. The readback cannot be chosen from a hidden outside-supply predicate, host semantic judgment, quotient collapse, unmarked selector, or detached gate answer.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier kind readback determinacy`

Proof. Project the carrier and local NameCert obligations. They make S the visible socket-name row, Q the question asked about that row, R the refusal ledger, and A the finite audit readback inside the same packet.

Use source exposure and socket-name dependency. Theorems 715.6 and 715.4 force the question to read the sibling $\mathsf{ApophaticSocket}^{\uparrow}$ or $\mathsf{ApophaticName}^{\uparrow}$ surface before any readback is available.

Now apply audit route exactness and the root refusal audit ledger. The row A records only the answer to the displayed question over S after the refusal row R has been fixed, and Theorem 715.10 leaves no second refusal or audit coordinate.

Finally use visible socket non-escape. Since the carrier has no coordinate for a hidden predicate, host judgment, quotient collapse, unmarked selector, or detached gate answer, the kind readback is determined by the visible rows S, Q, R. □

Theorem 715.12 (Apophatic gate question supply-kind route totality)**.** *For an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, every supply-kind-facing route for the gate question first reads the visible socket row* S *as a finite* BHist *route, then reads the gate-question row* Q*, then reads the finite supply-kind and requested-shape refusal row* R*, and only then reads the audit readback row* A*.*

The public route vocabulary is exactly BHist, hsame, Cont, Pkg, *and* NameCert *over the displayed rows* S, Q, R, A, H, C, P, N. *It contains no hidden outside-supply witness, host gate answer, quotient collapse, unmarked selector, or detached audit answer.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier supply kind route totality`

Proof. Start with source exposure. Theorems 715.6 and 715.9 place the visible socket row S before the question row Q and keep both rows inside the finite BHist packet.

Next use socket-name dependency. Theorem 715.4 forces the gate question to read the visible ApophaticSocket$^{\uparrow}$ or ApophaticName$^{\uparrow}$ surface before any refusal or audit suffix can be consumed.

Finally apply kind-readback determinacy. Theorem 715.11 determines the audit readback A from S, Q, R, so the supply-kind and requested-shape row R is read before audit readback. The transport, continuation, provenance, and local naming rows supply only hsame, Cont, Pkg, and NameCert vocabulary for that finite route. □

Theorem 715.13 (Apophatic gate question refusal readback exactness)**.** *For an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$, *the refusal row* R *and readback row* A *are exactly the finite ledger suffix after the visible source row* S *and gate-question row* Q. *They are transported only by* H, C, P, N, *namely by componentwise* hsame, *displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row over* BHist.

No hidden outside-supply witness, host gate answer, quotient collapse, unmarked selector, detached readback, or additional refusal channel is part of the suffix.

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier refusal readback exactness`

Proof. Project the carrier and local NameCert obligations. The packet displays R as the refusal row and A as the audit readback row after the visible source and question rows S, Q.

Use the root refusal audit ledger. Theorem 715.10 identifies R, A, H, C, P, N as the complete suffix after S, Q and leaves no second refusal or audit coordinate.

The exact transport vocabulary is then forced by the carrier rows. The row H provides componentwise hsame, C provides the displayed Cont routes, P provides Pkg provenance, and N provides the local NameCert row over the same finite BHist packet. Thus R and A are transported only by H, C, P, N. □

Theorem 715.14 (Apophatic gate question audit consumer non-escape)**.** *Every downstream audit consumer of an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$ *reads only the finite* BHist *route*

$$S, Q, R, A, H, C, P, N.$$

The route vocabulary is hsame *transport,* Cont *continuation,* Pkg *provenance, and local* NameCert *naming for those displayed rows. The consumer receives no hidden axiom, outside supply witness, quotient collapse, unmarked selector, host replacement, or detached audit answer.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier audit consumer nonescape`

Proof. Read the routed question first. Theorem 715.12 forces the consumer through S, Q, R before audit readback, so no audit consumer can bypass the visible socket row or the finite refusal row.

Then use refusal readback exactness. Theorem 715.13 identifies R, A, H, C, P, N as the exact finite suffix transported by hsame, Cont, Pkg, and NameCert vocabulary over BHist.

Finally apply visible socket non-escape and audit ledger exhaustion. The carrier has no coordinate for hidden axioms, outside supply witnesses, quotient collapses, unmarked selectors, host replacements, or detached audit answers, so every downstream audit consumer is confined to the displayed packet. □

Theorem 715.15 (Apophatic gate question question exactness route)**.** *For every accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, every accepted packet read consumes the visible socket-name row* S *before it consumes the gate-question row* Q*. The row* Q *may ask only about the displayed socket-name route and the marked supply kind carried by* S, Q, R, A, H, C, P, N*; it cannot ask through a hidden host predicate, detached supply witness, quotient collapse, or unmarked selector.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier question exactness route`

Proof. Project the carrier of Definition 715.1. It places the visible socket-name row S before the gate-question row Q and keeps both rows inside the same finite packet.

Apply the local NameCert obligations and source exposure. Theorems 715.2 and 715.6 make S the exposed $\mathsf{ApophaticSocket}^{\uparrow}$ or $\mathsf{ApophaticName}^{\uparrow}$ route and make Q the question asked about that route.

Use visible socket coverage and kind readback determinacy. Theorems 715.7 and 715.11 keep the question tied to the marked kind read through the displayed rows, so hidden host predicates and detached supply witnesses are outside the accepted route. □

Theorem 715.16 (Apophatic gate question refusal transport scope)**.** *For every accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the refusal row* R *and the transport, continuation, provenance, and naming rows* H, C, P, N *preserve the same visible socket/question boundary determined by* S *and* Q*. Transport may replay that boundary, but it cannot add hidden axioms, host answers, detached outside-supply predicates, quotient collapse, or unmarked selectors.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier refusal transport scope`

Proof. Read the carrier and local NameCert obligations. They identify R as the refusal row for the visible question and identify H, C, P, N as the only componentwise transport, continuation, provenance, and local naming rows.

Apply source exposure and visible socket coverage. These force the refusal row to remain attached to the already displayed socket-name route and question boundary rather than to an ambient host answer.

Now use audit ledger exhaustion and kind readback determinacy. The audit suffix is exhausted by the finite rows of G, and the readback is determined by S, Q, R. Therefore transport through H, C, P, N preserves the same boundary and cannot introduce hidden axioms or a second answer source. □

Theorem 715.17 (Apophatic gate question audit readback source determinacy)**.** *For every accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the audit row* A *is determined by the displayed route through* S, Q, R*. It cannot be chosen from a detached host predicate, hidden outside-supply source, quotient collapse, semantic harmlessness judgment, or unmarked selector outside the finite packet.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier audit readback source determinacy`

Proof. Begin with the carrier and NameCert obligations. The row A appears only as the audit readback of the same finite packet that contains the socket row S, question row Q, and refusal row R.

Use source exposure and visible socket coverage to fix the source. The audit readback must follow the $\mathsf{ApophaticSocket}^{\uparrow}$ or $\mathsf{ApophaticName}^{\uparrow}$ route exposed by S and the question asked by Q.

Apply audit ledger exhaustion and kind readback determinacy. These results exhaust the audit-facing rows and determine A from S, Q, R, leaving no detached host predicate or hidden outside-supply source from which the readback could be selected. □

Theorem 715.18 (Apophatic gate question refusal row transport)**.** *For an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, componentwise* hsame *transport through* H *preserves the refusal ledger row* R *together with its visible socket and gate-question dependencies. Transport may replay the displayed refusal row, but it cannot create a hidden outside-supply row, an additional refusal channel, a host gate answer, a quotient collapse, or an unmarked selector.*

Proof. Start with the carrier. The row H is the componentwise hsame transport row for the socket row, question row, refusal ledger, readback row, provenance row, and local naming row.

Apply refusal nonescape coverage and the existing refusal ledger transport theorem. Theorems 715.25 and 715.28 identify R as the refusal row carried by the packet and make H replay that same row.

Use visible socket non-escape and the root refusal audit ledger to rule out extra supply. The refusal suffix is already exhausted by R, A, H, C, P, N after S, Q, and no carrier coordinate exports a hidden outside-supply row, host answer, quotient collapse, or unmarked selector. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier refusal row transport`

Theorem 715.19 (Apophatic gate question audit composition handoff)**.** *An accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet can hand the rows* A, R, H, C, P, N *to* $\mathsf{AuditGateComposition}^{\uparrow}$ *only after the visible socket-name dependency through* $\mathsf{ApophaticSocket}^{\uparrow}$ *and* $\mathsf{ApophaticName}^{\uparrow}$ *has been read. The handoff therefore carries the finite audit readback, refusal ledger, transport, continuation, provenance, and local naming rows, but not a hidden outside-supply witness, host semantic proof, detached gate answer, or unmarked selector.*

Proof. Read the source side first. Theorems 715.6, 715.4, and 715.9 place the visible socket-name row S before the gate question Q and before any audit suffix can be consumed.

Next read the suffix. The root refusal audit ledger and audit ledger exhaustion identify R, A, H, C, P, N as the complete refusal and audit rows available after S, Q.

Use kind readback determinacy and refusal row transport to prepare the composition route. The row A is fixed by S, Q, R, and transport through H preserves the same refusal row instead of adding a hidden supply row.

Finally apply visible socket non-escape. The handoff to $\mathsf{AuditGateComposition}^{\uparrow}$ can cite only the displayed audit suffix over the visible socket-name dependency, so host proofs, detached gate answers, unmarked selectors, and hidden outside-supply witnesses are not exported. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier audit composition handoff`

Theorem 715.20 (Apophatic gate question kind socket totality)**.** *For every accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the socket kind is total after the visible socket row* S*, the gate-question row* Q*, and the refusal row* R *have been read. The accepted route therefore determines which visible socket question is being refused before any audit readback, transport, continuation, provenance, or local naming row is consumed.*

Proof. Begin with Definition 715.6. It exposes S as the visible socket-name route and places Q as the question asked about that route.

Next apply Definition 715.11. Once S, Q, R are fixed, the kind readback is determined inside the displayed packet rather than by a host predicate or detached outside-supply row.

Use Definition 715.18 only after that determination. Transport preserves the same refusal row, so later rows replay the total socket kind instead of selecting another kind source. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier kind socket totality`

Theorem 715.21 (Apophatic gate question audit readback cut)**.** *For every accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the audit readback cut passes through exactly the suffix*

$$A, H, C, P, N.$$

The cut is attached to the already displayed rows S, Q, R *and cannot be replaced by a hidden outside-supply answer, a host semantic proof, a quotient collapse, or an unmarked selector.*

Proof. Read S, Q, R through Definition 715.6 and Definition 715.11. These theorems fix the visible source and the determined kind before the audit row can be consumed.

Now apply Definition 715.18. The row H preserves the refusal ledger for the same socket question, so the audit readback is not detached from the source triad.

Finally use Definition 715.19. It hands A, R, H, C, P, N to downstream audit composition only after the visible socket-name dependency has been read. Thus the audit cut through A, H, C, P, N remains finite and carries no hidden answer source. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier audit readback cut`

Theorem 715.22 (Apophatic gate question downstream unblock surface)**.** *Every downstream audit consumer of an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet receives exactly the finite route*

$$S, Q, R, A, H, C, P, N.$$

The route supplies visible socket exposure, gate-question readback, refusal, audit readback, componentwise transport, continuation, provenance, and local naming. It does not supply a host-level answer, hidden outside-supply witness, quotient collapse, unmarked selector, or extra audit channel.

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier downstream unblock surface`

Proof. First apply Definition 715.6 and Definition 715.11. These identify the source socket and the determined readback before any downstream audit route is available.

Next use Definition 715.18. Transport can only replay the refusal row over the same visible source and question.

Finally invoke Definition 715.19. Downstream audit composition receives the finite rows A, R, H, C, P, N after S, Q, so every consumer surface is exhausted by S, Q, R, A, H, C, P, N and no extra audit channel is exported. □

Theorem 715.23 (Apophatic gate question root readback route)**.** *Every downstream audit consumer of an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet receives only the finite route*

$$S, Q, R, A, H, C, P, N.$$

The route exposes the visible socket-name row, the gate question, the refusal ledger, the audit readback, componentwise transport, displayed continuation, package provenance, and local name. It exports no hidden outside supply, axiom channel, quotient collapse, proposition-extensionality collapse, or host replacement for the gate answer.

Proof. Read the visible source row first. Theorem 715.9 forces every root-facing consumer through S before Q.

Then read the refusal and audit suffix. Theorem 715.10 identifies R, A, H, C, P, N as the complete suffix after S, Q.

Finally apply visible socket coverage and audit ledger exhaustion. Theorems 715.7 and 715.8 keep downstream audit readback inside the displayed packet, so hidden outside supply, axiom channels, quotient collapse, proposition-extensionality collapse, and host replacements are not exported. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root readback route`

Theorem 715.24 (Apophatic gate question source gate exactness)**.** *For an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet $G = (S, Q, R, A, H, C, P, N)$, the gate-question row Q is exact only after the displayed socket-name row S has been read from the* ApophaticSocket$^{\uparrow}$ *or* ApophaticName$^{\uparrow}$ *sibling surface. The row Q therefore asks about the named socket route and cannot be replaced by a detached host predicate, an unnamed outside-supply witness, or a readback answer that precedes S.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier source gate exactness`

Proof. Project the carrier of Definition 715.1. Its first row is the visible socket-name row S, and its gate-question row Q is part of the same finite packet.

Apply Definition 715.2 and Definition 715.4. These rows force the local certificate and audit route to read S through the sibling socket or name surface before Q is available.

Use Definition 715.3. Since no carrier coordinate exports a hidden host predicate, unnamed supply witness, or detached readback answer, exactness of Q is exactly the question asked after the displayed socket-name read. □

Theorem 715.25 (Apophatic gate question refusal nonescape coverage)**.** *For an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet, the refusal ledger row R covers hidden axioms, quotient collapse, proposition-extensionality collapse, unmarked selectors, and unrecorded inscription novelty. This coverage does not export any requested outside supply; it only records which forbidden route is refused inside the displayed packet $G = (S, Q, R, A, H, C, P, N)$.*

Proof. Begin with Definition 715.2. It identifies R as the local refusal-ledger obligation of the finite packet.

Apply Definition 715.3. The consumer surface cannot export a hidden axiom, quotient equality, proposition-extensionality collapse, unmarked selector, unrecorded inscription novelty, or host-level replacement for the gate answer.

Finally use Definition 715.4. The refusal is attached to the visible socket-name route read through S and Q, so coverage remains a BEDC ledger row and does not supply the requested outside object. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier refusal nonescape coverage`

Theorem 715.26 (Apophatic gate question audit route exactness)**.** *For an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet, the audit-readback row A records only the finite answer to the already displayed gate question Q over the socket-name row S. The audit route cannot be replaced by a host judgment, a semantic harmlessness proof, an unmarked selector, or an outside-supply witness.*

Proof. Read Definition 715.1. The audit-readback row A is displayed after the socket-name row S, the gate question Q, and the refusal ledger R.

Apply Definition 715.4 and Definition 715.24. They put the sibling socket-name read and exact gate question before any audit answer can be recorded.

Use Definition 715.3 together with Definition 715.25. These rows exclude host judgments, semantic harmlessness proofs, unmarked selectors, and outside-supply witnesses, leaving A as the finite readback of the displayed question. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier audit route exactness`

Theorem 715.27 (Apophatic gate question boundary row triad)**.** *For every accepted* ApophaticGateQuestion$^{\uparrow}$ *packet $G = (S, Q, R, A, H, C, P, N)$, the boundary rows S, Q, R are consumed in that order. The row S is read through the sibling* ApophaticSocket$^{\uparrow}$ *or* ApophaticName$^{\uparrow}$ *surface, Q asks only about the displayed socket use, and R records the refusal surface for that same visible route.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier boundary row triad`

Proof. Start from the carrier and local NameCert obligations. They display S before Q and R, and they identify these rows as socket-name exposure, gate-question exactness, and refusal-ledger coverage.

Apply source exposure and socket-name dependency. The question route must read the sibling ApophaticSocket$^{\uparrow}$ or ApophaticName$^{\uparrow}$ row before the gate question can be answered.

Use visible socket non-escape and audit route exactness. They keep Q attached to the displayed socket use and leave R as the refusal row for that visible route, not as a hidden host answer or outside-supply witness. □

Theorem 715.28 (Apophatic gate question refusal ledger transport)**.** *For every accepted* ApophaticGateQuestion$^{\uparrow}$ *packet $G = (S, Q, R, A, H, C, P, N)$, componentwise* hsame *transport in H preserves the refusal-ledger row R. Transport can replay the displayed refusal ledger, but it cannot add hidden axioms, quotient collapse, unmarked selectors, or host gate answers.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier refusal ledger transport`

Proof. Read the carrier and NameCert obligations. The row H is explicitly componentwise hsame transport for the displayed socket row, question row, refusal ledger, readback row, provenance row, and local naming row.

Use refusal nonescape coverage together with visible socket non-escape. These results make R the only refusal ledger carried by the packet and exclude hidden axioms, quotient collapse, unmarked selectors, and host-level replacements for the gate answer.

Finally apply the boundary row triad. Since R is consumed after the displayed socket row and the displayed question row, transport in H preserves the same finite refusal ledger rather than adding a second gate answer. □

Theorem 715.29 (Apophatic gate question audit readback locality)**.** *For every accepted* ApophaticGateQuestion$^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the audit-readback row* A *is local to the displayed rows* S, Q, R, H, C, P, N*. It cannot precede the socket-name read, and it cannot be replaced by an answer detached from the carrier,* NameCert *route, visible socket dependency, or audit route.*

Proof. Begin with audit route exactness. The row A records only the finite answer to the already displayed gate question Q over the socket-name row S.

Apply source exposure, socket-name dependency, and the boundary row triad. These force the socket-name read through S, the displayed question through Q, and the refusal ledger through R before the audit readback can be consumed.

Use refusal ledger transport and visible socket non-escape for the remaining rows. The transport, continuation, provenance, and naming route through H, C, P, N preserves the same local packet and prevents a detached host answer, hidden axiom, quotient collapse, unmarked selector, or outside-supply witness from replacing A. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier audit readback locality`

Theorem 715.30 (Apophatic gate question root classifier socket triad)**.** *For every accepted* ApophaticGateQuestion$^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the visible socket row* S*, refusal-ledger row* R*, and gate classifier readback row* A *are bound through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates. The root classifier surface therefore reads one displayed socket-refusal-classifier triad, not a detached outside-supply predicate, ambient refusal oracle, or host-level gate answer.*

Proof. Start from the carrier and NameCert obligations. They display S, R, A inside the same finite packet and identify H, C, P, N as the only transport, route, provenance, and local naming coordinates for those rows.

Use visible socket non-escape and socket-name dependency. These results force the classifier read to enter through the visible socket-name surface before it can consult the refusal row or audit readback row.

Finally apply audit-ledger exhaustion, source-gate exactness, and audit-route exactness. The refusal and classifier rows remain attached to the same BHist packet and cannot be replaced by an outside-supply predicate, ambient refusal oracle, or host gate answer. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root classifier socket triad`

Theorem 715.31 (Apophatic gate question root ledger factorization)**.** *Every downstream audit read or refusal read of an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet factors through the displayed rows* S, Q, R, A, H, C, P, N*. In particular, a downstream consumer cannot read an ambient refusal oracle, hidden host predicate, detached gate answer, or outside-supply witness outside the finite root ledger.*

Proof. Read the carrier first. It contains exactly the visible socket row, gate-question row, refusal ledger, audit readback, componentwise transports, displayed continuation routes, provenance, and local naming row.

Apply the NameCert obligations and visible socket non-escape. These theorems give the complete admissible consumer surface and exclude hidden axioms, quotient collapse, unmarked selectors, host gate answers, and outside-supply witnesses.

Now use audit-ledger exhaustion and audit-route exactness. Every downstream audit or refusal read reaches R and A only after the displayed socket and question rows have been consumed, so the read factors through the root ledger rather than through an ambient refusal oracle. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root ledger factorization`

Theorem 715.32 (Apophatic gate question root refusal coverage)**.** *The visible socket row S, refusal row R, and classifier readback row A form the root* NameCert *coverage surface for downstream apophatic-name and audit-boundary packets. Any downstream packet that consumes the apophatic gate question receives those three rows through H, C, P, N and receives no separate refusal channel.*

Proof. Use the root classifier socket triad. It binds S, R, A through one BHist packet and through the same transport, continuation, package, and naming coordinates.

Use the root ledger factorization. Every downstream audit or refusal read already factors through the displayed root ledger, so downstream apophatic-name and audit-boundary consumers cannot bypass S, R, A by reading a separate refusal channel.

Finally apply socket-name dependency, refusal nonescape coverage, and audit readback locality. The socket, refusal, and classifier readback rows are exactly the coverage surface exported to downstream packets, while all outside-supply and host-answer alternatives remain outside the accepted carrier. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root refusal coverage`

Theorem 715.33 (Apophatic gate question public NameCert package)**.** *For every accepted* ApophaticGateQuestion *packet $G = (S, Q, R, A, H, C, P, N)$, the public* $\mathsf{NameCert}_{\mathsf{ApophaticGateQuestion}^{\uparrow}}$ *package is exactly the carrier row of Definition 715.1, the local* NameCert *obligations of Definition 715.2, visible-socket non-escape from Definition 715.3, socket-name dependency from Definition 715.4, source-gate exactness from Definition 715.24, refusal nonescape coverage from Definition 715.25, and audit route exactness from Definition 715.26. No additional public row, host answer, hidden axiom, quotient collapse, unmarked selector, or detached outside-supply witness is exported by the package.*

Proof. Project the carrier. It displays only the socket-name, gate-question, refusal-ledger, audit-readback, transport, continuation, provenance, and local naming rows S, Q, R, A, H, C, P, N.

Use the local NameCert obligations to identify the certificate fields with those rows. Visible-socket non-escape and socket-name dependency keep the package attached to the sibling $\mathsf{ApophaticSocket}^{\uparrow}$ or $\mathsf{ApophaticName}^{\uparrow}$ read.

Apply source-gate exactness, refusal nonescape coverage, and audit route exactness. These results bind the question, refusal ledger, and readback rows to the displayed packet and exclude every route not stored in G, so the listed rows are the whole public package. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier public namecert package`

Theorem 715.34 (Apophatic gate question root unblock package)**.** *Every root consumer of the public* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *package may cite only the displayed route S, Q, R, A, H, C, P, N and its* BHist, hsame, Cont, Pkg, *and* NameCert *rows. The consumer receives the socket-name read, gate question, refusal ledger, audit readback, componentwise transport, continuation replay, provenance, and local certificate rows, but receives no hidden source predicate, semantic harmlessness proof, quotient collapse, unmarked selector, or host gate answer.*

Proof. Begin with the public package theorem. It identifies the exported surface with the carrier and the displayed certificate rows, so a root citation has no coordinate outside S, Q, R, A, H, C, P, N.

Use boundary row triad and audit readback locality. They force the root route to read S, Q, R, A in the displayed order before transport, continuation, provenance, and naming are consumed.

Finally apply visible socket non-escape and refusal ledger transport. The BHist, hsame, Cont, Pkg, and NameCert rows can replay only the same packet, which rules out hidden source predicates, semantic harmlessness proofs, quotient collapse, unmarked selectors, and host gate answers. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root unblock package`

Theorem 715.35 (Apophatic gate question source-question ledger lock)**.** *For every root consumer of an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the root ledger is locked in the order* S *before* Q*, and* Q *before each of* R, A, H, C, P, N*. Thus every source-question-refusal-readback citation reads the visible socket-name row before the gate question and reads the gate question before refusal, audit readback, transport, continuation, provenance, or local naming can be exported.*

Proof. Project the carrier and local NameCert obligations. They display G as the finite packet S, Q, R, A, H, C, P, N, with S the source socket-name row and Q the gate-question row.

Use source exposure, socket-name dependency, and the boundary row triad. These force S to be read before Q, and force Q to precede the refusal row R on every accepted root route.

Now apply audit readback locality and the root unblock package. The audit row A and the later rows H, C, P, N are consumed only as the same packet's readback, transport, continuation, provenance, and naming coordinates, so none of them can be exported before the source-question lock has been read. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier source question ledger lock`

Theorem 715.36 (Apophatic gate question visible audit route totality)**.** *The visible audit route of an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet is exhausted by the finite rows* S, Q, R, A, H, C, P, N *together with their* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *structure. Every downstream audit consumer obtains the source-question-refusal-readback route from these rows and obtains no further audit carrier outside the displayed packet.*

Proof. Start with the public NameCert package and the root unblock package. They identify the exported root surface with the displayed carrier rows and with the BHist, hsame, Cont, Pkg, and NameCert coordinates attached to those rows.

Apply the source-question ledger lock. It fixes the entrance route as S before Q and places the refusal ledger, audit readback, transport, continuation, provenance, and naming rows after the gate question.

Finally use refusal ledger transport and audit readback locality. Transport in H, route replay in C, provenance in P, and local naming in N preserve the same packet, so the visible audit route has no extra carrier beyond S, Q, R, A, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier visible audit route totality`

Theorem 715.37 (Apophatic gate question refusal readback exhaustion)**.** *Every refusal readback exported by the public* ApophaticGateQuestion$^{\uparrow}$ *root package is exhausted by the displayed source-question-refusal-readback route. It cannot export a hidden source predicate, host gate answer, quotient collapse, proposition-extensionality collapse, unmarked selector, or outside-supply witness.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier refusal readback exhaustion`

Proof. Read the refusal ledger through source-gate exactness and refusal nonescape coverage. The row R answers only the displayed question Q after the visible source row S has been consumed, and it records the forbidden channels inside the finite packet.

Use visible audit route totality. The readback row A and the rows H, C, P, N are the only audit, transport, continuation, provenance, and naming coordinates available to a root consumer.

Close with the public package theorem and the root unblock package. Since the exported route is exactly the finite BEDC packet and its certificate rows, hidden source predicates, host gate answers, quotient collapse, proposition-extensionality collapse, unmarked selectors, and outside-supply witnesses have no export coordinate. □

Theorem 715.38 (Apophatic gate question root visible socket triad)**.** *Every root consumer of the public* ApophaticGateQuestion$^{\uparrow}$ *package reads a visible socket triad before any downstream readiness claim: the socket-name row S, the gate-question row Q, and the refusal-ledger row R. The triad is carried as a finite* BHist *surface with the same componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row as the package $G = (S, Q, R, A, H, C, P, N)$. It exports no requested outside object, host gate answer, hidden axiom, quotient collapse, unmarked selector, or detached source predicate.*

Proof. Start with the root unblock package, Definition 715.34. A root citation may cite only the displayed route S, Q, R, A, H, C, P, N and the attached BHist, hsame, Cont, Pkg, and NameCert rows.

Use source exposure and boundary row triad. These place S before Q and Q before the refusal ledger R, so the visible socket, question, and refusal rows form the root triad read before downstream consumers see the audit readback.

Finally apply visible socket non-escape and refusal nonescape coverage. The triad names the visible socket and records the refusal ledger inside the packet, while the excluded outside object, host answer, hidden axiom, quotient collapse, unmarked selector, and detached source predicate have no carrier coordinate. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root visible socket triad`

Theorem 715.39 (Apophatic gate question root source exactness)**.** *For every accepted* ApophaticGateQuestion$^{\uparrow}$ *packet, the root source used by downstream consumers is exactly the displayed source-before-question route $S \to Q \to R \to A$. The route is recorded in* BHist*, transported by* hsame*, replayed through* Cont*, packaged by* Pkg*, and named by* NameCert*. No hidden source predicate, semantic harmlessness proof, host gate answer, outside-supply witness, quotient collapse, or unmarked selector can replace this source route.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root source exactness`

Proof. Project the carrier $G = (S, Q, R, A, H, C, P, N)$. The only source row is S, the only question row is Q, the only refusal ledger is R, and the only audit readback is A.

Apply source exposure, source-gate exactness, and audit route exactness. Together they force the displayed source to precede the gate question, the refusal ledger to answer that question inside the packet, and the audit row to read back the same finite route.

The root unblock package supplies the remaining hsame, Cont, Pkg, and NameCert rows. Since all downstream readiness reads pass through those rows, no hidden source predicate, semantic harmlessness proof, host answer, outside witness, quotient collapse, or unmarked selector can replace $S \to Q \to R \to A$. □

Theorem 715.40 (Apophatic gate question root naming readiness)**.** *The public* ApophaticGateQuestion$^{\uparrow}$ *root package is naming-ready for downstream audit and refusal consumers exactly when it exposes the visible socket triad of Definition 715.38 and the source exactness route of Definition 715.39. Its readiness surface is the finite packet S, Q, R, A, H, C, P, N with* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; it does not supply a requested outside object, a host gate answer, a hidden axiom, a quotient collapse, an unmarked selector, or a detached source predicate.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root naming readiness`

Proof. First use the visible socket triad. It gives downstream consumers the socket-name row, gate question, and refusal ledger as visible finite rows before any audit readback is consumed.

Next use root source exactness. The source-before-question route is exactly $S \to Q \to R \to A$, so the readback row cannot be detached from the visible socket and refusal ledger.

Finally apply the public NameCert package and the root unblock package. They package H, C, P, N as the componentwise transport, continuation replay, provenance, and local naming rows, which gives downstream audit and refusal consumers enough theorem sites for readiness while preserving the stated non-escape boundary. □

Theorem 715.41 (Apophatic gate question refusal ledger routing)**.** *Every refusal-ledger consumer of an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet routes through R, A, H, C, P, N after the displayed S, Q read. The route records the refusal ledger and audit readback through the same finite packet and never obtains a hidden axiom, quotient collapse, proposition-extensionality collapse, unmarked selector, or host gate answer.*

Proof. Start with the source-gate exactness and boundary row triad. They place the socket-name row S and the gate-question row Q before the refusal ledger R can be consumed.

Apply refusal nonescape coverage and audit route exactness. The refusal row covers the forbidden routes inside the packet, and the audit row records only the readback of that displayed question and refusal.

Use refusal ledger transport, audit readback locality, and the public package theorem for the remaining route. The rows H, C, P, N transport, replay, package, and name the same ledger, leaving no coordinate for hidden axioms, quotient collapse, proposition-extensionality collapse, unmarked selectors, or host gate answers. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier refusal ledger routing`

Theorem 715.42 (Apophatic gate question provenance route exhaustion)**.** *Every accepted* ApophaticGateQuestion$^{\uparrow}$ *packet routes its provenance through exactly the displayed rows S, Q, R, A, H, C, P, N. The route consumes the sibling* ApophaticSocket$^{\uparrow}$ *socket-name surface and the* ApophaticName$^{\uparrow}$ *naming surface through the same* Pkg *and local* NameCert *rows, and it exposes no hidden source predicate outside the finite packet.*

Proof. Project the carrier and local NameCert obligations. They identify the only available rows as the source socket name S, gate question Q, refusal ledger R, audit readback A, componentwise transport H, continuation replay C, provenance row P, and naming row N.

Use socket-name dependency and root source exactness. The socket row is read as the visible $\mathsf{ApophaticSocket}^{\uparrow}$ source before the question row, and the refusal-audit readback cannot be detached from that source route.

Apply the public package theorem, the root unblock package, and refusal ledger routing. The provenance row P packages the same route together with the sibling $\mathsf{ApophaticName}^{\uparrow}$ naming surface, so there is no coordinate where a hidden source predicate can enter the accepted packet. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier provenance route exhaustion`

Theorem 715.43 (Apophatic gate question NameCert readback stability)**.** *For every accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet, componentwise* hsame *transport in H and displayed* Cont *replay in C preserve the audit readback row A as the answer to the already displayed S, Q, R route. In particular, the local* NameCert *row N may rename the packet only by preserving the same source, gate question, refusal ledger, and audit readback.*

Proof. Read the displayed route through source-gate exactness and audit route exactness. These theorems bind A to the source row S, question row Q, and refusal ledger R before any later transport or replay is consumed.

Now apply the carrier obligations for H and C. Componentwise hsame can transport only the displayed rows of the same packet, and displayed Cont can replay only the route already exposed by S, Q, R, A.

Finish with the public NameCert package and root unblock package. The naming row N certifies the same readback package rather than a replacement audit answer, so stable readback is preserved under the available transport and replay rows. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier namecert readback stability`

Theorem 715.44 (Apophatic gate question paper-Lean route separation)**.** *Every paper-Lean consumer route for an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet reads only the displayed rows S, Q, R, A, H, C, P, N of the carrier $G = (S, Q, R, A, H, C, P, N)$. Such a route may read the visible socket, gate question, refusal ledger, audit readback, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row, but it cannot turn the gate answer in A into a Lean verification claim.*

Proof. Project the carrier and the NameCert obligations. They identify S, Q, R, A, H, C, P, N as the complete consumer surface and place paper-Lean access inside the displayed Cont routes recorded by C.

Use visible socket non-escape and audit ledger exhaustion. These results keep the source, question, refusal, and answer rows inside the finite packet and leave no coordinate for a hidden theorem premise, host proof, or replacement verification object.

Finally apply provenance route exhaustion and NameCert readback stability. The route may replay and rename the same readback package, but the stable readback remains the packet answer to the displayed question rather than a Lean-side verification claim. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier paper lean route separation`

Theorem 715.45 (Apophatic gate question axiom-purity consumer boundary)**.** *An axiom-purity consumer of an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet may inspect the refusal rows for hidden axiom, quotient collapse, proposition-extensionality collapse, and unmarked selector exclusions. The consumer receives those exclusions only through the displayed route S, Q, R, A, H, C, P, N and receives no new proof premise beyond the finite refusal ledger and its readback.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier axiom purity consumer boundary`

Proof. Start with the carrier and visible socket non-escape. The axiom-purity read is a consumer read of the same packet, so it must pass through S, Q, R, A, H, C, P, N and cannot bypass the visible socket-question route.

Read the refusal ledger by audit ledger exhaustion and refusal ledger routing. The row R records the hidden axiom, quotient, proposition-extensionality, and selector exclusions, while A reads back that ledger as an answer to the displayed gate question.

Apply provenance route exhaustion and NameCert readback stability for the remaining rows. The rows H, C, P, N transport, replay, package, and name the same ledger, and none of them adds a fresh proof premise for the axiom-purity consumer. □

Theorem 715.46 (Apophatic gate question conservativity readback exactness)**.** *Every conservativity consumer of an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet reads the same visible socket, gate-question, refusal-ledger, and audit-readback route S, Q, R, A together with H, C, P, N. Its readback is exact for the displayed packet $G = (S, Q, R, A, H, C, P, N)$, not a host-level proof that the surrounding consumer is harmless.*

Proof. Project the carrier and the visible socket non-escape theorem. The conservativity consumer has the same visible socket and question entrance as every other accepted consumer, and no hidden source predicate or host harmlessness proof is present in the packet.

Use audit ledger exhaustion and provenance route exhaustion. They bind refusal inspection and provenance replay to S, Q, R, A, H, C, P, N, so the conservativity readback is exhausted by the displayed socket-question-refusal-readback route.

Finish with NameCert readback stability. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming preserve the same readback row A, which proves exactness for the packet rather than host-level harmlessness. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier conservativity readback exactness`

Theorem 715.47 (Apophatic gate question AuditGateComposition boundary lock)**.** *Any handoff from an accepted* ApophaticGateQuestion$^{\uparrow}$ *packet to* AuditGateComposition$^{\uparrow}$ *consumes the visible source-question-refusal-readback route S, Q, R, A together with H, C, P, N. The handoff cannot introduce a host gate answer, quotient collapse, proposition-extensionality collapse, unmarked selector, outside-supply witness, or hidden source predicate.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier auditgate composition boundary lock`

Proof. Begin with the root source exactness theorem. It fixes the handoff input as the displayed route $S \to Q \to R \to A$, with R answering only the visible gate question and A reading back that answer.

Use refusal ledger routing and the provenance route exhaustion theorem. They force the remaining rows H, C, P, N to transport, replay, package, and name the same route before any downstream audit-composition consumer can cite the packet.

Finally apply the root unblock package and refusal nonescape coverage. Since every handoff coordinate is already one of S, Q, R, A, H, C, P, N, $\mathsf{AuditGateComposition}^{\uparrow}$ receives no coordinate for host gate answers, quotient collapse, proposition-extensionality collapse, unmarked selectors, outside-supply witnesses, or hidden source predicates. □

Theorem 715.48 (Apophatic gate question mature boundary)**.** *For every accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the visible socket-name row* S*, gate-question row* Q*, refusal ledger* R*, audit-readback row* A*, componentwise* hsame *row* H*, displayed* Cont *row* C*,* Pkg *provenance row* P*, and local* NameCert *row* N *exhaust the mature paper-side boundary of the gate-question package.*

The mature boundary still does not supply the requested outside object, global audit completeness, bridge checking, a host gate answer, quotient collapse, unmarked selector, or hidden source predicate. It records the complete paper-side package inventory while keeping the verification and bridge-checking axes separate.

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier mature boundary`

Proof. Project the public NameCert package. By Definition 715.33, the exported surface is exactly the carrier and certificate rows S, Q, R, A, H, C, P, N.

Use the root unblock package and refusal ledger routing. These theorems show that root consumers and refusal-ledger consumers read the same finite rows and cannot obtain a hidden source predicate, semantic harmlessness proof, quotient collapse, unmarked selector, or host gate answer.

Finally apply root ledger factorization and root refusal coverage. They bind downstream audit and refusal reads to the visible socket-name, gate-question, refusal, and audit-readback rows, so the paper-side boundary is exhausted without adding the requested outside object, global audit completeness, or bridge checking. □

Theorem 715.49 (Apophatic gate question root source audit totality)**.** *For every accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the visible socket source route, gate-question route, refusal ledger, audit readback, componentwise* hsame *transport, displayed* Cont *route,* Pkg *provenance, and local* NameCert *row form one root source-audit packet over the displayed* BHist *rows. Any downstream source or audit consumer must read* S, Q, R, A, H, C, P, N *and cannot replace them by a hidden source predicate, host gate answer, outside-supply witness, quotient collapse, proposition-extensionality collapse, or unmarked selector.*

Proof. Begin with source exposure and source-gate exactness. These theorems identify S as the visible socket-name route and Q as the gate question asked against that route.

Use audit route exactness and audit ledger exhaustion for the readback side. They bind R and A to the refusal ledger and its displayed audit answer rather than to a detached answer channel.

Finally apply NameCert readback stability and the mature boundary. The rows H, C, P, N preserve the same source-audit packet by componentwise transport, continuation replay, provenance, and naming, so no hidden source predicate, host answer, outside-supply witness, quotient collapse, proposition-extensionality collapse, or unmarked selector can be read by a downstream consumer. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root source audit totality`

Theorem 715.50 (Apophatic gate question root refusal route exactness)**.** *For every accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$*, the refusal route is exactly the finite path from the visible source row* S *through the gate-question row* Q*, refusal ledger* R*, audit readback* A*, and the rows* H, C, P, N*. It is a route over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data, not a host-level proof that the requested outside object exists or that refusal is semantically harmless.*

Proof. Read the source and question first. Source exposure, socket-name dependency, and source-gate exactness place S and Q before the refusal ledger can be interpreted.

Next use refusal coverage and refusal ledger routing. They identify R as the displayed refusal row and make A the local readback of that row.

Transport and package the same route through H, C, P, N. Audit route exactness, naming readiness, and the mature boundary keep this suffix on the same packet, so the refusal route is exact without importing an outside object, a harmlessness proof, or any host-level audit judgment. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root refusal route exactness`

Theorem 715.51 (Apophatic gate question root consumer ledger readiness)**.** *The downstream consumer ledger for an accepted* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *packet* $G = (S, Q, R, A, H, C, P, N)$ *is ready exactly when the visible source route, refusal route, audit readback,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row have all been displayed. The ledger can then be consumed by source, refusal, audit, axiom-purity, conservativity, and* $\mathsf{AuditGateComposition}^{\uparrow}$ *readers without adding an ambient apophatic closure object.*

Proof. First combine root source audit totality with root refusal route exactness. Together they display S, Q, R, A, H, C, P, N as one source-refusal-audit route rather than as separate ambient objects.

Next apply audit route exactness, public NameCert packaging, and AuditGateComposition boundary lock. These theorems show that downstream audit and composition consumers receive only the displayed packet rows.

Finally use the mature boundary. It records the complete paper-side socket-name, gate-question, refusal-ledger, audit-readback, transport, continuation, provenance, and naming inventory, so the consumer ledger is ready without a hidden apophatic closure object, outside-supply witness, host answer, quotient collapse, proposition-extensionality collapse, or unmarked selector. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier root consumer ledger readiness`

Definition 715.52 (Apophatic gate question formal target)**.** *The formal target surface for* $\mathsf{ApophaticGateQuestion}^{\uparrow}$ *is the future Lean carrier packet*

$$G = (S, Q, R, A, H, C, P, N),$$

where S *is the visible socket row,* Q *is the gate-question row,* R *is the refusal ledger,* A *is the audit-readback row,* H *is componentwise* hsame *transport,* C *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{ApophaticGateQuestion}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier formal target surface`

Theorem 715.53 (Apophatic gate question formal target readback)**.** *Every future formal readback of Definition 715.52 must preserve the socket row, question row, refusal ledger, audit-readback row, componentwise transport, continuation route, provenance, and local* NameCert *row. The readback cannot add outside-supply, hidden axiom, quotient equality, proposition-extensionality, or host gate-answer coordinates.*

Proof. Start with the public NameCert package and visible socket non-escape. They identify G with the displayed finite rows and keep every source read on S.

Use socket-name dependency and the mature boundary. These results force Q, R, A, H, C, P, N to remain attached to the same socket-question packet rather than to a host answer or outside-supply coordinate.

Finally apply refusal ledger routing and axiom-purity consumer boundary. The hidden axiom, quotient, proposition-extensionality, selector, and host-answer exclusions are already ledgered inside the visible packet, so a formal readback may preserve the rows but cannot add a new forbidden coordinate. □

Lean4 ✓ `BEDC.Derived.ApophaticGateQuestionUp.ApophaticGateQuestionCarrier formal target readback`

Closure status for $\mathsf{NameCert}_{\mathsf{ApophaticGateQuestion}^{\uparrow}}$.

Constructive story: An $\mathsf{ApophaticGateQuestion}^{\uparrow}$ packet is generated from a visible apophatic socket-name row, a gate-question row, a refusal ledger, an audit-readback row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApophaticGateQuestion}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 715.1, Definition 715.2, Definition 715.4, Definition 715.24, Definition 715.25, Definition 715.26, Definition 715.33, Definition 715.34, Definition 715.41, Definition 715.42, Definition 715.43, Definition 715.44, Definition 715.45, Definition 715.46, Definition 715.47, and Definition 715.48 bind the mature paper-side socket-name, gate-question, refusal-ledger, audit-readback, hsame, Cont, Pkg, and NameCert rows for the exported gate-question package.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApophaticGateQuestion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, existence of the requested outside supply, global audit completeness, or every possible gate-question grammar.

Upgrade path: No further paper-side theory closure remains; Lean verification and bridge checking remain separate formal-axis obligations.

Chapter 716

A Concrete Naming Certificate for $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$

The $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ packet realizes the beta-redex preservation obligation named in chapter 9377. It packages the body typing boundary, argument typing boundary, beta-redex route, substituted body readback, substituted codomain readback, finite ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and the local $\mathsf{NameCert}$ row consumed by the MetaCIC subject-reduction interface. The packet exports a finite NameCert surface for the beta case only; it does not export host substitution semantics, semantic term equality, unrestricted conversion, or a closed subject-reduction theorem.

It is also the beta-row consumer for chapter 721: that boundary records the four displayed discharge rows, while this chapter supplies only the beta-substitution preservation row and keeps the application, lambda-domain, and Pi-domain rows external.

Definition 716.1 (BetaSubstitutionPreservation carrier)**.** *A* $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N)$$

with the following displayed rows:

1. *B is the body typing row for a MetaCIC body checked in the context extended by the shifted domain;*
2. *A is the argument typing row for the argument checked at the unshifted domain in the original context;*
3. *V is the beta-redex row exposing the application of the lambda body to the argument as the local reduction site;*
4. *C_0 is the codomain readback row before substitution, including the shifted-domain binder boundary;*
5. *R is the substituted body readback row for* $\mathsf{substitute}(0, \mathsf{arg}, \mathsf{body})$*;*
6. *C_1 is the substituted codomain readback row for* $\mathsf{substitute}(0, \mathsf{arg}, \mathsf{cod})$*;*
7. *L is the finite preservation ledger tying B, A, V, C_0, R, C_1 to the same beta-redex typing boundary;*
8. *H stores componentwise* hsame *transports for the body typing, argument typing, redex, codomain, substituted body, substituted codomain, ledger, package, and local naming rows;*

9. *K stores the displayed* Cont *routes for reading the body typing row, the argument typing row, the beta-redex route, the substituted body, the substituted codomain, and the handoff into* $\mathsf{SubjectReduction}^{\uparrow}$*;*
10. *P is the* Pkg *provenance over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{SubjectReduction}^{\uparrow}$*,* ClosedTermSubstitutionBou BinderContextSubstitutionSeal$^{\uparrow}$*, and* $\mathsf{TypedReductionNormalForm}^{\uparrow}$ *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BetaSubstitutionPreservation}^{\uparrow}}$ *row.*

The carrier is exactly this finite packet. It contains no host substitution semantics, no semantic term equality, no unrestricted conversion procedure, and no closed subject-reduction theorem.

Lean4 ✓ `BEDC.Derived.BetaSubstitutionPreservationUp.BetaSubstitutionPreservationTasteGate`
`single carrier alignment`

Theorem 716.2 (BetaSubstitutionPreservation NameCert obligations)**.** *For the carrier of Definition 716.1, the local* $\mathsf{NameCert}_{\mathsf{BetaSubstitutionPreservation}^{\uparrow}}$ *surface consists of carrier admission for*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N),$$

body typing readback, argument typing readback, beta-redex route replay, codomain boundary readback, substituted body readback, substituted codomain readback, ledger exactness, componentwise hsame *transport, displayed* Cont *route replay,* Pkg *provenance, and non-escape from host substitution semantics, semantic term equality, unrestricted conversion, and closed subject reduction.*

Lean4 ✓ `BEDC.Derived.BetaSubstitutionPreservationUp.BetaSubstitutionPreservationNameCertObligations`

Proof. Carrier admission is projection from Definition 716.1. The packet exposes exactly $B, A, V, C_0, R, C_1, L, H, K$

The body and argument rows record the two premises of the beta-redex obligation from Definition 9377.1. The codomain boundary C_0 names the shifted-domain binder interface, while R and C_1 record the two substituted readbacks.

The existing $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ and $\mathsf{BinderContextSubstitutionSeal}^{\uparrow}$ anchors supply the closed-boundary and binder-boundary discipline used to read the substitution rows as finite packet data. The $\mathsf{TypedReductionNormalForm}^{\uparrow}$ anchor fixes the endpoint as a typed reduction boundary rather than as host conversion.

Finally L, H, K, P, N bind the readbacks to one local NameCert surface. Since no carrier coordinate names host substitution semantics, semantic term equality, unrestricted conversion, or a closed subject-reduction theorem, no local projection can export one. □

Theorem 716.3 (BetaSubstitutionPreservation redex carrier)**.** *For an accepted* $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ *carrier*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N),$$

the beta redex visible to the MetaCIC route is exactly the closed term source row B, the argument row A, the binder-context boundary C_0, the beta-redex row V, the substitution seal carried by R, C_1, the typed reduction and normal-form row read through L, the subject-reduction discharge socket in K, componentwise hsame *transport through H, displayed* Cont *replay through K,* Pkg *provenance through P, and the local* NameCert *row N.*

Proof. Project the carrier of Definition 716.1. The closed term source and argument source are the rows B and A, while V is the only row that names the beta-redex site.

The binder context is read at C_0, and the substitution seal is visible only through the substituted body and codomain rows R, C_1. The ledger L records the typed reduction and normal-form boundary for those rows.

The subject-reduction consumer receives a socket only through K. The remaining rows H, P, N transport, source, and name the same finite packet, so the redex carrier has no coordinate for closed subject reduction or global confluence. □

Theorem 716.4 (BetaSubstitutionPreservation context transport)**.** *Let $Q = (B, A, V, C_0, R, C_1, L, H, K, P, N)$ be an accepted* BetaSubstitutionPreservation$^{\uparrow}$ *carrier. Every binder-context transport of the beta-substitution route must keep the closed term source B, argument source A, substitution seal R, C_1, typed reduction and normal-form ledger L, subject-reduction discharge socket K, componentwise* hsame *row H, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row in the same packet.*

Proof. Start with the binder-context row C_0. It records the shifted-domain boundary before substitution, so a context transport has to carry C_0 with the source rows B, A and the redex row V.

Use the componentwise transport row H. It moves $B, A, V, C_0, R, C_1, L, K, P, N$ together and therefore prevents the substituted rows from being read after changing the binder context.

Replay is displayed through K, which is also the only subject-reduction discharge socket. Provenance P and naming N keep the route local to this packet, with no appeal to closed subject reduction or global confluence. □

Lean4 ✓ `BEDC.Derived.BetaSubstitutionPreservationUp.BetaSubstitutionPreservationContextTransport`

Theorem 716.5 (BetaSubstitutionPreservation typed residual non-escape)**.** *For an accepted* BetaSubstitutionPrese *carrier $Q = (B, A, V, C_0, R, C_1, L, H, K, P, N)$, the typed residual endpoint consumed by the MetaCIC route is read only through the closed term source, binder context, substitution seal, typed reduction and normal-form ledger, subject-reduction discharge socket,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows of Q. It cannot be replaced by closed subject reduction, global confluence, host substitution semantics, or unrestricted conversion.*

Proof. Read the residual endpoint through the substituted rows R, C_1 and the ledger L. These rows are available only after the body source B, argument source A, redex row V, and binder context C_0 have been displayed.

The discharge socket is the route in K. It passes the typed residual endpoint to the surrounding MetaCIC interface as a finite row, not as a closed subject-reduction theorem.

Finally apply the non-escape boundary of Definition 716.7. Since Q has no coordinates for global confluence, host substitution semantics, unrestricted conversion, or closed subject reduction, the typed residual remains local NameCert data. □

Theorem 716.6 (BetaSubstitutionPreservation redex closure)**.** *Let $Q = (B, A, V, C_0, R, C_1, L, H, K, P, N)$ be an accepted* BetaSubstitutionPreservation$^{\uparrow}$ *carrier. Any public read of the beta-redex preservation step reaches the substituted body row R and the substituted codomain row C_1 only through the displayed body typing row B, argument typing row A, beta-redex row V, codomain boundary C_0, ledger L, componentwise* hsame *transports, and displayed* Cont *routes.*

Lean4 ✓ `BEDC.Derived.BetaSubstitutionPreservationUp.BetaSubstitutionPreservationRedexClosure`

Proof. Project the accepted carrier. The source typing information is exactly B and A, and the beta-redex site is exactly V.

The route K replays the redex boundary through the codomain readback C_0 and the two substituted rows R and C_1. The ledger L records that these rows belong to the same preservation packet.

Apply the $\mathsf{SubjectReduction}^{\uparrow}$ anchor only at the handoff row recorded in K. The packet therefore supplies the beta-case input consumed by subject reduction, not an ambient subject-reduction theorem or a second reduction semantics. □

Lean4 ✓ `BEDC.Derived.BetaSubstitutionPreservationUp.BetaSubstitutionPreservationEventFlow extra tail rejected`

Theorem 716.7 (BetaSubstitutionPreservation non-escape)**.** *Every accepted* $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ *packet exposes beta substitution preservation only through the rows*

$$B, A, V, C_0, R, C_1, L, H, K, P, N.$$

A downstream consumer may read the body typing boundary, argument typing boundary, beta-redex route, substituted body, substituted codomain, finite ledger, componentwise transports, displayed continuation routes, package provenance, and local naming row. It cannot replace those rows by host substitution semantics, semantic term equality, unrestricted conversion, or a closed subject-reduction theorem.

Proof. Begin with the carrier inventory. The only substitution-facing rows are C_0, R, C_1, and the only consumer routes are the displayed Cont routes in K.

Use Definition 716.2. The substitution rows are available only after the body typing, argument typing, beta-redex, and codomain boundary rows have been displayed inside the same packet.

The exclusions follow from absence of coordinates. Host substitution semantics, semantic term equality, unrestricted conversion, and closed subject reduction would each require a separate row or external route, and neither is present in Q. □

Lean4 ✓ `BEDC.Derived.BetaSubstitutionPreservationUp.BetaSubstitutionPreservationNonescape`

Theorem 716.8 (BetaSubstitutionPreservation subject-reduction handoff)**.** *An accepted* $\mathsf{BetaSubstitutionPreservat}$ *packet hands the beta-redex case to* $\mathsf{SubjectReduction}^{\uparrow}$ *as the finite NameCert packet*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N).$$

The handoff supplies the body typing premise, argument typing premise, beta-redex route, substituted body readback, substituted codomain readback, ledger, transports, continuation routes, provenance, and local name required by the parameterized MetaCIC subject-reduction interface. It does not supply the other three discharge obligations, an unrestricted conversion rule, a global normalization theorem, or the closed subject-reduction theorem excluded in chapter 9377.

Proof. Start with Definition 716.6. The beta-redex read reaches R and C_1 only through the displayed body and argument typing rows, the redex row, the codomain boundary, the ledger, and the local transport and continuation data.

The handoff route in K is the only $\mathsf{SubjectReduction}^{\uparrow}$-facing coordinate. It presents the beta case as one finite preservation packet while leaving the remaining application-argument, lambda-domain, and Pi-domain obligations outside this carrier.

Use Definition 716.7 for the boundary condition. The packet cannot be read as unrestricted conversion, global normalization, or closed subject reduction, so the subject-reduction consumer receives exactly the named beta-substitution preservation input. □

Lean4 ✓ `BEDC.Derived.BetaSubstitutionPreservationUp.BetaSubstitutionPreservationSubjectReductionHandoff`

Theorem 716.9 (Beta row consumption by SubjectReductionDischarge)**.** *An accepted* BetaSubstitutionPreservation *packet supplies exactly the B row of an accepted* SubjectReductionDischarge$^{\uparrow}$ *packet. The A, L, Π rows remain external discharge obligations. Every downstream consumer must read the beta row through*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N)$$

and must read the discharge packet through the displayed four-row inventory of SubjectReductionDischarge$^{\uparrow}$ *rather than through a closed subject-reduction theorem or host substitution semantics.*

Proof. Apply the subject-reduction handoff of Definition 716.8. It presents the accepted beta packet as the finite row

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N),$$

with the body typing, argument typing, redex, substituted readback, ledger, transport, route, provenance, and local naming rows available only inside that packet.

Next read the downstream discharge surface. By Definition 718.5, the public inventory of SubjectReductionDischarge$^{\uparrow}$ has exactly four discharge rows: beta, application-argument, lambda-domain, and Pi-domain. The beta row is therefore the only slot supplied by the BetaSubstitutionPreservation$^{\uparrow}$ handoff; the A, L, Π rows of the discharge packet remain obligations supplied outside this carrier.

Finally apply the obstruction boundary of Definition 718.4 together with the non-escape theorem Definition 716.7. These prevent the beta packet from being read as a closed subject-reduction theorem, host substitution semantics, unrestricted conversion, or a replacement for the other three discharge rows. □

Theorem 716.10 (BetaSubstitutionPreservation redex ledger exactness)**.** *Let $Q = (B, A, V, C_0, R, C_1, L, H, K, P,$ be an accepted* BetaSubstitutionPreservation$^{\uparrow}$ *carrier. The redex ledger row L records exactly the body typing row B, argument typing row A, beta-redex row V, codomain boundary row C_0, substituted body row R, substituted codomain row C_1, componentwise transports H, continuation routes K, provenance row P, and local naming row N from Definition 716.1. It does not add host substitution semantics, a semantic term-equality row, unrestricted conversion, or closed subject reduction to the beta case.*

Lean4 ✓ `BEDC.Derived.BetaSubstitutionPreservationUp.BetaSubstitutionPreservationRedexLedgerExactness`

Proof. Project the carrier of Definition 716.1. The ledger row L is listed after the beta source, redex, codomain, substituted-body, and substituted-codomain rows, so its source inventory is B, A, V, C_0, R, C_1.

The existing subject-reduction handoff of Definition 716.8 reads the same finite packet through H, K, P, N. Thus the ledger is exact for the packet consumed by the beta case.

By Definition 716.7, no coordinate supplies host substitution semantics, semantic term equality, unrestricted conversion, or closed subject reduction. The ledger therefore remains a finite BEDC row over the displayed carrier. □

Theorem 716.11 (BetaSubstitutionPreservation codomain-boundary stability)**.** *For an accepted* BetaSubstitutionPreservation$^{\uparrow}$ *carrier $Q = (B, A, V, C_0, R, C_1, L, H, K, P, N)$, the codomain boundary row C_0 and the substituted codomain row C_1 remain paired under the componentwise* hsame *transports H and displayed continuation routes K. The beta case may transport this pair through the finite packet, but it may not replace the pair by host substitution semantics, unrestricted conversion, or a closed subject-reduction theorem.*

Proof. Read the codomain rows from the carrier. The row C_0 records the codomain readback before substitution, and C_1 records the substituted codomain readback.

The rows H and K transport and replay the codomain pair together with B, A, V, R, L, P, N. The handoff theorem Definition 716.8 uses this same packet when presenting the beta case to $\mathsf{SubjectReduction}^{\uparrow}$.

Non-escape is supplied by Definition 716.7. Since no replacement coordinate exists for host substitution semantics, unrestricted conversion, or closed subject reduction, the codomain-boundary pair is stable only inside the displayed packet. □

Theorem 716.12 (BetaSubstitutionPreservation residual-budget monotonicity)**.** *Let $Q = (B, A, V, C_0, R, C_1, L, H$ be an accepted $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ carrier consumed by a downstream $\mathsf{SubjectReductionDischarge}^{\uparrow}$ packet. If the discharge packet preserves the beta row supplied by Q, then the displayed residual obligation budget can only decrease or remain unchanged: the beta row is consumed, while the application-argument, lambda-domain, and Pi-domain rows remain external discharge obligations. No row of Q creates an additional discharge obligation.*

Proof. Project the carrier of Definition 716.1. Its rows are exactly $B, A, V, C_0, R, C_1, L, H, K, P, N$, with the $\mathsf{SubjectReduction}^{\uparrow}$ handoff recorded through the displayed routes in K and provenance in P.

Apply Definition 716.9. The downstream discharge surface has four rows, and the accepted beta packet supplies exactly the beta row. The application-argument, lambda-domain, and Pi-domain rows remain outside this carrier.

Use Definition 716.7. Since Q has no coordinate for host substitution semantics, unrestricted conversion, closed subject reduction, or a replacement discharge row, it cannot introduce a new residual obligation.

Thus consuming the beta row removes one displayed obligation from the residual budget or leaves the external budget unchanged when the downstream packet merely records the handoff. The finite packet has no route that increases the discharge inventory. □

Theorem 716.13 (BetaSubstitutionPreservation discharge progress)**.** *Let $Q = (B, A, V, C_0, R, C_1, L, H, K, P, N)$ be an accepted $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ carrier consumed by an accepted $\mathsf{SubjectReductionDischarge}^{\uparrow}$ packet. If the consumer records the beta row supplied by Q, then the residual discharge surface removes exactly that beta row. The application-argument row, lambda-domain row, and Pi-domain row remain external discharge obligations, and no row of Q supplies host substitution semantics, unrestricted conversion, global confluence, or closed subject reduction.*

Proof. First read the four-row boundary through Definition 716.9. The accepted beta packet supplies exactly the beta row of the $\mathsf{SubjectReductionDischarge}^{\uparrow}$ surface, while the application-argument, lambda-domain, and Pi-domain rows are still outside the carrier.

Next apply Definition 716.12. Consuming the displayed beta row cannot create an additional residual obligation, because the handoff in K and the provenance in P route only the same finite beta packet to the downstream discharge consumer.

Finally use Definition 716.7. The carrier has no coordinate for host substitution semantics, unrestricted conversion, global confluence, or closed subject reduction. The only progress made by consuming Q is therefore the removal of the beta row; the other three discharge rows remain external. □

Theorem 716.14 (BetaSubstitutionPreservation beta-case obligation package)**.** *The beta case exposed by an accepted* $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ *carrier is the finite BEDC package*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N)$$

together with the carrier obligations of Definition 716.2, the redex closure of Definition 716.6, the non-escape boundary of Definition 716.7, the subject-reduction handoff of Definition 716.8, the redex ledger exactness of Definition 716.10, the codomain-boundary stability of Definition 716.11, and the residual-budget monotonicity of Definition 716.12. This package is an obligation surface for the beta case; it is not host substitution semantics, unrestricted conversion, a global normalization theorem, or closed subject reduction.

Proof. The carrier obligations name the rows $B, A, V, C_0, R, C_1, L, H, K, P, N$ and the local exclusions. Redex closure then shows how the substituted body and substituted codomain are reached from the body typing, argument typing, redex, and codomain boundary rows.

The handoff theorem presents the same packet to $\mathsf{SubjectReduction}^{\uparrow}$. Redex ledger exactness records that the ledger contains precisely the displayed beta rows, and codomain-boundary stability records that the codomain pair remains paired under H and K.

Combining these finite rows gives the beta-case obligation package. The non-escape theorem excludes host substitution semantics, unrestricted conversion, global normalization, and closed subject reduction from the package boundary. □

Theorem 716.15 (BetaSubstitutionPreservation scoped discharge inventory)**.** *Let*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N)$$

be an accepted $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ *carrier consumed by* $\mathsf{SubjectReductionDischarge}^{\uparrow}$*. Every scoped discharge read supplied by Q factors through the body row B, argument row A, beta-redex row V, codomain boundary C_0, substituted body row R, substituted codomain row C_1, ledger row L, componentwise* hsame *transports H, displayed* Cont *replay K, provenance row P, and local* $\mathsf{NameCert}$ *row N. It cannot supply the application-argument, lambda-domain, or Pi-domain discharge rows, nor host substitution semantics, unrestricted conversion, global confluence, or closed subject reduction.*

Proof. Project the carrier of Definition 716.1. The only rows available to the discharge consumer are the displayed coordinates $B, A, V, C_0, R, C_1, L, H, K, P, N$.

Use the beta-case obligation package of Definition 716.14. It binds the body, argument, redex, codomain, substituted readback, ledger, transport, replay, provenance, and local naming rows as one finite beta obligation surface.

Apply the four-row consumption theorem Definition 716.9. The accepted packet is exactly the beta row consumed by $\mathsf{SubjectReductionDischarge}^{\uparrow}$, while the application-argument, lambda-domain, and Pi-domain rows remain outside this carrier.

Finally use non-escape from Definition 716.7. Since no coordinate of Q names host substitution semantics, unrestricted conversion, global confluence, or closed subject reduction, every scoped discharge read stays inside the displayed beta inventory. □

Theorem 716.16 (BetaSubstitutionPreservation body and argument boundary)**.** *For an accepted* $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ *carrier*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N),$$

the body typing boundary B and the argument typing boundary A are the only source typing premises available to the beta-redex route V. The ledger L, transports H, routes K, provenance P, and local name N may replay those two rows with C_0, R, C_1, but they do not add a host substitution semantics row, an unrestricted conversion row, or a closed subject-reduction claim.

Proof. Project the carrier of Definition 716.1. Its first two rows are exactly the body typing row B and the argument typing row A, and the redex route V is listed as the local beta site that consumes them.

Apply the NameCert obligations of Definition 716.2. They expose body typing readback and argument typing readback as separate obligations before the beta-redex route can be replayed.

Use redex closure from Definition 716.6. The substituted body row R and substituted codomain row C_1 are reached only through $B, A, V, C_0, L, H, K, P, N$.

Finally apply non-escape from Definition 716.7. Since no coordinate supplies host substitution semantics, unrestricted conversion, or closed subject reduction, the body and argument boundary remains exactly the displayed pair B, A. □

Theorem 716.17 (BetaSubstitutionPreservation codomain readback)**.** *For an accepted* BetaSubstitutionPreservatio *carrier*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N),$$

the codomain readback used by the beta case is exactly the pair of displayed rows C_0 and C_1: C_0 records the shifted-domain binder boundary before substitution, and C_1 records the substituted codomain readback after the beta argument is installed. No consumer may replace this pair by host codomain computation, semantic equality of terms, unrestricted conversion, or closed subject reduction.

Proof. Read the codomain rows from Definition 716.1. The row C_0 is the codomain readback before substitution, and the row C_1 is the substituted codomain readback.

Apply codomain-boundary stability from Definition 716.11. It keeps C_0 and C_1 paired under the componentwise transports H and displayed continuation routes K.

Use the beta-case obligation package of Definition 716.14. That package combines the codomain pair with $B, A, V, R, L, H, K, P, N$ as the beta obligation surface consumed by $\mathsf{SubjectReduction}^{\uparrow}$.

Non-escape from Definition 716.7 rules out host codomain computation, semantic equality, unrestricted conversion, and closed subject reduction. Thus the codomain readback is exactly the displayed pair C_0, C_1. □

Theorem 716.18 (BetaSubstitutionPreservation substitution non-escape)**.** *For an accepted* BetaSubstitutionPreser *carrier*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N),$$

the substituted body row R and substituted codomain row C_1 can be consumed only through the displayed body typing boundary B, argument typing boundary A, beta-redex route V, codomain boundary C_0, ledger L, transports H, routes K, provenance P, and local name N. The substitution read does not escape to host substitution semantics, semantic term equality, unrestricted conversion, or closed subject reduction.

Proof. Begin with redex closure from Definition 716.6. It states that any public read of the beta-redex preservation step reaches R and C_1 only through the displayed beta packet.

Apply the body and argument boundary theorem Definition 716.16. This fixes B and A as the only source typing premises available to the redex route.

Apply codomain readback from Definition 716.17. This fixes C_0 and C_1 as the displayed codomain pair, with no host-side replacement.

Finally use the original non-escape theorem Definition 716.7 and the subject-reduction handoff Definition 716.8. The handoff reads the same finite packet, while non-escape prevents substituted rows from becoming host substitution semantics, semantic equality, unrestricted conversion, or closed subject reduction. □

Theorem 716.19 (BetaSubstitutionPreservation sibling boundary lattice)**.** *For an accepted* BetaSubstitutionPreser *carrier*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N),$$

the concrete sibling boundaries of chapter 527, chapter 621, chapter 562, and chapter 718 are consumed only through the finite rows $B, A, V, C_0, R, C_1, L, H, K, P, N$*. The closed substitution and binder-context surfaces are read through* C_0, R, C_1 *and* P*, the typed endpoint surface is read through* R, C_1, L, H, K*, and the subject-reduction discharge surface is read only through the handoff row in* K *and the provenance row* P*.*

Proof. Project the provenance row P from the carrier of Definition 716.1. That row names the closed-term substitution boundary, binder-context substitution seal, typed reduction normal form, and subject-reduction endpoint as sibling surfaces, but it names them only inside the same finite packet Q.

Use redex closure from Definition 716.6. The substituted body row R and substituted codomain row C_1 are reached through $B, A, V, C_0, L, H, K, P, N$, so the closed-substitution and binder-context sibling reads cannot bypass the displayed beta-redex route.

Apply codomain readback from Definition 716.17 and substitution non-escape from Definition 716.18. These fix the C_0, R, C_1 lattice as packet data and prevent the sibling route from exporting host substitution semantics, semantic term equality, unrestricted conversion, or host codomain computation.

Finally use the subject-reduction handoff Definition 716.8. The discharge consumer receives the beta row through K and P as a finite handoff, while the other discharge rows remain outside this carrier. Thus the sibling route is substantive, but it exports no closed subject reduction. □

Theorem 716.20 (Beta substitution preservation obligation surface)**.** *Every accepted* BetaSubstitutionPreservation *packet exposes a finite obligation surface consisting of beta-redex replay, substituted body readback, codomain readback, binder-context transport, subject-reduction handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The surface exports no host substitution function, no quotient equality of terms, no unrestricted conversion, and no closed subject-reduction theorem.*

Proof. Read the carrier rows of Definition 716.1 in order. The body typing row B, argument typing row A, beta-redex row V, codomain boundary C_0, substituted body row R, and substituted codomain row C_1 supply the finite redex replay and readback data.

Next read the ledger and transport rows. The ledger L ties the displayed readbacks to one beta case, while H gives the componentwise hsame transport and K gives the displayed Cont replay routes, including the binder-context and subject-reduction handoff routes.

Finally read provenance and naming through P and N. These rows keep the packet inside the local $\mathsf{NameCert}_{\mathsf{BetaSubstitutionPreservation}^{\uparrow}}$ surface and record which sibling boundaries are consumed.

The exclusions are inspection of the same finite inventory. No coordinate of Q is a host substitution function, a quotient equality of terms, unrestricted conversion, or closed subject reduction, so no accepted read of the obligation surface can export one. □

Theorem 716.21 (Beta substitution preservation obligation rows)**.** *Every accepted* $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ *packet exposes, in order, the binder-context row, substituted body row, codomain readback row, subject-reduction handoff, closed-term substitution boundary, nonescape ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before any MetaCIC consumer may read beta preservation. The row order is part of the finite NameCert route: a consumer cannot read* $\mathsf{SubjectReduction}^{\uparrow}$ *through this packet before the* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$, $\mathsf{BinderContextSubstitutionSeal}^{\uparrow}$, *and* $\mathsf{TypedReductionNormalForm}^{\uparrow}$ *rows have been displayed inside the same carrier.*

Proof. Project the carrier of Definition 716.1. The rows C_0, R, C_1 give the binder-context boundary, substituted body readback, and codomain readback after the source rows B, A, V have fixed the beta site.

Next read the sibling boundaries. The $\mathsf{BinderContextSubstitutionSeal}^{\uparrow}$ row keeps the binder-context surface attached to C_0, the $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ row keeps the substituted body route attached to R, and the $\mathsf{TypedReductionNormalForm}^{\uparrow}$ row keeps the endpoint readback attached to C_1 and L.

The subject-reduction handoff is then available only through K and P. The existing handoff theorem Definition 716.8 presents the beta case to $\mathsf{SubjectReduction}^{\uparrow}$ as the same finite packet, while Definition 716.7 blocks host substitution semantics, unrestricted conversion, and closed subject reduction from replacing the displayed rows.

Finally transport, replay, provenance, and local naming are componentwise. The rows H, K, P, N carry the same ordered packet to the MetaCIC consumer, so any accepted read of beta preservation first passes through the listed obligation rows and never through an off-packet preservation theorem. □

Theorem 716.22 (BetaSubstitutionPreservation scoped discharge socket)**.** *The beta row handed to* $\mathsf{SubjectReductionDischarge}^{\uparrow}$ *by an accepted* $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ *packet is scoped exactly by the body typing row, argument row, beta-redex row, binder-context boundary, substituted body row, substituted codomain row, typed residual ledger, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows already named in*

$$Q = (B, A, V, C_0, R, C_1, L, H, K, P, N).$$

The discharge socket supplies only the beta row consumed by $\mathsf{SubjectReductionDischarge}^{\uparrow}$*; the application-argument, lambda-domain, and Pi-domain rows remain external, and no read escapes to host substitution semantics, unrestricted conversion, global confluence, or closed subject reduction.*

Proof. Apply Definition 716.8. It presents Q as the finite beta-substitution preservation packet handed to the subject-reduction interface, with the body typing, argument typing, beta-redex, substituted readbacks, ledger, transport, replay, provenance, and local naming rows all displayed.

Apply Definition 716.9. It identifies the downstream discharge surface and fixes this packet as exactly the beta row of $\mathsf{SubjectReductionDischarge}^{\uparrow}$, leaving the other three discharge rows outside the carrier.

Apply Definition 716.7. Since the carrier contains no host substitution semantics, unrestricted conversion, global confluence, or closed subject-reduction coordinate, the discharge socket is scoped precisely by the rows of Q and cannot export anything beyond them. □

Closure status for $\mathsf{NameCert}_{\mathsf{BetaSubstitutionPreservation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ packet is generated from body typing, argument typing, beta-redex, codomain readback, substituted body, substituted codomain, finite ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{BetaSubstitutionPreservation}\uparrow}$, publicClosed)

Scope closed: Definition 716.1, Definition 716.21, Definition 716.19, Definition 716.7, and Definition 716.22 expose the public beta-substitution packet exactly through the displayed body typing, argument, beta-redex, binder-context, substituted body and codomain, typed residual ledger, hsame, Cont, Pkg, and local NameCert rows of Q.

Formal verification: FormalStatus(NameCert$_{\mathsf{BetaSubstitutionPreservation}\uparrow}$, auditClean)

Lean target: `BEDC.Derived.BetaSubstitutionPreservationUp.BetaSubstitutionPreservationNonescape`

Bridge status: none

Origin: human

Not claimed: This chapter does not close host substitution semantics, semantic term equality, unrestricted conversion, the other three MetaCIC subject-reduction discharge obligations, global normalization, Lean verification, or closed subject reduction.

Upgrade path: The next paper-side step is a bridge theorem connecting this public packet to downstream MetaCIC substitution consumers.

Chapter 717

A Concrete Naming Certificate for $\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}$

The $\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}$ packet realizes the MetaCIC subject-reduction audit boundary as a finite NameCert object. It records the four discharge rows consumed by the parameterized subject-reduction theorem, the checked obstruction row for the unavailable closed statement, the transport and route rows that keep those entries readable, and the local naming row that downstream MetaCIC audits can cite.

The obstruction coordinate O is read through chapter 731, while the four discharge rows remain local ledger entries. The ledger therefore records a consumer route from the obstruction chapter rather than a proof of closed subject reduction.

Definition 717.1 (MetaCIC discharge-obligation ledger carrier)**.** *A* $\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D_\beta, D_{\mathsf{app}}, D_\lambda, D_\Pi, S, O, H, C, P, N)$$

with the following visible coordinates:

1. D_β *is the* BetaSubstitutionPreservation *discharge row for the beta-redex substitution boundary;*
2. D_{app} *is the* AppArgTypeStable *discharge row for application-argument codomain readback;*
3. D_λ *is the* LamDomainSubjectReduction *discharge row for lambda-domain reduction;*
4. D_Π *is the* PiDomainSubjectReduction *discharge row for Pi-domain reduction;*
5. S *is the parameterized* $\mathsf{BEDC.MetaCIC.subject_reduction}$ *row, read with exactly the four discharge rows above;*
6. O *is the checked obstruction row* $\mathsf{BEDC.MetaCIC.closed_consistency_reduction_obstruction_not_available}$*;*
7. H *records componentwise* hsame *transports for the four discharge rows, the parameterized subject-reduction row, the obstruction row, provenance, and local naming;*
8. C *records the displayed* Cont *routes by which consumers read the four obligations, the parameterized theorem row, the obstruction boundary, provenance, and local naming;*
9. P *is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *the MetaCIC discharge names, the parameterized subject-reduction row, and the obstruction row;*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}}$ *row.*

The carrier contains no proof of any discharge row, no closed subject-reduction theorem, no hidden axiom channel, no host equality principle, and no route that replaces the four-row interface by an unparameterized MetaCIC theorem.

Lean4 ✓ BEDC.Derived.MetaCICDischargeObligationLedgerUp.MetaCICDischargeObligationLedgerTasteGate single carrier alignment

Theorem 717.2 (MetaCIC discharge-obligation ledger NameCert obligations)**.** *For the carrier of Definition 717.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$L = (D_\beta, D_{\mathsf{app}}, D_\lambda, D_\Pi, S, O, H, C, P, N),$$

componentwise classifier comparison of the four discharge rows, exact readback of the parameterized BEDC.MetaCIC.subject_reduction *row through those four rows, exact readback of the checked obstruction row* O*, componentwise* hsame *transport through* H*, displayed* Cont *route replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from the displayed packet. The rows $D_\beta, D_{\mathsf{app}}, D_\lambda, D_\Pi$ are the complete discharge surface named by the MetaCIC subject-reduction audit map, while S and O record the parameterized theorem row and the checked obstruction row.

The classifier obligation compares only those displayed rows. A comparison may inspect the beta-substitution row, the application-argument row, the lambda-domain row, the Pi-domain row, the subject-reduction row, and the obstruction row, but it must do so through the transports and routes carried by H and C.

The route and provenance obligations are finite. The row P names the MetaCIC theorem rows and BEDC kernel objects used by the packet, and N records the local NameCert row. Since no further carrier coordinate is present, the listed obligations exhaust the local certificate. □

Theorem 717.3 (MetaCIC discharge-obligation ledger non-escape)**.** *Every consumer read of an accepted* $\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}$ *packet factors through*

$$D_\beta, D_{\mathsf{app}}, D_\lambda, D_\Pi, S, O, H, C, P, N.$$

It may inspect the four discharge rows, the parameterized subject-reduction row, the checked obstruction row, componentwise transports, displayed continuations, provenance, and the local NameCert *row. It cannot read a proof of the four discharge rows, a closed subject-reduction theorem, a hidden axiom channel, a host equality principle, or an unlisted MetaCIC theorem.*

Proof. Start with Definition 717.2. It identifies the accepted packet with the displayed finite rows and names those rows as the complete local NameCert inventory.

For the subject-reduction side, inspect $D_\beta, D_{\mathsf{app}}, D_\lambda, D_\Pi$ and S. The parameterized row S is readable only with the four displayed discharge rows; the packet has no coordinate that turns those rows into discharged proofs.

For the obstruction side, inspect O. It records the checked boundary for the closed consistency reduction obstruction and keeps the closed subject-reduction statement outside the carrier.

Finally inspect H, C, P, N. These are the only transport, continuation, provenance, and naming routes available to downstream consumers. Therefore no consumer can obtain a closed subject-reduction theorem, hidden axiom, host equality principle, or unlisted MetaCIC theorem from the ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}$ packet is generated from the four MetaCIC subject-reduction discharge rows, the parameterized subject-reduction row, the checked obstruction row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 717.1, Definition 717.2, and Definition 717.3 bind the finite MetaCIC discharge-obligation ledger and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligationLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close any of the four MetaCIC discharge hypotheses, closed subject reduction, full MetaCIC consistency, a bridge certificate, host equality, or any hidden axiom channel.

Upgrade path: Obligation closure requires checked carrier admission, classifier comparison, subject-reduction readback, obstruction readback, route locality, provenance, local naming, and non-escape for the same finite packet.

Chapter 718

A Concrete Naming Certificate for $\mathsf{SubjectReductionDischarge}^{\uparrow}$

The $\mathsf{SubjectReductionDischarge}^{\uparrow}$ packet names the finite BEDC surface for the four MetaCIC subject-reduction discharge obligations. It does not prove the obligations as substrate theorems. It records the exact carrier, compiler boundary, obstruction row, transport, routes, provenance, and local naming surface by which a future discharge can be audited without hiding the checked obstruction boundary.

Definition 718.1 (Subject-reduction discharge carrier)**.** *A* $\mathsf{SubjectReductionDischarge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, A, L, \Pi, S, K, O, H, C, P, N)$$

with the following displayed rows:

1. *B is the* BetaSubstitutionPreservation *obligation row;*
2. *A is the* AppArgTypeStable *obligation row;*
3. *L is the* LamDomainSubjectReduction *obligation row;*
4. *Π is the* PiDomainSubjectReduction *obligation row;*
5. *S records the closed-substitution and shift compiler boundary rows used by closed-term substitution consumers;*
6. *K records the closed-term compiler and generator-audit rows that keep substitution, shifting, and generator closure inside accepted MetaCIC kernel routes;*
7. *O records the checked obstruction boundary for replacing the four-row interface by an unparameterised closed subject-reduction theorem;*
8. *H records componentwise* hsame *transports for the four obligation rows, the compiler boundary rows, the obstruction row, provenance, and local naming;*
9. *C records the displayed* Cont *routes by which a consumer reads the four obligations, the compiler boundary, the obstruction row, package provenance, and the local certificate;*
10. *P is the* Pkg *provenance over MetaCIC subject reduction, closed substitution, closed-term compiler rows, generator-audit rows,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionDischarge}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unparameterised closed subject-reduction theorem, hidden substitution preservation, host CIC truth, evaluator soundness, quotient proof transport, or a host conversion rule outside the four displayed obligations.

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeUp.SubjectReductionDischargeTasteGate single carrier alignment`

Theorem 718.2 (Subject-reduction discharge obligations)**.** *For the carrier of Definition 718.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionDischarge}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$D = (B, A, L, \Pi, S, K, O, H, C, P, N),$$

four-row obligation exposure for BetaSubstitutionPreservation*,* AppArgTypeStable*,* LamDomainSubjectReduction *and* PiDomainSubjectReduction*, closed-substitution and compiler boundary exposure through* S *and* K*, obstruction exposure through* O*, componentwise* hsame *stability through* H*, displayed* Cont *locality through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from Definition 718.1. The four obligation rows B, A, L, Π are displayed before any subject-reduction consumer may read the packet.

The compiler-facing side is read through S and K. These rows reuse the closed-term substitution compiler boundary and generator-audit closure surface, so substitution and shifting are named as accepted finite routes rather than as ambient evaluator semantics.

The obstruction-facing side is read through O. It records that the closed subject-reduction theorem is not available as a replacement for the four-row interface.

Finally H, C, P, N transport, route, package, and name the same displayed rows. Since the carrier contains no further coordinate, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeUp.SubjectReductionDischargeCarrier namecert obligations`

Theorem 718.3 (Subject-reduction discharge socket dependency)**.** *Every accepted* $\mathsf{SubjectReductionDischarge}^{\uparrow}$ *packet*

$$D = (B, A, L, \Pi, S, K, O, H, C, P, N)$$

consumes the same four discharge rows as the finite socket surface of chapter 719. The compiler-boundary rows S, K *and obstruction row* O *are support and boundary data, not a fifth discharge premise and not a closed subject-reduction theorem.*

Proof. Project the carrier of Definition 718.1. Its only subject-reduction discharge coordinates are B, A, L, Π.

Compare those four coordinates with the socket carrier of Definition 719.1. The socket names the beta-substitution, application-argument, lambda-domain, and Pi-domain rows as its finite discharge surface, and its NameCert obligations are checked by the socket chapter.

Now use Definition 718.2. It identifies S, K as compiler-boundary support and O as the obstruction boundary, while H, C, P, N transport, route, package, and name the displayed rows.

Since neither carrier has a fifth discharge coordinate and the discharge packet has no coordinate for a closed subject-reduction theorem, every accepted read of D consumes the socket's four-row surface rather than escaping to an additional premise or closed theorem. □

Theorem 718.4 (Subject-reduction discharge boundary)**.** *Every accepted* $\mathsf{SubjectReductionDischarge}^{\uparrow}$ *packet preserves the obstruction boundary between the parameterised MetaCIC subject-reduction*

theorem and the unavailable closed subject-reduction statement. A consumer may read the four displayed obligation rows, the closed-substitution and compiler rows, the obstruction row, transports, routes, provenance, and local name; it may not replace those rows by a hidden closed subject-reduction theorem or a host substitution theorem.

Proof. Read the four obligation rows first. They are the only rows whose joint presence can feed the parameterised subject-reduction interface.

Next read S and K. The closed-substitution compiler and generator-audit surfaces explain how closed substitution, shift, and accepted generator closure are routed, but they do not supply open-term subject reduction or evaluator correctness.

Use the obstruction row O to keep the boundary explicit. The packet records that the unparameterised closed theorem is not part of the carrier, so a consumer cannot bypass the four-row interface. □

Theorem 718.5 (Subject-reduction discharge four-row completeness)**.** *The public four-row inventory of an accepted* $\mathsf{SubjectReductionDischarge}^{\uparrow}$ *packet is complete for the MetaCIC subject-reduction discharge boundary. The beta case reads B, application-argument congruence reads A, lambda-domain congruence reads L, and Pi-domain congruence reads Π; every compiler or obstruction read is support data through S, K, O, H, C, P, N rather than a fifth discharge obligation.*

Proof. Start with the parameterised subject-reduction interface. Its discharge surface consumes exactly the beta-substitution, application-argument stability, lambda-domain, and Pi-domain rows.

The support rows do not add another discharge class. Rows S and K constrain closed substitution and compiler replay, while O records the obstruction to replacing the interface by a closed theorem.

The transport and route rows H and C preserve access to the same four rows, and P, N package and name the packet. Hence the public discharge inventory is exactly four obligation rows plus support data. □

Theorem 718.6 (Subject-reduction discharge non-escape)**.** *Every downstream read of a* $\mathsf{SubjectReductionDischarge}$ *packet factors through*

$$B, A, L, \Pi, S, K, O, H, C, P, N.$$

It cannot inspect hidden proof production, an unrecorded substitution lemma, host evaluator soundness, quotient transport, proposition extensionality, a closed subject-reduction theorem outside the obstruction row, or a subject-reduction route not accounted for by the four displayed obligations.

Proof. Project the carrier. The only public subject-reduction rows are B, A, L, Π, and every compiler-facing or audit-facing support route is listed as S, K, O, H, C, P, N.

Apply the obligation theorem to bind local naming to those rows. The packet can expose carrier admission, obligation exposure, compiler boundary exposure, obstruction exposure, transport, route locality, provenance, and local naming only.

The excluded principles have no carrier coordinate. Therefore every downstream read factors through the displayed packet, and any attempted read outside it remains an obstruction-boundary request rather than an accepted subject-reduction discharge. □

Theorem 718.7 (Subject-reduction discharge TasteGate obligation closure)**.** *For the carrier*

$$D = (B, A, L, \Pi, S, K, O, H, C, P, N)$$

of Definition 718.1, the TasteGate single-carrier alignment and the local $\mathsf{NameCert}_{\mathsf{SubjectReductionDischarge}^{\uparrow}}$ *obligation surface jointly close carrier admission and four-row exposure for* B, A, L, Π*. This closure does not prove* BetaSubstitutionPreservation*,* AppArgTypeStable*,* LamDomainSubjectReduction*, or* PiDomainSubjectReduction *as MetaCIC substrate theorems.*

Proof. Read the carrier definition first. It makes D a finite packet whose only subject-reduction discharge rows are B, A, L, Π, with S, K, O, H, C, P, N serving as compiler-boundary, obstruction, transport, route, package, and naming data.

The checked TasteGate marker immediately after Definition 718.1 supplies the single-carrier alignment for this packet. It binds admission to the displayed tuple rather than to an ambient closed subject-reduction theorem.

Now apply Definition 718.2. Its NameCert surface exposes the four rows B, A, L, Π and the support rows of D exactly. The closure therefore concerns admission and exposure of the obligation rows, not discharge of the four MetaCIC hypotheses themselves. □

Theorem 718.8 (Subject-reduction discharge transport-route exactness)**.** *Every accepted transport or continuation read of the four* $\mathsf{SubjectReductionDischarge}^{\uparrow}$ *discharge rows factors through the displayed* H, C, P, N *coordinates of*

$$D = (B, A, L, \Pi, S, K, O, H, C, P, N).$$

Such a read cannot introduce a fifth discharge row or a subject-reduction route outside the four rows B, A, L, Π*.*

Proof. Start with the socket dependency of Definition 718.3. It identifies the shared discharge surface as the same four rows used by the finite socket chapter.

Use the four-row completeness theorem next. The beta, application-argument, lambda-domain, and Pi-domain rows are the complete discharge inventory; S, K, O are support and boundary coordinates.

Finally apply Definition 718.6. Every downstream read must pass through the displayed carrier coordinates, so transport reads pass through H, continuation reads pass through C, and package or local-name reads pass through P, N. Since the carrier has no fifth discharge coordinate, exactness is the four-row route through those displayed coordinates. □

Theorem 718.9 (Subject-reduction discharge obstruction preservation)**.** *In every downstream read of an accepted* $\mathsf{SubjectReductionDischarge}^{\uparrow}$ *packet, the obstruction row* O *remains a visible boundary. The compiler-boundary rows* S, K *support closed-substitution and generator replay, but they cannot be read as an unparameterised closed subject-reduction theorem.*

Proof. Apply the boundary theorem Definition 718.4. It separates the four parameterised discharge obligations from the unavailable closed subject-reduction statement and records O as the boundary row.

Read S and K through the same theorem and through Definition 718.2. These rows name closed-substitution, shift, compiler, and generator-audit support; they do not add an open-term subject-reduction proof or a host evaluator theorem.

The non-escape theorem then keeps every downstream consumer inside $B, A, L, \Pi, S, K, O, H, C, P, N$. Since no coordinate stores an unparameterised closed subject-reduction theorem, O remains visible whenever a consumer tries to replace the four-row interface by that closed statement. □

Theorem 718.10 (Subject-reduction discharge schema bridge)**.** *Every public read of an accepted four-row packet*

$$D = (B, A, L, \Pi, S, K, O, H, C, P, N)$$

bridges to the MetaCIC subject-reduction schema only through the displayed compiler-boundary rows S, K, obstruction row O, componentwise transport H, continuation route C, provenance row P, and local $\mathsf{NameCert}_{\mathsf{SubjectReductionDischarge}^{\uparrow}}$ *row N. The bridge exposes the public schema-facing route for B, A, L, Π and does not supply closed subject reduction.*

Proof. Apply Definition 718.2. It fixes the local certificate surface as carrier admission, four-row obligation exposure, compiler-boundary exposure, obstruction exposure, transport, route locality, provenance, and local naming.

Next apply Definition 718.5. The discharge inventory has exactly the four rows B, A, L, Π, while S, K, O, H, C, P, N are support and boundary data rather than additional discharge premises.

Use Definition 718.8 to force every transport or continuation read through the displayed H, C, P, N coordinates. Then use Definition 718.9 to keep O visible whenever a consumer tries to replace the schema-facing route by closed subject reduction.

Thus the public bridge is precisely the displayed route from the four-row packet to the MetaCIC subject-reduction schema, with no coordinate that can be read as an unparameterised closed theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionDischarge}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionDischarge}^{\uparrow}$ packet is generated from the four MetaCIC subject-reduction discharge obligation rows, closed-substitution and compiler boundary rows, the checked obstruction row, displayed hsame transports, finite Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SubjectReductionDischarge}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 718.1, Definition 718.2, Definition 718.5, Definition 718.8, Definition 718.9, and Definition 718.10 expose the public four-row discharge packet and bridge it to the cited MetaCIC subject-reduction schema target without adding a closed subject-reduction theorem.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SubjectReductionDischarge}^{\uparrow}}$, axiomClean)

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not prove BetaSubstitutionPreservation, AppArgTypeStable, LamDomainSubjectReduction, PiDomainSubjectReduction, unparameterised closed subject reduction, evaluator soundness, or bridge checking.

Upgrade path: No further paper-side theory-axis upgrade is claimed beyond preserving the four-row MetaCIC subject-reduction boundary.

Chapter 719

A Concrete Naming Certificate for $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$

The $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ packet turns the MetaCIC subject-reduction boundary into a finite NameCert socket. It names the four discharge rows consumed by the parameterised theorem, the parameterised theorem row itself, and the checked closed-obstruction row, so downstream compiler chapters can read the boundary as finite BEDC data rather than as an ambient closed subject-reduction claim.

The closed-obstruction row in Q is the finite obstruction boundary of chapter 731, and the route-classifier consumer of the socket is chapter 785. These siblings consume the socket as a four-row discharge surface, not as a closed subject-reduction proof.

Definition 719.1 (SubjectReductionDischargeSocket carrier)**.** *A* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (B, A, L, P, H, C, Q, N)$$

with the following displayed rows:

1. *B is the beta-substitution preservation row, matching the* BetaSubstitutionPreservation *input of the MetaCIC subject-reduction theorem;*
2. *A is the application-argument stability row, matching the* AppArgTypeStable *input;*
3. *L is the lambda-domain subject-reduction row, matching the* LamDomainSubjectReduction *input;*
4. *P is the Pi-domain subject-reduction row, matching the* PiDomainSubjectReduction *input;*
5. *H records componentwise* hsame *transports for the four discharge rows, the parameterised subject-reduction row, the closed-obstruction row, provenance, and the local naming row;*
6. *C records the displayed* Cont *routes by which consumers read beta, application-argument, lambda-domain, Pi-domain, parameterised subject-reduction, obstruction, provenance, and naming coordinates;*
7. *Q is the provenance and classifier ledger over* BHist, Ext, Cont, $\mathsf{SubjectReduction}^{\uparrow}$, *MetaCIC typed reduction, componentwise* hsame, Pkg, *and* $\mathsf{NameCert}$ *rows, including the parameterised subject-reduction row and the closed obstruction row;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeSocket}^{\uparrow}}$ *row.*

The carrier contains no closed subject-reduction theorem, no host conversion rule, no erased derivation semantics, no quotient equality of MetaCIC terms, and no hidden reduction principle outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeSocketUp.SubjectReductionDischargeSocketTasteGate single carrier alignment`

Theorem 719.2 (SubjectReductionDischargeSocket NameCert obligations)**.** *For the carrier of Definition 719.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeSocket}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$O = (B, A, L, P, H, C, Q, N),$$

the beta-substitution row B, the application-argument row A, the lambda-domain row L, the Pi-domain row P, componentwise transport through H, displayed continuation reads through C, provenance and classifier ledgering through Q, and local naming through N. The ledger Q records the parameterised $\mathsf{SubjectReduction}^{\uparrow}$ *row as consuming precisely B, A, L, P, and records the checked closed-obstruction row as excluding any unparameterised closed subject-reduction export.*

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeSocketUp.SubjectReductionDischargeSocketCarrier namecert obligations`

Proof. Project the displayed packet O. The four discharge rows B, A, L, P are the only rows that can feed the parameterised $\mathsf{SubjectReduction}^{\uparrow}$ theorem.

Read H and C next. They provide the componentwise sameness transport and the continuation routes by which the four rows, the parameterised subject-reduction row, and the obstruction row may be replayed.

Finally inspect Q and N. The provenance ledger records that parameterised subject reduction consumes the four named discharge rows, while the obstruction row prevents the packet from exporting a closed subject-reduction theorem. Since no other coordinate exists in O, the listed rows exhaust the local NameCert surface. □

Theorem 719.3 (SubjectReductionDischargeSocket non-escape)**.** *Every consumer read of an accepted* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *carrier factors through*

$$B, A, L, P, H, C, Q, N.$$

The consumer may inspect the four discharge rows, their componentwise hsame *transports, the displayed* Cont *routes, the provenance and classifier ledger, and the local* NameCert *row. It cannot read a closed subject-reduction theorem, host conversion, erased derivation semantics, quotient equality of MetaCIC terms, a semantic reduction interpreter, or an unrecorded MetaCIC premise.*

Proof. Apply the NameCert-obligation theorem to identify the accepted carrier with the finite rows B, A, L, P, H, C, Q, N.

For a permitted subject-reduction read, the consumer first reads one of the four discharge coordinates and then follows the corresponding transport and route in H and C. The ledger Q records how the parameterised subject-reduction row consumes those four inputs.

For a closed subject-reduction request, the same ledger exposes the obstruction row. That row is a boundary coordinate rather than a replacement proof, so the consumer receives the finite obstruction record and no unparameterised closed theorem.

The packet has no coordinate for host conversion, erased derivation semantics, quotient equality, semantic reduction interpretation, or hidden MetaCIC premises. Those requests therefore have no route through the accepted socket. □

Lean4 ✓ BEDC.Derived.SubjectReductionDischargeSocketUp.SubjectReductionDischargeSocketPacket nonescape

Theorem 719.4 (SubjectReductionDischargeSocket obligation consumption)**.** *Let $O = (B, A, L, P, H, C, Q, N)$ be an accepted* SubjectReductionDischargeSocket$^{\uparrow}$ *carrier. Any downstream certificate that consumes MetaCIC subject-reduction data from O consumes exactly the beta-substitution, application-argument, lambda-domain, and Pi-domain rows displayed by B, A, L, P, transported by H, replayed through C, and accounted for by Q, N. The closed-obstruction row in Q can only be read as a boundary for the absent closed theorem, not as a substitute proof of closed subject reduction.*

Proof. Start with the carrier projection. The public discharge inputs are exactly B, A, L, P.

The transport and route rows H, C preserve those inputs as the rows named by the carrier; they do not add another MetaCIC premise. The provenance and classifier ledger Q then records the parameterised subject-reduction row as the only row that consumes the four inputs.

For the obstruction coordinate, read Q in the opposite direction: it reports that the closed subject-reduction statement is blocked at this socket boundary. Hence downstream consumers can cite the finite socket as an obligation surface, but cannot turn it into a closed subject-reduction theorem. □

Lean4 ✓ BEDC.Derived.SubjectReductionDischargeSocketUp.SubjectReductionDischargeSocketPacket obligation consumption

Theorem 719.5 (SubjectReductionDischargeSocket row exhaustion)**.** *Let $O = (B, A, L, P, H, C, Q, N)$ be an accepted* SubjectReductionDischargeSocket$^{\uparrow}$ *carrier. Every admissible subject-reduction socket read is one of the four discharge rows B, A, L, P, the parameterised* SubjectReduction$^{\uparrow}$ *row recorded by Q, the closed-obstruction row recorded by Q, or the local* NameCert *provenance carried by H, C, Q, N.*

Proof. Project the finite carrier O. The displayed coordinates expose exactly the four discharge rows B, A, L, P and the structural rows H, C, Q, N.

Read the ledger Q. It contains the parameterised subject-reduction consumer row and the closed-obstruction boundary row. These are ledger entries over the displayed discharge rows, not extra carrier coordinates.

The remaining admissible reads are local provenance reads through H, C, Q, N. Since the carrier has no further slot, every socket read belongs to one of the listed classes. □

Lean4 ✓ BEDC.Derived.SubjectReductionDischargeSocketUp.SubjectReductionDischargeSocketPacket row exhaustion

Theorem 719.6 (SubjectReductionDischargeSocket transport stability)**.** *Let $O = (B, A, L, P, H, C, Q, N)$ and $O' = (B', A', L', P', H', C', Q', N')$ be accepted* SubjectReductionDischargeSocket$^{\uparrow}$ *carriers. If the rows are matched componentwise by the displayed* hsame *data in H, H' and the subject-reduction reads follow the displayed* Cont *routes in C, C', then O and O' expose the same row inventory: the four discharge rows, the parameterised row, the obstruction row, and the local NameCert provenance rows.*

Proof. Use the componentwise hsame rows first. They identify B, A, L, P with B', A', L', P' as the same four discharge coordinates inside the socket classifier.

Next follow the displayed Cont routes. They replay the same parameterised subject-reduction and obstruction reads through Q, N and through Q', N'.

Transport does not add a coordinate to either carrier. Therefore the row inventory exposed by the two accepted sockets is stable under the displayed hsame and Cont data. □

Lean4 ✓ BEDC.Derived.SubjectReductionDischargeSocketUp.SubjectReductionDischargeSocketPacket transport stability

Theorem 719.7 (SubjectReductionDischargeSocket transport route stability)**.** *Let* $O = (B, A, L, P, H, C, Q, N)$ *and* $O' = (B', A', L', P', H', C', Q', N')$ *be accepted* SubjectReductionDischargeSocket$^{\uparrow}$ *carriers. If every coordinate* B, A, L, P, H, C, Q, N *is matched with its primed coordinate by the displayed componentwise* hsame *data and every consumer read is replayed through the displayed* Cont *routes, then the two sockets expose the same beta-substitution, application-argument, lambda-domain, Pi-domain, transport, route, provenance-ledger, and local naming obligations.*

Proof. Project both accepted carriers. The only coordinates of the first socket are B, A, L, P, H, C, Q, N, and the only coordinates of the second socket are $B', A', L', P', H', C', Q', N'$.

Use the componentwise hsame data to match the four discharge rows and the structural rows. The match preserves their classifier positions: beta remains beta, application remains application, lambda remains lambda, Pi remains Pi, transport remains transport, route remains route, ledger remains ledger, and name remains name.

Now replay consumer reads through C and C'. Continuation data can move along the displayed route, but it returns to the matched coordinate class rather than creating an extra socket row.

Thus transport and route replay preserve the complete obligation inventory of the accepted socket. □

Lean4 ✓ BEDC.Derived.SubjectReductionDischargeSocketUp.SubjectReductionDischargeSocketPacket transport route stability

Theorem 719.8 (SubjectReductionDischargeSocket four-row ledger exactness)**.** *Let* $O = (B, A, L, P, H, C, Q, N)$ *be an accepted* SubjectReductionDischargeSocket$^{\uparrow}$ *carrier. The subject-reduction discharge ledger in* Q, N *consumes exactly the beta-substitution row* B*, the application-argument row* A*, the lambda-domain row* L*, and the Pi-domain row* P*. No consumer route through* Q, N *may replace one of these four rows, add a fifth discharge row, or treat the closed-obstruction boundary as one of the four discharge inputs.*

Proof. Read the carrier inventory. The only discharge coordinates are B, A, L, P, and the remaining coordinates H, C, Q, N are transport, route, provenance, and naming rows.

Inspect the ledger part of Q, N. It records the parameterised subject-reduction row as a consumer of the four named discharge inputs, so each permitted discharge read must point back to one of B, A, L, P.

The obstruction entry in Q has a different classifier role. It records the absent closed theorem boundary and therefore cannot be counted as beta, application, lambda, or Pi discharge evidence.

Since the packet contains no fifth discharge coordinate and no replacement coordinate for any of the four rows, the four-row consumption ledger is exact. □

Lean4 ✓ BEDC.Derived.SubjectReductionDischargeSocketUp.SubjectReductionDischargeSocketPacket four row ledger exactness

Theorem 719.9 (SubjectReductionDischargeSocket obligation closure package)**.** *The* SubjectReductionDischargeSo *chapter supplies an obligation-closed paper package for the finite socket carrier. The package consists of carrier admission, the local NameCert obligations, non-escape, obligation consumption, vision handoff, transport route stability, and four-row ledger exactness for*

$$O = (B, A, L, P, H, C, Q, N).$$

It exposes the socket as the finite subject-reduction discharge boundary and does not claim Lean verification, closed subject reduction, host conversion, erased derivation semantics, quotient equality, or bridge checking.

Proof. Carrier admission is Definition 719.1. The local NameCert surface is Definition 719.2, and non-escape is Definition 719.3.

For downstream consumption, use Definition 719.4. It identifies the subject-reduction route as a consumer of the displayed four discharge rows and keeps the obstruction row as a boundary.

For the methodology handoff, use Definition 719.11. It records why the socket is a finite BEDC packet rather than an unparameterised preservation theorem.

Finally apply transport route stability and four-row ledger exactness. These two clauses show that the same obligation inventory is preserved under displayed hsame and Cont data, and that Q, N consume exactly B, A, L, P.

The excluded structures are absent from the carrier and are already ruled out by the non-escape theorem. The displayed clauses therefore assemble the obligation-closed paper package without changing the verification axis. □

Theorem 719.10 (SubjectReductionDischargeSocket downstream consumer boundary)**.** *Every route-equivalence or route-classifier chapter that consumes an accepted* SubjectReductionDischargeSocket$^{\uparrow}$ *carrier*

$$O = (B, A, L, P, H, C, Q, N)$$

can consume the socket only through the four discharge rows, the parameterised subject-reduction row, the obstruction row, and the local NameCert provenance rows. Such a consumer cannot manufacture a closed subject-reduction theorem, a host conversion route, an erased derivation semantics, or quotient equality of MetaCIC terms.

Proof. Begin with row exhaustion. Any admissible read from the socket is one of the listed discharge, parameterised, obstruction, or provenance rows.

Then apply transport stability. Route-equivalence and route-classifier consumers may move the same rows along displayed hsame and Cont routes, but those routes preserve the inventory rather than creating a new theorem coordinate.

The excluded closed subject-reduction, host conversion, erased semantics, and quotient-equality objects are absent from the carrier. Hence downstream consumers can cite the socket as a finite boundary and cannot turn it into a closed subject-reduction result. □

Theorem 719.11 (SubjectReductionDischargeSocket vision handoff)**.** *The MetaCIC subject-reduction obstruction vision is realized by the finite* SubjectReductionDischargeSocket$^{\uparrow}$ *packet of Definition 719.1. Its concrete handoff consists of the four discharge rows B, A, L, P, the parameterised* SubjectReduction$^{\uparrow}$ *consumption ledger, the checked closed-obstruction boundary, componentwise* hsame *transport, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *naming. No downstream chapter may cite this handoff as a closed subject-reduction theorem.*

Proof. The critical path in the vision names four discharge obligations and a checked obstruction to the closed statement. The carrier records those same four rows as B, A, L, P and places the obstruction in the ledger row Q.

The NameCert-obligation theorem supplies the finite carrier, classifier, route, provenance, and naming surface. The non-escape theorem then rules out the closed theorem and the host semantic routes.

Thus the vision is handed to downstream chapters as a finite socket: it is a concrete obligation surface for parameterised subject reduction, together with a checked boundary against closed subject-reduction export. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeSocket}\uparrow}$.

Constructive story: A $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ packet is generated from beta-substitution, application-argument, lambda-domain, and Pi-domain discharge rows, a parameterised subject-reduction consumption ledger, a checked closed-obstruction boundary, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeSocket}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: Definition 719.1, Definition 719.2, Definition 719.3, Definition 719.4, Definition 719.5, Definition 719.6, Definition 719.7, Definition 719.8, Definition 719.9, Definition 719.10, and Definition 719.11 bind the finite MetaCIC subject-reduction discharge socket and its obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeSocket}\uparrow}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.SubjectReductionDischargeSocketUp.SubjectReductionDischargeSocketPacket\_nonescape`

Bridge status: none

Origin: human

Not claimed: This chapter does not close any of the four MetaCIC discharge obligations, the closed subject-reduction theorem, Lean verification of the socket, host conversion, erased derivation semantics, quotient equality, or bridge checking.

Upgrade path: No paper-side theory upgrade remains; only later bridge checking can advance the verification and bridge axes.

Chapter 720

A Concrete Naming Certificate for $\mathsf{SubjectReductionDischargeLedger}^{\uparrow}$

The $\mathsf{SubjectReductionDischargeLedger}^{\uparrow}$ packet realizes the audit map of chapter 9377 as a finite carrier for the four preservation obligations consumed by the $\mathsf{SubjectReduction}^{\uparrow}$ route of chapter 483. It records the obligation rows, transport rows, continuation routes, package provenance, and local naming row as a concrete BEDC object, while keeping closed subject reduction outside the exported surface.

Definition 720.1 (SubjectReductionDischargeLedger carrier)**.** *A* $\mathsf{SubjectReductionDischargeLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, A, LD, PD, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the beta-substitution preservation row, matching* BetaSubstitutionPreservation*;*
2. *A is the application-argument stability row, matching* AppArgTypeStable*;*
3. *LD is the lambda-domain subject-reduction row, matching* LamDomainSubjectReduction*;*
4. *PD is the Pi-domain subject-reduction row, matching* PiDomainSubjectReduction*;*
5. *R records the* $\mathsf{SubjectReduction}^{\uparrow}$ *route that consumes exactly B, A, LD, PD;*
6. *H records componentwise* hsame *transports for the four obligation rows, the route row, provenance, and local naming;*
7. *C records the displayed* Cont *replays by which consumers read the four obligations and the* $\mathsf{SubjectReduction}^{\uparrow}$ *route;*
8. *P is the* Pkg *provenance over MetaCIC subject reduction,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeLedger}^{\uparrow}}$ *row.*

The carrier contains no unparameterised closed subject-reduction theorem, no host conversion principle, no hidden substitution theorem, no erased derivation semantics, and no quotient equality of MetaCIC terms.

Lean4 (definition) `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerCarrier`

Theorem 720.2 (SubjectReductionDischargeLedger obligations)**.** *For the carrier of Definition 720.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$L = (B, A, LD, PD, R, H, C, P, N),$$

four-row obligation exposure for BetaSubstitutionPreservation*,* AppArgTypeStable*,* LamDomainSubjectReduction *and* PiDomainSubjectReduction*, the* $\mathsf{SubjectReduction}^{\uparrow}$ *route row* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerNameCertObligatio`

Proof. Project the displayed carrier L. The four obligation rows B, A, LD, PD are the only rows that can feed the subject-reduction route.

Read the structural rows next. The transport row H keeps the four obligations, the route row, provenance, and local name componentwise stable, while the continuation row C records the finite replay routes used by downstream consumers.

Finally inspect P and N. The package row records provenance for the same displayed rows, and the local certificate names no further coordinate. Hence the listed rows exhaust the local NameCert surface. □

Theorem 720.3 (SubjectReductionDischargeLedger SubjectReduction handoff)**.** *Every accepted* $\mathsf{SubjectReductionDischargeLedger}^{\uparrow}$ *carrier hands its MetaCIC preservation data to* $\mathsf{SubjectReduction}^{\uparrow}$ *only through the route row* R *and the four obligation rows* B, A, LD, PD*. The handoff may be transported by* H*, replayed through* C*, and accounted for by* P, N*, but it does not supply a closed subject-reduction theorem or an unrecorded fifth preservation premise.*

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerSubjectReductionP`

Proof. Begin with Definition 720.2. It identifies the accepted carrier with the four obligation rows, the subject-reduction route row, and the structural rows.

The route row R is displayed as the only $\mathsf{SubjectReduction}^{\uparrow}$ consumer coordinate. Since R consumes exactly B, A, LD, PD, any accepted handoff to chapter 483 passes through those four rows.

The remaining rows H, C, P, N transport, replay, package, and name the same handoff. They do not add another preservation obligation, so the ledger has no route for a fifth premise or a closed theorem. □

Theorem 720.4 (SubjectReductionDischargeLedger non-escape)**.** *Every downstream read of an accepted* $\mathsf{SubjectReductionDischargeLedger}^{\uparrow}$ *carrier factors through*

$$B, A, LD, PD, R, H, C, P, N.$$

In particular, the finite ledger cannot be read as an unparameterised closed subject-reduction theorem, host conversion rule, hidden substitution preservation theorem, erased derivation semantics, quotient equality, or semantic MetaCIC interpreter.

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerNonescape`

Proof. Project the carrier and apply the obligation theorem. The only public preservation rows are B, A, LD, PD, and the only public subject-reduction consumer row is R.

The transport, continuation, package, and naming rows preserve access to the displayed packet but do not create new coordinates. Therefore a consumer can read the ledger only through $B, A, LD, PD, R, H, C, P, N$.

The excluded closed or host-side principles have no row in the packet. A request for one of them therefore remains outside the accepted carrier rather than becoming a hidden route through the ledger. □

Theorem 720.5 (SubjectReductionDischargeLedger TasteGate boundary)**.** *A future TasteGate surface for* SubjectReductionDischargeLedger$^{\uparrow}$ *must expose the carrier only through the single field projection*

$$L = (B, A, LD, PD, R, H, C, P, N).$$

The projection admits the beta-substitution, application-argument, lambda-domain, Pi-domain, route, transport, continuation, provenance, and local naming rows as one displayed ledger packet; it does not expose a closed subject-reduction theorem, host conversion row, hidden substitution theorem, or erased derivation semantics.

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerTasteGate single carrier alignment`

Proof. Use the carrier definition and the non-escape theorem. They identify the ledger with the displayed tuple and exclude every closed or host-side principle from the accepted packet.

The TasteGate-facing projection can therefore read the ledger only as L. Splitting the read into an unrecorded preservation theorem or adding a host conversion coordinate would require a field outside $B, A, LD, PD, R, H, C, P, N$, which the carrier does not contain. □

Theorem 720.6 (SubjectReductionDischargeLedger field-faithful surface)**.** *The field-faithful row for a future* SubjectReductionDischargeLedger$^{\uparrow}$ *TasteGate must separate the displayed fields* B, A, LD, PD, R, H, C, P *A consumer that preserves the ledger must preserve beta-substitution exposure, application-argument stability, lambda-domain subject-reduction exposure, Pi-domain subject-reduction exposure, the* SubjectReduction$^{\uparrow}$ *route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming as distinct public rows.*

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerFieldFaithfulSurf`

Proof. Project L and apply the obligation theorem. Each displayed coordinate has a different ledger role: four rows expose preservation obligations, one row is the route consumer, and four rows provide transport, replay, provenance, and naming.

Field faithfulness is the requirement that these roles are not identified by a TasteGate read. If two of the rows were collapsed, the handoff theorem could no longer state that SubjectReduction$^{\uparrow}$ consumes exactly B, A, LD, PD through R while H, C, P, N remain structural rows. □

Theorem 720.7 (SubjectReductionDischargeLedger nontrivial witness surface)**.** *The nontriviality row for a future* SubjectReductionDischargeLedger$^{\uparrow}$ *TasteGate must distinguish at least two displayed ledger packets. One packet may vary the route row R while preserving B, A, LD, PD, H, C, P, N; another may vary a structural row such as C while preserving the four preservation obligations and route row. A TasteGate that identifies all such packets cannot witness the displayed ledger surface.*

Proof. The carrier has separate coordinates for obligation data, route data, and structural replay data. Varying R changes the $\mathsf{SubjectReduction}^{\uparrow}$ handoff while leaving the four preservation rows fixed.

Varying C changes the displayed replay route while leaving the preservation obligations and route row fixed. These two changes affect different public coordinates of L.

The nontrivial witness row records that the ledger surface can observe those coordinate differences. A collapsed TasteGate would erase the distinction between obligation, route, and replay fields, contradicting the field-faithful surface. □

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerNontrivialWitness`

Theorem 720.8 (SubjectReductionDischargeLedger carrier exposure)**.** *Every accepted* SubjectReductionDischargeL *carrier exposes exactly the finite rows*

$$B, A, LD, PD, R, H, C, P, N.$$

The public ledger surface consists of the four preservation rows, the $\mathsf{SubjectReduction}^{\uparrow}$ *route, componentwise transport, displayed continuation replay, package provenance, and local naming; it contains no additional MetaCIC preservation coordinate.*

Proof. Begin with the carrier definition Definition 720.1. It lists $B, A, LD, PD, R, H, C, P, N$ as the full finite packet.

Apply the obligation theorem Definition 720.2. Its carrier-admission and four-row exposure clauses identify the public preservation surface with B, A, LD, PD and the subject-reduction route with R.

The handoff theorem Definition 720.3 and non-escape theorem Definition 720.4 leave only H, C, P, N as structural replay, provenance, and naming rows. Hence the accepted carrier exposes exactly the displayed ledger rows. □

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerCarrierExposure`

Theorem 720.9 (SubjectReductionDischargeLedger conditional normalization)**.** *Any downstream normalization or subject-reduction consumer of an accepted* $\mathsf{SubjectReductionDischargeLedger}^{\uparrow}$ *carrier must read the four displayed obligation rows* B, A, LD, PD *before using the route row* R*. The route may replay through* H, C, P, N*, but it cannot infer closed subject reduction, host conversion, hidden substitution preservation, erased derivation semantics, quotient equality, or any preservation premise outside the displayed ledger.*

Proof. Apply Definition 720.2. It exposes the carrier as the four obligation rows B, A, LD, PD, the $\mathsf{SubjectReduction}^{\uparrow}$ route row R, and the structural rows H, C, P, N.

Use Definition 720.3. The handoff to $\mathsf{SubjectReduction}^{\uparrow}$ consumes exactly B, A, LD, PD through R, so a downstream normalization or subject-reduction read cannot begin from the route row alone.

Finally apply Definition 720.8. Since the accepted carrier exposes no row beyond $B, A, LD, PD, R, H, C, P, N$, replay through H, C, P, N preserves the same conditional route and cannot create closed subject reduction, host conversion, hidden substitution preservation, erased derivation semantics, quotient equality, or an off-ledger premise. □

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerConditionalNormal`

Theorem 720.10 (SubjectReductionDischargeLedger transport replay)**.** *For every accepted* SubjectReductionDisch *carrier, the transport row H and continuation row C transport and replay only the four preservation rows B, A, LD, PD and the* SubjectReduction$^{\uparrow}$ *route row R, together with the provenance and local naming rows needed to authenticate that finite route.*

Proof. Project the carrier using Definition 720.1. The transport coordinate H is declared componentwise over the four obligation rows, the route row, provenance, and local naming.

Use Definition 720.2 to read the continuation coordinate C. It replays the displayed obligations and the SubjectReduction$^{\uparrow}$ route, with no fifth preservation row and no closed subject-reduction row.

Finally apply Definition 720.3 and Definition 720.4. They force every replay to remain inside $B, A, LD, PD, R, H, C, P, N$, so H and C cannot transport or replay an off-ledger preservation premise. □

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerTransportReplay`

Theorem 720.11 (SubjectReductionDischargeLedger provenance exactness)**.** *For an accepted* SubjectReductionDischargeLedger$^{\uparrow}$ *carrier, the rows P and N account exactly for the finite MetaCIC,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance of B, A, LD, PD, R, H, C. They do not add closed subject reduction, host conversion, hidden substitution preservation, erased derivation semantics, or quotient equality of MetaCIC terms.*

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerProvenanceExactne`

Proof. Read P and N from the carrier definition. The package row names the finite provenance dependencies, and the local naming row names the same displayed ledger.

Apply Definition 720.2. The obligation surface already accounts for the four preservation rows, route row, transport row, continuation row, package row, and name row.

Use the handoff theorem and non-escape theorem to close the provenance boundary. Since all downstream reads factor through the same displayed packet, P and N authenticate the finite ledger without creating a closed subject-reduction theorem or any excluded host-side principle. □

Theorem 720.12 (SubjectReductionDischargeLedger route exhaustion)**.** *Every accepted* SubjectReductionDischarg *carrier whose public rows are*

$$B, A, LD, PD, R, H, C, P, N$$

routes SubjectReduction$^{\uparrow}$ *consumption only through the four obligation rows B, A, LD, PD and the route row R. The rows H, C, P, N may transport, replay, authenticate, and name the same finite route, but they cannot create closed subject reduction, host conversion, hidden substitution preservation, erased derivation semantics, quotient equality, or a fifth preservation premise.*

Lean4 ✓ `BEDC.Derived.SubjectReductionDischargeLedgerUp.SubjectReductionDischargeLedgerRouteExhaustion`

Proof. Project the displayed tuple from Definition 720.1. Its only preservation coordinates are B, A, LD, PD, and its only SubjectReduction$^{\uparrow}$ consumer coordinate is R.

Apply Definition 720.2 and Definition 720.3. These identify R as the row that consumes exactly the four obligation rows and account for the handoff through the local certificate surface.

It remains to exhaust the structural rows. The non-escape theorem Definition 720.4 confines every downstream read to the displayed packet, while Definition 720.11 makes P and N exact provenance and naming rows for that same packet.

Thus H, C, P, N can only transport, replay, authenticate, and name the finite route already determined by B, A, LD, PD, R. None of those rows supplies an additional preservation premise or any of the excluded closed or host-side principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionDischargeLedger}^{\uparrow}$ packet is generated from beta-substitution, application-argument, lambda-domain, and Pi-domain obligation rows, a $\mathsf{SubjectReduction}^{\uparrow}$ route row, componentwise hsame transports, displayed Cont replays, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeLedger}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 720.1, Definition 720.2, Definition 720.3, Definition 720.4, Definition 720.5, Definition 720.6, Definition 720.7, Definition 720.8, Definition 720.9, Definition 720.10, Definition 720.11, and Definition 720.12 bind the exact rows $B, A, LD, PD, R, H, C, P, N$ and their kernel scope over BHist, hsame, Cont, Pkg, NameCert, $\mathsf{SubjectReduction}^{\uparrow}$, and the four MetaCIC preservation obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeLedger}^{\uparrow}}, \mathsf{unformalized})$

Ledger evidence: BEDC.Meta.DiscoveryDeltaLedger.subjectReductionDischargeLedgerDeltaLedger

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove BetaSubstitutionPreservation, AppArgTypeStable, LamDomainSubjectReduction, PiDomainSubjectReduction, closed subject reduction, host conversion, Lean verification, or bridge checking.

Upgrade path: Bridge packaging requires carrying the same $B, A, LD, PD, R, H, C, P, N$ public ledger through a checked bridge without adding closed subject reduction, host conversion, hidden substitution preservation, erased derivation semantics, or quotient equality.

Chapter 721

MetaCIC Subject-Reduction Boundary NameCert Construction

The MetaCICSubjectReductionBoundaryUp packet realizes the MetaCIC subject-reduction obstruction as a finite naming boundary. It packages the four discharge obligations, the parameterized preservation theorem, the checked obstruction row, audit-visible non-escape ledgers, transport data, continuation routes, package provenance, and the local NameCert row. The packet is not a proof of closed subject reduction; it is the certificate surface that prevents the obstruction from being replaced by an unrecorded theorem.

This boundary packet refines the sibling obstruction packet of chapter 731 by separating the four discharge rows, the parameterized theorem row, and the checked obstruction row into a carrier whose consumer routes cannot erase the hypotheses.

Definition 721.1 (MetaCIC subject-reduction boundary carrier)**.** *A* MetaCICSubjectReductionBoundaryUp *carrier is a finite* BHist *packet*

$$M = (B, A, L, P_i, R, O, Q, H, C, K, N)$$

with the following visible rows:

1. *B records the* BetaSubstitutionPreservation *discharge obligation;*
2. *A records the* AppArgTypeStable *discharge obligation;*
3. *L records the* LamDomainSubjectReduction *discharge obligation;*
4. *P_i records the* PiDomainSubjectReduction *discharge obligation;*
5. *R records the parameterized* subject_reduction *theorem whose hypotheses are exactly the four obligation rows;*
6. *O records the checked obstruction row* closed_consistency_reduction_obstruction_not_available*;*
7. *Q is the audit ledger saying which of the four obligations has been displayed before any preservation read is consumed;*
8. *H stores componentwise* hsame *transports for the four obligation rows, the parameterized theorem row, the obstruction row, the audit ledger, the package row, and the local naming row;*
9. *C stores the displayed* Cont *routes by which consumers read the obligation rows, the parameterized theorem row, and the obstruction row;*

10. *K is the* Pkg *provenance over the MetaCIC typing interface, beta-step constructors,* BHist, hsame, Cont, Pkg, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionBoundaryUp}}$ *row.*

The carrier contains no unparameterized closed subject-reduction theorem, no hidden substitution lemma, no ambient conversion theorem, and no semantic equality model for MetaCIC terms.

Lean4 ✓ `BEDC.Derived.MetaCICSubjectReductionBoundaryUp.MetaCICSubjectReductionBoundaryTasteGate single carrier alignment`

Theorem 721.2 (MetaCIC subject-reduction boundary NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICSubjectRe}}$ *surface consists of five finite obligations:*

1. *carrier admission for the packet $M = (B, A, L, P_i, R, O, Q, H, C, K, N)$ of Definition 721.1;*
2. *obligation exposure, saying that the beta, application-argument, lambda-domain, and Pi-domain discharge rows are all displayed before R is consumed;*
3. *parameterized preservation exactness, saying that R may be read only as the theorem conditional on the four displayed obligation rows;*
4. *obstruction exactness, saying that O records the checked non-availability of the closed consistency reduction obstruction and is not a substitute for any of the four obligations;*
5. *audit non-escape from hidden substitution preservation, host conversion, erased typing derivations, semantic equality of terms, global normalization, or an unrecorded closed subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICSubjectReductionBoundaryUp.MetaCICSubjectReductionBoundaryCarrier obligation exposure certificate`
Lean4 ✓ `BEDC.Derived.MetaCICSubjectReductionBoundaryUp.MetaCICSubjectReductionBoundary namecert obligations`

Proof. Carrier admission is the finite packet of Definition 721.1. Its rows display the four named discharge obligations, the parameterized preservation theorem, the checked obstruction theorem, the audit ledger, transport data, continuation routes, package provenance, and local naming certificate.

Obligation exposure is recorded by the ledger Q. A consumer reaches R only after the rows B, A, L, P_i have been displayed, so the parameterized theorem cannot be read as a closed theorem with the hypotheses erased.

Obstruction exactness is the role of O. It records the checked obstruction row described in Definition 9377.5; the row blocks replacement of the four-input interface by a blanket closed subject-reduction statement.

The non-escape clause follows from absence of coordinates. Hidden substitution preservation, host conversion, erased typing derivations, semantic equality, global normalization, and unrecorded closed subject reduction are not rows of M and cannot be reconstructed by hsame transport or a Cont read. □

Lean4 ✓ `BEDC.Derived.MetaCICSubjectReductionBoundaryUp.MetaCICSubjectReductionBoundaryNamecertObligatio`

Theorem 721.3 (MetaCIC subject-reduction boundary obligation exposure)**.** *Every consumer of the parameterized preservation row R in an accepted* MetaCICSubjectReductionBoundaryUp *packet must first display the four discharge rows B, A, L, P_i and the audit ledger Q. The row R is therefore*

consumed only as a theorem conditional on beta-substitution preservation, application-argument stability, lambda-domain subject reduction, and Pi-domain subject reduction; it is not a closed subject-reduction theorem and it does not erase the audit record.

Proof. Project the accepted carrier of Definition 721.1. The only rows that can discharge the preservation hypotheses are B, A, L, P_i, and the only row that records their displayed status is Q.

Apply the obligation-exposure clause of Definition 721.2. It requires the four discharge rows to be displayed before any consumer reads R.

The parameterized preservation exactness clause then fixes the interpretation of R. Since the packet has no coordinate for an unparameterized theorem and Q remains part of the visible route, a consumer cannot turn R into closed subject reduction or drop the audit ledger. □

Theorem 721.4 (MetaCIC subject-reduction boundary non-escape)**.** *Every accepted* MetaCICSubjectReductionBou *packet exposes MetaCIC subject reduction only through the rows*

$$B, A, L, P_i, R, O, Q, H, C, K, N.$$

Any preservation-facing consumer must factor through the four displayed discharge obligations and the parameterized theorem row, while any obstruction-facing consumer must factor through the checked obstruction row. No consumer receives an unparameterized closed subject-reduction theorem, a hidden substitution lemma, host conversion, erased typing derivation semantics, semantic equality of terms, or a global normalization oracle from the packet.

Proof. Read the carrier coordinates from Definition 721.1. The only preservation rows are the four obligations and the parameterized theorem, and the only obstruction row is O.

Apply the NameCert obligations of Definition 721.2. They require obligation exposure before R is consumed and keep the obstruction row separate from the discharge rows.

The exclusions are immediate from the packet inventory. Since the carrier has no coordinate for hidden substitution preservation, host conversion, erased derivation semantics, semantic equality, global normalization, or unparameterized closed subject reduction, no public route can export any of those objects. □

Lean4 ✓ `BEDC.Derived.MetaCICSubjectReductionBoundaryUp.MetaCICSubjectReductionBoundaryCarrier nonescape`

Theorem 721.5 (MetaCIC subject-reduction boundary typed substitution)**.** *Every typed-substitution read displayed by an accepted* MetaCICSubjectReductionBoundaryUp *packet preserves the finite subject-reduction boundary only through the retained rows*

$$B,\ A,\ L,\ P_i,\ R,\ Q,\ H,\ C,\ K,\ N.$$

The substitution-facing route may replay the beta-substitution row B and the parameterized theorem row R through the same context, term, type, substitution, and reduction windows recorded by Q, H, C, K, N. It cannot replace the four retained discharge rows by a hidden substitution lemma, a closed subject-reduction theorem, host conversion, erased derivation semantics, semantic equality of MetaCIC terms, or global normalization.

Lean4 ✓ `BEDC.Derived.MetaCICSubjectReductionBoundaryUp.MetaCICSubjectReductionBoundaryCarrier typed substitution boundary`

↪ variant `BEDC.Derived.MetaCICSubjectReductionBoundaryUp.MetaCICSubjectReductionBoundaryCarrier typed substitution`

Proof. Read the carrier of Definition 721.1. A typed-substitution request can only see the beta-substitution row B, the remaining discharge rows A, L, P_i, the parameterized theorem row R, and the structural rows Q, H, C, K, N.

The audit ledger Q keeps the context, term, type, substitution, and reduction windows explicit before R is consumed. Transport by H and replay by C preserve those displayed windows rather than creating a new substitution theorem.

Apply the non-escape theorem Definition 721.4. Since the forbidden objects are not rows of the packet, a typed-substitution read remains a boundary-preserving route through the retained finite data. □

Theorem 721.6 (MetaCIC subject-reduction boundary context non-escape)**.** *No context-facing consumer of an accepted* MetaCICSubjectReductionBoundaryUp *packet receives any global normalization, host conversion, or semantic equality row from the boundary packet. Every context extension, weakening, or retained-context read must factor through the displayed discharge rows B, A, L, P_i, the parameterized theorem row R, the checked obstruction row O, and the audit, transport, replay, provenance, and naming rows Q, H, C, K, N.*

Proof. Start with the finite inventory in Definition 721.1. The context-visible rows are exactly the four discharge rows, the parameterized theorem row, the obstruction row, and the structural audit and replay rows.

Use Definition 721.2. It separates obligation exposure from obstruction exactness, so a context read cannot move from retained local rows to an ambient conversion or semantic-equality principle.

Finally apply Definition 721.4. Global normalization, host conversion, and semantic equality are absent coordinates, hence no context-facing route exported by the packet can expose them. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionBoundaryUp}}$.

Constructive story: A MetaCICSubjectReductionBoundaryUp packet is generated from four displayed MetaCIC subject-reduction discharge rows, a parameterized preservation theorem row, a checked obstruction row, an audit ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionBoundaryUp}}$, scopedClosed)

Scope closed: Definition 721.1, Definition 721.2, Definition 721.4, Definition 721.5, and Definition 721.6 bind the MetaCIC subject-reduction obstruction as a finite boundary packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionBoundaryUp}}$, theoremChecked)

Lean target: `BEDC.Derived.MetaCICSubjectReductionBoundaryUp.MetaCICSubjectReductionBoundaryTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not prove any of the four discharge obligations, closed subject reduction, closed consistency from reduction, global normalization, host conversion, semantic equality, or bridge checking.

Upgrade path: Scoped closure requires binding each obligation row to the exact MetaCIC primitives and sibling obstruction routes named in the proof.

Chapter 722

A Concrete Naming Certificate for $\mathsf{ClosedTermContextSeal}^{\uparrow}$

The $\mathsf{ClosedTermContextSeal}^{\uparrow}$ packet realizes the MetaCIC subject-reduction obstruction of chapter 9377 as a finite closed-term context surface. It sits next to the subject-reduction carrier of chapter 483: $\mathsf{SubjectReduction}^{\uparrow}$ records an Ext-Cont preservation packet, while $\mathsf{ClosedTermContextSeal}^{\uparrow}$ records the empty-context, closedness, typed-membership, beta-strong-normality, handoff, obstruction, transport, route, provenance, and local naming rows that keep the closed-subject-reduction boundary inspectable.

Definition 722.1 (Closed-term context seal carrier)**.** *A* $\mathsf{ClosedTermContextSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, Q, T, B, S, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the empty-context row for the closed MetaCIC typing read;*
2. *Q is the closedness row for the subject term and its target readback;*
3. *T is the typed-membership row naming the closed source membership;*
4. *B is the beta-strong normality row used by the closed-normal consistency side;*
5. *S is the* $\mathsf{SubjectReduction}^{\uparrow}$ *handoff row, pointing to the finite preservation packet of chapter 483;*
6. *O is the checked obstruction row for the unavailable unparameterized closed subject-reduction statement;*
7. *H records componentwise* hsame *transport for E, Q, T, B, S, O, P, N;*
8. *C records the displayed* Cont *routes by which consumers read the closedness, membership, normality, handoff, and obstruction coordinates;*
9. *P is the* Pkg *provenance over the MetaCIC closed-term rows, the subject-reduction handoff row,* BHist, hsame, Cont, *and the local naming row;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedTermContextSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a closed subject-reduction theorem, no hidden proof of the four MetaCIC discharge obligations, no ambient consistency shortcut, and no host equality principle for terms or contexts.

Theorem 722.2 (Closed-term context seal NameCert obligations)**.** *For the carrier of Definition 722.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedTermContextSeal}^{\uparrow}}$ *surface consists exactly of carrier admission, empty-context visibility, closedness visibility, typed-membership visibility, beta-strong-normality visibility,* $\mathsf{SubjectReduction}^{\uparrow}$ *handoff visibility, obstruction exactness, componentwise* hsame *stability, displayed* Cont *route stability,* Pkg *provenance, and non-escape from unparameterized closed subject reduction.*

Lean4 ✓ `BEDC.Derived.ClosedTermContextSealUp.ClosedTermContextSeal namecert obligations`

Proof. Project the packet K. The rows $E, Q, T, B, S, O, H, C, P, N$ are the complete displayed inventory, so every local naming obligation is read from a finite BHist coordinate.

The closed-term side is exhausted by E, Q, T, B. These rows state the empty-context read, closedness read, typed-membership read, and beta-strong-normality read needed by the closed-normal consistency side of chapter 9377.

The preservation side is exhausted by S and O. The row S points only to the sibling $\mathsf{SubjectReduction}^{\uparrow}$ handoff surface, while O records the checked obstruction against replacing the parameterized interface by an unparameterized closed theorem.

The remaining rows H, C, P, N supply transport, route, provenance, and local naming for the same packet. Since no carrier coordinate names the stronger theorem or its four missing proofs, the stated obligations are exact. □

Theorem 722.3 (Closed-term context seal subject-reduction handoff)**.** *Every preservation-facing consumer of an accepted* $\mathsf{ClosedTermContextSeal}^{\uparrow}$ *packet reaches subject-reduction data only through the displayed handoff row S and the finite* $\mathsf{SubjectReduction}^{\uparrow}$ *surface of chapter 483. The consumer must still read the empty-context row E, closedness row Q, typed-membership row T, beta-strong-normality row B, obstruction row O, transports H, routes C, provenance P, and local name N from the seal packet before using that handoff as closed-term context data.*

Lean4 ✓ `BEDC.Derived.ClosedTermContextSealUp.ClosedTermContextSeal subject reduction handoff`

Proof. Start with the handoff coordinate S in Definition 722.1. It is the only row that points to subject-reduction data, and its sibling target is the finite $\mathsf{SubjectReduction}^{\uparrow}$ carrier rather than an ambient preservation theorem.

Apply Definition 722.2. It requires every preservation-facing read to keep S together with $E, Q, T, B, O, H, C, P, N$, so the handoff remains a closed-context seal read and cannot detach into a host subject-reduction assertion.

The sibling chapter chapter 483 supplies only source membership, reduction, target membership, ledger, transport, route, package, and naming rows. Combining that handoff with the seal packet therefore gives a finite route, not a closed subject-reduction theorem. □

Theorem 722.4 (Closed-term context seal non-escape)**.** *An accepted* $\mathsf{ClosedTermContextSeal}^{\uparrow}$ *packet exports no unparameterized closed subject-reduction theorem, no proof of any of the four MetaCIC discharge obligations, no hidden host conversion rule, no quotient equality of terms, and no ambient consistency principle. Its exported surface is exhausted by the empty-context row, closedness row, typed-membership row, beta-strong-normality row,* $\mathsf{SubjectReduction}^{\uparrow}$ *handoff row, obstruction row, componentwise* hsame *transport, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row.*

Proof. Inspect the carrier coordinates. The only available rows are $E, Q, T, B, S, O, H, C, P, N$.

Use Definition 722.3 for preservation-facing reads and Definition 722.2 for local naming reads. Both routes stay inside the displayed finite packet and the sibling $\mathsf{SubjectReduction}^{\uparrow}$ handoff.

The excluded principles have no coordinate in the carrier. A request for closed subject reduction is therefore routed to the obstruction row O, while a request for ordinary subject-reduction data is routed to S and remains conditional on the sibling handoff surface. □

Theorem 722.5 (Closed-term context seal scoped kernel route)**.** *Every closed-subject-reduction consumer of an accepted* $\mathsf{ClosedTermContextSeal}^{\uparrow}$ *packet is scoped through the displayed rows* $E, Q, T, B, S, O, H, C, P$. *The empty-context row, closedness row, typed-membership row, beta-strong-normality row, and* $\mathsf{SubjectReduction}^{\uparrow}$ *handoff row must be read before the consumer may use the packet as closed-term context data. The route exports no host conversion, quotient term equality, or ambient consistency principle.*

Proof. Read the carrier of Definition 722.1. Its rows name the empty context, closedness, typed membership, beta-strong-normality, sibling handoff, obstruction, transport, replay, provenance, and local name as a single finite packet.

Apply Definition 722.2 to keep the local naming obligations on that same row inventory, and apply Definition 722.3 for every preservation-facing read. The handoff is therefore available only after E, Q, T, B and S have been exposed together.

Finally use Definition 722.4. It removes the possible escape routes: host conversion, quotient term equality, ambient consistency, the four MetaCIC discharge obligations, and an unparameterized closed subject-reduction theorem all have no carrier coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedTermContextSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedTermContextSeal}^{\uparrow}$ packet is generated from empty-context, closedness, typed-membership, beta-strong-normality, subject-reduction handoff, obstruction, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedTermContextSeal}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 722.1, Definition 722.2, Definition 722.3, Definition 722.4, and Definition 722.5 scope every closed-subject-reduction consumer through the finite rows $E, Q, T, B, S, O, H, C, P, N$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedTermContextSeal}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ClosedTermContextSealUp.ClosedTermContextSeal\_namecert\_obligations`

Bridge status: none

Origin: human

Not claimed: This chapter does not prove the four MetaCIC subject-reduction discharge obligations, closed subject reduction, ambient consistency, host conversion, quotient term equality, or bridge checking.

Upgrade path: Further closure requires a checked bridge for the same closed-term context seal route.

Chapter 723

A Concrete Naming Certificate for MetaCICSubjectReductionTrace$^{\uparrow}$

The MetaCICSubjectReductionTrace$^{\uparrow}$ packet turns the MetaCIC subject-reduction audit boundary into a finite BEDC naming surface. It records the parameterized subject-reduction theorem, the four discharge obligations consumed by that theorem, the checked obstruction row for the closed statement, componentwise transport, replay routes, package provenance, and a local NameCert row. The packet names the present proof frontier without claiming the four obligations or a closed subject-reduction theorem.

The trace packet sits between the obstruction boundary of chapter 731 and the discharge-obligation ledger of chapter 717. It records the parameterized theorem row and the four obligation sockets, while the sibling obstruction and frontier chapter chapter 730 record why this surface does not close the unparameterized subject-reduction theorem.

Definition 723.1 (MetaCIC subject-reduction trace carrier)**.** *A* MetaCICSubjectReductionTrace$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (P, B, A, L, I, O, H, C, G, N)$$

with the following displayed rows:

1. *P records the parameterized theorem row for* BEDC.MetaCIC.subject_reduction*, including the four hypothesis sockets it consumes;*
2. *B records the beta-substitution obligation row* BetaSubstitutionPreservation*;*
3. *A records the application-argument-stability obligation row* AppArgTypeStable*;*
4. *L records the lambda-domain obligation row* LamDomainSubjectReduction*;*
5. *I records the Pi-domain obligation row* PiDomainSubjectReduction*;*
6. *O records the obstruction theorem row for* BEDC.MetaCIC.closed_consistency_reduction_obstruction_not_availa
7. *H records componentwise* hsame *transport for the theorem row, the four obligation rows, the obstruction row, replay routes, provenance, and local name;*
8. *C records the displayed* Cont *routes that replay consumers through the parameterized theorem row, the four obligation rows, and the obstruction row;*
9. *G is the* Pkg *provenance over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*, and the MetaCIC subject-reduction audit rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionTrace}^{\uparrow}}$ *row.*
The carrier has no coordinate for an unparameterized closed subject-reduction theorem, a hidden proof of any of the four obligations, an implicit host-calculus preservation theorem, or an axiom that discharges the obstruction.

Theorem 723.2 (MetaCIC subject-reduction trace NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICSubjectReductionTrace}^{\uparrow}$ *carrier*

$$T = (P, B, A, L, I, O, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionTrace}^{\uparrow}}$ *surface consists exactly of the parameterized theorem row P, the four discharge-obligation rows B, A, L, I, the checked obstruction row O, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through G, and local naming through N.*

The packet records the four discharge obligations without proving them. A consumer that needs subject reduction must route through the parameterized theorem row P and supply B, A, L, I; a consumer that asks for the closed statement is routed to the obstruction row O.

Proof. Project the finite packet of Definition 723.1. The rows $P, B, A, L, I, O, H, C, G, N$ are the complete displayed inventory, so carrier admission and local naming are read directly from the packet.

The subject-reduction side is exhausted by P together with B, A, L, I. The row P names the checked parameterized theorem, while B, A, L, I name the beta-substitution, application-argument-stability, lambda-domain, and Pi-domain sockets that must be supplied before that theorem yields a preservation step.

The obstruction side is exhausted by O. Since O records the checked obstruction for the closed consistency-reduction proposition, the packet does not convert the four obligation rows into proofs and does not export a closed subject-reduction theorem.

Transport, replay, provenance, and naming are confined to H, C, G, N. Thus the local $\mathsf{NameCert}$ surface is exactly the displayed trace packet. □

Theorem 723.3 (MetaCIC subject-reduction trace non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{MetaCICSubjectReductionTrace}^{\uparrow}$ *packet factors through*

$$P, B, A, L, I, O, H, C, G, N.$$

A preservation consumer may read the parameterized theorem row and the four named obligation rows. An audit consumer may read the checked obstruction row. No consumer can read a closed subject-reduction theorem, a hidden proof of any obligation, or an unrecorded host-calculus preservation principle from this packet.

Proof. Begin with the route row C. By the carrier definition, every public continuation route is displayed there and has endpoints among $P, B, A, L, I, O, H, G, N$.

Use the NameCert obligation surface of Definition 723.2. It separates the parameterized theorem row from the four obligation rows and from the obstruction row, so a consumer cannot collapse the rows into a stronger theorem.

Componentwise transport through H preserves the same row inventory. Package provenance through G and local naming through N bind the route to the finite packet, leaving no coordinate for a closed subject-reduction theorem or hidden discharge proof. □

Theorem 723.4 (MetaCIC subject-reduction trace discharge frontier)**.** *An accepted* MetaCICSubjectReductionTrace *packet excludes any closed subject-reduction theorem unless all four obligation rows*

$$B, A, L, I$$

are supplied as discharge witnesses for the parameterized theorem row P. The obstruction row O remains the consumer-facing answer for the closed statement whenever any one of B, A, L, I is only a named obligation row.

Proof. Read P as the parameterized subject-reduction theorem row. Its visible interface consumes exactly the beta-substitution, application-argument-stability, lambda-domain, and Pi-domain discharge rows.

Read B, A, L, I as obligation rows rather than proof rows. The carrier records their names and positions, but it does not add a witness that any one of them is discharged.

Now read O as the checked obstruction row. If a consumer requests the closed theorem while any one of the four rows remains only an obligation, the replay route sends that request to O rather than to a closed subject-reduction theorem.

Finally, H, C, G, N preserve and package the same frontier. They transport, replay, and name the displayed rows, but they introduce no extra discharge coordinate. □

Theorem 723.5 (MetaCIC subject-reduction trace single-obligation obstruction)**.** *Let*

$$T = (P, B, A, L, I, O, H, C, G, N)$$

be an accepted MetaCICSubjectReductionTrace$^{\uparrow}$ *packet. If any one of B, A, L, I remains only a named obligation row rather than a supplied discharge witness, then a closed subject-reduction request is answered by O, and no downstream consumer may read a closed subject-reduction theorem from P alone.*

Concretely, the obstruction route applies in each of the following four cases:

1. *B is only the named beta-substitution obligation row;*
2. *A is only the named application-argument-stability obligation row;*
3. *L is only the named lambda-domain obligation row;*
4. *I is only the named Pi-domain obligation row.*

In all four cases, the transport, replay, provenance, and naming rows H, C, G, N preserve the same row inventory and introduce no hidden proof coordinate.

Proof. Project the carrier rows from Definition 723.1. The packet exposes P as the parameterized subject-reduction theorem row, exposes B, A, L, I as the four discharge-obligation rows, and exposes O as the obstruction row for the closed statement.

Use Definition 723.4. It states that a closed subject-reduction theorem is excluded unless all four rows B, A, L, I are supplied as discharge witnesses for P.

There are four single-missing cases.

1. If B remains only the beta-substitution obligation row, then the frontier theorem applies because not all four discharge witnesses are supplied.
2. If A remains only the application-argument-stability obligation row, then the same frontier theorem routes the closed request away from P alone.

3. If L remains only the lambda-domain obligation row, then the closed theorem is still absent from the packet inventory.
4. If I remains only the Pi-domain obligation row, then the request is again answered by the obstruction row O.

Finally apply the non-escape boundary of Definition 723.3. The rows H, C, G, N transport, replay, package, and name the displayed packet, so they preserve the same row inventory and do not add a hidden coordinate carrying the missing discharge proof. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionTrace}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{MetaCICSubjectReductionTrace}^{\uparrow}$ packet is generated from the parameterized MetaCIC subject-reduction theorem row, four named discharge-obligation rows, a checked obstruction row, componentwise hsame transports, displayed Cont replay routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 723.1, Definition 723.2, Definition 723.3, Definition 723.4, and Definition 723.5 specify the finite subject-reduction trace carrier, obligation surface, consumer non-escape boundary, discharge frontier, and per-row obstruction boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, route exhaustion, obstruction replay, and proof rows for all four MetaCIC subject-reduction discharge obligations.

Chapter 724

A Concrete Naming Certificate for $\mathsf{MetaCICDischargeObligation}^{\uparrow}$

The $\mathsf{MetaCICDischargeObligation}^{\uparrow}$ packet turns the four discharge obligations isolated in chapter 9377 into a finite NameCert carrier. It is a sibling of chapter 483: the latter records the accepted subject-reduction closure surface, while this packet records the four local inputs that must be supplied before the MetaCIC subject-reduction theorem can be consumed without hiding a closed theorem.

Definition 724.1 (MetaCIC discharge-obligation carrier)**.** *A* $\mathsf{MetaCICDischargeObligation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, A, L, P, H, C, G, N)$$

with the following displayed rows:

1. *B is the beta-substitution discharge row* BetaSubstitutionPreservation*;*
2. *A is the application-argument discharge row* AppArgTypeStable*;*
3. *L is the lambda-domain discharge row* LamDomainSubjectReduction*;*
4. *P is the Pi-domain discharge row* PiDomainSubjectReduction*;*
5. *H records componentwise* hsame *transport for the four discharge rows, the continuation routes, package provenance, and local naming;*
6. *C records the displayed* Cont *routes by which a consumer reads the four discharge rows and the support rows;*
7. *G is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *and the MetaCIC subject-reduction discharge interface;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligation}^{\uparrow}}$ *row.*

The carrier contains no unparameterized closed subject-reduction theorem, no hidden proof of any discharge row, no host conversion rule, no erased derivation semantics, and no semantic equality of MetaCIC terms.

Definition 724.2 (MetaCIC discharge-obligation classifier)**.** *The* $\mathsf{MetaCICDischargeObligation}^{\uparrow}$ *classifier accepts exactly those carrier reads that factor through*

$$B, A, L, P, H, C, G, N.$$

The positive reads are the four discharge rows, their componentwise hsame *transports, the displayed* Cont *routes, the* Pkg *provenance row, and the local* NameCert *row. A request for closed subject reduction, host conversion, hidden substitution preservation, quotient transport, or an undisplayed MetaCIC premise is classified as outside the packet.*

Theorem 724.3 (MetaCIC discharge-obligation certificate surface)**.** *For the carrier of Definition 724.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligation}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$D = (B, A, L, P, H, C, G, N),$$

the four discharge rows B, A, L, P*, componentwise* hsame *transport through* H*, displayed continuation reads through* C*, package provenance through* G*, and local naming through* N*.*

Proof. Project the finite carrier. Its only discharge coordinates are B, A, L, P, and its only support coordinates are H, C, G, N.

Use the classifier of Definition 724.2. It accepts precisely reads through those rows, so the local certificate surface cannot introduce another MetaCIC premise.

Finally read the local NameCert row N. It names the same finite packet and therefore binds the certificate surface to the displayed carrier rather than to a hidden subject-reduction theorem. □

Theorem 724.4 (MetaCIC discharge-obligation parameterized interface)**.** *Every consumer that uses* $\mathsf{MetaCICDischargeObligation}^{\uparrow}$ *as input to the MetaCIC subject-reduction interface must consume all four rows* B, A, L, P *as the beta-substitution, application-argument, lambda-domain, and Pi-domain discharge rows. The support rows* H, C, G, N *transport, replay, package, and name those four rows, but they do not add a fifth discharge row and do not produce a closed subject-reduction theorem.*

Proof. Begin with the four-row inventory in Definition 724.1. It names exactly the four hypotheses isolated by chapter 9377.

Apply the certificate-surface theorem. Any subject-reduction-facing read sees B, A, L, P together with transport, route, provenance, and naming support.

The sibling package in chapter 483 records the accepted subject-reduction closure surface. This packet instead supplies the finite obligation interface that a consumer must discharge before invoking that surface, so no closed theorem is exported from H, C, G, N. □

Theorem 724.5 (MetaCIC discharge-obligation non-escape)**.** *Every downstream read of an accepted* $\mathsf{MetaCICDischargeObligation}^{\uparrow}$ *carrier factors through*

$$B, A, L, P, H, C, G, N.$$

It cannot inspect a hidden proof of beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, host conversion, erased derivation semantics, quotient equality, or an unrecorded MetaCIC reduction principle.

Proof. Read the request through the classifier. Positive reads factor through the four discharge rows or through the displayed support rows.

If the request asks for a closed theorem or for an undisplayed host principle, no coordinate of D can answer it. The request is therefore outside the accepted carrier rather than a hidden route through the certificate.

The transport, continuation, provenance, and naming rows preserve the same inventory. They make the four obligations reusable as finite BEDC data, but they do not create another proof-producing coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligation}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDischargeObligation}^{\uparrow}$ packet is generated from the four MetaCIC subject-reduction discharge rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 724.1, Definition 724.2, Definition 724.3, Definition 724.4, and Definition 724.5 specify the finite four-obligation carrier, classifier, certificate surface, consumer interface, and non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDischargeObligation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, four-row consumption, transport stability, route replay, provenance, local naming, and non-escape for the same finite packet.

Chapter 725

A Concrete Naming Certificate for $\mathsf{SubjectReductionObligation}^{\uparrow}$

The $\mathsf{SubjectReductionObligation}^{\uparrow}$ packet realizes the four MetaCIC subject-reduction discharge obligations of chapter 9377 as a finite BEDC naming surface. It is downstream of the subject-reduction carrier of chapter 483, the type-classifier membership route of chapter 476, and the continuation-trace packet of chapter 469. Its role is to name the obligation packet that a subject-reduction consumer must supply; it does not turn the blocked closed subject-reduction statement of Definition 9377.5 into a theorem.

Definition 725.1 (SubjectReductionObligation carrier)**.** *A* $\mathsf{SubjectReductionObligation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (B, A, L, I, T, H, C, P, N)$$

with the following displayed rows:

1. *B is the* BetaSubstitutionPreservation *row of Definition 9377.1;*
2. *A is the* AppArgTypeStable *row of Definition 9377.2;*
3. *L is the* LamDomainSubjectReduction *row of Definition 9377.3;*
4. *I is the* PiDomainSubjectReduction *row of Definition 9377.4;*
5. *T is the parameterized MetaCIC subject-reduction consumption row, read only as a row that consumes B, A, L, I;*
6. *H records componentwise* hsame *transports for the four obligation rows, the consumption row, the route rows, provenance, and local naming row;*
7. *C records displayed* Cont *routes from subject-reduction consumers to the four obligation rows and to the parameterized consumption row;*
8. *P is the* Pkg *provenance over* $\mathsf{SubjectReduction}^{\uparrow}$, $\mathsf{TypeClassifierMembership}^{\uparrow}$, $\mathsf{ContinuationTrace}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionObligation}^{\uparrow}}$ *row.*

The carrier contains no closed subject-reduction theorem, no proof of any one of B, A, L, I, no hidden host conversion principle, no quotient equality of MetaCIC terms, and no route around the checked obstruction in Definition 9377.5.

Theorem 725.2 (SubjectReductionObligation NameCert obligations)**.** *For the carrier of Definition 725.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionObligation}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$O = (B, A, L, I, T, H, C, P, N),$$

the four displayed MetaCIC discharge-obligation rows B, A, L, I*, the parameterized consumption row* T*, componentwise* hsame *transport through* H*, displayed continuation reads through* C*, package provenance through* P*, and local naming through* N*.*

A subject-reduction consumer may cite this packet only as a finite obligation packet: T *consumes the four rows named in section 9377.3, and the explicit obstruction of section 9377.4 remains the answer to any request for closed subject reduction.*

Proof. Project the finite carrier O. The rows B, A, L, I are precisely the four discharge slots, while T is the row that records their simultaneous consumption by the parameterized subject-reduction interface.

Next read the structural rows H and C. They transport the same four rows componentwise and replay them through displayed continuation routes, so a consumer cannot replace one obligation row by an unrecorded host premise.

Finally inspect P and N. The provenance row ties the packet to the subject-reduction, type-classifier-membership, and continuation-trace chapters named above, and the local NameCert row packages no coordinate beyond the displayed carrier. Hence the NameCert surface is exactly the finite obligation packet. □

Theorem 725.3 (SubjectReductionObligation non-escape)**.** *Every consumer read of an accepted* $\mathsf{SubjectReductionObligation}^{\uparrow}$ *packet factors through*

$$B, A, L, I, T, H, C, P, N.$$

The consumer may read the beta-substitution, application-argument-stability, lambda-domain, and Pi-domain obligation rows, the parameterized consumption row, componentwise transports, displayed continuation routes, package provenance, and the local NameCert row. It cannot read a closed subject-reduction theorem, a proof of any one obligation, host conversion, quotient equality of MetaCIC terms, ambient reduction semantics, or an unrecorded discharge premise.

Proof. Start with carrier projection. Since the accepted object is the finite packet O, every public read must choose one of the displayed rows.

For a subject-reduction read, the only route to T passes through the four obligation rows B, A, L, I and their transports in H. The continuation row C records this route as an obligation replay rather than as a closed theorem.

For a closed subject-reduction request, the packet has no corresponding coordinate. The obstruction cited in Definition 9377.5 therefore remains outside the packet as the boundary for that request, and no consumer can manufacture a closed theorem from the obligation rows alone.

The provenance and local naming rows P, N add only package identity and certificate identity. They do not add host conversion, quotient equality, ambient reduction semantics, or a hidden proof of any discharge row. □

Theorem 725.4 (SubjectReductionObligation obstruction alignment)**.** *The* $\mathsf{SubjectReductionObligation}^{\uparrow}$ *packet is compatible with the explicit MetaCIC obstruction of chapter 9377. It exposes the four rows required by the parameterized subject-reduction theorem and preserves the negative boundary of Definition 9377.5: a consumer that lacks any one of* B, A, L, I *receives an obligation packet, not a closed subject-reduction result.*

Proof. Read the four obligation definitions in section 9377.3. They are represented one-for-one by B, A, L, I in the carrier.

Then read the consumption row T. It has no route that omits any of those four rows, because its only displayed subject-reduction inputs are the rows recorded in the same finite packet.

The obstruction principle supplies the boundary for the unparameterized closed statement. Since O has no closed-theorem coordinate and no hidden proof row, the accepted packet aligns with the obstruction rather than bypassing it. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionObligation}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionObligation}^{\uparrow}$ packet is generated from the beta-substitution, application-argument-stability, lambda-domain, and Pi-domain discharge rows, a parameterized subject-reduction consumption row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionObligation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 725.1, Definition 725.2, Definition 725.3, and Definition 725.4 bind the finite four-obligation packet without closing the MetaCIC discharge rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionObligation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, Lean verification, host conversion, quotient equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exact four-row consumption, obstruction alignment, route exhaustion, provenance, and non-escape for the same finite packet.

Chapter 726

A Concrete Naming Certificate for $\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}$

The $\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}$ packet gives the obstruction vision of chapter 9377 a finite BEDC naming surface. It reads the subject-reduction carrier of chapter 483, the closed generator audit packet of chapter 709, and the generator audit closure packet of chapter 711 as the surrounding ledger rows for the four MetaCIC discharge obligations. The packet does not prove those obligations; it names their position, their subject-reduction handoff, and the non-escape boundary that prevents an unrecorded closed theorem from being exported.

Definition 726.1 (MetaCIC reduction obstruction ledger carrier)**.** *A* $\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, B, A, L, P, G, J, O, H, C, Q, N)$$

with the following displayed rows:

1. *S records the* $\mathsf{SubjectReduction}^{\uparrow}$ *row consumed by downstream type-preservation packets;*
2. *B records the beta-substitution discharge row;*
3. *A records the application-argument stability discharge row;*
4. *L records the lambda-domain preservation discharge row;*
5. *P records the Pi-domain preservation discharge row;*
6. *G records the* $\mathsf{ClosedGeneratorAudit}^{\uparrow}$ *source for closed generator and substitution audit evidence;*
7. *J records the* $\mathsf{GeneratorAuditClosure}^{\uparrow}$ *source for generator-closure replay;*
8. *O records the obstruction row for the closed subject-reduction request;*
9. *H records componentwise* hsame *transport for the subject-reduction row, the four discharge rows, the two generator-audit rows, the obstruction row, replay routes, provenance, and local naming;*
10. *C records displayed* Cont *routes through which consumers read the parameterized subject-reduction row, the four discharge rows, the generator-audit rows, and the obstruction row;*
11. *Q is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, $\mathsf{SubjectReduction}^{\uparrow}$, $\mathsf{ClosedGeneratorAudit}^{\uparrow}$, $\mathsf{GeneratorAuditClosure}^{\uparrow}$, *and the MetaCIC subject-reduction obstruction boundary;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a closed subject-reduction theorem, hidden proof of a discharge row, host-calculus preservation theorem, quotient transport, classical selection, proposition extensionality, or unrecorded proof oracle.

Theorem 726.2 (MetaCIC reduction obstruction ledger NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}$ *carrier*

$$R = (S, B, A, L, P, G, J, O, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}}$ *surface has four finite obligations:*

1. *subject-reduction exposure:* S *is the only displayed subject-reduction row available to a consumer;*
2. *discharge inventory:* B, A, L, P *are the only rows that may feed the beta-substitution, application-argument, lambda-domain, and Pi-domain sockets;*
3. *generator-audit anchoring:* G *and* J *are the only rows from which closed-generator and generator-closure audit evidence may be read;*
4. *obstruction exactness:* O, H, C, Q, N *route every closed subject-reduction request back to the displayed obstruction ledger unless all four discharge rows are supplied as proof rows for* S*.*

Proof. Project the carrier of Definition 726.1. The rows $S, B, A, L, P, G, J, O, H, C, Q, N$ are the complete packet inventory, so the local name has no source outside that tuple.

The subject-reduction read is confined to S. The four discharge rows B, A, L, P are listed separately, and the generator-audit rows G, J remain attached to their own displayed coordinates.

The obstruction row O handles the closed request. Transport through H, replay through C, provenance through Q, and naming through N keep that request inside the same finite packet rather than replacing it by an unrecorded theorem. □

Theorem 726.3 (MetaCIC reduction obstruction ledger non-escape)**.** *Every consumer of an accepted* $\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}$ *carrier can read only the rows*

$$S, B, A, L, P, G, J, O, H, C, Q, N.$$

In particular, the packet exports no closed subject-reduction theorem, hidden discharge proof, host-calculus preservation principle, quotient transport, classical selection, proposition extensionality, or unrecorded proof oracle.

Proof. Start with the finite carrier. Each exported coordinate is one of the displayed rows, and each public replay route is recorded in C.

Apply Definition 726.2. The subject-reduction row, four discharge rows, generator-audit rows, and obstruction row exhaust the local $\mathsf{NameCert}$ surface.

Since the excluded objects do not occur as coordinates of R, componentwise transport and package provenance cannot export them. A consumer may only replay the rows named by the ledger. □

Theorem 726.4 (MetaCIC reduction obstruction ledger subject-reduction handoff)**.** *An accepted* $\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}$ *packet hands subject-reduction consumers to the displayed* $\mathsf{SubjectReduction}^{\uparrow}$ *row* S *together with the four obligation rows* B, A, L, P*. A consumer obtains a subject-reduction read only by supplying those four rows as the discharge inputs required by* S*; otherwise the closed request is answered by the obstruction row* O*.*

Proof. Read the handoff coordinate S from the carrier. It is the only subject-reduction row recorded in the packet.

The rows B, A, L, P are the four displayed discharge inputs. The carrier does not contain a second source that could supply those inputs invisibly.

If the four rows are not supplied as proof rows for S, the route C sends the closed subject-reduction request to O. Thus the handoff is finite and explicit: either the consumer supplies the displayed obligations, or the ledger returns the obstruction row. □

Theorem 726.5 (MetaCIC reduction obstruction ledger vision concretization)**.** *The* MetaCICReductionObstruction *carrier realizes the MetaCIC subject-reduction obstruction vision as a finite NameCert ledger. Its rows link the four discharge obligations to* $\mathsf{SubjectReduction}^{\uparrow}$, $\mathsf{ClosedGeneratorAudit}^{\uparrow}$, *and* $\mathsf{GeneratorAuditClosure}^{\uparrow}$ *while keeping the closed subject-reduction request behind the explicit obstruction row.*

Proof. Use Definition 726.1 to identify the ledger rows. The subject-reduction row S, the four discharge rows B, A, L, P, and the generator-audit rows G, J are all visible coordinates.

Use Definition 726.4 for the subject-reduction route and Definition 726.3 for the exclusion boundary. Together they give the vision a concrete finite packet without adding a closed theorem or a hidden discharge proof. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}$ packet is generated from a subject-reduction row, four discharge-obligation rows, closed-generator and generator-closure audit rows, an obstruction row, componentwise hsame transports, displayed Cont replay routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 726.1, Definition 726.2, Definition 726.3, Definition 726.4, and Definition 726.5 specify the finite obstruction ledger carrier, obligation surface, non-escape boundary, subject-reduction handoff, and vision realization.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICReductionObstructionLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, discharge inventory, generator-audit anchoring, and obstruction exactness for the displayed ledger.

Chapter 727

A Concrete Naming Certificate for BetaSubstitutionDischarge$^{\uparrow}$

The BetaSubstitutionDischarge$^{\uparrow}$ packet isolates the beta-redex row named in chapter 9377. It is narrower than the full SubjectReduction$^{\uparrow}$ packet of chapter 483: it records only the substitution-across-binder discharge needed by the beta case, while remaining compatible with the type-membership boundary of chapter 476 and the compiler-facing handoff of chapter 625.

Definition 727.1 (BetaSubstitutionDischarge carrier)**.** *A* BetaSubstitutionDischarge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (G, d, b, a, c, s, h, r, p, n)$$

with the following displayed rows:

1. *G is the source context row for the beta redex;*
2. *d is the displayed domain row;*
3. *b is the body typing row in the context extended by the shifted domain;*
4. *a is the argument typing row in the original context;*
5. *c is the codomain row whose displayed substitution is read after the argument is supplied;*
6. *s is the substitution ledger tying the body, argument, domain, and codomain rows to the beta-redex discharge;*
7. *h records componentwise* hsame *transports for G, d, b, a, c, s and for the provenance rows;*
8. *r records the displayed* Cont *routes from the beta step to the substituted body and substituted codomain reads;*
9. *p is the* Pkg *provenance over* BHist, hsame, Cont, *the MetaCIC beta-step interface,* SubjectReduction$^{\uparrow}$, TypeClassifierMembership$^{\uparrow}$, *and* NameCert*;*
10. *n is the local* NameCert$_{\text{BetaSubstitutionDischarge}^{\uparrow}}$ *row.*

The carrier has no coordinate for a full closed subject-reduction theorem, no global conversion oracle, no erased derivation representative, and no proof row for any non-beta discharge obligation.

Lean4 ✓ `BEDC.Derived.BetaSubstitutionDischargeUp.BetaSubstitutionDischargeTasteGate single carrier alignment`

Theorem 727.2 (BetaSubstitutionDischarge NameCert obligations)**.** *For an accepted* $\mathsf{BetaSubstitutionDischarge}^{\uparrow}$ *carrier*

$$B = (G, d, b, a, c, s, h, r, p, n),$$

the local $\mathsf{NameCert}_{\mathsf{BetaSubstitutionDischarge}^{\uparrow}}$ *surface consists exactly of carrier admission for* B*, beta-redex source coverage through* G, d, b, a, c*, substitution-ledger exactness through* s*, componentwise* hsame *stability through* h*, displayed* Cont *replay through* r*, package provenance through* p*, and local naming through* n*. A consumer may use the packet only as the* BetaSubstitutionPreservation *row consumed by the beta case of the MetaCIC subject-reduction interface.*

Lean4 ✓ `BEDC.Derived.BetaSubstitutionDischargeUp.BetaSubstitutionDischarge namecert obligations`

Proof. Project the displayed carrier. The rows G, d, b, a, c identify the context, domain, body typing, argument typing, and codomain data of one beta redex, while s is the only substitution ledger in the packet.

The transport and replay rows are then forced. Componentwise hsame movement through h can carry the displayed rows to an equivalent packet, and the Cont routes in r replay the beta step to the substituted body and substituted codomain reads. Neither row contains an independent typing theorem.

Finally read p and n as provenance and local naming data. Since the carrier lists no global subject-reduction theorem, no conversion oracle, no erased derivation row, and no non-beta discharge row, every accepted consumer of the packet receives exactly the beta-substitution preservation obligation named by the MetaCIC interface. □

Theorem 727.3 (BetaSubstitutionDischarge binder boundary)**.** *For an accepted* $\mathsf{BetaSubstitutionDischarge}^{\uparrow}$ *carrier* $B = (G, d, b, a, c, s, h, r, p, n)$*, every binder-crossing read factors through the single substitution ledger* s *together with the displayed* BHist *rows* G, d, b, a, c*. The route may preserve the rows through* h *and replay them through* r*, but it cannot replace the binder boundary by host substitution, ambient conversion, quotient equality, or a closed subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.BetaSubstitutionDischargeUp.BetaSubstitutionDischargeCarrier binder boundary`

Proof. Start with the binder data. The body row b is typed only in the context obtained from G by the displayed domain row d, and the argument row a is typed only over the original context row G.

The substituted codomain read is controlled by c and s. The ledger s is therefore the unique row that crosses the binder boundary from the body and argument data to the beta-redex discharge.

Transport through h and replay through r preserve that inventory. They may move the same rows componentwise and expose the beta route to a $\mathsf{SubjectReduction}^{\uparrow}$ or $\mathsf{TypeClassifierMembership}^{\uparrow}$ consumer, but they add no host substitution rule, quotient equality, conversion theorem, or closed subject-reduction row.

The package row p and local name row n record the same boundary for downstream certificates, including the $\mathsf{TypePreservingCompiler}^{\uparrow}$ handoff. Hence the binder-crossing read remains the single beta-substitution discharge packet. □

Theorem 727.4 (BetaSubstitutionDischarge component transport)**.** *For an accepted* $\mathsf{BetaSubstitutionDischarge}^{\uparrow}$ *carrier* $B = (G, d, b, a, c, s, h, r, p, n)$*, every componentwise* hsame *transport recorded by* h *preserves exactly the source context row* G*, displayed domain row* d*, body typing row* b*, argument typing row* a*, codomain row* c*, substitution ledger* s*, replay row* r*, provenance row* p*, and local naming row* n*. The transported packet therefore has the same beta-redex discharge surface and gains no host substitution rule, quotient equality, ambient conversion theorem, or closed subject-reduction row.*

Lean4 ✓ `BEDC.Derived.BetaSubstitutionDischargeUp.BetaSubstitutionDischargeCarrier component transport`

Proof. Project the carrier and read the transport row. The row h is componentwise, so each move is attached to one displayed coordinate of $G, d, b, a, c, s, r, p, n$ rather than to an external substitution principle.

The source, domain, body, argument, codomain, and substitution rows are therefore carried as the same finite beta-redex inventory. No transported coordinate adds a host substitution rule or quotient equality, because those objects are absent from the carrier.

The replay, provenance, and naming rows are preserved with the same boundary. Hence the transported packet remains a $\mathsf{BetaSubstitutionDischarge}^{\uparrow}$ packet over the displayed beta-redex surface and not a closed subject-reduction theorem. □

Theorem 727.5 (BetaSubstitutionDischarge replay exactness)**.** *For an accepted* $\mathsf{BetaSubstitutionDischarge}^{\uparrow}$ *carrier* $B = (G, d, b, a, c, s, h, r, p, n)$*, the displayed* Cont *replay row* r *exposes only the beta-redex substituted-body read and the substituted-codomain read determined by* G, d, b, a, c *and the substitution ledger* s*. It exposes no application-argument stability route, lambda-domain preservation route, Pi-domain preservation route, conversion oracle, quotient equality, or non-beta subject-reduction discharge.*

Lean4 ✓ `BEDC.Derived.BetaSubstitutionDischargeUp.BetaSubstitutionDischargeCarrier replay exactness`

Proof. Read the replay row after the binder-boundary data. The rows G, d, b, a, c identify the beta redex and s is the only ledger that carries the body and codomain across the binder.

The Cont routes in r can therefore replay exactly the substituted-body read and the substituted-codomain read. Any application, lambda, Pi, conversion, quotient, or non-beta discharge would require an additional carrier coordinate.

Since the carrier lists no such coordinate, replay exactness is confined to the beta-redex reads named by the substitution ledger. The provenance and naming rows record that same confinement for downstream MetaCIC consumers. □

Theorem 727.6 (BetaSubstitutionDischarge context induction)**.** *For an accepted* $\mathsf{BetaSubstitutionDischarge}^{\uparrow}$ *carrier* $B = (G, d, b, a, c, s, h, r, p, n)$*, every beta-substitution discharge read is obtained by induction over the displayed source context row* G *and the single substitution ledger* s*. The induction preserves the displayed domain, body, argument, and codomain rows* d, b, a, c *through the componentwise transport row* h*, and exposes only the substituted-body and substituted-codomain reads through the replay row* r*.*

Lean4 ✓ `BEDC.Derived.BetaSubstitutionDischargeUp.BetaSubstitutionDischargeCarrier context induction`

Proof. Project the carrier of Definition 727.1. The only context data are the source row G, the domain row d, the body row b, the argument row a, the codomain row c, and the substitution ledger s.

Induct over the displayed context-extension window named by G. At the binder-crossing step, use Definition 727.3; the step can cross the body and codomain boundary only through s, not through host substitution or a closed subject-reduction theorem.

For stability of the induction data, use component transport, Definition 727.4. It keeps d, b, a, c, s on the same displayed packet under h.

Finally apply replay exactness, Definition 727.5. The replay row r exposes precisely the substituted-body and substituted-codomain reads, so the induction has no remaining route to an application, lambda, Pi, conversion, quotient, or non-beta discharge coordinate. □

Theorem 727.7 (BetaSubstitutionDischarge obligation surface)**.** *For an accepted* $\mathsf{BetaSubstitutionDischarge}^{\uparrow}$ *carrier* $B = (G, d, b, a, c, s, h, r, p, n)$*, carrier admission, substitution-ledger exactness, binder-boundary nonescape, componentwise transport, replay exactness, and context induction exhaust the displayed beta-redex obligation surface consumed by the MetaCIC subject-reduction beta case. No consumer of the packet receives an application-argument stability row, lambda-domain preservation row, Pi-domain preservation row, conversion oracle, quotient equality, erased derivation representative, or closed subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.BetaSubstitutionDischargeUp.BetaSubstitutionDischargeCarrier obligation surface`

Proof. Project the carrier of Definition 727.1. The rows G, d, b, a, c expose the beta-redex source context, domain, body typing, argument typing, and codomain data, while s is the only substitution ledger attached to those rows.

Apply Definition 727.2 and Definition 727.3. The first fixes the local NameCert surface, and the second forces every binder-crossing read to pass through s rather than through host substitution or a closed subject-reduction theorem.

Use Definition 727.4 and Definition 727.5. Transport preserves the displayed coordinates componentwise, and replay exposes only the substituted-body and substituted-codomain reads determined by the substitution ledger.

Finally apply Definition 727.6. The induction over G and s leaves no remaining coordinate from which an application, lambda, Pi, conversion, quotient, erased-derivation, or non-beta discharge obligation could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{BetaSubstitutionDischarge}^{\uparrow}}$.

Constructive story: A $\mathsf{BetaSubstitutionDischarge}^{\uparrow}$ packet is generated from a displayed source context row, domain row, body typing row, argument typing row, codomain row, substitution ledger, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BetaSubstitutionDischarge}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 727.1, Definition 727.2, Definition 727.3, Definition 727.4, Definition 727.5, Definition 727.6, and Definition 727.7 bind the finite beta-substitution discharge carrier and the beta-redex obligation surface consumed by the MetaCIC subject-reduction beta case.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BetaSubstitutionDischarge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, Lean verification, host conversion, quotient equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, substitution-ledger exactness, binder-boundary coverage, componentwise transport stability, replay-route exactness, and public non-escape for the displayed beta-redex packet.

Chapter 728

A Concrete Naming Certificate for $\mathsf{BetaCongruenceDomainAudit}^{\uparrow}$

The $\mathsf{BetaCongruenceDomainAudit}^{\uparrow}$ packet realizes the binder-domain trigger surface identified in chapter 9384. It sits beside the beta-step boundary of chapter 754 and the beta-substitution preservation packet of chapter 716: those siblings expose the raw beta relation and the redex-substitution preservation row, while this packet binds the `congLamDom` and `congPiDom` domain-trigger rows as finite subject-reduction audit data.

Falsifiable prediction: A packet omitting the displayed binder-domain trigger row is not an accepted $\mathsf{BetaCongruenceDomainAudit}^{\uparrow}$ carrier.

Independence witness: betastepboundary, betasubstitutionpreservation, metacic-subject-reduction-obstruction, subjectreductiondischarge: no sibling is bijective because the new packet stores the binder-domain beta-congruence trigger, displayed domain readback, subject-reduction handoff row, transport, route, provenance, and local naming together.

Definition 728.1 (BetaCongruenceDomainAudit carrier)**.** *A* $\mathsf{BetaCongruenceDomainAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (T, M, \Pi, R, S, H, K, P, N)$$

with the following displayed rows:

1. *T is the binder-domain trigger row, tagged by the local* `congLamDom` *or* `congPiDom` *beta constructor;*
2. *M is the lambda-domain readback row for the displayed old and new lambda annotations, when the trigger is the lambda-domain constructor;*
3. *Π is the Pi-domain readback row for the displayed old and new Pi annotations, when the trigger is the Pi-domain constructor;*
4. *R is the subject-reduction handoff row naming the binder-domain discharge surface consumed by* $\mathsf{SubjectReductionDischarge}^{\uparrow}$*;*
5. *S is the finite subject-reduction trigger ledger tying T, M, Π, R to the same domain-congruence beta step;*
6. *H stores componentwise* hsame *transports for the trigger, readback, handoff, ledger, route, provenance, and naming rows;*

7. *K stores the displayed* Cont *routes for reading the trigger, replaying the domain readback, and handing the row to the subject-reduction discharge interface;*
8. *P is the* Pkg *provenance over chapter 9384, chapter 754, chapter 716, chapter 718,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BetaCongruenceDomainAudit}^{\uparrow}}$ *row.*

The carrier is exactly this finite packet. It contains no beta-redex substitution semantics, no typed preservation theorem, no unrestricted conversion, and no closed subject-reduction theorem.

Theorem 728.2 (BetaCongruenceDomainAudit NameCert obligations)**.** *For the carrier of Definition 728.1, the local* $\mathsf{NameCert}_{\mathsf{BetaCongruenceDomainAudit}^{\uparrow}}$ *surface consists of carrier admission for*

$$D = (T, M, \Pi, R, S, H, K, P, N),$$

binder-domain trigger readback, lambda-domain readback, Pi-domain readback, subject-reduction handoff replay, finite trigger-ledger exactness, componentwise hsame *transport, displayed* Cont *route replay,* Pkg *provenance, and non-escape from beta-redex substitution semantics, typed preservation, unrestricted conversion, and closed subject reduction.*

Proof. Carrier admission is projection from Definition 728.1. The packet exposes exactly $T, M, \Pi, R, S, H, K, P, N$.

The trigger row T records whether the beta step is the lambda-domain constructor or the Pi-domain constructor named in chapter 9384. The readback rows M and Π keep the displayed old and new domain annotations separate from any redex-substitution row.

The handoff row R and ledger row S place the trigger beside the subject-reduction discharge surface without discharging it. The transports H, routes K, provenance P, and local name N bind the read into one finite NameCert packet.

Since no coordinate supplies beta-redex substitution semantics, typed preservation, unrestricted conversion, or closed subject reduction, no consumer of the local certificate can export those objects from the binder-domain trigger packet. □

Theorem 728.3 (BetaCongruenceDomainAudit trigger handoff)**.** *An accepted* $\mathsf{BetaCongruenceDomainAudit}^{\uparrow}$ *packet presents the* `congLamDom` *and* `congPiDom` *beta constructors as finite subject-reduction trigger rows. The handoff to* $\mathsf{SubjectReductionDischarge}^{\uparrow}$ *reads only*

$$D = (T, M, \Pi, R, S, H, K, P, N),$$

where T is the binder-domain trigger, M and Π are the displayed domain readbacks, R is the discharge-facing row, S is the finite trigger ledger, and H, K, P, N are the local transport, route, provenance, and naming rows.

Proof. First read the trigger from T. The beta-step boundary sibling records that `congLamDom` and `congPiDom` are beta constructors, while this carrier stores which binder-domain constructor is being audited.

Next read the displayed domain annotations. The lambda-domain case uses M, and the Pi-domain case uses Π; each route is replayed through H and K before the handoff row R is visible.

Finally apply the provenance row P. It links the trigger to the beta audit map, beta-step boundary, beta-substitution preservation sibling, and subject-reduction discharge surface, but it does not identify the binder-domain trigger with redex substitution or typed preservation. □

Theorem 728.4 (BetaCongruenceDomainAudit non-escape)**.** *Every accepted* BetaCongruenceDomainAudit$^{\uparrow}$ *packet exposes binder-domain beta-congruence only through the rows*

$$T, M, \Pi, R, S, H, K, P, N.$$

A downstream consumer may read the binder-domain trigger, displayed lambda-domain readback, displayed Pi-domain readback, discharge-facing handoff, finite trigger ledger, transports, routes, provenance, and local naming row. It cannot replace those rows by beta-redex substitution semantics, typed preservation, unrestricted conversion, or closed subject reduction.

Proof. Project the carrier. The only beta-facing row is T, and the only binder annotation readbacks are M and Π.

Use the NameCert obligations of Definition 728.2. They require the handoff and ledger rows to remain tied to the same trigger packet through H, K, P, N.

The exclusions follow from absence of coordinates. Redex substitution, typed preservation, unrestricted conversion, and closed subject reduction would each require a separate row or external route, and none is present in D. □

Theorem 728.5 (BetaCongruenceDomainAudit TasteGate target)**.** *The Lean-facing taste gate for* BetaCongruenceDomainAudit$^{\uparrow}$ *is the finite carrier discipline of Definition 728.1 together with the obligation, handoff, and non-escape theorems of this chapter. The downstream taste-gate module* `Derived/BetaCongruenceDomainAuditUp/TasteGate.lean` *must provide* `Nontrivial BetaCongruenceDomainAu` *and* `FieldFaithful BetaCongruenceDomainAuditUp` *instances for the rows* $T, M, \Pi, R, S, H, K, P, N$.

Lean4 ✓ `BEDC.Derived.BetaCongruenceDomainAuditUp.BetaCongruenceDomainAuditTasteGate single carrier alignment`

Proof. The carrier theorem fixes the finite row inventory. The NameCert obligations identify the admission, readback, handoff, ledger, transport, route, provenance, and naming fields.

The handoff theorem shows the packet is not merely a beta-step boundary: it has a discharge-facing route for binder-domain triggers. The non-escape theorem shows it is not a typed preservation theorem or unrestricted conversion rule.

These three facts are exactly the paper-side target for a nontrivial instance and a field-faithful instance: an accepted carrier has the displayed rows, and each row is recoverable without adding hidden host semantics. □

Closure status for NameCert$_{\text{BetaCongruenceDomainAudit}^{\uparrow}}$.

Constructive story: A BetaCongruenceDomainAudit$^{\uparrow}$ packet is generated from beta-domain admission rows, readback rows, a discharge-facing handoff, a binder-domain trigger ledger, componentwise hsame transport, displayed Cont routes, provenance, and local naming. The BHist carrier records where beta congruence is allowed to be consumed and where the domain audit must refuse an unrestricted conversion read. Its classifier first exposes the admission surface, then the handoff and trigger ledger, and only then lets downstream consumers read the audit row. The route is finite and syntactic, not a host conversion theorem.

Theory closure: TheoryGate(NameCert$_{\text{BetaCongruenceDomainAudit}^{\uparrow}}$, seed)

Scope closed: This chapter binds the beta congruence domain audit carrier, handoff theorem, non-escape theorem, and paper-side TasteGate target.

Formal verification: FormalStatus(NameCert$_{\text{BetaCongruenceDomainAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim unrestricted conversion, typed preservation, subject reduction, or host beta-equivalence semantics.

Upgrade path: To reach obligationClosure, formalize the beta-domain admission and discharge-trigger rows as nontrivial and field-faithful carrier data.

Chapter 729

A Concrete Naming Certificate for $\mathsf{SubjectReductionObligationLedger}^{\uparrow}$

The $\mathsf{SubjectReductionObligationLedger}^{\uparrow}$ packet records the four MetaCIC discharge rows named in chapter 9377 as a finite BEDC ledger adjacent to the ordinary $\mathsf{SubjectReduction}^{\uparrow}$ certificate of chapter 483. It does not close subject reduction. It exposes the exact obligation surface that a later discharge must fill before any closed MetaCIC preservation claim can be read.

Definition 729.1 (Subject-reduction obligation ledger carrier)**.** *A* $\mathsf{SubjectReductionObligationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, A, D, I, R, O, H, C, P, N)$$

with the following displayed rows:

1. *B records the* BetaSubstitutionPreservation *discharge row consumed by the beta case;*
2. *A records the* AppArgTypeStable *discharge row consumed by application-argument congruence;*
3. *D records the* LamDomainSubjectReduction *discharge row consumed by lambda-domain congruence;*
4. *I records the* PiDomainSubjectReduction *discharge row consumed by Pi-domain congruence;*
5. *R records the parameterized subject-reduction theorem row whose visible inputs are exactly B, A, D, I;*
6. *O records the obstruction row for the unavailable closed subject-reduction statement;*
7. *H records componentwise* hsame *transport for the four obligation rows, R, O, package provenance, and local naming;*
8. *C records the displayed* Cont *routes from obligation reads to the parameterized theorem row and from closed-statement requests to the obstruction row;*
9. *P is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *the MetaCIC subject-reduction interface, and the earlier* $\mathsf{SubjectReduction}^{\uparrow}$ *packet;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionObligationLedger}^{\uparrow}}$ *row.*

The carrier contains no proof of any one of the four discharge rows, no closed subject-reduction theorem, no hidden substitution lemma, no host conversion relation, and no semantic equality model for MetaCIC terms.

Theorem 729.2 (Subject-reduction obligation ledger NameCert obligations)**.** *For every accepted* $\mathsf{SubjectReductionObligationLedger}^{\uparrow}$ *carrier* $L = (B, A, D, I, R, O, H, C, P, N)$*, the local* $\mathsf{NameCert}$ *surface consists of five finite rows:*

1. *carrier admission for the displayed packet* L*;*
2. *obligation inventory for the beta, application-argument, lambda-domain, and Pi-domain discharge rows* B, A, D, I*;*
3. *parameterized theorem routing, which permits* R *to be consumed only after all four obligation rows have been displayed;*
4. *obstruction routing, which sends any closed subject-reduction request not backed by the four rows to* O*;*
5. *non-escape provenance through* H, C, P, N*, excluding hidden discharge proofs, host conversion, erased typing derivations, semantic equality, and a global preservation theorem.*

Proof. Carrier admission is the tuple of Definition 729.1. The four discharge coordinates B, A, D, I are displayed separately, so a consumer can inspect which obligation row is present without receiving a proof of that obligation.

The parameterized theorem route is the R coordinate. Its continuation row in C has the four obligation rows as displayed inputs, and the package row P ties that route to the MetaCIC subject-reduction interface and to the earlier $\mathsf{SubjectReduction}^{\uparrow}$ certificate surface.

The obstruction route is the O coordinate. It is the consumer-facing answer for a closed statement request when the four rows have not all been discharged; it is not a substitute for any one of B, A, D, I.

The transport and naming rows H, C, P, N complete the ledger. Since the carrier has no coordinate for hidden substitution preservation, host conversion, erased typing derivations, semantic equality, or global preservation, these five rows exhaust the local certificate obligations. □

Theorem 729.3 (Subject-reduction obligation ledger non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{SubjectReductionObligationLedger}^{\uparrow}$ *packet factors through*

$$B, A, D, I, R, O, H, C, P, N.$$

Preservation-facing consumers may read the four displayed obligation rows and the parameterized theorem row. Audit-facing consumers may read the obstruction row. No consumer can extract a closed MetaCIC subject-reduction theorem, a hidden proof of beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, host conversion, erased typing semantics, or semantic equality of terms from the packet.

Proof. Start with the finite carrier. The only preservation-facing rows are B, A, D, I, R, and the only obstruction-facing row is O.

Apply Definition 729.2. The obligation inventory separates the four rows, the parameterized theorem route requires those rows before R is consumed, and the obstruction route keeps a closed-statement request attached to O.

Finally read the transport, continuation, package, and naming rows. They preserve and replay the same finite inventory, but none of them adds a proof row or a host semantic object. Thus every consumer remains inside $B, A, D, I, R, O, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionObligationLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionObligationLedger}^{\uparrow}$ packet is generated from four displayed MetaCIC subject-reduction discharge rows, the parameterized theorem row, the obstruction row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionObligationLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 729.1, Definition 729.2, and Definition 729.3 bind the four discharge rows and the obstruction route as one finite obligation ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionObligationLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove beta substitution preservation, application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, closed consistency from reduction, global normalization, or bridge checking.

Upgrade path: Formal work remains to encode the ledger carrier and then supply checked rows for the four MetaCIC discharge obligations.

Chapter 730

A Concrete Naming Certificate for $\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}$

The $\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}$ packet names the finite subject-reduction boundary that remains after the parameterized MetaCIC theorem has been isolated. It records exactly the four discharge obligations consumed by that theorem, together with transport, replay, provenance, and local naming rows. The packet is a frontier object: it exposes the boundary without asserting a closed subject-reduction theorem.

The frontier consumes the obstruction packet of chapter 731 as the finite boundary separating named discharge obligations from a closed subject-reduction theorem.

Definition 730.1 (MetaCIC subject-reduction frontier carrier)**.** *A* $\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, A, L, P, H, C, G, N)$$

with the following displayed rows:

1. *B is the* BetaSubstitutionPreservation *obligation row;*
2. *A is the* AppArgTypeStable *obligation row;*
3. *L is the* LamDomainSubjectReduction *obligation row;*
4. *P is the* PiDomainSubjectReduction *obligation row;*
5. *H records componentwise* hsame *transport for the four obligation rows, displayed replay, provenance, and local naming;*
6. *C records the displayed* Cont *routes by which a preservation consumer reads the four obligation rows;*
7. *G is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *and the four MetaCIC subject-reduction discharge rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}}$ *row.*

The carrier has no row for the parameterized theorem itself, no row for a closed subject-reduction theorem, and no row that turns an obligation name into a proof of that obligation.

Theorem 730.2 (MetaCIC subject-reduction frontier obligation surface)**.** *For every accepted* $\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}$ *carrier*

$$F = (B, A, L, P, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}}$ *surface consists exactly of the four discharge-obligation rows* B, A, L, P*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* G*, and local naming through* N*.*

Proof. Project the carrier of Definition 730.1. Its only subject-reduction coordinates are B, A, L, P, so the visible preservation boundary is the beta-substitution, application-argument-stability, lambda-domain, and Pi-domain obligation surface.

The transport row H preserves those four coordinates componentwise, and the continuation row C displays the only routes by which a consumer may read them. Provenance through G and local naming through N package the same finite inventory as a $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}}$ row.

Since the carrier contains no theorem coordinate and no hidden discharge coordinate, the local naming surface is exactly the displayed frontier packet. □

Theorem 730.3 (MetaCIC subject-reduction frontier non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}$ *carrier factors through*

$$B, A, L, P, H, C, G, N.$$

The consumer may learn which four MetaCIC subject-reduction obligations must be supplied, and may transport or replay that finite list through the displayed rows. It cannot read a closed subject-reduction theorem, a proof of any listed obligation, an unlisted preservation principle, or an axiom from the frontier packet.

Proof. Begin with the displayed continuation row C. It names the consumer routes for the four obligation rows and supplies no endpoint outside B, A, L, P, H, G, N.

Next use componentwise transport through H. Transport preserves the same four obligation coordinates rather than adding a theorem coordinate or a discharge witness.

Finally, package the result through G and N. Package provenance and local naming certify the finite frontier surface, while the missing coordinates in the carrier rule out escape into a closed theorem, hidden proof, unlisted preservation principle, or axiom. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}$ packet is generated from the beta-substitution, application-argument-stability, lambda-domain, and Pi-domain subject-reduction obligation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 730.1, Definition 730.2, and Definition 730.3 specify the finite obligation frontier and its consumer boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, parameterized subject reduction, closed subject reduction, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of the frontier carrier, route exhaustion, and checked non-escape for the four MetaCIC subject-reduction discharge rows.

Chapter 731

A Concrete Naming Certificate for MetaCICSubjectReductionObstruction$^{\uparrow}$

The MetaCICSubjectReductionObstruction$^{\uparrow}$ packet turns the MetaCIC subject-reduction obstruction into finite BEDC data. It records the checked parameterized subject-reduction theorem, the four named discharge obligations, the closed-term consistency obstruction theorem, the audit consumer, and the NameCert rows that keep this surface separate from a closed subject-reduction theorem.

The obstruction packet is consumed beside chapter 717 for the four discharge slots and beside chapter 739 for the closed-normal branch. The present carrier keeps those sibling surfaces separate, so the missing subject-reduction edge cannot be read as a full consistency theorem.

Definition 731.1 (MetaCIC subject-reduction obstruction carrier)**.** *A* MetaCICSubjectReductionObstruction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (T, B, A, L, \Pi, K, U, H, C, P, N)$$

with the following displayed rows:

1. *T is the checked parameterized MetaCIC subject-reduction theorem row, naming* BEDC.MetaCIC.subject_reductio *as a four-input interface;*
2. *B is the beta-substitution preservation obligation row consumed by the beta case;*
3. *A is the application-argument stability obligation row consumed by application-argument congruence;*
4. *L is the lambda-domain subject-reduction obligation row consumed by lambda-domain congruence;*
5. *Π is the Pi-domain subject-reduction obligation row consumed by Pi-domain congruence;*
6. *K is the checked obstruction row naming* BEDC.MetaCIC.closed_consistency_reduction_obstruction_not_availab
7. *U is the audit-consumer row for self-compilation, consistency, and manuscript citation checks;*
8. *H records componentwise* hsame *transports for the theorem row, four obligation rows, obstruction row, audit consumer, and local structural rows;*
9. *C records the displayed* Cont *routes for reading the parameterized theorem, the four obligations, the obstruction theorem, and the audit consumer without leaving the packet;*

10. *P is the* Pkg *provenance over MetaCIC typing, beta reduction, closed-term consistency,* BHist*,* hsame*,* Cont*, and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObstruction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the visible rows $T, B, A, L, \Pi, K, U, H, C, P, N$.

Theorem 731.2 (MetaCIC subject-reduction obstruction NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICSubject}}$ *surface for Definition 731.1 consists of carrier admission, four-obligation exposure, parameterized-theorem exactness, checked-obstruction readback, audit-consumer accountability, componentwise* hsame *stability, displayed* Cont *route stability,* Pkg *provenance, and non-escape from an unparameterized closed subject-reduction theorem.*

Proof. Carrier admission is projection from the displayed tuple O. The theorem row T, the four obligation rows B, A, L, Π, the obstruction row K, the audit consumer U, and the structural rows H, C, P, N are all finite coordinates.

The four-obligation exposure is componentwise: B names beta substitution preservation, A names application-argument stability, L names lambda-domain subject reduction, and Π names Pi-domain subject reduction. The parameterized theorem row T consumes exactly those obligation rows and does not erase them.

Checked-obstruction readback is the role of K. The audit consumer can inspect T, B, A, L, Π, K only through C, while H, P, N record transport, provenance, and local naming. Since the carrier has no coordinate for a closed subject-reduction theorem, non-escape follows by inspection of the packet. □

Theorem 731.3 (MetaCIC subject-reduction obstruction consumer boundary)**.** *Every self-compilation, consistency, or manuscript consumer of an accepted* $\mathsf{MetaCICSubjectReductionObstruction}^{\uparrow}$ *packet reads the MetaCIC subject-reduction boundary only through*

$$T, B, A, L, \Pi, K, U, H, C, P, N.$$

The consumer may cite the parameterized theorem row, inspect the four obligation rows, and read the checked obstruction row, but it receives no closed subject-reduction theorem, hidden substitution lemma, host normalization principle, or ambient consistency shortcut.

Proof. Start from the carrier in Definition 731.1. The consumer coordinate U names the downstream audit route, and the continuation coordinate C records how that route reads the finite packet.

Apply Definition 731.2. It forces the consumer to see the parameterized theorem together with the four discharge obligations and the checked obstruction row.

The remaining rows H, P, N supply only transport, package provenance, and local naming for the same packet. None of the coordinates names a closed subject-reduction theorem, a hidden substitution lemma, a host normalization principle, or an ambient consistency shortcut, so the consumer boundary is exact. □

Theorem 731.4 (MetaCIC subject-reduction obstruction no-escape)**.** *An accepted* MetaCICSubjectReductionObstru *carrier cannot be used to recover an unparameterized closed subject-reduction theorem. Agreement on the rows $T, B, A, L, \Pi, K, U, H, C, P, N$ fixes the public obstruction surface, but it does not identify any proof of the four discharge obligations, any closed subject-reduction proof, or any stronger consistency theorem outside the finite packet.*

Proof. Use the classifier clause from the carrier definition. Public comparison is restricted to the theorem row, the four obligation rows, the obstruction row, the audit consumer, and the displayed structural rows.

The NameCert obligations expose K as the checked obstruction readback and expose T as a parameterized theorem row. Thus the public surface records both what is available and which four inputs remain required.

If a consumer tried to read a closed subject-reduction proof, it would need a coordinate outside $T, B, A, L, \Pi, K, U, H, C, P, N$. No such coordinate is present. The packet therefore fixes the obstruction boundary without manufacturing any proof beyond the displayed MetaCIC rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObstruction}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSubjectReductionObstruction}^{\uparrow}$ packet is generated from the parameterized subject-reduction theorem row, the four discharge-obligation rows, the checked obstruction theorem row, an audit-consumer row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObstruction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 731.1, Definition 731.2, Definition 731.3, and Definition 731.4 bind the MetaCIC subject-reduction obstruction as a finite NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObstruction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close the four MetaCIC discharge obligations, unparameterized closed subject reduction, closed-term consistency beyond the checked obstruction surface, Lean verification for this packet, or a public standard bridge.

Upgrade path: Formal closure requires checked carrier admission, four-obligation exposure, parameterized-theorem exactness, checked-obstruction readback, consumer accountability, transport stability, route stability, provenance, and non-escape for the same finite packet.

Chapter 732

A Concrete Naming Certificate for $\mathsf{NormalFalseExclusion}^{\uparrow}$

The $\mathsf{NormalFalseExclusion}^{\uparrow}$ packet exposes the closed-normal exclusion row from chapter 9375 as finite BEDC naming data. It sits beside the subject-reduction obstruction packet of chapter 731: the present chapter names the already-normal false-proof exclusion, while the sibling obstruction records why arbitrary closed proofs are not transported into that normal fragment.

Definition 732.1 (NormalFalseExclusion carrier)**.** *A* $\mathsf{NormalFalseExclusion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, C, B, Y, H, R, P, N)$$

with the following visible rows:

1. *T is the closed MetaCIC proof-term row whose type read is internal False;*
2. *C records the closedness witness for T;*
3. *B records the* $\mathsf{BetaStrong}$ *normality witness for T;*
4. *Y is the internal False typing row consumed by the MetaCIC consistency assembly;*
5. *H records componentwise* hsame *transports for the closedness, normality, false typing, theorem row, provenance, and local naming rows;*
6. *R records displayed* Cont *routes for reading the closed proof-term row, the normality row, and the false typing row without leaving the packet;*
7. *P is the* Pkg *provenance over MetaCIC typing, closedness, beta-strong normality,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{NormalFalseExclusion}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a reduction sequence from an arbitrary closed proof, a subject-reduction theorem, a host consistency theorem, a quotient proof identity, or a hidden normalization selector.

Theorem 732.2 (NormalFalseExclusion NameCert obligations)**.** *For every accepted* $\mathsf{NormalFalseExclusion}^{\uparrow}$ *carrier*

$$F = (T, C, B, Y, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NormalFalseExclusion}^{\uparrow}}$ *surface consists of carrier admission, closed proof-term exposure, beta-strong normality exposure, internal False typing exposure, componentwise* hsame *stability, displayed* Cont *route stability,* Pkg *provenance, and non-escape from arbitrary closed consistency or subject-reduction transport.*

Proof. Project the carrier of Definition 732.1. The proof-term row, closedness row, normality row, false typing row, transport row, route row, provenance row, and local naming row are all displayed coordinates.

The closed-normal obligations are componentwise. The row C supplies closedness, B supplies beta-strong normality, and Y supplies internal False typing for the same proof-term row T.

The structural rows then restrict all consumer access. Transports through H, routes through R, provenance through P, and naming through N replay only the displayed rows, so the local certificate has no source for arbitrary reduction, subject reduction, quotient proof identity, or host consistency. □

Theorem 732.3 (NormalFalseExclusion displayed route admission)**.** *For an accepted* $\mathsf{NormalFalseExclusion}^{\uparrow}$ *carrier*

$$F = (T, C, B, Y, H, R, P, N),$$

the displayed rows T, C, B, Y, H, R, P, N *are the only admitted route from a closed term row, its closedness witness, its beta-strong normality witness, and its internal False typing row to the local* $\mathsf{NameCert}_{\mathsf{NormalFalseExclusion}^{\uparrow}}$ *row. No route is admitted through subject reduction, arbitrary normalization, quotient proof identity, host consistency, or an external proof-search coordinate.*

Proof. Project the carrier in Definition 732.1. Its visible input side is exactly the closed proof-term row T, closedness row C, beta-strong normality row B, and false typing row Y.

Apply Definition 732.2. The structural rows H, R, P, N are the only transport, route, provenance, and local naming rows available to the certificate.

Finally use the boundary inventory of Definition 732.6. Since the checked closed-normal exclusion consumes precisely the displayed rows and the carrier has no subject-reduction or arbitrary-normalization coordinate, the admitted route is exactly the listed finite route. □

Theorem 732.4 (NormalFalseExclusion route stability)**.** *Componentwise* hsame *transport through* H *and displayed* Cont *replay through* R *preserve exactly the route*

$$T, C, B, Y, H, R, P, N$$

from the closed-normal false-proof input rows to the local $\mathsf{NameCert}_{\mathsf{NormalFalseExclusion}^{\uparrow}}$ *row. They do not create a second route through reduction semantics, global normalization, quotient proof identity, or host consistency.*

Proof. Start with the route admitted by Definition 732.3. The only transport-bearing row is H, and the only continuation-bearing row is R.

Use Definition 732.2 to replay those rows componentwise. The replay can move the displayed closedness, normality, false typing, provenance, and naming coordinates, but it cannot introduce an unlisted coordinate.

The closed-normal boundary of Definition 732.6 is therefore stable under the same replay. The non-displayed routes remain absent because the carrier still contains no subject-reduction, normalization, quotient-identity, or host-consistency row after transport. □

Theorem 732.5 (NormalFalseExclusion consumer route exactness)**.** *Every consumer of the checked* no_closed_normal_proof_of_false *row factors through the displayed route rows*

$$T, C, B, Y, H, R, P, N$$

of the accepted NormalFalseExclusion$^{\uparrow}$ *carrier. Such a consumer cannot read subject reduction, arbitrary normalization, quotient proof identity, host consistency, or any hidden consistency principle.*

Proof. Project the consumer surface from Definition 732.1. Any consumer starts with the finite tuple F and therefore sees only the rows T, C, B, Y, H, R, P, N.

Invoke Definition 732.2 and Definition 732.3. These identify the route from the closed-normal input rows to the local naming row and make the structural rows part of the same route.

Close by Definition 732.6 and Definition 732.8. The checked exclusion rejects the displayed closed-normal false-proof input, while the non-escape inventory rules out every stronger read demanded by arbitrary closed consistency. □

Theorem 732.6 (NormalFalseExclusion closed-normal boundary)**.** *An accepted* NormalFalseExclusion$^{\uparrow}$ *carrier cannot contain a closed beta-strong normal proof term whose internal type is False. Equivalently, any attempted read of the displayed rows T, C, B, Y is rejected by the MetaCIC closed-normal false-proof exclusion theorem before it can be exported as a consumer-facing proof row.*

Lean4 ✓ `BEDC.MetaCIC.no closed normal proof of false`

Proof. Read the closedness, beta-strong normality, and internal False typing rows from the carrier. These are exactly the inputs named by the closed-normal exclusion node in chapter 9375.

Apply the checked MetaCIC exclusion theorem. It rules out a closed proof term of internal False once beta-strong normality is already part of the input.

The conclusion is a boundary statement for the displayed packet. It rejects the closed-normal false-proof row, but it does not derive a reduction route from arbitrary closed proofs into normal form. □

Theorem 732.7 (NormalFalseExclusion subject-reduction boundary)**.** *The* NormalFalseExclusion$^{\uparrow}$ *packet names only the already-normal false-proof exclusion. It does not supply the subject-reduction route needed to reduce an arbitrary closed proof of internal False to the normal-form input of Definition 732.6; that route remains outside the packet and is recorded by chapter 731.*

Proof. Inspect the carrier coordinates. They include a proof-term row, closedness, beta-strong normality, internal False typing, structural transport, routes, provenance, and local naming.

No coordinate records a beta-reduction path from an arbitrary closed proof to T. No coordinate records a subject-reduction theorem along such a path.

Thus the packet can invoke the closed-normal exclusion only when normality is already displayed. The neighboring subject-reduction obstruction chapter names the missing route and prevents this packet from being read as a full closed consistency certificate. □

Theorem 732.8 (NormalFalseExclusion consumer non-escape)**.** *Every consumer of an accepted* NormalFalseExclusion$^{\uparrow}$ *packet can read only the finite rows*

$$T, C, B, Y, H, R, P, N.$$

The consumer may use the checked closed-normal exclusion on those rows, but it receives no arbitrary closed-proof normalization, no subject-reduction discharge, no host consistency principle, no quotient proof identity, and no hidden proof search oracle.

Proof. Start from Definition 732.1. The tuple F lists the whole consumer surface.

Use Definition 732.2 for the certificate obligations. It confines reads to the closed proof-term row, the normality row, the internal False typing row, and the displayed structural rows.

Finally use Definition 732.6. The checked exclusion rejects the closed-normal false-proof input itself, while the absence of arbitrary normalization and subject-reduction coordinates blocks every stronger consistency read. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalFalseExclusion}^{\uparrow}}$.

Constructive story: A $\mathsf{NormalFalseExclusion}^{\uparrow}$ packet is generated from a closed proof-term row, a beta-strong normality row, an internal False typing row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalFalseExclusion}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 732.1, Definition 732.2, Definition 732.3, Definition 732.4, Definition 732.5, Definition 732.6, Definition 732.7, and Definition 732.8 bind the carrier, NameCert obligations, displayed route admission, route stability, consumer route exactness, closed-normal boundary, subject-reduction boundary, and consumer non-escape as the closed packet scope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalFalseExclusion}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.MetaCIC.no\_closed\_normal\_proof\_of\_false`

Bridge status: none

Origin: human

Not claimed: This chapter does not close arbitrary closed consistency, subject reduction, normalization of arbitrary closed proof terms, quotient proof identity, host consistency, or bridge checking.

Upgrade path: Scoped closure requires the same displayed closed-normal packet to bind carrier admission, route stability, consumer exactness, boundary, and non-escape as one closed scope.

Chapter 733

A Concrete Naming Certificate for $\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}$

The $\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}$ packet realizes the closed-normal MetaCIC consistency assembly of chapter 9375 as finite BEDC data. It sits beside the obstruction ledger of chapter 726 and the subject-reduction frontier of chapter 730: those packets display the blocked lift, while this one records the positive normal-form consistency node and the exact boundary that prevents it from becoming full closed consistency.

Definition 733.1 (Closed-normal consistency boundary carrier)**.** *A* $\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, C, N, F, O, R, H, Q, P, M)$$

with the following displayed rows:

1. *T is the empty-context MetaCIC typing row for the closed proof candidate;*
2. *C is the closedness row for the same term;*
3. *N is the beta-strong normality row consumed by the closed-normal consistency theorem;*
4. *F is the displayed internal false-type row;*
5. *O is the checked no-closed-normal-false row and the closed-normal consistency assembly row read as positive obstruction-to-false data;*
6. *R is the subject-reduction refusal row inherited from the closed reduction obstruction;*
7. *H records componentwise* hsame *transport for the typing, closedness, normality, false-type, positive theorem, refusal, route, provenance, and naming rows;*
8. *Q records the displayed* Cont *routes by which a consumer reads the positive closed-normal node before it reaches the refusal boundary;*
9. *P is the* Pkg *provenance over the MetaCIC consistency assembly, the reduction obstruction ledger, the subject-reduction frontier,* BHist, hsame, Cont, *and local certificate rows;*
10. *M is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unparameterized closed subject-reduction theorem, no route from arbitrary closed proofs to beta-strong normal proofs, no hidden discharge of beta substitution or dependent-codomain stability, and no host consistency theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.ClosedNormalConsistencyBoundaryUp.ClosedNormalConsistencyBoundaryTasteGate single carrier alignment`

Theorem 733.2 (Closed-normal consistency boundary NameCert obligations)**.** *For an accepted* $\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}$ *carrier* $B = (T, C, N, F, O, R, H, Q, P, M)$*, the local* NameCert *surface exposes exactly the empty-context typing row* T*, closedness row* C*, beta-strong normality row* N*, false-type row* F*, positive closed-normal consistency row* O*, subject-reduction refusal row* R*, componentwise transport* H*, displayed replay routes* Q*, package provenance* P*, and local naming* M*. A consumer may eliminate only the closed normal false-proof configuration displayed by* T, C, N, F, O*; it may not use the packet as a full closed consistency theorem.*

Lean4 ✓ `BEDC.Derived.ClosedNormalConsistencyBoundaryUp.ClosedNormalConsistencyBoundaryUp taste gate boundary`

Proof. Project the carrier of Definition 733.1. The rows T, C, N, F display the precise closed normal false-proof input consumed by the positive theorem row O.

Use the assembly chapter chapter 9375. Its positive node is closed-normal consistency, so the elimination route requires beta-strong normality as an input row rather than deriving it from an arbitrary closed proof.

Use the sibling obstruction ledger chapter 726 and the subject-reduction frontier chapter 730. They account for the missing lift through the displayed refusal and frontier rows, which this packet records as R instead of erasing.

The support rows H, Q, P, M transport, replay, package, and name the same inventory. Since no further coordinate is present, the local certificate exposes the closed-normal boundary and does not export closed subject reduction or full closed consistency. □

Theorem 733.3 (Closed-normal consistency boundary non-discharge)**.** *The* $\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}$ *packet does not discharge the MetaCIC subject-reduction frontier. Every request to turn an arbitrary closed false proof into the beta-strong input required by* O *must pass through the refusal row* R *and the sibling frontier packets of chapter 726 and chapter 730; no compiler semantics, host normalization theorem, quotient conversion, hidden discharge proof, or ambient consistency principle can replace those rows.*

Proof. Begin with the positive route. The carrier exposes O only together with T, C, N, F, so the theorem it packages is the closed-normal node described in chapter 9375.

Now consider a request for full closed consistency. Such a request needs a route from arbitrary closed typing to the beta-strong row N while preserving the false-type row F.

The only row addressing that route is R. By the construction of the packet, R points outward to the obstruction ledger and subject-reduction frontier rather than supplying the missing preservation theorem internally.

Finally inspect the remaining support rows. Transport, replay, provenance, and local naming preserve the displayed packet, but none of them adds compiler semantics, quotient conversion, a hidden discharge proof, or an ambient consistency principle. Thus the boundary is recorded without discharging it. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}$ packet is generated from empty-context typing, closedness, beta-strong normality, internal false typing, the positive closed-normal consistency row, the subject-reduction refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 733.1, Definition 733.2, and Definition 733.3 bind the finite positive-normal node and its blocked closed-consistency lift.

Formal verification: FormalStatus(NameCert$_{\mathsf{ClosedNormalConsistencyBoundary}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove closed subject reduction, beta-substitution preservation, dependent-codomain stability, full closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exact positive-theorem consumption, refusal replay, provenance accounting, transport stability, and non-escape for the same finite packet.

Chapter 734

A Normal-Fragment Certificate for $\mathsf{ClosedNormalConsistency}^{\uparrow}$

This chapter turns the closed-normal node of chapter 9375 into a concrete finite packet. It sits next to chapter 731: the present packet records the positive beta-strong normal fragment, while the sibling obstruction packet records why that fragment is not silently promoted to closed subject reduction.

Definition 734.1 (Closed-normal consistency packet)**.** *A* $\mathsf{ClosedNormalConsistency}^{\uparrow}$ *packet is a finite* BHist *carrier*

$$Q = (T, F, S, K, H, C, P, N)$$

with the following rows:

1. *T is the empty-context MetaCIC typing row for a closed proof candidate;*
2. *F is the internal false-type row named by the displayed typing certificate;*
3. *S is the beta-strong normality row used by the closed-normal theorem;*
4. *K is the checked closed-normal consistency row naming* BEDC.MetaCIC.closed_normal_consistency_assembly*;*
5. *H records componentwise* hsame *transports for the typing, false-type, beta-strong, and theorem rows;*
6. *C records the displayed* Cont *routes by which a consumer reads those rows;*
7. *P is the* Pkg *provenance over MetaCIC typing, closedness, beta-strong normality,* BHist*,* hsame*,* Cont*, and* NameCert*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistency}^{\uparrow}}$ *row.*

The carrier has no coordinate for host consistency, closed subject reduction, hidden normalization transport, or an ambient logical shortcut.

Definition 734.2 (Closed-normal consistency classifier)**.** *The classifier for* $\mathsf{ClosedNormalConsistency}^{\uparrow}$ *compares accepted packets only through the visible rows T, F, S, K, H, C, P, N. Two packets are classifier-equivalent exactly when the empty-context typing row, false row, beta-strong normality row, checked closed-normal theorem row, componentwise transports, displayed routes, package provenance, and local naming row agree through the displayed* hsame *data.*

Theorem 734.3 (Closed-normal consistency normal-fragment boundary)**.** *Every accepted* ClosedNormalConsistency *packet exposes a positive consistency statement only for the beta-strong normal fragment. A consumer may read T, F, S, K, H, C, P, N and conclude that a closed beta-strong proof candidate typed at the internal false row is impossible through the checked closed-normal row K. The packet does not assert that an arbitrary closed proof candidate reaches such a normal row while preserving its displayed type.*

Proof. Start from the carrier of Definition 734.1. Its theorem coordinate K names the closed-normal assembly row, and the coordinates T, F, S provide exactly the displayed typing, false-type, and beta-strong inputs read by that row.

The structural rows H, C, P, N keep the same finite evidence under componentwise transport, route replay, provenance, and local naming. They do not add a reduction sequence or a type-preservation theorem.

Thus the consumer obtains the beta-strong normal contradiction and nothing outside that fragment. Host consistency, closed subject reduction, hidden normalization transport, and ambient logical shortcuts are absent from the carrier. □

Theorem 734.4 (Closed-normal consistency subject-reduction frontier)**.** *The* ClosedNormalConsistency$^{\uparrow}$ *packet is separate from the subject-reduction frontier recorded by chapter 731. Agreement on T, F, S, K, H, C, P, N does not supply the four MetaCIC subject-reduction discharge rows, a closed subject-reduction theorem, or a transport from arbitrary closed proofs to beta-strong normal inhabitants of the same displayed false type.*

Proof. Read the classifier in Definition 734.2. It fixes the positive normal-fragment packet by the rows T, F, S, K, H, C, P, N and has no coordinates for the beta-substitution, application-argument, lambda-domain, or Pi-domain discharge rows.

Compare this with the sibling obstruction packet in chapter 731. That chapter names the missing subject-reduction surface as a different finite packet, so it cannot be recovered by reclassifying the closed-normal rows.

Consequently the closed-normal packet cannot transport arbitrary closed proofs to the normal fragment. It keeps the positive theorem and the subject-reduction frontier as distinct BEDC objects. □

Theorem 734.5 (Closed-normal consistency NameCert obligation surface)**.** *The local* NameCert$_{\text{ClosedNormalConsistency}}$ *obligation surface consists of carrier admission, classifier exactness, closed-normal theorem readback, beta-strong normal-fragment exposure, componentwise* hsame *transport, displayed* Cont *route replay,* Pkg *provenance, and non-escape from host consistency, closed subject reduction, hidden normalization transport, and ambient logical shortcuts.*

Proof. Carrier admission and classifier exactness are supplied by Definition 734.1 and Definition 734.2. They restrict all visible data to T, F, S, K, H, C, P, N.

The closed-normal theorem readback is the row K, consumed together with the typing row T, false row F, and beta-strong row S. The structural rows H, C, P, N preserve that same finite surface through transport, route replay, provenance, and local naming.

Non-escape follows by inspection of the packet. None of its rows names host consistency, closed subject reduction, hidden normalization transport, or an ambient logical shortcut, so the NameCert surface cannot export those claims. □

Theorem 734.6 (Closed-normal consistency scoped route)**.** *Every scoped read of a* ClosedNormalConsistency$^{\uparrow}$ *packet must expose the empty-context typing row, internal false row, beta-strong normality row,*

checked closed-normal theorem row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistency}^{\uparrow}}$ *row. The same read separately preserves the subject-reduction frontier of chapter 731: it does not import the four subject-reduction discharge rows, a closed subject-reduction theorem, or a transport from arbitrary closed proofs to beta-strong normal inhabitants of the same false type.*

Proof. The carrier and classifier of Definition 734.1 and Definition 734.2 restrict every accepted packet to T, F, S, K, H, C, P, N. These rows display the empty-context typing, false-type, beta-strong, checked theorem, transport, replay, provenance, and local naming data.

The normal-fragment boundary of Definition 734.3 supplies the positive read only inside the beta-strong fragment. The subject-reduction frontier of Definition 734.4 keeps the sibling obstruction packet separate from that read.

Finally, the NameCert obligation surface of Definition 734.5 records the same finite rows as the local obligation boundary. Composing these displays yields a scoped route for the normal-fragment certificate while preserving the subject-reduction frontier as a distinct BEDC object. □

Corollary 734.7 (Closed-normal consistency strict local obstruction)**.** *For an accepted* $\mathsf{ClosedNormalConsistency}^{\uparrow}$ *packet, the obstruction carried by the normal-fragment boundary is strict and local. It blocks only the converse route that would turn an arbitrary closed proof candidate into a beta-strong normal inhabitant of the same displayed false row, and only the reuse route that would treat* T, F, S, K, H, C, P, N *as evidence for host consistency, closed subject reduction, hidden normalization transport, or an ambient logical shortcut. The displayed separation cannot be reinterpreted as a global impossibility theorem, a host theorem, or hidden external validation outside the named* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistency}^{\uparrow}}$ *surface.*

Proof. By Definition 734.3, every consumer-facing positive use of the packet passes through the visible rows T, F, S, K, H, C, P, N. The only contradiction exposed there is the beta-strong normal-fragment contradiction read through the checked row K together with the typing, false-type, and beta-strong rows T, F, S. The same theorem also excludes the converse route from an arbitrary closed proof candidate to such a normal row while preserving the displayed type.

By Definition 734.5, the local obligation surface is exhausted by carrier admission, classifier exactness, closed-normal theorem readback, beta-strong normal-fragment exposure, componentwise hsame transport, displayed Cont route replay, Pkg provenance, and local non-escape. In particular, none of the available rows names host consistency, closed subject reduction, hidden normalization transport, or an ambient logical shortcut.

Therefore any attempted consumer interpretation outside those rows must ask for either the excluded converse route or an unlisted reuse coordinate. The packet supplies neither. Its obstruction is consequently confined to those named local routes, and it has no content as a global impossibility claim, host-level theorem, or external validation principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistency}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedNormalConsistency}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 734.1, Definition 734.2, Definition 734.3, Definition 734.4, Definition 734.5, and Definition 734.6 enumerate the carrier, classifier, closed-normal readback, beta-strong exposure, transport and replay, provenance, subject-reduction frontier obligations, and scoped route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedNormalConsistency}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.MetaCIC.closed\_normal\_consistency\_assembly`

Bridge status: none

Not claimed: This chapter does not close host consistency, closed subject reduction, hidden normalization transport, Lean verification, public bridge checking, or an ambient logical shortcut.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, closed-normal theorem readback, beta-strong normal-fragment exposure, transport and replay stability, provenance non-escape, and the subject-reduction frontier.

Constructive story: A ClosedNormalConsistency$^{\uparrow}$ packet is generated from empty-context typing, an internal false row, beta-strong normality, the checked closed-normal theorem row, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 735

A Concrete Naming Certificate for $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$

The $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ packet gives the confluence audit map of chapter 9378 a finite BEDC landing. It is a sibling of the subject-reduction boundary packets chapter 719, chapter 723, and chapter 717: those chapters separate the dependent typing discharge rows, while the present packet separates the residual substitution boundary for MetaCIC confluence.

Definition 735.1 (MetaCIC confluence audit packet carrier)**.** *A* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, C, N, A_0, S, R, H, T, P, L)$$

with the following displayed rows:

1. *D is the conditional* BetaParallel *diamond row, naming the substitution-compatibility input and the parallel diamond obtained from it;*
2. *C is the closed-diamond-to-star-confluence row, naming the route from a closed parallel diamond to closed* BetaStarStep *confluence;*
3. *N records the unconditional closed-normal confluence fragment;*
4. *A_0 records the atom, sort, closed-variable-impossible, and non-lambda-application shape fragments that do not consume the full substitution input;*
5. *S is the substitution-compatibility boundary row, stating that the packet names the input and the obstruction without proving the input;*
6. *R is the subject-reduction separation row, linking the confluence boundary to the sibling subject-reduction packets without merging the two interfaces;*
7. *H stores componentwise* hsame *transports for the displayed rows;*
8. *T stores the displayed* Cont *routes by which consumers read the conditional bridges, the unconditional fragments, and the non-claim boundary;*
9. *P is the* Pkg *provenance over MetaCIC reduction,* BetaParallel, BetaStarStep, *closedness,* BHist, hsame, Cont, *and* NameCert*;*
10. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}}$ *row.*

The local classifier relates two carriers exactly when their ten displayed rows compare componentwise through H and are replayed through the routes in T. The carrier contains no coordinate proving BetaParallelSubstitutionCompatibility*, no coordinate proving* BetaParallelDiamondClosed*, and no coordinate for arbitrary closed-term Church–Rosser.*

Lean4 ✓ `BEDC.Derived.MetaCICConfluenceAuditPacketUp.MetaCICConfluenceAuditPacketTasteGate`
`single carrier alignment`

Theorem 735.2 (MetaCIC confluence audit packet obligations)**.** *For the carrier of Definition 735.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}}$ *surface consists exactly of carrier admission for* $A = (D, C, N, A_0, S, R, H, T, P, L)$*, conditional parallel-diamond exposure, closed-diamond-to-star-confluence exposure, closed-normal and atom fragment exposure, substitution-boundary exposure, subject-reduction separation, componentwise* hsame *transport, displayed* Cont *route replay,* Pkg *provenance, and the local naming row.*

Proof. Project the accepted packet through Definition 735.1. The rows D and C give the conditional bridge surface: D exposes the substitution-sensitive parallel diamond, and C exposes the route from a closed parallel diamond to closed star confluence.

The rows N and A_0 give the unconditional fragment surface. They record closed-normal confluence and the atom or impossible-source cases without adding the full substitution-compatibility row as a proved theorem.

The boundary rows S and R then fix the negative reading. The first names the substitution compatibility input as a boundary, and the second keeps the confluence audit separate from the sibling subject-reduction discharge packets. Transport, route replay, provenance, and local naming are exactly the rows H, T, P, L, so the displayed coordinates exhaust the obligation surface. □

Theorem 735.3 (MetaCIC confluence audit packet conditional boundary)**.** *An accepted* MetaCICConfluenceAuditP *carrier may be cited for the conditional route from substitution compatibility to a parallel diamond and for the conditional route from a closed parallel diamond to closed* BetaStarStep *confluence. It may not be cited as a proof of* BetaParallelSubstitutionCompatibility*, as a proof of* BetaParallelDiamondClosed*, or as arbitrary closed-term Church–Rosser.*

Proof. Inspect the first two rows of the carrier. The row D records a bridge that consumes the substitution-compatibility input, and the row C records a bridge that consumes the closed parallel-diamond input.

The row S is the explicit substitution-boundary row. It states that the input is named and routed, not generated by the packet.

Since the carrier has no coordinate whose projection is the input itself, no consumer can turn the displayed bridges into unconditional endpoints. The accepted readings are therefore conditional bridge citations and the listed unconditional fragments, not the full confluence claims. □

Theorem 735.4 (MetaCIC confluence audit packet closed substitution boundary)**.** *An accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier may expose* BetaParallelClosedSubstitutionCompatibility *only as a closed-face boundary whose inputs include* ClosedAt 0 *a and* ClosedAt 1 *b. The unclosed substitution obstruction remains outside that face, so the packet may not cite the obstruction as a closed-diamond proof or as a discharge of the closed Church–Rosser substitution input.*

Proof. Project the row S. It records substitution compatibility as a named boundary, and Definition 735.3 already states that the generic substitution input is not produced by the packet.

The closed face is narrower than the generic input. Its stated compatibility requires the closedness hypotheses ClosedAt 0 a and ClosedAt 1 b, while the Lean-side theorem `betaParallel_closed_substitution_` records the obstruction that prevents the unclosed path from supplying those closed inputs.

Therefore a downstream closed Church–Rosser consumer still needs an explicit closed compatibility row. The audit packet can route the boundary and can name the obstruction, but it cannot convert the obstruction into the closed substitution premise demanded by the closed diamond route. □

Lean4 ✓ `BEDC.Derived.MetaCICConfluenceAuditPacketUp.MetaCICConfluenceAuditPacketClosedSubstitutionBound`

Theorem 735.5 (MetaCIC confluence audit closed-face coverage)**.** *Let*

$$A = (D, C, N, A_0, S, R, H, T, P, L)$$

be an accepted MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier. Every closed-face confluence consumer of A that cites the closed diamond route must first read the rows $D, C, N, A_0, S, H, T, P, L$ together with the displayed hypotheses* ClosedAt 0 a *and* ClosedAt 1 b*. The row R may be read only as the subject-reduction separation pointer to neighboring discharge packets, not as a closed-face confluence row.*

Proof. Project the accepted carrier through Definition 735.1. The rows available to a closed-face confluence consumer are the conditional diamond row D, the closed-diamond-to-star row C, the normal and source-shape rows N, A_0, the substitution-boundary row S, and the structural rows H, T, P, L.

Compose the two boundary theorems. Theorem 735.3 keeps the route through D, C conditional, while Definition 735.4 requires the displayed closedness hypotheses before the closed substitution face may be cited.

The subject-reduction row is separate. The row R points to the neighboring subject-reduction discharge packets, so it can record a horizontal dependency but cannot replace $D, C, N, A_0, S, H, T, P, L$ in a closed-face confluence read.

Thus the coverage claim is exactly the displayed closed-face boundary. It does not promote the packet to full substitution compatibility, arbitrary subject reduction, BetaParallelDiamondClosed, or unrestricted closed Church–Rosser. □

Theorem 735.6 (MetaCIC confluence audit residual-substitution determinacy)**.** *Let*

$$A = (D, C, N, A_0, S, R, H, T, P, L)$$

be an accepted MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier. Any residual-substitution read of A is determined by the substitution-boundary row S together with the transport, replay, provenance, and local naming rows H, T, P, L and the closed-face hypotheses named by Definition 735.4. This determinacy is a boundary reading only: it cannot be promoted to* BetaParallelSubstitutionCompatibility*,* BetaParallelDiamondClosed*, subject reduction, or unrestricted closed Church–Rosser.*

Proof. Project the carrier of Definition 735.1. The residual-substitution coordinate is S, and the only structural rows available to transport or replay that coordinate are H, T, P, L.

Use the conditional and closed-substitution boundaries. Theorem 735.3 prevents the conditional diamond row from becoming an unconditional substitution theorem, while Definition 735.4 confines the closed face to its displayed closedness hypotheses.

The determinacy claim is therefore row-level. Once S and the closed-face hypotheses are fixed, H, T, P, L determine the residual-substitution read of the accepted carrier, but the remaining rows add no stronger coordinate.

Finally inspect the absent coordinates. The carrier has no proof row for BetaParallelSubstitutionCompatibility, BetaParallelDiamondClosed, subject reduction, or unrestricted closed Church–Rosser, so no consumer can promote the residual-substitution boundary into those claims. □

Theorem 735.7 (MetaCIC confluence audit closed-face obligations)**.** *Let $A = (D, C, N, A_0, S, R, H, T, P, L)$ be an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier. Any closed-face confluence consumer that cites the closed diamond route must first expose the hypotheses* ClosedAt 0 *a and* ClosedAt 1 *b, the substitution-boundary row S, the componentwise transport row H, the replay row T, the provenance row P, and the local name row L. The citation is a read of the displayed closed-face boundary only; it is not a proof of full substitution compatibility, arbitrary subject reduction, or unrestricted Church–Rosser.*

Proof. Project the accepted carrier through Definition 735.1. The rows available to a closed-face consumer are displayed coordinates of the same finite packet, so the substitution boundary is read as S and any transported reading is routed through H, T, P, L.

Apply Definition 735.4. It confines the face to the hypotheses ClosedAt 0 a and ClosedAt 1 b before the closed diamond route may be cited.

The remaining rows do not add a stronger metatheorem. The carrier has no coordinate for full substitution compatibility, arbitrary subject reduction, or unrestricted Church–Rosser, so the consumer obligation is exactly the displayed closed-face exposure and not a promotion beyond it. □

Theorem 735.8 (MetaCIC confluence audit closed-face row separation)**.** *Let $A = (D, C, N, A_0, S, R, H, T, P, L)$ be an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier. Even when the closed-face hypotheses* ClosedAt 0 *a and* ClosedAt 1 *b are displayed, the substitution-boundary row S and subject-reduction separation row R remain boundary and handoff rows. They may route a closed-face confluence consumer, but they cannot be cited as* BetaParallelSubstitutionCompatibility*,* BetaParallelDiamondClosed*, subject reduction, or unrestricted Church–Rosser.*

Proof. Project the accepted carrier through Definition 735.1. The substitution data are named by S, the subject-reduction boundary is named by R, and the closed-face route is read through the displayed rows D, C, N, A_0 together with H, T, P, L.

Apply Definition 735.3 and Definition 735.4. These theorems keep the conditional confluence rows and closed substitution row tied to displayed hypotheses rather than promoting them to unrestricted substitution compatibility or a closed diamond theorem.

Use Definition 735.5 and Definition 735.6. Coverage exposes only the finite closed face, while determinacy keeps the residual-substitution read at the row level once the closed-face hypotheses are fixed.

Finally apply Definition 735.7. The closed-face consumer must pass through S, R, H, T, P, L as boundary data, and no carrier coordinate supplies the excluded global metatheorems. □

Theorem 735.9 (MetaCIC confluence audit obligation scope upgrade)**.** *Let $A = (D, C, N, A_0, S, R, H, T, P, L)$ be an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier. The scoped obligation surface of A separates three readable boundaries: the closed-face confluence route through D, C, N, A_0, the residual-substitution boundary through S, H, T, P, L, and the subject-reduction boundary through R and chapter 719. The separation upgrades the packet only to scoped obligation inventory: it does not assert full substitution compatibility, unrestricted Church–Rosser, or a combined confluence-and-typing theorem.*

Proof. Project the accepted carrier through Definition 735.1. The rows D, C, N, A_0 name the closed confluence fragments, S names the residual-substitution boundary, R names the subject-reduction separation row, and H, T, P, L carry transport, replay, provenance, and local naming.

Use the ground recognition boundary of chapter 1048 and the finite reflection tuple boundary of chapter 993 to keep these rows finite and readable. They provide recognition and reflection routing, not a new metatheorem stronger than the displayed rows.

Finally compare with the subject-reduction discharge socket. The socket is a sibling dependency read by R, so the confluence packet can cite it as a boundary while keeping typing discharge outside the confluence carrier. The result is exactly a scoped obligation inventory and not a proof of the excluded global principles. □

Theorem 735.10 (MetaCIC confluence audit closed-face scope)**.** *For an accepted carrier $A = (D, C, N, A_0, S, R, H, T, P, L)$, every closed-face confluence read factors through the displayed rows D, C, N, A_0, H, T, P, L and the closedness hypotheses required by Definition 735.7. The residual substitution row S may be cited only as the boundary of the face, and the subject-reduction row R may be cited only as a sibling dependency route through chapter 719. No consumer of this scope obtains unrestricted substitution compatibility or closed-term Church–Rosser.*

Proof. Start with Definition 735.7. It requires the closedness hypotheses and the displayed substitution, transport, replay, provenance, and naming rows before any closed diamond route can be read.

Now restrict the confluence read to D, C, N, A_0. These rows provide the conditional diamond route, closed-diamond-to-star route, closed-normal fragment, and atom or impossible-source fragments already stored in the carrier. The finite recognition and reflection surfaces of chapter 1048 and chapter 993 keep those reads inside the displayed closed face.

It remains to account for the boundary rows. The row S records the residual substitution obstruction rather than solving it, and R points to the sibling subject-reduction discharge socket rather than importing it. Therefore the closed-face scope is the displayed finite boundary and not an unrestricted confluence theorem. □

Theorem 735.11 (MetaCIC confluence audit subject-reduction separation scope)**.** *Let $A = (D, C, N, A_0, S, R, H, T, P, L)$ be an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier. The subject-reduction information available to a confluence consumer is exactly the row R together with its transport through H, T, P, L and its dependency on chapter 719. The residual-substitution row S and the closed-face rows D, C, N, A_0 remain separate obligation families, so the carrier does not merge typing preservation, substitution compatibility, and confluence into a single public theorem.*

Proof. Project R from the carrier definition. It is the only row whose stated role is to link the confluence boundary to subject-reduction packets, and its reads are transported only by H, T, P, L.

Apply the subject-reduction discharge socket as a sibling dependency. The socket supplies the typing-discharge boundary that R may cite, while the confluence carrier keeps D, C, N, A_0 and S as separate rows.

Finally inspect the remaining coordinates. The rows D, C, N, A_0 give closed-face confluence fragments, and S records residual substitution obligations; neither row contains a subject-reduction proof. Thus the scoped surface separates the three obligation families instead of exporting a combined subject-reduction and confluence theorem. □

Theorem 735.12 (MetaCIC confluence audit closed-face decider boundary)**.** *Any finite decider row for the closed substitution face of an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier may*

be consumed only through the rows S, H, T, P, L together with the existing closed-face hypotheses. It may not be promoted to full substitution compatibility, subject reduction, global β-conversion decidability, or arbitrary closed Church–Rosser.

Proof. Project the carrier of Definition 735.1. The row S is the substitution-boundary coordinate, while H, T, P, L are the displayed transport, route replay, provenance, and local naming rows through which any finite closed-face decider must be read.

Apply Definition 735.3 and Definition 735.4. The first keeps the generic substitution input conditional, and the second confines the closed substitution face to the hypotheses ClosedAt 0 a and ClosedAt 1 b.

The nonescape reading of the carrier then prevents promotion beyond those rows. There is no coordinate for full substitution compatibility, subject reduction, global β-conversion decidability, or arbitrary closed Church–Rosser. □

Theorem 735.13 (MetaCIC confluence audit redex boundary)**.** *Let*

$$A = (D, C, N, A_0, S, R, H, T, P, L)$$

be an accepted MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier. Any redex-boundary consumer of A can read only the rows*

$$D, C, N, A_0, S, R, H, T, P, L$$

together with the closed-face hypotheses used by Definition 735.4 and Definition 735.12. That read cannot be promoted to unrestricted substitution compatibility, subject reduction, or closed Church–Rosser.

Proof. Project the carrier of Definition 735.1. A redex-boundary consumer sees exactly the displayed packet rows $D, C, N, A_0, S, R, H, T, P, L$.

Apply the conditional boundary. Theorem 735.3 keeps D, C as conditional bridge rows rather than unrestricted substitution compatibility or a closed parallel diamond theorem.

Apply the closed-substitution and closed-face boundaries. Theorem 735.4 supplies the closed-face hypotheses, and Definition 735.12 keeps finite closed-face decisions inside S, H, T, P, L.

The remaining rows do not add a stronger metatheorem. The normal-fragment, source-shape, subject-reduction separation, transport, replay, provenance, and local naming rows are finite audit data, so the redex-boundary read remains a boundary lemma and not a verification claim for substitution compatibility, subject reduction, or closed Church–Rosser. □

Theorem 735.14 (MetaCIC confluence audit closed-diamond candidate exhaustion)**.** *Let $A = (D, C, N, A_0, S, R, H, T, P, L)$ be an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier. Any closed-diamond candidate read of A is exhausted by the rows*

$$D, C, N, A_0, S, R, H, T, P, L$$

together with the displayed ClosedAt *hypotheses attached to the closed substitution face. The candidate read may consume the conditional diamond row, closed star handoff, normal-fragment rows, source-shape row, substitution-boundary row, subject-reduction separation row, transport, replay, provenance, and local naming, but it cannot be promoted to* BetaParallelSubstitutionCompatibility*,* BetaParallelDiamondClosed*, arbitrary subject reduction, or unrestricted closed Church–Rosser.*

Proof. Project the accepted carrier through Definition 735.1. A closed-diamond candidate can read only the displayed packet rows $D, C, N, A_0, S, R, H, T, P, L$.

Apply the conditional boundary of Definition 735.3. This keeps the diamond candidate tied to the conditional bridge rows D, C rather than turning it into an unconditional closed parallel diamond.

Next apply the closed substitution boundary of Definition 735.4 and the closed-face decider boundary of Definition 735.12. These force any closed-face use through S, H, T, P, L and the displayed ClosedAt hypotheses.

Finally use the subject-reduction separation and packet nonescape boundaries. The row R remains a separation row, while N, A_0 supply only the named normal and source-shape fragments. Since no carrier coordinate names full substitution compatibility, a closed parallel diamond theorem, arbitrary subject reduction, or unrestricted closed Church–Rosser, the listed rows exhaust the candidate read. □

Theorem 735.15 (MetaCIC confluence audit packet subject-reduction separation)**.** *The subject-reduction separation row R of an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier permits downstream chapters to cite chapter 719, chapter 723, and chapter 717 as neighboring MetaCIC audit packets. It does not identify the confluence substitution boundary with the four subject-reduction discharge obligations.*

Proof. Project the row R. Its job is referential: it names the sibling subject-reduction packets as separate finite surfaces available to downstream MetaCIC audits.

Now project the confluence rows D, C, N, A_0, S. These rows concern parallel reduction, closed star confluence, closed-normal and atom fragments, and the residual substitution boundary. They do not contain beta, application-argument, lambda-domain, or Pi-domain typing-discharge coordinates.

Thus the packet records a horizontal dependency rather than a fusion of interfaces. A downstream consumer may cite both families, but each obligation must be discharged on its own carrier surface. □

Theorem 735.16 (MetaCIC confluence audit packet non-escape)**.** *Every consumer read of an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier factors through the finite rows*

$$D, C, N, A_0, S, R, H, T, P, L.$$

The packet exports no hidden confluence theorem, no unrecorded substitution lemma, no host quotient over reductions, and no conversion from conditional bridges into an unconditional closed Church–Rosser result.

Proof. Start from the carrier definition. A consumer can project only the named rows $D, C, N, A_0, S, R, H, T, P, L$.

The positive rows expose conditional bridges and unconditional fragments. The transport and route rows explain how those entries are read componentwise, and the provenance and local naming rows identify the packet boundary.

The substitution boundary row blocks the only possible escape from the conditional bridge to a full endpoint. Because no further coordinate exists, there is no hidden confluence theorem, unrecorded substitution lemma, host quotient over reductions, or conversion into arbitrary closed Church–Rosser. □

Theorem 735.17 (MetaCIC confluence audit packet obligation-closure package)**.** *For an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier, the carrier row, conditional confluence boundary,*

closed substitution boundary, subject-reduction separation, and non-escape theorem form the whole obligation surface of the packet. The surface packages the conditional confluence rows and their obstruction boundary; it does not claim arbitrary closed Church–Rosser, unparameterized subject reduction, a proof of full substitution compatibility, or a hidden conversion from conditional bridges into unconditional endpoints.

Proof. Project the carrier of Definition 735.1 and the NameCert obligations of Definition 735.2. They expose the conditional bridge rows, unconditional fragments, substitution-boundary row, subject-reduction separation row, transport, replay, provenance, and local naming.

Use the conditional boundary and closed substitution boundary, Definition 735.3 and Definition 735.4. These keep the MetaCIC audit-map obstruction visible instead of turning it into full substitution compatibility or a closed parallel diamond.

Apply the subject-reduction separation and non-escape rows, Definition 735.15 and Definition 735.16. The first prevents fusion with the sibling subject-reduction packets, and the second exhausts every consumer read by $D, C, N, A_0, S, R, H, T, P, L$. Hence the packaged surface is obligation closure for the finite packet and not a stronger MetaCIC metatheorem. □

Theorem 735.18 (MetaCIC confluence audit candidate-mediated SN boundary)**.** *Any strong-normalization-facing consumer of an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier must pass through the displayed conditional-boundary rows D, C, the closed-substitution boundary row S, the subject-reduction separation row R, the nonescape route over $D, C, N, A_0, S, R, H, T, P, L$, and the obligation-closure package before it may read a candidate-mediated normalization claim. The read may use a candidate row only as finite audit data attached to that dependency chain; it does not prove global confluence, subject reduction, full substitution compatibility, or arbitrary strong normalization.*

Proof. First project the carrier rows. The conditional confluence surface is held by D, C, while S records the closed-substitution boundary and R records the subject-reduction separation.

Apply Definition 735.3, Definition 735.4, and Definition 735.15. These rows give the finite dependency chain a consumer must read before any candidate-mediated normalization datum can be interpreted.

Now apply Definition 735.16 and Definition 735.17. The first confines the consumer to $D, C, N, A_0, S, R, H, T, P,$ and the second packages those rows as the whole obligation surface of the packet.

Thus a candidate-mediated normalization claim is only a row-facing read downstream of the displayed boundaries. Since the carrier has no coordinate for global confluence, subject reduction, full substitution compatibility, or arbitrary strong normalization, none of those principles is exported. □

Theorem 735.19 (MetaCIC confluence audit obligation surface)**.** *For an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier $A = (D, C, N, A_0, S, R, H, T, P, L)$, the confluence audit obligations are exactly the conditional diamond row D, the closed-diamond-to-star row C, the closed-normal fragment row N, the atom and source-shape fragment row A_0, the substitution-boundary row S, the subject-reduction separation row R, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. The TasteGate alignment named in the chapter's Lean marker reads these obligations as rows of the same finite packet rather than as a second MetaCIC confluence object.*

Proof. Project the carrier and apply Definition 735.2. The positive confluence reads are D, C, N, A_0, while the negative boundary and horizontal separation reads are S and R.

The kernel support rows are H, T, P, L. They give componentwise transport, consumer replay, provenance, and local naming for precisely those confluence and boundary entries.

Finally use the already displayed TasteGate carrier alignment: it reads the same carrier as the public audit packet. Thus the obligations are not transported into an untracked confluence theorem or a second carrier surface. □

Theorem 735.20 (MetaCIC confluence audit candidate-mediated strong normalization)**.** *Any candidate-mediated strong-normalization witness consumed by an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier must enter as a finite audit row attached to S and replayed through T. The packet may record that such a candidate row blocks the substitution obstruction for the displayed closed face, and it may transport the row through H with provenance P and local name L. It may not convert the candidate witness into an unconditional proof of* BetaParallelSubstitutionCompatibility*, arbitrary strong normalization, or closed Church–Rosser.*

Proof. Start with the substitution-boundary row S. It is the only coordinate that names the obstruction, so any candidate-mediated witness relevant to the obstruction must be recorded there as audit data.

Next replay the candidate row through T and transport it through H. The replay can feed the closed-face boundary described by Definition 735.4, but it remains a row of the same finite packet with provenance P and local name L.

The conditional-boundary theorem then prevents the final step from becoming unconditional. Since A has no coordinate for full substitution compatibility, arbitrary strong normalization, or closed Church–Rosser, the candidate witness is an audit row and not an exported MetaCIC theorem. □

Theorem 735.21 (MetaCIC confluence audit normal-fragment route)**.** *The normal-fragment confluence route of an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier is exactly the finite read of N, A_0, H, T, P, L. It covers the closed-normal, atom, sort, closed-variable-impossible, and non-lambda-application fragments named by the carrier, and it cites D, C, S, R only as the surrounding conditional and separation boundary. The route does not export full substitution compatibility, subject reduction, arbitrary closed-term Church–Rosser, or a host quotient over reductions.*

Proof. Project the unconditional fragment rows. The row N carries the closed-normal fragment, and A_0 carries the atom, sort, closed-variable-impossible, and non-lambda-application source-shape fragments.

Read those rows through H, T, P, L. Transport and replay keep the fragments inside the finite audit packet, while provenance and local naming record the same public carrier read used by the TasteGate alignment.

The remaining rows D, C, S, R are boundary data. They explain the conditional diamond route and the subject-reduction separation, but they do not add a coordinate for full substitution compatibility, subject reduction, arbitrary closed-term Church–Rosser, or a quotient over reductions. □

Theorem 735.22 (MetaCIC critical-pair normalization audit)**.** *For an accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier*

$$A = (D, C, N, A_0, S, R, H, T, P, L),$$

any critical-pair normalization consumer of the audit packet must route through the candidate-mediated strong-normalization row, the normal-fragment row N, the conditional parallel-diamond boundary D, C, the closed substitution boundary S, and the subject-reduction separation row R

before any confluence claim is read. The carrier may therefore audit a critical-pair normalization path only through the finite route

$$D, C, N, A_0, S, R \longmapsto H, T, P, L.$$

It exports no full substitution compatibility, no arbitrary strong-normalization theorem, no subject-reduction discharge, and no closed Church–Rosser theorem.

Proof. Project the carrier rows $D, C, N, A_0, S, R, H, T, P, L$. These are the only rows visible to a critical-pair normalization consumer.

First read the candidate-mediated strong-normalization boundary of Definition 735.20. It permits a candidate witness to be recorded as audit data attached to the obstruction surface, but it does not turn that witness into arbitrary strong normalization.

Next read the normal-fragment route of Definition 735.21. The row N and the source-shape row A_0 cover only the listed closed-normal and atom or source-shape fragments, with H, T, P, L preserving and replaying that finite surface.

The conditional and closed-substitution boundaries must still be crossed. Apply Definition 735.3 for the D, C bridge rows, and Definition 735.4 for the substitution row S.

Finally apply the subject-reduction separation of Definition 735.15. The row R keeps the confluence audit apart from the sibling subject-reduction discharge packets, so the consumer can read a normalization audit route but cannot extract full substitution compatibility, arbitrary strong normalization, subject reduction, or closed Church–Rosser. □

Theorem 735.23 (MetaCIC confluence audit critical-pair scope)**.** *For an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier*

$$A = (D, C, N, A_0, S, R, H, T, P, L),$$

any critical-pair consumer reads only through the displayed rows $D, C, N, A_0, S, R, H, T, P, L$. Candidate-mediated strong normalization may be attached as an audit row through the candidate-normalization handoff, and the normal-fragment route supplies the unconditional fragment. The scope exports no full confluence theorem, no subject reduction, no full substitution compatibility, and no arbitrary strong-normalization theorem.

Proof. Project the accepted carrier and the critical-pair normalization route of Definition 735.22. That theorem already forces a critical-pair normalization consumer through D, C, N, A_0, S, R before the structural rows H, T, P, L replay and name the read.

Attach candidate-mediated strong normalization only through the audit boundary of Definition 735.20 and the handoff of Definition 735.26. These rows record candidate evidence inside the packet; they do not export arbitrary strong normalization.

For the unconditional fragment, use Definition 735.21. Its rows N, A_0 cover only the closed-normal and source-shape fragments preserved by H, T, P, L.

Finally apply carrier nonescape from Definition 735.16. Since the carrier contains no row for full confluence, subject reduction, full substitution compatibility, or arbitrary strong normalization, no critical-pair consumer can read such a theorem from the packet. □

Theorem 735.24 (MetaCIC confluence audit residual critical-pair boundary)**.** *Every residual critical-pair read of an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier factors through the displayed rows $D, C, N, A_0, S, R, H, T, P, L$ and through the same* $\mathsf{BetaCriticalPair}$*-facing boundary named by the confluence audit packet. The read may classify a residual pair as belonging to the conditional diamond window, the normal-fragment window, or the substitution-obstruction window,*

but it does not prove closed Church–Rosser, subject reduction, full substitution compatibility, or a hidden substitution oracle.

Proof. Project the carrier. The rows D, C are the conditional diamond and closed-star routes, while N, A_0 are the normal and source-shape fragments available without the full substitution input.

Residual critical-pair data can only be attached to those rows through the boundary rows S, R and replayed by T. Componentwise transport through H keeps the same finite packet and prevents the residual classification from becoming a separate confluence theorem.

The provenance and local naming rows P, L close the packet boundary. Since the carrier has no coordinate for subject reduction, arbitrary closed Church–Rosser, full substitution compatibility, or an unrecorded substitution oracle, no residual critical-pair read can export one. □

Theorem 735.25 (MetaCIC confluence audit critical-pair coverage)**.** *Every accepted residual critical-pair consumer of a* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier*

$$A = (D, C, N, A_0, S, R, H, T, P, L)$$

is covered by exactly one of the displayed finite routes: the conditional diamond rows D, C, the normal and source-shape fragments N, A_0, the closed substitution-boundary row S, the subject-reduction separation row R, or the candidate-normalization handoff. In every case transport, replay, provenance, and local naming pass through H, T, P, L. The coverage exports no full substitution compatibility, arbitrary strong-normalization theorem, subject reduction, closed Church–Rosser theorem, or host quotient over reductions.

Proof. Project the residual consumer to the carrier rows. The carrier exposes only D, C, N, A_0, S, R as analytic confluence-audit rows and H, T, P, L as the structural rows by which those reads are transported and replayed.

If the consumer asks for the conditional diamond route, apply Definition 735.3. The rows D, C cover exactly the conditional parallel-diamond and closed-star handoff, while the substitution input remains named as a boundary.

If the consumer asks for a normal or source-shape fragment, apply Definition 735.21. The rows N, A_0 cover the closed-normal, atom, sort, closed-variable-impossible, and non-lambda-application fragments without adding the full substitution row as a proved theorem.

If the consumer asks for substitution or subject-reduction data, use Definition 735.4 and Definition 735.15. These rows cover S and R as boundary and separation data, not as full substitution compatibility or subject reduction.

It remains to cover candidate-mediated normalization reads. Apply Definition 735.26; the candidate row enters only through the displayed audit surface and is replayed by T with transport through H.

Finally apply Definition 735.24 and Definition 735.27. The first forces every residual critical-pair read into one of the displayed windows, and the second says the listed windows exhaust the obstruction ledger. Thus coverage is finite and exclusive at the packet boundary, with P, L naming the same source and with no export of the stronger MetaCIC principles excluded in the statement. □

Theorem 735.26 (MetaCIC confluence audit candidate-normalization handoff)**.** *Any candidate-normalization row consumed by an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier must enter through the substitution-boundary row S, the normal-fragment row N, or the source-shape fragment*

row A_0, and must be replayed through T with componentwise transport H. The handoff may route a candidate witness to a displayed normal-fragment or closed-face obstruction check, but it does not convert that witness into arbitrary strong normalization, subject reduction, full substitution compatibility, or global confluence.

Proof. Start with the candidate-mediated strong-normalization boundary already recorded in Definition 735.20. A candidate row relevant to the confluence audit is an audit datum attached to the obstruction surface, not a theorem outside the packet.

The normal-fragment route then restricts how the row is consumed. It may interact with N and A_0, and it may be replayed through T over the same packet, but the boundary rows D, C, S, R remain conditional and separated from subject-reduction discharge.

Finally apply carrier non-escape. The rows H, P, L transport, source, and name the same handoff, while the packet contains no coordinate for arbitrary strong normalization, subject reduction, full substitution compatibility, or global confluence. The candidate-normalization handoff therefore remains a finite audit route. □

Theorem 735.27 (MetaCIC confluence audit obstruction ledger exhaustion)**.** *The obstruction ledger of an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier is exhausted by the conditional bridge rows D, C, the normal-fragment rows N, A_0, the substitution-boundary row S, the subject-reduction separation row R, the residual critical-pair boundary, and the candidate-normalization handoff. A consumer that reads all those rows has read the whole finite obstruction surface; there remains no hidden row for closed Church–Rosser, subject reduction, full substitution compatibility, or an implicit substitution oracle.*

Proof. First collect the positive and boundary rows from the carrier. The rows D, C, N, A_0, S, R are the only analytic coordinates for confluence, normal fragments, substitution obstruction, and subject-reduction separation.

Next add the two displayed consumer routes. The residual critical-pair boundary and candidate-normalization handoff explain how downstream audits may consume those rows without creating a stronger MetaCIC theorem.

Finally use transport, replay, provenance, and local naming. The rows H, T, P, L preserve and name the same finite surface, and no further coordinate is present. Thus the ledger is exhausted exactly at the stated boundary and cannot conceal closed Church–Rosser, subject reduction, full substitution compatibility, or a substitution oracle. □

Theorem 735.28 (MetaCIC confluence audit substitution-obligation inversion)**.** *Any consumer that claims to use an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier for closed substitution compatibility must invert the carrier to the explicit substitution-obligation row S together with the transport, replay, provenance, and local naming rows H, T, P, L. Residual critical-pair reads, candidate-normalization reads, normal-fragment reads, and subject-reduction-separation reads do not supply S.*

Proof. Begin with Definition 735.3 and Definition 735.4. The former exposes only the conditional rows D, C, while the latter names S as the closed-substitution boundary row.

The residual, candidate, normal-fragment, and subject-reduction routes are then bounded by Definition 735.24, Definition 735.26, and Definition 735.27. They can consume the displayed audit surface but cannot manufacture the missing substitution row.

Thus a substitution-compatibility consumer must read S directly and replay it through H, T, P, L. Without that inversion, the packet exports only boundary data and not full closed substitution compatibility. □

Theorem 735.29 (MetaCIC confluence critical-pair obligations)**.** *Every accepted* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier exposes the critical-pair surface as obligation rows rather than as a closed confluence theorem. The rows include candidate-mediated overlap formation, bounded local diamond witness, and normal-form readback nonescape, each routed through the carrier rows of Definition 735.1, the NameCert obligations of Definition 735.2, the residual boundary of Definition 735.24, the candidate-normalization handoff of Definition 735.26, and the obstruction ledger of Definition 735.27. These rows preserve the TasteGate discipline of the chapter: without a displayed TasteGate marker for obligation promotion, they do not promote the packet beyond seed closure and they do not export closed Church–Rosser, subject reduction, full substitution compatibility, or global confluence.*

Proof. First form the candidate-mediated overlap row. The carrier rows expose conditional bridge data, normal-fragment data, substitution-boundary data, subject-reduction separation, transports, replay, provenance, and local naming, while the candidate-normalization handoff allows a candidate witness to be consumed only through that displayed audit surface.

Next form the bounded local diamond witness row. The conditional boundary and residual critical-pair boundary route any overlap request into the finite windows already named by the packet, so the witness remains bounded by the displayed local audit rows rather than becoming an arbitrary parallel-diamond theorem.

Finally read the normal-form nonescape row. The normal-fragment theorem and obstruction-ledger exhaustion account for the closed-normal, atom, source-shape, substitution-boundary, subject-reduction, residual, and candidate rows. Since the chapter is origin-ai and carries no displayed TasteGate marker for the promotion step, the theorem records obligation content only at seed closure and leaves stronger confluence principles outside the exported surface. □

Theorem 735.30 (MetaCIC confluence critical-pair frontier)**.** *Every accepted confluence-frontier read of a* MetaCICConfluenceAuditPacket$^{\uparrow}$ *carrier must pass through the candidate-mediated strong-normalization row, the closed-face decider boundary, the residual critical-pair boundary, the critical-pair coverage row, the obstruction-ledger exhaustion row, the substitution-obligation inversion row, and the local* NameCert *route before it can be exported as a MetaCIC confluence audit packet. The export is a finite audit boundary over*

$$D, C, N, A_0, S, R, H, T, P, L,$$

not a proof of global confluence, subject reduction, full substitution compatibility, arbitrary strong normalization, or closed Church–Rosser.

Proof. Project the accepted carrier. The local route is the displayed NameCert surface over the carrier rows $D, C, N, A_0, S, R, H, T, P, L$, so any frontier read begins inside the same finite packet.

Read the normalization and closed-face rows next. The candidate-mediated strong-normalization boundary of Definition 735.20 records candidate evidence only as audit data, while the closed-face decider boundary of Definition 735.12 confines closed substitution reads to S, H, T, P, L and the stated closed-face hypotheses.

Now route residual critical-pair data through Definition 735.24 and Definition 735.25. These theorems force every residual read into one of the displayed finite windows and keep transport, replay, provenance, and local naming in H, T, P, L.

Finally apply Definition 735.27 and Definition 735.28. The first says that the listed rows exhaust the obstruction ledger, and the second says that any substitution-compatibility consumer must invert to S rather than manufacture a hidden substitution theorem. Therefore the frontier exports only the finite audit packet and none of the stronger MetaCIC principles excluded in the statement. □

Theorem 735.31 (MetaCIC confluence audit critical-pair obligation closure)**.** *For an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier*

$$A = (D, C, N, A_0, S, R, H, T, P, L),$$

the closed-face decider boundary, subject-reduction separation row, candidate-normalization handoff, critical-pair scope, critical-pair coverage theorem, and obstruction ledger together form the finite obligation surface for the critical-pair confluence audit packet. The surface is the packet route

$$D, C, N, A_0, S, R, H, T, P, L,$$

with the closed-face hypotheses and residual windows named explicitly; it is not a proof of arbitrary Church–Rosser, unchecked substitution compatibility, unbounded subject reduction, or a hidden confluence theorem outside the displayed carrier.

Proof. Project the accepted carrier to the rows $D, C, N, A_0, S, R, H, T, P, L$. The local $\mathsf{NameCert}$ row L and provenance row P keep the audit inside the same finite packet, while H and T provide only componentwise transport and replay for those displayed rows.

First read the closed-face decider and subject-reduction boundaries. Apply Definition 735.12 for the closed substitution face and Definition 735.15 for the horizontal separation row R. These two facts expose the closed-face and subject-reduction obligations without turning either one into a global MetaCIC theorem.

Next read the normalization and critical-pair routing data. Apply Definition 735.26 and Definition 735.23. The handoff allows candidate evidence only as row-facing audit data, and the scope theorem keeps every critical-pair consumer inside $D, C, N, A_0, S, R, H, T, P, L$.

Finally apply Definition 735.25 and Definition 735.27. Coverage assigns each residual read to one displayed window, and the ledger says those windows exhaust the obstruction surface. Therefore the named rows close the critical-pair obligation package and still refuse arbitrary Church–Rosser, unchecked substitution compatibility, unbounded subject reduction, and hidden confluence outside the packet. □

Theorem 735.32 (MetaCIC confluence audit finite critical-pair frontier)**.** *Every accepted* MetaCICConfluenceAuditP *carrier routes each displayed finite critical pair through exactly the candidate-normalization handoff, the residual substitution boundary, or the obstruction ledger. These are the only public outcomes of the packet frontier; there is no fourth outcome exporting arbitrary Church–Rosser, unchecked substitution compatibility, unbounded subject reduction, or hidden confluence outside the displayed rows.*

Proof. Project the carrier rows $D, C, N, A_0, S, R, H, T, P, L$. Critical-pair normalization and scope first force the read through Definition 735.22 and Definition 735.23.

The residual boundary and coverage rows then separate candidate-normalization reads from residual substitution reads by Definition 735.24, Definition 735.25, and Definition 735.26.

Finally apply Definition 735.27 and Definition 735.28. The obstruction ledger exhausts the remaining displayed rows, and substitution inversion prevents a residual read from becoming a hidden compatibility theorem, so no fourth public outcome is available. □

Theorem 735.33 (MetaCIC confluence audit candidate-obstruction classifier)**.** *For an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier*

$$A = (D, C, N, A_0, S, R, H, T, P, L),$$

every failed confluence candidate row is classified by exactly one displayed obstruction family: substitution-boundary failure through S, residual critical-pair failure through D, C, A_0, closed-face coverage failure through N, S, H, T, P, L, or subject-reduction separation failure through R. The classification is read only from the theorem rows of this chapter, namely the closed-substitution boundary, residual critical-pair boundary, closed-face decider boundary, subject-reduction separation, critical-pair coverage, obstruction-ledger exhaustion, substitution-obligation inversion, and critical-pair obligation closure.

Proof. Project the carrier to $D, C, N, A_0, S, R, H, T, P, L$. A failed candidate row first exposes which displayed audit face it attempts to read.

If the read asks for substitution compatibility, apply the closed-substitution boundary and substitution-obligation inversion rows; the obstruction is the S boundary. If it asks for residual overlap data, apply the residual critical-pair boundary, critical-pair scope, and critical-pair coverage rows; the obstruction is the residual family over D, C, A_0.

If the read asks for closed-face coverage, apply the closed-face decider boundary together with obstruction-ledger exhaustion; the obstruction is the closed-face family over N, S, H, T, P, L. If it asks for subject reduction, apply the subject-reduction separation row; the obstruction is the R family.

The obstruction ledger lists no fifth face, and the four displayed faces use disjoint carrier rows for their deciding evidence. Hence the finite case split is exhaustive and assigns exactly one obstruction family to each failed confluence candidate row. □

Theorem 735.34 (MetaCIC confluence audit candidate-obstruction determinacy)**.** *Let two failed confluence candidate rows for a* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier read the same displayed carrier rows*

$$D, C, N, A_0, S, R, H, T, P, L$$

and the same audit face. Then their obstruction classifications agree. The common family is substitution-boundary failure through S, residual critical-pair failure through D, C, A_0, closed-face coverage failure through N, S, H, T, P, L, or subject-reduction separation failure through R, according to the shared face named by the classifier.

Proof. Apply Definition 735.33 to both failed candidate rows. Since the carrier rows and the audit face are identical, both classifier reads enter the same displayed case split.

If the shared face asks for substitution compatibility, both rows are classified by the S boundary. If it asks for residual overlap data, both rows read the residual family over D, C, A_0.

If the shared face asks for closed-face coverage, both rows are classified by the family over N, S, H, T, P, L. If it asks for subject reduction, both rows are classified by the R separation family.

The classifier theorem lists no fifth family and the deciding rows for the four families are fixed by the common carrier read. Hence the two failed rows receive the same obstruction classification. This proves determinacy only for the displayed candidate obstruction surface, not global confluence, subject reduction, full substitution compatibility, or Church–Rosser. □

Theorem 735.35 (MetaCIC confluence audit scoped kernel route)**.** *Let $A = (D, C, N, A_0, S, R, H, T, P, L)$ be an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier. Before any confluence consumer can read A as a packet, the kernel-visible read exposes the diamond row D, the closed-star row C, the normal-form row N, the atom-fragment row A_0, the componentwise* hsame *transport row H, the displayed* Cont *replay row T, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}}$ *row L.*

Proof. Project the carrier of Definition 735.1. The only confluence-facing rows available to the consumer are the displayed audit rows D, C, N, A_0 together with the transport, replay, provenance, and naming rows H, T, P, L.

The substitution-boundary row S and subject-reduction separation row R remain boundary data. They can route later checks, but they are not read as global strong normalization, unrestricted confluence, full substitution compatibility, or arbitrary subject reduction.

Thus the scoped kernel route is exhausted by carrier-row projection. Any confluence consumer that has not read D, C, N, A_0, H, T, P, L has not yet read the finite audit packet itself. □

Theorem 735.36 (MetaCIC confluence audit critical-pair obligations)**.** *Let $A = (D, C, N, A_0, S, R, H, T, P, L)$ be an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier. Every candidate strong-normalization or critical-pair consumer of A must first expose the finite rows D, C, A_0, S, H, T, P, L as* BHist *entries transported by* hsame *and replayed through* Cont*. The consumer may classify a residual critical-pair face only through those rows and the local* $\mathsf{NameCert}$ *row L; it may not cite an ambient confluence proof or a hidden subject-reduction discharge.*

Proof. Project the accepted carrier through Definition 735.1. The critical-pair surface is named by the conditional confluence rows D, C, the atom and source-shape fragments A_0, and the substitution-boundary row S.

Transport and replay are constrained by H, T, P, L. These rows keep the read inside displayed BHist data and prevent a consumer from replacing the critical-pair face by a host reduction theorem.

The subject-reduction row R is a handoff pointer, not a confluence row. Hence candidate strong-normalization and critical-pair consumers receive the listed finite audit rows only, with no hidden proof of confluence or subject reduction. □

Theorem 735.37 (MetaCIC confluence audit residual stability)**.** *Let $A = (D, C, N, A_0, S, R, H, T, P, L)$ be an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier. Residual substitution readings of A are stable under componentwise* hsame *transport exactly when the substitution-boundary row S, the conditional bridge rows D, C, the closed-face row N, and the replay rows H, T, P, L are transported together. This stability is a NameCert-row claim over finite* BHist *data, not a proof of* $\mathsf{BetaParallelSubstitutionCompatibility}$*.*

Proof. Read the residual-substitution boundary as the row S. A transported read must also carry D, C for the conditional bridge, N for the closed face, and H, T, P, L for componentwise comparison, replay, provenance, and local naming.

If these rows are transported together, the residual read names the same finite audit face after replacement. If any one of them is absent, the replay route cannot determine which substitution boundary the consumer is reading.

The result is therefore row stability. Since the carrier still has no coordinate proving $\mathsf{BetaParallelSubstitutionCom}$ stable residual transport does not become the missing substitution theorem. □

Theorem 735.38 (MetaCIC confluence audit decidability handoff)**.** *Let $A = (D, C, N, A_0, S, R, H, T, P, L)$ be an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier. Any confluence decidability consumer receives a finite handoff consisting of the candidate obstruction family over D, C, A_0, S, R, the closed-face rows N, S, H, T, P, L, and the local* $\mathsf{NameCert}$ *row. The handoff may decide only which displayed audit face is available or obstructed; it does not decide unrestricted confluence, subject reduction, closed Church–Rosser, or full substitution compatibility.*

Proof. Start with the finite carrier inventory. The candidate obstruction family is read from D, C, A_0, S, R, while the closed-face consumer also reads N, S, H, T, P, L.

The classifier can therefore branch only over displayed audit faces: conditional bridge availability, residual-substitution boundary, closed-face coverage, and subject-reduction separation. Each branch is a finite BHist row with a local NameCert read.

No branch contains the excluded metatheorems. The handoff gives a decidable finite audit classification for the packet, not unrestricted confluence, subject reduction, closed Church–Rosser, or full substitution compatibility. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ packet is generated from conditional confluence bridges, unconditional closed-normal and atom fragments, a substitution-compatibility boundary row, a subject-reduction separation row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 735.1, Definition 735.2, Definition 735.3, Definition 735.4, Definition 735.15, Definition 735.9, Definition 735.10, Definition 735.11, Definition 735.45, and the checked single-carrier alignment target bind the confluence audit-map boundary as a finite mature NameCert export surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.MetaCICConfluenceAuditPacketUp.MetaCICConfluenceAuditPacketTasteGate\_single\_carrier\_`
Lean4 ✓ `BEDC.Derived.MetaCICConfluenceAuditPacketUp.taste gate`

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not prove substitution compatibility, a closed parallel diamond, arbitrary closed-term Church–Rosser, subject reduction, checked Lean coverage beyond carrier alignment, or a public standard bridge.

Upgrade path: Bridge checking requires the standard-bridge theorem for the same finite packet and its checked single-carrier alignment target.

Lemma 735.39 (Candidate-normalization sibling route)**.** *Every accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier that is read by a candidate-normalization consumer may cite chapter 5547 only as a boundary route. The audit packet contributes its conditional confluence rows, residual-substitution boundary, closed-face hypotheses, transport, replay, provenance, and local NameCert; the candidate-normalization handoff contributes the candidate gate, normal endpoint row, residual envelope, decidable boundary, and blocked-edge retention.*

Proof. Project the audit packet through Definition 735.1. Its confluence-facing data are still the rows $D, C, N, A_0, S, R, H, T, P, L$, with S retaining the substitution boundary and R acting only as a separation pointer.

Read the sibling handoff as the neighboring candidate-normalization route of chapter 5547. The composition identifies where the candidate-normalization consumer may attach to the audit map, but it does not add a new coordinate to the audit carrier.

Therefore the route preserves the existing no-claim boundary: it is not a proof of full Church–Rosser, subject reduction, unrestricted closed consistency, full substitution compatibility, or a premise-free parallel diamond. □

Theorem 735.40 (MetaCIC confluence candidate residual diamond handoff)**.** *Every candidate-normalization read consumed by an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier must expose the residual-row packet* S, R, H, T, P, L*, the finite critical-pair window* D, C, A_0*, the substitution route through* S*, and the local join budget named by the MetaCIC critical-path packet of chapter 765 before any diamond conclusion is exported. The handoff may route a candidate witness into the residual diamond boundary, but it does not export full confluence, subject reduction, full substitution compatibility, unrestricted Church–Rosser, or kernel consistency.*

Proof. Project the accepted audit carrier of Definition 735.1. The residual-facing rows are the substitution boundary S, the subject-reduction separation row R, transport H, replay T, provenance P, and the local name L.

Read the candidate-normalization sibling route of Definition 735.39 and the candidate-normalization handoff of Definition 735.26. These keep candidate evidence inside the displayed audit surface and replay it through T with componentwise transport through H.

Now attach the residual and finite critical-pair windows. Theorems Definition 735.24, Definition 735.25, and Definition 735.32 force each residual read into the displayed $D, C, A_0, S, R, H, T, P, L$ windows before any local diamond read can be interpreted.

Finally use Definition 735.27. The obstruction ledger exhausts the substitution, residual, candidate, and subject-reduction boundaries, while chapter 765 supplies the critical-path budget consumed by the handoff. Thus the candidate read reaches only the residual diamond boundary and not the stronger MetaCIC principles excluded in the statement. □

Theorem 735.41 (MetaCIC confluence audit mature crosscheck)**.** *Every mature read of an accepted* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier that consumes the candidate-normalization handoff factors through the audit anchor, candidate evidence, residual confluence envelope, decidable boundary, blocked-edge row, transport, replay, provenance, and local* $\mathsf{NameCert}$ *rows of the displayed packet. The handoff is therefore a bounded residual route; it does not export full confluence, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Start with the candidate-normalization sibling route of Definition 735.39. It allows the neighboring handoff to attach only as a boundary route, not as a new carrier coordinate.

Read the candidate evidence through Definition 735.26 and the residual envelope through Definition 735.40. These rows keep the candidate witness inside the displayed audit surface and route residual diamond use through the finite critical-pair and substitution windows.

Next expose the decidable boundary and blocked-edge row. The closed-face decider boundary, residual critical-pair boundary, and obstruction ledger force the read through $D, C, N, A_0, S, R, H, T, P, L$ before any confluence-facing conclusion can be consumed.

Finally project the audit carrier and its NameCert obligations. The rows H, T, P, L supply componentwise transport, displayed replay, provenance, and local naming for the same packet, while the carrier has no coordinate for full confluence, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency. The candidate-normalization handoff is therefore consumed only as a bounded residual route. □

Theorem 735.42 (MetaCIC confluence audit candidate-SN discharge boundary)**.** *Let*

$$A = (D, C, N, A_0, S, R, H, T, P, L)$$

be an accepted $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *carrier. A candidate strong-normalization consumer may read the audit packet only through the displayed rows* $D, C, N, A_0, S, R, H, T, P, L$ *together with the candidate-normalization sibling route of Definition 735.39. The handoff may discharge candidate-mediated finite normalization data into the audit boundary, but it does not discharge full confluence, subject reduction, closed Church–Rosser, full substitution compatibility, or kernel consistency.*

Proof. Project the accepted carrier. The displayed audit packet has exactly the rows $D, C, N, A_0, S, R, H, T, P, L$, so a candidate strong-normalization consumer starts with the same finite row surface as every other confluence-audit read.

Next attach the candidate-normalization sibling route. By Definition 735.39 and Definition 735.26, candidate evidence enters only through the displayed audit surface and is replayed by T with componentwise transport through H.

Now read the critical-pair and residual boundaries. Theorems Definition 735.25, Definition 735.24, and Definition 735.27 force each critical-pair or residual read into the conditional diamond rows, normal and source-shape fragments, substitution boundary, subject-reduction separation row, or candidate-normalization handoff.

Finally use the decidability and substitution handoff. The closed-face decider boundary and substitution-obligation inversion keep closed substitution compatibility at the explicit S, H, T, P, L face, while the subject-reduction separation row R remains a pointer to sibling discharge packets. Thus the candidate-SN consumer receives a finite audit discharge boundary and none of the full confluence, subject-reduction, closed Church–Rosser, full substitution-compatibility, or kernel-consistency endpoints. □

The $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ route consumes the critical-path classifier surface of chapter 765 and the decidable-boundary rows of chapter 749 before exporting confluence-audit rows to downstream MetaCIC consumers.

Theorem 735.43 (MetaCIC confluence audit bridge boundary)**.** *The public* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *audit packet exports a bridged boundary only through the candidate-normalization sibling route, the residual-diamond handoff, the candidate SN discharge boundary, and the sibling lattice route displayed by the hub. No bridge-facing consumer may bypass those sibling rows or read a host confluence certificate outside the finite* BHist *route named by the packet.*

Proof. Read the public audit packet through its displayed siblings. The candidate-normalization route fixes the normal-form boundary, the residual-diamond handoff records the local confluence comparison, the candidate SN discharge boundary records the terminating candidate side, and the sibling lattice route records the shared dependency order.

A bridged consumer therefore receives only the route that has passed through these four rows. Since the hub exposes no additional host certificate coordinate, the bridge boundary is exactly the displayed finite route through those siblings. □

The bridge marker records the checked single-carrier alignment as the finite confluence-audit bridge surface for $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, not a full Church–Rosser theorem.

Theorem 735.44 (MetaCIC confluence audit bridged route export)**.** *The public* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *audit packet exports a bridged boundary only through the candidate-normalization sibling route, the residual-diamond handoff, the candidate strong-normalization discharge boundary, the sibling lattice route, and the bridge boundary route. This export packages the checked single-carrier alignment as a finite confluence-audit boundary; it does not assert full substitution compatibility, unrestricted Church–Rosser, or a global confluence theorem outside the displayed audit route.*

Proof. Read the public audit packet through its existing NameCert carrier and public-closure surface. The candidate-normalization sibling route supplies the candidate shapes admitted by the packet, while the residual-diamond handoff records the local overlap boundary available to the audit.

Next use the candidate strong-normalization discharge boundary together with the sibling lattice route. These rows keep the normalization and residual evidence inside the displayed packet and prevent the audit from becoming an unrestricted substitution-compatibility theorem.

Finally apply the bridge boundary route. The checked single-carrier alignment is exported only as the bridged boundary named by those sibling rows, so the conclusion is a finite audit export and not a free Church–Rosser principle. □

Theorem 735.45 (MetaCIC confluence audit mature closure record)**.** *For an accepted* MetaCICConfluenceAuditPac *carrier, the carrier row, candidate-normalization route, residual-diamond handoff, candidate strong-normalization discharge boundary, sibling lattice route, and bridge boundary route exhaust the public mature export. The record refuses full Church–Rosser, unrestricted substitution compatibility, subject reduction, global confluence, and any host evaluator equality outside those displayed rows.*

Proof. Read the carrier row first through the NameCert obligations and the checked single-carrier alignment. This exposes only the finite audit packet and its displayed rows.

Next apply the bridged route export theorem. The candidate-normalization route, residual-diamond handoff, candidate strong-normalization discharge boundary, sibling lattice route, and bridge boundary route are the public export surface named by the hub.

No remaining row exports full Church–Rosser, unrestricted substitution compatibility, subject reduction, global confluence, or host evaluator equality. The mature record is therefore exactly the displayed public audit boundary. □

Chapter 736

A Concrete Naming Certificate for $\mathsf{ClosedNormalConsistency}^{\uparrow}$

The $\mathsf{ClosedNormalConsistency}^{\uparrow}$ packet gives the closed-normal branch of chapter 9375 a finite BEDC landing. It is deliberately downstream of chapter 731: the packet records the normal-fragment consistency object that is already assembled from closed typing, closedness, and beta-normality, while keeping the subject-reduction obstruction as a separate boundary row.

Definition 736.1 (Closed normal consistency carrier)**.** *A* $\mathsf{ClosedNormalConsistency}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, T, C, S, O, H, R, P, N)$$

with the following displayed rows:

1. *F is the closed proof-of-false target row, naming the false encoding and the empty-context typing boundary;*
2. *T is the closed-term row, recording that the inspected term is closed at the empty context;*
3. *C is the closed-normal consistency statement row, naming* BEDC.MetaCIC.ClosedNormalConsistencyAssemblyStat
4. *S is the beta-strong normality row consumed by the closed-normal consistency statement;*
5. *O is the subject-reduction obstruction handoff row, read from chapter 731;*
6. *H records componentwise* hsame *transports for the target, closed-term, statement, normality, obstruction, package, and local naming rows;*
7. *R records the displayed* Cont *routes by which consistency-audit consumers read the finite packet;*
8. *P is the* Pkg *provenance over MetaCIC typing, closed terms, beta-strong normality, the subject-reduction obstruction boundary,* BHist, hsame, Cont, *and local* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistency}^{\uparrow}}$ *row.*

The carrier contains no coordinate for full closed consistency, no unblocked closed subject-reduction theorem, no proof of the four subject-reduction discharge obligations, and no ambient normalization principle.

Theorem 736.2 (Closed normal consistency subject-reduction obstruction handoff)**.** *Every consumer of an accepted* $\mathsf{ClosedNormalConsistency}^{\uparrow}$ *packet reads the normal-fragment consistency row through*

$$F, T, C, S, H, R, P, N$$

and reads the subject-reduction boundary only through the separate obstruction row O supplied by chapter 731. The handoff permits citation of the closed-normal consistency statement for already-normal closed terms, but it does not convert the obstruction row into full closed subject reduction, closed reduction consistency, or a discharge of the beta, application-argument, lambda-domain, and Pi-domain obligations.

Proof. Project the carrier of Definition 736.1. The normal-fragment side consists of the false target row F, the closed-term row T, the statement row C, and the beta-strong row S, transported and routed only through H, R, P, N.

The obstruction side is the single row O. By Definition 731.2, that row exposes the parameterized subject-reduction theorem, the four discharge obligations, and the checked obstruction readback as a finite packet rather than as a closed subject-reduction theorem.

The consumer boundary is therefore separated into two reads. The closed-normal consistency row may eliminate a closed normal proof-of-false candidate, while the subject-reduction obstruction row records why a closed reduction route to such a normal candidate is not part of this packet.

Since no carrier coordinate supplies the four discharge obligations, an unparameterized closed subject-reduction proof, or closed reduction consistency, the handoff cannot be repacked into a stronger MetaCIC consistency claim. □

Chapter 737

A Concrete Naming Certificate for $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$

This chapter turns the closed-normal and atom part of chapter 9378 into a finite certificate packet. It sits next to chapter 731: the present packet records the checked confluence fragment already available for closed normal and atom-shaped sources, while the sibling obstruction packet keeps substitution-sensitive and subject-reduction boundaries visible.

Definition 737.1 (MetaCIC confluence normal-fragment carrier)**.** *A* $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (T, B, S, A, G, H, C, P, N)$$

with the following rows:

1. *T is the closed source term row at the empty context;*
2. *B is the beta-normality row consumed by the closed-normal confluence fragment;*
3. *S is the checked* BetaStarStep *closed-normal confluence row;*
4. *A is the atom-shape join row for sort and impossible closed-variable sources;*
5. *G is the conditional confluence-boundary row naming the remaining closed parallel-diamond and substitution-compatibility interfaces;*
6. *H records componentwise* hsame *transports for the source, normality, star-confluence, atom, boundary, package, and local naming rows;*
7. *C records the displayed* Cont *routes by which confluence consumers read those rows;*
8. *P is the* Pkg *provenance over MetaCIC beta reduction, closedness, normality, atom joins,* BHist*,* hsame*,* Cont*, and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}}$ *row.*

The carrier contains no coordinate for arbitrary closed-term Church–Rosser, no proof of BetaParallelDiamondClose *and no proof of* BetaParallelSubstitutionCompatibility*.*

Theorem 737.2 (MetaCIC confluence normal-fragment NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenc}}$ *surface for Definition 737.1 consists exactly of carrier admission, closed-source row readback, beta-normality readback, checked closed-normal star-confluence readback, atom-shape join readback, conditional-boundary exposure, componentwise* hsame *transport, displayed* Cont *route replay,* Pkg *provenance, and non-escape from arbitrary closed-term Church–Rosser.*

Proof. Carrier admission is projection from the displayed tuple J. The confluence rows are S for the closed-normal star fragment and A for the atom-shaped source fragment, with T and B supplying the closed source and beta-normality inputs.

The row G is part of the obligation surface because it names what remains conditional: a closed parallel diamond and the substitution compatibility input that would supply such a diamond. It is read as a boundary row, not as a proof of the endpoint.

The structural rows H, C, P, N carry exactly this finite packet under transport, route replay, provenance, and local naming. Since the carrier has no coordinate for an arbitrary closed-source Church–Rosser theorem, the NameCert surface cannot export one. □

Lean4 ✓ `BEDC.MetaCIC.betaParallel diamond closed normal`

Theorem 737.3 (MetaCIC confluence closed-normal scope)**.** *Every accepted* MetaCICConfluenceNormalFragment$^{\uparrow}$ *packet exposes closed multi-step confluence only for sources whose displayed closed row T is paired with the beta-normality row B. A consumer may read the checked row S through H, C, P, N, but it cannot replace B by an arbitrary closed reduction source or infer full closed-source Church–Rosser for* BetaStarStep*.*

Proof. Read the carrier rows T, B, S. The theorem row S is attached to the closed-normal input surface, so its source is not merely a closed term; it is a closed term together with the beta-normality evidence recorded by B.

Transport and route replay through H, C, P, N preserve the same dependency shape. They do not add a reduction-to-normal row, a subject-reduction row, or a closed parallel-diamond row.

Thus the consumer obtains the closed-normal confluence fragment and no stronger closed-source confluence theorem. The missing arbitrary-source step remains the boundary row G. □

Lean4 ✓ `BEDC.MetaCIC.betaStarStep confluence closed normal`

Theorem 737.4 (MetaCIC confluence atom-join scope)**.** *The atom component A of an accepted* MetaCICConfluenceNormalFragment$^{\uparrow}$ *packet exposes only the sort and impossible closed-variable joins already present in the confluence substrate. It may be consumed together with T, S, H, C, P, N as an atom-shaped supplement to the closed-normal fragment, but it does not provide a beta-redex join for arbitrary applications, lambdas, or Pi terms.*

Proof. Project the atom row A. Its role is to record the atom-shaped joins listed in chapter 9378, where sort sources join directly and closed variable sources are blocked by the closedness premise.

The row is consumed beside the normal-fragment row S, not above it. This keeps atom geometry and closed-normal confluence inside the same finite packet while leaving beta-redex and componentwise application branches outside the atom row.

Since no carrier coordinate names a substitution-compatible parallel diamond, the atom row cannot be repacked as arbitrary closed confluence. It remains a shape-limited join surface. □

Theorem 737.5 (MetaCIC confluence ledger boundary)**.** *Every confluence read exported by an accepted* MetaCICConfluenceNormalFragment$^{\uparrow}$ *packet factors through*

$$T, B, S, A, G, H, C, P, N.$$

The packet exposes closed-normal star confluence, atom-shaped joins, and the conditional-boundary ledger, but it has no row for full parallel diamond, substitution compatibility, arbitrary closed-term Church–Rosser, host normalization, or a hidden subject-reduction theorem.

Proof. Start from Definition 737.1. The only consumer-visible confluence rows are S and A, and the only row naming a larger confluence endpoint is the conditional boundary row G.

Apply Definition 737.2. It accounts for carrier admission, fragment readback, boundary exposure, and the structural rows that route the packet.

No listed coordinate contains the full parallel diamond, the substitution compatibility input, a host normalization principle, or subject reduction. The ledger is therefore exhausted by the displayed rows. □

Theorem 737.6 (MetaCIC confluence normal-fragment public certificate)**.** *The public certificate exported by* $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$ *is the finite packet* $J = (T, B, S, A, G, H, C, P, N)$ *together with the four surfaces of Definition 737.2, Definition 737.3, Definition 737.4, and Definition 737.5. A downstream consumer may cite the checked closed-normal and atom fragments through this packet while the full arbitrary closed-source confluence claim remains outside the certificate.*

Proof. The NameCert obligations identify the carrier and its local structural rows. The closed-normal theorem fixes the positive BetaStarStep scope, and the atom theorem fixes the available shape-limited joins.

The ledger theorem then exhausts the exported rows. It lists the conditional boundary row G as a boundary, so the public certificate does not erase the remaining closed parallel-diamond and substitution-compatibility inputs.

Together these rows form a finite BEDC certificate: positive where the Lean fragment is checked, and explicitly bounded where arbitrary closed confluence is not part of the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$ packet is generated from a closed source row, beta-normality row, checked closed-normal confluence row, atom-join row, conditional-boundary row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 737.1, Definition 737.2, Definition 737.3, Definition 737.4, Definition 737.5, and Definition 737.6 bind the closed-normal and atom confluence fragment as a finite NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.MetaCIC.betaStarStep\_confluence\_closed\_normal`

Bridge status: none

Origin: human

Not claimed: This chapter does not close arbitrary closed-term Church–Rosser, BetaParallelDiamondClosed, BetaParallelSubstitutionCompatibility, host normalization, or a public standard bridge.

Upgrade path: The next formal step is a checked certificate wrapper over the same carrier and a bridge once the remaining closed confluence boundary is discharged.

Chapter 738

A Concrete Naming Certificate for ClosedConsistencyReductionBoundary$^{\uparrow}$

The ClosedConsistencyReductionBoundary$^{\uparrow}$ packet turns the frontier of chapter 9375 into a finite NameCert object. It is downstream of chapter 483: the packet names the rows that would be consumed by a closed-consistency reduction path, while keeping the blocked subject-reduction discharge as a public obstruction row rather than as an available theorem. It also supplies the reduction-obstruction row consumed by the closed-normal consistency route of chapter 764, so that the closed-normal endpoint is never read as full closed consistency without the displayed discharge boundary.

Definition 738.1 (Closed-consistency reduction-boundary carrier)**.** *A* ClosedConsistencyReductionBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, Q, E, D, K, O, H, C, P, N)$$

with the following displayed rows:

1. *S is the closed source proof row, naming the empty-context proof candidate and its displayed false type;*
2. *Q is the reduction-route row, recording the finite beta route from the source proof row toward a normal endpoint;*
3. *E is the normal endpoint row, naming the reached term together with its closedness and beta-strong normality data;*
4. *D is the subject-reduction discharge row, exposing the beta, application-argument, lambda-domain, and Pi-domain obligations required before the false type may be transported along Q;*
5. *K is the closed-normal consistency row consumed after the endpoint row has retained the displayed false type;*
6. *O is the obstruction ledger row, recording that the present packet does not contain the missing closed subject-reduction discharge;*
7. *H records componentwise* hsame *transports for the source, route, endpoint, discharge, closed-normal consistency, obstruction, package, and local naming rows;*
8. *C records the displayed* Cont *routes by which consistency consumers read S, Q, E, D, K, O inside the finite packet;*

9. *P is the* Pkg *provenance over* BHist*, MetaCIC closed typing, beta-reduction routes, beta-strong normal endpoints,* hsame, Cont*, subject reduction, closed-normal consistency, obstruction rows, and local* NameCert *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionBoundary}^{\uparrow}}$ *row.*

The carrier contains no full closed consistency theorem, no unparameterized closed subject-reduction theorem, and no route that transports the displayed false type from S to E without the discharge row D.

Lean4 (definition) `BEDC.Derived.ClosedConsistencyReductionBoundaryUp.ClosedConsistencyReductionBoundaryUp`

Theorem 738.2 (Closed-consistency reduction-boundary NameCert obligations)**.** *For the carrier of Definition 738.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionBoundary}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *source exposure: every accepted packet displays the closed source proof row S together with the false type it claims to inhabit;*

2. *route exposure: the beta route Q and normal endpoint E are public rows, not ambient normalization data;*

3. *discharge exposure: the subject-reduction discharge row D is the only row that may preserve the displayed false type along Q;*

4. *normal-consistency handoff: the closed-normal consistency row K is read only after the endpoint row E has retained the displayed false type;*

5. *obstruction accounting: the ledger row O records the missing closed subject-reduction discharge and prevents K from being repacked as full closed consistency.*

Proof. Project the displayed packet R. The rows $S, Q, E, D, K, O, H, C, P, N$ are finite coordinates, so source exposure, route exposure, discharge exposure, normal handoff, and obstruction accounting are all read from the same carrier.

The subject-reduction sibling chapter 483 supplies the discipline for reading preservation as a named row rather than as an ambient conversion principle. Here that row is D, and the packet gives no second coordinate that can preserve the false type along Q.

The closed-normal consistency row K is therefore downstream of E only under the displayed discharge boundary. Since O records the missing closed discharge, the local certificate exposes the reduction boundary without closing full closed consistency. □

Theorem 738.3 (Closed-consistency reduction-boundary obstruction readback)**.** *Every downstream read of an accepted* $\mathsf{ClosedConsistencyReductionBoundary}^{\uparrow}$ *packet factors through*

$$S, Q, E, D, K, O, H, C, P, N.$$

A consumer may inspect the source proof row, reduction route, normal endpoint, subject-reduction discharge row, closed-normal consistency row, obstruction ledger, transports, continuations, provenance, and local naming certificate. It cannot read full closed consistency, a closed subject-reduction theorem, an undisplayed false-type transport, or an endpoint consistency result detached from the discharge row.

Proof. Use the classifier clause of Definition 738.1. Public comparison and downstream reading are restricted to the displayed rows and their hsame, Cont, Pkg, and NameCert provenance.

The normal endpoint can be consumed by the closed-normal consistency row only through the route and discharge rows. Thus the readback exposes the precise place where arbitrary closed proof reduction would need subject reduction, and it does not supply that missing theorem.

The non-readable objects are exactly absent from the carrier. Full closed consistency, a closed subject-reduction theorem, hidden false-type transport, and detached endpoint consistency have no coordinate in R and no continuation route in C. □

Lean4 ✓ `BEDC.Derived.ClosedConsistencyReductionBoundaryUp.ClosedConsistencyReductionBoundaryCarrier obstruction readback`

Theorem 738.4 (Closed-consistency reduction-boundary vision handoff)**.** *The* ClosedConsistencyReductionBoundar *packet realizes the frontier of chapter 9375 as finite BEDC data. It connects the closed source proof row, beta route, normal endpoint, subject-reduction discharge boundary, closed-normal consistency row, and obstruction ledger without claiming that arbitrary closed proofs can already be transported to beta-strong normal endpoints of the same displayed false type.*

Proof. Read the frontier in section 9375.3. Full closed consistency is blocked at the step where an arbitrary closed proof must retain its displayed false type along reduction to a beta-strong normal endpoint.

The carrier of Definition 738.1 names exactly that interface. The source row S, route row Q, endpoint row E, discharge row D, closed-normal consistency row K, and obstruction row O are separate finite coordinates with displayed transport, continuation, package, and naming data.

Therefore the packet is a handoff from the vision frontier to the concrete-instance layer. It records the boundary that a later formal target may consume, while the obstruction ledger keeps the manuscript from citing the packet as a proof of full closed consistency. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedConsistencyReductionBoundary}^{\uparrow}$ packet is generated from finite BHist rows for closed-consistency premises, reduction-route rows, obstruction and boundary rows, componentwise transports, displayed continuation replay, provenance, and local naming. The route exposes where a closed reduction read may use existing finite rows and where it must stop before being treated as a full consistency proof. Cont keeps each consumer read on the displayed route, hsame transports the same boundary inventory, and Pkg records the closed-normal, reduction, and audit dependencies. The packet therefore names a reduction boundary rather than a completed metatheorem.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the closed-consistency reduction-boundary carrier, route audit, obstruction preservation, and boundary statement around closed reduction consistency.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedConsistencyReductionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim full closed consistency, closed subject reduction, unrestricted reduction consistency, host conversion semantics, or quotient equality of terms.

Upgrade path: Obligation closure requires Lean encodings of the boundary carrier, route audit, obstruction preservation, and non-escape theorem.

Chapter 739

A Concrete Naming Certificate for $\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}$

The $\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}$ surface makes the assembly map of chapter 9375 into a finite naming certificate. It sits beside chapter 562: typed normal-form packets expose a finite endpoint normal-form read, while the present packet records how closedness, typing, beta-strong normality, the contradiction row, and the subject-reduction obstruction are kept as separate rows of one MetaCIC consistency boundary.

Definition 739.1 (Closed-normal consistency packet carrier)**.** *A* $\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, T, B, F, K, G, H, C, P, N)$$

with the following displayed rows:

1. *L is the closedness row for the inspected MetaCIC term at the empty context;*
2. *T is the empty-context typing row for the same term;*
3. *B is the beta-strong normality row consumed by the closed-normal theorem;*
4. *F is the internal false-type row named by the typing certificate;*
5. *K is the checked closed-normal consistency row naming* BEDC.MetaCIC.closed_normal_consistency_assembly*;*
6. *G is the subject-reduction obstruction row recording that arbitrary closed proofs are not transported to the normal fragment inside this packet;*
7. *H records componentwise* hsame *transports for the closedness, typing, beta-strong, false-type, theorem, obstruction, provenance, and local naming rows;*
8. *C records the displayed* Cont *routes by which consumers read those rows;*
9. *P is the* Pkg *provenance over MetaCIC closedness, empty-context typing, beta-strong normality, internal false, subject-reduction obstruction,* BHist*,* hsame*,* Cont*, and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}}$ *row.*

The carrier has no coordinate for full closed consistency, hidden subject reduction, host conversion, quotient behaviour, or a normalization oracle.

Lean4 ✓ `BEDC.Derived.ClosedNormalConsistencyPacketUp.ClosedNormalConsistencyPacketTasteGate`
`single carrier alignment`

Theorem 739.2 (Closed-normal consistency packet NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistenc}}$ *surface for Definition 739.1 consists of carrier admission, classifier exactness on* $L, T, B, F, K, G, H, C, P, N$*, closedness readback, empty-context typing readback, beta-strong normality readback, contradiction-row readback, checked closed-normal theorem readback, subject-reduction obstruction exposure, componentwise* hsame *transport, displayed* Cont *route replay,* Pkg *provenance, and non-escape from full closed consistency or hidden normalization transport.*

Lean4 ✓ `BEDC.Derived.ClosedNormalConsistencyPacketUp.ClosedNormalConsistencyPacketNameCertObligations`

Proof. Carrier admission is the finite row list of Definition 739.1. Classifier exactness compares only the displayed coordinates $L, T, B, F, K, G, H, C, P, N$, so no unlisted semantic equality can enter the packet.

The positive MetaCIC data are the closedness row L, the typing row T, the beta-strong row B, the false row F, and the checked theorem row K. These are exactly the rows needed to read the closed-normal contradiction fragment of chapter 9375.

The obstruction row G is a separate obligation. It records that the carrier has not supplied subject reduction from arbitrary closed proofs into the beta-strong normal fragment.

The structural rows H, C, P, N preserve and name that same finite surface. Since no coordinate names full closed consistency, hidden subject reduction, host conversion, quotient behaviour, or a normalization oracle, the local NameCert cannot export any of those claims. □

Theorem 739.3 (Closed-normal consistency normal-fragment boundary)**.** *Every accepted* ClosedNormalConsistency *carrier reads the positive closed-normal consistency fragment only through* $L, T, B, F, K, H, C, P, N$*. A consumer may use these rows to exclude a closed beta-strong proof candidate at the displayed internal false row, but the consumer obtains no route from an arbitrary closed proof candidate to that beta-strong boundary.*

Proof. Project the carrier of Definition 739.1. The rows L, T, B, F, K provide closedness, empty-context typing, beta-strong normality, the contradiction target, and the checked closed-normal theorem.

The rows H, C, P, N only transport, route, package, and locally name that surface. They do not introduce a reduction sequence or a theorem preserving typing along such a sequence.

Thus the packet supports the positive normal-fragment read and stops there. The missing route from arbitrary closed proofs is not present in the carrier. □

Theorem 739.4 (Closed-normal consistency subject-reduction gap boundary)**.** *The subject-reduction gap of a* $\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}$ *carrier is exactly the displayed obstruction row* G*. Agreement on* $L, T, B, F, K, H, C, P, N$ *cannot be repacked as closed subject reduction, as closed reduction consistency, or as a transport from arbitrary closed proof terms to beta-strong normal inhabitants of the same false type.*

Proof. The classifier for the packet fixes the positive rows L, T, B, F, K and the structural rows H, C, P, N. These rows authenticate the closed-normal contradiction fragment.

The row G is not derived from those rows; it is displayed as the boundary separating the positive fragment from the subject-reduction problem. Reading G gives the consumer a named obstruction, not a discharge of the obstruction.

Therefore the packet cannot be strengthened into closed subject reduction or closed reduction consistency by reusing the positive fragment. Any such strengthening would require a row absent from the carrier. □

Theorem 739.5 (Closed-normal consistency obstruction readback)**.** *Every closed-consistency consumer of an accepted* $\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}$ *packet that uses the positive rows* L, T, B, F, K *must also expose the obstruction row* G *before asking for arbitrary closed proof transport, closed subject reduction, or closed reduction consistency. The rows* H, C, P, N *transport, replay, source, and name the same finite surface; no absent row discharges the subject-reduction obstruction.*

Proof. Project the carrier $Q = (L, T, B, F, K, G, H, C, P, N)$ of Definition 739.1. The positive rows L, T, B, F, K read only the beta-strong normal fragment named by the closed-normal theorem row.

Apply the normal-fragment boundary, Definition 739.3. It allows the consumer to use the closedness, typing, beta-strong, false-type, and checked-theorem rows only inside that finite normal fragment.

Apply the subject-reduction gap boundary, Definition 739.4. It identifies G as the exact displayed obstruction between the positive fragment and arbitrary closed proof transport.

The structural rows do not remove the obstruction. Rows H, C, P, N preserve and name the same finite packet, so any request for closed subject reduction or closed reduction consistency still has to expose G and cannot be discharged by an absent row. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}$ packet is generated from finite BHist rows for closed-normal positive fragments, reduction-consistency evidence, a displayed obstruction boundary, transports, continuations, provenance, and local naming. The positive rows are read by Cont as finite fragment evidence, while the obstruction row stays visible as the boundary separating that fragment from closed subject reduction. Componentwise hsame preserves both positive and obstruction rows, and Pkg records the closed-normal and reduction dependencies. The packet names exactly the finite consistency surface it carries and refuses any strengthening that needs absent rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the closed-normal consistency packet carrier, positive-fragment readback, obstruction row, and non-strengthening boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyPacket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim closed subject reduction, full closed reduction consistency, host conversion semantics, quotient term equality, or hidden discharge of the obstruction.

Upgrade path: Obligation closure requires Lean encodings of the packet carrier, positive-fragment projection, obstruction preservation, and non-strengthening theorem.

Chapter 740

A Concrete Naming Certificate for NormalFormConsistencySeal$^{\uparrow}$

The NormalFormConsistencySeal$^{\uparrow}$ packet gives the closed-normal branch of chapter 9375 a finite NameCert object. It sits between the closed-context carrier of chapter 722 and the subject-reduction socket of chapter 719: the seal records what the normal-form consistency theorem consumes, and it keeps the missing subject-reduction discharge outside the packet.

Definition 740.1 (Normal-form consistency seal carrier)**.** *A* NormalFormConsistencySeal$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, F, N, K, X, H, C, P, L)$$

with the following displayed rows:

1. *T is the empty-context MetaCIC typing row for the inspected closed proof candidate;*
2. *F is the internal false-type row named by that typing certificate;*
3. *N is the beta-strong normality row for the same inspected candidate;*
4. *K is the checked closed-normal consistency row naming* BEDC.MetaCIC.closed_normal_consistency_assembly*;*
5. *X is the subject-reduction boundary row, read only through chapter 719;*
6. *H records componentwise* hsame *transports for the typing, false, normality, theorem, boundary, provenance, and local naming rows;*
7. *C records the displayed* Cont *routes by which a consumer reads those finite rows;*
8. *P is the* Pkg *provenance over MetaCIC typing, closed contexts, beta-strong normality,* BHist*,* hsame*,* Cont*, and sibling* NameCert *rows;*
9. *L is the local* NameCert$_{\text{NormalFormConsistencySeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary closed reduction, no closed subject-reduction theorem, no hidden normalization transport, and no host-level consistency principle.

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealTasteGate single carrier alignment`

Theorem 740.2 (Normal-form consistency seal obligations)**.** *Every accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet binds a local NameCert surface whose obligations are exactly carrier admission, classifier exactness for $S = (T, F, N, K, X, H, C, P, L)$, readback of the checked closed-normal theorem row K,*

componentwise hsame *transport, displayed* Cont *route replay, package provenance, and non-escape from the subject-reduction boundary row X.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealObligations`

Proof. Carrier admission is the displayed finite packet of Definition 740.1. Classifier exactness is componentwise: two seal packets compare only through the rows $T, F, N, K, X, H, C, P, L$ and the displayed hsame transports.

The theorem row K is read together with T, F, N, so the consumer obtains only the normal-form contradiction already assembled in BEDC.MetaCIC.closed_normal_consistency_assembly. The structural rows H, C, P, L preserve that same read under transport, route replay, provenance, and local naming.

The boundary row X is named but not discharged. Therefore the NameCert surface records the subject-reduction frontier without turning it into a closed subject-reduction theorem. □

Theorem 740.3 (Normal-form consistency seal subject-reduction boundary)**.** *The* NormalFormConsistencySeal$^{\uparrow}$ *packet factors every preservation-facing read through chapter 719 and every closed-context read through chapter 722. Hence the seal may eliminate a closed beta-strong proof candidate of the internal false row, but it does not provide a route from an arbitrary closed proof candidate to such a normal endpoint.*

Proof. For closed-context data, project the rows T, F, N together with the provenance row P. These rows are interpreted through the closed-term context seal, which keeps the empty-context typing and closedness information as finite BEDC data.

For preservation-facing data, project the boundary row X. Its only named consumer is the subject-reduction discharge socket, so the seal can cite the frontier while leaving the beta, application-argument, lambda-domain, and Pi-domain discharge rows outside the present carrier.

Combining these projections gives the normal-form use of K without a reduction-to-normal-form bridge for arbitrary closed proof candidates. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealSubjectReductionBoundary`

Theorem 740.4 (Normal-form consistency seal closed-normal frontier)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. The packet may export the closed-normal contradiction route exactly through the rows T, F, N, K, H, C, P, L: the typing row T, internal false row F, beta-strong normality row N, checked closed-normal theorem row K, componentwise transports, displayed continuation replay, provenance, and local naming. The row X remains only the visible subject-reduction boundary citation and cannot discharge arbitrary subject reduction or turn an arbitrary closed proof candidate into the closed-normal endpoint consumed by K.*

Proof. Project the carrier of Definition 740.1. The positive closed-normal route is carried by T, F, N, K and by the structural rows H, C, P, L that transport, replay, source, and name the same finite packet.

Apply Definition 740.2. Its readback clause exposes the checked theorem row K only together with the displayed typing, false, and beta-strong normality rows, while its non-escape clause keeps the subject-reduction boundary row separate.

Finally use Definition 740.3. That boundary permits the seal to cite X as the open preservation-facing socket, but it does not supply a closed subject-reduction theorem. Hence consumers may use the closed-normal contradiction route through T, F, N, K, H, C, P, L and no stronger subject-reduction route. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealClosedNormalFrontier`

Theorem 740.5 (Normal-form consistency seal critical-pair route)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. Any critical-pair read, residual-discharge read, or preservation-facing consumer of S must pass through the displayed finite route*

$$T, F, N, K, X, H, C, P, L.$$

The route exposes the typing row, internal false row, beta-strong normality row, checked closed-normal theorem row, subject-reduction boundary row, transport, continuation replay, provenance, and local naming, but it does not discharge subject reduction internally.

Proof. Project the carrier in Definition 740.1. Its only visible rows are $T, F, N, K, X, H, C, P, L$, so a critical-pair or residual-discharge consumer has no coordinate outside that displayed packet.

Apply Definition 740.2. The local NameCert obligations read the checked closed-normal theorem row K with the typing, false, and beta-strong normality rows, while the row X is recorded as the non-escaped subject-reduction boundary.

Use Definition 740.3 and Definition 740.4. Together they identify the closed-normal contradiction route and keep arbitrary subject-reduction discharge outside the seal.

Thus every preservation-facing read must expose $T, F, N, K, X, H, C, P, L$ before it can cite the open frontier, and the present packet cannot turn that citation into an internal subject-reduction proof. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealCriticalPairRoute`

Theorem 740.6 (Normal-form consistency seal subject-reduction socket readiness)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. Every preservation-facing consumer must read the socket row X as a visible subject-reduction boundary row and cannot treat that socket as already discharged by the closed-normal theorem row K.*

Proof. Project the carrier of Definition 740.1. The row X is separate from K, so the checked closed-normal theorem row and the subject-reduction socket occupy distinct coordinates.

Apply Definition 740.2. Its non-escape clause records the subject-reduction frontier without turning it into a closed subject-reduction theorem.

Use Definition 740.3. The boundary theorem routes preservation-facing data through the sibling subject-reduction discharge socket, and it leaves the beta, application, lambda, and Pi discharge rows outside the present seal.

Finally apply Definition 740.5. Every critical-pair or preservation-facing read must expose X with the finite packet route, so readiness of the socket is visible but not discharged. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealSubjectReductionSocketReadine`

Theorem 740.7 (Normal-form consistency seal critical-pair frontier exhaustion)**.** *For an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet $S = (T, F, N, K, X, H, C, P, L)$, every critical-pair read and residual-discharge read is exhausted by the displayed route*

$$T, F, N, K, X, H, C, P, L.$$

No additional evaluator equality, quotient syntax equality, hidden reduction schedule, or subject-reduction discharge row is exported by the seal.

Proof. Use Definition 740.5. It already identifies the displayed route required by critical-pair, residual-discharge, and preservation-facing consumers.

Apply Definition 740.4. The closed-normal contradiction route is confined to T, F, N, K, H, C, P, L, while X remains the visible subject-reduction boundary citation.

Apply Definition 740.6. Since X is only a socket row, a residual consumer cannot use it as a hidden discharge theorem.

The exhaustion claim follows from the carrier shape and the obligation theorem: the local NameCert surface contains no coordinate beyond $T, F, N, K, X, H, C, P, L$ from which an extra evaluator, quotient, reduction-schedule, or preservation row could be read. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealCriticalPairFrontierExhaustic`

Theorem 740.8 (Normal-form consistency seal MetaCIC consumer boundary)**.** *Every closed-normal MetaCIC consistency consumer of an accepted* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *packet may use the checked row K only together with the displayed closed-context typing row T, internal false row F, beta-strong normality row N, and structural rows H, C, P, L. The consumer may also cite X as an open subject-reduction socket, but not as a discharged preservation theorem.*

Proof. Project T, F, N, K from the carrier. These rows are the closed-context typing, false-type, normality, and checked closed-normal theorem data consumed by the MetaCIC consistency read.

Apply Definition 740.4. It states that the closed-normal contradiction route is exactly T, F, N, K, H, C, P, L and that X remains outside the closed-normal endpoint.

Use Definition 740.6 and Definition 740.7. Together they keep the subject-reduction socket visible and exhaust every critical-pair or residual read by the displayed finite route.

Thus a MetaCIC consumer may cite K only with the closed-context and normality rows that the packet displays, and any preservation-facing use remains a socket handoff rather than a completed theorem. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealMetacicConsumerBoundary`

Theorem 740.9 (Normal-form consistency seal constructor frontier)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *packet. The constructor frontier exported by S is exactly the closed-normal contradiction route through T, F, N, K, H, C, P, L. The subject-reduction row X remains a boundary citation: no beta, application, lambda, or Pi constructor discharge is internal to the seal.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealConstructorFrontier`

Proof. Read the carrier of Definition 740.1. The rows T, F, N, K provide the typed closed-normal false candidate and the checked closed-normal theorem row, while H, C, P, L transport, replay, source, and name that same finite route.

Apply the obligation theorem Definition 740.2. Its readback clause keeps K tied to the displayed typing, false-type, and beta-strong normality rows, and its non-escape clause prevents the boundary row X from being read as a constructor discharge.

Finally use the subject-reduction boundary and closed-normal frontier theorems, Definition 740.3 and Definition 740.4. They leave beta, application, lambda, and Pi preservation obligations at the subject-reduction socket, so the seal exports only the closed-normal contradiction route and no internal discharge for those constructors. □

Theorem 740.10 (Normal-form consistency seal critical-pair obligation)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. Any constructor-facing read of S that mentions beta, application, lambda, or Pi critical pairs must display the critical-pair boundary through $T, F, N, K, X, H, C, P, L$ before it may use the checked closed-normal theorem row K. The read cannot treat K as an arbitrary confluence theorem or as a discharge of the subject-reduction boundary row X.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealCriticalPairObligation`

Proof. Project the carrier of Definition 740.1. The row K is available only together with the typing row T, false row F, beta-strong normality row N, subject-reduction boundary row X, and the structural rows H, C, P, L.

Use Definition 740.9. It states that beta, application, lambda, and Pi constructor discharges remain outside the seal. The constructor-facing read therefore sees those critical-pair cases only as boundary data.

Finally apply Definition 740.2, Definition 740.3, and Definition 740.4. These rows permit use of K only as the displayed closed-normal contradiction route, so no arbitrary confluence or subject-reduction discharge is exported. □

Theorem 740.11 (Normal-form consistency seal residual-context obligation)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. The empty-context row T and the subject-reduction boundary row X keep every residual context transport visible: a consumer must read residual context information through the displayed rows T, X, H, C, P, L and cannot replace that route by host substitution or an ambient weakening theorem.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealResidualContextObligation`

Proof. Project the seal carrier. The row T is the empty-context MetaCIC typing row, and X is the visible subject-reduction boundary; neither row is a host substitution operation.

Apply the subject-reduction boundary theorem Definition 740.3. It forces preservation-facing data through the sibling discharge socket and keeps the closed-context read tied to the displayed finite rows.

The obligation theorem and constructor frontier, Definition 740.2 and Definition 740.9, then route all transport through H, C, P, L. Hence residual contexts remain visible BEDC data rather than an implicit host substitution principle. □

Theorem 740.12 (Normal-form consistency seal joinability obligation)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. Any joinability read must factor through all displayed rows $T, F, N, K, X, H, C, P, L$. It may use the closed-normal route named by K only after the typing, false, normality, boundary, transport, replay, provenance, and local naming rows are visible, and it may not assert arbitrary confluence or arbitrary joinability for MetaCIC terms.*

Proof. Read the carrier in Definition 740.1. The finite packet exposes exactly the rows $T, F, N, K, X, H, C, P, L$, so a joinability-facing consumer has no other coordinate to inspect.

Use Definition 740.4. The positive route is the closed-normal contradiction route through T, F, N, K, H, C, P, L, while X remains the visible subject-reduction boundary.

Now apply Definition 740.9 and Definition 740.10. The constructor and critical-pair cases are boundary obligations, not internal confluence data. Therefore any joinability read factors through the displayed seal rows and cannot export arbitrary confluence. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealJoinabilityObligation`

Theorem 740.13 (Normal-form consistency seal finite-window determinacy)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ and $S' = (T', F', N', K', X', H', C', P', L')$ be accepted* NormalFormConsistencySeal$^{\uparrow}$ *packets. Suppose the two packets agree componentwise on the displayed typing row, false-type row, beta-strong normality row, checked closed-normal consistency row, subject-reduction boundary row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. Then every closed-normal consumer read exposed by S and S' has the same BEDC classifier boundary.*

Proof. Project both carriers through Definition 740.1. The displayed agreement identifies the paired rows T, T', F, F', N, N', K, K', X, X', H, H', C, C', P, P', and L, L' componentwise.

The closed-normal read is routed through the same K row together with the same typing, false-type, and beta-strong normality rows. The boundary row X is only the visible subject-reduction frontier, so the comparison does not assert arbitrary subject reduction or move an arbitrary closed proof candidate to a normal endpoint.

The remaining agreement on H, C, P, L transports, replays, sources, and names the same finite packet. Therefore the two exposed consumer reads meet the same BEDC classifier boundary. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealFiniteWindowDeterminacy`

Theorem 740.14 (Normal-form consistency seal non-escape)**.** *No consumer of an accepted* NormalFormConsistency *packet can read a claim stronger than the displayed normal-form consistency surface. In particular, the packet exports neither full closed consistency, nor closed subject reduction, nor hidden normalization transport, nor a host equality principle beyond the displayed* hsame *rows.*

Proof. Inspect the carrier coordinates in Definition 740.1. The only theorem coordinate is K, and K is explicitly the closed-normal consistency row. The row X records the subject-reduction boundary rather than a discharge of that boundary.

The remaining coordinates H, C, P, L are structural rows for transport, routing, provenance, and local naming. They preserve the finite packet but do not add new MetaCIC reduction, typing, or normalization facts.

Thus every public read stays inside the visible normal-form seal. Anything requiring arbitrary closed reduction or full consistency must pass through a separate subject-reduction discharge packet. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealNonescape`

Theorem 740.15 (Normal-form consistency seal vision handoff)**.** *The concrete* NormalFormConsistencySeal$^{\uparrow}$ *packet realizes the assembled node of chapter 9375 as a finite BEDC object: the closed-normal theorem row is public inside the seal, while the lift to full closed consistency remains blocked until the subject-reduction socket is filled by its own discharge data.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealVisionHandoff`

Proof. The vision chapter separates three items: the available closed-normal consistency theorem, the missing subject-reduction route, and the blocked full closed-consistency conclusion. The carrier of Definition 740.1 mirrors that separation by placing K and X in different rows.

The obligation theorem and boundary theorem show how consumers may use K with the closed-context rows while routing every preservation-facing request to the sibling socket. The non-escape theorem then prevents the packet from being read as a stronger consistency claim.

Therefore the handoff is a concrete finite packet rather than a promise of a larger MetaCIC theorem. □

Theorem 740.16 (Normal-form consistency seal continuation replay)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. Every continuation replay read first projects the MetaCIC typing row T, the false-type row F, the beta-strong normality row N, the closed-normal consistency row K, and the subject-reduction boundary row X, and only then reads through the displayed* Cont *row C. No continuation consumer may bypass these rows to obtain a closed subject-reduction discharge.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealContinuationReplay`

Proof. Read the carrier in Definition 740.1. The packet lists T, F, N, K, X before the structural rows, so any replay route has a displayed typing, false-type, normality, closed-normal consistency, and boundary source.

Apply the obligation surface of Definition 740.2. It makes the continuation row part of the finite NameCert obligations for the same carrier.

The subject-reduction boundary theorem Definition 740.3 and the non-escape theorem Definition 740.14 keep the read from becoming a closed subject-reduction theorem. Thus continuation replay is a route through C after the displayed rows T, F, N, K, X have been projected. □

Theorem 740.17 (Normal-form consistency seal provenance exactness)**.** *For an accepted packet $S = (T, F, N, K, X, H, C, P, L)$, every dependency claim made by the* NormalFormConsistencySeal$^{\uparrow}$ *surface is confined to the provenance row P over MetaCIC typing, closed contexts, beta-strong normality,* BHist*,* hsame*,* Cont*, and sibling* NameCert *rows. The packet contains no additional provenance route for full closed consistency or closed subject reduction.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealProvenanceExactness`

Proof. Carrier admission in Definition 740.1 displays P as the only package provenance coordinate. The remaining structural rows H, C, L transport and name the packet but do not create dependency claims.

Use Definition 740.2 to identify the obligation rows governed by that provenance: MetaCIC typing, closed-context data, beta-strong normality, history transport, continuation routing, and the local naming surface.

The boundary result Definition 740.3 and Definition 740.14 exclude a hidden dependency on full closed consistency or a closed subject-reduction theorem. Therefore every dependency claim remains exactly in the displayed row P. □

Theorem 740.18 (Normal-form consistency seal local naming boundary)**.** *For an accepted packet $S = (T, F, N, K, X, H, C, P, L)$, the local naming row L names only this finite normal-form consistency seal. It identifies the displayed carrier, obligations, subject-reduction boundary, continuation replay, and provenance rows, but it does not discharge closed subject reduction.*

Proof. The carrier of Definition 740.1 makes L the local naming coordinate for the finite seal. It names the same packet rows T, F, N, K, X, H, C, P and no row outside the packet.

The obligation theorem Definition 740.2 supplies the local NameCert surface, while Definition 740.3 marks X as a boundary row rather than a discharge row.

The non-escape theorem Definition 740.14 prevents the local name from being read as full closed consistency, closed subject reduction, hidden normalization transport, or host equality. Hence L names the finite seal and nothing stronger. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealLocalNamingBoundary`

Theorem 740.19 (Normal-form consistency seal obligation closure)**.** *For every accepted* NormalFormConsistencySea *packet $S = (T, F, N, K, X, H, C, P, L)$, the closed-normal theorem row K is consumed only after the typing row T, false-type row F, beta-strong normality row N, subject-reduction boundary row X, componentwise transport row H, continuation replay row C, provenance row P, and local naming row L have been projected. Thus the packet closes the MetaCIC obligation surface for the displayed closed-normal theorem row while keeping arbitrary subject reduction outside the carrier.*

Proof. Project the carrier of Definition 740.1. The rows T, F, N, K, X are the only MetaCIC rows available before the structural coordinates are read.

Apply Definition 740.2. Its readback clause forces the checked closed-normal theorem row K to be consumed together with the displayed typing, false-type, and normality rows, while its boundary clause keeps X visible as a subject-reduction frontier.

Finally use continuation replay, provenance exactness, and local naming from Definition 740.16, Definition 740.17, and Definition 740.18. These rows preserve the same packet and add no closed subject-reduction discharge. Hence the closed-normal theorem row is consumed only over the stated obligation surface. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealObligationClosure`

Theorem 740.20 (Normal-form consistency seal candidate route)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. Any candidate read that attempts to use* BEDC.MetaCIC.closed_ *must first pass through the closed-context typing row T, the internal false-type row F, the beta-strong normality row N, the named theorem row K, the subject-reduction boundary row X, transport H, replay C, provenance P, and local naming L. The route contains no coordinate for arbitrary reduction to a normal endpoint, full closed consistency, or a hidden subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealCandidateRoute`

Proof. Begin with a candidate read from the finite packet. Carrier projection exposes T, F, N before the theorem row can be interpreted, so the candidate is already read as a closed, typed, beta-strong normal proof candidate for the internal false row.

The row K is the named closed-normal theorem row. By Definition 740.4, it is available only through the closed-normal route and not through a route from arbitrary closed candidates to normal endpoints.

The boundary row X and structural rows H, C, P, L then fix the public reading of the packet. The subject-reduction boundary theorem and non-escape theorem exclude any hidden discharge, so the candidate route is exactly the displayed finite route through $T, F, N, K, X, H, C, P, L$. □

Theorem 740.21 (Normal-form consistency seal candidate-mediated SN handoff)**.** *Let $S = (T, F, N, K, X, H, C, P$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. Any read of S that exports candidate-mediated strong-normalization evidence must first expose the closed typed-term row T, candidate row, normalization-frontier row, consistency-seal row K,* hsame *transport H,* Cont *replay C, provenance P, and local NameCert row L. The handoff cannot turn candidate-mediated SN into arbitrary closed subject reduction, full closed consistency, hidden normalization transport, or host equality.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealCandidateMediatedSNHandoff`

Proof. Project the seal carrier. The closed typed-term information is read through T, and the consistency-seal conclusion is read only through K together with the finite rows carried by the packet.

Use the candidate route Definition 740.20. It forces any candidate-facing read of the closed-normal theorem row to pass through $T, F, N, K, X, H, C, P, L$ rather than through an arbitrary normalization endpoint.

Use the MetaCIC discharge frontier Definition 740.23 together with the normalization-frontier chapter chapter 892. These references keep candidate-mediated SN attached to the displayed frontier and leave subject reduction at its separate discharge socket.

Finally apply the non-escape theorem Definition 740.14. The structural rows H, C, P, L preserve and name the same finite handoff, so no consumer can read a stronger consistency or normalization claim from the seal. □

Theorem 740.22 (Normal-form consistency seal reduction determinacy)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ and $S' = (T', F', N', K', X', H', C', P', L')$ be accepted* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *packets. If the two packets agree componentwise on typing, false-type, beta-strong normality, the closed-normal theorem row, subject-reduction boundary, transport, replay, provenance, and local naming, then every closed-normal theorem read from S and S' has the same BEDC classifier boundary. This determinacy is confined to the closed-normal route and does not decide arbitrary reduction, full closed consistency, or closed subject reduction.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealReductionDeterminacy`

Proof. Project both carriers. The displayed componentwise agreement identifies the pairs T, T', F, F', N, N', K, K', X, X', H, H', C, C', P, P', and L, L' as the same finite classifier boundary data.

Apply Definition 740.13. It says that agreement on exactly these rows determines the closed-normal consumer read and keeps X as a boundary row rather than a subject-reduction discharge.

The non-escape and local naming boundary theorems then rule out any additional coordinate that could distinguish the two reads by arbitrary reduction or full closed consistency. Therefore the closed-normal theorem reads have the same BEDC classifier boundary and no stronger determinacy is claimed. □

Theorem 740.23 (Normal-form consistency seal MetaCIC discharge frontier)**.** *Any* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *consumer that attempts to promote closed-normal consistency into closed consistency must first pass through the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *route of chapter 765 and the subject-reduction discharge socket of chapter 719. The seal itself exposes only the rows $T, F, N, K, X, H, C, P, L$ and supplies no closed subject-reduction discharge.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealMetacicDischargeFrontier`

Proof. Project the carrier of Definition 740.1. Its visible rows are the typing row T, false-type row F, beta-strong normality row N, checked closed-normal theorem row K, subject-reduction boundary row X, transport H, replay C, provenance P, and local naming row L.

Apply Definition 740.3 and Definition 740.4. These results identify X as a boundary citation and restrict K to the closed-normal route, so the packet can expose a closed-normal contradiction only after the displayed normality and typing rows have been read.

Apply Definition 740.22. It fixes the classifier boundary of the closed-normal read but does not provide arbitrary reduction to a normal endpoint. Thus determinacy does not turn the seal into a closed-consistency proof.

The $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet records the same open route through the subject-reduction discharge socket. A consumer seeking closed consistency must therefore leave the seal and discharge that socket; the present packet records the frontier rather than filling it. □

Theorem 740.24 (Normal-form consistency seal residual schedule discharge)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet whose candidate route, residual-context obligation, finite-window determinacy, and MetaCIC discharge frontier rows are displayed. Then S admits a single residual schedule for candidate-mediated strong-normalization and confluence checking. Every residual read in that schedule is replayed through the same continuation and provenance rows before any strong-normalization or confluence consumer may inspect the closed-normal theorem row.*

Proof. Project the accepted packet. The visible schedule has only the typing row T, false-type row F, beta-strong normality row N, checked closed-normal theorem row K, subject-reduction boundary row X, transport row H, replay row C, provenance row P, and local naming row L.

Apply Definition 740.20 and Definition 740.11. These rows put candidate-mediated normality and residual-context reads before any closed-normal theorem consumer.

Next use Definition 740.12 and Definition 740.13. They force every joinability or determinacy read to reuse the same finite window rather than opening a second residual route.

Finally apply Definition 740.23. The MetaCIC frontier keeps closed consistency behind the subject-reduction socket, while C and P replay and source the same residual schedule for any strong-normalization or confluence consumer exposed by K. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealResidualScheduleDischarge`

Theorem 740.25 (Normal-form consistency seal candidate boundary)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. Any normal endpoint read that consumes the seal must first expose the Candidate or ClosedCandidate evidence named by the candidate route, the closed-normal frontier rows T, F, N, K, X, the residual schedule rows used for candidate-mediated strong-normalization and confluence checking, componentwise* hsame *transport H,* Cont *replay C,* Pkg *provenance P, and local naming L. The boundary contains no coordinate for arbitrary reduction to a normal endpoint, global closed consistency, hidden subject reduction, evaluator equality, or quotient syntax equality.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealCandidateBoundary`

Proof. Start with the candidate route Definition 740.20. It forces every candidate-facing read of the closed-normal theorem row to pass through $T, F, N, K, X, H, C, P, L$ before the seal can be consumed.

Use the candidate-mediated SN handoff Definition 740.21. This pins the Candidate or ClosedCandidate evidence to the same displayed frontier and prevents it from becoming arbitrary closed subject reduction or full closed consistency.

Next apply the reduction determinacy and residual schedule theorems, Definition 740.22 and Definition 740.24. They identify the finite classifier boundary and require every residual read for strong-normalization or confluence checking to reuse the same replay and provenance rows.

Finally use the MetaCIC discharge frontier Definition 740.23. The frontier leaves closed consistency behind the subject-reduction socket, so the exposed boundary is exactly the candidate, closed-normal, residual-schedule, transport, replay, provenance, and local-name surface stated above. □

Theorem 740.26 (Normal-form consistency seal MetaCIC critical-path handoff)**.** *The boundary of Definition 740.25 is the handoff consumed by* MetaCICCriticalPath$^{\uparrow}$ *and by confluence-facing packets that inspect* NormalFormConsistencySeal$^{\uparrow}$*. Such consumers may cite the candidate route, closed-normal frontier, residual schedule, transport, replay, provenance, and local naming rows,*

but they may not read subject reduction, global closed consistency, evaluator equality, or quotient syntax equality from the seal itself.

Proof. Apply Definition 740.25. It packages the normal endpoint read as a finite boundary consisting of candidate evidence, closed-normal frontier rows, residual schedule rows, transport, replay, provenance, and local naming.

Use Definition 740.23. The MetaCICCriticalPath$^{\uparrow}$ consumer receives the boundary as an open handoff to the subject-reduction discharge socket, not as a completed closed-consistency theorem.

For confluence-facing packets, use Definition 740.24. The same schedule controls candidate-mediated strong-normalization and confluence checking before any consumer inspects the closed-normal theorem row.

The non-escape, candidate-mediated handoff, and reduction determinacy theorems then rule out stronger readings. The seal supplies no row for evaluator equality, quotient syntax equality, arbitrary subject reduction, or global closed consistency, so every MetaCIC critical-path or confluence-facing read is confined to the stated boundary. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealMetacicCriticalPathHandoff`
↪ variant `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealMetaCICCriticalPathHandoff`

Theorem 740.27 (Normal-form consistency seal obligation closure route)**.** *The carrier admission of Definition 740.1, the NameCert obligations of Definition 740.2, the candidate route of Definition 740.20, the residual-context obligation of Definition 740.11, the joinability obligation of Definition 740.12, finite-window determinacy of Definition 740.13, residual schedule discharge of Definition 740.24, the candidate boundary of Definition 740.25, and the MetaCIC critical-path handoff of Definition 740.26 together form the* obligation *route for the same* NormalFormConsistencySeal$^{\uparrow}$ *packet. The route records the displayed candidate, residual, joinability, determinacy, schedule, boundary, transport, replay, provenance, and local-name obligations, while closed consistency and hidden subject reduction remain outside the packet.*

Proof. Each cited theorem projects or replays the same accepted packet $S = (T, F, N, K, X, H, C, P, L)$. The carrier and NameCert obligations expose the finite rows, the candidate and residual theorems order the normal-endpoint reads, and the joinability and determinacy obligations keep those reads inside the same finite window.

The residual schedule, candidate boundary, and MetaCIC handoff then repack the same rows for strong-normalization, confluence, and critical-path consumers. None of those steps adds a row for global closed consistency or hidden subject reduction, so the assembled route is exactly the stated obligation surface. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealObligationClosureRoute`

Theorem 740.28 (Normal-form consistency seal public export)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* NormalFormConsistencySeal$^{\uparrow}$ *packet. Its public export is exactly the consumer-facing route through the candidate route, closed-normal frontier, residual schedule, componentwise transport, continuation replay, provenance, and local naming rows:*

$$T, F, N, K, X, H, C, P, L.$$

Every MetaCIC critical-path or confluence-facing consumer may cite that route as a public seal surface only after the candidate evidence, closed-normal frontier rows, residual schedule rows, hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row are displayed. The export supplies no closed subject reduction, hidden normalization transport, evaluator equality, quotient syntax equality, or host equality.*

Proof. Start with the candidate route and closed-normal frontier. Theorems 740.20 and 740.4 force every normal-endpoint read to pass through the displayed candidate evidence and the rows T, F, N, K, X before it can be consumed.

Next use the residual schedule and determinacy rows. Theorems 740.24 and 740.13 keep strong-normalization and confluence-facing reads inside the same finite schedule and prevent a second residual route from being opened.

The transport, replay, provenance, and local naming rows are fixed by Definition 740.16, Definition 740.17, and Definition 740.18. These theorems identify the public support rows as H, C, P, L and do not add any hidden normalization coordinate.

Finally apply Definition 740.25 and Definition 740.26. They package the same rows for MetaCIC and confluence-facing consumers while keeping closed subject reduction, evaluator equality, quotient syntax equality, and host equality outside the packet. Thus the public export is exactly the displayed finite surface. □

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealPublicExport`

Theorem 740.29 (Normal-form consistency seal mature treatment)**.** *Let $S = (T, F, N, K, X, H, C, P, L)$ be an accepted* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *packet. Its mature treatment is the route that first exposes the candidate route of Definition 740.20, then the residual schedule of Definition 740.24, and then the MetaCIC handoff of Definition 740.26. The route permits MetaCIC and confluence-facing consumers to inspect the closed-normal theorem row only through the displayed candidate, residual, schedule, transport, replay, provenance, and local naming rows. It refuses arbitrary normal endpoints, global closed consistency, hidden subject reduction, evaluator equality, quotient syntax equality, host equality, and any completion of the seal outside those rows.*

Lean4 ✓ `BEDC.Derived.NormalFormConsistencySealUp.NormalFormConsistencySealMatureTreatment`

Proof. Read the candidate route first. The cited route fixes the only admissible normal-endpoint evidence available to S and keeps that evidence attached to the displayed rows T, F, N, K, X.

Next read the residual schedule. The residual schedule discharge theorem supplies the single schedule used for candidate-mediated strong-normalization and confluence checks, while the finite-window determinacy theorem prevents a second residual route from being opened.

Finally use the MetaCIC handoff and the public export surface. They package the same candidate route, residual schedule, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row for downstream consumers. Because none of these rows contains global closed consistency, hidden subject reduction, evaluator equality, quotient syntax equality, or host equality, the mature treatment is exactly the stated refused-endpoint boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalFormConsistencySeal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ packet is generated from closed-context typing, false-type, beta-strong normality, closed-normal consistency, subject-reduction boundary, transport, continuation, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalFormConsistencySeal}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 740.1, Definition 740.2, Definition 740.3, Definition 740.14, Definition 740.16, Definition 740.17, Definition 740.18, Definition 740.27, Definition 740.28, and Definition 740.29 bind carrier admission, boundary routing, normal-form non-escape, continuation replay, provenance, local naming, the finite obligation route, the public export surface, and the mature candidate-residual-MetaCIC route for the same seal packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalFormConsistencySeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: paperBridge

Origin: human

Not claimed: This chapter keeps full closed consistency, closed subject reduction, hidden normalization transport, and host equality outside the finite seal.

Upgrade path: Mature closure requires machine-checked bridge verification for the listed public export and MetaCIC handoff surface, without adding closed subject reduction, hidden normalization transport, or host equality.

Chapter 741

A Concrete Naming Certificate for $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$

The $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$ packet turns the normal-source branch of chapter 9378 into finite BEDC data. It is placed after the typed reduction and preservation surfaces of chapter 562 and chapter 483: the present packet records the closed normal source, two visible beta-star routes, their displayed join, and the boundary row that prevents this normal-source seal from being read as full closed Church–Rosser.

Definition 741.1 (Closed normal confluence seal carrier)**.** *A* $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (t, n, r_1, r_2, j, H, C, P, N)$$

with the following displayed rows:

1. *t is the closed MetaCIC term row serving as the source of both beta-star routes;*
2. *n is the beta-normality witness row for t;*
3. *r_1 is the first displayed* BetaStarStep *route from t to a target row;*
4. *r_2 is the second displayed* BetaStarStep *route from t to a target row;*
5. *j is the join row supplied by the normal-source confluence theorem, recording the common target and the two residual beta-star routes into it;*
6. *H records componentwise* hsame *transports for the source, normality, route, join, provenance, and local certificate rows;*
7. *C records the displayed* Cont *routes by which consumers read the closedness witness, the normality witness, the two beta-star routes, and the join row;*
8. *P is the* Pkg *provenance over MetaCIC closed terms, beta normality,* BetaStarStep*, normal-source confluence, the closed-substitution compatibility obstruction,* BHist*,* hsame*,* Cont*, and sibling* NameCert *packets;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary closed-source confluence, no proof of BetaParallelSubstitutionCompatibi *no closed parallel diamond for all closed terms, and no hidden subject-reduction or normalization oracle.*

Lean4 (definition) `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealUp`
Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealTasteGate single carrier alignment`

Theorem 741.2 (Closed normal confluence seal normal source)**.** *Every accepted* ClosedNormalConfluenceSeal$^{\uparrow}$ *carrier exposes confluence only from the closed beta-normal source row t. A consumer may read t, n, r_1, r_2, j through H, C, P, N and obtain the displayed join of the two beta-star routes, but it cannot use the packet as a confluence theorem for an arbitrary closed source.*

Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealNormalSource`

Proof. Project the carrier of Definition 741.1. The source row t and the normality witness row n are not auxiliary decoration: they are the hypotheses that select the normal-source theorem named in chapter 9378.

The routes r_1 and r_2 are the only beta-star routes exposed by the packet, and the join row j is read only as their common normal-source join. The transport and route rows H and C replay this finite surface without adding new sources.

The sibling packets provide the typed-route and preservation discipline around the read. chapter 562 keeps terminal route access finite, while chapter 483 keeps target membership reads behind the displayed preservation boundary.

Since no coordinate supplies an arbitrary closed-source theorem, a closed parallel diamond, or a substitution-compatibility discharge, the accepted seal cannot be repacked into full closed Church–Rosser. □

Theorem 741.3 (Closed normal confluence seal join-window inversion)**.** *For every accepted* ClosedNormalConfluenc *carrier $Z = (t, n, r_1, r_2, j, H, C, P, N)$, any consumer that reads the join row j must first expose the closed source row t, the beta-normality row n, and both displayed* BetaStarStep *routes r_1, r_2. Conversely, the row j exports only the common target and residual routes attached to those two displayed routes.*

Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealJoinWindowInversion`

Proof. Project the carrier of Definition 741.1. The join coordinate j is not an independent global confluence field; it is listed after the closed source t, the beta-normality witness n, and the displayed routes r_1, r_2.

Apply Definition 741.2. It fixes the available source as the displayed closed beta-normal row and keeps both beta-star routes visible before the join is read.

The structural rows H, C, P, N transport, replay, source, and name only this finite window. Therefore a consumer of j recovers precisely the common target and residual routes attached to r_1, r_2, while arbitrary closed Church–Rosser, closed parallel diamond, substitution compatibility, subject reduction, and normalization remain outside the packet. □

Theorem 741.4 (Closed normal confluence seal public export)**.** *The public export of an accepted* ClosedNormalConfluenceSeal$^{\uparrow}$ *packet is exactly the displayed closed beta-normal source row t, the beta-normality witness row n, the two beta-star route rows r_1, r_2, the join row j, and the structural surface H, C, P, N for componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. This export contains no arbitrary closed Church–Rosser theorem, no* BetaParallelSubstitutionCompatibility *discharge, no closed parallel diamond, and no subject-reduction or normalization oracle.*

Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealPublicExport`

Proof. Start with the normal-source theorem Definition 741.2. It identifies the source of the export as the displayed closed beta-normal row t together with the normality witness n and the two beta-star route rows r_1, r_2.

The join row j is therefore read only as the join for those two displayed routes. The transport, replay, provenance, and naming rows H, C, P, N preserve that finite surface for public consumers without adding a new source or a substitution theorem.

The carrier of Definition 741.1 has no coordinate for arbitrary closed Church–Rosser, closed parallel diamond, subject reduction, or normalization. Hence the public export is exactly the finite normal-source seal and not any of the excluded global endpoints. □

Theorem 741.5 (Closed normal confluence seal substitution boundary)**.** *The* $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$ *carrier separates the available normal-source join from the substitution-compatibility boundary. Agreement on* $t, n, r_1, r_2, j, H, C, P, N$ *records the checked closed-normal confluence read, but it does not produce* BetaParallelSubstitutionCompatibility*,* BetaParallelDiamondClosed*, or arbitrary closed-term confluence for* BetaStarStep*.*

Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealSubstitutionBoundary`

Proof. Read the provenance row P. It names the checked normal-source confluence surface and also names the closed-substitution compatibility obstruction recorded by chapter 9378.

These two entries have different roles. The normal-source entry justifies the join row j for the displayed closed beta-normal source, while the obstruction entry keeps the substitution interface visible as a boundary rather than as a field filled by the carrier.

The structural rows H, C, N preserve this separation. They transport and replay the finite seal rows, but no row in the carrier contains the substitution compatibility proof, the closed parallel diamond, or the general closed star-confluence endpoint.

Therefore the packet is a local confluence seal for closed normal sources. It is not a certificate for the substitution-sensitive branch that would be needed to close arbitrary closed-term Church–Rosser. □

Theorem 741.6 (Closed normal confluence seal obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}}$ *obligation surface consists of carrier admission for*

$$t, n, r_1, r_2, j, H, C, P, N,$$

closed normal-source exposure, the two displayed beta-star route rows, the displayed join row, route stability, transport stability, provenance, and boundary nonescape from substitution compatibility or full Church–Rosser.

Proof. Carrier admission is the row inventory of Definition 741.1. It exposes the closed source t, the normality row n, the two beta-star routes r_1, r_2, the join row j, and the structural rows H, C, P, N.

The normal-source component is supplied by Definition 741.2. It restricts the join row to the displayed closed beta-normal source and prevents the route from being read as arbitrary closed-source confluence.

The boundary clauses are supplied by Definition 741.5. They keep substitution compatibility, the closed parallel diamond, and full closed Church–Rosser outside the obligation surface while leaving the finite normal-source seal available to local consumers. □

Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealObligationSurface`

Theorem 741.7 (Closed normal confluence seal carrier admission ledger)**.** *An accepted* ClosedNormalConfluenceSea *carrier admits exactly the displayed rows*

$$t, n, r_1, r_2, j, H, C, P, N$$

as its local admission ledger: closed source, beta-normality, two beta-star routes, their normal-source join, componentwise transport, continuation replay, provenance, and local naming.

Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealCarrierAdmissionLedger`

Proof. Project the carrier in Definition 741.1. The first five rows record the closed source, normality witness, two beta-star routes, and the join row supplied by the normal-source confluence theorem.

The final four rows record the admissible BEDC infrastructure for reading those data. The transport row H and replay row C keep the read componentwise and displayed, while P and N record provenance and local naming.

No further coordinate is available in the carrier. Hence the admission ledger is exactly $t, n, r_1, r_2, j, H, C, P, N$. □

Theorem 741.8 (Closed normal confluence seal route stability)**.** *If two accepted* $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$ *carriers agree componentwise along the displayed* hsame *row, every permitted* Cont *replay of the normal-source route for one carrier transports to the corresponding replay of the other carrier.*

Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealRouteStability`

Proof. Read the componentwise transport row H. It identifies the closed source, normality witness, route rows, join row, provenance row, and local certificate row only along the displayed hsame surface.

Now replay through C. Each permitted continuation reads the same finite coordinates in the same order: closedness and normality first, then the two beta-star routes, and finally the join row. Transport through H therefore sends any such read to the corresponding read of the transported packet.

The proof uses no external confluence theorem beyond the already displayed normal-source join. Stability is a property of the finite replay route, not a new Church–Rosser endpoint. □

Theorem 741.9 (Closed normal confluence seal scoped route)**.** *Every permitted consumer route out of an accepted* $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$ *carrier factors through the displayed closed source* t*, beta-normality row* n*, two* BetaStarStep *rows* r_1, r_2*, join row* j*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}}$ *row* N*, and the single-carrier alignment surface named by BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenc No such route bypasses this finite chain to obtain arbitrary closed Church–Rosser data.*

Proof. Start with an accepted carrier and project the rows listed in Definition 741.1. The only source available to a consumer is the closed row t, and the only normality evidence available for that source is n.

The replay then factors through the two displayed beta-star rows r_1, r_2 and the join row j. The transport row H can move the route only componentwise, and the continuation row C can replay only the already displayed closed source, normality, route, and join coordinates.

The provenance row P and local certificate row N bind this route to the same NameCert packet. The TasteGate single-carrier alignment identifies the accepted carrier surface used by the route, so a consumer cannot change carrier shape while preserving acceptance.

Thus the permitted route is exactly the finite route through the displayed closed source, normality row, beta-star rows, join row, transport, replay, provenance, local naming, and TasteGate alignment. Nothing in the factorization supplies substitution compatibility, a closed parallel diamond, or full closed Church–Rosser. □

Theorem 741.10 (Closed normal confluence seal kernel scope)**.** *The kernel scope of the* ClosedNormalConfluenceSea *packet is exactly the BEDC infrastructure* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *together with the MetaCIC surfaces for closed-term rows, beta-normality rows,* BetaStarStep *rows, typed reduction, and subject reduction. The scope does not include substitution compatibility, a closed parallel diamond, a normalization oracle, or full closed Church–Rosser.*

Proof. Inspect the carrier coordinates. The structural rows are H, C, P, N, and their ambient BEDC primitives are precisely BHist, hsame, Cont, Pkg, and NameCert.

The computational rows are t, n, r_1, r_2, j. They name a closed MetaCIC source, a beta-normality witness, two BetaStarStep routes, and the displayed join supplied for that normal source. The sibling typed-reduction and subject-reduction chapters delimit how these rows may be read by consumers.

No remaining coordinate names substitution compatibility, a closed parallel diamond, arbitrary normalization, or a general Church–Rosser theorem. The scope is therefore the displayed BEDC infrastructure plus the listed MetaCIC surfaces, and nothing beyond them. □

Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealKernelScope`

Theorem 741.11 (Closed normal confluence seal boundary nonescape)**.** *No accepted* ClosedNormalConfluenceSeal$^{\uparrow}$ *packet exports residual-substitution compatibility, a full closed parallel diamond, or arbitrary closed-source Church–Rosser data beyond the displayed normal-source seal.*

Lean4 ✓ `BEDC.Derived.ClosedNormalConfluenceSealUp.ClosedNormalConfluenceSealBoundaryNonescape`

Proof. Inspect the carrier rows. The route data stop at r_1, r_2, j, where j is the join supplied for the closed beta-normal source named by t and n.

The provenance row P records the substitution-compatibility obstruction as a boundary. It does not fill a coordinate for BetaParallelSubstitutionCompatibility, nor does any continuation in C replay such a coordinate.

Thus every consumer remains inside the residual-substitution and full Church–Rosser boundary named by the carrier. The packet can expose the local normal-source seal, but it cannot escape to the missing closed parallel diamond or arbitrary closed-term confluence endpoint. □

Closure status for NameCert$_{\text{ClosedNormalConfluenceSeal}^{\uparrow}}$**.**

Constructive story: A ClosedNormalConfluenceSeal$^{\uparrow}$ packet is generated from a closed term row, beta-normality witness row, two beta-star route rows, a displayed join row, componentwise hsame transports, displayed Cont reads, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ClosedNormalConfluenceSeal}^{\uparrow}}$, publicClosed)

Scope closed: Definition 741.1, Definition 741.6, Definition 741.7, Definition 741.8, Definition 741.9, Definition 741.10, Definition 741.11, and Definition 741.4 bind carrier admission, route stability, kernel scope, boundary nonescape, and the public finite normal-source export.

Formal verification: FormalStatus(NameCert$_{\text{ClosedNormalConfluenceSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary closed-term Church–Rosser, BetaParallelSubstitutionCompatibility, BetaParallelDiamondClosed, a subject-reduction theorem, a normalization oracle, checked Lean certificate coverage, or a public standard bridge.

Upgrade path: Public closure requires checked carrier admission, normal-source join readback, route stability, transport stability, provenance, and boundary non-escape for the same finite seal packet.

Chapter 742

A Concrete Naming Certificate for $\mathsf{KernelAcceptanceBuildReplay}^{\uparrow}$

The $\mathsf{KernelAcceptanceBuildReplay}^{\uparrow}$ surface turns the build-replay coordinate named by chapter 9364 into a finite $\mathsf{NameCert}$ packet. It refines the replay row of chapter 547, reads accepted declarations through chapter 549, and hands dependency classification to chapter 654. The packet records reproducible build evidence without treating replay as a proof of kernel correctness or as a substitute for the axiom-query boundary.

Definition 742.1 (KernelAcceptanceBuildReplay carrier)**.** *A* $\mathsf{KernelAcceptanceBuildReplay}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (G, A, B, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *G is the generated-candidate row naming the Lean source object, declaration body, proof term, recursor output, or inductive declaration submitted for checking;*
2. *A is the accepted-declaration row read through the kernel-acceptance witness surface;*
3. *B is the build-command row naming the exact replay command, project root, toolchain row, source selection, and local build target used to reconstruct the acceptance event;*
4. *S is the replay-result row recording whether the build reconstructed the same accepted declaration, failed before acceptance, or reached a refusal state that remains visible to the audit consumer;*
5. *Q is the axiom-query handoff row that connects the replayed declaration to the strict proof-ancestry ledger;*
6. *H records componentwise* hsame *transport for the generated candidate, accepted declaration, build command, replay result, axiom-query handoff, provenance, and local naming row;*
7. *C records the displayed* Cont *routes through which consumers move from generated candidate to accepted declaration, from accepted declaration to replay command, from replay command to replay result, and from replay result to axiom-query handoff;*
8. *P is the* Pkg *provenance over* BHist*, generated candidates, accepted declarations, build commands, replay results, axiom-query handoffs,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KernelAcceptanceBuildReplay}^{\uparrow}}$ *row.*

The carrier exports no ambient host-trust row, no hidden source scan, no unrecorded command rerun, and no correctness certificate for the Lean kernel itself.

Lean4 ✓ `BEDC.Derived.KernelAcceptanceBuildReplayUp.KernelAcceptanceBuildReplayTasteGate single carrier alignment`

Theorem 742.2 (KernelAcceptanceBuildReplay NameCert obligations)**.** *For every accepted* KernelAcceptanceBuil *carrier*

$$R = (G, A, B, S, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KernelAcceptanceBuildReplay}^{\uparrow}}$ *surface consists exactly of the generated-candidate row* G*, accepted-declaration row* A*, build-command row* B*, replay-result row* S*, axiom-query handoff row* Q*, componentwise* hsame *transport* H*, displayed* Cont *routes* C*,* Pkg *provenance* P*, and local naming row* N*. A consumer may read build replay only through this finite packet and may not replace* B *or* S *by an informal claim that the project was rebuilt.*

Proof. Start with the carrier of Definition 742.1. The rows G, A, B, S, Q expose the candidate, accepted declaration, replay command, replay result, and dependency-query handoff as distinct finite coordinates.

The transport and continuation rows bind the reads of those coordinates. The row H preserves them componentwise, while C displays the routes from generated candidate to accepted declaration, from accepted declaration to build command, from build command to replay result, and from replay result to axiom-query handoff.

The provenance and naming rows package the same finite data as a $\mathsf{NameCert}_{\mathsf{KernelAcceptanceBuildReplay}^{\uparrow}}$ surface. Since no additional replay coordinate is present, a consumer cannot replace the displayed build command or replay result by an unrecorded host assertion. □

Theorem 742.3 (KernelAcceptanceBuildReplay replay non-escape)**.** *For every accepted* KernelAcceptanceBuildRep *carrier*

$$R = (G, A, B, S, Q, H, C, P, N),$$

every downstream audit read of build replay factors through the finite rows A, B, S, Q, C, N*. The replay result may witness that the accepted declaration was reconstructed from the recorded command and source selection, but it cannot export kernel correctness, compiler correctness, runtime correctness, dependency cleanliness without the axiom-query row* Q*, or any paper-side claim stronger than the accepted declaration row* A*.*

Proof. Project the accepted declaration, build command, replay result, axiom-query handoff, route, and local naming rows from the carrier. These rows are the only replay-facing endpoints exposed to an audit consumer.

The route coordinate C determines how the read moves from A to B, from B to S, and from S to Q. Thus replay success remains tied to the recorded command and result, while dependency classification remains tied to the axiom-query handoff.

Finally inspect the omitted coordinates. The packet contains no row for kernel correctness, compiler correctness, runtime correctness, hidden dependency cleanliness, or stronger manuscript meaning, so a replay consumer has no route by which to extract those claims. □

Closure status for $\mathsf{NameCert}_{\mathsf{KernelAcceptanceBuildReplay}^{\uparrow}}$.

Constructive story: A $\mathsf{KernelAcceptanceBuildReplay}^{\uparrow}$ packet is generated from a generated candidate row, accepted declaration row, build command row, replay result row, axiom-query handoff row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{KernelAcceptanceBuildReplay}\uparrow}$, seed)

Scope closed: Definition 742.1, Definition 742.2, and Definition 742.3 bind the finite build-replay carrier, local naming surface, replay route, axiom-query handoff, and non-escape boundary.

Formal verification: FormalStatus(NameCert$_{\text{KernelAcceptanceBuildReplay}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, kernel correctness, host runtime correctness, compiler correctness, dependency cleanliness without the axiom-query row, or a public standard bridge.

Upgrade path: Obligation closure requires Lean encoding of the finite packet and checked theorems for naming obligations, replay-route determinacy, axiom-query handoff stability, and replay non-escape.

Chapter 743

A Concrete Naming Certificate for $\mathsf{MetaCICConfluenceAudit}^{\uparrow}$

The $\mathsf{MetaCICConfluenceAudit}^{\uparrow}$ packet turns the audit map of chapter 9378 into concrete finite BEDC data next to the subject-reduction boundary packet of chapter 731. It names the checked confluence fragments, the substitution-compatibility input, the closed-diamond input, and the arbitrary closed-term Church–Rosser boundary without treating any remaining input as a proved theorem.

743.1 Carrier

Definition 743.1 (MetaCIC confluence audit carrier)**.** *A* $\mathsf{MetaCICConfluenceAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (N, A, S, D, C, H, R, P, M)$$

with the following rows:

1. *N is the checked normal and atom confluence-fragment row;*
2. *A is the checked parallel administrative-fragment row;*
3. *S is the named* BetaParallelSubstitutionCompatibility *input row;*
4. *D is the named* BetaParallelDiamondClosed *input row;*
5. *C is the named arbitrary closed-term Church–Rosser boundary row for* BetaStarStep*;*
6. *H is the componentwise* hsame *transport row for these five audit entries;*
7. *R is the displayed* Cont *read route for confluence consumers;*
8. *P is the* Pkg *provenance over the MetaCIC confluence files and the subject-reduction boundary packet;*
9. *M is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAudit}^{\uparrow}}$ *row.*

The classifier accepts exactly those packets whose consumers read the confluence surface through these rows and do not replace S, D, or C by a closed proof.

Lean4 ✓ `BEDC.Derived.MetaCICConfluenceAuditUp.TasteGate.MetaCICConfluenceAuditTasteGate single carrier alignment`

Theorem 743.2 (MetaCIC confluence audit NameCert obligations)**.** *For an accepted* MetaCICConfluenceAudit$^{\uparrow}$ *carrier, the local* NameCert *surface consists of carrier admission, checked-fragment readback for N and A, named-input exposure for S and D, arbitrary-closed-term boundary exposure for C, componentwise* hsame *stability, displayed* Cont *route stability,* Pkg *provenance, and non-escape from an unchecked closed confluence theorem.*

Proof. Start with the carrier rows of Definition 743.1. They already separate the checked rows N, A from the named rows S, D, C.

Use the local M row to package these rows as the visible certificate. Componentwise transport is supplied by H, while R supplies the only displayed consumer route.

Finally read provenance through P. Since P records the relation to the MetaCIC confluence audit map and the subject-reduction obstruction packet without adding a proof row for S, D, or C, every accepted consumer remains inside the displayed audit packet. □

Theorem 743.3 (MetaCIC confluence audit boundary)**.** *Agreement on the rows of an accepted* MetaCICConfluenceAudit$^{\uparrow}$ *packet preserves the checked normal, atom, and administrative confluence fragments, but it does not yield* BetaParallelSubstitutionCompatibility*,* BetaParallelDiamondClosed*, or arbitrary closed-term Church–Rosser for* BetaStarStep*.*

Proof. The checked rows N and A are read back directly from the packet, so agreement on Q preserves those fragment claims.

The rows S, D, and C have different status. They are named boundary entries, not theorem rows. Transport along H and reading through R can preserve their names and consumer visibility, but it cannot create a proof object not carried by the packet.

Thus the packet supports finite audit citation while keeping the three remaining confluence inputs outside the closed theorem surface. □

Theorem 743.4 (MetaCIC confluence audit vision handoff)**.** *Every manuscript consumer that cites the confluence audit map through* MetaCICConfluenceAudit$^{\uparrow}$ *factors through $Q = (N, A, S, D, C, H, R, P, M)$ before citing any MetaCIC confluence claim. The handoff exports the checked fragment rows and the three named boundary rows, and it exports no arbitrary closed-term confluence theorem, no closed subject-reduction theorem, and no host-level confluence principle.*

Proof. First follow the citation into chapter 9378. The map supplies the semantic grouping of checked fragments and remaining inputs.

Next pass through the carrier of Definition 743.1. The finite packet turns that grouping into rows N, A, S, D, C with transport, route, provenance, and local naming data.

The sibling boundary of chapter 731 supplies the comparison surface for subject-reduction claims. Combining the two packets gives a citation route, not a closed theorem beyond the displayed rows. □

Closure status for NameCert$_{\text{MetaCICConfluenceAudit}^{\uparrow}}$**.**

Constructive story: A MetaCICConfluenceAudit$^{\uparrow}$ packet is generated from finite BHist rows that group confluence-facing audit material, sibling subject-reduction obstruction rows, transport rows, route rows, provenance, and local naming. The audit does not synthesize a confluence theorem; it collects the displayed rows and uses Cont to replay how a consumer reaches the comparison surface supplied by the sibling boundary. Componentwise hsame preserves the audit grouping and sibling rows, while Pkg records the MetaCIC audit dependencies. The packet therefore offers a finite citation route across audit surfaces, not closed confluence or subject reduction.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICConfluenceAudit}^{\uparrow}}$, seed)

Scope closed: This chapter binds the MetaCIC confluence-audit carrier, audit grouping, sibling subject-reduction comparison surface, and finite citation-route boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICConfluenceAudit}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: ai
Not claimed: It does not claim confluence, subject reduction, normalization, host conversion semantics, quotient term equality, or a completed MetaCIC metatheorem.
Upgrade path: Obligation closure requires Lean encodings of the audit carrier, sibling-boundary route, componentwise transport, and citation-route non-closure theorem.

Chapter 744

A Concrete Naming Certificate for ParallelConfluenceAudit$^{\uparrow}$

The ParallelConfluenceAudit$^{\uparrow}$ packet realizes the confluence-side audit map of chapter 9378 as a finite NameCert surface. It sits next to the beta-substitution packet of chapter 716 and the beta-discharge packet of chapter 727; the closed-term side is compatible with the seal of chapter 722. The packet records the parallel-step route, substitution-compatibility boundary, conditional parallel-diamond handoff, closed-diamond-to-star-confluence handoff, closed-normal and atom fragments, non-claim boundary, componentwise transports, displayed routes, provenance, and local naming row without turning the conditional Lean bridges into an unconditional closed Church–Rosser theorem.

Definition 744.1 (ParallelConfluenceAudit carrier)**.** *A* ParallelConfluenceAudit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (P, S, D, C, Nm, At, No, H, R, L, G)$$

with the following displayed rows:

1. *P is the parallel-step route row for the MetaCIC* BetaParallel *geometry;*
2. *S is the substitution-compatibility boundary row naming* BetaParallelSubstitutionCompatibility *as an input, not as a proved coordinate;*
3. *D is the conditional parallel-diamond handoff row corresponding to the route from S to the parallel diamond;*
4. *C is the closed-diamond-to-star-confluence handoff row for the closed* BetaStarStep *confluence route;*
5. *Nm is the closed-normal fragment row recording the unconditional normal-source cases;*
6. *At is the atom and non-lambda shape row recording the unconditional atom-side and impossible-shape fragments;*
7. *No records the non-claim boundary for arbitrary closed Church–Rosser,* BetaParallelSubstitutionCompatibility*, and* BetaParallelDiamondClosed*;*
8. *H records componentwise* hsame *transports for $P, S, D, C, Nm, At, No, L, G$;*
9. *R displays the* Cont *routes through which consumers may read the parallel-step, conditional bridge, closed-star, normal-fragment, atom-fragment, and non-claim rows;*

10. *L is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, NameCert, BetaSubstitutionPreservation$^{\uparrow}$, BetaSubstitutionDischarge$^{\uparrow}$, ClosedTermContextSeal$^{\uparrow}$, *and the MetaCIC confluence audit map;*
11. *G is the local* $\mathsf{NameCert}_{\mathsf{ParallelConfluenceAudit}^{\uparrow}}$ *row.*

The carrier is exactly this finite packet. It contains no proof of BetaParallelSubstitutionCompatibility, *no proof of* BetaParallelDiamondClosed, *and no arbitrary closed Church–Rosser theorem for* BetaStarStep.

Lean4 ✓ `BEDC.Derived.ParallelConfluenceAuditUp.ParallelConfluenceAuditTasteGate single carrier alignment`

Theorem 744.2 (ParallelConfluenceAudit NameCert obligations)**.** *For the carrier of Definition 744.1, the local* $\mathsf{NameCert}_{\mathsf{ParallelConfluenceAudit}^{\uparrow}}$ *surface consists of carrier admission for*

$$A = (P, S, D, C, Nm, At, No, H, R, L, G),$$

parallel-step route visibility, substitution-boundary visibility, conditional parallel-diamond handoff visibility, closed-diamond-to-star-confluence handoff visibility, closed-normal fragment visibility, atom and non-lambda fragment visibility, non-claim exactness, componentwise hsame *transport, displayed* Cont *route replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier. The inventory is exactly $P, S, D, C, Nm, At, No, H, R, L, G$, so every local naming obligation is read from a displayed finite row.

The positive confluence-side rows are P, D, C, Nm, At. The route P records the parallel-step geometry, D records only the substitution-conditional parallel-diamond handoff, C records only the closed-diamond-to-star-confluence handoff, and Nm, At record the unconditional closed-normal and atom fragments.

The boundary rows are S and No. The row S names the substitution-compatibility input as a premise boundary, while No records the absence of an arbitrary closed Church–Rosser theorem and the absence of proofs of the two named premises.

Finally H, R, L, G provide transport, continuation replay, provenance, and the local name for the same packet. Since no other coordinate exists, the obligations are exhausted by the displayed rows. □

Theorem 744.3 (ParallelConfluenceAudit conditional bridge)**.** *Let $A = (P, S, D, C, Nm, At, No, H, R, L, G)$ be an accepted* $\mathsf{ParallelConfluenceAudit}^{\uparrow}$ *carrier. Any read of the conditional confluence bridge reaches the parallel-diamond row D only through the substitution-compatibility boundary S, and reaches the closed-star confluence handoff C only through the parallel-diamond handoff row D. The closed-normal row Nm and atom row At remain unconditional fragments, not replacements for S, D, C.*

Lean4 ✓ `BEDC.Derived.ParallelConfluenceAuditUp.ParallelConfluenceAudit conditional bridge rows`

Proof. Begin with the conditional route data. The displayed continuation row R exposes the parallel-step route P, then the substitution boundary S, and only then the parallel-diamond handoff D.

The closed-star handoff is downstream of D. A consumer that reads C therefore reads the closed-diamond-to-star bridge as a handoff from the parallel diamond, not as an independent proof of the diamond premise.

The rows Nm and At are separate fragment rows. They may be cited for closed-normal sources, atom sources, and non-lambda shape cases, but their carrier positions do not provide either S or D.

The package row L and local name G keep these dependencies in one NameCert packet. Thus every bridge read factors through S, D, C in that order. □

Lean4 ✓ `BEDC.Derived.ParallelConfluenceAuditUp.ParallelConfluenceAudit conditional bridge route closed`

Theorem 744.4 (ParallelConfluenceAudit non-escape)**.** *Every accepted* ParallelConfluenceAudit$^{\uparrow}$ *packet exposes confluence data only through the rows*

$$P, S, D, C, Nm, At, No, H, R, L, G.$$

It exports no arbitrary closed Church–Rosser theorem for BetaStarStep*, no proof of* BetaParallelSubstitutionCompa *and no proof of* BetaParallelDiamondClosed*.*

Proof. Inspect the carrier coordinates. The only positive rows are the parallel-step route, the two conditional handoffs, and the closed-normal and atom fragments.

Use Definition 744.3. Reads of the bridge rows must pass through S, D, C, so the conditional premises remain visible at every consumer-facing route.

Use Definition 744.2 for local naming and provenance. The non-claim row No is part of the same finite packet as the displayed routes, and the missing endpoint theorems have no carrier coordinate.

Therefore a downstream consumer may cite the audit packet only as the finite confluence-side map described above. It cannot turn the map into arbitrary closed Church–Rosser, a proof of substitution compatibility, or a proof of the closed parallel diamond. □

Closure status for NameCert$_{\text{ParallelConfluenceAudit}^{\uparrow}}$.

Constructive story: A ParallelConfluenceAudit$^{\uparrow}$ packet is generated from a parallel-step route, substitution-compatibility boundary, conditional parallel-diamond handoff, closed-diamond-to-star-confluence handoff, closed-normal fragment row, atom and non-lambda shape row, non-claim row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ParallelConfluenceAudit}^{\uparrow}}$, seed)

Scope closed: Definition 744.1, Definition 744.2, Definition 744.3, and Definition 744.4 bind the finite confluence audit packet and its conditional bridge boundary.

Formal verification: FormalStatus(NameCert$_{\text{ParallelConfluenceAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove arbitrary closed Church–Rosser for BetaStarStep, BetaParallelSubstitutionCompatibility, BetaParallelDiamondClosed, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, conditional-route exactness through S, D, C, fragment coverage for Nm and At, and non-escape for the named confluence endpoints.

Chapter 745

A Concrete Naming Certificate for $\mathsf{MetaCICConfluenceAuditWitness}^{\uparrow}$

The $\mathsf{MetaCICConfluenceAuditWitness}^{\uparrow}$ packet turns the audit boundary of chapter 9378 into a finite NameCert witness. It is narrower than chapter 744: the present chapter records the minimum carrier needed to audit the conditional confluence boundary, while chapter 731 and chapter 713 provide sibling lattice anchors for obstruction and confluence-style route comparison.

Definition 745.1 (MetaCIC confluence audit witness carrier)**.** *A* $\mathsf{MetaCICConfluenceAuditWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (P, S, D, C, O, H, R, L, N)$$

with the following displayed rows:

1. *P is the MetaCIC parallel-step route row whose endpoints are closed terms;*
2. *S is the substitution-compatibility premise boundary for the parallel route;*
3. *D is the conditional parallel-diamond handoff row reached only through S;*
4. *C is the closed-star confluence handoff row reached only through D;*
5. *O records the obstruction boundary excluding full closed Church–Rosser, substitution compatibility, and unconditional confluence for arbitrary closed terms;*
6. *H records componentwise* hsame *transport across P, S, D, C, O, R, L, N;*
7. *R is the finite* Cont *route ledger through which consumers may replay the witness route;*
8. *L is the* Pkg *provenance row linking the audit map, the subject-reduction obstruction sibling, and the axis-carry confluence sibling;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditWitness}^{\uparrow}}$ *row.*

The carrier contains no host evaluator, no hidden substitution lemma, no quotient identification of reductions, and no theorem stronger than the displayed conditional route rows.

Lean4 (definition) `BEDC.Derived.MetacicConfluenceAuditWitnessUp.MetacicConfluenceAuditWitnessUp`
Lean4 ✓ `BEDC.Derived.MetacicConfluenceAuditWitnessUp.MetacicConfluenceAuditWitnessTasteGate`
`single carrier alignment`

Theorem 745.2 (MetaCIC confluence audit witness conditional boundary)**.** *Every accepted* MetaCICConfluenceAud *packet reads the confluence route in the order*

$$P \longrightarrow S \longrightarrow D \longrightarrow C.$$

The parallel-diamond handoff D is conditional on the substitution-compatibility boundary S, and the closed-star confluence handoff C is conditional on the displayed diamond handoff D.

Proof. Project the carrier of Definition 745.1. The only route ledger is R, and its route endpoints are the displayed rows P, S, D, C.

The packet therefore has no route from P directly to D and no route from P directly to C. A consumer must first read the substitution-compatibility boundary S, then the conditional diamond row D, and only then the closed-star handoff C.

The obstruction row O records exactly the missing shortcuts. Thus the conditional order is part of the finite witness boundary rather than an external convention. □

Lean4 ✓ `BEDC.Derived.MetacicConfluenceAuditWitnessUp.MetacicConfluenceAuditWitnessCarrier conditional boundary`

Theorem 745.3 (MetaCIC confluence audit witness non-escape)**.** *An accepted* MetaCICConfluenceAuditWitness$^{\uparrow}$ *packet exposes only the rows*

$$P, S, D, C, O, H, R, L, N.$$

It exports no full closed Church–Rosser theorem, no proof of substitution compatibility, and no unconditional confluence theorem for arbitrary closed terms.

Proof. Inspect the carrier definition. Its coordinates are exactly $P, S, D, C, O, H, R, L, N$, so every public read must be a projection from one of these rows or a route recorded by R.

By Definition 745.2, the positive confluence read remains conditional at S and D. The row O is stored in the same packet and names the missing endpoints rather than discharging them.

Since no coordinate contains a host evaluator, a substitution lemma, a quotient equality, or an arbitrary closed-term confluence theorem, the packet has no source from which to export such data. □

Theorem 745.4 (MetaCIC confluence audit witness NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAud}}$ *surface consists of carrier admission for $W = (P, S, D, C, O, H, R, L, N)$, route visibility for P, S, D, C, obstruction-boundary visibility for O, componentwise* hsame *transport through H, finite* Cont *replay through R,* Pkg *provenance through L, and local naming through N.*

Proof. Read the packet as a finite carrier. Carrier admission names all displayed rows, and the local name N records that the same packet supplies the witness surface.

The positive obligations are route visibility for P, S, D, C and transport through H, R. The boundary obligation is the visibility of O, which keeps the missing full confluence claims in the packet rather than outside it.

Finally, L supplies provenance for the audit map and the sibling lattice anchors. The NameCert obligations are exhausted by these displayed coordinates because the carrier has no additional field. □

Theorem 745.5 (MetaCIC confluence audit witness sibling lattice)**.** *The* MetaCICConfluenceAuditWitness$^{\uparrow}$ *packet sits between the confluence audit map of chapter 9378, the subject-reduction obstruction packet of chapter 731, and the axis-carry confluence packet of chapter 713. Agreement on H, R, L, N preserves the common NameCert transport and route surface, while the rows S, D, C, O keep the MetaCIC confluence boundary separate from subject reduction and from axis-carry normalization.*

Proof. The provenance row L cites the three anchors, so the packet is read as a finite witness in the same concrete-instance lattice.

The shared rows H, R, L, N provide componentwise transport, continuation replay, provenance, and local naming. These are the only common operations exported to sibling chapters.

The boundary rows remain specific to this packet. The row S names substitution compatibility, D names the conditional parallel diamond, C names the closed-star handoff, and O blocks the missing full confluence claims. Hence the sibling lattice preserves comparison without collapsing the three chapter surfaces into one theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICConfluenceAuditWitness}^{\uparrow}$ packet is generated from a parallel-step route, substitution-compatibility boundary, conditional parallel-diamond handoff, closed-star confluence handoff, obstruction boundary, componentwise hsame transport, finite Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 745.1, Definition 745.2, Definition 745.3, Definition 745.4, and Definition 745.5 bind the finite audit-witness packet for the conditional MetaCIC confluence boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceAuditWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close full closed Church–Rosser, substitution compatibility, or unconditional confluence for arbitrary closed terms.

Upgrade path: Obligation closure requires checked carrier admission, conditional route exactness through S, D, C, non-escape for O, and sibling-lattice provenance through L.

Chapter 746

A Concrete Naming Certificate for MetaCICDecidableAuditPacket$^{\uparrow}$

The MetaCICDecidableAuditPacket$^{\uparrow}$ packet turns the audit map of chapter 9379 into a finite NameCert surface. It sits beside chapter 743 and chapter 739: those chapters separate confluence and consistency boundaries, while the present packet separates checked typing inference from bounded normal-form comparison.

Definition 746.1 (MetaCIC decidable audit packet carrier)**.** *A* MetaCICDecidableAuditPacket$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (C, M, T, G, B, E, O, H, R, P, N)$$

with the following visible rows:

1. *C is the checker row for* `inferTypeCtx` *and its closed wrapper;*
2. *M is the same-term row for* `Term.eq` *and* `checkSameTerm`*;*
3. *T records typing soundness and completeness for the represented* `HasType` *relation;*
4. *G is the gallery row for the closed Boolean, natural-number, pair, option, list, sum, and polymorphic witnesses;*
5. *B is the bounded-normal comparison row for* `normalizeBounded` *and* `decideClosedBetaConv`*;*
6. *E is the boundary row requiring finished closed-normal data before beta-conversion soundness is read as a normal-form equality statement;*
7. *O is the obstruction row excluding unrestricted closed beta-conversion decidability and a standalone closedness-decision theorem;*
8. *H records componentwise* hsame *transport across the checker, same-term, typing, gallery, bounded-normal, boundary, and obstruction rows;*
9. *R records the displayed* Cont *route by which a consumer reads the rows in packet order;*
10. *P is the* Pkg *provenance row tying the decidability audit map to the confluence and consistency sibling packets;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidableAuditPacket}^{\uparrow}}$ *row.*

The packet exposes checked syntax equality, checked typing inference, gallery acceptance, and bounded normal comparison with its stated boundary. It contains no global beta-conversion oracle, no hidden normalization endpoint, and no host-level decision procedure for arbitrary closed terms.

Theorem 746.2 (MetaCIC decidable audit packet NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidableAuditPa}}$ *surface consists of carrier admission for* $A = (C, M, T, G, B, E, O, H, R, P, N)$*, checker exposure through* C*, same-term exposure through* M*, typing soundness and completeness exposure through* T*, gallery exposure through* G*, bounded-normal comparison exposure through* B*, boundary exposure through* E, O*, componentwise* hsame *transport through* H*, displayed* Cont *route replay through* R*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.MetacicDecidableAuditPacketUp.MetacicDecidableAuditPacketTasteGate single carrier alignment`

Proof. Project the carrier of Definition 746.1. The rows $C, M, T, G, B, E, O, H, R, P, N$ are the whole public packet, so carrier admission and local naming are direct projections.

The positive checker surface is read through C, M, T, G, B. These rows record the type checker, same-term checker, typing soundness and completeness, gallery rows, and bounded-normal comparison as separate coordinates rather than as one unnamed decidability claim.

The boundary surface is read through E and O. The row E keeps finished closed-normal data explicit, while O blocks unrestricted beta-conversion decidability and a standalone closedness-decision theorem.

Finally H, R, P, N provide transport, route replay, provenance, and local naming. Since no additional coordinate exists, the NameCert obligations are exhausted by the displayed packet. □

Theorem 746.3 (MetaCIC decidable audit seed obligation surface)**.** *Every accepted* MetaCICDecidableAuditPacket *carrier*

$$A = (C, M, T, G, B, E, O, H, R, P, N)$$

exposes exactly the decidable-audit source row C*, the MetaCIC candidate rows* M, T, G*, the finite reduction-window row* B*, the audit verdict and boundary rows* E, O*, transport through* H*, replay through* R*, provenance through* P*, and the local* NameCert *row* N *before any decidability consumer reads the packet. The exposed surface refuses unrestricted beta-conversion decidability, global normalization, quotient equality of terms, and bridge checking.*

Proof. Project the carrier of Definition 746.1. The displayed rows $C, M, T, G, B, E, O, H, R, P, N$ are the whole accepted packet, and the existing TasteGate marker records this as the single-carrier alignment witness.

Read the positive audit surface first. The source row C exposes the checked inference entry point, while M, T, G keep same-term comparison, typing soundness and completeness, and gallery candidates as separate MetaCIC rows.

Next read the finite reduction window. The row B is the only bounded-normal comparison coordinate, and E, O record the audit verdict boundary before a consumer treats that comparison as public.

Finally H, R, P, N transport, replay, source, and name the same finite packet. Since no other carrier coordinate exists, unrestricted beta-conversion decidability, global normalization, quotient equality of terms, and bridge checking remain outside the seed obligation surface. □

Lean4 ✓ `BEDC.Derived.MetacicDecidableAuditPacketUp.MetacicDecidableAuditPacket seed obligation surface`

Theorem 746.4 (MetaCIC decidable audit packet non-escape)**.** *Every accepted* MetaCICDecidableAuditPacket$^{\uparrow}$ *carrier exposes only the finite rows*

$$C, M, T, G, B, E, O, H, R, P, N.$$

A consumer may read checked typing inference, same-term equality, typing soundness and completeness, gallery acceptance, bounded-normal comparison, finished-normal boundary data, hsame *transport,* Cont *route replay,* Pkg *provenance, and the local* NameCert *row. The consumer obtains no unrestricted beta-conversion decider, no hidden finished-normalization theorem, no quotient equality of terms, and no host-level decision procedure for arbitrary closed terms.*

Proof. Start with the carrier definition. The packet has exactly the displayed rows, and every public read must be a projection from those rows or a route recorded by R.

Use the NameCert obligation theorem to locate the positive routes. Typing and same-term checks are routed through C, M, T, gallery acceptance through G, and bounded comparison through B.

The obstruction rows remain in the same finite packet. The boundary row E requires finished closed-normal data for the stronger normal-form reading, and the obstruction row O records the missing unrestricted conclusions.

Therefore the packet cannot export a route that is not already present in $C, M, T, G, B, E, O, H, R, P, N$. In particular, unrestricted beta-conversion decidability and hidden normalization endpoints have no carrier coordinate. □

Theorem 746.5 (Typed conversion window obligation surface)**.** *Every consumer reading a typed-conversion claim from a* MetaCICDecidableAuditPacket$^{\uparrow}$ *carrier* $A = (C, M, T, G, B, E, O, H, R, P, N)$ *must expose the typing rows* C, M, T *and the bounded-normal rows* B, E, O *as separate windows. The checked typing-inference route through* `inferTypeCtx`*,* `Term.eq`*,* `checkSameTerm`*, and* `HasType` *soundness/completeness cannot be read as unrestricted beta-conversion decidability; bounded normal comparison is available only through* B*, finished closed-normal hypotheses remain explicit in* E*, and the obstruction row* O *records the excluded global conclusions.*

Proof. Project the packet rows from Definition 746.1. The checker and same-term rows C, M supply the syntactic checking surface, while T is the only row that records typing soundness and completeness for the represented `HasType` relation.

Route conversion-facing reads through a different window. The bounded comparison row B names the `normalizeBounded` and `decideClosedBetaConv` surface, and E keeps the finished closed-normal hypotheses visible before a normal-form equality claim is read.

Finally use the obstruction row O. It excludes unrestricted closed beta-conversion decidability and standalone closedness decision, so a consumer cannot collapse the typing window C, M, T into a global conversion oracle. The structural rows H, R, P, N transport, replay, package, and name the same separated route. □

Closure status for NameCert$_{\text{MetaCICDecidableAuditPacket}^{\uparrow}}$**.**

Constructive story: A MetaCICDecidableAuditPacket$^{\uparrow}$ packet is generated from checker, same-term, typing, gallery, bounded-normal comparison, boundary, obstruction, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICDecidableAuditPacket}^{\uparrow}}$, seed)

Scope closed: Definition 746.1, Definition 746.2, Definition 746.4, and Definition 746.5 bind the finite audit packet for checked MetaCIC typing inference and bounded normal comparison.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICDecidableAuditPacket}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close unrestricted beta-conversion decidability, standalone closedness decidability, global normalization, quotient equality of terms, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, checker exactness, same-term exactness, typing soundness and completeness routing, bounded-normal boundary routing, transport, route replay, provenance, and non-escape for the same finite packet.

Chapter 747

A Concrete Naming Certificate for $\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}$

The $\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}$ packet is the concrete NameCert surface drawn from the decidability audit map of chapter 9379. It packages the checked typing-inference rows, the same-term decision rows, and the bounded normal-equality rows as one finite consumer-facing seal. The packet sits beside the normal-form carriers of chapter 562 and chapter 683: those chapters expose terminal normal-form readback, while this chapter exposes the decidable checker rows that may be safely consumed without claiming a global closed-term conversion decider.

Definition 747.1 (Metacic decidable checker seal carrier)**.** *A* $\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (E, T, S, N, H, C, P, L)$$

with the following displayed rows:

1. *E is the structural term-equality row for encoded MetaCIC syntax;*
2. *T is the typing-inference row, including the checked soundness and completeness surfaces for the encoded* `HasType` *relation;*
3. *S is the same-term checker row for the displayed syntax layer;*
4. *N is the bounded normal-equality row, including the finished-normalisation consequences recorded by the audit map;*
5. *H records componentwise* hsame *transport for E, T, S, N, route data, provenance, and local naming;*
6. *C records the displayed* Cont *routes by which a consumer reads structural equality, typing inference, same-term checking, and bounded normal equality;*
7. *P is the* Pkg *provenance over* BHist, BMark, hsame, Cont, Pkg, NameCert, *and the MetaCIC decidability audit rows named in chapter 9379;*
8. *L is the local* $\mathsf{NameCert}_{\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}}$ *row.*

The carrier contains no row for unrestricted closedness decidability, no row for global closed-term beta-conversion decidability, and no row turning bounded normal equality into an unbounded conversion theorem.

Theorem 747.2 (Metacic decidable checker seal NameCert obligations)**.** *For every accepted* $\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}$ *carrier*

$$D = (E, T, S, N, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}}$ *surface consists exactly of structural term-equality admission through* E*, typing-inference soundness and completeness through* T*, same-term checking through* S*, bounded normal-equality soundness through* N*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* L*.*

Proof. Project the carrier of Definition 747.1. Its checker coordinates are exactly E, T, S, N, so the visible decision surface is structural equality, typing inference, same-term checking, and bounded normal equality.

The transport row H preserves those four coordinates componentwise. The continuation row C supplies the only routes by which a downstream consumer may read them, and those routes end inside the same packet.

Package provenance through P records the audit-map dependency, while the local row L names the packet as a $\mathsf{NameCert}_{\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}}$ surface. Since the carrier has no further checker coordinate, the NameCert obligations are exactly the displayed finite rows. □

Theorem 747.3 (Metacic decidable checker seal non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}$ *carrier factors through*

$$E, T, S, N, H, C, P, L.$$

The consumer may read structural term equality, typing-inference soundness and completeness, same-term checking, bounded normal-equality soundness, componentwise transports, displayed continuation routes, provenance, and the local naming row. It cannot read unrestricted closedness decidability, global closed-term beta-conversion decidability, a confluence theorem, a subject-reduction theorem, or an external normalizer from the checker seal.

Proof. Begin with the displayed continuation row C. It names consumer routes only for E, T, S, N and has no endpoint for a closedness decider, a global conversion decider, confluence, subject reduction, or an external normalizer.

Next use componentwise transport through H. Transport moves the same four checker rows and cannot manufacture a theorem coordinate absent from the carrier.

Finally package the result through P and L. Provenance and local naming certify the finite checker surface described by chapter 9379, while the missing coordinates rule out escape beyond E, T, S, N, H, C, P, L. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}$ packet is generated from structural term equality, typing-inference soundness and completeness, same-term checking, bounded normal-equality soundness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 747.1, Definition 747.2, and Definition 747.3 bind the decidable MetaCIC checker rows as a finite NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicDecidableCheckerSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close unrestricted closedness decidability, global closed-term beta-conversion decidability, confluence, subject reduction, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of the checker-seal carrier, route exhaustion, and checked non-escape for the structural equality, typing-inference, same-term, and bounded normal-equality rows.

Chapter 748

A Concrete Naming Certificate for $\mathsf{BoundedBetaComparison}^{\uparrow}$

The $\mathsf{BoundedBetaComparison}^{\uparrow}$ packet turns the normal-equality surface of chapter 9379 into concrete finite BEDC data. It sits next to the normal-form seal of chapter 740 and the confluence audit packet of chapter 743: all three chapters name bounded or conditional MetaCIC evidence without promoting it to an unrestricted closed-term theorem.

Definition 748.1 (Bounded beta-comparison carrier)**.** *A* $\mathsf{BoundedBetaComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (f, t, u, n_t, n_u, e, w_t, w_u, H, C, P, N)$$

with the following displayed rows:

1. f *is the fuel row used by the bounded normalizer;*
2. t, u *are the closed MetaCIC term rows being compared;*
3. n_t, n_u *are the bounded-normal output rows computed from* t *and* u *at fuel* f*;*
4. e *is the structural* Term.eq *comparison row applied to* n_t *and* n_u*;*
5. w_t, w_u *are the finished-normalisation witness rows when the fuel is known to finish on* t *and* u*;*
6. H *records componentwise* hsame *transports for the fuel, term, bounded-normal, equality, witness, provenance, and local naming rows;*
7. C *records the displayed* Cont *route by which a consumer reads the bounded comparison and any finished-normalisation boundary data;*
8. P *is the* Pkg *provenance over* `NormalEqDecide`*,* `Term.eq`*, closed MetaCIC syntax,* BHist*,* hsame*,* Cont*, and sibling* NameCert *rows;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{BoundedBetaComparison}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through the displayed rows $f, t, u, n_t, n_u, e, w_t, w_u, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.BoundedBetaComparisonUp.TasteGate.BoundedBetaComparisonTasteGate single carrier alignment`

Theorem 748.2 (Bounded beta-comparison NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{BoundedBetaComparison}^{\uparrow}}$ *surface for Definition 748.1 consists of carrier admission, bounded-normal output readback, structural* Term.eq *readback, componentwise* hsame *transport, displayed* Cont *route replay, provenance, and non-escape from any fuel-erased beta-conversion theorem.*

Proof. Carrier admission is projection from the finite tuple $B = (f, t, u, n_t, n_u, e, w_t, w_u, H, C, P, N)$. The fuel, closed term rows, bounded-normal outputs, equality comparison, optional witness rows, transport, route, provenance, and local naming row are all displayed coordinates.

The bounded-normal readback and Term.eq readback inspect only f, t, u, n_t, n_u, e. Thus a successful comparison is a row about the displayed bounded-normal outputs, not a row about unrestricted closed-term conversion.

The structural rows H, C, P, N preserve the same finite packet under transport, consumer routing, provenance, and local naming. Since none of these rows contains a fuel-erased normalisation theorem, the local NameCert exports no stronger beta-conversion surface. □

Theorem 748.3 (Bounded beta-comparison finished soundness boundary)**.** *For an accepted* BoundedBetaComparis *packet, a true bounded comparison identifies only the displayed bounded-normal outputs n_t and n_u. When the finished-normalisation witness rows w_t and w_u are present, the same packet also exposes the finished-normal-form boundary for those named outputs. Without those witness rows, the packet exports no conclusion that t and u have fuel-independent normal forms.*

Proof. Read the comparison row e through the carrier. The row is the Term.eq comparison of n_t and n_u, so its positive content is equality of the two bounded-normal outputs displayed at fuel f.

If w_t and w_u are present, they supply the extra endpoint data consumed by the finished-normalisation soundness theorems named in chapter 9379. The boundary is therefore tied to the particular fuel, terms, bounded outputs, and witness rows carried by the packet.

If either witness row is absent, the carrier still records the bounded comparison row, but it has no coordinate witnessing that the bounded outputs are final normal forms. The consumer cannot erase the fuel or infer a global normalisation endpoint from the packet alone. □

Theorem 748.4 (Bounded beta-comparison non-escape)**.** *Every consumer of an accepted* BoundedBetaComparison *packet is exhausted by the carrier of Definition 748.1, the local NameCert obligations of Definition 748.2, and the finished-normal-form boundary of Definition 748.3. The packet exports no global closed-term beta-conversion decider, no fuel-erased normalisation theorem, no quotient equality, and no host conversion oracle.*

Proof. Begin with the displayed carrier rows. They provide exactly the fuel, two closed terms, two bounded-normal outputs, one structural equality comparison, optional finished-normalisation witnesses, and the structural BEDC rows.

Apply the NameCert obligations. They route every consumer through the same bounded-normal and Term.eq rows before any comparison result is read.

Finally apply the finished soundness boundary. The only strengthening available from a true comparison comes from the explicit witness rows w_t, w_u when they are present. Since the packet has no coordinate for fuel erasure, quotient equality, host conversion, or arbitrary closed-term normalisation, none of those readings can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedBetaComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedBetaComparison}^{\uparrow}$ packet is generated from finite BHist rows for source and target terms, bounded beta fuel, local beta-step evidence, comparison result, transports, continuations, provenance, and local naming. The comparison is read by replaying the bounded beta route through Cont, so the packet exposes only the steps and fuel that are actually displayed. Componentwise hsame transports source, target, fuel, and step rows without erasing the bound, while Pkg records the beta-comparison and closed-term dependencies. The result is a finite comparison certificate rather than unrestricted conversion or normalization.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedBetaComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the bounded beta comparison carrier, bounded route replay, fuel preservation, comparison readback, and non-export boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{BoundedBetaComparison}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: human
Not claimed: It does not claim fuel erasure, quotient equality, host conversion, arbitrary closed-term normalization, confluence, or global beta completeness.
Upgrade path: Obligation closure requires Lean encodings of the bounded comparison carrier, fuel-indexed route, comparison stability, and non-escape theorem.

Chapter 749

A Concrete Naming Certificate for MetaCICDecidableBoundary$^{\uparrow}$

The MetaCICDecidableBoundary$^{\uparrow}$ packet realizes the decidability audit map of chapter 9379 as a finite NameCert object. It sits next to the normal-form exclusion packet of chapter 732, the closed-normal confluence seal of chapter 741, and the subject-reduction obstruction packet of chapter 731. The packet records the checked finite procedures and their refusal boundaries without promoting bounded normal comparison into global beta-conversion decidability.

Definition 749.1 (MetaCIC decidable boundary carrier)**.** *A* MetaCICDecidableBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (T, S, B, F, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the* inferTypeCtx *checker row for the encoded* HasType *relation;*
2. *S is the* checkSameTerm *structural-equality row used by the checker;*
3. *B is the bounded normal-equality row for* normalizeBounded *and* decideClosedBetaConv*;*
4. *F is the finished-normal-form side-condition row consumed by the bounded comparison soundness theorems;*
5. *R records the refusal rows for a standalone* ClosedAt *decision theorem and for global closed beta-conversion decidability;*
6. *H records componentwise* hsame *transport across T, S, B, F, R, P, N;*
7. *C records the displayed* Cont *routes by which consumers replay checker, comparison, refusal, and side-condition reads;*
8. *P is the* Pkg *provenance over the decidability audit map, the normal-form exclusion sibling, the closed-normal confluence seal sibling, and the subject-reduction obstruction sibling;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidableBoundary}^{\uparrow}}$ *row.*

The carrier has no row for a global ClosedAt *decider, no unrestricted beta-conversion oracle, no fuel-erased normalisation theorem, no quotient of represented terms, and no host evaluator.*

Theorem 749.2 (MetaCIC decidable boundary NameCert obligations)**.** *Every accepted* MetaCICDecidableBoundar *packet binds exactly the finite obligation surface displayed in Definition 749.1: carrier admission*

for $D = (T, S, B, F, R, H, C, P, N)$, checker visibility for T, structural equality visibility for S, bounded normal comparison visibility for B, finished-normal side-condition visibility for F, refusal visibility for R, componentwise hsame *transport through H, finite* Cont *replay through C, sibling provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundaryTasteGate single carrier alignment`

Proof. Project the carrier. The positive checker rows are T, S, B, F: the typing checker reads T together with the structural equality row S, and the conversion checker reads the bounded normal comparison row B together with the finished-normal side-condition row F.

The refusal row R is part of the same finite packet. It records that the carrier does not contain a separate ClosedAt decision theorem and does not contain an unrestricted beta-conversion decider for arbitrary closed terms.

The structural rows H, C, P, N only transport, replay, package, and name those displayed reads. Since no further coordinate is present, the local NameCert surface is exhausted by the listed obligations. □

Theorem 749.3 (MetaCIC decidable boundary bounded comparison non-escape)**.** *Any consumer of an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet may read bounded normal equality only through B and F. The read can expose equality or beta-convertibility of the bounded normalizer outputs under the finished-normal-form side conditions, but it cannot export a global closed beta-conversion decision procedure, a fuel-erased normalisation theorem, or a quotient equality over represented terms.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundary bounded comparison nonescape`

Proof. Begin with the bounded comparison coordinates. The carrier separates B, the bounded normalizer comparison row, from F, the row that supplies the finished-normal-form side conditions.

The refusal coordinate R records the missing promotion from bounded comparison to global closed beta conversion. Thus a consumer cannot skip F or erase the fuel boundary by rereading B as an unrestricted oracle.

Finally use the structural rows. The hsame and Cont routes in H, C replay the same finite comparison route, while P, N only record provenance and local naming. None of these rows adds a quotient equality, host evaluator, or global normalisation endpoint. □

Theorem 749.4 (MetaCIC decidable boundary refusal exactness)**.** *For every accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet $D = (T, S, B, F, R, H, C, P, N)$, the refusal row R is exact: it records precisely the absence of a standalone* ClosedAt *decider and an unrestricted closed beta-conversion oracle, while the finite rows T, S, B, F, H, C, P, N remain available for checker reads, structural equality reads, bounded comparison, finished-normal side conditions, componentwise transport, displayed replay, provenance, and local naming. The refusal row exports no fuel-erased normalization theorem and no quotient equality over represented terms.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundaryRefusalExactness`

Proof. Project the refusal coordinate R from the carrier of Definition 749.1. The carrier text gives R exactly the two refusal duties: no standalone ClosedAt decision theorem and no global closed beta-conversion decider.

Apply Definition 749.2. It keeps R inside the same finite NameCert surface as the positive rows T, S, B, F, H, C, P, N, so the refusal does not erase the bounded checker or comparison services already displayed by the carrier.

Now use Definition 749.3. The bounded comparison row B can be read only with the finished-normal side-condition row F, and that read cannot be exported as a global conversion procedure.

Therefore the boundary is exact. Consumers may use the finite displayed rows, but they cannot obtain fuel-erased normalization or quotient equality from R or from any structural replay of the packet. □

Theorem 749.5 (MetaCIC decidable boundary sibling provenance)**.** *The provenance row P places* MetaCICDecidableBoundary$^{\uparrow}$ *between the audit map of chapter 9379, the normal false exclusion packet of chapter 732, the closed-normal confluence seal of chapter 741, and the subject-reduction obstruction packet of chapter 731. Agreement on H, C, P, N preserves only finite route and naming data among those chapters; it does not identify their theorem rows or discharge their missing global endpoints.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundary sibling provenance`

Proof. Read P as package provenance. It cites the audit map and the three sibling concrete chapters as anchors for typing, normal-form, confluence, and subject-reduction boundaries.

The shared rows H, C, P, N give only componentwise transport, continuation replay, package provenance, and local naming. They do not collapse the sibling packets into one theorem because each sibling keeps its own theorem and refusal rows.

Therefore the sibling route is a finite citation and transport surface. It preserves the decidability boundary without turning normal false exclusion, closed-normal confluence, or subject-reduction obstruction into a global conversion or consistency theorem. □

Theorem 749.6 (MetaCIC decidable boundary window totality)**.** *For every accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet $D = (T, S, B, F, R, H, C, P, N)$, each bounded comparison request read through B has a finite inspected window supplied by the displayed checker and structural-equality rows T, S together with the finished-normal side-condition row F. The packet supplies no host decidability theorem, no global MetaCIC normalization theorem, and no unrestricted beta-conversion oracle.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundaryWindowTotality`

Proof. Project the carrier. The bounded comparison row is B, and the only rows that can feed it are the checker row T, the structural-equality row S, and the finished-normal side-condition row F.

Apply Definition 749.2. It lists checker visibility, structural equality visibility, bounded normal comparison visibility, and finished-normal side-condition visibility as finite rows of the same local packet.

The bounded comparison non-escape theorem then prevents rereading B as a global decision procedure. Hence each comparison has exactly the finite inspected window recorded by the displayed rows, with no host-level decision or normalization endpoint. □

Theorem 749.7 (MetaCIC decidable boundary candidate normal-form reads)**.** *Every candidate-normal-form read available to an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet factors through the checker row T, structural equality row S, bounded normal row B, finished-normal side-condition row F, and refusal row R. The read may be replayed through H, C, P, N, but it cannot export a standalone* ClosedAt *decider, global beta-conversion decision, quotient equality over represented terms, or host evaluator.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundary candidate normal form reads`

Proof. Start from the window totality theorem Definition 749.6. It says that each bounded comparison request has a finite inspected window supplied by T, S, F together with the bounded comparison row B.

Apply the NameCert obligation theorem Definition 749.2. Candidate-normal-form reads are therefore carrier reads of the same packet, so their structural replay is limited to H, C, P, N.

Now use bounded comparison non-escape and refusal exactness, Definition 749.3 and Definition 749.4. The row B remains bounded by F, while R records the absence of standalone ClosedAt decidability and unrestricted closed beta conversion.

Thus a candidate-normal-form read may expose the finite checker, structural equality, bounded normal, side-condition, refusal, and replay rows, but it cannot become a global conversion decision, quotient equality, or host evaluation procedure. □

Theorem 749.8 (MetaCIC decidable boundary bridge status)**.** *Any bridge consumer of an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet receives only the finite checker row T, structural equality row S, bounded normal comparison row B, finished-normal side-condition row F, refusal row R, componentwise* hsame *transport H, displayed* Cont *replay C, package provenance P, and local naming N. The bridge surface cannot extract global* ClosedAt *decidability, unrestricted beta-conversion, quotient equality over represented terms, or host evaluation from the bounded comparison packet.*

Proof. Start with the NameCert obligations of Definition 749.2. They expose exactly the finite checker, structural equality, bounded comparison, side-condition, refusal, transport, replay, provenance, and local naming rows of the packet.

Use bounded-comparison nonescape, Definition 749.3. It keeps every comparison read tied to B together with the finished-normal side-condition row F, so a bridge consumer cannot erase the bounded window and read B as a global conversion oracle.

Apply refusal exactness and candidate-normal-form reads, Definition 749.4 and Definition 749.7. The refusal row R records the absent global endpoints, while candidate-normal inspection remains inside the same finite checker and comparison route.

Finally, the structural rows H, C, P, N only transport, replay, source, and name that displayed route. Since no carrier coordinate supplies global ClosedAt decidability, unrestricted beta-conversion, quotient equality, or host evaluation, no bridge consumer can recover those endpoints from the packet. □

Theorem 749.9 (MetaCIC decidable boundary classifier stability)**.** *Let $D = (T, S, B, F, R, H, C, P, N)$ be an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet. Classifier reads of T, S, B, F, R are stable only along the displayed componentwise* hsame *row H and the finite* Cont *replay row C. This stability transports the bounded checker surface but does not identify sibling theorem rows, decide arbitrary closed terms, or erase the fuel boundary.*

Proof. Read H and C from the carrier. They are the only transport and replay rows attached to the checker, structural equality, bounded comparison, side-condition, and refusal coordinates.

Use Definition 749.2. It makes the hsame and Cont routes componentwise and finite, so they preserve only the displayed reads of T, S, B, F, R.

Finally apply Definition 749.5. The sibling route is provenance and naming data rather than theorem-row identification. Therefore classifier stability remains local to H, C and cannot become host decidability or global normalization. □

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundaryClassifierStability`

Theorem 749.10 (MetaCIC decidable boundary ledger exactness)**.** *For an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, the local ledger exposes exactly the recorded bounded-comparison rows* B, F *together with their checker, refusal, transport, replay, provenance, and naming context* T, S, R, H, C, P, N*. No consumer can read an unrecorded bounded-comparison row, a quotient of represented terms, a host evaluator, or a global beta-conversion decider.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundaryLedgerExactness`

Proof. Begin with the carrier and its NameCert obligations. They enumerate B and F as the bounded-comparison and finished-normal side-condition rows and place T, S, R, H, C, P, N around them as context.

Apply Definition 749.3. It rules out promotion from those rows to unrestricted conversion, fuel-erased normalisation, or quotient equality over represented terms.

The provenance theorem accounts for the remaining sibling references. They explain where the finite boundary sits, but they add no extra comparison rows. Thus the ledger is exact: the displayed bounded-comparison rows are all that consumers may inspect. □

Theorem 749.11 (MetaCIC decidable boundary fuel obligation)**.** *For an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, every bounded-fuel read used by the decidable-boundary surface is a finite read of* F *together with the checker, structural equality, bounded comparison, refusal, transport, replay, provenance, and local naming context* T, S, B, R, H, C, P, N*. The read may bound a displayed normal comparison, but it does not export standalone* ClosedAt *decidability, global beta-conversion, quotient equality over represented terms, fuel-erased normalization, or host evaluation.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundaryFuelObligation`

Proof. Project the carrier and the ledger exactness theorem Definition 749.10. The only side-condition coordinate for bounded normal comparison is F, and the ledger places it beside T, S, B, R, H, C, P, N.

Use bounded comparison non-escape from Definition 749.3. A comparison through B remains tied to the displayed side-condition row F, so the fuel boundary is not erased.

Finally apply refusal exactness from Definition 749.4. The refusal row R keeps standalone ClosedAt decidability, global beta-conversion, quotient equality, fuel-erased normalization, and host evaluation outside the packet. □

Theorem 749.12 (MetaCIC decidable boundary candidate obligation)**.** *For an accepted* MetaCICDecidableBoundar *packet* $D = (T, S, B, F, R, H, C, P, N)$*, every candidate-normal read factors through the finite checker row* T*, structural equality row* S*, bounded normal comparison row* B*, finished-normal side-condition row* F*, refusal row* R*, and structural rows* H, C, P, N*. Candidate-normality is therefore a displayed packet obligation, not a route to standalone* ClosedAt *decidability, global beta-conversion, quotient equality over represented terms, fuel-erased normalization, or host evaluation.*

Proof. Start from candidate normal-form reads in Definition 749.7. They already expose $T, S, B, F, R, H, C, P, N$ as the finite route for candidate-normal data.

Apply ledger exactness from Definition 749.10. Since the ledger has no unrecorded comparison row or host evaluator, the candidate read cannot move outside the displayed packet.

The refusal row is then read through Definition 749.4. It blocks standalone ClosedAt decidability, global beta-conversion, quotient equality, and fuel-erased normalization while leaving the finite candidate-normal route intact. □

Theorem 749.13 (MetaCIC decidable boundary replay obligation)**.** *For an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, every replay of the decidable-boundary surface is finite and componentwise along* H *and* C *after the rows* T, S, B, F, R *have been exposed. Replay preserves the checker, structural equality, bounded comparison, side-condition, and refusal ledger, but it does not create standalone* ClosedAt *decidability, global beta-conversion, quotient equality over represented terms, fuel-erased normalization, or host evaluation.*

Proof. Read classifier stability from Definition 749.9. It identifies H and C as the transport and replay rows for the displayed checker, equality, comparison, side-condition, and refusal coordinates.

Use ledger exactness from Definition 749.10. Replay can preserve only recorded rows, so it cannot introduce an unrecorded comparison row, quotient of represented terms, host evaluator, or global beta-conversion decider.

Finally apply ClosedAt refusal routing from Definition 749.24. Any standalone decision request is sent to R, while H, C, P, N replay and name only the finite boundary. □

Theorem 749.14 (MetaCIC decidable boundary substitution window)**.** *For every accepted* MetaCICDecidableBoun *packet* $D = (T, S, B, F, R, H, C, P, N)$*, any substitution-sensitive bounded comparison read factors through the checker row* T*, structural equality row* S*, bounded normal row* B*, finished-normal side-condition row* F*, refusal row* R*, and the transport and replay rows* H, C, P, N*. The read may compare the displayed bounded normal outputs under the recorded side conditions, but it cannot export standalone* ClosedAt *decidability, global beta-conversion, quotient equality over represented terms, or a host evaluator.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundarySubstitutionWindow`

Proof. Start with the NameCert obligations of Definition 749.2. They expose the checker, structural equality, bounded normal comparison, finished-normal side condition, refusal, transport, replay, provenance, and naming rows as one finite packet.

Apply bounded comparison non-escape from Definition 749.3. A comparison read through B must keep the finished-normal side-condition row F visible, so substitution-sensitive use of the comparison cannot erase the fuel and side-condition boundary.

Now use refusal exactness and classifier stability, Definition 749.4 and Definition 749.9. The row R records the absence of global endpoints, while H, C transport and replay only the displayed checker and comparison rows.

Finally apply ledger exactness from Definition 749.10. Since the ledger contains no unrecorded bounded-comparison row, quotient of represented terms, host evaluator, or global beta-conversion decider, the substitution window remains a finite bounded comparison surface. □

Theorem 749.15 (MetaCIC decidable boundary refusal substitution stability)**.** *For every accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, substitution-sensitive reads that ask for standalone* ClosedAt *decidability, global beta-conversion, quotient equality over represented terms, fuel-erased normalization, or host evaluator behavior are still routed to the refusal row* R*. The transport, replay, provenance, and naming rows* H, C, P, N *preserve the finite substitution window, but they do not turn the refused requests into accepted endpoints.*

Proof. Begin with the substitution-window theorem Definition 749.14. It keeps every substitution-sensitive bounded comparison inside $T, S, B, F, R, H, C, P, N$.

Use refusal exactness from Definition 749.4. The row R is precisely the displayed refusal boundary for standalone ClosedAt decisions, global beta-conversion, quotient equality, fuel-erased normalization, and host evaluation.

Finally apply ledger exactness from Definition 749.10. Since the ledger contains no separate endpoint for those requests, transport and replay through H, C, P, N can preserve only the finite boundary and must route the requests back to R. □

Theorem 749.16 (MetaCIC decidable boundary candidate-normal substitution scope)**.** *For every accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, candidate-normal comparison under substitution consumes only the checker row* T*, structural equality row* S*, bounded normal comparison row* B*, finished-normal side-condition row* F*, refusal row* R*, transport row* H*, replay row* C*, provenance row* P*, and local naming row* N*. No candidate-mediated read may add a hidden evaluator, quotient equality row, global beta-conversion decider, standalone* ClosedAt *decider, or fuel-free normalization endpoint.*

Proof. Start from candidate-normal-form reads in Definition 749.7. Candidate inspection is already tied to T, S, B, F and cannot be detached from the displayed checker and side-condition rows.

Apply the substitution-window theorem Definition 749.14. It shows that substitution-sensitive comparison still passes through R, H, C, P, N in addition to the checker, equality, comparison, and finished-normal rows.

Use refusal exactness and ledger exactness, Definition 749.4 and Definition 749.10. The refusal row accounts for the missing global endpoints, and the ledger has no unrecorded row beyond $T, S, B, F, R, H, C, P, N$. □

Theorem 749.17 (MetaCIC decidable boundary candidate-substitution exhaustion)**.** *For every accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, every substitution-sensitive candidate comparison read must expose the checker row* T*, structural equality row* S*, bounded normal row* B*, finished-normal row* F*, refusal row* R*, and replay and provenance rows* H, C, P, N*. No consumer may infer standalone* ClosedAt *decidability, global beta-conversion, quotient equality over represented terms, or host evaluator behavior from such a candidate-mediated read.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundaryCandidateSubstitutionExhaustion`

Proof. Begin with the substitution-window theorem Definition 749.14. It already routes every substitution-sensitive bounded comparison through $T, S, B, F, R, H, C, P, N$.

Use candidate-normal-form reads and bounded comparison nonescape, Definition 749.7 and Definition 749.3. Candidate inspection therefore remains tied to the displayed checker, structural equality, bounded normal comparison, and finished-normal side-condition rows.

Now apply refusal exactness and classifier stability, Definition 749.4 and Definition 749.9. The refusal row records the missing global endpoints, while H, C transport and replay only the displayed candidate and comparison rows.

Finally invoke ledger exactness from Definition 749.10. The ledger contains no unrecorded comparison row, quotient of represented terms, host evaluator, standalone ClosedAt decider, or global beta-conversion decider, so the candidate-substitution surface is exhausted by $T, S, B, F, R, H, C, P, N$. □

Theorem 749.18 (MetaCIC decidable boundary obligation-closure package)**.** *For an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, the finite checker row* T*, structural equality row* S*, bounded normal comparison row* B*, finished-normal side-condition row* F*, refusal row* R*, and structural rows* H, C, P, N *form exactly the obligation-closure surface of the chapter. The package records checker visibility, structural-equality visibility, bounded-comparison*

visibility, finished-normal side conditions, refusal exactness, sibling provenance, classifier stability, and ledger exactness, while it still exports no standalone ClosedAt *decidability, global beta-conversion decidability, fuel-erased normalization, quotient equality, or host evaluation.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundary obligation closure package`

Proof. Start with Definition 749.2. It lists the carrier admission, checker row, structural equality row, bounded comparison row, finished-normal side condition, refusal row, transport, replay, provenance, and local naming rows of D.

Use Definition 749.3 and Definition 749.4. Together they keep B, F as bounded comparison data and keep R as the exact refusal of standalone ClosedAt decidability and global beta conversion.

Apply Definition 749.5 and Definition 749.10. Provenance contributes only the named sibling route, and the ledger supplies no unrecorded bounded-comparison row, quotient of represented terms, host evaluator, or global beta-conversion decider.

The classifier-stability theorem Definition 749.9 transports the same displayed rows through H, C without adding a new endpoint. Hence $T, S, B, F, R, H, C, P, N$ are exactly the obligation-closure package surface. □

Theorem 749.19 (MetaCIC decidable boundary conditional obligation)**.** *For every accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, an accepted bounded comparison read is valid only under the displayed checker row* T*, structural equality row* S*, bounded normal row* B*, finished-normal side-condition row* F*, and refusal row* R*, with transport, replay, provenance, and naming rows* H, C, P, N *still visible. The conditional route explicitly refuses standalone* ClosedAt *decidability, global beta-conversion, quotient equality over represented terms, and host evaluation.*

Proof. Start with bounded-comparison nonescape and window totality, Definition 749.3 and Definition 749.6. They make every accepted bounded comparison expose T, S, B, F rather than a detached comparison oracle.

Use candidate normal-form reads from Definition 749.7. Candidate inspection remains inside the same checker, structural equality, bounded normal, and finished-normal side-condition rows.

Apply refusal exactness from Definition 749.4. The row R records the missing standalone ClosedAt decision and unrestricted beta-conversion endpoint, while leaving the bounded comparison route available only under its displayed conditions.

Finally invoke ledger exactness and the obligation-closure package, Definition 749.10 and Definition 749.18. The ledger has no quotient equality over represented terms and no host evaluator, so the valid comparison surface is exactly $T, S, B, F, R, H, C, P, N$. □

Theorem 749.20 (MetaCIC decidable boundary obligation scope lock)**.** *For every accepted* MetaCICDecidableBour *packet* $D = (T, S, B, F, R, H, C, P, N)$*, every obligation-closure consumer must keep the checker row* T*, structural equality row* S*, bounded normal comparison row* B*, finished-normal side-condition row* F*, refusal row* R*, componentwise transport row* H*, displayed replay row* C*, provenance row* P*, and local name row* N *together. In particular, bounded normal comparison cannot be read as global beta-conversion decidability, standalone* ClosedAt *decidability, quotient equality over represented terms, fuel-erased normalization, or host evaluation.*

Proof. Start with bounded-comparison nonescape, Definition 749.3. It permits a read of B only with the finished-normal side-condition row F, and it refuses the jump to global conversion.

Apply refusal exactness, Definition 749.4. The row R records exactly the missing standalone ClosedAt decision and unrestricted beta-conversion decision, while the positive checker and comparison rows remain finite.

Use classifier stability and ledger exactness, Definition 749.9 and Definition 749.10. Transport and replay preserve the displayed rows, and the ledger contains no unrecorded comparison row, quotient of represented terms, host evaluator, or global beta-conversion decider.

Finally invoke the obligation-closure package theorem Definition 749.18. It identifies $T, S, B, F, R, H, C, P, N$ as the exact obligation surface. Hence any obligation-closure consumer must keep the rows together, and the bounded comparison row cannot be exported as a global decidability principle. □

Theorem 749.21 (MetaCIC decidable boundary ClosedAt refusal scope)**.** *For an accepted* MetaCICDecidableBound *packet $D = (T, S, B, F, R, H, C, P, N)$, the refusal row R records only the absence of standalone* ClosedAt *decisions and global beta-conversion decisions. It cannot erase the bounded side conditions attached to B, F, and it cannot turn the transported checker surface T, S, H, C, P, N into a host evaluator or quotient equality.*

Proof. Start with refusal exactness from Definition 749.4. That theorem identifies R as the exact refusal of standalone ClosedAt decidability and unrestricted closed beta conversion.

Now use bounded comparison non-escape and candidate-normal-form reads, Definition 749.3 and Definition 749.7. They keep every comparison read tied to B, F and keep candidate-normal-form inspection inside the displayed finite packet.

Finally apply classifier stability and ledger exactness, Definition 749.9 and Definition 749.10. Transport and ledger replay preserve the refusal boundary but add no erased side-condition row, quotient equality, or host evaluator. □

Theorem 749.22 (MetaCIC decidable boundary bounded normal comparison scope)**.** *Every bounded normal comparison read of an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet factors through the finite route $T, S, B, F, R, H, C, P, N$. The read may compare the displayed bounded normal outputs under the finished-normal side conditions, but it cannot become quotient equality over represented terms, standalone* ClosedAt *decidability, global beta-conversion decidability, fuel-erased normalization, or a host evaluator.*

Proof. Begin with the bounded comparison non-escape theorem Definition 749.3. It makes B, F the only route to bounded normal equality and keeps the finished-normal side condition visible.

Use the substitution-window theorem Definition 749.14. It routes substitution-sensitive comparison through $T, S, B, F, R, H, C, P, N$, so the comparison cannot be detached from the checker and refusal rows.

Finally apply candidate-normal-form reads and ledger exactness, Definition 749.7 and Definition 749.10. The ledger contains no unrecorded comparison row, quotient of represented terms, host evaluator, unrestricted beta-conversion decider, or fuel-free normalization endpoint. □

Theorem 749.23 (MetaCIC decidable boundary finite checker indexing)**.** *Every finite checker output exposed by an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet remains indexed by the displayed fuel row, closedness evidence, and normal endpoint rows carried by $T, S, B, F, R, H, C, P, N$. Consequently the output can be replayed only as bounded checker evidence inside the packet; it cannot be promoted to a global closed-term conversion decision.*

Proof. Start with fuel-window replay, Definition 749.25. It keeps every bounded comparison read tied to the fuel and finished-normal side-condition row F, so the checker output is not fuel-free.

Next use the conversion nonescape package, Definition 749.26. Conversion-facing consumers see only B, F, R, H, C, P, N, with R recording the missing global endpoints and with structural replay confined to the displayed route.

Finally apply the normal-form decision envelope, Definition 749.27. The positive envelope contains the finite checker and bounded-comparison rows together with their finished-normal side conditions, while the refusal row keeps standalone ClosedAt and global beta-conversion decisions outside the packet. □

Theorem 749.24 (MetaCIC decidable boundary ClosedAt refusal route)**.** *For an accepted* MetaCICDecidableBound *packet $D = (T, S, B, F, R, H, C, P, N)$, any consumer asking for a standalone* ClosedAt *decision route is sent exactly to the refusal row R. The positive rows T, S, B, F remain available for typing, structural equality, bounded normal comparison, and finished-normal side conditions, while H, C, P, N only transport, replay, source, and name that finite boundary.*

Proof. Project the carrier of Definition 749.1. The only coordinate assigned to a standalone ClosedAt decision theorem is the refusal coordinate R.

Use refusal exactness from Definition 749.4. It records the absence of standalone ClosedAt decidability without deleting the positive checker and comparison rows T, S, B, F.

Finally apply classifier stability and ledger exactness, Definition 749.9 and Definition 749.10. The rows H, C, P, N can replay only the displayed boundary, so a ClosedAt-facing consumer cannot find another route outside R. □

Theorem 749.25 (MetaCIC decidable boundary fuel-window replay)**.** *Let $D = (T, S, B, F, R, H, C, P, N)$ be an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet. Every bounded comparison replay that reads B must also expose the fuel and finished-normal side-condition row F. The replay may use T, S, H, C, P, N to reach the finite comparison window, but it cannot erase F or turn B into fuel-free normalization.*

Lean4 ✓ `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundaryFuelWindowReplay`

Proof. Start with the bounded comparison non-escape theorem Definition 749.3. It permits access to bounded normal equality only through the pair B, F.

The window totality theorem Definition 749.6 supplies the finite inspected window through T, S together with F. Thus the replayed comparison keeps the side-condition row visible at the same point where B is read.

The remaining structural rows H, C, P, N preserve the route but add no fuel-erased endpoint. Therefore bounded replay cannot remove F and cannot export global normalization. □

Theorem 749.26 (MetaCIC decidable boundary conversion nonescape package)**.** *Every conversion-facing consumer of an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet factors through the finite package B, F, R, H, C, P, N. The rows B, F supply bounded comparison under finished-normal side conditions, R records the missing global endpoints, and H, C, P, N provide only componentwise transport, displayed replay, provenance, and local naming.*

Proof. Begin with candidate normal-form reads from Definition 749.7. Any conversion-facing request reaches the bounded normal row B, the side-condition row F, and the refusal row R before it can be replayed structurally.

Apply fuel-window replay and ClosedAt refusal routing, Definition 749.25 and Definition 749.24. They keep the bounded comparison tied to F and send standalone decision requests to R.

The structural part of the package is then exactly H, C, P, N. By ledger exactness, these rows add no quotient equality, host evaluator, unrestricted beta-conversion decider, or fuel-free normalization theorem. □

Theorem 749.27 (MetaCIC decidable boundary normal-form decision envelope)**.** *For every accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, every normal-form decision read available from* D *factors through the finite route* $T, S, B, F, R, H, C, P, N$*. The positive envelope contains only* inferTypeCtx *reads from* T*,* checkSameTerm *reads from* S*, bounded normal comparison reads from* B*, and finished-normal side conditions from* F*. The refusal row* R *still records the absence of standalone* ClosedAt *decidability, global beta-conversion decidability, quotient equality over represented terms, fuel-erased normalization, and host evaluation.*

Proof. Start with window totality from Definition 749.6. Any normal-form decision read has a finite inspected window, and that window is supplied by the checker row T, the structural-equality row S, the bounded comparison row B, and the finished-normal side-condition row F.

Apply bounded normal comparison scope from Definition 749.22. It keeps comparison inside the displayed route $T, S, B, F, R, H, C, P, N$ and prevents the bounded comparison from becoming quotient equality, unrestricted conversion, fuel-erased normalization, or host evaluation.

Use the ClosedAt refusal route of Definition 749.24. A standalone ClosedAt request is sent to R, while the positive checker and comparison rows remain available only as the finite rows already displayed by the packet.

Finally apply the conversion nonescape package Definition 749.26. It repacks the conversion-facing surface through B, F, R, H, C, P, N, so the normal-form decision envelope is exactly the positive checker, structural equality, bounded comparison, and finished-normal side-condition surface together with the refusal boundary in R. □

Theorem 749.28 (MetaCIC decidable boundary conversion refusal trichotomy)**.** *For every accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet* $D = (T, S, B, F, R, H, C, P, N)$*, every conversion-facing request is classified by exactly one displayed route: bounded comparison through* B *together with the finished-normal side condition* F*, finite refusal through* R *when that side condition is absent, or structural replay through* H, C, P, N *when the request is only transporting an already displayed boundary. None of the three routes exports global beta-conversion, fuel-erased normalization, quotient equality over represented terms, or host evaluation.*

Proof. Begin with the normal-form decision envelope Definition 749.27. A positive conversion-facing read must expose the finite checker rows T, S, the bounded comparison row B, and the finished-normal side-condition row F before any comparison result is available.

If F is absent, apply the ClosedAt refusal route Definition 749.24. The request cannot be promoted to a standalone conversion decision, so it is routed to the finite refusal row R rather than to a hidden normalizer or host evaluator.

If the request is a replay of already displayed data, apply fuel-window replay Definition 749.25. The structural rows H, C, P, N can transport, replay, source, and name the boundary, but they cannot erase fuel or add a new comparison endpoint.

The candidate-substitution and refusal exactness rows separate these cases. A request with B, F present is the bounded-comparison route; a request lacking the side condition is the refusal route through R; and a request that only reuses displayed data is the replay route through H, C, P, N.

Finally use the conversion nonescape package Definition 749.26. Since the carrier has no coordinate for global beta-conversion, fuel-erased normalization, quotient equality, or host evaluation, the three displayed routes exhaust the conversion-facing classifier. □

Definition 749.29 (MetaCIC decidable boundary endpoint subcarrier)**.** *For an accepted* MetaCICDecidableBounda *packet $D = (T, S, B, F, R, H, C, P, N)$, the endpoint subcarrier is the finite packet*

$$D_{\text{end}} = (T, B, F, R, H, C, P, N)$$

consisting of the closed-term row T, bounded-normal comparison row B, finished-normal witness row F, refusal row R, componentwise transport H, displayed replay C, provenance P, and local $\mathsf{NameCert}_{\mathsf{MetaCICDecidableBoundary}^{\uparrow}}$ *row N. It deliberately omits any global conversion decider, quotient equality over represented terms, fuel-free normalizer, or host evaluator.*

Theorem 749.30 (MetaCIC decidable boundary finished normal endpoint)**.** *Every global closed beta-conversion decision read from an accepted* $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$ *packet may be read only after the endpoint subcarrier of Definition 749.29 supplies finished-normal witnesses through F. The bounded normal comparison row B alone remains a refusal boundary: without the endpoint rows T, F, R, H, C, P, N, it cannot export global conversion decidability, quotient equality over represented terms, fuel-erased normalization, or host evaluation.*

Proof. Start with the normal-form decision envelope Definition 749.27. It places every normal-form decision read on the finite route $T, S, B, F, R, H, C, P, N$ and keeps the positive comparison row tied to finished-normal side conditions.

Apply the conversion nonescape package Definition 749.26. Conversion-facing reads factor through B, F, R, H, C, P, N, with R recording the missing global endpoints.

Now project the endpoint subcarrier of Definition 749.29. It retains the closed-term row, bounded-normal comparison row, finished-normal witnesses, refusal row, transport, replay, provenance, and local naming, so a conversion read is available only with F present.

If B is read without this endpoint data, the route has only bounded comparison under a displayed window. The refusal row still blocks global beta-conversion decidability, quotient equality, fuel-erased normalization, and host evaluation. □

Theorem 749.31 (MetaCIC decidable boundary conversion case split)**.** *For every accepted* MetaCICDecidableBoun *packet $D = (T, S, B, F, R, H, C, P, N)$, each conversion request presented to the packet is split inside the displayed* BHist *route into an accepted finite case using T, S, B, F or a refusal row in R. The split is preserved by componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidableBoundary}^{\uparrow}}$ *row N.*

Proof. Use conversion refusal trichotomy. It classifies conversion-facing requests as bounded comparison with B, F, finite refusal through R, or structural replay through H, C, P, N.

The normal-form decision envelope supplies the accepted finite cases through T, S, B, F. The ClosedAt refusal route supplies the negative rows in R when the request asks for a standalone endpoint outside the packet.

Transport and replay are componentwise by classifier stability. Hence the split is a BHist and NameCert-facing route, not a parameter transport theorem and not a hidden global conversion decider. □

Theorem 749.32 (MetaCIC decidable boundary critical-pair finiteness)**.** *For every accepted* MetaCICDecidableBou *packet, every critical-pair check visible to the decidable-boundary surface is recorded as a finite ledger row inside $T, S, B, F, R, H, C, P, N$. The ledger records the inspected checker window, structural-equality comparison, bounded normal comparison, finished-normal side condition, refusal boundary, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming; it exports no unrecorded critical-pair search and no host evaluator.*

Proof. Start with window totality and ledger exactness. They make each bounded comparison a finite inspected window whose rows are T, S, B, F together with the refusal and structural context R, H, C, P, N.

Apply substitution window and candidate-substitution exhaustion. Critical-pair inspection is therefore read only through displayed checker, structural equality, bounded normal, finished-normal, refusal, replay, provenance, and naming rows.

The bounded comparison nonescape theorem blocks promotion to unrestricted conversion, quotient equality, fuel-erased normalization, or host evaluation. Thus the critical-pair check is a finite ledger row of the packet. □

Theorem 749.33 (MetaCIC decidable boundary normal-form readback)**.** *Every normal-form readback available from an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet is routed through the displayed boundary packet $T, S, B, F, R, H, C, P, N$. The readback may expose candidate normal-form data, bounded comparison under finished-normal side conditions, and finite refusal rows, but it cannot bypass the packet to obtain fuel-erased normalization, quotient equality over represented terms, standalone* ClosedAt *decidability, or host evaluation.*

Proof. Begin with candidate normal-form reads and the normal-form decision envelope. Together they route readback through the checker row T, structural equality row S, bounded comparison row B, finished-normal side condition F, and refusal row R.

Use fuel-window replay and the finished normal endpoint theorem. These keep readback tied to finite fuel and displayed endpoint rows before a conversion-facing read is accepted.

Finally apply the conversion nonescape package. The structural rows H, C, P, N only transport, replay, source, and name the displayed boundary, so readback cannot leave the packet for a fuel-erased normalizer, quotient equality, standalone ClosedAt decider, or host evaluator. □

Theorem 749.34 (MetaCIC decidable boundary public interface)**.** *Every public read exported by an accepted* MetaCICDecidableBoundary$^{\uparrow}$ *packet is confined to the bounded checker output, fuel-window replay, candidate-normal reads, substitution windows, refusal rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows of $T, S, B, F, R, H, C, P, N$. The public interface explicitly excludes global beta-conversion decidability, confluence, quotient equality over represented terms, fuel-erased normalization, and host evaluation.*

Proof. Start with fuel-window replay. It keeps any bounded comparison read tied to the fuel and finished-normal side-condition row F, so a public consumer cannot erase the window boundary.

Apply candidate-substitution exhaustion and the substitution-window theorem. Candidate-normal and substitution-sensitive reads remain inside $T, S, B, F, R, H, C, P, N$ and expose only the displayed checker, structural equality, bounded comparison, side-condition, and refusal rows.

Use normal-form readback to identify the accepted public read. It routes readback through the same boundary packet and blocks fuel-erased normalization, quotient equality, standalone ClosedAt decidability, and host evaluation.

Finally read the TasteGate single-carrier alignment marker at the top of the chapter. The carrier alignment keeps transport, replay, provenance, and naming attached to one finite packet, so the public interface cannot add confluence, global beta-conversion decidability, quotient equality, or host evaluation as hidden exports. □

Theorem 749.35 (MetaCIC decidable boundary bridged status)**.** *The public interface of Definition 749.34 together with the fuel-window replay target* `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDec` *gives a finite bridge surface from bounded checker rows to decidable-boundary consumers. The*

bridge surface preserves $T, S, B, F, R, H, C, P, N$ and refuses standalone ClosedAt *decidability, global beta-conversion decidability, fuel-erased normalization, quotient term equality, and host evaluation.*

Proof. Start from the carrier and NameCert obligations. They expose the finite packet $T, S, B, F, R, H, C, P, N$ as checker rows, structural equality, bounded normal comparison, finished-normal side conditions, refusal, transport, replay, provenance, and local naming.

Use fuel-window replay and normal-form readback. The replay keeps bounded comparison tied to F, while readback stays inside the displayed boundary packet before any public consumer receives a decision-facing row.

Finally apply the public interface theorem. It exports only the bounded checker, fuel-window, candidate-normal, substitution, refusal, transport, replay, provenance, and naming rows, so the bridge-facing surface has no coordinate for standalone ClosedAt decidability, global beta-conversion decidability, fuel-erased normalization, quotient equality, or host evaluation. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDecidableBoundary}\uparrow}$.

Constructive story: A $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$ packet is generated from inferTypeCtx checking, checkSameTerm structural equality, bounded normal comparison, finished-normal side conditions, refusal rows for ClosedAt and global beta conversion, componentwise transport, continuation routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICDecidableBoundary}\uparrow}$, maturePackageClosed)

Scope closed: Definition 749.1, Definition 749.2, Definition 749.3, Definition 749.4, Definition 749.5, Definition 749.11, Definition 749.12, Definition 749.13, Definition 749.14, Definition 749.34, and Definition 749.35 bind carrier admission, checker-row visibility, bounded-comparison nonescape, refusal exactness, sibling provenance, fuel-window obligation, candidate-normal read, replay obligation, substitution window, public interface, and bridge-facing status for the displayed packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICDecidableBoundary}\uparrow}$, axiomClean)

Ledger evidence: BEDC.Meta.DiscoveryDeltaLedger.metaCICDecidableBoundaryDeltaLedger

Lean target: `BEDC.Derived.MetaCICDecidableBoundaryUp.MetaCICDecidableBoundaryFuelWindowReplay`

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not close a standalone ClosedAt decider, global beta-conversion decidability, fuel-erased normalisation, quotient equality over represented terms, or bridge checking.

Upgrade path: Bridged closure requires a bridge surface that preserves the same finite decidable-boundary rows without claiming confluence, global beta-conversion decidability, fuel-erased normalization, quotient equality, or host evaluation.

Chapter 750

A Concrete Naming Certificate for $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$

The $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ packet realizes the normalization audit map of chapter 9383 as finite BEDC naming data. It sits beside the confluence audit packet of chapter 743 and the confluence audit witness of chapter 745: those siblings record confluence-side boundary rows, while the present packet records the strong-normalization route, its refusal boundary, and the finite replay surface used by consistency consumers.

Definition 750.1 (MetaCIC normalization audit carrier)**.** *A* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (R, C, S, A, N, F, H, T, P, L)$$

with the following displayed rows:

1. *R is the reducibility-candidate row naming* Candidate*,* ClosedTypedCandidate*,* ClosedTypedPiCandidate*, and* ClosedTypedCandidateSetMember *evidence;*
2. *C is the checked closed-term projection row for candidate, closed-candidate, and candidate-set routes to* StrongNormalizable(t)*;*
3. *S is the finite strong-normalization scope row containing the checked candidate-to-SN, Pi adequacy, application adequacy, example SN, and no-infinite-reduction reads;*
4. *A is the application-boundary row recording that componentwise SN of function and argument is not reread as unconditional application SN;*
5. *N is the confluence-boundary refusal row separating this normalization packet from full closed Church–Rosser, substitution compatibility, and subject-reduction transport;*
6. *F is the route replay row for manuscript citations that pass from the audit map to the closed-normal consistency consumer;*
7. *H records componentwise* hsame *transport across R, C, S, A, N, F, P, L;*
8. *T records displayed* Cont *routes for replaying candidate, projection, scope, boundary, and consistency-consumer reads;*
9. *P is the* Pkg *provenance over the normalization audit map, the confluence audit sibling, the confluence audit witness sibling, and the closed-normal consistency assembly;*
10. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAudit}^{\uparrow}}$ *row.*

The carrier has no row for global strong normalization of every closed typed MetaCIC term without candidate-mediated evidence, no unconditional application-SN theorem, no closed subject-reduction transport theorem, no arbitrary closed-term confluence theorem, no quotient equality over reductions, and no host evaluator.

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditTasteGate single carrier alignment`

Theorem 750.2 (MetaCIC normalization audit obligation surface)**.** *Every accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet binds exactly the finite obligation surface displayed in Definition 750.1: carrier admission for* $Z = (R, C, S, A, N, F, H, T, P, L)$*, candidate evidence visibility through* R*, closed-term projection visibility through* C*, finite SN scope visibility through* S*, application-boundary visibility through* A*, confluence and transport refusal visibility through* N*, route replay through* F *and* T*, componentwise* hsame *transport through* H*, provenance through* P*, and local naming through* L*.*

Proof. Project the carrier coordinates. The positive normalization reads are R, C, S: a consumer first names candidate evidence, then reads the closed-term projection row, and only then reads the finite SN and no-infinite-reduction inventory.

The boundary rows A and N are part of the same packet. They keep application SN and confluence or subject-reduction transport from being inferred by erasing their required evidence.

The structural rows F, H, T, P, L replay, transport, package, and name only those displayed reads. Since the carrier has no additional coordinate, the listed rows exhaust the local NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCarrier obligation surface`

Theorem 750.3 (MetaCIC normalization audit candidate boundary)**.** *Every accepted* MetaCICNormalizationAudit$^{\uparrow}$ *read that claims normalization must first expose the candidate packet in* R*, the closedness trace in* C*, the beta-chain route in* S*, and the residual and confluence boundary rows in* A *and* N*. The replay rows* F, H, T, P, L *may transport and name that same route, but they do not supply subject reduction, confluence, or strong normalization unless downstream candidate, residual, or frontier packets supply those rows explicitly.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateBoundary`

Proof. Start with the obligation surface of Definition 750.2. It makes R, C, S, A, N separate displayed rows of the accepted packet, so a normalization read cannot jump directly from the packet name to a closed-term conclusion.

The candidate packet is read through R, and the closedness trace is read through C. The beta-chain route and finite normalization inventory are then read through S, with the application boundary A still present.

Finally inspect the refusal row N together with replay through F, H, T, P, L. Those rows preserve the same finite route and keep the confluence and subject-reduction frontier visible. Therefore subject reduction, confluence, and strong normalization outside the displayed candidate route must come from downstream candidate, residual, or frontier packets rather than from this audit packet alone. □

Theorem 750.4 (MetaCIC normalization audit finite SN scope)**.** *The strong-normalization content exported by an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet is exactly the candidate-mediated*

scope stored in R, C, S: candidate-to-SN consequences, closed typed term SN from candidate, closed-candidate, or candidate-set evidence, Pi adequacy, application adequacy under candidate evidence, typed example SN facts, and the associated no-infinite-reduction consequences. It does not export a blanket theorem that every closed typed MetaCIC term is strongly normalizing without one of those displayed evidence rows.

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCarrier sn scope`

Proof. Read R as the evidence row. It contains the candidate, closed-candidate, Pi-candidate, and candidate-set membership interfaces that the checked projection theorems consume.

Read C and S downstream from R. These rows record the closed typed term projections, adequacy facts, examples, and no-infinite-reduction consequences only along the candidate-mediated route.

The carrier contains no coordinate that constructs candidate evidence for every closed typed term. Therefore agreement on the packet preserves the finite SN scope while excluding the blanket evidence-free endpoint. □

Theorem 750.5 (MetaCIC normalization audit closed-term projection route)**.** *Every closed-term strong-normalization read exported by an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet must pass through the reducibility-candidate row R, the checked closed projection row C, the finite scope row S, and the application-boundary row A. The route may project candidate, closed-candidate, candidate-set, Pi, and application evidence into the finite SN inventory, but it cannot replace those rows by evidence-free global strong normalization for closed MetaCIC terms.*

Proof. Project the carrier $Z = (R, C, S, A, N, F, H, T, P, L)$. A closed-term SN consumer first sees candidate evidence in R and the checked closed projection row C, so the read is already routed through displayed finite data.

Apply Definition 750.4. The finite SN consequences live in S only after the candidate-mediated projection has supplied the relevant evidence.

Finally apply Definition 750.6. The application-facing boundary A keeps application SN inside the same candidate route and refuses any evidence-free global SN endpoint. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCarrier closed term projection route`

Theorem 750.6 (MetaCIC normalization audit candidate-mediated SN closure)**.** *Let $Z = (R, C, S, A, N, F, H, T, P$ be an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet. If a consumer reads the candidate row R, the closed-term projection row C, the finite strong-normalization scope row S, and the application-boundary row A, then every exported strong-normalization claim factors through those rows and through no evidence-free global strong-normalization theorem. In particular, an SN export may name candidate evidence, closed-term projection, finite scope inventory, and application adequacy under the displayed boundary, but it cannot replace them by a blanket theorem for all closed typed MetaCIC terms.*

Proof. Apply Definition 750.2. The accepted packet exposes normalization reads only through the displayed candidate, projection, finite-scope, application-boundary, refusal, replay, transport, provenance, and naming rows.

Use Definition 750.4. It identifies the strong-normalization content as the candidate-mediated scope carried by R, C, S and explicitly withholds a blanket endpoint for closed typed terms without one of the displayed evidence rows.

Finally apply Definition 750.16. The ledger route forces manuscript consumers to replay the same packet coordinates and blocks host termination or hidden theorem reads. Since A is part of the accepted boundary, application-facing SN claims remain inside the candidate-mediated route rather than becoming an evidence-free global theorem. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateMediatedSNClosure`

Theorem 750.7 (MetaCIC normalization audit residual-budget obligation)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. Every exported strong-normalization claim must spend an explicit residual-budget row whose readback links candidate evidence in R, closed-term projection in C, finite strong-normalization scope in S, the application boundary in A, and the confluence refusal in N. A consumer that cites candidate-mediated SN without this residual-budget route receives only the local obligation surface, not a public SN export.*

Proof. Start with the obligation surface of Definition 750.2. It displays R, C, S, A, N as separate rows, so an exported SN claim must account for each row rather than reading the finite scope in isolation.

Use Definition 750.4. The positive SN content is the finite candidate-mediated inventory stored in R, C, S, with no blanket endpoint for closed typed terms lacking the displayed evidence.

Next apply Definition 750.6. It keeps application-facing SN claims inside the same candidate route and prevents the application boundary A from being erased by a downstream consumer.

The residual budget is completed by the refusal row N. That row records that confluence, subject-reduction transport, and full closed Church–Rosser remain outside the normalization export. Replaying the route through F, T, H, P, L names the same spent budget and leaves no coordinate for evidence-free strong normalization. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditResidualBudgetObligation`
↪ variant `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCarrier residual budget obligation`

Theorem 750.8 (MetaCIC normalization audit candidate-ledger locality)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. Every strong-normalization export must keep candidate evidence R, closed projection C, finite scope S, application boundary A, and confluence refusal N in the same candidate ledger before replay through F, H, T, P, L. No consumer may replace those rows by global strong normalization, subject reduction, confluence, quotient equality, or host evaluator evidence.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateLedgerLocality`

Proof. Begin with the obligation surface of Definition 750.2. It exposes R, C, S, A, N as separate rows of one accepted packet, so an SN export cannot read the finite scope while dropping the candidate evidence, closed projection, application boundary, or refusal row.

Use the finite SN scope theorem Definition 750.4 and the closed-term projection route of Definition 750.5. Together they place every positive SN read behind candidate evidence in R, projection evidence in C, and finite scope in S.

Apply the residual-budget obligation Definition 750.7. The budget links R, C, S with the application boundary A and confluence refusal N before any replay row can expose the claim downstream.

Finally replay through F, H, T, P, L. These structural rows preserve the same candidate ledger and cannot supply global strong normalization, subject reduction, confluence, quotient equality, or a host evaluator, since none of those objects appears as a carrier row. □

Theorem 750.9 (MetaCIC normalization audit confluence refusal split)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. The packet may export candidate-mediated strong normalization only through the displayed rows*

$$R, C, S, A, N, F, H, T, P, L.$$

The row N keeps confluence, subject-reduction transport, quotient reduction equality, and host evaluator evidence outside the export unless a downstream confluence packet supplies those rows explicitly. Thus a consistency consumer may read candidate evidence, closed projection, finite SN scope, application boundary, refusal boundary, replay, transport, continuation, provenance, and local naming, but it may not turn that read into confluence or subject reduction by erasing N.

Proof. Begin with the obligation surface of Definition 750.2. It makes $R, C, S, A, N, F, H, T, P, L$ the complete carrier inventory for an accepted normalization audit packet.

Use the finite SN scope theorem Definition 750.4. Positive normalization content is confined to the candidate-mediated rows R, C, S, with the application boundary A still visible.

Next apply the residual-budget obligation of Definition 750.7. The budget explicitly spends the refusal row N before an SN export can reach downstream replay.

Finally apply candidate-ledger locality, Definition 750.8. The replay and provenance rows F, H, T, P, L preserve the same candidate ledger and add no confluence, subject-reduction transport, quotient reduction equality, or host evaluator evidence. Those objects can enter only from a separate downstream confluence packet that displays them as its own rows. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditConfluenceRefusalSplit`

Theorem 750.10 (MetaCIC normalization audit public candidate export)**.** *For an accepted* MetaCICNormalization*packet*

$$Z = (R, C, S, A, N, F, H, T, P, L),$$

the public export available to consistency consumers is exactly the candidate-mediated strong-normalization route through R, C, S, A, N and replay through F, H, T, P, L. It may cite the finite SN inventory, the closed-term projection route, the application boundary, the residual-budget obligation, and candidate-ledger locality, but it exports no evidence-free global strong normalization, subject reduction, confluence, quotient equality, or host evaluator.

Proof. First read the obligation surface and finite SN scope. Apply Definition 750.2 and Definition 750.4; together they place every positive normalization read behind candidate evidence R, checked projection C, and finite inventory S.

Next use the closed-term projection route and application boundary. Apply Definition 750.5; the row A remains visible, so a closed-term SN consumer cannot erase the candidate route and read the claim as global normalization.

Now spend the residual budget. Apply Definition 750.7; the row N keeps confluence, subject reduction, and full closed Church–Rosser outside the normalization export.

Finally apply candidate-ledger locality. The replay rows F, H, T, P, L preserve the same displayed ledger and add no host evaluator, quotient equality, confluence theorem, subject-reduction theorem, or evidence-free SN endpoint. Thus the public candidate export is exactly the finite route stated above. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditPublicCandidateExport`

Theorem 750.11 (MetaCIC normalization audit public candidate-confluence refusal)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. A public consumer that combines this normalization audit with confluence claims must display the candidate rows R, C, S, A, N and the confluence-audit sibling rows of chapter 743 and chapter 745 before exporting any route. Without those displayed sibling rows, the consumer receives only candidate-mediated strong normalization through $R, C, S, A, N, F, H, T, P, L$, not confluence, subject reduction, quotient conversion, or global normalization.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetaCICNormalizationAuditPublicCandidateConfluenceRefu`

Proof. Start with the obligation surface and finite SN scope. Theorems 750.2 and 750.4 force every positive normalization read through the candidate, projection, finite-scope, application-boundary, and refusal rows R, C, S, A, N.

Next apply the public candidate export of Definition 750.10. It exposes exactly the candidate-mediated SN route and keeps replay through F, H, T, P, L inside the same finite ledger.

Finally use the confluence boundary of Definition 750.15. The row N points to the confluence-audit siblings, but it does not contain their confluence, subject-reduction, or quotient-conversion rows. A public route that omits those siblings therefore has only the normalization packet's candidate-mediated SN export. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditPublicCandidateConfluenceRefu`

Theorem 750.12 (MetaCIC normalization audit candidate-frontier refusal)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. Any strong-normalization export that crosses from candidate evidence to closed-term normalization must display the rows*

$$R, C, S, A, N, F, H, T, P, L.$$

If the candidate row R, the closed-candidate projection row C, or the finite candidate-set scope row S is absent, the packet returns only the local obligation surface and does not export closed-term normalization.

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateFrontierRefusal`

Proof. Start with the obligation surface of Definition 750.2. It exposes candidate evidence, closed-term projection, finite SN scope, application boundary, refusal, route, transport, replay, provenance, and local naming as separate rows, so a closed-term normalization read cannot skip directly to a conclusion.

Use the SN scope theorem Definition 750.4 and the closed-term projection route recorded by Definition 750.6. Together they allow closed-term SN only when the candidate evidence, closed-candidate projection, and candidate-set scope rows have already been displayed.

Now apply the residual-budget obligation of Definition 750.7. The residual row accounts for the application boundary and confluence refusal before any SN export leaves the candidate side.

If any of R, C, S is absent, the route lacks the evidence needed to cross the frontier. The structural rows F, H, T, P, L can only replay and name the local obligation surface, so the packet refuses evidence-free closed-term normalization. □

Theorem 750.13 (MetaCIC normalization audit candidate-frontier refusal tightening)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. If a consumer route omits at least one of the reducibility-candidate row R, the closed projection row C, or the finite scope row S, then the accepted packet exports only the local obligation surface. In particular it exports no closed-term strong-normalization claim.*

Proof. Begin with the obligation surface of Definition 750.2. It separates candidate evidence, closed projection, finite SN scope, application boundary, confluence refusal, replay, transport, provenance, and local naming into distinct rows.

If R is absent, no reducibility-candidate evidence is available. The finite SN scope theorem Definition 750.4 therefore has no candidate source from which a positive normalization read can begin.

If C is absent, the closed-term projection route of Definition 750.5 cannot connect candidate evidence to a closed term. The route remains an internal candidate ledger, not a closed-term SN export.

If S is absent, the finite inventory of accepted normalization entries is missing. The residual-budget obligation of Definition 750.7 and candidate-ledger locality of Definition 750.8 can only preserve replay of the local obligation surface.

Thus every missing-row case leaves the consumer below the candidate frontier isolated by Definition 750.12. The packet may still expose carrier, boundary, replay, transport, provenance, and naming data, but it cannot export closed-term strong normalization. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.CandidateFrontierRefusalTightening.MetacicNormalizatio`

Theorem 750.14 (MetaCIC normalization audit closed-term budget totality)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. Every closed-term strong-normalization export must display all rows*

$$R, C, S, A, N, F, H, T, P, L.$$

The rows R, C, S supply candidate evidence, checked closed-term projection, and finite SN inventory; the row A preserves application-boundary spending; and the row N retains the confluence, subject-reduction, and closed Church–Rosser refusal. Thus the packet exports only candidate-mediated closed-term SN with an explicit finite budget, and it exports no evidence-free global strong-normalization theorem.

Proof. Begin with Definition 750.2. It lists $R, C, S, A, N, F, H, T, P, L$ as the complete local obligation surface, so a closed-term SN export cannot omit a carrier row.

Use Definition 750.4. The positive SN content is candidate-mediated: R names candidate evidence, C records the checked closed-term projection, and S stores the finite strong-normalization inventory.

Apply Definition 750.7. It ties every exported SN read to a residual budget that also passes through the application boundary A and the confluence refusal row N.

Finally use Definition 750.12. If the candidate frontier is not displayed, the packet returns only the local obligation surface. Therefore totality of the closed-term budget means total display of the finite rows above, not an evidence-free global SN theorem. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditClosedTermBudgetTotality`

Theorem 750.15 (MetaCIC normalization audit confluence boundary)**.** *Agreement on the rows of an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet preserves normalization-side reads, but it does not discharge the confluence or subject-reduction rows isolated by chapter 743 and chapter 745. In particular, the packet exports no proof of full closed Church–Rosser, no proof of substitution compatibility, and no subject-reduction transport theorem for arbitrary closed proofs.*

Proof. The provenance row P places the packet beside the two confluence audit siblings, so a consumer can compare the three audit surfaces through finite NameCert data.

The normalization rows R, C, S, A are separate from the refusal row N. Transport through H and replay through T preserve that separation instead of identifying normalization with confluence or subject reduction.

Thus the packet can feed the closed-normal branch of the consistency assembly through F while leaving the confluence and subject-reduction boundaries in their own sibling packets. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCarrier confluence boundary`

Theorem 750.16 (MetaCIC normalization audit ledger policy)**.** *Every manuscript route that cites the normalization audit map through* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *factors through the ledger*

$$R, C, S, A, N, F, H, T, P, L.$$

The route may replay candidate evidence, closed-term SN projections, finite no-infinite-reduction reads, confluence-boundary refusals, and local NameCert provenance, but it may not replace the packet by vision prose, a host-level termination oracle, or a hidden theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCarrier ledger policy`

Proof. Start with a citation to the audit map. The finite carrier replaces that prose handle by displayed rows $R, C, S, A, N, F, H, T, P, L$.

Route replay is controlled by F and T, while H preserves componentwise agreement and P, L preserve provenance and local naming. These rows are sufficient for every packet read named in the theorem.

Because the carrier has no coordinate for a host oracle, hidden theorem, quotient equality, or evidence-free global SN theorem, the ledger policy blocks any consumer from bypassing the finite packet. □

Theorem 750.17 (MetaCIC normalization audit residual fuel decreases)**.** *Let* $Z = (R, C, S, A, N, F, H, T, P, L)$ *be an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet equipped with a finite residual-fuel ledger for candidate-mediated strong-normalization reads. Each permitted reduction replay spends one displayed unit of that ledger before the next candidate read is consulted, and the spent ledger is transported through* $R, C, S, A, N, F, H, T, P, L$*. Hence a manuscript consumer may cite a decreasing finite measure for the audited route, but not a global normalization measure for arbitrary closed MetaCIC terms.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditResidualFuelDecreases`

Proof. Project the finite audit rows. The candidate evidence row R, closed-term projection row C, and finite SN scope row S are the only rows from which a reduction replay can obtain normalization evidence.

Attach the residual-fuel ledger to that replay. A permitted step consumes one named fuel entry and then returns to the candidate-mediated rows; the application boundary A prevents the consumer from reading the step as unconditional application SN.

Transport and refusal close the measure. The row H preserves the spent fuel under componentwise agreement, F, T, P, L replay and package the same finite ledger, and N keeps confluence and subject-reduction boundaries outside the measure. The resulting decrease is therefore local to the packet. □

Theorem 750.18 (MetaCIC normalization audit candidate frontier extension)**.** *Let $Z = (R, C, S, A, N, F, H, T, P,$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. If a new closed term is admitted at the candidate frontier by displayed* ClosedTypedCandidateSetMember *evidence in R and its closed-term projection is recorded in C, then the finite SN scope S may be extended by one frontier entry with its residual-fuel row. The extension preserves the application boundary A and the confluence refusal N; it does not assert arbitrary substitution compatibility or full Church–Rosser.*

Proof. Begin at the candidate frontier. The new closed term is not admitted by syntax alone; it arrives with displayed candidate-set membership in R and a matching closed-term projection in C.

Extend the finite scope by adding the corresponding entry to S. The residual-fuel obligation of Definition 750.17 supplies the finite measure attached to the new frontier item.

Finally preserve the boundaries. The application row A keeps application-facing uses inside candidate evidence, while N leaves confluence, substitution compatibility, and subject reduction in their sibling audit surfaces. Structural replay through F, H, T, P, L packages the extended frontier without turning it into a global normalization theorem. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateFrontierExtension`

Theorem 750.19 (MetaCIC normalization audit confluence socket)**.** *For an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet $Z = (R, C, S, A, N, F, H, T, P, L)$, the confluence boundary row N acts as a socket to chapter 743 and chapter 745: normalization-side candidate evidence may be compared with those sibling confluence rows only after the residual-fuel and candidate-frontier obligations have been displayed. The socket records compatibility of audit surfaces, not full closed Church–Rosser, arbitrary substitution compatibility, or subject reduction.*

Proof. Read the normalization route first. The rows R, C, S, A provide candidate-mediated SN and application-boundary evidence, while the residual-fuel and frontier obligations expose the finite measure and admitted candidate boundary.

Now inspect N. It does not prove confluence; it names the boundary at which the normalization audit can be placed beside the confluence audit siblings for comparison of finite rows.

The structural rows F, H, T, P, L preserve that comparison as a socket. They allow the manuscript route to carry normalization evidence up to the confluence boundary, but no row identifies the socket with full Church–Rosser, substitution compatibility, or subject reduction for arbitrary closed proofs. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditConfluenceSocket`

Theorem 750.20 (MetaCIC normalization audit obligation pack)**.** *For an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet $Z = (R, C, S, A, N, F, H, T, P, L)$, the exact audit package is the displayed row family*

$$R, C, S, A, N, F, H, T, P, L.$$

The package contains reducibility-candidate evidence, closed-term projection, finite strong-normalization scope, application boundary, confluence refusal, route replay, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It contains no evidence-free global strong-normalization theorem, no unconditional application-SN theorem, no full closed Church–Rosser theorem, no arbitrary substitution-compatibility theorem, no subject-reduction transport theorem, no quotient equality over reductions, and no host evaluator.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditObligationPack`

Proof. Project the carrier of Definition 750.1. Its coordinates are exactly $R, C, S, A, N, F, H, T, P, L$, with no hidden normalization, confluence, quotient, or evaluator coordinate.

Apply Definition 750.2. That theorem identifies the local NameCert obligations for carrier admission, candidate visibility, projection visibility, finite SN scope, application boundary, confluence refusal, replay, transport, provenance, and local naming.

Use Definition 750.4, Definition 750.5, and Definition 750.7. Together they keep every SN read inside candidate evidence, closed-term projection, finite scope, residual budget, and refusal rows. The refused global endpoints therefore have no row in the exact audit package. □

Theorem 750.21 (MetaCIC normalization audit candidate-route pack)**.** *Before any strong-normalization export from an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet is public, the manuscript route must display candidate evidence in R, closed-term projection in C, residual fuel through the finite scope and replay rows S, F, T, the application boundary A, and the confluence refusal row N. The resulting public-facing route is*

$$R, C, S, A, N, F, H, T, P, L.$$

Consequently a candidate-mediated SN export may cite closed-term projection, candidate-set membership, residual fuel, application adequacy under the displayed boundary, and the confluence socket, but it cannot cite evidence-free global SN, full closed Church–Rosser, arbitrary substitution compatibility, subject reduction, quotient reduction equality, or a host evaluator.

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateRoutePack`

Proof. Begin with the closed-term projection route of Definition 750.5. It forces a closed-term SN read through candidate evidence R, projection C, finite scope S, and the application boundary A.

Attach the candidate-mediated closure theorem Definition 750.6. This keeps application-facing SN inside the displayed candidate route and blocks the evidence-free global endpoint.

Now spend the residual budget using Definition 750.7. The residual route links R, C, S, A to the refusal row N, while replay and transport through F, H, T, P, L preserve the same public-facing packet.

Finally apply the confluence socket of Definition 750.19. The socket permits comparison with sibling confluence rows only after the residual-fuel and candidate-frontier obligations are visible, so the candidate-route pack remains a finite audit route rather than a global SN or confluence theorem. □

Theorem 750.22 (MetaCIC normalization audit public route)**.** *Any public normalization export from an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet $Z = (R, C, S, A, N, F, H, T, P, L)$ must display the complete route*

$$R, C, S, A, N, F, H, T, P, L.$$

Here R is candidate evidence, C is closed-term projection, S is finite strong-normalization scope, A is the application boundary, N is the confluence refusal row, F is route replay, H is componentwise hsame *transport, T is displayed* Cont *replay, P is provenance, and L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAudit}^{\uparrow}}$ *row. This public route may be consumed by closed-normal consistency routes, but it is not evidence-free global strong normalization, full closed Church–Rosser, arbitrary substitution compatibility, subject-reduction transport, quotient reduction equality, or a host evaluator.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditPublicRoute`

Proof. Start with Definition 750.21. It already identifies the candidate-facing public route as the displayed row family $R, C, S, A, N, F, H, T, P, L$.

Use Definition 750.6. The strong-normalization content remains inside candidate evidence, closed-term projection, finite scope, and the application boundary; no evidence-free global SN endpoint is introduced.

Apply Definition 750.7. The residual-budget row ties the SN read to the confluence refusal N before replay, transport, provenance, and local naming can expose it to a public consumer.

Finally apply Definition 750.19. The socket allows the route to meet closed-normal consistency consumers beside the confluence audit siblings, but it records only compatibility of finite audit surfaces. Thus the public export is exactly the displayed finite route and not a global confluence, substitution, subject-reduction, quotient, or evaluator claim. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCarrier public route`

Theorem 750.23 (MetaCIC normalization audit candidate-substitution boundary)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. Any substitution-shaped normalization export must display candidate evidence R, closed projection C, finite strong-normalization scope S, application boundary A, confluence refusal N, and replay rows F, H, T, P, L in the same finite route. Without those rows, the export remains a local obligation surface; it is not subject reduction, arbitrary substitution compatibility, full closed Church–Rosser, quotient reduction equality, or a host evaluator read.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateSubstitutionBoundary`

Proof. Start with the public route of Definition 750.22. It already exposes the candidate-facing normalization read only through $R, C, S, A, N, F, H, T, P, L$.

Apply the candidate-frontier refusal of Definition 750.12. A substitution-shaped consumer cannot cross from candidate evidence to closed-term normalization unless R, C, S are present.

Use the residual-budget obligation Definition 750.7. The residual row links the candidate route to the application boundary A and the confluence refusal N before the replay rows can expose the claim downstream.

Finally apply the confluence socket of Definition 750.19. The socket permits comparison with sibling confluence rows only as finite audit-surface compatibility. Since the carrier has no row for subject reduction, arbitrary substitution compatibility, full closed Church–Rosser, quotient equality, or a host evaluator, a route missing the displayed rows remains local. □

Theorem 750.24 (MetaCIC normalization audit candidate-substitution scope)**.** *Let $Z = (R, C, S, A, N, F, H, T, P,$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. Any substitution-shaped normalization read must keep all rows $R, C, S, A, N, F, H, T, P, L$ visible in the same finite candidate ledger. It cannot erase the refusal row N into subject reduction, full confluence, quotient equality, or evaluator evidence, and it cannot replace the candidate, projection, scope, application, replay, transport, provenance, or naming rows by an ambient normalization theorem.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateSubstitutionScope`

Proof. Start with candidate-ledger locality, Definition 750.8. It keeps every positive normalization export inside the candidate evidence R, closed projection C, finite scope S, application boundary A, and confluence refusal N before replay through F, H, T, P, L.

Use the closed-term projection route Definition 750.5. A substitution-shaped read that reaches a closed-term normalization conclusion still has to pass through R, C, S, A; it does not obtain a separate subject reduction or evaluator row.

Apply the confluence-refusal split Definition 750.9. The row N names the confluence and transport frontier, so it remains a displayed refusal coordinate rather than being converted into full confluence, quotient equality, or subject-reduction transport.

Finally apply the refusal scope of Definition 750.33. Since the refused endpoints are not carrier coordinates of Z, the substitution-shaped read retains exactly $R, C, S, A, N, F, H, T, P, L$ and no stronger normalization, confluence, quotient, or evaluator evidence. □

Theorem 750.25 (MetaCIC normalization audit candidate-confluence handoff)**.** *Let $Z = (R, C, S, A, N, F, H, T, P$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. Candidate rows from Z may be compared with the confluence-audit sibling rows of chapter 743 and chapter 745 only through the displayed candidate-frontier row, residual-substitution row, residual-fuel row, and confluence socket row. A consumer that omits any of those rows receives only the local normalization-audit surface.*

The handoff is not full Church–Rosser, arbitrary substitution compatibility, subject reduction, quotient conversion, global normalization, or a host evaluator read.

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateConfluenceHandoff`

Proof. Start with the candidate-substitution boundary above. It already requires candidate evidence R, closed projection C, finite scope S, application boundary A, confluence refusal N, and replay rows F, H, T, P, L before a substitution-shaped normalization export is visible.

Read the candidate-frontier row next. The frontier obligations admit only displayed candidate evidence and matching closed-term projection into the finite scope, so a confluence-facing comparison cannot be made from syntax alone.

Now spend the residual rows. The residual-substitution compatibility theorem keeps substitution-shaped reads inside the same candidate ledger, while the residual-fuel decrease row supplies the finite replay measure used by the handoff.

Finally apply the confluence socket. It permits comparison with the sibling confluence rows only as compatibility of displayed audit surfaces. Since the carrier has no coordinate for full Church–Rosser, arbitrary substitution compatibility, subject reduction, quotient conversion, global normalization, or a host evaluator, none of those endpoints is exported by the handoff. □

Theorem 750.26 (MetaCIC normalization audit candidate-confluence boundary)**.** *Let $Z = (R, C, S, A, N, F, H, T,$ be an accepted* MetaCICNormalizationAudit$^{\uparrow}$ *packet. Any consumer comparing the normalization-audit rows of Z with the confluence-audit siblings must display candidate evidence R, closed projection C, finite SN scope S, application boundary A, residual-fuel and replay rows F, H, T, P, L, and the confluence refusal N in the same route. Omitting any of these rows leaves only the local normalization-audit surface, not substitution compatibility, subject reduction, closed Church–Rosser, quotient conversion, global normalization, or evaluator evidence.*

Proof. Start with the candidate-confluence handoff above. It permits comparison with the sibling confluence audits only through displayed candidate-frontier, residual-substitution, residual-fuel, and confluence-socket rows.

Use the residual-substitution compatibility theorem below. It keeps every substitution-shaped read inside the same candidate ledger before any socket read is exported, so the comparison cannot drop R, C, S, A or the replay rows F, H, T, P, L.

Now inspect the confluence socket of Definition 750.19. The socket names a place where finite audit surfaces can be compared; it is not itself full confluence, substitution compatibility, subject reduction, quotient conversion, global normalization, or evaluator evidence.

Finally apply the refusal scope of Definition 750.33. The refusal row N keeps those endpoints outside the packet unless a separate confluence-side certificate displays them. Hence a consumer that omits any listed row has only the local normalization-audit surface. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateConfluenceBoundary`

Theorem 750.27 (MetaCIC normalization audit retained-premise budget)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet. Every normalization-audit consumer that uses candidate-mediated strong normalization must retain, in the same finite route, the candidate witness in R, the closed-candidate wrapper or candidate-set membership row in C, the Π and application adequacy row in A, the residual-fuel row through F, H, T, P, L, and the confluence-refusal row N before citing any closed-term budget. A consumer that drops one of these premises has only the local candidate ledger, not full Church–Rosser, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Begin with the candidate boundary Definition 750.3. It keeps the candidate witness, closed projection, and finite strong-normalization inventory visible as rows of the accepted packet before any closed-term consequence is read.

Next spend the residual budget by Definition 750.7. The closed-term budget is tied to the application boundary and to the confluence refusal before replay through F, H, T, P, L can expose it downstream.

Now pass through the public route Definition 750.22. That route displays exactly $R, C, S, A, N, F, H, T, P, L$, so the candidate witness, closed-candidate or candidate-set row, adequacy row, residual fuel, and refusal row remain retained premises rather than ambient assumptions.

Finally apply the candidate-confluence boundary above and the refusal scope of Definition 750.33. These theorems allow only compatibility with displayed audit surfaces and explicitly keep full Church–Rosser, subject reduction, evaluator equality, quotient term equality, and kernel consistency outside the normalization-audit packet. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditRetainedPremiseBudget`

Theorem 750.28 (MetaCIC normalization audit candidate-mediated SN/confluence boundary)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet. Any candidate-mediated read that joins strong-normalization evidence to the public candidate-confluence handoff must retain the closed-term budget C, residual fuel and replay rows F, H, T, P, L, candidate frontier R, finite scope S, substitution boundary A, and confluence refusal N in the same finite route. Only after those rows are displayed may the read use Definition 750.25.*

The boundary refuses evidence-free global strong normalization, unconditional application SN, full Church–Rosser, quotient equality over reductions, and arbitrary subject-reduction transport.

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateMediatedSNConfluence`

Proof. Begin with the finite SN scope Definition 750.4 and the residual-budget obligation Definition 750.7. They keep the normalization read inside the displayed closed projection, finite scope, application boundary, confluence refusal, and replay rows before any public comparison is made.

Next apply the residual-fuel decrease theorem Definition 750.17. The fuel row is spent along the accepted replay, so a candidate-mediated SN read cannot be detached from F, H, T, P, L or treated as a global normalization theorem.

Now use the candidate-frontier extension Definition 750.18 and the candidate-substitution boundary Definition 750.23. The frontier admits only displayed candidate evidence with a matching closed-term projection, and the substitution boundary keeps application-shaped reads inside $R, C, S, A, N, F, H, T, P, L$.

Finally apply the candidate-confluence handoff and boundary, Definition 750.25 and Definition 750.26. They permit comparison with confluence-audit siblings only as a finite audit-surface handoff. Since the refused endpoints are not carrier rows, the accepted packet cannot export global SN, unconditional application SN, full Church–Rosser, quotient reduction equality, or arbitrary subject-reduction transport. □

Theorem 750.29 (MetaCIC normalization audit residual-substitution compatibility)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet. If the candidate frontier is extended by displayed candidate evidence and the residual-fuel ledger decreases along the accepted replay, then every substitution-shaped read remains inside the same candidate ledger R, C, S, A before any confluence-socket read through N is exported. The packet may therefore compare the resulting finite audit surface with its confluence siblings, but it cannot export arbitrary substitution compatibility, subject reduction, full closed Church–Rosser, quotient reduction equality, or a host evaluator.*

Proof. Begin with the candidate frontier extension of Definition 750.18. The new frontier item is admitted only with displayed candidate-set evidence in R and a matching closed-term projection in C, so the enlarged finite scope remains a candidate-ledger entry rather than a syntax-only substitution claim.

Next apply the residual-fuel decrease theorem Definition 750.17. Each accepted replay spends a named residual entry before the next candidate read is consulted, and the rows F, H, T, P, L transport and replay that same finite route.

Now use the candidate-substitution boundary of Definition 750.23. It keeps substitution-shaped normalization exports inside $R, C, S, A, N, F, H, T, P, L$ and blocks any route that omits the candidate ledger, closed projection, finite scope, or application boundary.

Finally read the confluence socket of Definition 750.19. The socket can be exported only after the residual-fuel and candidate-frontier obligations have been displayed, so the compatibility result is a finite audit-surface route and not a global substitution, subject-reduction, confluence, quotient, or evaluator theorem. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditResidualSubstitutionCompatibi`

Theorem 750.30 (MetaCIC normalization audit candidate residual replay handoff)**.** *Let $Z = (R, C, S, A, N, F, H, T, P, L)$ be an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet. Any public strong-normalization consumer that combines candidate evidence, residual-fuel replay, and confluence-facing comparison must pass through*

$$R, C, S, A, N, F, H, T, P, L$$

in that order. The handoff cannot erase N into subject reduction, full Church–Rosser, arbitrary substitution compatibility, quotient equality, or a host evaluator.

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.CandidateResidualReplayHandoff.MetacicNormalizationAud`

Proof. Apply the residual-budget obligation Definition 750.7. It places candidate evidence, closed projection, finite strong-normalization scope, application boundary, and confluence refusal in the ordered ledger R, C, S, A, N before any public read leaves the packet.

Next use the residual-fuel decrease theorem Definition 750.17. The finite replay spends displayed fuel and then returns through F, H, T, P, L, so the consumer receives replayed candidate evidence rather than an evidence-free global normalization endpoint.

Now read the confluence socket of Definition 750.19. The socket permits comparison with the confluence-audit siblings only after the candidate frontier and residual fuel are visible, and it keeps the refusal row N as a displayed boundary.

Finally apply the residual-substitution compatibility theorem above. Substitution-shaped reads remain inside the same candidate ledger and confluence-facing socket, so the public handoff cannot replace N by subject reduction, full Church–Rosser, arbitrary substitution compatibility, quotient equality, or a host evaluator. □

Theorem 750.31 (MetaCIC normalization audit kernel-scope route)**.** *Every normalization-audit read from an accepted* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet is scoped to the displayed kernel and certificate rows*

$$\mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert},\ R,\ C,\ S,\ A,\ N.$$

Here R is reducibility-candidate evidence, C is closed projection, S is the finite strong-normalization inventory, A is the application boundary, and N is the confluence refusal. A consumer that omits any of these rows receives only the local obligation surface and not a public normalization export.

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditKernelScopeRoute`

Proof. Begin with the obligation surface of Definition 750.2. It presents the carrier as finite BHist data transported by hsame, replayed through Cont, sourced by Pkg, and named by the local $\mathsf{NameCert}$ row.

Use the candidate boundary Definition 750.3, the finite SN scope Definition 750.4, and the closed-term projection route Definition 750.5. These three rows force candidate evidence, closed projection, and finite SN inventory to remain visible before a normalization read is public.

Finally apply the residual-budget obligation Definition 750.7. It attaches the application boundary and confluence refusal before replay can expose the read downstream, so the kernel-scope route is exactly the displayed finite packet. □

Theorem 750.32 (MetaCIC normalization audit candidate-boundary scope)**.** *Before any strong-normalization export from* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *is visible, the consumer must display candidate evidence R, closed projection C, finite scope S, application boundary A, and confluence refusal N together with the replay rows F, H, T, P, L. Thus the export remains a candidate-ledger read and not an evidence-free global SN theorem.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditCandidateBoundaryScope`

Proof. Start with candidate-ledger locality, Definition 750.8. It keeps every positive SN read inside candidate evidence, closed projection, and finite scope.

Apply the candidate-route pack of Definition 750.21. The route pack requires $R, C, S, A, N, F, H, T, P, L$ before the public-facing candidate route is exposed.

Use the residual-substitution compatibility theorem above. It shows that even substitution-shaped reads remain inside the candidate ledger until the residual budget and confluence refusal are displayed. Hence the boundary scope is stable for SN exports. □

Theorem 750.33 (MetaCIC normalization audit refusal scope)**.** *The scoped* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet refuses subject reduction, full confluence, quotient equality, host evaluator evidence, and*

evidence-free global strong normalization. These endpoints can be mentioned only as excluded rows attached to the confluence refusal N and cannot be reconstructed from $R, C, S, A, F, H, T, P, L$.

Proof. Read the confluence socket Definition 750.19. It permits comparison with sibling confluence rows only as finite audit-surface compatibility, not as full confluence or subject reduction.

Use the public route Definition 750.22. The only exported surface is $R, C, S, A, N, F, H, T, P, L$, and the theorem explicitly withholds quotient reduction equality and host evaluator evidence.

Finally apply the kernel-scope route and candidate-boundary scope above. They force every normalization read through displayed candidate, projection, finite scope, application boundary, refusal, replay, provenance, and naming rows. Since the refused endpoints are not carrier coordinates, the refusal scope is closed under all displayed reads. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditRefusalScope`

Theorem 750.34 (MetaCIC normalization audit frontier formal target)**.** *A Lean formalization target for* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *must cover exactly the finite candidate-ledger route of the accepted carrier $Z = (R, C, S, A, N, F, H, T, P, L)$. The route starts with candidate evidence in R, closed projection in C, finite strong-normalization inventory in S, application boundary in A, and confluence refusal in N, then exposes replay, transport, continuation, provenance, and local naming through F, H, T, P, L. The target is therefore a candidate-mediated frontier statement, not a broad closed-term normalization theorem, and it must not export evidence-free global strong normalization, arbitrary subject reduction, quotient reduction equality, or host evaluator evidence.*

Proof. Start with the public candidate export of Definition 750.10. It exposes exactly the candidate-mediated route through R, C, S, A, N and replay through F, H, T, P, L, rather than a syntax-wide normalization theorem.

Spend the residual budget by Definition 750.7. The budget keeps candidate evidence, closed projection, finite scope, application boundary, and confluence refusal in the same finite ledger before any public read leaves the packet.

Use candidate-ledger locality, Definition 750.8, and the confluence-refusal split, Definition 750.9. The replay rows F, H, T, P, L preserve the candidate ledger, while N keeps evidence-free global strong normalization, subject reduction, quotient reduction equality, and host evaluator evidence as refused endpoints. Thus the formal target is exactly the finite candidate-mediated frontier named in the statement. □

Lean4 ✓ `BEDC.Derived.MetacicNormalizationAuditUp.MetacicNormalizationAuditFrontierFormalTarget`

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ packet is generated from candidate evidence rows, checked closed-term SN projection rows, finite strong-normalization scope rows, application-boundary rows, confluence-boundary refusal rows, route replay, componentwise transport, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAudit}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 750.1, Definition 750.11, Definition 750.29, Definition 750.33, and Definition 750.34 display the mature paper surface: candidate-mediated SN and confluence boundary, residual-substitution compatibility inside the same finite ledger, refusal scope for excluded endpoints, and the formal-target frontier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close evidence-free global strong normalization, unconditional application SN, full closed Church–Rosser, substitution compatibility, subject-reduction transport for arbitrary closed proofs, quotient equality over reductions, or bridge checking.

Upgrade path: Lean verification must catch up to the mature paper surface by checking BEDC.Derived.MetacicNormalizationAuditUp.Me and its candidate-mediated boundary obligations.

Chapter 751

A Concrete Naming Certificate for MetaCICDecidabilityWitness$^{\uparrow}$

The MetaCICDecidabilityWitness$^{\uparrow}$ packet realizes the decidability audit map of chapter 9379 as a finite NameCert witness. It sits beside the normal false exclusion packet of chapter 732 and the confluence normal-fragment packet of chapter 737: those siblings keep normal-form and confluence boundaries visible, while this packet separates typing-checker exactness from bounded beta-conversion evidence.

Definition 751.1 (MetaCIC decidability witness carrier)**.** *A* MetaCICDecidabilityWitness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, S, B, F, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the* inferTypeCtx *exactness row, containing the soundness and completeness surfaces for the encoded* HasType *relation;*
2. *S is the* checkSameTerm *structural equality row used by the typing checker;*
3. *B is the bounded beta-comparison row for* normalizeBounded *and* decideClosedBetaConv*;*
4. *F is the finished-normal-form side-condition row consumed when a bounded comparison result is read as equality or beta-convertibility of named normal forms;*
5. *R records refusal of a standalone* ClosedAt *decision theorem, unrestricted closed beta-conversion decidability, and fuel-erased normalisation;*
6. *H records componentwise* hsame *transport for T, S, B, F, R, P, N;*
7. *C records displayed* Cont *routes for typing exactness, same-term checking, bounded comparison, finished-normal side conditions, and refusal reads;*
8. *P is the* Pkg *provenance row over the decidability audit map and its normal-form and confluence siblings;*
9. *N is the local* NameCert$_{\text{MetaCICDecidabilityWitness}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the rows $T, S, B, F, R, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessCarrier route ledger certificate`

Theorem 751.2 (MetaCIC decidability witness NameCert obligations)**.** *Every accepted* MetaCICDecidabilityWitnes *packet binds exactly the finite NameCert obligation surface of Definition 751.1: typing-checker exactness through T, same-term structural equality through S, bounded beta comparison through B, finished-normal side conditions through F, refusal boundaries through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier. The positive checker rows are T and S: typing exactness is read through the inferTypeCtx row, while structural equality is read through the same-term checker row used by that typing surface.

The bounded conversion rows are B and F. The comparison row exposes only bounded normalizer output comparison, and the finished-normal side-condition row supplies the additional hypotheses under which the audit map permits equality or beta-convertibility reads for named normal forms.

The refusal row R remains part of the same packet. It records that no coordinate exports a standalone closedness decider, an unrestricted closed beta-conversion decider, or fuel-erased normalisation.

Finally H, C, P, N transport, replay, cite, and name only those displayed rows. Since the carrier has no further coordinate, the local NameCert surface is exhausted by the finite obligations listed above. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessTasteGate single carrier alignment`

Theorem 751.3 (MetaCIC decidability witness bounded conversion non-escape)**.** *Any consumer of an accepted* MetaCICDecidabilityWitness$^{\uparrow}$ *packet may read conversion evidence only through B together with F. The read can expose bounded-normal output equality and the finished-normal consequences named by the audit map, but it cannot export a global closed beta-conversion decision procedure, a fuel-erased normalisation theorem, a quotient equality over represented terms, or a host evaluator.*

Proof. Begin with the conversion coordinates. The carrier separates the bounded comparison row B from the finished-normal side-condition row F, so a consumer route that asks for conversion evidence must pass through both rows.

The refusal row R records the missing endpoints. It prevents the bounded comparison route from being reread as a global closed beta-conversion decider, fuel-erased normalisation theorem, quotient equality, or host evaluator.

Transport and replay do not add data. The rows H and C preserve the same displayed comparison and side-condition routes, while P and N only record provenance and local naming. Thus the conversion read stays inside the bounded witness packet. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessBoundedConversionNonescape`
↪ variant `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessCarrier bounded conversion nonescape`

Theorem 751.4 (MetaCIC decidability witness bounded normal-form split)**.** *An accepted* MetaCICDecidabilityWitn *packet may expose bounded checker output and normal-form endpoint rows only through its displayed candidate row T, structural comparison row S, fuel and window row B, normal-form side-condition row F, refusal row R, componentwise transport H, displayed replay C, provenance P, and*

local $\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}$ *row* N*. A later confluence or decidability consumer may inspect those rows as bounded normal-form evidence, but the packet does not expose global closed-term conversion decidability, unrestricted subject reduction, quotient syntax equality, or consistency.*

Proof. Project the carrier of Definition 751.1. The checker candidate, structural comparison, bounded fuel and window, normal-form side condition, refusal, transport, replay, provenance, and naming rows are exactly $T, S, B, F, R, H, C, P, N$.

Invoke the NameCert obligations of Definition 751.2. They identify the admissible checker and normal-form reads with the displayed rows and leave no additional coordinate for a global conversion decider or host syntax equality.

Use the bounded-conversion non-escape theorem Definition 751.3. It confines conversion evidence to B together with F, while R records the missing global endpoints. Thus a later consumer may inspect bounded normal-form evidence through the named rows only, and cannot reread it as unrestricted conversion decidability, subject reduction, quotient syntax equality, or consistency. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessBoundedNormalFormSplit`
↪ variant `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitness bounded normal form split`

Theorem 751.5 (MetaCIC decidability witness typing-exactness route)**.** *Every accepted* MetaCICDecidabilityWitne *packet routes typing-checker exactness through the inferTypeCtx row* T *before any consumer may combine structural equality* S*, bounded beta comparison* B*, and finished-normal row* F*. A request that skips* T *cannot be read as* HasType *exactness or as closed conversion evidence for the packet.*

Proof. Project the carrier of Definition 751.1. The row T is the unique displayed coordinate that names inferTypeCtx soundness and completeness for the encoded HasType relation, while S, B, F record structural equality, bounded comparison, and finished-normal side conditions.

Apply the NameCert obligations of Definition 751.2. They bind typing-checker exactness to T and leave S, B, F as later consumer rows, so the structural and bounded-normal data cannot be promoted into a typing-exactness witness without first exposing T.

Use the bounded normal-form split of Definition 751.4. It permits bounded normal-form inspection only through the displayed rows and keeps the refusal row R visible. Together with Definition 751.3, this excludes a global ClosedAt decision theorem, unrestricted beta conversion, quotient syntax equality, and evaluator rows.

Thus any route skipping T lacks the only row that carries inferTypeCtx exactness. Such a route may inspect bounded comparison evidence after the displayed side conditions, but it is not a HasType exactness route and does not close conversion for the packet. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessCarrier typing exactness route`

Theorem 751.6 (MetaCIC decidability witness bounded-search exhaustion)**.** *For every accepted* $\mathsf{MetaCICDecidabilityWitness}^{\uparrow}$ *packet* $W = (T, S, B, F, R, H, C, P, N)$*, every bounded conversion or typing decision requested inside the displayed finite depth bound is exhausted by the rows already visible in the packet: the syntax window in* T*, the bounded conversion ledger* B*, the normal-form split through* F*, the typing-exactness route through* T*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}$ *row* N*.*

The packet exports no unbounded strong-normalisation theorem, global confluence theorem, or ambient decision oracle.

Lean4 ✓ BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessBoundedSearchExhaustion
↪ variant BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitness bounded search exhaustion

Proof. Proceed by induction over the displayed finite depth bound in the carrier row. At depth zero, the syntax window in T and the structural row S expose only the immediate inferTypeCtx and checkSameTerm reads, so the decision is already inside the displayed packet.

For the successor depth, the induction hypothesis exhausts all smaller conversion and typing requests through the same finite rows. A bounded conversion request then reads B and the finished-normal side-condition row F; a typing request reads the inferTypeCtx exactness row T before it may combine S, B, F.

Apply Definition 751.4 and Definition 751.5. These results keep bounded normal-form evidence and typing exactness inside $T, S, B, F, R, H, C, P, N$.

The remaining structural rows preserve the same finite search. Transport through H, replay through C, provenance through P, and local naming through N do not add a decision oracle. The refusal row R therefore keeps unbounded strong normalisation, global confluence, and ambient decidability outside the exported surface. □

Theorem 751.7 (MetaCIC decidability witness confluence-handoff boundary)**.** *Every confluence or decidability consumer of an accepted* MetaCICDecidabilityWitness$^{\uparrow}$ *packet must read the bounded checker rows*

$$T, S, B, F, R, H, C, P, N$$

together with any confluence-normal-fragment sibling row as bounded evidence only. The handoff cannot export BetaParallelDiamondClosed*, full closed Church–Rosser, subject reduction, quotient syntax equality, kernel consistency, unrestricted beta-conversion decidability, or a host evaluator.*

Proof. Start with the bounded normal-form split of Definition 751.4. It confines normal-form inspection to the displayed typing, same-term, bounded beta, finished-normal, refusal, transport, replay, provenance, and local naming rows.

Apply the typing-exactness route of Definition 751.5. A confluence or decidability consumer cannot combine S, B, F as checker evidence before T exposes the inferTypeCtx exactness row.

Finally use bounded-search exhaustion, Definition 751.6. It exhausts all requested finite conversion and typing reads inside the displayed depth bound. A confluence-normal-fragment sibling row may therefore be consumed only as another bounded row beside $T, S, B, F, R, H, C, P, N$, with the global diamond, Church–Rosser, subject-reduction, quotient-equality, consistency, and evaluator endpoints still absent. □

Lean4 ✓ BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessConfluenceHandoffBoundary

Definition 751.8 (MetaCIC parallel-diamond fuel window)**.** *A* MetaCICDecidabilityWitness$^{\uparrow}$ *parallel-diamond fuel-window packet is a finite* BHist *row*

$$V = (T, S, B, F, R, H, C, P, N, D)$$

where $T, S, B, F, R, H, C, P, N$ are the displayed rows of the carrier in Definition 751.1, and D is the confluence normal-fragment sibling row from chapter 737. The row D is read only inside the same bounded fuel window as B and F: it records bounded parallel-diamond evidence for the displayed normal fragments, not a global confluence theorem, unrestricted beta-conversion decision, quotient syntax equality, consistency theorem, or host evaluator.

Lean4 (definition) BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicParallelDiamondFuelWindow

Theorem 751.9 (MetaCIC parallel-diamond fuel monotonicity)**.** *Let $V = (T, S, B, F, R, H, C, P, N, D)$ be an accepted* MetaCICDecidability Witness$^{\uparrow}$ *parallel-diamond fuel-window packet. Increasing the displayed bounded fuel window preserves only the bounded-normal evidence already routed through B, F, D together with the typing, same-term, refusal, transport, replay, provenance, and naming rows T, S, R, H, C, P, N. The enlarged window does not export global* ClosedAt *decidability, unrestricted beta conversion, quotient syntax equality, consistency, fuel-erased normalisation, or a host evaluator.*

Proof. Start with the TasteGate single-carrier marker recorded for the chapter. It fixes the MetaCIC decidability witness boundary at the displayed carrier rows $T, S, B, F, R, H, C, P, N$, so adding fuel cannot introduce a new decision coordinate.

Use the bounded-search exhaustion theorem, Definition 751.6. It says that each request inside a finite depth bound is exhausted by the visible syntax window, bounded conversion ledger, normal-form split, typing-exactness route, transport, replay, provenance, and local naming rows.

Now enlarge the finite fuel window. The bounded-conversion non-escape theorem, Definition 751.3, keeps conversion evidence inside B together with F, while the sibling row D contributes only bounded confluence-normal-fragment evidence at the displayed window.

Transport through H and replay through C preserve the same row inventory, and P, N record provenance and naming. The refusal row R therefore remains active after the enlargement, preventing the bounded parallel-diamond evidence from being reread as global ClosedAt decidability, unrestricted beta conversion, quotient syntax equality, consistency, fuel-erased normalisation, or a host evaluator. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicParallelDiamondFuelMonotonicity`

Theorem 751.10 (MetaCIC decidability witness fuel-window exhaustion)**.** *Let $V = (T, S, B, F, R, H, C, P, N, D)$ be an accepted* MetaCICDecidability Witness$^{\uparrow}$ *parallel-diamond fuel-window packet. Every bounded conversion, typing, or candidate-mediated parallel-diamond request inside the displayed finite fuel window is exhausted by the rows $T, S, B, F, D, R, H, C, P, N$: typing exactness routes through T, structural same-term comparison through S, bounded beta comparison through B, finished-normal side conditions through F, bounded parallel-diamond evidence through D, refusal through R, transport through H, replay through C, provenance through P, and local naming through N. The packet exports no unbounded strong normalization, global confluence, subject reduction, quotient syntax equality, consistency, fuel-erased normalization, or host evaluator.*

Proof. Start with the TasteGate single-carrier alignment marker recorded after the NameCert obligations. It fixes the accepted MetaCIC decidability witness at the displayed carrier rows, so a bounded request has no hidden coordinate outside $T, S, B, F, R, H, C, P, N$ and the parallel-diamond row D.

Apply bounded-search exhaustion, Definition 751.6. It accounts for every finite conversion or typing read by the visible syntax window, bounded conversion row, finished-normal row, typing route, refusal row, transport, replay, provenance, and local naming.

Use bounded-conversion nonescape, Definition 751.3, and the typing-exactness route, Definition 751.5. These force conversion reads through B, F and typing reads through T before any candidate-mediated request can consume the packet.

Finally invoke the parallel-diamond fuel monotonicity theorem, Definition 751.9. The row D contributes only bounded normal-fragment evidence inside the displayed fuel window, and the refusal row R prevents that evidence from being read as unbounded strong normalization, global confluence, subject reduction, quotient syntax equality, consistency, fuel-erased normalization, or a host evaluator. □

Lean4 ✓ BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessFuelWindowExhaustion

Theorem 751.11 (MetaCIC decidability witness obligation-closure package)**.** *For the carrier of Definition 751.1, the* $\mathsf{MetaCICDecidabilityWitness}^{\uparrow}$ *obligation surface is closed by the carrier row, the NameCert obligations, bounded-conversion nonescape, bounded normal-form split, and typing-exactness route. Equivalently, every accepted packet* $W = (T, S, B, F, R, H, C, P, N)$ *exposes exactly inferTypeCtx exactness through* T*, checkSameTerm structural equality through* S*, bounded beta comparison through* B*, finished-normal side conditions through* F*, refusal rows through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}$ *row* N*.*

Proof. Carrier admission supplies the displayed tuple $T, S, B, F, R, H, C, P, N$, and the existing TasteGate marker above fixes the AI chapter boundary at that single carrier. The NameCert obligations of Definition 751.2 then assign typing exactness, structural equality, bounded comparison, finished-normal side conditions, refusal reads, transport, replay, provenance, and naming to those rows.

The bounded-conversion theorem Definition 751.3 blocks escape from B and F to global conversion, fuel-erased normalisation, quotient equality, or a host evaluator. The bounded normal-form split of Definition 751.4 keeps every bounded checker and normal-form read inside $T, S, B, F, R, H, C, P, N$.

Finally, the typing-exactness route of Definition 751.5 forces every HasType exactness read through T before structural or bounded-normal evidence is combined. These cited rows cover every obligation named by the carrier and leave no additional coordinate for a separate decidability, transport, replay, provenance, or local naming obligation. □

Lean4 ✓ BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessCarrier obligation closure package

Theorem 751.12 (MetaCIC decidability witness scope assignment)**.** *For every accepted* MetaCICDecidabilityWitnes *packet* $W = (T, S, B, F, R, H, C, P, N)$*, the rows are scoped as follows:* T *is the* inferTypeCtx *exactness row,* S *is the* checkSameTerm *structural-equality row,* B *is the bounded beta-comparison row,* F *is the finished-normal side-condition row,* R *is the refusal-boundary row,* H *is componentwise* hsame *transport,* C *is displayed* Cont *replay,* P *is package provenance, and* N *is local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}$ *naming. No consumer may read these rows as* ClosedAt *decidability, unrestricted beta-conversion, quotient syntax equality, consistency, fuel-erased normalisation, or a host evaluator.*

Proof. Project the carrier of Definition 751.1. The displayed tuple is exactly $T, S, B, F, R, H, C, P, N$, so every scoped assignment must be read from one of those coordinates.

Apply the NameCert obligations of Definition 751.2. They assign typing exactness to T, structural equality to S, bounded comparison to B, finished-normal side conditions to F, refusal boundaries to R, transport to H, replay to C, provenance to P, and naming to N.

Use bounded-conversion non-escape, Definition 751.3, together with the bounded normal-form split of Definition 751.4. These keep conversion reads inside B, F and keep bounded normal-form evidence inside the displayed packet.

Finally apply the typing-exactness route of Definition 751.5 and the TasteGate single-carrier alignment marker already recorded for the chapter. The accepted packet therefore has one finite scope assignment for the nine rows, with no coordinate from which a consumer can extract ClosedAt decidability, unrestricted beta-conversion, quotient syntax equality, consistency, or a host evaluator. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessCarrier scope assignment`

Theorem 751.13 (MetaCIC decidability witness candidate-normalization scope)**.** *Every candidate-normalization consumer of an accepted* MetaCICDecidabilityWitness$^{\uparrow}$ *packet* $W = (T, S, B, F, R, H, C, P, N)$ *may inspect only the typing exactness row* T*, same-term row* S*, bounded beta row* B*, finished-normal side condition* F*, refusal row* R*, and structural rows* H, C, P, N*. The packet keeps strong normalization, global confluence, subject reduction, evaluator equality, quotient syntax equality, and consistency outside the candidate-normalization scope.*

Proof. Start with the TasteGate single-carrier alignment marker recorded after the NameCert obligations. It fixes the packet boundary at the carrier $W = (T, S, B, F, R, H, C, P, N)$, so a candidate-normalization consumer has no row beyond those nine displayed coordinates.

Apply the bounded normal-form split of Definition 751.4. It allows bounded normal-form inspection only through the typing, same-term, bounded beta, finished-normal, refusal, and structural rows already visible in the carrier.

Use the typing-exactness route of Definition 751.5 and the bounded-search exhaustion theorem Definition 751.6. These force typing reads through T and bounded conversion reads through B, F before any finite candidate-normalization request can be exhausted.

Finally apply the scope assignment of Definition 751.12. It identifies S, R, H, C, P, N as structural equality, refusal, transport, replay, provenance, and local naming rows, and it leaves no coordinate for strong normalization, global confluence, subject reduction, evaluator equality, quotient syntax equality, or consistency. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessCarrier candidate normalization scope`

Theorem 751.14 (MetaCIC decidability witness scope routes)**.** *For every accepted* MetaCICDecidabilityWitness$^{\uparrow}$ *packet* $W = (T, S, B, F, R, H, C, P, N)$*, each consumer route is assigned to the displayed row that owns it: typing-checker exactness routes through* T*, structural same-term equality routes through* S*, bounded conversion routes through* B *together with the finished-normal side condition* F*, refusal routes through* R*, and transport, replay, provenance, and local naming route through* H, C, P, N*. No route exports* ClosedAt *decidability, unrestricted beta conversion, quotient syntax equality, consistency, fuel-erased normalisation, or a host evaluator.*

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessCarrier scope routes`

Proof. Project the carrier of Definition 751.1. The displayed tuple has exactly the rows $T, S, B, F, R, H, C, P, N$, so every accepted route must be assigned to one of those coordinates.

Apply the NameCert obligations of Definition 751.2 and the scope assignment of Definition 751.12. These identify T with typing exactness, S with same-term structural equality, B with bounded beta comparison, F with the finished-normal side condition, R with refusal, and H, C, P, N with transport, replay, provenance, and local naming.

Use bounded-conversion non-escape, Definition 751.3, together with the bounded normal-form split of Definition 751.4. Conversion can therefore be read only through B and F, and bounded normal-form evidence remains inside the displayed packet.

Finally invoke the typing-exactness route of Definition 751.5 and the candidate-normalization scope of Definition 751.13. They force typing reads through T and keep candidate-normalization consumers inside the same finite rows. Since the carrier has no additional coordinate, none of

the listed routes can export ClosedAt decidability, unrestricted beta conversion, quotient syntax equality, consistency, fuel-erased normalisation, or a host evaluator. □

Theorem 751.15 (MetaCIC decidability witness formal-target ledger)**.** *Any later Lean formal target for the* MetaCICDecidabilityWitness$^{\uparrow}$ *chapter must read typing exactness through T, same-term comparison through S, bounded beta comparison through B and F, refusal through R, and structural movement through H, C, P, N. It may not claim* ClosedAt *decidability, unrestricted conversion, quotient syntax equality, consistency, fuel-erased normalisation, or host evaluation.*

Proof. Start with the NameCert obligations of Definition 751.2. They make the accepted witness a finite carrier $W = (T, S, B, F, R, H, C, P, N)$, so any formal target that belongs to this chapter must read from one of those rows.

Apply bounded-search exhaustion, Definition 751.6, together with bounded-conversion non-escape and the bounded normal-form split. These route bounded beta comparison through B and F and keep finished-normal evidence inside the displayed finite packet.

Use the typing-exactness route and scope routes, Definition 751.5 and Definition 751.14. They force typing reads through T, same-term comparison through S, refusal through R, and transport, replay, provenance, and local naming through H, C, P, N.

Since those cited rows exhaust the carrier, no later formal target licensed by this chapter can export ClosedAt decidability, unrestricted conversion, quotient syntax equality, consistency, fuel-erased normalisation, or host evaluation. Such endpoints would require a separate carrier coordinate not present in the accepted packet. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessFormalTargetLedger`

Theorem 751.16 (MetaCIC decidability witness scoped closure package)**.** *For every accepted* MetaCICDecidabilityWitness$^{\uparrow}$ *packet $W = (T, S, B, F, R, H, C, P, N)$, the scope routes assign all nine rows to one finite MetaCIC decidability witness: T to typing exactness, S to same-term structural equality, B to bounded beta comparison, F to finished-normal side conditions, R to refusal, H to transport, C to replay, P to provenance, and N to local naming. The existing TasteGate marker*

BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessTasteGate_single_carrier_alignment

fixes the AI chapter boundary at that single carrier surface.

Thus the scoped closure package is the union of the NameCert obligations, bounded-conversion non-escape, bounded normal-form split, typing-exactness route, candidate-normalization scope, scope routes, and TasteGate single-carrier alignment. It exports no standalone ClosedAt *decision theorem, unrestricted closed beta-conversion decider, quotient syntax equality, consistency theorem, fuel-erased normalisation theorem, or host evaluator.*

Proof. Begin with the TasteGate marker already recorded after Definition 751.2. It aligns the chapter with the single displayed carrier $W = (T, S, B, F, R, H, C, P, N)$, so any scoped package must be read through those rows.

The NameCert obligations and scope routes assign the rows. They place typing exactness in T, same-term equality in S, bounded beta comparison in B, finished-normal side conditions in F, refusal in R, and the structural transport, replay, provenance, and local naming data in H, C, P, N.

Use bounded-conversion non-escape and the bounded normal-form split to confine conversion and normal-form reads to B, F together with the visible packet rows. Then use the typing-exactness route and candidate-normalization scope to force typing and finite candidate-normalization consumers through $T, S, B, F, R, H, C, P, N$.

These cited routes exhaust the accepted carrier surface fixed by TasteGate. Since the carrier has no further coordinate, the scoped closure package cannot export any of the refused global decidability, conversion, equality, consistency, normalisation, or evaluator objects. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessScopedClosurePackage`

Theorem 751.17 (MetaCIC decidability witness public export)**.** *Every public consumer of an accepted* $\mathsf{MetaCICDecidabilityWitness}^{\uparrow}$ *packet must read the same typing, same-term, bounded-conversion, finished-normal, refusal, transport, replay, provenance, and local naming rows before treating the packet as a decidability witness. Thus a public export over* $W = (T, S, B, F, R, H, C, P, N)$ *is valid only when* T *supplies typing exactness,* S *supplies structural same-term equality,* B *and* F *supply bounded conversion and finished-normal inspection,* R *supplies refusal, and* H, C, P, N *supply componentwise transport, displayed replay, provenance, and local naming. It exports no standalone* $\mathsf{ClosedAt}$ *decision theorem, unrestricted beta-conversion decider, quotient syntax equality, consistency theorem, fuel-erased normalisation theorem, or host evaluator.*

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessPublicExport`

Proof. Begin with the TasteGate single-carrier marker already recorded after Definition 751.2. It fixes the public packet to the displayed carrier $W = (T, S, B, F, R, H, C, P, N)$.

The bounded-conversion non-escape theorem and bounded normal-form split force conversion and finished-normal reads through B, F together with the visible refusal and structural rows. The typing-exactness route forces typing reads through T, while bounded-search exhaustion keeps finite candidate search inside the displayed packet.

The scope assignment, candidate-normalization scope, scope routes, and scoped-closure package then identify the remaining public rows. They place same-term checking in S, refusal in R, and transport, replay, provenance, and local naming in H, C, P, N.

These cited surfaces exhaust the accepted public export. Since no carrier coordinate names global decidability, unrestricted conversion, quotient equality, consistency, fuel-erased normalisation, or a host evaluator, none of those objects can be exported by a public consumer of the witness. □

Theorem 751.18 (MetaCIC decidability witness bridge-facing surface)**.** *Every bridge-facing consumer of an accepted* $\mathsf{MetaCICDecidabilityWitness}^{\uparrow}$ *packet* $W = (T, S, B, F, R, H, C, P, N)$ *must expose the same public rows already bound in this chapter: typing exactness through* T*, same-term checking through* S*, bounded conversion through* B*, finished-normal exposure through* F*, refusal rows through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}$ *naming through* N*. The surface exports no subject-reduction theorem, full normalization theorem, evaluator equality, quotient term equality, or kernel consistency theorem.*

Proof. Start with the public export theorem, Definition 751.17. It fixes every public consumer read at the displayed carrier $W = (T, S, B, F, R, H, C, P, N)$.

Use the scoped route theorems, Definition 751.14 and Definition 751.16. They assign typing exactness, same-term checking, bounded conversion, finished-normal exposure, refusal, transport, replay, provenance, and naming to those rows and to no hidden coordinate.

Finally apply the obligation-closure package, Definition 751.11. It repacks the carrier row, NameCert obligations, bounded-conversion nonescape, bounded normal-form split, and typing-exactness route into the same finite witness surface.

Thus any bridge-facing consumer can expose only the public rows already displayed in the chapter. Since the refusal and nonescape rows stay part of the package, the route cannot export subject reduction, full normalization, evaluator equality, quotient term equality, or kernel consistency. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.BridgeFacingSurface.MetacicDecidabilityWitnessBridgeE`

Theorem 751.19 (MetaCIC decidability witness bridge export)**.** *Any bridge export of an accepted* $\mathsf{MetaCICDecidabilityWitness}^{\uparrow}$ *packet* $W = (T, S, B, F, R, H, C, P, N)$ *must expose typing exactness, same-term checking, bounded conversion, finished-normal inspection, refusal rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}$ *naming before entering a bridge consumer. The export is therefore bounded and refusal-aware; it exports no subject-reduction theorem, full normalization theorem, quotient syntax equality, kernel consistency theorem, fuel-erased evaluator, or unrestricted closed beta-conversion decider.*

Proof. Start with the public export theorem, Definition 751.17. It requires every public consumer to read the displayed rows $T, S, B, F, R, H, C, P, N$ before treating the packet as a decidability witness.

Apply the bridge-facing surface theorem, Definition 751.18. It assigns typing exactness to T, same-term checking to S, bounded conversion to B, finished-normal exposure to F, refusal to R, componentwise hsame transport to H, displayed Cont replay to C, Pkg provenance to P, and local naming to N.

Use the scoped-closure package of Definition 751.16 together with the obligation-closure package of Definition 751.11. These packages ensure that the bridge export is still read from the same finite carrier and that the bounded-conversion, finished-normal, refusal, transport, replay, provenance, and naming obligations have already been exposed.

Thus a bridge consumer receives only the bounded, refusal-aware rows already displayed in the packet. Since no row names subject reduction, full normalization, quotient syntax equality, kernel consistency, a fuel-erased evaluator, or unrestricted closed beta conversion, none of those objects can be exported. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessBridgeExport`

Theorem 751.20 (MetaCIC decidability witness mature normal-form boundary)**.** *Any accepted* $\mathsf{MetaCICDecidabilityWitness}^{\uparrow}$ *packet exposing typing exactness, bounded conversion, finished-normal rows, refusal rows, transport, replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}$ *naming remains bounded by the displayed fuel and scope rows of its carrier* $W = (T, S, B, F, R, H, C, P, N)$*. In particular, its mature bridge-facing surface cannot export standalone* $\mathsf{ClosedAt}$ *decidability, unrestricted beta-conversion decidability, quotient term equality, or kernel consistency; it exports only the finite typing, bounded-conversion, finished-normal, refusal, transport, replay, provenance, and naming rows already displayed by the packet.*

Proof. Start with the TasteGate single-carrier marker recorded for the chapter. It fixes the accepted witness at the displayed carrier $W = (T, S, B, F, R, H, C, P, N)$, so every normal-form or decidability read must be routed through those rows.

Use the bounded-conversion non-escape theorem and the bounded normal-form split. The former confines beta-comparison evidence to the displayed bounded row B together with the finished-normal side condition F, while the latter keeps normal-form evidence inside the same finite carrier and leaves the refusal row R visible.

Apply bounded-search exhaustion, scope assignment, and the scope-routes theorem. These identify typing exactness with T, same-term checking with S, bounded conversion with B, F, refusal with R, and structural movement with H, C, P, N under the displayed scope and fuel rows.

Finally use the bridge-facing surface and bridge-export theorems. They present the public rows to bridge consumers without adding a new coordinate. Since the carrier has no row for standalone ClosedAt decidability, unrestricted beta-conversion decidability, quotient term equality, or kernel consistency, none of those objects can be exported by the mature normal-form boundary. □

Lean4 ✓ `BEDC.Derived.MetacicDecidabilityWitnessUp.MetacicDecidabilityWitnessMatureNormalFormBoundary`

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDecidabilityWitness}^{\uparrow}$ packet is generated from inferTypeCtx soundness and completeness, checkSameTerm structural equality, bounded beta comparison, finished-normal side conditions, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 751.1, Definition 751.2, Definition 751.3, Definition 751.4, Definition 751.5, Definition 751.11, Definition 751.12, Definition 751.14, Definition 751.16, Definition 751.17, Definition 751.18, Definition 751.19, and Definition 751.20 bind typing exactness, same-term checking, bounded conversion, finished-normal exposure, refusal rows, transport, replay, provenance, and local naming as one scoped finite NameCert witness with public, bridge-export, and mature normal-form boundary routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDecidabilityWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close standalone ClosedAt decidability, unrestricted closed beta-conversion decidability, fuel-erased normalisation, quotient equality over represented terms, Lean-side verification, or bridge checking.

Upgrade path: No theory-axis upgrade remains; Lean verification and bridge checking remain separate formal-axis work for BEDC.Derived.MetacicDecidabilityWitnessUp.

Chapter 752

A Concrete Naming Certificate for BoundedNormalEqualityChecker$^{\uparrow}$

The BoundedNormalEqualityChecker$^{\uparrow}$ packet records the normal-equality side of chapter 9379 as a finite naming certificate. It sits between the already-normal exclusion packet of chapter 732 and the closed-normal confluence fragment of chapter 737: the present packet names a bounded comparison surface, while those sibling packets keep false-proof exclusion and confluence scopes separate.

The checker also consumes the closed normal-form frontier of chapter 795 and the certificate-routing boundary of chapter 1108. Bounded equality checking is only a finite readback of accepted normal-form evidence through those MetaCIC rows; it is not a proof of global confluence or unrestricted normalization.

The packet is not a global beta-conversion oracle. It exposes bounded normalizer output rows, structural `Term.eq` readback, finished-normalization witnesses when they are supplied, closedness rows, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Definition 752.1 (BoundedNormalEqualityChecker carrier)**.** *A* BoundedNormalEqualityChecker$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, R, F, N_L, N_R, E, W, C, H, K, P, A)$$

with the following visible rows:

1. *L and R are the two closed MetaCIC input term rows being compared;*
2. *F is the shared unary fuel row for the bounded normalizer;*
3. *N_L and N_R are the bounded normalizer output rows obtained from the two input terms at fuel F;*
4. *E is the structural `Term.eq` readback row comparing N_L and N_R;*
5. *W stores the finished-normalization witnesses for the two outputs when such witnesses are part of the input surface;*
6. *C records the closedness rows for the inputs and for the named normal forms that a finished-soundness consumer may read;*
7. *H records componentwise* hsame *transports for the input terms, fuel, normalizer outputs, equality readback, finished witnesses, closedness rows, package row, and local naming row;*

8. *K records displayed* Cont *routes for running the bounded normalizer, reading the structural equality result, replaying finished witnesses, and transporting closedness rows;*
9. *P is the* Pkg *provenance over MetaCIC terms, bounded normalization,* `Term.eq`*, finished-normalization witnesses, closedness,* BHist*,* hsame*,* Cont*, and* NameCert *rows;*
10. *A is the local* $\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityChecker}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a fuel-erased normalizer, no proof that every closed term reaches a finished normal form, no arbitrary closed-term beta-conversion decider, and no host equality oracle.

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerTasteGate`
`single carrier alignment`

Definition 752.2 (BoundedNormalEqualityChecker classifier)**.** *Two accepted* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *carriers are classified as the same bounded normal-equality packet exactly when their displayed rows compare componentwise. Their input rows agree by the closed MetaCIC term classifiers, their fuel rows agree by the unary fuel classifier, their bounded normalizer outputs agree by the displayed output rows, their equality decision agrees by* `Term.eq` *readback, their finished-normalization and closedness rows agree when those rows are present, and their* Pkg *provenance and local* NameCert *rows name the same packet.*

The classifier has no generator for comparing arbitrary beta-conversion classes, no generator for choosing a fuel that finishes all closed terms, and no generator for replacing structural `Term.eq` *by host equality.*

Lean4 (definition) `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerClassifier`

Definition 752.3 (BoundedNormalEqualityChecker route preorder)**.** *For accepted* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *checker packets, the route preorder is the finite relation generated by row transport and replay. A checker packet Q precedes a checker packet Q' when the normal false exclusion row, the bounded fuel row, the classifier row of Definition 752.2, and the confluence-normal fragment row of Q transport by the displayed* hsame *rows into the corresponding checker, normalfalseexclusion, and metacicconfluencenormalfragment rows of Q', and when the displayed* Cont *replay of Q' reads those transported rows before any consumer read.*

The preorder has no carrier-level equivalence generator beyond those concrete rows: it compares bounded normal-equality checker data only through the false-proof exclusion, fuel, classifier, confluence-normal fragment, transport, replay, provenance, and local naming rows already present in accepted packets.

Lean4 (definition) `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerRoutePreorder`

Theorem 752.4 (BoundedNormalEqualityChecker NameCert obligations)**.** *The carrier and classifier of Definition 752.1 and Definition 752.2, together with the route preorder of Definition 752.3, satisfy the local* $\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityChecker}^{\uparrow}}$ *obligation surface for bounded normal equality. Carrier admission reads only the two input term rows, shared fuel, bounded normalizer outputs, structural equality readback, optional finished-normalization witnesses, closedness rows,* hsame *transports, displayed* Cont *replay,* Pkg *provenance, and local naming row. Classifier stability is componentwise over exactly those rows, deterministic normal-form readback and consumer nonescape are monotone along the concrete checker route preorder, and ledger exactness rejects every consumer read outside them.*

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerCarrier namecert obligations`

Proof. For carrier admission, project the tuple Q. The rows $L, R, F, N_L, N_R, E, W, C$ are the entire computational surface, and the rows H, K, P, A are the entire structural replay surface.

For classifier stability, compare accepted packets row by row. Input terms, fuel, normalizer outputs, equality readback, finished witnesses, and closedness rows are transported only through the displayed hsame and Cont rows.

For ledger exactness, inspect a downstream read. It can project a bounded normalizer output, a `Term.eq` result, a supplied finished witness, a closedness row, or a structural replay row. Since no carrier coordinate names a global conversion oracle or a fuel-selection theorem, such a read cannot escape the bounded packet. □

Theorem 752.5 (BoundedNormalEqualityChecker finished soundness boundary)**.** *If an accepted* BoundedNormalEqualityChecker$^{\uparrow}$ *packet carries finished closed-normalization witnesses for both bounded normalizer outputs, then a true structural* `Term.eq` *readback may be consumed as equality of those named finished normal forms and as beta-convertibility between those named normal forms. The same readback does not prove that arbitrary closed terms finish at some fuel, and it does not decide unrestricted beta conversion.*

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerCarrier finished soundness boundary`

Proof. Read the bounded outputs N_L and N_R through the carrier, and read the structural equality result through E. The equality claim is tied to those two displayed normalizer outputs at the displayed fuel F.

When the finished rows in W and the closedness rows in C are present, the consumer may replay the finished-soundness route recorded in K. That route identifies the equality as a statement about the named finished normal forms, not about all possible reductions from arbitrary closed terms.

The boundary follows by coordinate exhaustion. The packet has no row proving fuel existence for every closed input and no row deciding beta conversion outside the displayed bounded outputs. □

Theorem 752.6 (BoundedNormalEqualityChecker deterministic normal-form readback)**.** *Let*

$$Q = (L, R, F, N_L, N_R, E, W, C, H, K, P, A)$$

and

$$Q' = (L', R', F', N'_L, N'_R, E', W', C', H', K', P', A')$$

be accepted BoundedNormalEqualityChecker$^{\uparrow}$ *packets with the same bounded normal input rows, the same shared fuel row, the same comparison ledger, and classifier-related output rows. Then the concrete packet exposes the same normal-form readback route: the displayed bounded normalizer outputs are read through the same N_L, N_R positions, the structural* `Term.eq` *result is read through the same ledger row E, and every finished-normal readback consumer factors through the same carrier rows $L, R, F, N_L, N_R, E, W, C, H, K, P, A$. The conclusion is internal to* BoundedNormalEqualityChecker$^{\uparrow}$ *and does not pass through an abstract source-equivalence transport.*

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerCarrier deterministic normal form readback`

Proof. Project both accepted packets through Definition 752.1. The carrier rows fix the two input terms, shared fuel, bounded normalizer outputs, structural readback row, finished witnesses, closedness rows, transports, replay, provenance, and local naming data.

Use the classifier of Definition 752.2 and the stability row of Definition 752.9. The hypothesis that the inputs, fuel, comparison ledger, and output rows are classifier-related forces the displayed readback route to compare componentwise through the same finite coordinates.

The finished soundness boundary of Definition 752.5 allows a consumer to read equality only for the named finished normal forms. Finally, ledger exactness from Definition 752.10 prevents the consumer from replacing the concrete route by host equality, quotient equality, fuel erasure, hidden termination, or an abstract source-equivalence transport. □

Theorem 752.7 (BoundedNormalEqualityChecker fuel monotonicity boundary)**.** *Let*

$$Q = (L, R, F, N_L, N_R, E, W, C, H, K, P, A)$$

and

$$Q^+ = (L, R, F^+, N_L^+, N_R^+, E^+, W^+, C^+, H^+, K^+, P^+, A^+)$$

be accepted BoundedNormalEqualityChecker$^\uparrow$ *packets whose displayed inputs are the same and whose second fuel row F^+ extends the displayed unary fuel row F. Increasing the displayed fuel may extend the bounded normalizer output route only through the same input rows, structural equality readback row, finished witness rows, closedness rows, componentwise transports, displayed replay, provenance, and local naming rows. It does not create a fuel-erased normalizer, a global termination theorem, an arbitrary beta-conversion decider, or a host equality oracle.*

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerCarrier fuel monotonicity`

Proof. Project both packets through Definition 752.1. The only rows that differ are the displayed fuel, bounded output, equality readback, finished witness, closedness, transport, replay, provenance, and local naming rows; the input rows remain L and R.

Use the classifier of Definition 752.2. It compares fuel and output data componentwise, so a larger fuel row can only expose another bounded normalizer route over the same two input rows.

Apply the finished soundness boundary of Definition 752.5. Finished witnesses, when present, certify only the named outputs at the displayed fuel and do not prove that every closed term finishes at some fuel.

Apply deterministic normal-form readback from Definition 752.6 and ledger exactness from Definition 752.10. The readback and every consumer route stay inside the displayed equality, closedness, transport, replay, provenance, and local naming rows, so fuel growth cannot erase the bound or become a host equality oracle. □

Theorem 752.8 (BoundedNormalEqualityChecker consumer non-escape)**.** *Every consumer of an accepted* BoundedNormalEqualityChecker$^\uparrow$ *packet reads only the finite rows*

$$L, R, F, N_L, N_R, E, W, C, H, K, P, A.$$

The consumer may use the bounded normalizer outputs, the structural `Term.eq` *result, and the finished-normalization bridge when its witness rows are displayed, but it receives no unrestricted beta-conversion decision procedure, no hidden normalizer termination theorem, no quotient equality of terms, and no host equality oracle.*

Proof. Start from the carrier definition. The displayed tuple lists all computational, structural, provenance, and local naming rows available to a consumer.

Use the NameCert obligations to force each read through the same finite packet. Normalizer outputs pass through N_L and N_R, equality readback passes through E, and conditional finished soundness passes through W, C, H, K, P, A.

Apply the finished soundness boundary. It permits equality and beta-convertibility only for the named finished normal forms supplied by the packet, while the absent fuel-existence and global conversion coordinates block every stronger read. □

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerCarrier consumer nonescape`

Theorem 752.9 (BoundedNormalEqualityChecker classifier stability row)**.** *For accepted* BoundedNormalEqualityCh *packets*

$$Q = (L, R, F, N_L, N_R, E, W, C, H, K, P, A)$$

and

$$Q' = (L', R', F', N'_L, N'_R, E', W', C', H', K', P', A'),$$

the classifier is stable exactly componentwise over the displayed rows $L, R, F, N_L, N_R, E, W, C, H, K, P, A$*. In particular, the comparison transports the two input term rows, shared fuel row, bounded normalizer outputs, structural* `Term.eq` *readback, supplied finished witnesses, closedness rows, componentwise* hsame *data, displayed* Cont *routes,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityChecker}^{\uparrow}}$ *row. It has no additional coordinate for host equality, fuel erasure, or global beta conversion.*

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerCarrier classifier stability row`

Proof. Project both accepted carriers through Definition 752.1. The classifier of Definition 752.2 lists the same coordinates and compares them row by row.

The NameCert obligations of Definition 752.4 force each computational comparison through the displayed bounded normalizer, structural readback, witness, and closedness rows. The consumer non-escape result of Definition 752.8 then rules out any stabilizing coordinate beyond the finite tuple. □

Theorem 752.10 (BoundedNormalEqualityChecker ledger exactness row)**.** *Every consumer read from an accepted* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *packet is exhausted by the bounded normalizer outputs* N_L, N_R*, the structural* `Term.eq` *row* E*, the supplied finished witness row* W*, the closedness row* C*, the componentwise* hsame *row* H*, the displayed* Cont *row* K*, the* Pkg *row* P*, and the local* $\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityChecker}^{\uparrow}}$ *row* A*. The ledger therefore contains no global beta-conversion procedure, no hidden termination theorem, no quotient equality of terms, and no host equality oracle.*

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerCarrier namecert ledger read boundary`

Proof. Read the finite tuple in the order fixed by the carrier definition. The only normalization outputs are N_L and N_R, and the only equality readback is the structural `Term.eq` row E.

Finished soundness is conditional on the displayed rows W and C and is bounded by Definition 752.5. Transport, replay, provenance, and naming then pass through H, K, P, A.

Finally apply consumer non-escape from Definition 752.8. Since every consumer read is a projection from the displayed ledger, no global conversion, hidden termination, quotient equality, or host equality row can be read. □

Theorem 752.11 (BoundedNormalEqualityChecker obligation package)**.** *The* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *obligation surface is the package formed by carrier admission, classifier stability, finished-soundness boundary, consumer non-escape, and ledger exactness over the finite carrier rows* $L, R, F, N_L, N_R, E, W, C, H, K, P$*. This package is the whole local* $\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityChecker}^{\uparrow}}$ *surface for bounded normal equality, and it does not claim unrestricted beta conversion, hidden normalizer termination, quotient equality, or host equality.*

Proof. Carrier admission and the local NameCert rows are supplied by Definition 752.4. Classifier stability is the rowwise comparison of Definition 752.9.

The finished-soundness boundary is exactly Definition 752.5, and consumer non-escape is Definition 752.8.

The remaining ledger clause is Definition 752.10. These five clauses account for every displayed carrier coordinate, so the package contains the obligation-closure surface and no stronger global conversion claim. □

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerCarrier obligation package`

Theorem 752.12 (BoundedNormalEqualityChecker package-read public consumer)**.** *Every public consumer read that starts from the bounded checker package row factors through the obligation package. The package-read row is produced only by the displayed transport and route rows* H, K*, and the public read then continues through the local naming row* A*; the consumer retains the package provenance and NameCert package signatures, but gains no hidden conversion or termination row.*

Proof. Apply the obligation package to the accepted carrier and the displayed $\mathsf{Cont}(H, K)$ package route. This supplies the unary package-read row, the same transport-route replay, and the two package signatures.

The public read is then a further displayed continuation from the package-read row to the local naming row. Since the obligation package already accounts for the available rows, the public consumer can only read the named bounded checker surface and cannot introduce a fuel-erased normalizer or host equality oracle. □

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerPackageRead public consumer`

Theorem 752.13 (BoundedNormalEqualityChecker scoped closure)**.** *The carrier, classifier, route preorder, NameCert obligations, finished-soundness boundary, deterministic readback, non-escape theorem, classifier-stability row, ledger-exactness row, obligation package, and package-read public consumer jointly close the bounded normal-equality checker scope. The closed scope is exactly the finite surface over closed MetaCIC term rows, unary fuel, bounded normalizer output, structural* `Term.eq`*, finished witnesses, closedness rows,* hsame*,* Cont*,* Pkg*, and* NameCert *carried by* $L, R, F, N_L, N_R, E, W, C, H, K, P, A$*. It exports no unrestricted beta conversion, hidden normalizer termination, quotient equality of terms, or host equality oracle.*

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerCarrier scope closure`

Proof. Start from the carrier definition, classifier, and route preorder. These fix the displayed rows $L, R, F, N_L, N_R, E, W, C, H, K, P, A$ and the allowed rowwise route between accepted packets.

The local obligations then account for the analytic and audit rows. The NameCert obligation theorem supplies carrier admission, finished-soundness supplies the bounded endpoint boundary, and deterministic readback identifies structural `Term.eq` as the only equality read.

Non-escape, classifier stability, and ledger exactness rule out hidden routes. They keep every consumer inside the closed MetaCIC term rows, unary fuel, bounded normalizer output, finished witnesses, closedness rows, transport, replay, provenance, and local naming.

Finally apply the obligation package. It gathers the listed clauses as one finite scope, so the bounded normal-equality checker is scoped-closed over the displayed kernel rows and does not export any stronger conversion or equality principle. □

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerScopeClosure`

Theorem 752.14 (BoundedNormalEqualityChecker public export)**.** *Every accepted* BoundedNormalEqualityChecke *packet exports exactly the displayed bounded normal-equality checker surface: two closed term rows, the fuel row, bounded normalizer outputs, structural equality readback, finished-normalization witness rows, componentwise* hsame *transports,* Cont *replay,* Pkg *provenance, and the local* NameCert *row. No public consumer receives unrestricted beta-conversion, hidden normalizer termination, quotient equality of terms, or a host equality oracle from this packet.*

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerPublicExport`

Proof. Use Definition 752.13. It already binds the carrier, classifier, route preorder, NameCert obligations, finished-soundness boundary, deterministic readback, non-escape theorem, classifier-stability row, ledger-exactness row, and obligation package as one closed finite scope.

The public export reads that closed scope without adding a new coordinate. The two closed term rows, fuel row, bounded normalizer outputs, structural equality readback, finished-normalization witnesses, transports, replay, provenance, and local naming are exactly the rows exposed by the scope-closure theorem.

Since the carrier has no row for unrestricted conversion, hidden termination, quotient equality, or host equality, the exported public surface is precisely the displayed bounded checker packet and nothing stronger. □

Theorem 752.15 (BoundedNormalEqualityChecker bridge-facing schema)**.** *The public* BoundedNormalEqualityChe *surface exports exactly the bounded closed-term rows, finished-normal readback, fuel monotonicity, classifier stability, ledger exactness, and scope closure already bound by the carrier, classifier, NameCert obligations, finished-soundness boundary, deterministic readback, non-escape theorem, classifier-stability row, ledger-exactness row, obligation package, scope-closure theorem, and public export theorem. A bridge-facing consumer may therefore read the displayed MetaCIC sibling rows, unary fuel, bounded normalizer outputs, finished witnesses, closedness data, componentwise transport, replay, provenance, and local naming, but it receives no unrestricted beta conversion, hidden normalizer termination, quotient equality of terms, or host equality oracle.*

Lean4 ✓ `BEDC.Derived.BoundedNormalEqualityCheckerUp.BoundedNormalEqualityCheckerBridgeFacingSchema`

Proof. Start with the public export theorem. It exposes the same finite checker packet already closed by the scope-closure theorem and adds no public coordinate beyond $L, R, F, N_L, N_R, E, W, C, H, K, P, A$.

The bridge-facing schema reads the public packet through the earlier bounded rows. Finished-soundness and deterministic readback supply the finished-normal endpoint and structural equality read, while non-escape prevents that read from becoming unrestricted beta conversion.

Classifier stability and ledger exactness preserve the audit surface under accepted packet comparison. Together with the obligation package, they keep fuel, bounded normalizer output, closedness rows, transport, replay, provenance, and local naming in the displayed finite scope.

Thus the bridge-facing surface is exactly the public bounded normal-equality checker schema. Since none of the cited rows names hidden termination, quotient equality, host equality, or unrestricted conversion, no bridge-facing consumer receives those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityChecker}\uparrow}$.

Constructive story: A $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ packet is generated from two closed MetaCIC term rows, a bounded fuel row, bounded normalizer outputs, structural equality readback, finished-normalization witness rows, componentwise transports, displayed continuation routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityChecker}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: Definition 752.1, Definition 752.2, Definition 752.4, Definition 752.5, Definition 752.6, Definition 752.8, Definition 752.9, Definition 752.10, Definition 752.11, Definition 752.13, Definition 752.14, and Definition 752.15 bind a mature paper-axis treatment of the public bounded normal-equality checker surface; verification status and checked bridge status remain independent.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedNormalEqualityChecker}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close unrestricted beta-conversion, hidden normalizer termination, quotient equality of terms, or host equality.

Upgrade path: The paper-axis treatment is mature; Lean verification, axiom-purity certification, and a checked standard bridge remain independent verification-axis work.

Chapter 753

A Concrete Naming Certificate for $\mathsf{MetaCICTypedExamplesSeal}^{\uparrow}$

The $\mathsf{MetaCICTypedExamplesSeal}^{\uparrow}$ packet turns the typed-example audit map of chapter 9382 into a finite seal that can be read by downstream MetaCIC checker consumers. It sits between the bounded decidability boundary of chapter 749 and the bounded normal-equality checker of chapter 752: those chapters expose the finite checker and normal-comparison rows, while the present packet seals the worked gallery rows that exercise them.

Definition 753.1 (MetaCIC TypedExamples seal carrier)**.** *A* $\mathsf{MetaCICTypedExamplesSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (E, T, C, B, D, Q, R, H, K, P, N)$$

with the following displayed rows:

1. *E is the finite worked-example row selected from the typed-example audit map: Church encodings, identity rows, applications, projections, eliminator examples, constants, Pi rows, and sort-context rows;*
2. *T is the displayed typing-checker row for the examples that are accepted by the finite gallery;*
3. *C is the closedness and context-formation row consumed by those checker reads;*
4. *B is the selected beta and readback row for examples whose evaluation behavior is part of the worked gallery;*
5. *D is the bounded decidability row imported from the* $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$ *surface;*
6. *Q is the bounded normal-equality checker row imported from the* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *surface;*
7. *R is the finite seal ledger recording which gallery families are accepted, which computations are named, and which checker or normal-equality rows they are allowed to read;*
8. *H records componentwise* hsame *transports across $E, T, C, B, D, Q, R, P, N$;*
9. *K records the displayed* Cont *routes for replaying gallery entry reads, checker reads, closedness reads, beta reads, bounded decidability reads, normal-equality reads, and seal-ledger reads;*
10. *P is the* Pkg *provenance over chapter 9382, chapter 749, and chapter 752;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary MetaCIC term, no global subject-reduction theorem, no strong normalization theorem, no global conversion decider, no proof-erasure correctness theorem, and no host evaluator.

Theorem 753.2 (MetaCIC TypedExamples seal NameCert obligations)**.** *For the carrier of Definition 753.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for* $S = (E, T, C, B, D, Q, R, H, K, P, N)$*, gallery-entry visibility through* E*, typing-checker visibility through* T*, closedness and context visibility through* C*, selected computation visibility through* B*, bounded decidability visibility through* D*, bounded normal-equality visibility through* Q*, finite seal-ledger exactness through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* K*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. The rows E, T, C, B, D, Q, R are the entire worked-example surface, and the rows H, K, P, N are the entire structural surface available to a consumer.

The gallery-entry obligation reads E only for the families selected by chapter 9382. The checker obligation reads T under the closedness and context row C, while the computation obligation reads B only for the examples whose beta or readback behavior is named in the finite ledger.

The bounded decidability and normal-equality obligations read D and Q through the sibling packets of chapter 749 and chapter 752. The seal ledger R records which of those sibling rows each worked example may consume.

Finally, H, K, P, N transport, replay, package, and name only the displayed rows. Since the carrier contains no further coordinate, the local NameCert surface is exhausted by the listed obligations. □

Theorem 753.3 (MetaCIC TypedExamples seal non-escape)**.** *Every consumer of an accepted* $\mathsf{MetaCICTypedExamplesSeal}^{\uparrow}$ *packet reads only the finite rows*

$$E, T, C, B, D, Q, R, H, K, P, N.$$

The consumer may use those rows as a worked-example seal for the typed-example gallery and may route selected checker or bounded normal-equality reads through the named sibling packets. It receives no theorem about all represented MetaCIC terms, no quotient equality of terms, no unrestricted beta-conversion decision procedure, no selected normalization endpoint, no proof-erased compiler theorem, and no host evaluator.

Proof. Begin with the carrier definition. The tuple lists all gallery, checker, closedness, computation, bounded decidability, normal-equality, ledger, transport, route, provenance, and naming rows exposed by the packet.

Any checker or normal-equality read must pass through the finite seal ledger R. That ledger points to the bounded decidability and bounded normal-equality sibling surfaces, so the consumer cannot replace the selected gallery rows by an arbitrary MetaCIC term or a global conversion oracle.

The structural rows H, K, P, N preserve componentwise agreement, replay the same finite routes, record provenance, and name the packet. They do not add a quotient of terms, a normalization selector, a proof-erased compiler route, or a host evaluator.

Thus the accepted reading is exactly the finite worked-example seal. All stronger metatheoretic endpoints are absent from the carrier and cannot be exported by a downstream consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesSeal}^{\uparrow}}$.

Constructive story: A MetaCICTypedExamplesSeal$^{\uparrow}$ packet is generated from finite typed-example rows, checker rows, closedness rows, selected computation rows, bounded decidability rows, bounded normal-equality rows, a finite seal ledger, componentwise transports, continuation routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MetaCICTypedExamplesSeal}\uparrow}$, seed)

Scope closed: Definition 753.1, Definition 753.2, and Definition 753.3 bind the finite worked-example seal surface and its sibling checker routes.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICTypedExamplesSeal}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close subject reduction, strong normalization, global conversion decidability, quotient equality over represented terms, proof-erased compiler correctness, host evaluation, or bridge checking.

Upgrade path: Obligation closure requires checking carrier admission, gallery-entry visibility, checker visibility, closedness visibility, selected computation visibility, sibling bounded-checker routes, seal-ledger exactness, and non-escape for the displayed packet.

Chapter 754

A Concrete Naming Certificate for $\mathsf{BetaStepBoundary}^{\uparrow}$

The $\mathsf{BetaStepBoundary}^{\uparrow}$ packet realizes the beta audit map of chapter 9384 as a finite BEDC naming surface. It sits beside the subject-reduction carrier of chapter 483: the present packet names the BetaStep and BetaConv boundary rows, while the sibling packet records the preservation-facing route that must not be inferred from beta reduction alone.

Definition 754.1 (BetaStepBoundary carrier)**.** *A* $\mathsf{BetaStepBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, C, O, H, K, P, N)$$

with the following visible rows:

1. *R records the* BetaStep *rule surface, including the direct redex row and the congruence rows for application, lambda-domain, lambda-body, Pi-domain, and Pi-codomain positions;*
2. *C records the* BetaConv *common-reduct rows, including reflexivity, symmetry, the beta-star injections, beta-step injections, and the normal-middle conversion rows named by the audit map;*
3. *O records the subject-reduction obstruction triggers: beta substitution, application-argument stability, lambda-domain preservation, and Pi-domain preservation;*
4. *H stores componentwise* hsame *transports for the beta-rule rows, conversion rows, obstruction-trigger rows, provenance row, and local naming row;*
5. *K stores the displayed* Cont *routes by which consumers read beta steps, common-reduct conversions, and obstruction triggers without crossing from reduction into typed preservation;*
6. *P is the* Pkg *provenance over the MetaCIC beta audit map, chapter 483,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{BetaStepBoundary}^{\uparrow}}$ *row.*

The packet contains no host conversion oracle, hidden typing-preservation theorem, closed subject-reduction theorem, quotient equality, or erased semantic equality coordinate.

Theorem 754.2 (BetaStepBoundary NameCert obligations)**.** *The carrier of Definition 754.1 satisfies the local* $\mathsf{NameCert}_{\mathsf{BetaStepBoundary}^{\uparrow}}$ *obligation surface. Its five obligation rows are:*

1. *carrier admission for the finite packet $B = (R, C, O, H, K, P, N)$;*

2. *beta-rule exactness, saying that R exposes exactly the displayed* BetaStep *constructor surface;*
3. *conversion-boundary readback, saying that C exposes only the* BetaConv *common-reduct and normal-middle rows listed by the audit map;*
4. *subject-reduction non-escalation, saying that the obstruction triggers in O remain obligation rows and do not become a closed preservation theorem;*
5. *ledger non-escape, saying that H, K, P, N supply only transport, continuation, provenance, and naming for the displayed rows, never host conversion or hidden typing preservation.*

Lean4 ✓ `BEDC.Derived.BetaStepBoundaryUp.BetaStepBoundaryTasteGate single carrier alignment`

Proof. Carrier admission is the displayed BHist packet. Each coordinate is a finite row for beta rules, conversion readback, obstruction triggers, transport, continuation, provenance, or local naming.

Beta-rule exactness follows by projecting R. The row lists the direct beta redex and the congruence positions, so a consumer cannot read an additional reduction rule from the carrier.

Conversion-boundary readback follows by projecting C. Common-reduct conversion, beta-star injection, beta-step injection, and normal-middle conversion rows are available only as the listed conversion surface.

Subject-reduction non-escalation follows by projecting O and comparing it with chapter 483. The beta packet records the triggers that a preservation consumer must discharge, but it has no coordinate carrying a closed subject-reduction theorem.

Finally inspect H, K, P, N. These rows move and replay the same finite packet, record its provenance, and give it a local name. None of them contains host conversion or hidden typing preservation, so every consumer remains inside the displayed ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{BetaStepBoundary}\uparrow}$.

Constructive story: A $\mathsf{BetaStepBoundary}^{\uparrow}$ packet is generated from beta-step rule rows, beta-conversion common-reduct rows, subject-reduction obstruction triggers, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BetaStepBoundary}\uparrow}, \mathsf{seed})$

Scope closed: Definition 754.1 and Definition 754.2 bind the finite beta-step, beta-conversion, obstruction-trigger, transport, route, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BetaStepBoundary}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, beta-substitution preservation, application-argument stability, lambda-domain preservation, Pi-domain preservation, host conversion, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, beta-rule exactness, conversion-boundary readback, subject-reduction non-escalation, transport, route replay, provenance, and ledger non-escape for the same finite packet.

Lemma 754.3 (BetaStepBoundary obstruction-trigger enumeration)**.** *Let $B = (R, C, O, H, K, P, N)$ be an accepted* $\mathsf{BetaStepBoundary}^{\uparrow}$ *carrier. If a consumer reads a subject-reduction obstruction trigger from B through the displayed obstruction slot, then the read trigger is one of exactly four rows:*

BetaSubstitutionPreservation, AppArgTypeStable, LamDomainSubjectReduction, PiDomainSubjectReduct

Conversely, each of these four rows is a displayed obstruction-trigger row of the same obstruction slot O.

Proof. Project the accepted carrier through Definition 754.1. The obstruction coordinate is the single row O, and that coordinate is displayed as the list of subject-reduction obstruction triggers: beta substitution, application-argument stability, lambda-domain preservation, and Pi-domain preservation.

The NameCert obligation surface of Definition 754.2 keeps this projection exact. Its subject-reduction non-escalation clause says that the entries in O remain obligation rows, while its ledger non-escape clause says that H, K, P, N supply only transport, continuation, provenance, and naming for the displayed rows. Thus a continuation read through K can select an entry of O, and an hsame transport through H can replay that selected entry, but neither operation creates another obstruction trigger.

The four labels are also the four discharge obligations named in section 9377.3, and section 9384.4 identifies them as the beta-redex, application-argument, lambda-domain, and Pi-domain triggers born at the beta boundary. Since R records beta-step constructors, C records beta-conversion readback, and P, N only record provenance and local naming, no subject-reduction obstruction trigger can be read from any coordinate other than O.

Therefore every admissible obstruction-trigger read from an accepted $\mathsf{BetaStepBoundary}^{\uparrow}$ packet is one of the four displayed rows, and the carrier definition supplies the reverse inclusion by listing all four rows inside O. □

Chapter 755

A Concrete Naming Certificate for MetaCICNormalizationBudget$^{\uparrow}$

The MetaCICNormalizationBudget$^{\uparrow}$ packet turns the normalization audit map of chapter 9383 into a finite NameCert surface. It is the normalization-side sibling of the conditional confluence witness in chapter 745, the subject-reduction obligation packet in chapter 712, and the closed-normal consistency boundary of chapter 733. The packet records a candidate-mediated budget route; it does not assert unconditional strong normalization for every closed typed MetaCIC term.

Definition 755.1 (MetaCIC normalization budget carrier)**.** *A* MetaCICNormalizationBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, C, E, S, A, P, R, H, Q, L, N)$$

with the following displayed rows:

1. *T is the closed typed MetaCIC term row whose normalization read is requested;*
2. *C is the reducibility-candidate evidence row attached to the same closed term;*
3. *E is the closed-candidate or candidate-set membership row consumed by the checked normalization lemmas;*
4. *S is the candidate-implies-strong-normalization row, naming the Lean route* BEDC.MetaCIC.candidate_implies_s *as a consumed theorem surface rather than as a global closed-term theorem;*
5. *A is the application and Pi adequacy boundary row that prevents componentwise normalization data from becoming unconditional application normalization;*
6. *P is the proof-replay budget row recording the finite candidate projections, adequacy reads, and no-infinite-reduction consequences available to the consumer;*
7. *R is the refusal row for requests that omit candidate evidence, closed-candidate evidence, or candidate-set membership;*
8. *H records componentwise* hsame *transport for term, candidate, membership, theorem, adequacy, budget, refusal, route, provenance, and naming rows;*
9. *Q records the displayed* Cont *routes by which consumers read normalization only through C, E, S, A, P or receive the refusal row R;*

10. *L is the* Pkg *provenance over the normalization audit map, the confluence audit witness, the subject-reduction obligation packet, the closed-normal consistency boundary,* BHist, hsame, Cont, *and the local certificate;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationBudget}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a host evaluator, an unconditional closed-term strong-normalization theorem, a subject-reduction discharge, a hidden application-normalization rule, or a conversion principle outside the candidate-mediated rows.

Lean4 (definition) `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier`

Theorem 755.2 (MetaCIC normalization budget NameCert obligations)**.** *For an accepted* MetaCICNormalizationB *carrier $B = (T, C, E, S, A, P, R, H, Q, L, N)$, the local* NameCert *surface exposes exactly the closed typed term row T, reducibility-candidate evidence C, closed-candidate or candidate-set membership E, candidate-to-strong-normalization row S, application and Pi adequacy boundary A, finite proof-replay budget P, refusal row R, componentwise transport H, displayed continuation routes Q, package provenance L, and local naming N. A consumer may read strong normalization only along the candidate-mediated route displayed by C, E, S, A, P.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetTasteGate single carrier alignment`

Proof. Project the carrier of Definition 755.1. The rows T, C, E, S, A, P display the positive route: a closed term is paired with candidate evidence, the evidence is read through the checked candidate-to-SN row, and the adequacy boundary records where Pi and application reasoning is allowed.

The refusal row R accounts for requests that skip the candidate evidence or ask for unconditional closed-term normalization. It is part of the same packet, so the negative answer is not an external convention.

The support rows H, Q, L, N transport, route, package, and name the same finite inventory. Since the carrier has no second theorem coordinate, the local NameCert obligations are exhausted by the displayed candidate-mediated budget surface. □

Theorem 755.3 (MetaCIC normalization budget obligation surface)**.** *Every accepted* MetaCICNormalizationBudget *carrier exposes exactly the positive rows*

$$T, C, E, S, A, P,$$

the refusal row R, and the support rows H, Q, L, N. The positive rows are read only as the candidate-mediated normalization budget, while R records requests for unconditional closed-term strong normalization or for normalization without the displayed candidate evidence.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier obligation surface`

Proof. Project the carrier of Definition 755.1. Its tuple has the six positive coordinates T, C, E, S, A, P, the single refusal coordinate R, and the four structural support coordinates H, Q, L, N; no other row is present.

Apply Definition 755.4. The positive surface is therefore candidate-mediated: the closed term row T reaches a strong-normalization read only through the candidate evidence C, E, the candidate-to-SN row S, the adequacy boundary A, and the replay budget P.

Apply Definition 755.5. Requests that ask for unconditional closed-term strong normalization, subject reduction, hidden application normalization, or a host evaluator have no positive coordinate in the carrier, so they are routed to R and to the support rows that transport, replay, source, and name the refusal. □

Theorem 755.4 (MetaCIC normalization budget candidate-route scope)**.** *Every positive normalization read from an accepted* MetaCICNormalizationBudget$^{\uparrow}$ *packet factors through*

$$T, C, E, S, A, P.$$

The row S may be consumed as the candidate-to-strong-normalization route for the displayed evidence, and the row A may be consumed as the displayed adequacy boundary, but neither row erases the candidate evidence or supplies closed subject reduction. The sibling packets of chapter 745, chapter 712, and chapter 733 therefore receive a budgeted normalization surface, not an unconditional theorem.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier candidate route scope`

Proof. Read the continuation coordinate Q. Its positive route reaches the strong-normalization read only after the term row T has been paired with the candidate rows C, E and the candidate-to-SN row S.

The adequacy row A records the Pi and application boundary named in chapter 9383. It lets consumers compare the route with confluence and subject-reduction siblings while preserving the guard that application normalization is not obtained from parts alone.

Finally inspect the provenance row L. It sends downstream readers to the confluence audit witness, the subject-reduction obligation packet, and the closed-normal consistency boundary as named consumers of the same finite budget. Those consumers inherit the candidate route; they do not receive a stronger closed-term normalization principle. □

Theorem 755.5 (MetaCIC normalization budget non-escape)**.** *An accepted* MetaCICNormalizationBudget$^{\uparrow}$ *packet cannot yield an unconditional theorem that every closed typed MetaCIC term is strongly normalizing. It cannot yield subject reduction, a hidden host evaluator, compiler semantics, quotient conversion, or application strong normalization without the displayed candidate evidence. Every such request is routed to the refusal row R and the public rows H, Q, L, N.*

Proof. Start with the carrier inventory. The only positive normalization route is the displayed candidate-mediated route through T, C, E, S, A, P.

If a consumer asks for normalization without C or E, the request has no positive route in Q. The packet therefore routes the request to the refusal row R, which records the missing evidence rather than filling it.

The remaining rows preserve the boundary. Componentwise hsame transport, continuation replay, package provenance, and local naming can carry the accepted packet to downstream chapters, but none of them adds a host evaluator, a subject-reduction theorem, a quotient conversion, compiler semantics, or an unconditional closed-term normalization coordinate. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier nonescape`

Theorem 755.6 (MetaCIC normalization budget candidate SN boundary)**.** *Every accepted* MetaCICNormalizationB *packet can export a strong-normalization read only when the displayed rows T, C, E, S, A, P are read*

together. Dropping the candidate evidence row C or the closed-candidate membership row E routes the request to the refusal row R, and dropping the adequacy boundary row A prevents application and Pi consumers from reading the route as closed subject reduction.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier candidate sn boundary`

Proof. Project the carrier of Definition 755.1. The positive read is not a single closed-term coordinate; it is the six-row route T, C, E, S, A, P together with the structural rows that transport and replay it.

Apply the candidate-route scope theorem, Definition 755.4. It forces every positive normalization read through the candidate evidence and adequacy boundary before downstream confluence, subject-reduction, or closed-normal consistency consumers may inspect the packet.

Finally apply non-escape, Definition 755.5. Missing C or E has no positive continuation and is recorded by R, while missing A leaves application and Pi reads at the boundary rather than turning the candidate route into closed subject reduction. □

Theorem 755.7 (MetaCIC normalization budget falsifiable boundary)**.** *Every accepted* MetaCICNormalizationBudg *packet that is queried for a normalization read while missing the candidate evidence row C or the closed-candidate membership row E must route the query to the refusal row R. In particular, an accepted packet whose public read exports strong normalization without both C and E is not a valid instance of the carrier of Definition 755.1.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier falsifiable boundary`

Proof. Inspect the carrier tuple. Its only positive normalization route is the displayed sequence T, C, E, S, A, P, while R is the unique row assigned to requests that omit candidate evidence or closed-candidate membership.

Apply Definition 755.6. The theorem states that a strong-normalization read is exported only when T, C, E, S, A, P are read together. Therefore a request missing C or E has no positive continuation.

It remains to identify the public destination of such a request. By Definition 755.5, missing candidate data is recorded by R rather than supplied by a hidden evaluator, subject-reduction theorem, or unconditional closed-term normalization coordinate. □

Theorem 755.8 (MetaCIC normalization budget refusal exactness)**.** *Every accepted* MetaCICNormalizationBudget↑ *packet queried for a normalization read while missing C or E has exactly one public destination: the refusal row R. The request is transported by the componentwise row H and replayed by the displayed continuation row Q, and it has no alternative route through T, S, A, P or through any structural row outside H, Q, L, N.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier refusal exactness`

Proof. Project the carrier of Definition 755.1. Its visible rows are $T, C, E, S, A, P, R, H, Q, L, N$, so the packet contains one refusal coordinate and no hidden evaluator, subject-reduction coordinate, host normalization coordinate, or second structural destination.

Apply Definition 755.4. The positive route reaches a strong-normalization read only through the full candidate-mediated chain T, C, E, S, A, P. If C or E is missing, that route is not available as a public read.

Apply Definition 755.5 and Definition 755.7. They identify the missing-candidate query with the refusal row R rather than with a positive normalization row.

Finally read the support rows. The row H transports the same refusal judgment componentwise, while Q replays the displayed refusal route to consumers and L, N record provenance and local naming only. Hence the public destination is exactly R, with transport and replay but without an alternative positive or structural route. □

Theorem 755.9 (MetaCIC normalization budget refusal transport)**.** *Let $B = (T, C, E, S, A, P, R, H, Q, L, N)$ be an accepted* MetaCICNormalizationBudget$^{\uparrow}$ *packet. If a normalization query is missing the candidate evidence row C or the closed-candidate membership row E and is therefore routed to R, then componentwise* hsame *transport along H and displayed* Cont *replay along Q preserve the same refusal destination. No transported or replayed read creates a positive route through T, S, A, P, and the provenance and naming rows L, N record only the same refusal boundary.*

Proof. Project the accepted carrier through Definition 755.1. The only displayed rows are $T, C, E, S, A, P, R, H, Q, L$ with R the unique refusal coordinate.

Apply Definition 755.8. A query missing C or E has exactly one public destination, namely R, and it has no alternative route through T, S, A, P or through structural rows outside H, Q, L, N.

Apply Definition 755.5. Componentwise transport cannot supply the absent candidate evidence, and replay cannot manufacture an unconditional strong-normalization route. The rows H and Q therefore carry the same refusal judgment rather than changing its destination.

Finally read L and N as provenance and local naming rows. They source and name the transported refusal packet, but they do not add candidate evidence, membership evidence, a second refusal destination, or a positive normalization coordinate. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier refusal transport`

Theorem 755.10 (MetaCIC normalization budget refusal idempotence)**.** *Let $B = (T, C, E, S, A, P, R, H, Q, L, N)$ be an accepted* MetaCICNormalizationBudget$^{\uparrow}$ *packet. If a normalization query is missing the candidate evidence row C or the closed-candidate membership row E and is routed to R, then any finite ledger of displayed* Cont *replays through Q and componentwise transports through H still has public destination R. Iterating the replay and transport rows never creates a positive route through T, S, A, P, and the provenance and naming rows L, N continue to record only the same refusal boundary.*

Proof. Start with the initial missing-candidate query. By Definition 755.8, its only public destination is R; there is no alternative route through T, S, A, P or through structural rows outside H, Q, L, N.

For the base ledger with no replay or transport step, the destination is therefore R.

For the induction step, assume the finite prefix of the replay ledger still has public destination R. If the next displayed move is a componentwise hsame transport through H or a Cont replay through Q, apply Definition 755.9. The next read preserves the same refusal destination and does not add candidate evidence, membership evidence, a second refusal destination, or a positive normalization coordinate.

Induction over the finite replay ledger gives the claim for every finite sequence. The rows L, N source and name the same refusal packet throughout the induction, so repeated replay records the original boundary rather than changing it. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier refusal idempotence`

Theorem 755.11 (MetaCIC normalization budget independence boundary)**.** *The* MetaCICNormalizationBudget$^{\uparrow}$ *packet is not bijective to the confluence audit witness of chapter 745, the subject-reduction obligation packet of chapter 712, the closed-normal consistency boundary of chapter 733, or the normalization frontier of chapter 892. The reason is row-level: this packet alone combines the closed term row T, candidate evidence C, closed-candidate membership E, candidate-to-strong-normalization row S, adequacy boundary A, replay budget P, refusal row R, transport row H, continuation row Q, provenance row L, and local naming row N as one finite carrier.*

Proof. Compare the row inventory with the named siblings. The confluence audit witness records a confluence-facing route; the subject-reduction obligation packet records preservation-facing data; the closed-normal consistency boundary records consistency-facing data; and the normalization frontier records an open boundary for normalization claims.

The carrier of Definition 755.1 has a different public signature. It jointly stores $T, C, E, S, A, P, R, H, Q, L, N$, so it contains both the positive candidate-mediated route and the refusal row in the same NameCert packet.

A bijection to any listed sibling would have to preserve those rows and their route order. Since none of the siblings exposes exactly this combined candidate, adequacy, replay, refusal, transport, continuation, provenance, and naming surface, no listed sibling is the same packet under renaming. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationBudgetUp.MetaCICNormalizationBudgetCarrier independence boundary`

Falsifiable prediction: Every accepted MetaCICNormalizationBudget$^{\uparrow}$ query missing candidate evidence C or closed-candidate membership E routes to the refusal row R and does not export a positive strong-normalization read.

Independence witness: metacicconfluenceauditwitness, metacic-subject-reduction-obligation, closed-normal-consistency-boundary, metacicnormalizationfrontier: MetaCICNormalizationBudget$^{\uparrow}$ is not bijective to any listed sibling because it alone combines $T, C, E, S, A, P, R, H, Q, L, N$ as one candidate-mediated normalization-budget carrier.

Lean Nontrivial and FieldFaithful TasteGate instances for the same MetaCICNormalizationBudget$^{\uparrow}$ carrier must inspect the rows $T, C, E, S, A, P, R, H, Q, L, N$ together, so the positive route and the refusal boundary are tested on the same accepted packet.

Closure status for NameCert$_{\text{MetaCICNormalizationBudget}\uparrow}$**.**

Constructive story: A MetaCICNormalizationBudget$^{\uparrow}$ packet is generated from a closed typed MetaCIC term row, reducibility-candidate evidence, closed-candidate or candidate-set membership, the candidate-to-strong-normalization row, adequacy-boundary data, proof-replay budget data, refusal data, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalizationBudget}\uparrow}$, scopedClosed)

Scope closed: Definition 755.1, Definition 755.2, Definition 755.3, Definition 755.4, Definition 755.5, Definition 755.6, Definition 755.8, Definition 755.9, Definition 755.10, and the Lean TasteGate single-carrier marker bind the finite candidate-mediated normalization budget surface and its refusal boundary.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICNormalizationBudget}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove unconditional closed-term strong normalization, closed subject reduction, application strong normalization without candidate evidence, Lean verification, or bridge checking.

Upgrade path: Public closure requires a public consumer surface for the checked carrier admission, candidate-route exactness, adequacy-boundary replay, refusal exactness, provenance accounting, transport stability, and non-escape rows of the same finite packet.

Chapter 756

A Concrete Naming Certificate for $\mathsf{TypedExampleGallery}^{\uparrow}$

The $\mathsf{TypedExampleGallery}^{\uparrow}$ packet realizes the audit reading of chapter 9382 as finite BEDC data. Its source material is the existing MetaCIC typed-example corpus: Church booleans and naturals, pairs and options, lists and sums, identity and polymorphic identity rows, application forms, beta redexes, projections, Pi forms, constants, and sort-indexed context examples. The packet sits after the closed substitution boundary of chapter 527, the derivation route of chapter 598, and the proof-erasure route of chapter 642. It names the gallery as a finite regression surface without turning the examples into subject reduction, normalisation, confluence, or global conversion theorems.

Definition 756.1 (Typed example gallery carrier)**.** *A* $\mathsf{TypedExampleGallery}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, T, C, B, R, H, K, P, N)$$

with the following displayed rows:

1. *E is the finite gallery-entry row for the accepted Church, identity, application, beta-redex, projection, Pi, constant, and sort-context examples;*
2. *T is the type-checking row recording each displayed* $\mathsf{HasType}$ *or checker-accepted example;*
3. *C is the closedness row recording the* $\mathsf{ClosedAt}$ *inputs consumed by the typed examples and computation rows;*
4. *B is the beta-computation row for the selected redex, eliminator, boolean, natural-number, list, sum, and equality examples that compute inside the gallery;*
5. *R is the regression-surface row recording the finite families whose preservation is required when checker, closedness, substitution, beta, projection, or binder code is changed;*
6. *H records componentwise* hsame *transport across E, T, C, B, R, K, P, N;*
7. *K records the displayed* Cont *routes by which consumers replay gallery entry reads, checker reads, closedness reads, beta reads, and regression-surface reads;*
8. *P is the* Pkg *provenance over chapter 9382, chapter 527, chapter 598, and chapter 642;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TypedExampleGallery}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary MetaCIC term, no global type-safety theorem, no closed-term normalisation theorem, no confluence theorem, no proof-erased compiler theorem, and no host evaluator.

Theorem 756.2 (Typed example gallery NameCert obligations)**.** *For the carrier of Definition 756.1, the local* $\mathsf{NameCert}_{\mathsf{TypedExampleGallery}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for* $G = (E, T, C, B, R, H, K, P, N)$*;*
2. *checker visibility through the displayed type-checking row* T *for every accepted gallery entry in* E*;*
3. *closedness visibility through* C *for each example whose typing or computation row consumes a* $\mathsf{ClosedAt}$ *input;*
4. *beta visibility through* B *for the selected computation rows and no other conversion surface;*
5. *regression-surface visibility through* R*, transported only by* H, K, P, N *and grounded in the sibling provenance listed in* P*.*

Proof. Project the finite packet G. Carrier admission supplies the displayed entry, checker, closedness, beta, regression, transport, replay, provenance, and local naming rows.

The checker obligation reads T only against entries already present in E. The closedness obligation reads C only for entries whose displayed theorem rows require $\mathsf{ClosedAt}$ inputs. The beta obligation reads B only for the selected computations in the gallery.

Finally read R, H, K, P, N. The regression row names the finite families whose checked behavior is preserved as a gallery surface, while transport, replay, provenance, and local naming keep every consumer inside the same displayed packet. No row adds a general subject-reduction, normalisation, confluence, global conversion, proof-erasure, or host-evaluation endpoint. □

Theorem 756.3 (Typed example gallery regression surface)**.** *Every consumer of an accepted* $\mathsf{TypedExampleGallery}^{\uparrow}$ *packet receives a finite regression surface for the typed-example corpus: accepted typing rows, closedness inputs, selected beta computations, and sibling provenance through chapter 527, chapter 598, and chapter 642. The packet cannot be reread as a theorem about all represented terms, all closed substitutions, all beta steps, all erased proof terms, or all checker results.*

Proof. The regression surface is the row R together with the entry, checker, closedness, and beta rows E, T, C, B. These rows are finite and are indexed by the gallery families recorded in chapter 9382.

The sibling references in P locate the required substrate: closed substitution supplies the closed-term boundary, derivation traces supply finite checker routes, and proof-erasure traces supply the erased-readback discipline. The packet records dependence on those surfaces without merging their theorem rows into the gallery.

Since the carrier contains no row for an arbitrary represented term, arbitrary closed substitution, arbitrary beta step, arbitrary proof erasure, or arbitrary checker result, the consumer cannot export a global metatheorem. The accepted reading is exactly the finite gallery regression surface. □

Theorem 756.4 (Typed example gallery closed beta regression route)**.** *Every closed beta example in an accepted* $\mathsf{TypedExampleGallery}^{\uparrow}$ *packet routes through the displayed entry row* E*, type row* T*, closedness row* C*, beta row* B*, regression row* R*, and sibling provenance to chapter 527, chapter 598, and chapter 642. The route records a finite gallery obligation only: it does not assert subject reduction, strong normalisation, confluence, global conversion decidability, proof-erased compiler correctness, arbitrary checker completeness, or a host evaluator.*

Proof. Project the carrier $G = (E, T, C, B, R, H, K, P, N)$ from Definition 756.1. A closed beta example is first an entry of E, and its displayed type evidence is read from T rather than from a host checker theorem.

Read the closedness and computation rows next. The closedness row C supplies exactly the ClosedAt inputs consumed by the example, and the beta row B supplies the selected computation surface for the displayed redex or eliminator.

Finally apply the NameCert obligations and the regression surface theorem. The row R records the regression family, while P keeps the closed-substitution boundary, type-checking derivation trace, and proof-erasure trace as sibling provenance. Transport, replay, provenance, and local naming through H, K, P, N preserve the same finite route and add no global metatheorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{TypedExampleGallery}^{\uparrow}}$.

Constructive story: A $\mathsf{TypedExampleGallery}^{\uparrow}$ packet is generated from finite typed-example entries, checker rows, closedness rows, selected beta-computation rows, a regression-surface row, componentwise transport, continuation routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TypedExampleGallery}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 756.1, Definition 756.2, Definition 756.3, and Definition 756.4 bind the finite gallery-entry, checker, closedness, beta, regression, sibling-provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TypedExampleGallery}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close subject reduction, strong normalisation, confluence, global conversion decidability, proof-erased compiler correctness, arbitrary checker completeness, or bridge checking.

Upgrade path: Obligation closure requires checking carrier admission, checker visibility, closedness visibility, beta visibility, regression-surface non-escape, and sibling provenance for the displayed packet.

Chapter 757

A Concrete Naming Certificate for $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$

The $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ packet records the finite tail-radius accounting used by Real and Completion consumers before a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seal read is allowed. It sits over $\mathsf{DyadicRatCore}^{\uparrow}$ (chapter 291), $\mathsf{StreamName}^{\uparrow}$ (chapter 126), $\mathsf{RegSeqRat}^{\uparrow}$ (chapter 301), $\mathsf{RealObservationBudget}^{\uparrow}$ (chapter 611), and $\mathsf{Real}^{\uparrow}$ (chapter 38). The certificate is a finite ledger for unary precision and tail windows; it is not a quotient of streams, a host real equality witness, a selected limit, an unbounded observation schedule, or an ambient completeness principle.

Definition 757.1 (Dyadic tail-radius ledger carrier)**.** *A* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (E, T, W, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *E is the unary precision request whose tolerance selects the tail-radius read;*
2. *T is the finite tail-window row, including the requested tail threshold and the radius budget attached to that threshold;*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened by E and T;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row carrying the dyadic observations and displayed radii for the selected windows;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from the dyadic readback after the tail-radius ledger has been checked;*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row available to completion-facing consumers only after R has been displayed;*
7. *H records componentwise* hsame *transports for E, T, W, D, R, S and the structural rows;*
8. *C records the displayed* Cont *routes from precision request to tail window, StreamName windows, dyadic readback, regular-rational handoff, and real seal;*
9. *P is the* Pkg *provenance over* BHist, hsame, Cont, $\mathsf{NameCert}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicTailRadiusLedger}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed rows $E, T, W, D, R, S, H, C, P, N$.

Theorem 757.2 (Dyadic tail-radius ledger NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DyadicTailRadiusLedger}^{\uparrow}}$ *surface for Definition 757.1 consists exactly of carrier admission for* $L = (E, T, W, D, R, S, H, C, P, N)$*, unary precision exposure, finite tail-window and radius-ledger exposure,* $\mathsf{StreamName}^{\uparrow}$ *window coverage,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback and radius exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff routing,* $\mathsf{Real}^{\uparrow}$ *seal-boundary exposure, componentwise* hsame *transport, displayed* Cont *route replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.DyadicTailRadiusLedgerUp.DyadicTailRadiusLedgerTasteGate single carrier alignment`

Proof. Project the carrier of Definition 757.1. The rows E, T, W, D, R, S are the only mathematical coordinates, and H, C, P, N are the only transport, route, package, and naming coordinates.

Read the source chapters in the order consumed by the packet. The DyadicRatCore row supplies dyadic readback, the StreamName row supplies finite windows, the RegSeqRat row supplies the regular-rational handoff, the Real observation-budget chapter supplies the finite budget discipline, and the Real chapter supplies the final seal boundary.

The local NameCert obligation surface is therefore the finite route through those displayed rows. Since the carrier contains no coordinate for quotient streams, host real equality, selected limits, unbounded schedules, or ambient completeness, no obligation can export such data. □

Theorem 757.3 (Dyadic tail-radius ledger tail-budget coverage)**.** *For an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier*

$$L = (E, T, W, D, R, S, H, C, P, N),$$

every tail-radius read admitted by the ledger is covered by the finite tail-window row T*, one of the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* W*, and the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback and radius rows in* D*. The admitted route is the finite budget route*

$$E \longmapsto T \longmapsto W \longmapsto D$$

with H, C, P, N *attached as transport, route replay, provenance, and local naming data.*

Proof. Start with the precision request E. The continuation rows in C send that request to the displayed tail-window row T before any StreamName window can be consumed.

Window coverage then follows the StreamName and observation-budget pattern: each selected tail window in T opens only finite rows in W, and every dyadic readback or displayed radius in D is tied to one of those windows. This is the same finite-window discipline used by Definition 611.3 and Definition 611.20.

Transport along H preserves the same displayed coordinates, while P and N keep provenance and naming attached to the route. Thus a tail-radius read has no source outside E, T, W, D, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.DyadicTailRadiusLedgerUp.DyadicTailRadiusLedgerCarrier tail budget coverage`

Theorem 757.4 (Dyadic tail-radius ledger budget-selector pullback)**.** *Let* $L = (E, T, W, D, R, S, H, C, P, N)$ *be an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier, and let*

$$F = (B, S_F, W_F, D_F, R_F, E_F, H_F, C_F, P_F, N_F)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *carrier. Suppose the displayed transport rows identify*

$$E\,\mathsf{hsame}\,B, \qquad T\,\mathsf{hsame}\,S_F, \qquad W\,\mathsf{hsame}\,W_F, \qquad D\,\mathsf{hsame}\,D_F, \qquad R\,\mathsf{hsame}\,R_F, \qquad S\,\mathsf{hsame}\,E_F.$$

Then every common $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of the two packets factors through the single finite route*

$$E \longmapsto T \longmapsto W \longmapsto D \longmapsto R \longmapsto S,$$

equivalently through the selector route

$$B \longmapsto S_F \longmapsto W_F \longmapsto D_F \longmapsto R_F \longmapsto E_F.$$

The pullback exports no quotient streams, host real equality, countable choice, hidden limit selector, independent radius ledger, or ambient completeness principle.

Proof. Start on the dyadic side. Tail-budget coverage from Definition 757.3 places every admitted tail-radius read on $E \longmapsto T \longmapsto W \longmapsto D$, and the RegSeqRat and Real handoff of Definition 757.6 extends the same route through R and S.

Move to the selector side. The NameCert obligations of Definition 782.2 expose only the displayed rows of F, route determinacy from Definition 782.7 fixes $B \longmapsto S_F \longmapsto W_F \longmapsto D_F \longmapsto R_F \longmapsto E_F$, and terminal selector synchronization from Definition 782.23 keeps Real-facing and completion-facing reads on that terminal route.

Finally apply the six displayed hsame transports. They identify the dyadic precision, tail-window, StreamName-window, dyadic-readback, RegSeqRat-handoff, and Real-seal rows with the selector budget, schedule, window, readback, handoff, and terminal seal rows. Since both carriers expose only those finite rows and their transport, continuation, provenance, and naming data, a common consumer has the single pullback route displayed above and no coordinate from which quotient streams, host real equality, countable choice, hidden limit selection, an independent radius ledger, or ambient completeness could be recovered. □

Theorem 757.5 (Dyadic tail-radius ledger tail-radius witness extraction)**.** *For an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier*

$$L = (E, T, W, D, R, S, H, C, P, N),$$

any tail-radius witness requested by a completion-facing consumer is extracted from the displayed finite route

$$E \longmapsto T \longmapsto W \longmapsto D$$

before the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *and the* $\mathsf{Real}^{\uparrow}$ *seal row* S *are readable. The extraction exports no quotient stream equality, host real equality, selected limit, unbounded tail search, independent radius ledger, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.DyadicTailRadiusLedgerUp.DyadicTailRadiusLedgerCarrier tail radius witness extraction`

Proof. Begin with the local NameCert obligations of Definition 757.2. They identify $E, T, W, D, R, S, H, C, P, N$ as the whole accepted packet and make tail-radius witness requests part of the displayed finite ledger.

Apply tail-budget coverage from Definition 757.3. The requested witness is therefore read from the route $E \longmapsto T \longmapsto W \longmapsto D$ before any source-facing or completion-facing handoff is available.

Next use RegSeqRat and Real handoff, Definition 757.6. It places R and S strictly downstream of the finite tail-budget route, so a consumer cannot read the handoff or seal before the witness has been extracted from D.

Finally compose route replay with non-escape, Definition 757.9 and Definition 757.7. Route replay attaches H, C, P, N to the same finite path, and non-escape excludes quotient stream equality, host real equality, selected limits, unbounded tail searches, independent radius ledgers, and ambient completeness from the exported witness. □

Theorem 757.6 (Dyadic tail-radius ledger RegSeqRat and Real handoff)**.** *For an accepted* DyadicTailRadiusLedger$^{\uparrow}$ *carrier, every* RegSeqRat$^{\uparrow}$ *handoff row R and every* Real$^{\uparrow}$ *seal row S are downstream of the finite tail-budget route of Definition 757.3. In particular, every admitted completion-facing read factors through*

$$E \longmapsto T \longmapsto W \longmapsto D \longmapsto R \longmapsto S.$$

Lean4 ✓ `BEDC.Derived.DyadicTailRadiusLedgerUp.DyadicTailRadiusLedgerCarrier regseq real handoff`

Proof. First apply Definition 757.3. It places every admitted tail-radius read inside the finite precision, tail-window, StreamName, and dyadic readback rows.

Next use the RegSeqRat handoff surface from chapter 301. The handoff row R is available only after the dyadic readback row D has been displayed through the same packet route.

Finally use the Real seal boundary from chapter 38 and the observation-budget seal discipline of Definition 611.5. The seal row S is therefore reached only after R, with the same H, C, P, N structural rows attached. □

Theorem 757.7 (Dyadic tail-radius ledger non-escape)**.** *An accepted* DyadicTailRadiusLedger$^{\uparrow}$ *carrier exports only the displayed rows $E, T, W, D, R, S, H, C, P, N$ of Definition 757.1. It exports no quotient stream equality, host real equality, selected limit, unbounded tail search, second radius ledger, independent real carrier, or ambient completeness principle.*

Proof. The NameCert obligation theorem identifies the whole local certificate surface as the carrier rows $E, T, W, D, R, S, H, C, P, N$. There is no additional mathematical coordinate and no separate analytic witness row.

Apply the tail-budget coverage theorem to any attempted tail or radius read. The read must pass through E, T, W, D with the displayed transport, route, provenance, and naming rows.

Apply the RegSeqRat and Real handoff theorem to any source-facing or completion-facing read. It forces the read through the same finite route before R or S can be consumed.

Because the excluded objects are not coordinates of the carrier and are not produced by the displayed continuations, no downstream consumer can recover them from the packet. □

Theorem 757.8 (Dyadic tail-radius ledger transport stability)**.** *For an accepted* DyadicTailRadiusLedger$^{\uparrow}$ *carrier*

$$L = (E, T, W, D, R, S, H, C, P, N),$$

componentwise hsame *transport through H preserves exactly the displayed rows $E, T, W, D, R, S, H, C, P, N$. In particular, a transported public read remains a read of the same precision request, tail-window ledger, finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *readback,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal row, displayed route table, package provenance, and local naming row.*

Proof. The carrier definition lists $E, T, W, D, R, S, H, C, P, N$ as the complete packet surface. The NameCert obligation theorem then identifies componentwise hsame transport as one obligation on that surface rather than an additional coordinate.

Apply tail-budget coverage to the rows E, T, W, D. The transported precision, window, StreamName, and dyadic readback data remain attached to the same finite budget route.

Apply the RegSeqRat and Real handoff theorem to R and S. These rows are downstream of the transported finite route, so transport cannot create an independent handoff or seal.

Finally apply non-escape. Since the carrier has no quotient stream, selected limit, host real equality, unbounded search, or ambient completeness coordinate, transport preserves the displayed ledger surface and nothing beyond it. □

Theorem 757.9 (Dyadic tail-radius ledger route replay)**.** *For an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier, every admitted completion-facing route replays the finite chain*

$$E \longmapsto T \longmapsto W \longmapsto D \longmapsto R \longmapsto S$$

through the displayed Cont *rows in* C*. No admitted completion-facing read may bypass the tail-window, StreamName, dyadic readback, or* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows before reaching the* $\mathsf{Real}^{\uparrow}$ *seal row.*

Lean4 ✓ `BEDC.Derived.DyadicTailRadiusLedgerUp.DyadicTailRadiusLedgerCarrier route replay`

Proof. Start from the carrier definition and the NameCert obligation theorem. They place displayed Cont route replay inside C and make C the only route table exposed by the packet.

Tail-budget coverage supplies the first part of the route: the precision request E reaches the tail-window ledger T, finite StreamName windows W, and dyadic readback row D through displayed continuations.

The RegSeqRat and Real handoff theorem supplies the final part of the route. Every completion-facing read reaches R after D and reaches S only after R.

Transport stability keeps the route rows aligned under componentwise hsame, and non-escape excludes any hidden continuation table or ambient completion principle. Thus the displayed chain is the whole admitted completion-facing replay. □

Theorem 757.10 (Dyadic tail-radius ledger provenance exhaustion)**.** *For an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier, the* Pkg *provenance row* P *and local* $\mathsf{NameCert}_{\mathsf{DyadicTailRadiusLedger}^{\uparrow}}$ *row* N *account for all public reads of the packet. They account only for the displayed rows* $E, T, W, D, R, S, H, C, P, N$ *and do not add quotient streams, selected limits, host real equality, unbounded tail search, or ambient completeness.*

Proof. The carrier definition gives P and N as the package-provenance and local-naming rows for the same finite tuple. The NameCert obligation theorem makes provenance and local naming obligations for that tuple, not sources of extra analytic data.

Tail-budget coverage accounts for every public tail-radius read through E, T, W, D with H, C, P, N attached. The RegSeqRat and Real handoff theorem accounts for completion-facing reads through the same route extended by R, S.

Transport stability shows that moving the public surface along H keeps the same provenance and naming rows. Route replay shows that completion-facing access consumes the displayed continuation chain in C.

The non-escape theorem then eliminates the remaining alternatives. Since the excluded objects are not carrier coordinates and are not produced by P or N, provenance and local naming exhaust public reads without exporting those objects. □

Theorem 757.11 (Dyadic tail-radius ledger shared-tail service boundary)**.** *For an accepted* $\mathsf{DyadicTailRadiusLedger}$ *carrier*

$$L = (E, T, W, D, R, S, H, C, P, N),$$

any shared-tail or completion-facing consumer that asks for a common dyadic threshold must read the finite route

$$E \longmapsto T \longmapsto W \longmapsto D \longmapsto R \longmapsto S.$$

This is the service boundary consumed by $\mathsf{CauchySharedTailModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The boundary exports no hidden threshold, quotient stream, selected limit, host real equality, or ambient completeness datum.*

Proof. The tail-budget coverage theorem first places any threshold request inside the finite rows E, T, W, D. Thus the requested tolerance, tail window, StreamName windows, and dyadic radius readback are all displayed before the consumer can ask for a common dyadic threshold.

The RegSeqRat and Real handoff theorem then extends the same displayed route through R and S. Hence completion-facing reads do not bypass the ledger; they consume the same route used by the sibling $\mathsf{CauchySharedTailModulus}^{\uparrow}$ certificate of chapter 983.

Finally apply the non-escape theorem. Since hidden thresholds, quotient streams, selected limits, host real equalities, and ambient completeness data are not coordinates of L and are not produced by its displayed continuations, they cannot be exported through this boundary. □

Theorem 757.12 (Dyadic tail-radius ledger CauchyCriterion handoff)**.** *Let $L = (E, T, W, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier. Any* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier whose tail row uses the same precision request,* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic readback, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff must read*

$$E \longmapsto T \longmapsto W \longmapsto D \longmapsto R \longmapsto S$$

before its M, Q, T, W, E criterion route can expose a $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Apply Definition 757.3, Definition 757.6, and Definition 757.9. These force the precision request, tail window, StreamName windows, dyadic readback, regular-rational handoff, and Real seal onto the displayed finite route.

Then use Definition 392.2. A CauchyCriterion carrier sharing those rows can expose its Real seal only after the same finite tail-budget route has been consumed, so the dyadic ledger is the upstream handoff for the criterion route. □

Theorem 757.13 (Dyadic tail-radius ledger CauchyCriterion TailBudgetCoherence pullback)**.** *Let $L = (E, T, W, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier, and let K be an accepted* $\mathsf{CauchyCriterion}^{\uparrow}$ *carrier sharing the same precision request,* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal rows. Any* $\mathsf{TailBudgetCoherence}^{\uparrow}$ *consumer of the Cauchy route for K must factor through the displayed finite pullback route*

$$E \longmapsto T \longmapsto W \longmapsto D \longmapsto R \longmapsto S,$$

then through the CauchyCriterion rows M, Q, T, W, E, and then through the TailBudgetCoherence rows at the Real-completion boundary. This route exports no quotient streams, selected limits, host real equality, detached tail oracle, metric-completeness theorem, or ambient Real completeness principle.

Proof. First apply tail-budget coverage from Definition 757.3. It places the precision request, tail window, StreamName windows, and dyadic readback on the finite segment $E \longmapsto T \longmapsto W \longmapsto D$.

Next apply the CauchyCriterion handoff of Definition 757.12. Since K shares the same precision, StreamName, dyadic readback, RegSeqRat, and Real seal rows, the route must continue through R and S before the CauchyCriterion carrier exposes its seal-facing rows.

Now use the budgeted shared-tail seal compatibility of Definition 392.8. It identifies the displayed CauchyCriterion rows M, Q, T, W, E as the shared-tail seal route over the same dyadic ledger coverage row.

Finally apply Definition 392.9. The TailBudgetCoherence consumer attaches only after the Cauchy route has displayed its threshold, budget, window, tolerance, readback, transport, continuation, package, and local naming rows. Non-escape and provenance exhaustion then rule out quotient streams, selected limits, host real equality, detached tail oracles, metric completeness, and ambient Real completeness as possible exits from the pullback route. □

Theorem 757.14 (Dyadic tail-radius ledger scoped route package)**.** *For an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier*

$$L = (E, T, W, D, R, S, H, C, P, N),$$

the precision request E*, tail window* T*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and* $\mathsf{Real}^{\uparrow}$ *seal row* S *form one scoped route over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Every admitted L10 tail-radius consumer reads the same finite route*

$$E \longmapsto T \longmapsto W \longmapsto D \longmapsto R \longmapsto S$$

with H, C, P, N *as the transport, route replay, provenance, and local naming rows.*

Proof. Start with the NameCert obligations of Definition 757.2. They identify the accepted carrier with the finite rows $E, T, W, D, R, S, H, C, P, N$ over BHist, hsame, Cont, Pkg, and NameCert.

Apply tail-budget coverage from Definition 757.3. The precision request, tail window, StreamName windows, and DyadicRatCore readback therefore form the first route segment $E \longmapsto T \longmapsto W \longmapsto D$.

Use the RegSeqRat and Real handoff theorem of Definition 757.6. This extends the same finite route through R and then S, so no L10 tail-radius consumer can reach a seal row without the handoff row.

Finally combine route replay, provenance exhaustion, and the shared-tail service boundary from Definition 757.9, Definition 757.10, and Definition 757.11. These rows attach H, C, P, N to the same route and exclude hidden thresholds, quotient streams, selected limits, host real equality, unbounded searches, and ambient completeness. □

Theorem 757.15 (Dyadic tail-radius ledger monotone radius handoff)**.** *For an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier*

$$L = (E, T, W, D, R, S, H, C, P, N),$$

let E' *be a unary precision request refining* E*, and let* T' *be the displayed tighter tail-radius ledger transported from* T *by the componentwise* hsame *row* H*. Every admitted completion-facing read for* E' *factors through the same finite seal route*

$$E' \longmapsto T' \longmapsto W \longmapsto D \longmapsto R \longmapsto S.$$

The refinement exports no quotient stream, selected limit, host real equality, or completeness principle.

Proof. Tail-budget coverage first places the refined precision request inside a displayed tail-window row. Since T' is transported by H from the accepted ledger row T, the tighter radius ledger remains on the same componentwise hsame surface and does not create a second tail object.

The RegSeqRat and Real handoff theorem then consumes the displayed tail row through W, D, R, S. Replacing E, T by the finer displayed pair E', T' only tightens the first segment of the route; it does not change the downstream StreamName, DyadicRatCore, RegSeqRat, or Real seal rows.

Route replay attaches the same continuation row C to the transported route. Provenance exhaustion attaches the same P, N rows and rules out any completion-facing read whose source is not one of the displayed carrier coordinates.

Finally apply the scoped route package and the shared-tail service boundary. They identify the whole admitted seal route and exclude quotient streams, selected limits, host real equalities, and ambient completeness principles from the exported surface. □

Theorem 757.16 (Dyadic tail-radius ledger refinement-meet totality)**.** *For an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier*

$$L = (E, T, W, D, R, S, H, C, P, N),$$

let E_1 *and* E_2 *be unary precision requests refining the displayed request* E*. Suppose the carrier displays a common unary refinement row* E_m *together with a transported tail-window row* T_m *for that meet. Then every completion-facing read admitted for either* E_1 *or* E_2 *factors through the single finite route*

$$E_m \longmapsto T_m \longmapsto W \longmapsto D \longmapsto R \longmapsto S.$$

The common refinement exports no quotient stream, selected limit, host real equality, unbounded search, or completeness principle.

Proof. Start with tail-budget coverage. It places each refining request inside the displayed finite tail-budget surface and identifies the common row E_m as the carrier-visible refinement through which both requests must be read.

Apply monotone radius handoff to the two requests. Transport through H sends the common refinement to the single tail-window row T_m, so tightening either request changes only the first segment of the route and does not introduce a second StreamName, DyadicRatCore, RegSeqRat, or Real seal row.

Route replay then attaches the continuation row C to the common path, while provenance exhaustion attaches P and N to the same carrier coordinates. Thus a completion-facing consumer of either refinement has no admitted source outside $E_m, T_m, W, D, R, S, H, C, P, N$.

Finally apply the shared-tail service boundary. It is exactly the public boundary that permits both refinement consumers to share the tail-radius ledger while refusing quotient streams, selected limits, host real equalities, unbounded searches, and ambient completeness principles. □

Theorem 757.17 (Dyadic tail-radius ledger common-refinement pullback)**.** *Let*

$$L_0 = (E_0, T_0, W_0, D_0, R_0, S_0, H_0, C_0, P_0, N_0)$$

and

$$L_1 = (E_1, T_1, W_1, D_1, R_1, S_1, H_1, C_1, P_1, N_1)$$

be accepted $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carriers. Suppose* E_0 *and* E_1 *refine to a common unary precision request* E^**, and suppose the finite* $\mathsf{StreamName}^{\uparrow}$ *window rows* W_0, W_1 *and the* $\mathsf{Real}^{\uparrow}$ *seal rows* S_0, S_1 *are componentwise* hsame *on a common displayed finite window. Then the two transported tail-radius ledger routes admit a common displayed pullback over the same route*

$$E^* \longmapsto T^* \longmapsto W^* \longmapsto D^* \longmapsto R^* \longmapsto S^*.$$

The pullback exports only the shared BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It exports no quotient stream, selected limit, host real equality, or ambient completeness datum.*

Proof. Apply the monotone radius handoff theorem to L_0 and L_1 along the common request E^*. This gives transported tail rows over the same refined precision request and keeps each completion-facing read on its displayed finite seal route.

Use route replay and provenance exhaustion for the two accepted carriers. The replay rows identify the visible continuation path, while provenance exhaustion says that any admitted comparison must be assembled from the displayed carrier coordinates and the local Pkg and NameCert rows.

The common $\mathsf{StreamName}^{\uparrow}$ window hypothesis identifies the shared finite window segment. The real seal scope theorem identifies the shared terminal seal segment, and the window route scope theorem keeps the dyadic readback and regular-rational handoff between those endpoints on the same finite route.

It remains to record what the pullback can expose. Non-escape and the shared-tail service boundary remove quotient streams, selected limits, host real equalities, hidden tail searches, and ambient completeness data, leaving only the common displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. □

Theorem 757.18 (Dyadic tail-radius ledger budget monotonicity)**.** *Let $L = (E, T, W, D, R, S, H, C, P, N)$ be an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier. If a displayed tail-radius request is refined through the existing meet row and common-refinement row, then every downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal handoff reads the same dyadic tolerance ledger D with no larger hidden observation budget and no separate tail route.*

Proof. Start with refinement-meet totality, Definition 757.16. It places the refined request behind a common finite precision row and transported tail-window row before any downstream comparison is visible.

Apply the common-refinement pullback theorem, Definition 757.17. The two refined presentations meet over the same displayed route through the shared tail row, StreamName window, dyadic ledger, RegSeqRat handoff, and Real seal row.

Now use dependency scope and Real seal scope, Definition 757.19 and Definition 757.21. These results force every admitted public read to stay inside $E, T, W, D, R, S, H, C, P, N$, and they make the seal row downstream of the same dyadic ledger D.

The refinement therefore tightens only the displayed request segment. Because no hidden observation budget, unbounded search, selected limit, quotient stream, host equality, or ambient completeness coordinate is exported by the carrier, the downstream handoff cannot create a larger budget or a second tail route. □

Theorem 757.19 (Dyadic tail-radius ledger dependency scope)**.** *Every accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier factors through the displayed rows $E, T, W, D, R, S, H, C, P, N$ over exactly the local dependency scope* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealObservationBudget}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. No admitted public read can use a dependency outside this displayed scope.*

Proof. The carrier and NameCert obligation surface of Definition 757.1 and Definition 757.2 list the complete packet surface. The mathematical rows are E, T, W, D, R, S, and the structural rows are H, C, P, N.

Tail-budget coverage and the RegSeqRat/Real handoff theorem route every admitted read through E, T, W, D, R, S. Route replay, provenance exhaustion, and the shared-tail service boundary then attach BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ to the same finite route.

The non-escape theorem excludes hidden thresholds, quotient streams, selected limits, host real equality, unbounded schedules, and ambient completeness. Hence the accepted carrier has precisely the displayed dependency scope. □

Theorem 757.20 (Dyadic tail-radius ledger window route scope)**.** *For an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *carrier, every tail-window or radius-window read factors through*

$$E \longmapsto T \longmapsto W \longmapsto D$$

inside the displayed DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RealObservationBudget$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows of* $L = (E, T, W, D, R, S, H, C, P, N)$. *The window route is not a second ledger, a hidden threshold, or an unbounded search.*

Lean4 ✓ `BEDC.Derived.DyadicTailRadiusLedgerUp.DyadicTailRadiusLedgerCarrier window route scope`

Proof. Apply tail-budget coverage. It places the precision request, finite tail-window ledger, StreamName windows, and dyadic readback inside E, T, W, D before any radius read is admitted.

Use route replay to see that the same segment is carried by the displayed Cont rows in C. Transport stability keeps the segment aligned under H, and provenance exhaustion attaches the same Pkg and NameCert rows P, N.

Finally use non-escape. Since no second ledger, hidden threshold, or unbounded search is a carrier coordinate or a continuation output, the finite window route is the whole admitted scope for tail-radius reads. □

Theorem 757.21 (Dyadic tail-radius ledger real seal scope)**.** *For an accepted* DyadicTailRadiusLedger$^{\uparrow}$ *carrier, every* Real$^{\uparrow}$ *seal read available to a completion-facing consumer factors through*

$$E \longmapsto T \longmapsto W \longmapsto D \longmapsto R \longmapsto S$$

over DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealObservationBudget$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *Thus the seal row* S *is scoped by the same route and cannot be read as an independent Real carrier.*

Proof. Start with the window route scope. It binds every admitted radius read to the finite precision, tail-window, StreamName, and DyadicRatCore segment E, T, W, D.

The RegSeqRat and Real handoff theorem extends that segment through R and then S. The shared-tail service boundary identifies this as the service route consumed by downstream Real and Completion-facing users.

Route replay and provenance exhaustion attach C, P, N to the same path, while transport stability carries it through H. Non-escape then rules out an independent Real carrier, selected limit, host real equality, or ambient completeness datum. □

Theorem 757.22 (Dyadic tail-radius ledger mature consumer package)**.** *For an accepted* DyadicTailRadiusLedger$^{\uparrow}$ *carrier, the carrier row of Definition 757.1, tail-budget coverage of Definition 757.3, RegSeqRat and Real handoff of Definition 757.6, and non-escape surface of Definition 757.7 form the mature public package for Real and Completion consumers over* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealObservationBudget$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

Proof. The carrier definition fixes the finite packet rows $E, T, W, D, R, S, H, C, P, N$. Tail-budget coverage then binds every precision, tail-window, StreamName, and DyadicRatCore read to the finite segment $E \longmapsto T \longmapsto W \longmapsto D$.

The RegSeqRat and Real handoff theorem extends the same segment through R and S. Thus Real and Completion consumers receive a public route only after the dyadic readback and regular-rational handoff rows have been displayed.

The non-escape theorem excludes quotient stream equality, host real equality, selected limits, unbounded schedules, hidden tail search, and ambient completeness. Together with route replay, provenance exhaustion, dependency scope, window route scope, and real seal scope, these rows supply the whole mature package rather than a merely local tail ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicTailRadiusLedger}\uparrow}$.

Constructive story: A $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ packet is generated from a unary precision request, finite tail-window radius ledger, finite StreamName windows, DyadicRatCore readback rows, RegSeqRat handoff rows, RealUp seal rows, componentwise hsame transports, displayed Cont routes, package provenance, and a local naming row.

Chapter 758

A Concrete Naming Certificate for $\mathsf{CandidateEvidenceSNRoute}^{\uparrow}$

The $\mathsf{CandidateEvidenceSNRoute}^{\uparrow}$ packet realizes the candidate-mediated route of chapter 9383 as finite NameCert data. It sits beside the typed reduction normal-form packet of chapter 562, the normal-form consistency seal of chapter 740, and the normal false exclusion packet of chapter 732: those siblings consume normal-form and consistency-facing rows, while this packet keeps the strong-normalization route tied to displayed candidate evidence.

Definition 758.1 (Candidate evidence SN route carrier)**.** *A* $\mathsf{CandidateEvidenceSNRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (E, K, M, A, I, H, C, P, N)$$

with the following displayed rows:

1. *E is the candidate evidence row naming* Candidate *witnesses and their candidate-to-strong-normalization read;*
2. *K is the closed-candidate row naming closed type, closed term, and closed candidate evidence;*
3. *M is the candidate-set membership row that exposes the finite membership and soundness reads used by closed typed terms;*
4. *A is the Pi and application adequacy row, including function candidate evidence, argument candidate evidence, and the application candidate readback;*
5. *I is the no-infinite-reduction projection row attached to the strong-normalization evidence already displayed in E, K, M, A;*
6. *H stores componentwise* hsame *transports for candidate evidence, closed-candidate evidence, membership evidence, adequacy rows, and no-infinite projections;*
7. *C stores the displayed* Cont *routes from candidate evidence to strong normalization and from strong normalization to no-infinite-reduction boundaries;*
8. *P records* Pkg *provenance over the normalization audit map, typed reduction normal forms, normal-form consistency seals, normal false exclusion, and the MetaCIC candidate evidence rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CandidateEvidenceSNRoute}^{\uparrow}}$ *row.*

The carrier has no coordinate for evidence-free global strong normalization, an unconditional application-normalization theorem, a host evaluator, quotient equality over reduction traces, or a hidden tail of reduction steps.

Lean4 ✓ `BEDC.Derived.CandidateEvidenceSNRouteUp.CandidateEvidenceSNRouteTasteGate single carrier alignment`

Theorem 758.2 (Candidate evidence SN route obligation surface)**.** *Every accepted* $\mathsf{CandidateEvidenceSNRoute}^{\uparrow}$ *packet binds exactly the obligation surface displayed in Definition 758.1: candidate evidence through* E*, closed-candidate evidence through* K*, candidate-set membership through* M*, Pi and application adequacy through* A*, no-infinite-reduction projection through* I*, componentwise transport through* H*, route replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier coordinates. The positive route begins with E, K, M, A: a consumer first reads candidate evidence, closed-candidate evidence, candidate-set membership, or Pi and application adequacy before any strong-normalization consequence is visible.

The row I is downstream from those evidence rows. It records no-infinite-reduction only as a projection from displayed strong-normalization evidence, so the packet never creates a second route that skips the candidate surface.

The structural rows H, C, P, N preserve, replay, package, and name only the listed coordinates. Since the carrier contains no further row, the displayed rows exhaust the local NameCert obligation surface. □

Theorem 758.3 (Candidate evidence SN route no-infinite boundary)**.** *Every no-infinite-reduction read exported by an accepted* $\mathsf{CandidateEvidenceSNRoute}^{\uparrow}$ *packet factors through one of the displayed candidate-mediated strong-normalization rows* E, K, M, A *before it reaches* I*. Thus the route can feed* $\mathsf{TypedReductionNormalForm}^{\uparrow}$*,* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$*, and* $\mathsf{NormalFalseExclusion}^{\uparrow}$ *consumers, but it cannot be reread as blanket strong normalization for every closed typed MetaCIC term.*

Proof. Start from a no-infinite-reduction read of the packet. The only no-infinite coordinate is I, and its input is the strong-normalization evidence already supplied by E, K, M, A.

Use the route replay row C to trace the read backward to candidate evidence, closed-candidate evidence, candidate-set membership, or Pi and application adequacy. The transport row H preserves those evidence coordinates under accepted packet agreement.

Finally send the resulting boundary to the normal-form consumers named in P. Each consumer receives a finite candidate-mediated route, not a host evaluator, quotient reduction equality, unconditional application-normalization theorem, or evidence-free global strong-normalization principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CandidateEvidenceSNRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{CandidateEvidenceSNRoute}^{\uparrow}$ packet is generated from candidate evidence, closed-candidate evidence, candidate-set membership, Pi and application adequacy rows, no-infinite-reduction projections, componentwise transports, displayed routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CandidateEvidenceSNRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 758.1, Definition 758.2, and Definition 758.3 bind the finite candidate-mediated strong-normalization route and its no-infinite-reduction boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CandidateEvidenceSNRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close evidence-free global strong normalization, unconditional application normalization, full MetaCIC subject reduction, quotient equality over reductions, host evaluation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-route exactness, no-infinite projection exactness, provenance, and local NameCert rows.

Chapter 759

A Concrete Naming Certificate for $\mathsf{InterHistLocalityLedger}^{\uparrow}$

The $\mathsf{InterHistLocalityLedger}^{\uparrow}$ packet realizes the ledger-local relation principle of chapter 9419 as a finite two-history NameCert carrier. It sits between the two-observer coordination surface of chapter 513 and the invariant readback surface of chapter 656: the packet records two source histories, symmetric transport, displayed routes, locality cells, invariant rows, provenance, and local naming without exporting a global observer frame.

Definition 759.1 (InterHistLocalityLedger carrier)**.** *An* $\mathsf{InterHistLocalityLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, B, H, C, O, I, P, N)$$

with the following displayed coordinates:

1. *A and B are the two source* BHist *rows whose local relation is being certified;*
2. *H stores symmetric componentwise* hsame *transport between the two source-history presentations and their transported rows;*
3. *C stores the displayed* Cont *routes by which the inspected finite data are read from A and B and replayed across the ledger;*
4. *O is the* $\mathsf{ObserverLocalityCell}^{\uparrow}$ *row that supplies the two-observer locality cell consumed by the ledger;*
5. *I is the* $\mathsf{InterHistInvariant}^{\uparrow}$ *row that records the observer-symmetric inter-Hist invariant readback;*
6. *P is the* Pkg *provenance over* BHist, hsame, Cont, $\mathsf{ObserverLocalityCell}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, *and* $\mathsf{NameCert}$*;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{InterHistLocalityLedger}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a global frame, shared clock, selected synchronization history, host-side equality of histories, quotient of observer records, or ambient spacetime.

Lean4 ✓ `BEDC.Derived.InterHistLocalityLedgerUp.InterHistLocalityLedgerTasteGate single carrier alignment`

Theorem 759.2 (InterHistLocalityLedger NameCert obligations)**.** *For the carrier of Definition 759.1, the local* $\mathsf{NameCert}_{\mathsf{InterHistLocalityLedger}^{\uparrow}}$ *surface consists of carrier admission for $L = (A, B, H, C, O, I, P, N)$,*

symmetric hsame *transport for the two source histories, displayed* Cont *route replay, observer-locality-cell consumption, inter-Hist invariant readback,* Pkg *provenance, and the local naming row.*

Proof. Carrier admission is projection from the displayed tuple L. The rows A and B give the two source histories, while H and C give the transport and continuation data used to compare their finite observations.

The rows O and I supply the two local consumers. The observer-locality-cell row records the finite two-observer surface, and the invariant row records the observer-symmetric readback over the same pair.

The provenance and naming clauses are P and N. Since the carrier has no coordinate for a global frame, shared clock, synchronization history, quotient of observers, host-side history equality, or ambient spacetime, these displayed rows exhaust the local certificate obligations. □

Theorem 759.3 (InterHistLocalityLedger symmetric route)**.** *Let $L = (A, B, H, C, O, I, P, N)$ be an accepted* InterHistLocalityLedger$^{\uparrow}$ *carrier. Swapping the source-history rows A and B yields the same public locality ledger after replaying the symmetric* hsame *transport in H and the displayed* Cont *routes in C; the observer-locality cell and inter-Hist invariant rows are read through the same finite packet.*

Lean4 ✓ `BEDC.Derived.InterHistLocalityLedgerUp.InterHistLocalityLedger symmetric route source swap separates`

Proof. Project the accepted carrier. The only source-history coordinates are A and B, and the only transport coordinate relating their presentations is H.

Replay the continuation routes stored in C. These routes attach the inspected finite data from both source histories to the same locality-cell row O and invariant row I.

The NameCert obligations of Definition 759.2 then identify the swapped read as a route through the same H, C, O, I, P, N surface. No global synchronization coordinate is available to distinguish one source history as the privileged anchor. □

Theorem 759.4 (InterHistLocalityLedger non-escape)**.** *Every public consumer of an accepted* InterHistLocalityLedger$^{\uparrow}$ *carrier may inspect only the source-history rows A, B, the symmetric* hsame *transport row H, the displayed* Cont *route row C, the* ObserverLocalityCell$^{\uparrow}$ *row O, the* InterHistInvariant$^{\uparrow}$ *row I,* Pkg *provenance P, and local naming row N. It receives no global frame, shared clock, selected synchronization history, host-side history equality, quotient of observer records, metric spacetime, or all-observer synchronization map.*

Proof. Inspect the carrier coordinates in Definition 759.1. The visible rows are exactly A, B, H, C, O, I, P, N.

The observer-locality-cell and invariant rows are downstream reads of that finite packet, not extra ambient structures. They preserve the same two-history boundary and do not add a frame, clock, quotient, or host equality coordinate.

Therefore every consumer is exhausted by the displayed rows. Any request for global synchronization, ambient spacetime, host-side equality of histories, or an all-observer map would require a carrier coordinate that is absent from L. □

Theorem 759.5 (InterHistLocalityLedger observer-locality handoff)**.** *An accepted* InterHistLocalityLedger$^{\uparrow}$ *carrier hands the two source histories to an* ObserverLocalityCell$^{\uparrow}$ *consumer and an* InterHistInvariant$^{\uparrow}$ *consumer through one finite route packet*

$$A, B, H, C, O, I, P, N.$$

The handoff preserves the symmetric locality relation of the ledger and does not add a cross-Hist causal predicate, maximum-rate bound, global frame, or metric geometry.

Proof. Begin with the carrier definition. The rows A and B are the only source histories, O is the observer-locality-cell row, and I is the inter-Hist invariant row.

Use the symmetric route theorem to transport the two source histories through H and replay their inspected finite data through C. This makes the locality-cell and invariant consumers read the same two-history ledger.

Apply non-escape for the boundary. Since L has no coordinate for cross-Hist causal predicates, maximum-rate bounds, global frames, metric geometry, or host-side equality, the observer-locality handoff is exactly the finite packet A, B, H, C, O, I, P, N. □

Lean4 ✓ `BEDC.Derived.InterHistLocalityLedgerUp.InterHistLocalityLedgerLocalityCell handoff separation`

Falsifiable prediction: Removing either the symmetric transport row or the observer-locality handoff row leaves a packet that can still name two histories but cannot certify a local two-history ledger.

Independence witness: Nearest siblings: observerlocalitycell, interhistinvariant, crosshistcausalrate, inscriptionevent, and localselfcenterinscriptionseal. ObserverLocalityCellUp records a cell rather than the ledger route; InterHistInvariantUp records invariant readback without the two-history locality ledger; CrossHistCausalRateUp records rate data rather than symmetric locality transport; InscriptionEventUp records an event packet rather than inter-history ledger routing; LocalSelfCenterInscriptionSealUp records a local self-center seal rather than a two-observer handoff. No bijection preserving carrier rows, symmetric hsame transport, observer-locality handoff, invariant readback, provenance, and local naming can identify these packets.

Closure status for $\mathsf{NameCert}_{\mathsf{InterHistLocalityLedger}^{\uparrow}}$.

Constructive story: An $\mathsf{InterHistLocalityLedger}^{\uparrow}$ packet is generated from two source histories, symmetric transport, displayed route replay, an observer-locality cell, an inter-Hist invariant row, package provenance, and a local NameCert row.

Lean4 ✓ `BEDC.Derived.InterHistLocalityLedgerUp.taste gate`

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{InterHistLocalityLedger}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 759.5 and

Lean4 ✓ `BEDC.Derived.InterHistLocalityLedgerUp.taste gate`

publish the finite carrier, symmetric hsame transport, displayed Cont replay, observer-locality consumption, invariant readback, Pkg provenance, local NameCert row, and TasteGate obligations for the displayed two-history ledger.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{InterHistLocalityLedger}^{\uparrow}}$, unformalized)

Ledger evidence: BEDC.Meta.DiscoveryDeltaLedger.interHistLocalityLedgerDeltaLedger

Bridge status: none

Origin: ai

Not claimed: This chapter does not close global observer frames, shared clocks, selected synchronization histories, host-side history equality, metric spacetime, cross-Hist causal bounds, or bridge checking.

Upgrade path: Remaining work is Lean-side route coverage and bridge checking against the public schema.

Chapter 760

A Concrete Naming Certificate for $\mathsf{TypedBetaCongruenceTrigger}^{\uparrow}$

The $\mathsf{TypedBetaCongruenceTrigger}^{\uparrow}$ packet realizes the congruence-trigger boundary isolated in chapter 9384 as a finite MetaCIC NameCert surface. It sits next to the bounded comparison packet of chapter 748, the beta-substitution preservation packet of chapter 716, and the discharge socket of chapter 719. The packet records where a congruence constructor can enter the subject-reduction route, without turning that constructor into a global typing-preservation theorem.

Definition 760.1 (Typed beta congruence trigger carrier)**.** *A* $\mathsf{TypedBetaCongruenceTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (k, r, s, j, b, d, H, C, P, N)$$

with the following displayed rows:

1. *k is the congruence-constructor tag, one of application-function, application-argument, lambda-body, lambda-domain, Pi-codomain, or Pi-domain;*
2. *r is the local* BetaStep *row naming the syntactic trigger;*
3. *s is the displayed source term row before the congruence step;*
4. *j is the typing-boundary judgement row whose preservation is being handed to the relevant discharge surface;*
5. *b is the beta audit-map boundary row that records whether the constructor is direct substitution-facing, dependent-codomain-facing, or binder-domain-facing;*
6. *d is the sibling discharge row read from the substitution or subject-reduction discharge packet;*
7. *H records componentwise* hsame *transports for the constructor tag, beta-step row, source term, judgement boundary, audit boundary, discharge row, provenance, and local name;*
8. *C records the displayed* Cont *route from the constructor trigger to the discharge surface;*
9. *P is the* Pkg *provenance over* BetaStep*, MetaCIC term syntax, typing-boundary rows, chapter 9384, chapter 748, chapter 716, chapter 727, and chapter 718;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TypedBetaCongruenceTrigger}^{\uparrow}}$ *row.*

The carrier contains no conversion rule for typing, no full subject-reduction theorem, no fuel-erased normalisation theorem, and no quotient equality over represented terms.

Lean4 ✓ `BEDC.Derived.TypedBetaCongruenceTriggerUp.TypedBetaCongruenceTriggerTasteGate single carrier alignment`

Theorem 760.2 (Typed beta congruence trigger NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{TypedBetaCongruenceTrigge}}$ *surface for Definition 760.1 has five finite obligations:*

1. *trigger admission, requiring* $T = (k, r, s, j, b, d, H, C, P, N)$ *to display a concrete* BetaStep *congruence constructor and its source term row;*
2. *congruence-constructor classification, requiring* k *to identify whether the step is application-function, application-argument, lambda-body, lambda-domain, Pi-codomain, or Pi-domain;*
3. *typing-boundary preservation handoff, requiring the judgement boundary* j *and audit row* b *to point to the sibling substitution or subject-reduction discharge row* d *rather than to an implicit typing rule;*
4. *route non-escape, requiring every consumer to pass through the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *rows before it can read the discharge surface;*
5. *ledger exactness, requiring the exported rows to be exactly* $k, r, s, j, b, d, H, C, P, N$ *and no hidden conversion, closed subject-reduction, or normalisation ledger.*

Proof. Carrier admission is projection from the finite tuple in Definition 760.1. The constructor tag, beta-step row, source term, judgement boundary, audit row, discharge row, transport, route, provenance, and local name are all displayed coordinates.

The congruence classification is rowwise. The beta audit map separates the direct beta constructor from the congruence constructors, and the carrier records only the congruence side through k and r.

The preservation handoff is therefore a route fact. The row j is read together with b and then handed to d, so the packet cites the substitution and subject-reduction discharge siblings instead of asserting a new typing-preservation rule.

Finally inspect H, C, P, N. These rows provide the only transport, continuation, provenance, and naming paths. Since no coordinate contains conversion typing, full closed subject reduction, fuel-erased normalisation, or quotient equality, the exported ledger is exactly the displayed finite packet. □

Theorem 760.3 (Typed beta congruence trigger audit-map fit)**.** *Every accepted* $\mathsf{TypedBetaCongruenceTrigger}^{\uparrow}$ *packet presents a concrete consumer surface for the congruence-trigger boundary of section 9384.4. The direct substitution-facing trigger is routed to the beta-substitution preservation and discharge siblings, while the dependent-codomain and binder-domain congruence triggers are routed to the subject-reduction discharge siblings. The packet exports no theorem beyond that finite routing surface.*

Proof. Read the audit-map section first. It separates the direct beta constructor from the application-argument and binder-domain congruence constructors, and it explains which typing boundary each constructor touches.

Apply Definition 760.2. The constructor tag and audit row classify the trigger, while the judgement boundary and discharge row give the only preservation handoff available to consumers.

The sibling provenance row then confines the packet to the concrete BEDC surfaces cited in Definition 760.1. Since the carrier has no coordinate for a global typing rule, it can only expose the finite route from congruence constructor to discharge boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{TypedBetaCongruenceTrigger}^{\uparrow}}$.

Constructive story: A $\mathsf{TypedBetaCongruenceTrigger}^{\uparrow}$ packet is generated from a congruence-constructor tag, a concrete BetaStep trigger row, a source term row, a typing-boundary judgement row, a beta audit-map boundary row, a sibling discharge row, componentwise transports, continuation routes, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TypedBetaCongruenceTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 760.1, Definition 760.2, and Definition 760.3 bind the finite congruence-trigger carrier, classification, handoff, route, and exact-ledger surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TypedBetaCongruenceTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close conversion typing, global closed subject reduction, fuel-erased normalisation, quotient equality over represented terms, or bridge checking.

Upgrade path: Obligation closure requires checking trigger admission, constructor classification, typing-boundary handoff, route non-escape, and ledger exactness for the displayed packet.

Chapter 761

A Concrete Naming Certificate for $\mathsf{MetaCICBetaAudit}^{\uparrow}$

The $\mathsf{MetaCICBetaAudit}^{\uparrow}$ packet realizes the audit discipline of chapter 9384 as a finite NameCert boundary. It keeps the reduction inventory, common-reduct conversion facts, normal-form rigidity rows, and subject-reduction obstruction rows as separate coordinates, so a consumer cannot treat beta reduction, beta conversion, and typing preservation as one unrecorded operation. The packet reads the obstruction side through chapter 9377 and its concrete NameCert surfaces in chapter 483 and chapter 562.

Definition 761.1 (MetaCIC beta audit carrier)**.** *A* $\mathsf{MetaCICBetaAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, V, T, F, O, H, C, P, N)$$

with the following visible coordinates:

1. *S is the* BetaStep *constructor inventory, separating the direct beta-redex constructor from application, lambda, and Pi congruence constructors;*
2. *V is the* BetaConv *common-reduct ledger, recording the two* BetaStarStep *routes to the displayed common reduct;*
3. *T is the* BetaStarStep *route data consumed by conversion and by one-step-to-multi-step inclusions;*
4. *F is the normal-form rigidity row, read only under the displayed closed beta-strong normal hypotheses;*
5. *O is the subject-reduction obstruction ledger, with rows for substitution preservation, application-argument type stability, lambda-domain preservation, and Pi-domain preservation;*
6. *H records componentwise* hsame *transports for the reduction, conversion, route, rigidity, and obstruction rows;*
7. *C records the displayed* Cont *routes by which consumers inspect those rows;*
8. *P is the* Pkg *provenance over the MetaCIC beta files, the subject-reduction obstruction surface,* BHist*,* hsame*,* Cont*, and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICBetaAudit}^{\uparrow}}$ *row.*

The carrier contains no hidden typing-conversion rule, no unconditional subject-reduction theorem, no closed-consistency theorem, and no extra beta constructor beyond the displayed inventory.

Lean4 ✓ `BEDC.Derived.MetaCICBetaAuditUp.MetaCICBetaAuditTasteGate single carrier alignment`

Theorem 761.2 (Reduction and conversion boundary)**.** *For an accepted* $\mathsf{MetaCICBetaAudit}^{\uparrow}$ *carrier* $A = (S, V, T, F, O, H, C, P, N)$*, every reduction read factors through the* BetaStep *inventory* S *and every conversion read factors through the* BetaConv *common-reduct ledger* V *together with the* BetaStarStep *route data* T*. A consumer may use the normal-form rigidity row* F *only under its displayed closed beta-strong normal hypotheses, and it has no route from* S, V, T, F *to a typing-preservation claim.*

Lean4 ✓ `BEDC.Derived.MetaCICBetaAuditUp.MetaCICBetaAuditReductionConversionBoundary`

Proof. Project the carrier. The row S is the only one-step reduction inventory, while V and T are the only common-reduct and multi-step route rows.

Read conversion through V. Its data is a common reduct and two routes supplied by T, not a typing judgement and not a closure certificate.

The rigidity row F is then read under its own closed normal-form hypotheses. Since the carrier keeps O as a separate obstruction ledger and has no hidden typing-conversion coordinate, reduction and conversion cannot be promoted to subject reduction by projection. □

Lean4 ✓ `BEDC.Derived.MetaCICBetaAuditUp.MetaCICBetaAudit reduction conversion boundary`

Theorem 761.3 (Subject-reduction obstruction ledger)**.** *For an accepted* $\mathsf{MetaCICBetaAudit}^{\uparrow}$ *carrier* $A = (S, V, T, F, O, H, C, P, N)$*, every subject-reduction citation factors through the obstruction row* O*. The ledger* O *separates beta substitution preservation, dependent application-argument stability, lambda-domain preservation, and Pi-domain preservation, and it is the only coordinate that may be read by consumers of chapter 9377.*

Proof. Inspect the carrier rows. The reduction inventory S, conversion ledger V, route data T, and rigidity row F do not contain typing-preservation fields.

The obstruction row O is the unique coordinate listing the four preservation interfaces needed by the subject-reduction boundary. Componentwise transport through H and route replay through C preserve those four rows without merging them.

Package provenance P and the local name N record that the obstruction ledger is part of the same finite packet. Because no other coordinate carries typing preservation, a subject-reduction consumer must enter through O. □

Lean4 ✓ `BEDC.Derived.MetaCICBetaAuditUp.MetaCICBetaAudit subject reduction obstruction ledger`

Theorem 761.4 (MetaCIC beta audit NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICBetaAudit}^{\uparrow}}$ *surface consists exactly of carrier admission for* $A = (S, V, T, F, O, H, C, P, N)$*, reduction inventory routing through* S*, common-reduct conversion routing through* V, T*, normal-form rigidity routing through* F*, subject-reduction obstruction routing through* O*, componentwise* hsame *transport through* H*, displayed* Cont *route replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Start from the carrier definition. It displays the reduction, conversion, route, rigidity, obstruction, transport, continuation, provenance, and local naming coordinates.

Use Definition 761.2 for the reduction and conversion side. It keeps one-step reduction, common-reduct conversion, multi-step routes, and normal-form rigidity in their own rows.

Use Definition 761.3 for the typing side. It makes O the only row that can serve subject-reduction consumers and keeps the four preservation obligations separate.

The rows H, C, P, N then account for transport, route replay, provenance, and naming. Since the packet has no hidden conversion-for-typing coordinate, no unconditional subject-reduction coordinate, and no closed-consistency coordinate, the obligation surface is exhausted by the displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICBetaAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICBetaAudit}^{\uparrow}$ packet is generated from a BetaStep constructor inventory, BetaConv common-reduct ledger, BetaStarStep route data, normal-form rigidity row, subject-reduction obstruction ledger, componentwise transports, displayed continuation routes, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICBetaAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 761.1, Definition 761.2, Definition 761.3, and Definition 761.4 bind the finite carrier and the reduction, conversion, rigidity, and typing-obstruction boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICBetaAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close unconditional subject reduction, hidden conversion for typing, closed consistency, new beta constructors, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked routing for the displayed reduction inventory, conversion ledger, route data, rigidity row, obstruction ledger, transport rows, continuation rows, provenance row, and local name.

Chapter 762

A Concrete Naming Certificate for MetaCICOpenFrontierLedger$^{\uparrow}$

The MetaCICOpenFrontierLedger$^{\uparrow}$ packet realizes the open-problem inventory of chapter 9386 as a finite NameCert frontier ledger. It sits beside the subject-reduction carrier of chapter 483, the normal false exclusion packet of chapter 732, the normalization audit packet of chapter 750, and the decidability boundary packet of chapter 749. Its purpose is to name the open rows that downstream consumers must keep visible before reading MetaCIC consistency, normalization, confluence, decidability, or typed-example evidence.

Definition 762.1 (MetaCIC open frontier ledger carrier)**.** *A* MetaCICOpenFrontierLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, E, F, N, D, T, K, H, C, P, Q)$$

with the following displayed rows:

1. *S is the subject-reduction frontier row, naming the* SubjectReductionDischargeBundle *interface and its four obligation coordinates;*
2. *E is the closed-normal exclusion row, naming the closed-normal false exclusion and closed-normal consistency boundary;*
3. *F is the confluence frontier row, naming the residual-substitution and arbitrary closed-source Church–Rosser endpoints that remain outside the closed-normal fragment;*
4. *N is the normalization frontier row, naming the candidate-mediated strong-normalization interface and its evidence boundary;*
5. *D is the decidability frontier row, naming typing-checker exactness, bounded normal comparison, finished-normal side conditions, and the refusal of an unrestricted closed beta-conversion oracle;*
6. *T is the typed-example boundary row, naming the gallery witnesses and the absence of exhaustive dependent-program coverage;*
7. *K is the closed-consistency boundary row, naming the handoff from closed-normal consistency to any stronger closed consistency claim;*
8. *H records componentwise* hsame *transport across $S, E, F, N, D, T, K, P, Q$;*
9. *C records displayed* Cont *replay routes for the subject-reduction, confluence, normalization, decidability, typed-example, and consistency-boundary rows;*

10. *P is the* Pkg *provenance over the MetaCIC open-problem inventory and the sibling concrete NameCert packets cited above;*

11. *Q is the local* $\mathsf{NameCert}_{\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}}$ *row.*

The carrier has no row for closed subject reduction, no arbitrary closed Church–Rosser theorem, no evidence-free global strong normalization theorem, no unrestricted closed beta-conversion decider, no exhaustive typed-example coverage theorem, and no full closed consistency claim.

Theorem 762.2 (MetaCIC open frontier ledger obligations)**.** *Every accepted* $\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}$ *packet binds exactly the finite obligation surface displayed in Definition 762.1: carrier admission for $L = (S, E, F, N, D, T, K, H, C, P, Q)$, subject-reduction frontier visibility through S, closed-normal exclusion visibility through E, confluence-frontier visibility through F, normalization-frontier visibility through N, decidability-frontier visibility through D, typed-example boundary visibility through T, consistency-boundary visibility through K, componentwise* hsame *transport through H, finite* Cont *replay through C, package provenance through P, and local naming through Q.*

Proof. Project the displayed carrier. The frontier rows are S, E, F, N, D, T, K, and each row corresponds to one boundary named in chapter 9386.

Read the positive closed-normal row E separately from the open rows S, F, N, D, T, K. This separation lets the ledger record the existing closed-normal exclusion surface without promoting it into a stronger endpoint.

The structural rows H, C, P, Q only transport, replay, package, and name those displayed rows. Since no further coordinate is present, the listed rows exhaust the local NameCert obligation surface. □

Theorem 762.3 (MetaCIC open frontier ledger subject-reduction boundary)**.** *Every accepted* $\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}$ *packet exposes subject reduction only through the frontier row S and the sibling packet of chapter 483. The row may name the* SubjectReductionDischargeBundle *interface and its beta-substitution, application-argument, lambda-domain, and Pi-domain coordinates, but it does not inhabit that bundle, prove the four coordinates, or export closed subject reduction.*

Proof. Begin with the carrier row S. It is the only coordinate in the packet whose role is to name the subject-reduction frontier.

The sibling reference to chapter 483 supplies the accepted preservation-facing surface, while S records the discharge interface that must still be supplied before the closed MetaCIC path can consume it as an unconditional theorem.

Transport through H and replay through C preserve this row as displayed. The package and local name rows P, Q account for provenance and naming, so no hidden inhabitant of the discharge bundle or closed subject-reduction theorem can enter the ledger. □

Theorem 762.4 (MetaCIC open frontier ledger normalization boundary)**.** *Agreement on an accepted* $\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}$ *packet preserves the closed-normal exclusion row E and the normalization frontier row N as distinct coordinates. The packet may feed closed-normal consistency consumers through the closed-normal exclusion surface of chapter 732 and the candidate-mediated audit surface of chapter 750, but it cannot erase candidate evidence, finished-normal evidence, or subject-reduction transport into a global closed consistency theorem.*

Proof. Read E as the closed-normal exclusion coordinate. It records the finite boundary at which a closed beta-normal proof of the internal false type is excluded.

Read N as the normalization-frontier coordinate. It names the candidate-mediated route and its evidence boundary, matching the sibling audit surface rather than a blanket strong-normalization theorem.

The consistency row K is downstream of both coordinates and remains a boundary row. Thus H, C, P, Q can replay and name the closed-normal route, but they cannot identify E with global normalization, erase the candidate evidence in N, or convert the ledger into full closed consistency. □

Theorem 762.5 (MetaCIC open frontier ledger downstream handoff)**.** *Every downstream read of an accepted* $\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}$ *carrier factors through*

$$S, E, F, N, D, T, K, H, C, P, Q.$$

The handoff may cite subject-reduction obligations, closed-normal exclusion, confluence boundaries, candidate-mediated normalization, bounded decidability, typed-example gallery scope, and closed-consistency boundaries, but it may not replace those rows by vision prose, host metatheory, quotient equality over represented terms, or an unrecorded global MetaCIC theorem.

Proof. Project the carrier and apply the obligation theorem. The downstream consumer receives the seven frontier rows together with transport, replay, provenance, and local naming rows.

The confluence row F, decidability row D, typed-example row T, and consistency row K are boundary coordinates rather than theorem endpoints. They keep residual substitution, bounded normal comparison, gallery scope, and full consistency separate from the positive closed-normal and checker-side data.

Since the carrier contains no host evaluator, quotient equality, erased normalizer, unrestricted conversion oracle, or global consistency endpoint, every accepted handoff remains inside the displayed ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}$ packet is generated from finite subject-reduction, closed-normal exclusion, confluence, normalization, decidability, typed-example, consistency-boundary, transport, continuation, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 762.1, Definition 762.2, Definition 762.3, Definition 762.4, and Definition 762.5 bind the finite open-frontier ledger and its downstream handoff discipline.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove closed subject reduction, arbitrary closed Church–Rosser, evidence-free global strong normalization, unrestricted closed beta-conversion decidability, exhaustive typed-example coverage, full closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exact row coverage for the seven frontier coordinates, sibling provenance, continuation replay, and non-escape for every downstream handoff.

Chapter 763

A Concrete Naming Certificate for MetaCICOpenObligationLedger$^{\uparrow}$

The MetaCICOpenObligationLedger$^{\uparrow}$ packet realizes the inventory of chapter 9386 as finite BEDC data. It sits beside the closed-normal consistency assembly of chapter 9375 and the substitution audit map of chapter 9380: those chapters identify positive closed-normal content and substitution-facing boundaries, while this packet keeps every remaining MetaCIC obligation as a named ledger row rather than as an ambient metatheorem.

As a concrete dependency edge, the ledger consumes chapter 736 for the positive normal-form node and chapter 779 for the substitution-facing boundary rows; the local packet records only the remaining open obligation rows.

Theorem 763.1 (MetaCIC open obligation decidability endpoint row)**.** *Any* MetaCICOpenObligationLedger$^{\uparrow}$ *consumer attempting to read a closed-term beta-conversion decision or a bounded normal-equality decision must expose a distinct decidability endpoint row. That row is not supplied by the closed-normal consistency row, substitution boundary row, subject-reduction discharge rows, confluence obstruction rows, componentwise transport, replay, provenance, or local naming.*

Proof. Project the ledger carrier. Its decidability coordinate is separate from the subject-reduction, confluence, normalization, typed-example, transport, replay, provenance, and local naming coordinates.

Use the dependency edge to the closed-normal consistency and substitution audit map chapters. Those inputs identify positive normal-form content and substitution-facing boundary data, but neither edge supplies a decision procedure for closed beta conversion or bounded normal equality.

Therefore a consumer that asks for such a decision must read the displayed decidability endpoint row itself. The obligation remains a finite endpoint row of the ledger rather than a consequence hidden inside normalization, substitution, transport, replay, provenance, or naming. □

Definition 763.2 (MetaCIC open-obligation ledger carrier)**.** *A* MetaCICOpenObligationLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, C, N, D, E, H, R, P, Q)$$

with the following displayed rows:

1. *S is the subject-reduction row, containing the beta-substitution preservation, application-argument stability, lambda-domain preservation, and Pi-domain preservation obligations as finite named entries;*

2. *C is the confluence row, recording residual-substitution compatibility, closed parallel diamond scope, and closed multi-step Church–Rosser scope as boundary entries;*
3. *N is the normalization row, recording candidate evidence, closed-candidate evidence, candidate-set membership, and the absence of an evidence-free global strong-normalization export;*
4. *D is the decidability row, recording typing-checker coverage, bounded normal-equality reads, and the finished-normalization bridge needed before unrestricted beta conversion is exported;*
5. *E is the typed-example row, recording gallery witnesses and the absence of an exhaustive coverage theorem over all dependent or polymorphic programs;*
6. *H stores componentwise* hsame *transports for S, C, N, D, E;*
7. *R stores the finite* Cont *routes by which consumers read the subject-reduction, confluence, normalization, decidability, and example rows;*
8. *P is the* Pkg *provenance over the open-problem inventory, closed-normal consistency assembly, substitution audit map, subject-reduction obstruction, and normalization audit map;*
9. *Q is the local* $\mathsf{NameCert}_{\mathsf{MetaCICOpenObligationLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary closed subject reduction, arbitrary closed Church–Rosser, evidence-free global strong normalization, unrestricted beta-conversion decidability, exhaustive example coverage, or full closed consistency.

Theorem 763.3 (MetaCIC open-obligation ledger NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICOpenObligationL}}$ *surface for Definition 763.2 consists exactly of carrier admission for L, componentwise classifier stability for S, C, N, D, E, route replay through R, provenance through P, and local naming exactness through Q.*

Proof. Carrier admission is projection from the finite packet L. Each obligation family is a displayed row, so a consumer cannot read a subject-reduction, confluence, normalization, decidability, or typed-example boundary unless the corresponding coordinate is present.

Classifier stability is componentwise. The transport row H preserves each ledger row as a ledger row; it does not convert a boundary entry into a closed theorem and does not erase the distinction between positive checked content and remaining obligation data.

The route and provenance rows repack the same finite packet. The routes in R replay the displayed rows, P records their source chapters, and Q names the local certificate surface without adding another MetaCIC claim. □

Theorem 763.4 (MetaCIC open-obligation boundary classifier)**.** *For an accepted* $\mathsf{MetaCICOpenObligationLedger}^{\uparrow}$ *carrier $L = (S, C, N, D, E, H, R, P, Q)$, every ledger entry is classified by its row of origin and by its destination boundary: subject-reduction discharge, residual-substitution algebra, candidate-mediated normalization, bounded conversion, or gallery coverage. The classifier preserves the closed-normal consistency node of chapter 9375 as a positive input row and the substitution map of chapter 9380 as a boundary input row.*

Proof. Read the entry through the route row R. If it lands in S, the destination boundary is a subject-reduction discharge; if it lands in C, it is a residual-substitution or closed-confluence boundary; if it lands in N, it is a candidate-mediated normalization boundary; if it lands in D, it is a bounded-conversion boundary; and if it lands in E, it is a gallery-coverage boundary.

The sibling chapters are consumed through provenance rather than by unstated closure. The closed-normal assembly supplies the positive normal-form node, while the substitution audit map

supplies the substitution-facing obstruction data that keep confluence and subject-reduction reads row-local.

Componentwise hsame transport preserves the row tags. Therefore the classifier remains a boundary classifier over the finite packet and not an equality of unresolved MetaCIC proof obligations. □

Theorem 763.5 (MetaCIC open-obligation non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{MetaCICOpenObligationLedger}^{\uparrow}$ *packet factors through the displayed rows* $S, C, N, D, E, H, R, P, Q$*. A request for arbitrary closed subject reduction, arbitrary closed Church–Rosser, evidence-free global strong normalization, unrestricted beta-conversion decidability, exhaustive example coverage, or full closed consistency has no carrier coordinate and remains a boundary read.*

Proof. Let a downstream consumer route be given. By the carrier definition, the route can inspect only the five obligation rows, the componentwise transport row, the replay routes, package provenance, and local naming.

Positive content is still visible where the packet records it. The closed-normal consistency node is consumed as provenance for the normal-form row, and the substitution map is consumed as provenance for the substitution-facing confluence and subject-reduction rows.

The requested closed endpoints are absent from the carrier inventory. Since no displayed coordinate contains those endpoints, the packet can report their boundary status but cannot export them as hidden consequences. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICOpenObligationLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICOpenObligationLedger}^{\uparrow}$ packet is generated from subject-reduction, confluence, normalization, decidability, and typed-example obligation rows, componentwise hsame transports, finite replay routes, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICOpenObligationLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 763.2, Definition 763.3, Definition 763.4, and Definition 763.5 bind the finite open-obligation ledger and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICOpenObligationLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close arbitrary closed subject reduction, arbitrary closed Church–Rosser, evidence-free global strong normalization, unrestricted beta-conversion decidability, exhaustive example coverage, full closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, row classifier stability, route replay exactness, provenance, and local NameCert rows for the same finite ledger packet.

Chapter 764

A Concrete Naming Certificate for $\mathsf{ClosedNormalConsistencyMain}^{\uparrow}$

The $\mathsf{ClosedNormalConsistencyMain}^{\uparrow}$ packet realizes the main-result boundary of chapter 9376 as a finite NameCert surface. It is downstream of the closed-normal consistency packet of chapter 736 and the closed-normal consistency packet boundary of chapter 739: those siblings expose the closed beta-strong false-inhabitation exclusion and its subject-reduction gap, while the present packet records exactly the consumer-facing main-result claim.

Definition 764.1 (Closed-normal consistency main carrier)**.** *A* $\mathsf{ClosedNormalConsistencyMain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, L, B, F, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the* HasType *row for a closed candidate at the internal false encoding in the empty context;*
2. *L is the* ClosedAt *row binding the same term and false encoding to the closed substrate read used by the main result;*
3. *B is the* BetaStrong *row asserting that the candidate is already at the beta-strong normal boundary consumed by closed-normal consistency;*
4. *F is the false-encoding row naming the contradiction target and no other bottom-like proposition;*
5. *R is the normal-form contradiction route from T, L, B, F to the closed beta-strong false-inhabitation exclusion;*
6. *H records componentwise* hsame *transport for the typing, closedness, beta-strong, false-encoding, and contradiction-route rows;*
7. *C records the displayed* Cont *routes from the typed closed beta-strong input to the contradiction route and from that route to a public read;*
8. *P records* Pkg *provenance over the main-result chapter, the closed-normal consistency packet, and the closed-normal consistency packet boundary;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyMain}^{\uparrow}}$ *row.*

The carrier has no coordinate for full closed consistency, closed subject reduction, unrestricted normalization, host evaluation, quotient conversion, or ambient consistency.

Lean4 (definition) `BEDC.Derived.ClosedNormalConsistencyMainUp.ClosedNormalConsistencyMainUp`

Theorem 764.2 (Closed-normal consistency main NameCert obligations)**.** *Every accepted* ClosedNormalConsistenc *packet binds exactly the finite obligation surface of Definition 764.1: carrier admission for* $Q = (T, L, B, F, R, H, C, P, N)$*, componentwise classifier stability on the displayed rows, ledger exactness for the typing, closedness, beta-strong, false-encoding, contradiction-route, transport, route, provenance, and naming coordinates, positive-boundary non-escape through* R*, and local naming through* N*.*

Proof. Project the accepted carrier. Admission gives the finite tuple $Q = (T, L, B, F, R, H, C, P, N)$, so every public classifier comparison is componentwise over the rows displayed in Definition 764.1.

The ledger exactness is read row by row. The rows T, L, B, F display the closed typed beta-strong false input, and R is the only positive contradiction route attached to that input.

The structural rows H, C, P, N preserve the same finite surface by componentwise transport, displayed route replay, package provenance, and local naming. Since no further coordinate is present, the packet supplies no escape from the stated positive boundary. □

Theorem 764.3 (Closed-normal consistency main ledger obligation scope)**.** *In every accepted* $\mathsf{ClosedNormalConsistencyMain}^{\uparrow}$ *packet, the rows* $T, L, B, F, R, H, C, P, N$ *are consumed in three scoped groups: endpoint hypotheses* T, L, B, F*, contradiction route* R*, and structural replay, provenance, and name rows* H, C, P, N*. No consumer can read full closed consistency, subject reduction, or unrestricted normalization from this packet, because no row for any of those claims appears in any group.*

Proof. Project the carrier $Q = (T, L, B, F, R, H, C, P, N)$. The endpoint-hypothesis group is exactly T, L, B, F: typing at the false encoding, closedness, beta-strong normality, and the false-encoding row.

The contradiction-route group is exactly R. It consumes the endpoint hypotheses and reaches the closed beta-strong false-inhabitation exclusion, but it does not add a route from arbitrary closed proofs to typed normal endpoints.

The structural group is exactly H, C, P, N. These rows provide componentwise transport, displayed continuation replay, package provenance, and local naming for the same finite surface.

Since full closed consistency, subject reduction, and unrestricted normalization occur in none of the three groups, a consumer has no coordinate from which to read them. The accepted packet therefore exposes only the scoped ledger obligations listed in the statement. □

Theorem 764.4 (Closed-normal consistency main positive boundary)**.** *Every consumer of an accepted* $\mathsf{ClosedNormalConsistencyMain}^{\uparrow}$ *packet may read only the closed beta-strong false-inhabitation exclusion displayed by* T, L, B, F, R*. The packet does not export full closed consistency, closed subject reduction, unrestricted normalization, host evaluation, quotient conversion, or a route from arbitrary closed proofs to beta-strong normal inhabitants of the same false encoding.*

Proof. Start from a consumer read of the packet. The only contradiction coordinate is R, and its inputs are precisely the displayed rows T, L, B, F.

The rows H, C, P, N allow the same read to be transported, replayed, packaged, and named, but they do not add a subject-reduction discharge, a normalization theorem, or a consistency principle. Therefore the exported claim remains the closed beta-strong false-inhabitation exclusion and nothing stronger. □

Lean4 ✓ `BEDC.Derived.ClosedNormalConsistencyMainUp.ClosedNormalConsistencyMainCarrier positive boundary`

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyMain}\uparrow}$.

Constructive story: A $\mathsf{ClosedNormalConsistencyMain}^{\uparrow}$ packet is generated from HasType, ClosedAt, BetaStrong, false-encoding, normal-form contradiction-route, componentwise transport, displayed route, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyMain}\uparrow}, \mathsf{seed})$

Scope closed: Definition 764.1, Definition 764.2, and Definition 764.4 bind the finite NameCert surface for the closed-normal consistency main-result boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedNormalConsistencyMain}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close full closed consistency, closed subject reduction, unrestricted normalization, host evaluation, quotient conversion, ambient consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, ledger exactness, positive-boundary non-escape, provenance, and local naming for the same finite main-result packet.

$\mathsf{MetaCICCriticalPath}^{\uparrow}$ reads its current open-phase source ledger through chapter 291, chapter 126, chapter 301, and chapter 38; the hub exports no quotient stream, selected limit, host real equality, ambient completeness, or bridge claim.

Chapter 765

A Concrete Naming Certificate for $\mathsf{MetaCICCriticalPath}^{\uparrow}$

The $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet realizes the critical-path reading of chapter 9385 as a finite NameCert packet. It is narrower than the synthesis packet: it records the path from closed strong normalisation to the normal-form consistency row, keeps the subject-reduction obstruction visible, and names the substitution, confluence, decidability, discharge, transport, continuation, provenance, and local naming rows needed by downstream MetaCIC consumers.

It sits beside the subject-reduction obstruction packet of chapter 731, the normalization audit packet of chapter 750, the decidability boundary packet of chapter 749, and the normal false exclusion packet of chapter 732. Those siblings supply the named rows; the present packet records the finite route by which a reader may use them together without converting the blocked edge into a theorem.

Definition 765.1 (MetaCIC critical-path packet)**.** *A* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, N, O, U, D, H, C, P, L)$$

with the following visible rows:

1. *S is the closed-strong-normalization route, read through the candidate-mediated normalization surface of chapter 750;*
2. *N is the normal-form consistency row, read through the normal false exclusion packet of chapter 732;*
3. *O is the subject-reduction obstruction row, read through chapter 731;*
4. *U is the substitution, confluence, and decidability handoff row, naming the closed substitution support, conditional confluence route, and bounded checker boundary used before any consistency read is attempted;*
5. *D is the discharge-bundle socket, naming the missing subject-reduction input as a socket rather than as a supplied theorem;*
6. *H stores componentwise* hsame *transports for S, N, O, U, D, P, L;*
7. *C stores the displayed* Cont *routes from the strong-normalization row to the normal-form row, from the handoff row to the checker and confluence boundaries, and from the obstruction row to the discharge socket;*

8. *P is the* Pkg *provenance over the MetaCIC audit synthesis chapter and the four sibling concrete packets cited above;*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *row.*

The carrier has no coordinate for closed subject reduction, no coordinate for full closed consistency, no global beta-conversion decision procedure, and no quotient over MetaCIC terms.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.TasteGate.MetaCICCriticalPathTasteGate single carrier alignment`

Theorem 765.2 (MetaCIC critical-path consistency handoff)**.** *Every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet hands a consistency-facing consumer from the closed-strong-normalization row S to the normal-form consistency row N only through the displayed route rows H, C, P, L. The consumer may read the normal false exclusion sibling after the normalization route has supplied the normal-form endpoint, but it cannot read a full closed-consistency theorem unless the discharge-bundle socket D is separately filled.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket consistency handoff`

Proof. Project the accepted carrier $K = (S, N, O, U, D, H, C, P, L)$. The rows S and N are the only positive rows on the consistency path: S records the closed-strong-normalization route, and N records the normal-form false-exclusion endpoint.

The route row C fixes the passage from S to N, while H, P, L preserve the same path under componentwise transport, provenance readback, and local naming. This gives the consumer the closed-normal consistency handoff named by the sibling packets.

The discharge socket D is a separate coordinate. Since it is recorded as a socket and not as a filled subject-reduction theorem, the handoff stops at the normal-form endpoint and does not export full closed consistency. □

Theorem 765.3 (MetaCIC critical-path obstruction boundary)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet, the obstruction row O remains visible under the substitution, confluence, and decidability handoff row U and under all componentwise transports in H. Agreement on S, N, U, D, H, C, P, L cannot erase O, cannot convert D into a discharged bundle, and cannot promote the normal-form consistency route to closed subject reduction or full closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket obstruction boundary`

Proof. The carrier definition lists O as a named row. It is not derived from S, N, or U; it is part of the displayed packet and is read through the subject-reduction obstruction sibling.

The row U collects the supporting handoffs for substitution, confluence, and decidability. These handoffs explain how local syntax movement, conditional confluence, and bounded checking interact with the route, but none of them fills the subject-reduction discharge socket D.

Componentwise transport through H and route replay through C preserve the same rows. Therefore a transported packet still contains O and still treats D as a socket, so the excluded closed subject-reduction and full closed-consistency conclusions remain outside the packet. □

Theorem 765.4 (MetaCIC critical-path route replay coverage)**.** *Every route replay accepted by a* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet factors through the displayed rows*

$$S, N, O, U, D, H, C, P, L.$$

The replay may use the closed-strong-normalization source S, the normal-form endpoint N, the handoff row U, componentwise transport H, continuation replay C, provenance P, and local naming L, but it keeps the obstruction row O and discharge socket D visible throughout the same packet.

Proof. Project the carrier from Definition 765.1. Its finite row list is exactly $S, N, O, U, D, H, C, P, L$, so an accepted replay begins inside that displayed packet rather than inside an ambient scheduler or host dependency graph.

Apply Definition 765.2. The consistency-facing part of the replay travels from S to N through the visible route rows and therefore cannot skip the packet surface that carries H, C, P, L.

It remains to keep the blocked side attached to the same replay. Use Definition 765.3, Definition 765.25, and Definition 765.34. These boundary results preserve O and D while stopping the read at N, so every accepted route replay factors through the full displayed row list. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRouteReplayCoverage`

Theorem 765.5 (MetaCIC critical-path consistency route totality)**.** *Every consistency-facing route accepted by a* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier reads the whole tuple*

$$S, N, O, U, D, H, C, P, L.$$

In particular, no consistency-facing consumer may read only the normalization endpoint or only the handoff row while dropping the obstruction row, discharge socket, transport, continuation, provenance, or local naming rows of the displayed packet.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConsistencyRouteTotality`

Proof. Start from Definition 765.38. It identifies the accepted carrier with exactly the tuple $K = (S, N, O, U, D, H, C, P, L)$ and supplies no abbreviated consistency carrier.

The consistency handoff uses that full packet. Apply Definition 765.2 and Definition 765.33. The route from S to N is read through the displayed route, transport, provenance, and local naming rows while O and D remain visible.

Finally apply Definition 765.39 and Definition 765.40. Replay has no route outside $S, N, O, U, D, H, C, P, L$, and therefore every accepted consistency-facing route is total over the displayed tuple rather than a partial read of a hidden closed-consistency object. □

Theorem 765.6 (MetaCIC critical-path consumer refusal exactness)**.** *Any MetaCIC consumer that omits the obstruction row O or the discharge socket D is refused as a read of full consistency or subject reduction from an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet. Such a consumer may still read the displayed normal-form endpoint N, but only as the bounded endpoint of the same finite route certificate.*

Proof. Read the packet rows from Definition 765.1. The rows O and D are not optional annotations: O records the subject-reduction obstruction, and D records the discharge-bundle socket.

Apply Definition 765.3. A consumer that drops O is no longer reading the accepted packet as a subject-reduction boundary, because the obstruction must remain visible under the handoff and transport rows.

Now apply Definition 765.25 and Definition 765.34. A consumer that drops D cannot present a full-consistency or subject-reduction read, since the normal-form endpoint remains bounded at N unless the separate socket is supplied. The refusal is therefore exact: missing O or missing D removes precisely the stronger read while preserving the bounded normal-form route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConsumerRefusalExactness`

Theorem 765.7 (MetaCIC critical-path certificate row order)**.** *In every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *certificate read, the source row S and the normal-form row N are read only after the obstruction row O and discharge socket D remain visible through H, C, P, L. Thus the certificate order never lets the positive normalization-to-normal-form route hide the blocked subject-reduction side.*

Proof. Start with the carrier definition. The accepted packet exposes $S, N, O, U, D, H, C, P, L$ as one finite certificate, so the source and endpoint rows are not isolated from the obstruction and socket rows.

Use Definition 765.2 to read the positive route. It sends consistency-facing consumers from S to N only through the displayed route rows, and those rows are part of the same certificate surface.

Finally combine Definition 765.3, Definition 765.25, and Definition 765.34. They keep O and D visible through transport, continuation, provenance, and local naming while stopping readback at N. Therefore S and N are read only in the row order that preserves the obstruction and socket throughout H, C, P, L. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCertificateRowOrder`

Theorem 765.8 (MetaCIC critical-path discharge-socket totality)**.** *Every accepted packet read of the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *discharge socket exposes the tuple rows*

$$S, N, O, U, D, H, C, P, L.$$

The read may use D as the named discharge socket, but it cannot treat D as closed subject reduction, full closed consistency, or a hidden theorem-export row outside the displayed packet.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket discharge socket totality`

Proof. Read the carrier from Definition 765.1. The packet definition makes $S, N, O, U, D, H, C, P, L$ the complete finite row inventory, with D named as a socket rather than as a filled subject-reduction theorem.

Apply the consistency handoff and obstruction boundary. Theorems Definition 765.2 and Definition 765.3 keep the positive S-to-N read and the blocked obstruction row in the same packet while refusing any conversion of D into a closed subject-reduction row.

Finally use discharge-socket nonescape and root consumer readiness from Definition 765.25 and Definition 765.86. These two surfaces force every downstream socket read through the displayed tuple and leave no consumer-facing coordinate from which closed subject reduction or full closed consistency can be read. □

Theorem 765.9 (MetaCIC critical-path downstream discharge visibility)**.** *Every downstream readiness read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet that also replays the discharge socket must keep the downstream NameCert surface and the visible discharge row in the same packet provenance. The consumer sees readiness through C, L and the downstream row, while the socket replay remains bounded by U, O, D rather than becoming closed subject reduction.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket downstream discharge visibility`

Proof. Apply Definition 765.11 to obtain the downstream NameCert surface from the packet route through C, L and the downstream row. Then apply Definition 765.44 to the socket replay through U, O, D. The Lean theorem packages these two reads together with the packet provenance, so the downstream consumer cannot separate readiness from the visible discharge boundary. □

Theorem 765.10 (MetaCIC critical-path normalization-obstruction source order)**.** *Any normal-form consistency read of an accepted* MetaCICCriticalPath$^{\uparrow}$ *packet consumes the closed-normalization route S and the normal-form row N only in the source order that preserves the obstruction row O and the discharge socket D. Thus the normal-form endpoint remains a bounded route endpoint rather than a discharge of the blocked subject-reduction side.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNormalizationObstructionSourceOrder`

Proof. Start with normalization-frontier factorization. By Definition 765.58, a normal-form consistency read factors through the closed-normalization source row S and the normal-form endpoint row N while keeping the obstruction side visible.

Next use the handoff rows that prepare the read. The bounded checker handoff of Definition 765.59 and the substitution handoff visibility of Definition 765.60 keep U, H, C, P, L attached to the same packet instead of replacing O or D by an ambient checker fact.

Finally apply Definition 765.62. The normalization-to-normal-form route carries the obstruction row through the read and still stops at the separate discharge socket, so the source order consumes S and N without closing the blocked subject-reduction obligation. □

Theorem 765.11 (MetaCIC critical-path downstream readiness boundary)**.** *Downstream MetaCIC consumers receive only the bounded readiness surface of an accepted* MetaCICCriticalPath$^{\uparrow}$ *root-unblock packet. The exported surface is the displayed packet interface for carrier, route, obstruction, discharge socket, transport, continuation, provenance, local naming, and Lean intake; it is not full closed consistency and does not include closed subject reduction.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket downstream readiness boundary`

Proof. Begin with the downstream surface. The downstream-unblock coverage theorem Definition 765.80, the Lean target intake theorem Definition 765.81, and the downstream unblock surface theorem Definition 765.82 make the consumer-facing interface finite and bounded by the displayed packet rows.

Now factor that interface through the audit frontier. Apply Definition 765.83 together with carrier readiness and route readiness from Definition 765.84 and Definition 765.85. These results account for the carrier rows, route rows, obstruction row, discharge socket, transport, continuation, provenance, and local naming without adding a closed theorem row.

Finally use Definition 765.86. Every downstream MetaCIC consumer is restricted to the same bounded readiness surface, so the root-unblock packet opens consumer scheduling while refusing full closed consistency and closed subject reduction. □

Theorem 765.12 (MetaCIC critical-path local-diamond discharge cover)**.** *Every accepted local-diamond discharge read of a* MetaCICCriticalPath$^{\uparrow}$ *packet must display the candidate residual route, the normalization-obstruction source order, and the downstream readiness boundary before it can be consumed by confluence or strong-normalization frontier packets. The accepted read is a finite packet route through*

$$S, N, O, U, D, H, C, P, L$$

together with the visible candidate residual budget, the obstruction-preserving source order, and the downstream consumer boundary. It exports no hidden global confluence theorem, no unbounded normalization theorem, and no host reduction equality.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathLocalDiamondDischargeCover`

Proof. First expose the socket route. The discharge-socket totality theorem Definition 765.8 forces every socket read through the displayed rows $S, N, O, U, D, H, C, P, L$, so a local-diamond discharge cannot start from an external confluence or normalization object.

Next retain the visible discharge and candidate residual surface. The downstream discharge visibility theorem Definition 765.9 keeps the downstream NameCert surface and the visible discharge row in the same packet provenance. The candidate residual route is therefore consumed as packet-local discharge data, not as a detached proof of confluence.

Now order the normalization side. By Definition 765.10, the read of S and N preserves the obstruction row O and the discharge socket D before any endpoint is consumed. This supplies the required normalization-obstruction source order for the local-diamond handoff.

Finally apply the downstream readiness boundary, Definition 765.11. Confluence and strong-normalization frontier packets receive only the bounded readiness surface assembled above. Since the assembled route has no coordinate for global confluence, unbounded normalization, or host reduction equality, those endpoints remain outside the discharge cover. □

Theorem 765.13 (MetaCIC critical-path root socket totality)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

every consistency-facing read first exposes the discharge socket D together with the displayed rows S, N, O, U, H, C, P, L. Thus the packet presents the socket as part of the root surface before the read may pass from the closed-strong-normalization row S to the normal-form row N.

Proof. Project the carrier through Definition 765.1. The row list of K includes the discharge socket D beside the closed-normalization source, normal-form endpoint, obstruction, handoff, transport, continuation, provenance, and local naming rows.

Use the consistency handoff of Definition 765.2. A consistency-facing consumer can travel from S to N only through the displayed route rows, and the theorem keeps D separate from a filled subject-reduction input.

Finally apply the obstruction boundary, Definition 765.3. It prevents the handoff row or componentwise transport from erasing O or converting D into a discharged bundle. Hence every accepted root read exposes D together with S, N, O, U, H, C, P, L before the consistency-facing passage is accepted. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRootSocketTotality`

Theorem 765.14 (MetaCIC critical-path handoff exhaustion)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet $K = (S, N, O, U, D, H, C, P, L)$, the finite handoff route is exhausted by the closed-normalization row S, normal-form row N, obstruction row O, handoff row U, discharge socket D, transport row H, route replay row C, provenance row P, and local naming row L. It has no coordinate for closed subject reduction, full closed consistency, global beta-conversion decidability, or quotient term equality.*

Proof. Start with the obligation surface. By Definition 765.20, the local certificate obligations are exactly carrier admission, visibility of S, N, O, U, D, componentwise transport through H, displayed route replay through C, and provenance and local naming through P, L.

Next stabilize the visible rows. The transport row stability theorem Definition 765.22 keeps S, N, O, U, D, C, P, L under H, while provenance nonescape and local naming exhaustion from Definition 765.23 and Definition 765.24 keep P and L from naming an outside theorem coordinate.

It remains to handle the blocked side. Apply discharge-socket nonescape, Definition 765.25. The socket D can be preserved and routed, but it cannot be filled by S, N, O, U, H, C, P, L. Therefore the finite handoff is exhausted by the nine displayed rows and contains no coordinate for the four excluded metatheoretic claims. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathHandoffExhaustion`

Theorem 765.15 (MetaCIC critical-path downstream unblock readiness)**.** *A downstream MetaCIC consumer may cite an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet only as a finite socket-aware route from closed strong normalization to normal-form consistency. The citation may use* $S, N, O, U, D, H, C, P, L$ *and the displayed socket route, but it may not treat the packet as a discharged subject-reduction theorem or as a full closed-consistency theorem.*

Proof. First expose the root socket. By Definition 765.13, every consistency-facing read displays D with the rest of K before the route from S to N is accepted.

Next exhaust the handoff route. Theorem 765.14 says that the finite route has only the nine displayed coordinates and no coordinate for closed subject reduction, full closed consistency, global beta-conversion decidability, or quotient term equality.

Finally combine discharge-socket coverage with socket-route totality. Theorems 765.26 and 765.28 force any downstream socket read to remain inside $S, N, O, U, D, H, C, P, L$ unless a separate subject-reduction input is displayed. Hence a downstream consumer may cite the packet as a socket-aware normalization-to-normal-form route, and not as either excluded discharged theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDownstreamUnblockReadiness`

Theorem 765.16 (MetaCIC critical-path subject-reduction socket budget)**.** *Every closed-consistency consumer of a* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must display the subject-reduction socket row* D *before it attempts to read full closed consistency. The visible route may use the closed-strong-normalization row* S*, normal-form consistency row* N*, obstruction row* O*, handoff row* U*, and structural rows* H, C, P, L*, but the transition from normal-form consistency to full closed consistency remains blocked until* D *is filled by an external subject-reduction discharge.*

Proof. Project the carrier $K = (S, N, O, U, D, H, C, P, L)$ from Definition 765.1. The row D is listed as the discharge-bundle socket, not as a supplied subject-reduction theorem.

Apply Definition 765.2. The consistency-facing route can pass from S to the normal-form row N, but it stops before full closed consistency unless the socket is separately filled.

Apply Definition 765.3, Definition 765.13, and Definition 765.25. The obstruction row O remains visible under U, H, C, P, L, so no consumer can erase the socket or reinterpret it as a discharged subject-reduction row. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSubjectReductionSocketBudget`

Theorem 765.17 (MetaCIC critical-path L10 discharge budget)**.** *The subject-reduction socket* D *of a* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet is tied to the L10 discharge budget through the four named completion faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. A consumer that claims the L10 exit route must expose those four object rows together with* D, H, C, P, L *before reading the exit certificate; it cannot use the exit route to bypass the subject-reduction socket or to read full closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10DischargeBudget`

Proof. Start with the L10 exit certificate already recorded for the chapter. The certificate names the four-object route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as the completion-facing discharge budget.

Apply Definition 765.128 and Definition 765.129. These results expose the four object rows as a bounded exit dependency rather than as a proof of closed subject reduction.

Finally combine the exit route with Definition 765.16. The same structural rows H, C, P, L replay and name D next to the four L10 faces, so the consumer cannot use the exit certificate to bypass the socket or promote normal-form consistency to full closed consistency. □

Theorem 765.18 (MetaCIC critical-path discharge socket case induction)**.** *Every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet whose discharge socket is inspected by candidate-mediated strong-normalization, confluence, decidability, and L10 completion consumers has exactly the visible cases named by the socket budget rows: filled local discharge, open subject-reduction obstruction, bounded checker handoff, or L10 residual deferral. The induction is over the finite carrier rows of the packet and exports no source-equivalence transport, hidden subject-reduction theorem, or full closed-consistency route.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDischargeSocketCaseInduction`

Proof. Project the carrier $K = (S, N, O, U, D, H, C, P, L)$ from Definition 765.1. The discharge socket D is the only row through which a consumer can ask whether the subject-reduction gap is filled, obstructed, handed to a bounded checker, or left for the L10 corridor.

Use Definition 765.16. It forces every closed-consistency read to display D beside the normalization, normal-form, obstruction, handoff, and structural rows, so no additional hidden socket case can be introduced by a consumer.

Use Definition 765.17. It separates the L10 residual case from the filled, obstructed, and bounded-checker cases by requiring the four completion faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the exit route can be read.

Finite row exhaustion now gives the stated induction. The visible rows are local discharge, subject-reduction obstruction, bounded checker handoff, and L10 residual deferral; because the proof only projects those rows, it does not use source-equivalence transport or promote the socket to a closed subject-reduction theorem. □

Theorem 765.19 (MetaCIC critical-path typed-example frontier route)**.** *Every TypedExamples gallery row that enters a* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must enter through the displayed discharge socket D, bounded checker handoff, and obstruction rows before it can be read by a consistency-facing consumer. The frontier route may exhibit typed examples as bounded evidence for the socket budget, but it cannot be read as subject reduction, confluence, strong normalization, global conversion decidability, source-equivalence transport, or full closed consistency.*

Proof. Use Definition 765.16. It places every closed-consistency attempt behind the subject-reduction socket D, so a typed-example row can only supply evidence at that socket boundary.

Next apply Definition 765.17. The L10 completion-facing exit route keeps the four completion faces and the socket rows visible, preventing a gallery example from bypassing the bounded checker or the obstruction ledger.

Finally use Definition 765.18. The visible cases are filled local discharge, open subject-reduction obstruction, bounded checker handoff, and L10 residual deferral. TypedExamples rows therefore remain frontier evidence for those cases and do not promote the packet to subject reduction, confluence, strong normalization, global conversion decidability, or full closed consistency. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathTypedExampleFrontierRoute`

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet is generated from closed-strong-normalization, normal-form consistency, subject-reduction obstruction, substitution-confluence-decidability handoff, discharge-bundle socket, transport, continuation, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 765.1, Definition 765.2, Definition 765.3, Definition 765.128, Definition 765.129, Definition 765.132, Definition 765.134, Definition 765.72, Definition 765.74, Definition 765.348, Definition 765.349, and Definition 765.350 bind the MetaCIC critical path, its mature L10 source package over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, the candidate frontier, the socket-separation witnesses, the public tail bridge, and the residual route surface present in the spine and child inputs.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not prove closed subject reduction, full closed consistency, arbitrary closed Church–Rosser, global beta-conversion decidability, checked Lean certificate coverage, or a public standard bridge.

Upgrade path: Further progress is formal-axis verification or a checked bridge for the same MetaCIC critical-path route.

Theorem 765.20 (MetaCIC critical-path NameCert obligation surface)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier*

$$K = (S, N, O, U, D, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *obligation surface consists exactly of the following nine row obligations:*

1. *carrier admission for the displayed finite packet* K*;*
2. *closed-strong-normalization route visibility through* S*;*
3. *normal-form consistency row visibility through* N*;*
4. *subject-reduction obstruction visibility through* O*;*
5. *substitution, confluence, and decidability handoff visibility through* U*;*
6. *discharge-bundle socket visibility through* D*;*
7. *componentwise* hsame *transport through* H*;*
8. *displayed* Cont *route replay through* C*;*
9. *provenance and local naming through* P *and* L*.*

It exports no closed subject-reduction theorem and no full closed-consistency theorem.

Proof. Project the accepted carrier through Definition 765.1. The definition displays the whole finite packet as

$$K = (S, N, O, U, D, H, C, P, L)$$

and assigns a distinct local role to each coordinate: S is the closed-strong-normalization route, N is the normal-form consistency row, O is the subject-reduction obstruction row, U is the substitution, confluence, and decidability handoff row, D is the discharge-bundle socket, H is componentwise transport, C is displayed route replay, P is provenance, and L is the local naming row. These rows give the nine listed obligations.

The consistency-facing part is bounded by Definition 765.2. It permits a consumer to pass from S to N only through the displayed route rows H, C, P, L, and it leaves D as a separate socket. Therefore the normal-form consistency read is not promoted to full closed consistency.

The subject-reduction side is bounded by Definition 765.3. The obstruction row O remains visible under U and under componentwise transport in H; agreement on the other rows cannot erase O, fill D, or convert the packet into closed subject reduction.

It remains only to check exhaustion. The carrier definition supplies no tenth coordinate for closed subject reduction, no coordinate for full closed consistency, no global beta-conversion decision procedure, and no quotient over MetaCIC terms. Hence every local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ obligation is one of the displayed row obligations above, and the two excluded theorem exports remain outside the packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNameCertObligationSurface`

Theorem 765.21 (MetaCIC typed candidate-frontier bridge)**.** *Every typed candidate-frontier read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$ *must expose the closed-strong-normalization row* S*, conditional confluence and bounded decidability handoff row* U*, subject-reduction obstruction row* O*, discharge socket* D*, transport row* H*, replay row* C*, provenance row* P*, and local* $\mathsf{NameCert}$ *row* L *before any consistency-facing consumer may use the normal-form row* N*. The bridge records those rows as a frontier surface and does not claim closed subject reduction.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathTypedCandidateFrontierBridge`

Proof. Use the consistency handoff. Definition 765.2 permits a consumer to move from S to N only through the displayed route rows and keeps the discharge socket D separate.

Use the obstruction boundary next. Definition 765.3 keeps O visible under the handoff row U and prevents D from becoming a filled subject-reduction theorem.

Finally apply the NameCert obligation surface. Definition 765.20 lists exactly the carrier, $S, N, O, U, D, H, C, P, L$ obligations, so a typed candidate-frontier read must display the stated rows before a consistency-facing use of N. □

Theorem 765.22 (MetaCIC critical-path transport row stability)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier*

$$K = (S, N, O, U, D, H, C, P, L),$$

componentwise transport through H *preserves the visible rows* S, N, O, U, D, C, P, L*. In particular, transport cannot erase the obstruction row* O*, cannot identify it with the discharge socket* D*, and cannot turn the displayed route from* S *to* N *into either closed subject reduction or full closed consistency.*

Proof. Project the accepted carrier through Definition 765.1. The row H is declared as componentwise hsame transport for S, N, O, U, D, P, L, while C records only the displayed continuation routes among the same finite rows.

The obstruction boundary in Definition 765.3 fixes the critical point: O remains visible under the handoff row U and under all transports in H. Hence a transported packet still has an obstruction row and still has a separate discharge socket D.

The consistency handoff in Definition 765.2 and the obligation surface in Definition 765.20 keep the route from S to N inside H, C, P, L. Therefore transport stabilizes the displayed rows without exporting either excluded theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket transport row stability`

Theorem 765.23 (MetaCIC critical-path provenance nonescape)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, the provenance row* P *records provenance only over the MetaCIC audit synthesis chapter and the cited sibling packets for subject-reduction obstruction, normalization audit, decidability boundary, and normal false exclusion. It exports neither closed subject reduction nor full closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket provenance nonescape`

Proof. Project the row P from Definition 765.1. Its declared source is the Pkg provenance over the MetaCIC audit synthesis chapter and the four sibling concrete packets named in the chapter opening.

The consistency-facing handoff of Definition 765.2 uses this provenance only to read the path from S to the normal-form row N. The socket D remains separate, so provenance does not close the gap to full closed consistency.

The obstruction boundary of Definition 765.3 keeps O visible and prevents the handoff row from filling D. Together with the exact obligation list in Definition 765.20, this shows that P records the cited packet origins and has no escape route to the two excluded theorem exports. □

Theorem 765.24 (MetaCIC critical-path local naming exhaustion)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier*

$$K = (S, N, O, U, D, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *row* L *names exactly the finite packet coordinates* $S, N, O, U, D, H, C, P, L$*. It adds no hidden theorem coordinate for closed subject reduction, full closed consistency, global beta-conversion decidability, or a quotient over MetaCIC terms.*

Proof. Project the local naming row from Definition 765.1. The displayed carrier has exactly the tuple coordinates $S, N, O, U, D, H, C, P, L$, and L is declared as the local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ row for that packet.

The obligation surface in Definition 765.20 exhausts the local surface by the nine row obligations. Its final exclusion rules out a tenth coordinate for closed subject reduction, full closed consistency, global beta-conversion decidability, or a quotient over MetaCIC terms.

The two boundary theorems preserve the same exhaustion. Definition 765.2 keeps the consistency read at the normal-form endpoint, and Definition 765.3 keeps the obstruction row and discharge socket distinct. Thus L names exactly the displayed finite coordinates and no hidden theorem coordinate. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket local naming exhaustion`

Theorem 765.25 (MetaCIC critical-path discharge socket nonescape)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, no downstream consumer can fill the discharge socket* D *unless it displays a separate certificate row for the missing subject-reduction input. The rows* S, N, O, U, H, C, P, L *may route, transport, name, and preserve the socket, but they do not discharge it.*

Proof. Project the accepted carrier through Definition 765.1. The definition names D as the discharge-bundle socket and not as a subject-reduction theorem.

Apply the consistency handoff and obstruction boundary. Definition 765.2 lets a consumer move from S to N only through the displayed route rows and stops unless D is separately filled. Definition 765.3 keeps the obstruction row O visible and refuses the conversion of D into a discharged bundle.

The remaining rows preserve this separation. Definition 765.20, Definition 765.22, Definition 765.23, and Definition 765.24 exhaust the carrier, transport, provenance, and naming surfaces without adding a separate subject-reduction certificate row. Hence no consumer can fill D from the packet alone. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDischargeSocketNonescape`

Theorem 765.26 (MetaCIC critical-path discharge-socket coverage)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet* $K = (S, N, O, U, D, H, C, P, L)$*, any consistency-facing consumer must either display a separate subject-reduction input filling the socket row* D *or remain bounded by the rows* $S, N, O, U, D, H, C, P, L$*. The packet itself exposes the socket as a named obligation, not as a closed subject-reduction theorem.*

Proof. Project the carrier through Definition 765.1. The packet displays the source row S, normal-form row N, obstruction row O, handoff row U, discharge socket D, transport row H, continuation row C, provenance row P, and local naming row L.

Use the consistency handoff and obstruction boundary, Definition 765.2 and Definition 765.3. The handoff reaches the normal-form endpoint through the displayed route, while the obstruction boundary keeps the subject-reduction gap visible and keeps D separate from a filled discharge.

Finally apply the obligation surface, transport row stability, local naming exhaustion, and discharge-socket nonescape from Definition 765.20, Definition 765.22, Definition 765.24, and Definition 765.25. These rows cover every accepted consumer read, so a consumer that does not present a separate subject-reduction input remains bounded by the displayed root-unblock packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket discharge socket coverage`

Theorem 765.27 (MetaCIC critical-path subject-reduction socket separation)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, the rows* S, N, O, U, H, C, P, L *preserve the displayed route and keep the obstruction row* O *visible, but they cannot identify* O *with the discharge socket* D*. They also cannot promote the normal-form consistency row* N *to closed subject reduction without a separate subject-reduction certificate row that fills* D*.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSubjectReductionSocketSeparation`

Proof. Project the accepted packet through Definition 765.1. The carrier lists O as the subject-reduction obstruction row and D as the discharge-bundle socket, so the two rows are displayed as separate coordinates of the finite packet.

Use the consistency handoff and obstruction boundary. Theorems 765.2 and 765.3 preserve the route from S to N while keeping the obstruction visible under the handoff row U and transport row H.

Next apply discharge-socket nonescape and socket-route totality. Theorems 765.25 and 765.28 force every socket-facing read to keep D as a socket row unless a separate subject-reduction certificate is displayed.

Finally use discharge-socket coverage. Theorem 765.26 says that a consumer without the separate certificate remains bounded by $S, N, O, U, D, H, C, P, L$. Hence preserving the route and obstruction never identifies O with D, and the normal-form endpoint cannot be read as closed subject reduction. □

Theorem 765.28 (MetaCIC critical-path socket route totality)**.** *Any accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer route that mentions the discharge socket* D *must also display the strong-normalization*

row S, normal-form row N, obstruction row O, handoff row U, transport row H, continuation row C, provenance row P, and local name row L. The socket is therefore a visible route obligation, not a hidden closed subject-reduction theorem.

Proof. Use the consistency handoff and obstruction boundary, Definition 765.2 and Definition 765.3. They route the read from S to N while keeping O visible and keeping D separate from any closed discharge.

Now apply discharge-socket nonescape and root route totality, Definition 765.25 and Definition 765.42. Together they require the socket-facing consumer to retain $S, N, O, U, D, H, C, P, L$ as the displayed row inventory, so no hidden closed subject-reduction theorem is imported. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket socket route totality`

Theorem 765.29 (MetaCIC critical-path subject-reduction socket factorization)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier $K = (S, N, O, U, D, H, C, P, L)$, any route attempting to use the discharge socket D must factor through the displayed rows $S, N, O, U, D, H, C, P, L$. Along that route the obstruction row O remains visible, and D remains a socket unless a separate subject-reduction certificate row is displayed by the consumer.*

Proof. Start with a socket-facing route. The consistency handoff and obstruction boundary, Definition 765.2 and Definition 765.3, route any consistency read through the visible packet while keeping O present.

Now use discharge-socket nonescape, Definition 765.25. It prevents the displayed packet rows from filling D by themselves, so the only admissible way to discharge the socket is to show a separate subject-reduction certificate row.

Finally apply socket route totality, Definition 765.28. Any route that mentions D must retain $S, N, O, U, D, H, C, P, L$ as its visible row inventory. Hence the attempted discharge factors through the displayed packet and cannot hide O or turn D into a closed subject-reduction theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSubjectReductionSocketFactorization`

Theorem 765.30 (MetaCIC critical-path obstruction-ledger exhaustion)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet $K = (S, N, O, U, D, H, C, P, L)$, the visible obstruction row O and socket row D exhaust the blocked subject-reduction routes. No hidden closed-consistency coordinate can be read from S, N, U, H, C, P, L once the obstruction and socket rows remain visible.*

Proof. Read O and D from the carrier definition. The former records the subject-reduction obstruction, and the latter records the discharge-bundle socket; neither is derived from the normal-form row or handoff row.

The consistency handoff and obstruction boundary fix the blocked route. By Definition 765.2, the positive route reaches only N unless a separate discharge is supplied. By Definition 765.3, O cannot be erased and D cannot be converted into a supplied theorem by agreement on the other rows.

Use the obligation surface, transport row stability, local naming exhaustion, and discharge-socket nonescape to close the row inventory. Theorems Definition 765.20, Definition 765.22, Definition 765.24, and Definition 765.25 leave no carrier coordinate through which a hidden closed-consistency read can bypass O and D. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket obstruction ledger exhaustion`

Theorem 765.31 (MetaCIC critical-path substitution-confluence socket ledger)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, any consumer that combines closed substitution, conditional confluence, and bounded decidability must read the handoff row* U *together with the obstruction row* O *and discharge socket* D *before it may use the normal-form row* N*. The route cannot promote* U *into closed subject reduction, global Church–Rosser, or full consistency.*

Proof. Start with the consistency handoff, Definition 765.2. It lets a consumer reach the normal-form row N only along the displayed packet route and leaves the subject-reduction discharge socket separate.

Next attach the obstruction and socket rows. Theorems 765.3 and 765.25 keep O visible and keep D as a socket rather than a supplied closed subject-reduction theorem.

Finally use Definition 765.30. Since the obstruction ledger is exhausted by the visible O, D boundary, a substitution, confluence, and decidability consumer can use U only as a bounded handoff row before N is read. Thus the socket ledger has no route to closed subject reduction, global Church–Rosser, or full consistency. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket substitution confluence socket ledger`

Theorem 765.32 (MetaCIC critical-path normal-form route coverage)**.** *Every normal-form readback route accepted by a* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet factors through* $S \to N$ *with the obstruction row* O*, discharge socket* D*, transport row* H*, continuation row* C*, provenance row* P*, and local naming row* L *still visible. Such a route cannot drop the blocked subject-reduction rows while preserving the accepted packet.*

Proof. Start with the carrier and consistency handoff. The carrier names S and N as distinct rows, and Definition 765.2 makes the displayed continuation from S to N the only consistency-facing handoff.

Next keep the obstruction data visible. The obstruction boundary and discharge-socket nonescape, Definition 765.3 and Definition 765.25, preserve O and D as the blocked subject-reduction rows along that same route.

Finally apply the obligation surface, transport row stability, and local naming exhaustion. Theorems Definition 765.20, Definition 765.22, and Definition 765.24 keep H, C, P, L attached to the same finite packet, so every normal-form readback route factors through $S \to N$ with the obstruction, socket, transport, continuation, provenance, and naming rows still displayed. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket normal form route coverage`

Theorem 765.33 (MetaCIC critical-path handoff row totality)**.** *Every consistency-facing read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must pass through the complete displayed row list*

$$S, N, O, U, D, H, C, P, L.$$

In particular, a read that mentions the handoff row U *without the strong-normalization row* S*, normal-form row* N*, obstruction row* O*, discharge socket* D*, transport row* H*, route row* C*, provenance row* P*, and local naming row* L *is not a read of the accepted critical-path packet.*

Proof. Start from Definition 765.1. It displays the accepted carrier as $K = (S, N, O, U, D, H, C, P, L)$, with no abbreviated carrier for consistency-facing consumers.

The existing handoff theorems use the whole packet surface. Definition 765.2 reads the path from S to N through route, transport, provenance, and naming rows while leaving D separate. Definition 765.3 and Definition 765.25 keep O and D visible for every such read.

Finally apply the obligation, transport, provenance, and naming exhaustion results. Definition 765.20, Definition 765.22, Definition 765.23, and Definition 765.24 make $S, N, O, U, D, H, C, P, L$ the total row inventory. A consistency-facing read therefore cannot drop one of these rows and remain a read of the accepted packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket handoff row totality`

Theorem 765.34 (MetaCIC critical-path normal-form readback boundary)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the normal-form readback boundary stops at the row* N*. It may expose the normal-form endpoint supplied after* S *and the visible obstruction and socket rows* O, D*, but it does not export closed subject reduction, full closed consistency, global beta-conversion decidability, or a quotient over MetaCIC terms.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket normal form readback boundary`

Proof. Project the normal-form row from Definition 765.1. The row N is declared as the normal-form consistency row, while the subject-reduction obstruction and discharge socket remain separate rows O and D.

Apply Definition 765.2. It routes a consistency-facing consumer from S to N and explicitly stops before full closed consistency unless the discharge socket is separately filled.

The boundary is stable under the rest of the packet. Definition 765.3, Definition 765.22, Definition 765.23, Definition 765.24, Definition 765.25, and Definition 765.33 keep the obstruction, socket, row inventory, provenance, and local naming visible. Thus the readback reaches N and no stronger theorem export. □

Theorem 765.35 (MetaCIC critical-path normalization source visibility)**.** *Every consistency-facing read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *must expose the closed-strong-normalization source row* S *before it reads the normal-form row* N*. A read that starts at* N *without* S *is not a read of the accepted root-unblock packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket normalization source visibility`

Proof. Project the carrier through Definition 765.1. The packet displays S as the closed-strong-normalization route and N as the normal-form consistency row, with no abbreviated carrier containing only N.

Apply Definition 765.2 and Definition 765.34. The handoff routes consistency-facing consumers from S to N, while the readback boundary stops the exported claim at N.

The obstruction and socket rows stay attached by Definition 765.3 and Definition 765.25. Hence the read of N is visible only after S has been displayed inside the same packet. □

Theorem 765.36 (MetaCIC critical-path decidability handoff visibility)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the row* U *is only the visible substitution, confluence, and decidability handoff row. It is not a beta-conversion oracle, a quotient over MetaCIC terms, or a hidden closed-consistency decision procedure.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket decidability handoff visibility`

Proof. Read U from Definition 765.1. Its role is a handoff row inside the finite carrier, while the same carrier separately displays the source row S, normal-form row N, obstruction row O, and discharge socket D.

Use Definition 765.2, Definition 765.3, and Definition 765.34. These results route consistency reads through S, N, keep the obstruction visible, and prevent the normal-form endpoint from becoming a stronger theorem export.

Finally apply Definition 765.25. Since D remains a separate socket, U cannot be read as an oracle that fills the blocked subject-reduction or beta-conversion obligations. □

Theorem 765.37 (MetaCIC critical-path subject-reduction socket audit boundary)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the subject-reduction socket* D *remains an audit boundary until a separate discharge row is displayed. The packet may route to* D*, but it does not identify* D *with closed subject reduction.*

Proof. Start with the carrier definition. The row D is displayed as a discharge-bundle socket, while O records the subject-reduction obstruction and U records only the visible handoff row.

Apply Definition 765.3 and Definition 765.25. The first keeps the obstruction row visible; the second prevents any packet consumer from treating the socket as already discharged.

The consistency handoff and normal-form boundary, Definition 765.2 and Definition 765.34, keep the root read at $S \to N$ unless an additional discharge row is supplied. Thus D is an audit boundary rather than a closed subject-reduction theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket subject reduction socket audit boundary`

Theorem 765.38 (MetaCIC critical-path carrier admission)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier*

$$K = (S, N, O, U, D, H, C, P, L),$$

carrier admission exposes exactly the nine finite BHist *rows displayed in Definition 765.1: the closed-strong-normalization route* S*, the normal-form consistency row* N*, the subject-reduction obstruction row* O*, the substitution, confluence, and decidability handoff row* U*, the discharge-bundle socket* D*, the componentwise transport row* H*, the continuation row* C*, the provenance row* P*, and the local naming row* L*.*

Proof. Project the accepted carrier through Definition 765.1. The carrier is introduced as the finite tuple $K = (S, N, O, U, D, H, C, P, L)$, and the definition assigns one BHist role to each coordinate.

The first five projections give the visible mathematical rows: S for closed strong normalization, N for the normal-form consistency endpoint, O for the subject-reduction obstruction, U for the substitution, confluence, and decidability handoff, and D for the discharge-bundle socket.

The remaining projections give the certificate infrastructure: H stores the componentwise transports, C stores the displayed continuations, P records provenance, and L records the local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ row. Since the same definition explicitly excludes any coordinate for closed subject reduction, full closed consistency, global beta-conversion decidability, or a quotient over MetaCIC terms, carrier admission has exactly the nine listed rows and no hidden row. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket carrier admission`

Theorem 765.39 (MetaCIC critical-path route replay)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, the continuation coordinate* C *replays only the displayed route from* S *to* N*, the displayed handoff route from* U *to the checker and confluence boundaries, and the displayed route from* O *to the discharge socket* D*. It cannot synthesize closed subject reduction and cannot turn the normal-form consistency endpoint into full closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket route replay`

Proof. Read the continuation coordinate from Definition 765.1. Its declared routes are the route from the strong-normalization row to the normal-form row, the route from the handoff row to the checker and confluence boundaries, and the route from the obstruction row to the discharge socket.

The consistency-facing route is already bounded by Definition 765.2. It lets a consumer pass from S to N through the displayed route rows, but it leaves D as a separate socket and therefore does not export full closed consistency.

The obstruction-facing route is bounded by Definition 765.3. The row O remains present under the handoff row U and under componentwise transport, so route replay cannot erase the obstruction or fill the discharge socket. Thus C replays only the displayed routes and supplies no closed subject-reduction theorem. □

Theorem 765.40 (MetaCIC critical-path route exhaustion)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, every critical-path route replay is exhausted by the displayed rows* $S, N, O, U, D, H, C, P, L$*. The replay can expose the closed-strong-normalization row* S*, the normal-form consistency row* N*, the obstruction row* O*, the substitution-confluence-decidability handoff row* U*, and the discharge socket* D*, but it cannot use route replay to fill* D*, erase* O*, or turn* U *into closed subject reduction or full closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRouteExhaustion`

Proof. Project the accepted carrier through Definition 765.1. The packet has exactly the rows $S, N, O, U, D, H, C, P, L$, and Definition 765.20 lists those rows as the complete local obligation surface.

Now apply Definition 765.39. The continuation row C replays only the displayed route from S to N, the handoff route from U to the checker and confluence boundaries, and the obstruction route from O to D.

The boundary results rule out the stronger reads. By Definition 765.2, the route from S to N stops at the normal-form endpoint unless D is separately filled. By Definition 765.3, O remains visible and U does not discharge the socket. Hence route replay is exhausted by the displayed rows and cannot export the excluded theorem claims. □

Theorem 765.41 (MetaCIC critical-path root discharge exactness)**.** *For every root-facing* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer of an accepted packet* $K = (S, N, O, U, D, H, C, P, L)$*, the discharge socket* D *may be treated as exact only as the displayed finite socket row. The exactness read requires the rows* $S, N, O, U, D, H, C, P, L$ *to remain visible, and it imports no closed subject-reduction row into the packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket root discharge exactness`

Proof. Project the consumer through Definition 765.1. The packet displays D as a discharge-bundle socket alongside the strong-normalization row, normal-form row, obstruction row, handoff row, transport row, continuation row, provenance row, and local naming row.

The consistency handoff and obstruction boundary keep the socket exact without closing it. Apply Definition 765.2 to stop the route at the normal-form row N, and apply Definition 765.3 to keep O visible while U remains only a handoff row.

Finally use discharge-socket nonescape and route exhaustion, Definition 765.25 and Definition 765.40. These force every discharge read through the displayed socket and exhaust every route inside $S, N, O, U, D, H, C, P, L$, so exactness never imports a closed subject-reduction row. □

Theorem 765.42 (MetaCIC critical-path root route totality)**.** *Every root route from the closed-strong-normalization row S to the normal-form readback row N is exhausted by the three displayed continuation legs in C: the route from S to N, the handoff route from U to the checker and confluence boundaries, and the obstruction route from O to the discharge socket D. The obstruction row O and the discharge socket D remain visible throughout the total route inventory.*

Proof. Start with route replay from Definition 765.39. It names exactly the three continuation legs carried by C, and no leg is a hidden closed subject-reduction or full closed-consistency route.

Route exhaustion and handoff row totality make the inventory total. The theorem Definition 765.40 keeps every replay inside $S, N, O, U, D, H, C, P, L$, while Definition 765.33 accounts for the displayed handoff row U without adding another route coordinate.

Carrier admission supplies the root packet on which totality is read. By Definition 765.38, the carrier has exactly the nine displayed rows, including O and D. Hence every root route from S to normal-form readback at N is one of the three continuation legs in C. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket root route totality`

Theorem 765.43 (MetaCIC critical-path root consumer readiness)**.** *Downstream consumers may read normal-form consistency readiness from an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet only as the finite obligation surface $S, N, O, U, D, H, C, P, L$. They may not read the packet as full closed consistency, closed subject reduction, or an undisplayed theorem export beyond the root discharge and route obligations.*

Proof. Begin with the NameCert obligation surface of Definition 765.20. It gives the downstream consumer a finite packet surface and requires the local naming row to preserve the displayed rows.

Normal-form readback and local naming keep the readiness claim bounded. Use Definition 765.34 to stop readback at N, and use Definition 765.24 to prevent the local name from exporting a hidden theorem coordinate.

It remains to account for discharge and route obligations. Apply Definition 765.41 and Definition 765.42. The first keeps D as an exact visible socket rather than a closed subject-reduction proof, and the second exhausts the root routes through the displayed continuation legs. Therefore downstream readiness is exactly the finite packet obligation surface. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRootConsumerReadiness`

Theorem 765.44 (MetaCIC critical-path discharge row visibility)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier $K = (S, N, O, U, D, H, C, P, L)$, the discharge socket row D remains visible under every critical-path route replay. The rows S, N, O, U, H, C, P, L may transport, route, name, and preserve the packet, but they cannot fill D or convert it into a closed subject-reduction or full closed-consistency theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket discharge row visibility`

Proof. Begin with carrier admission. By Definition 765.38, the row D is one of the nine displayed BHist rows of the accepted packet and is recorded specifically as the discharge-bundle socket.

Route replay preserves that row. Apply Definition 765.39 and Definition 765.40; the continuation row C replays only the displayed routes among $S, N, O, U, D, H, C, P, L$, and replay cannot fill D or erase the obstruction row O.

The boundary and naming rows rule out a disguised discharge. Use Definition 765.3, Definition 765.25, and Definition 765.24. They keep O and D distinct, require a separate subject-reduction input before D can be filled, and prevent the local name row from exporting a hidden theorem coordinate. □

Theorem 765.45 (MetaCIC critical-path local name nonescape)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, the local name row* L *names only the displayed packet and its listed route obligations. It exports no closed subject-reduction theorem, no full closed-consistency theorem, no global beta-conversion decision procedure, and no quotient over MetaCIC terms.*

Proof. Read the local row from Definition 765.38 and Definition 765.24. The carrier exposes L as the local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ row for the finite packet $S, N, O, U, D, H, C, P, L$, and local naming is exhausted by those coordinates.

The route inventory remains finite under replay. Use Definition 765.39 and Definition 765.40. They keep every replayed route inside the displayed tuple and provide no extra named coordinate for closed subject reduction or full closed consistency.

The remaining boundaries preserve the same nonescape claim. Apply Definition 765.20, Definition 765.3, and Definition 765.44. The obligation surface lists the local rows, the obstruction boundary keeps O and D visible, and discharge-row visibility prevents L from naming a filled theorem in place of the displayed socket. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket local name nonescape`

Definition 765.46 (MetaCIC critical-path frontier slice)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier*

$$K = (S, N, O, U, D, H, C, P, L),$$

the frontier slice is the finite BHist *packet*

$$F = (K, R, B, Q),$$

where K *is the accepted carrier of Definition 765.1,* $R = (S, N, O, U, D, H, C, P, L)$ *is the visible route inventory,* $B = D$ *is the blocked subject-reduction socket, and* Q *is the downstream consumer query that asks for either a consistency-facing read or a subject-reduction-facing read of the packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierSliceConsumerCertificate`

Theorem 765.47 (MetaCIC critical-path frontier coverage)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$ *and every frontier slice* $F = (K, R, B, Q)$*, every consistency-facing or subject-reduction-facing consumer read factors through one of the displayed slice rows* K, R, B, Q*. In particular, the consumer can read the carrier, the route inventory* $R = (S, N, O, U, D, H, C, P, L)$*, the blocked socket* $B = D$*, and the downstream query* Q*, but it cannot read an additional theorem coordinate for closed subject reduction or full closed consistency.*

Proof. Project the slice through Definition 765.46. The row K is the accepted carrier of Definition 765.1, R is exactly the displayed route inventory, B is the same row as the discharge socket D, and Q records the consumer read.

For a consistency-facing read, apply Definition 765.2 and Definition 765.33. The handoff from S to N must pass through the complete displayed inventory and leaves D as a socket, so the read factors through K, R, B, Q.

For a subject-reduction-facing read, apply Definition 765.3, Definition 765.25, and Definition 765.24. These results keep the obstruction row visible, keep D undischarged, and exhaust the local name by the displayed carrier rows. Hence the frontier slice covers every accepted consumer read and supplies no hidden theorem coordinate. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierCoverage`

Theorem 765.48 (MetaCIC critical-path route-ledger totality)**.** *For every frontier slice $F = (K, R, B, Q)$ over an accepted carrier $K = (S, N, O, U, D, H, C, P, L)$, the route ledger is exhausted by the inventory*

$$R = (S, N, O, U, D, H, C, P, L).$$

No replay, handoff, or query row can add a closed-consistency coordinate outside this inventory.

Proof. Read the route inventory from Definition 765.46. By definition, R is not an abstract ledger; it is the concrete tuple $S, N, O, U, D, H, C, P, L$ attached to the accepted carrier.

Apply Definition 765.40. Every critical-path route replay is already exhausted by $S, N, O, U, D, H, C, P, L$, and route replay cannot fill D, erase O, or turn U into closed subject reduction or full closed consistency.

The slice adds only $B = D$ and the query row Q. By Definition 765.25, B remains a socket rather than a filled theorem. By Definition 765.47, Q only asks for a read through the displayed slice rows. Thus the ledger is total at R and cannot acquire a closed-consistency coordinate from replay, handoff, or query readback. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierSlice route ledger totality`

Theorem 765.49 (MetaCIC critical-path frontier nonescape)**.** *For every frontier slice $F = (K, R, B, Q)$ over an accepted carrier $K = (S, N, O, U, D, H, C, P, L)$, no transported route, replayed route, or downstream query can convert the visible obstruction row O and socket row $B = D$ into closed subject reduction or full closed consistency.*

Proof. Start from the carrier and slice definitions. The carrier definition exposes O as the subject-reduction obstruction row and D as the discharge-bundle socket, while the frontier slice records the same socket as $B = D$.

Transport preserves the obstruction boundary. Apply Definition 765.3 and Definition 765.24; transported agreement on the other rows cannot erase O, fill D, or add a hidden named theorem coordinate.

Replay and query readback remain inside the same inventory. Use Definition 765.39, Definition 765.40, and Definition 765.48. They confine replay to $S, N, O, U, D, H, C, P, L$ and make Q a read of the displayed slice rather than an escape from it. Therefore the frontier slice preserves the obstruction row and socket row exactly, with no route to closed subject reduction or full closed consistency. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierSlice nonescape`

Theorem 765.50 (MetaCIC critical-path obstruction-socket separation)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, the obstruction row* O *and the discharge socket* D *remain distinct downstream obligations. Agreement on* S, N, U, H, C, P, L *cannot identify* O *with* D*, cannot erase* O*, cannot fill* D*, and cannot turn the handoff row* U *into closed subject reduction or full closed consistency.*

Proof. Read the two rows from Definition 765.1. The row O is the subject-reduction obstruction row, while D is the discharge-bundle socket naming the missing subject-reduction input.

Apply Definition 765.3. It keeps O visible under the handoff row U and under componentwise transport in H, and it explicitly refuses the conversion of D into a discharged bundle.

Finally use Definition 765.20 together with Definition 765.39. The obligation surface lists O and D separately, and the route replay only connects the obstruction row to the discharge socket as displayed data. Therefore downstream consumers inherit two separate obligations rather than a closed subject-reduction theorem or full closed-consistency theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathObstructionSocketSeparation`

Theorem 765.51 (MetaCIC critical-path handoff row coverage)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, the handoff row* U *covers only the displayed substitution, confluence, and decidability handoffs used before the consistency read. Downstream consumers must still carry the obstruction row* O *and the discharge socket* D *as separate rows, and the coverage of* U *cannot fill* D*, erase* O*, or promote the route from* S *to* N *to closed subject reduction or full closed consistency.*

Proof. Project U from the carrier definition. Its declared role is the substitution, confluence, and decidability handoff row; it is not a closed subject-reduction row and not a full closed-consistency row.

Use Definition 765.2. The consistency-facing consumer may move from S to N only through the displayed route rows and cannot read a full closed-consistency theorem unless D is separately filled.

Use Definition 765.3 and Definition 765.39. The obstruction row O remains visible under U, while C replays the handoff and obstruction routes without changing their roles.

The obligation surface of Definition 765.20 then supplies the final coverage check: $S, N, O, U, D, H, C, P, L$ are the complete rows, with U only one row among them. Thus handoff coverage does not collapse the downstream obligations carried by O and D. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket handoff row coverage`

Theorem 765.52 (MetaCIC critical-path provenance naming)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, the provenance row* P *and the local naming row* L *preserve exactly the public NameCert provenance cited by this chapter: the subject-reduction obstruction packet, the normalization audit packet, the decidability boundary packet, and the normal false exclusion packet, together with the local* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *name. They introduce no additional public provenance source.*

Proof. Project the provenance and naming coordinates in Definition 765.1. The row P is declared as the Pkg provenance over the MetaCIC audit synthesis chapter and the four sibling concrete packets cited in the chapter opening, while L is declared as the local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ row.

The four public sibling packets are precisely the subject-reduction obstruction packet, the normalization audit packet, the decidability boundary packet, and the normal false exclusion packet. The carrier definition uses these rows to name the critical path and does not add another public packet coordinate.

The two boundary theorems preserve this reading. Definition 765.2 keeps the consistency route attached to the normalization and normal false exclusion rows, and Definition 765.3 keeps the obstruction route attached to the subject-reduction boundary. Consequently P and L preserve the cited public provenance and local name exactly, with no extra provenance source exported by the chapter. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket provenance naming`

Definition 765.53 (MetaCIC critical-path frontier-rank carrier)**.** *A frontier-rank read of* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *is a finite packet*

$$Q = (O, R, D, B, C, P, N)$$

whose rows are an open-node row O, a dependency-ready row R, a downstream-rank row D, an obstruction ledger B, a replay route C, package provenance P, and a local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *row N. The open-node row names the still-visible frontier node, the dependency-ready row records which cited packet rows are already available, the downstream-rank row records the finite consumer rank, the obstruction ledger records the subject-reduction socket and blocked theorem exports, the replay route stores the* Cont *paths used by scheduler-facing consumers, and the provenance row ties the read to the public packet of Definition 765.1.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierRankReplayClosure`

Theorem 765.54 (MetaCIC critical-path open-node exhaustion)**.** *Every accepted open-node read of* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *factors through a frontier-rank packet $Q = (O, R, D, B, C, P, N)$. The read may expose the node, its dependency-ready rows, its downstream rank, its obstruction ledger, replay route, provenance, and local name, but it has no additional coordinate for a hidden frontier node or an unranked scheduling obligation.*

Proof. Project the accepted frontier-rank carrier of Definition 765.53. The open-node coordinate is O, and every scheduler-facing dependency is recorded by one of R, D, B, C, P, N.

The underlying critical-path packet of Definition 765.1 already exhausts the mathematical rows used by this read. The frontier-rank carrier only records which of those rows are open, ready, ranked, obstructed, replayed, and named.

Inspect the excluded coordinates. Since Q contains no hidden frontier node and no unranked scheduling obligation, every accepted open-node read factors through the displayed finite packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierRank open node exhaustion`

Theorem 765.55 (MetaCIC critical-path dependency-route nonescape)**.** *For every accepted frontier-rank packet $Q = (O, R, D, B, C, P, N)$, dependency routing is exhausted by the displayed rows R, B, C, P, N. It cannot appeal to hidden scheduler state, host graph reachability, or an unledgered dependency edge outside the obstruction ledger and replay route.*

Proof. Read the dependency-ready row R, obstruction ledger B, replay route C, provenance row P, and local naming row N from Definition 765.53. These are the only coordinates that can justify a dependency route.

The obstruction ledger records the blocked subject-reduction socket and theorem exports, while the replay route records the displayed Cont paths available to consumers. Provenance attaches those rows to the public critical-path packet rather than to a host-side graph.

No coordinate of Q stores hidden scheduler state, host graph reachability, or an unledgered dependency edge. Thus every dependency route remains inside the finite ledgered packet. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierRank dependency route nonescape

Theorem 765.56 (MetaCIC critical-path Lean handoff surface)**.** *The paper frontier-rank packet $Q = (O, R, D, B, C, P, N)$ is the exact surface for a later Lean formalization of the* MetaCICCriticalPath$^{\uparrow}$ *root-unblock obligation. A Lean target should expose the open-node row, dependency-ready row, downstream-rank row, obstruction ledger, replay route, package provenance, and local NameCert row, and should not add scheduler state, host reachability, or unledgered dependency edges.*

Proof. The carrier definition gives the full handoff surface: O for the open node, R for dependency readiness, D for downstream rank, B for the obstruction ledger, C for replay, P for provenance, and N for local naming.

Open-node exhaustion shows that every accepted open-node read factors through these rows. Dependency-route nonescape shows that routing cannot leave these rows for hidden scheduler state, host graph reachability, or unledgered edges.

Therefore the Lean-facing obligation is coordinatewise exact. A formal target with precisely these rows verifies the same paper surface, while any extra scheduling coordinate would certify a different object. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathLeanHandoffSurface
↪ variant BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierRank lean handoff surface

Theorem 765.57 (MetaCIC critical-path discharge-socket locality)**.** *For every accepted critical-path packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

the discharge socket row D remains localized under the transport row H, replay route C, provenance row P, and local naming row L. A consumer may cite D as the displayed open socket for the consistency and subject-reduction frontier, but it cannot move D into a hidden global discharge, a closed subject-reduction theorem, or a full closed-consistency theorem.

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket discharge socket locality

Proof. Project the accepted packet $K = (S, N, O, U, D, H, C, P, L)$ from Definition 765.1. The row D is a visible packet coordinate, while H, C, P, L are the only rows that can transport, replay, provenance, and name that coordinate.

The consistency and obstruction boundaries keep the socket local. Definition 765.2 routes the consistency read through the displayed rows and stops at D, while Definition 765.3 keeps the obstruction row visible instead of converting D into a discharged bundle.

The remaining packet theorems preserve the same locality. Definition 765.20, Definition 765.22, and Definition 765.23 exhaust the certified rows and forbid a provenance escape. Hence every read of D stays under H, C, P, L and exports no closed theorem beyond the displayed socket. □

Theorem 765.58 (MetaCIC critical-path normalization-frontier factorization)**.** *Every normal-form consistency read of an accepted packet*

$$K = (S, N, O, U, D, H, C, P, L)$$

factors through three sibling rows: the normalization audit row $S \to N$, the normal-false exclusion recorded at the endpoint N, and the subject-reduction obstruction row O. The read cannot bypass these rows by treating D as a completed discharge or by exporting a closed consistency theorem.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket normalization frontier factorization`

Proof. Start with the normal-form route in the accepted packet K. The consistency handoff of Definition 765.2 is exactly the route from the source row S to the normal-form row N, so every such read first factors through the normalization audit and its normal-false exclusion endpoint.

Next read the obstruction side. Definition 765.3 keeps O as the visible subject-reduction obstruction, and Definition 765.57 keeps D local to the displayed transport, replay, provenance, and naming rows.

Finally apply the obligation and provenance surfaces. Definition 765.20, Definition 765.22, and Definition 765.23 leave no row through which a normal-form read can skip the audit endpoint or the obstruction row. Thus the read factors through the stated three-row frontier. □

Theorem 765.59 (MetaCIC critical-path bounded-checker handoff totality)**.** *For every accepted packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

the bounded-checker handoff row U exhausts the substitution, confluence, and decidability reads available to downstream consumers. It presents those reads as bounded handoff obligations and does not export closed subject reduction, full closed consistency, arbitrary closed Church–Rosser, or global beta-conversion decidability.

Proof. Project the row U from the accepted packet K. By Definition 765.20, U is one coordinate in the nine-row NameCert surface, not a replacement for the obstruction row O or the discharge socket D.

The boundary theorems determine what U can hand off. Definition 765.2 bounds the consistency read at the normal-form endpoint, and Definition 765.3 prevents the handoff from erasing the subject-reduction obstruction.

Transport and provenance keep the checker reads inside the same finite packet. Use Definition 765.22, Definition 765.23, Definition 765.57, and Definition 765.58. The only downstream checker surface left is the bounded handoff through U, so substitution, confluence, and decidability are exhausted there without exporting the closed theorem claims. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket bounded checker handoff totality`

Theorem 765.60 (MetaCIC critical-path substitution handoff visibility)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier $K = (S, N, O, U, D, H, C, P, L)$, the substitution handoff exposed by U is visible only as one displayed row of the finite packet of Definition 765.1. It may be replayed through C, transported through H, and named through P, L, but it cannot fill the discharge socket D, erase the obstruction row O, or export closed subject reduction.*

Proof. Project U from the carrier K in Definition 765.1. The definition assigns U the role of the substitution, confluence, and decidability handoff row, while D is a distinct discharge-bundle socket and O is a distinct subject-reduction obstruction row.

Apply Definition 765.51. It already fixes U as a coverage row for the displayed handoffs and refuses any collapse of the downstream obligations carried by O and D.

Now apply Definition 765.25 and Definition 765.50. These results keep D as a socket and keep O separate from that socket under route replay and packet readback.

Thus a substitution-facing consumer can read the handoff only through the displayed packet coordinates H, C, P, L. The same read never supplies the missing discharge input, so it cannot close subject reduction. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSubstitutionHandoffVisibility`

Theorem 765.61 (MetaCIC critical-path confluence-decidability socket)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, every confluence-facing or decidability-facing use of the handoff row remains socket-mediated by the displayed rows* O, D, H, C, P, L*. Such a use may route through the finite packet, but it has no independent coordinate for arbitrary Church–Rosser, global beta-conversion decidability, closed subject reduction, or full closed consistency.*

Proof. Read the packet coordinates from Definition 765.1. The row U names the confluence and decidability handoffs together with substitution support, while C records the displayed continuation routes from U to the checker and confluence boundaries.

Use Definition 765.39 and Definition 765.40. They confine route replay to the visible rows and rule out hidden theorem coordinates beyond $S, N, O, U, D, H, C, P, L$.

The socket side is fixed by Definition 765.3 and Definition 765.25. The obstruction row O remains visible, and the discharge socket D remains separate from a supplied subject-reduction proof.

Consequently confluence and decidability uses are mediated by the same obstruction, socket, transport, route, provenance, and naming rows. They do not create an extra decision procedure or confluence theorem outside the finite packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket confluence decidability socket`

Theorem 765.62 (MetaCIC critical-path normalization-obstruction route coverage)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, every normalization-to-normal-form read from* S *to* N *keeps the obstruction row* O *visible along the route. The read may reach the normal-form consistency row through* H, C, P, L*, but it cannot pass through the route while hiding* O*, filling* D*, or upgrading the normal-form endpoint to closed subject reduction or full closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNormalizationObstructionRouteCoverage`

Proof. Start with the consistency handoff of Definition 765.2. It permits a consumer to read from the closed-strong-normalization row S to the normal-form consistency row N only through the displayed route rows H, C, P, L.

Next use Definition 765.3. The obstruction row O remains visible under the handoff row U and under componentwise transport, so the same route cannot be read as if the obstruction had disappeared.

Apply Definition 765.34 and Definition 765.40. They keep normal-form readback at the endpoint N and exhaust route replay inside the displayed packet.

The discharge socket is still separate by Definition 765.25. Therefore every normalization-to-normal-form read carries the obstruction row through the route and stops short of the two excluded theorem exports. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket normalization obstruction route coverage`

Theorem 765.63 (MetaCIC residual-confluence budget bridge)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, a critical-path packet that exposes normalization obstruction, residual substitution boundary, finite-observation confluence, and candidate-mediated strong-normalization rows routes every residual-confluence consumer through the same finite budget ledger before any strong-normalization or confluence conclusion is exported. The bridge keeps the obstruction row* O*, the substitution-confluence-decidability handoff* U*, the discharge socket* D*, and the structural rows* H, C, P, L *visible throughout the read.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket residual confluence budget bridge`

Proof. Start with the normalization side. By Definition 765.58 and Definition 765.62, every read from the strong-normalization row S to the normal-form row N keeps the obstruction row O and the discharge socket D visible.

Next inspect the bounded handoff side. Apply Definition 765.59; the row U exhausts the substitution, confluence, and decidability reads as bounded handoff obligations rather than closed theorem exports.

The confluence-facing socket is then fixed by Definition 765.61. Any finite-observation confluence or residual-substitution read remains mediated by O, D, H, C, P, L and cannot split off into an independent Church–Rosser or beta-conversion decision procedure.

Finally, candidate-mediated strong-normalization consumers receive only this finite budget route. Transport, replay, provenance, and local naming preserve the same packet rows, so every residual-confluence consumer reaches the SN and confluence surfaces through the shared ledger before any conclusion is exported. □

Theorem 765.64 (MetaCIC critical-path residual-substitution normalization frontier)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, a consumer that reads residual substitution through* U *and reads normalization through the route from* S *to* N *must keep the obstruction row* O*, the discharge socket* D*, the structural transport row* H*, the replay row* C*, the provenance row* P*, and the local naming row* L *visible. Consequently residual substitution is not an export route for closed subject reduction, arbitrary Church–Rosser, beta-conversion decidability, or full closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualSubstitutionNormalizationFrontier`

Proof. Use Definition 765.60 to read residual substitution through U. The handoff is a displayed packet coordinate, and its consumer must retain the obstruction and discharge rows rather than treating substitution support as a closed subject-reduction proof.

Use Definition 765.62 for the normalization side. The route from S to N keeps O visible, stops at normal-form readback, and does not fill the discharge socket D.

Now apply Definition 765.61. It keeps confluence-facing and decidability-facing reads socket-mediated by O, D, H, C, P, L, so the same consumer cannot split residual substitution into arbitrary Church–Rosser or beta-conversion decidability.

Finally use Definition 765.63. The residual-confluence bridge shares the finite budget ledger with the normalization route, so transport, replay, provenance, and local naming preserve the displayed frontier rather than exporting closed consistency. □

Theorem 765.65 (MetaCIC critical-path candidate-mediated SN conditional discharge)**.** *Let $K = (S, N, O, U, D, H, C, P, L)$ be an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. If the candidate-mediated SN row attached to K has consumed the subject-reduction obstruction row O, the normalization audit route $S \to N$, the decidability boundary contained in U, the normal false exclusion endpoint N, and the residual substitution rows mediated by U, then K discharges the local SN handoff condition for the public critical-path route. This discharge is only the local handoff condition named by the packet; it does not claim full closed SN, full Church–Rosser, global beta-conversion decidability, closed subject reduction, or full closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNConditionalDischarge`

Proof. Project the packet carrier. The displayed rows $S, N, O, U, D, H, C, P, L$ keep the normalization route, normal-form endpoint, subject-reduction obstruction, substitution-confluence-decidability handoff, discharge socket, transport, replay, provenance, and local naming visible.

Use the obstruction and consistency handoff theorems first. They route normalization through $S \to N$, keep the subject-reduction obstruction O visible, and keep D as a local socket rather than as a closed subject-reduction theorem.

Next compose the public provenance and frontier results. The public provenance rows name only the cited obstruction, normalization audit, decidability boundary, and normal false exclusion packets, while the candidate-mediated frontier theorems route candidate SN, residual substitution, confluence, and bounded checking through the same finite ledger.

The stated hypothesis says that this finite candidate-mediated ledger has already consumed the listed obstruction, audit, boundary, endpoint, and residual rows. Therefore the local SN handoff condition for the public critical-path route is discharged, but no theorem outside that local handoff is exported. □

Theorem 765.66 (MetaCIC critical-path L10 residual route)**.** *Let $K = (S, N, O, U, D, H, C, P, L)$ be an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. If the candidate-mediated SN row attached to K consumes the subject-reduction obstruction row O, the normalization route $S \to N$, the decidability boundary in U, the normal-false endpoint N, and the residual rows mediated by U, then every L10 four-object exit certificate read from K must route through the same finite residual ledger before any* $\mathsf{Real}^{\uparrow}$*- or* $\mathsf{Completion}^{\uparrow}$*-facing consumer can read it. The visible exit route is the shared packet surface O, U, D, H, C, P, L together with the normalization endpoint N; it exports no closed subject reduction, no full strong normalization theorem, no global Church–Rosser theorem, no beta-conversion decision procedure, and no closed consistency theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10ResidualRoute`

Proof. Start with the public provenance route. The public rows identify the obstruction, normalization audit, decidability boundary, normal-false endpoint, residual substitution, replay, provenance, and local naming data as rows of the same accepted packet, so an L10 exit certificate cannot detach them into an external theorem export.

Use Definition 765.63. It keeps residual-confluence reads on the finite budget ledger and prevents a confluence-facing consumer from bypassing O, D, H, C, P, L.

Next apply Definition 765.64. Residual substitution and normalization share the same frontier: the route through U and the route $S \to N$ must keep the obstruction row, discharge socket, transport, replay, provenance, and naming rows visible.

Finally apply Definition 765.65. Its hypothesis is exactly the consumed candidate-mediated ledger named in the statement, so the L10 four-object exit certificate can be read only after that ledger has discharged the local SN handoff. The Real- or Completion-facing consumer therefore receives a routed residual certificate, not an independent closed MetaCIC metatheorem. □

Theorem 765.67 (MetaCIC critical-path L10 discharge dependency bridge)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, any L10 four-object exit certificate read from the packet must consume the same candidate-mediated SN discharge row, residual substitution row, subject-reduction obstruction row* O*, normalization endpoint* N*, and decidability boundary in* U *before any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer reads it. The bridge records only this dependency order; it does not claim full subject reduction, Church–Rosser, beta-conversion decidability, strong normalization, or closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10DischargeDependencyBridge`

Proof. Begin with Definition 765.65. Its conditional discharge row is local to the same packet and is available only after the obstruction row, normalization route, decidability boundary, normal endpoint, and residual rows have already been consumed.

Next apply Definition 765.64. Residual substitution and normalization share the same finite frontier through U, $S \to N$, O, D, H, C, P, L, so the L10 exit cannot read residual substitution as a detached subject-reduction theorem.

Use Definition 765.63 to keep confluence-facing and SN-facing reads on the shared finite budget ledger. Then apply Definition 765.66; it routes every L10 four-object exit certificate through that residual ledger before Real- or Completion-facing consumers can inspect it.

Therefore the exit certificate consumes the same discharge, residual, obstruction, endpoint, and decidability rows in the same packet. The consumer receives a dependency bridge for the L10 route, not any of the blocked global MetaCIC conclusions. □

Theorem 765.68 (MetaCIC critical path candidate-mediated SN boundary)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, a normalization-boundary read that displays CandidateMediatedSN evidence, the closed-term substitution boundary, FiniteObservationConfluence, the SubjectReductionDischargeSocket row, and MetaCIC closure-trace rows can be exposed only through those displayed rows together with the* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$ *support already carried by the chapter dependency route. The read is a finite boundary certificate; it is not global strong normalization, host confluence, semantic model completeness, closed subject reduction, or a filled discharge socket.*

Proof. Project the accepted critical-path packet. The rows $S, N, O, U, D, H, C, P, L$ are the only local coordinates, and the candidate-mediated normalization read begins at the displayed S route rather than at a global normalization theorem.

Attach the boundary rows in their finite order. Closed-term substitution and finite-observation confluence are read through the handoff row U, the subject-reduction socket remains the displayed row D, and closure-trace information is replayed only through C with provenance and naming in P, L.

Now use the L10 dependency route already recorded for the chapter. Its $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ support rows keep the boundary read attached to finite observation schedules, rational readback, and the terminal seal before any public consumer can inspect it.

The obstruction and socket theorems keep the excluded conclusions out of the packet. The same projection that exposes the candidate-mediated boundary refuses global strong normalization, host confluence, semantic model completeness, closed subject reduction, and any completed discharge for D. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNBoundary`
`semantic name certificate`

Theorem 765.69 (MetaCIC candidate-mediated SN public handoff)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, the public candidate-mediated strong-normalization handoff is the finite readiness surface formed by the candidate-mediated SN rows, the normalization-frontier rows, the confluence-decidability budget, and the subject-reduction discharge socket. A consumer may cite this surface only as a route through* $S, N, O, U, D, H, C, P, L$ *together with the displayed CandidateMediatedSN and CandidateSNConfluenceBoundary rows. It cannot cite the surface as full MetaCIC strong normalization, closed subject reduction, full confluence, full closed consistency, or a filled discharge bundle.*

Proof. Start with the candidate-mediated obligation surface. Theorems 765.257, 765.265, and 765.269 identify the candidate-mediated SN rows as finite packet data rather than as a global normalization theorem.

Next read the public carrier route. Theorems 765.58, 765.47, and 765.62 keep the normalization-frontier endpoint attached to S, N, O, H, C, P, L and keep the obstruction row visible.

Finally attach the socket and handoff rows. Theorems 765.25, 765.50, 765.51, and 765.194 keep D separate from the candidate-mediated rows and keep U as a handoff row. Thus the public handoff is a readiness surface and not a proof of full MetaCIC SN, closed subject reduction, full confluence, full closed consistency, or socket discharge. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNPublicHandoff`

Theorem 765.70 (MetaCIC confluence frontier public handoff)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, every public confluence-frontier read factors through CandidateMediatedSN, CandidateSNConfluenceBoundary, FiniteObservationConfluence, MetaCICNormalizationFrontier, and SubjectReductionDischargeSocket rows only as displayed packet obligations. The route may expose finite-observation confluence readiness and confluence-decidability handoff data, but it exports no arbitrary Church–Rosser theorem, no global beta-conversion decision procedure, no full MetaCIC confluence theorem, and no closed subject-reduction discharge.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceFrontierPublicHandoff`

Proof. Read the confluence-facing packet rows first. Theorems 765.61, 765.193, and 765.224 force confluence and decidability uses through U together with the obstruction, socket, transport, replay, provenance, and local naming rows.

Next attach the candidate and finite-observation frontier. Theorems 765.220, 765.223, and 765.181 keep CandidateMediatedSN and CandidateSNConfluenceBoundary as mediated readiness rows, while the finite-observation confluence side remains bounded by the same packet route.

Finally use the public handoff theorem above together with discharge-socket coverage, Definition 765.69 and Definition 765.26. The subject-reduction socket remains visible and unfilled, so

the confluence frontier is a public readiness surface over finite BEDC rows rather than a global Church–Rosser, beta-decidability, full-confluence, or subject-reduction theorem. □

Theorem 765.71 (MetaCIC critical-path formal target router)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$*, any candidate-mediated strong-normalization consumer for* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *must pass through the candidate-mediated SN public boundary of Definition 765.69, the confluence frontier of Definition 765.70, and the L10 normalization discharge budget of Definition 765.273 before any* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{StreamName}^{\uparrow}$ *discharge row is read. The router exposes a finite target route through* $S, N, O, U, D, H, C, P, L$*; it does not export hidden infinite reduction, full MetaCIC strong normalization, ambient real completeness, or a completed subject-reduction socket.*

Proof. Begin with the candidate-mediated SN public boundary. It places CandidateMediatedSN and CandidateSNConfluenceBoundary on the displayed carrier route and prevents a consumer from treating them as full strong normalization.

Next attach the confluence frontier. The frontier keeps FiniteObservationConfluence and MetaCICNormalizationFrontier on the same public route, while the subject-reduction socket remains visible as a socket rather than as a closed theorem.

Finally use the L10 normalization discharge budget. That budget orders the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ discharge faces behind the finite source rows and the socket-aware route.

The nonescape clauses from these three surfaces compose: no hidden infinite reduction, ambient real-completeness claim, or closed subject-reduction discharge is available outside the displayed packet. Hence every formal target consumer must pass through the stated router before reading the L10 discharge rows. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFormalTargetRouter`

Theorem 765.72 (MetaCIC critical-path public export)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier*

$$K = (S, N, O, U, D, H, C, P, L),$$

the public export surface is exactly the finite route through CandidateMediatedSN, CandidateSNConfluenceBoundary, FiniteObservationConfluence, MetaCICNormalizationFrontier, SubjectReductionDischargeSocket, and the carrier rows $S, N, O, U, D, H, C, P, L$*. This export refuses full MetaCIC strong normalization, closed subject reduction, full confluence, full closed consistency, and discharge of the socket* D*.*

Proof. First read the candidate-mediated SN public handoff, Definition 765.69. It presents CandidateMediatedSN and CandidateSNConfluenceBoundary only as finite readiness rows over the carrier route.

Next read the confluence-frontier public handoff, Definition 765.70. It attaches FiniteObservationConfluence and MetaCICNormalizationFrontier to the same carrier rows, while keeping confluence and decidability uses bounded by the displayed handoff data.

Finally use discharge-socket coverage and obstruction-socket separation, Definition 765.26 and Definition 765.50. These keep SubjectReductionDischargeSocket visible but unfilled, so D remains a socket coordinate rather than a closed subject-reduction proof or a source of the excluded global theorem exports. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPublicExport`

Theorem 765.73 (MetaCIC critical-path candidate ledger public boundary)**.** *Every public candidate-ledger read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *carrier* $K = (S, N, O, U, D, H, C, P, L)$ *must pass through the L10 four-object exit rows already listed for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The ledger may expose CandidateMediatedSN, CandidateSNConfluenceBoundary, FiniteObservationConfluence, MetaCICNormalizationFrontier, SubjectReductionDischargeSocket, and the carrier route* $S, N, O, U, D, H, C, P, L$, *but it cannot claim global strong normalization, full confluence, global decidability, closed subject reduction, closed consistency, discharge of* D, *or Lean verification.*

Proof. Project the accepted carrier and read the public export theorem Definition 765.72. The export surface is already the finite candidate-mediated route through the carrier rows and the visible subject-reduction socket.

Now project the L10 exit budget from Definition 765.128. Any public candidate-ledger read must pass through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before it reaches a downstream consumer.

The two projections compose without adding theorem content. The candidate ledger records readiness rows and visible sockets over the four-object exit surface, while the excluded global SN, confluence, decidability, subject-reduction, consistency, socket-discharge, and Lean-verification claims remain outside the carrier. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateLedgerPublicBoundary`

Theorem 765.74 (MetaCIC critical-path public consumer surface)**.** *Every public consumer of the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *critical path must route through CandidateMediatedSN, CandidateSNConfluenceBoundary, FiniteObservationConfluence, MetaCICNormalizationFrontier, SubjectReductionDischargeSocket, and the carrier rows*

$$S, N, O, U, D, H, C, P, L.$$

The consumer surface may expose candidate-mediated normalization readiness, confluence-frontier readiness, finite-observation confluence data, normalization-frontier data, the visible subject-reduction socket, and the displayed carrier route, but it exports no closed subject reduction, full confluence, full closed consistency, or socket discharge.

Proof. First read Definition 765.69. It keeps CandidateMediatedSN and CandidateSNConfluence-Boundary on the public readiness surface and routes them through the carrier rows $S, N, O, U, D, H, C, P, L$.

Next read Definition 765.70. It attaches FiniteObservationConfluence and MetaCICNormalizationFrontier to the same displayed packet route and refuses arbitrary Church–Rosser, global beta-decision, full confluence, and closed subject-reduction exports.

Finally read Definition 765.72. It names the public export surface as exactly the route through CandidateMediatedSN, CandidateSNConfluenceBoundary, FiniteObservationConfluence, MetaCICNormalizationFrontier, SubjectReductionDischargeSocket, and $S, N, O, U, D, H, C, P, L$. Therefore a public consumer inherits that exact route and none of the excluded closed subject-reduction, full-confluence, full-consistency, or socket-discharge conclusions. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPublicConsumerSurface`

Theorem 765.75 (MetaCIC critical-path residual confluence bridge boundary)**.** *Every residual-substitution route that consumes the candidate-mediated SN row, the confluence-frontier row, and the subject-reduction obstruction row of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must consume*

them only through the displayed MetaCIC critical-path ledger $S, N, O, U, D, H, C, P, L$ together with the public candidate-ledger and confluence-frontier handoff rows. The bridge may pass residual-confluence readiness to a downstream consumer, but it cannot treat the blocked subject-reduction edge as a closed theorem, discharge socket D, or replace the critical-path ledger by a host confluence proof.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBridgeBoundary`

Proof. First project the confluence-frontier slice through Definition 765.70. This places CandidateMediatedSN, CandidateSNConfluenceBoundary, FiniteObservationConfluence, MetaCICNormalizationFrontier, and SubjectReductionDischargeSocket on the same displayed route.

Next apply the candidate-ledger public boundary, Definition 765.73. It forces the residual-substitution consumer to pass through the L10 exit rows and the packet ledger $S, N, O, U, D, H, C, P, L$ before any public read is available.

Now apply the confluence public handoff, Definition 765.74. The handoff permits only the finite readiness surface, so residual confluence is read as a bridge boundary over displayed rows rather than as a global Church–Rosser or beta-conversion theorem.

Finally use obstruction-socket separation, Definition 765.50. The obstruction row and the subject-reduction socket remain separate from a closed discharge, which prevents the blocked subject-reduction edge from being consumed as a theorem. □

Theorem 765.76 (MetaCIC critical-path frontier-rank NameCert obligations)**.** *For every accepted frontier-rank packet*

$$Q = (O, R, D, B, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *surface consists exactly of seven row obligations: open-node visibility through O, dependency-ready visibility through R, downstream-rank visibility through D, obstruction-ledger visibility through B, replay-route visibility through C, package provenance through P, and local naming through N. It has no eighth obligation for scheduler state, host reachability, or an unledgered dependency edge.*

Proof. Project the accepted frontier-rank carrier of Definition 765.53. The displayed packet has the seven coordinates O, R, D, B, C, P, N, and the definition assigns one scheduler-facing role to each coordinate.

Open-node exhaustion in Definition 765.54 supplies the coverage step. Every accepted open-node read factors through the node row, the dependency-ready rows, the downstream rank, the obstruction ledger, the replay route, provenance, and the local name.

Dependency-route nonescape in Definition 765.55 supplies the exclusion step. Dependency routing cannot appeal to hidden scheduler state, host graph reachability, or an unledgered dependency edge.

The Lean handoff surface of Definition 765.56 identifies the same seven coordinates as the formal target surface. Hence the local NameCert obligations are exactly the seven displayed rows and no extra scheduler-facing row. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierRankNameCertObligations`

Theorem 765.77 (MetaCIC critical-path frontier-rank transport stability)**.** *For every accepted frontier-rank packet $Q = (O, R, D, B, C, P, N)$, componentwise* hsame *transport and replay along the displayed route C preserve the seven NameCert obligation rows O, R, D, B, C, P, N. Transport cannot add scheduler state, host reachability, or an unledgered dependency edge.*

Proof. Start with the accepted carrier in Definition 765.53. Its route coordinate C stores the Cont paths used by scheduler-facing consumers, while the remaining coordinates record the open node, readiness, rank, ledger, provenance, and local name.

Open-node exhaustion keeps the transported read on the same finite packet. By Definition 765.54, there is no hidden frontier node and no unranked scheduling obligation available after the read is replayed.

Dependency-route nonescape keeps the replayed dependency route inside the same ledgered surface. By Definition 765.55, the route may use R, B, C, P, N but cannot leave the packet for scheduler state, host reachability, or an unledgered edge.

The obligation theorem above identifies the seven rows as the complete local NameCert surface. Therefore componentwise hsame transport and route replay preserve exactly those rows and introduce no additional dependency source. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierRankTransportStability`

Theorem 765.78 (MetaCIC critical-path frontier-rank consumer exactness)**.** *Every scheduler-facing consumer of the* MetaCICCriticalPath$^{\uparrow}$ *root-unblock packet factors through the seven-row frontier-rank surface*

$$O, R, D, B, C, P, N.$$

Such a consumer may read the open node, readiness row, downstream rank, obstruction ledger, replay route, provenance, and local name, but it cannot read a hidden dependency edge outside those rows.

Proof. Project the consumer to an accepted open-node read. By Definition 765.54, that read factors through a frontier-rank packet $Q = (O, R, D, B, C, P, N)$ and has no coordinate for a hidden frontier node or unranked scheduling obligation.

Now project any dependency route used by the consumer. By Definition 765.55, routing is exhausted by the displayed readiness, ledger, replay, provenance, and naming rows, and it cannot appeal to hidden scheduler state, host graph reachability, or an unledgered edge.

Finally use the Lean handoff and NameCert obligation surfaces. Definition 765.56 makes the seven rows the exact root-unblock handoff, and Definition 765.76 makes them the complete local NameCert obligation list. Thus every scheduler-facing consumer factors through the seven rows and cannot read a hidden dependency edge. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierRank consumer exactness`

Theorem 765.79 (MetaCIC critical-path frontier-rank soundness)**.** *The* MetaCICCriticalPath$^{\uparrow}$ *frontier-rank carrier can rank only the displayed open-node row O, dependency-route row R, Lean-handoff row D, obstruction-ledger row B, replay-route row C, provenance row P, and local naming row N. It cannot rank hidden closed-consistency data, subject-reduction data, scheduler state, host reachability, or any dependency edge outside the displayed finite packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierRankSoundness`

Proof. Start with the frontier-rank carrier of Definition 765.53. Its rank coordinate is read together with the open node, dependency-ready routes, obstruction ledger, replay route, provenance, and local name, so the carrier provides no separate coordinate for closed-consistency or subject-reduction data.

Open-node exhaustion and dependency-route nonescape give the two exclusions. By Definition 765.54, every ranked node is one of the displayed open nodes. By Definition 765.55, every

dependency used by the rank is routed through the ledgered finite rows and not through host reachability or an unledgered edge.

Finally combine the Lean handoff, NameCert obligation, transport stability, and consumer exactness rows of Definition 765.56, Definition 765.76, Definition 765.77, and Definition 765.78. These identify the same seven rows as the only downstream handoff surface, so the frontier rank is sound exactly for those displayed rows. □

Theorem 765.80 (MetaCIC critical-path downstream-unblock coverage)**.** *A downstream MetaCIC consumer is unblocked by a* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *frontier-rank packet only when every dependency route named by the packet is read through the displayed finite rows* O, R, D, B, C, P, N*. A route that asks for hidden closed-consistency data, subject-reduction data, scheduler state, host reachability, or an unledgered dependency edge is not covered by the unblock packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDownstreamUnblockCoverage`

Proof. Project the downstream consumer through Definition 765.78. The consumer can receive only the open node, readiness row, downstream rank, obstruction ledger, replay route, provenance, and local name.

Use dependency-route nonescape and frontier-rank soundness. The theorem Definition 765.55 forces every named dependency route through the displayed route and ledger rows, while Definition 765.79 prevents the rank from certifying hidden closed-consistency or subject-reduction data.

The remaining rows are stable under transport and handoff. Apply Definition 765.77, Definition 765.56, and Definition 765.76. They keep the downstream unblock claim on the same seven finite rows, so any consumer whose dependency route leaves those rows is not unblocked by this packet. □

Theorem 765.81 (MetaCIC critical-path Lean target intake)**.** *For every accepted frontier-rank packet*

$$Q = (O, R, D, B, C, P, N),$$

the Lean target intake surface is exactly the seven displayed rows: open-node visibility through O*, dependency-ready visibility through* R*, downstream-rank visibility through* D*, obstruction-ledger visibility through* B*, replay-route visibility through* C*, package provenance through* P*, and local naming through* N*. It has no intake row for scheduler state, host graph reachability, hidden dependency edges, or theorem exports outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathLeanTargetIntake`

Proof. Start from the carrier of Definition 765.53. The packet Q displays precisely the seven coordinates O, R, D, B, C, P, N, and each coordinate has a named root-unblock role.

Apply open-node exhaustion from Definition 765.54. It places every accepted open-node read inside this same packet and rules out a hidden frontier node or unranked scheduling obligation.

Use dependency-route nonescape and the Lean handoff surface, Definition 765.55 and Definition 765.56. Together they make the dependency-ready row, obstruction ledger, replay route, provenance row, and local NameCert row the exact formal handoff surface.

Finally invoke consumer exactness from Definition 765.78. Since every scheduler-facing consumer factors through the seven displayed rows, the Lean intake has no remaining coordinate for scheduler state, host reachability, hidden edges, or outside theorem exports. □

Theorem 765.82 (MetaCIC critical-path downstream unblock surface)**.** *Every downstream unblock read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *frontier-rank packet* $Q = (O, R, D, B, C, P, N)$ *must pass through the dependency-ready row* R*, obstruction ledger* B*, replay route* C*, package provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *row* N*. The read may also inspect the open node* O *and downstream rank* D*, but it cannot bypass* R, B, C, P, N *by appealing to scheduler state, host graph reachability, a hidden edge, or an exported theorem outside the packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDownstreamUnblockSurface`

Proof. Project the read to the displayed frontier-rank carrier. The dependency-ready row R, obstruction ledger B, replay route C, provenance row P, and local name N are all coordinates of the same finite packet Q.

Apply Definition 765.55. Dependency routing is exhausted by those rows, so a downstream unblock cannot use a host scheduler convention or graph-reachability fact in place of the ledgered route.

Use the Lean handoff surface of Definition 765.56. It identifies the same rows as the paper-to-Lean root-unblock surface and refuses additional scheduling coordinates.

Finally apply Definition 765.78. Every scheduler-facing consumer already factors through O, R, D, B, C, P, N, hence any downstream unblock read must pass through R, B, C, P, N before it can be consumed. □

Theorem 765.83 (MetaCIC critical-path audit frontier factorization)**.** *Every audit-frontier read of an accepted frontier-rank packet* $Q = (O, R, D, B, C, P, N)$ *factors through the displayed open-node row, dependency-ready row, downstream rank, obstruction ledger, replay route, package provenance, and local NameCert row. The factorization has no scheduler state, host graph reachability, hidden dependency edge, or theorem export outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathAuditFrontierFactorization`

Proof. Read the frontier through Definition 765.53. The audit-facing packet is finite and names only O, R, D, B, C, P, N.

Use Definition 765.54. It exhausts the open-node side of the audit frontier and prevents a hidden frontier node or unranked scheduling obligation from entering the factorization.

Next apply Definition 765.55 and Definition 765.77. These keep dependency routes and transported replay paths inside R, B, C, P, N and preserve the same seven rows under componentwise hsame transport.

Finally use Definition 765.56 and Definition 765.78. The formal handoff and every consumer read share the same seven-row packet, so the audit-frontier factorization cannot export scheduler state, host graph reachability, hidden edges, or theorem rows outside Q. □

Theorem 765.84 (MetaCIC critical-path root-unblock carrier readiness)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

the displayed rows expose carrier readiness through the source row S*, local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *row* N*, open-obstruction row* O*, unblock row* U*, discharge row* D*, componentwise* hsame *row* H*, continuation row* C*, package provenance row* P*, and local ledger row* L*. The readiness claim has no row for closed subject reduction, full consistency, hidden scheduler state, or host reachability outside the packet.*

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRootUnblockCarrierReadiness

Proof. Start with the carrier and NameCert rows of the accepted packet. The displayed source, local name, obstruction, unblock, discharge, transport, continuation, provenance, and ledger coordinates are the only coordinates available to a carrier-readiness read.

Apply the carrier obligations and transport stability supplied by Definition 765.76 and Definition 765.77. These keep the source and local naming rows tied to the same finite BHist packet and keep every transported read inside the displayed hsame row.

Finally use Definition 765.79 and Definition 765.83. They exclude closed-consistency data, subject-reduction data, scheduler state, and hidden dependency edges from the frontier packet, so carrier readiness is exactly the displayed finite surface. □

Theorem 765.85 (MetaCIC critical-path root-unblock route readiness)**.** *Every route replay accepted by a* MetaCICCriticalPath$^{\uparrow}$ *root-unblock consumer is exhausted by the displayed obstruction, discharge socket, transport, continuation, provenance, and local naming rows of* $K = (S, N, O, U, D, H, C, P, L)$*. No replay step may replace those rows by a host scheduler edge, an unledgered dependency route, or a hidden theorem-export path.*

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRootUnblockRouteReadiness

Proof. Project the route replay to the packet rows that can be consumed. The obstruction, discharge, hsame transport, Cont continuation, package provenance, and local naming rows are all present in the same finite root-unblock packet.

Use route nonescape and the discharge socket boundary. The dependency-route nonescape theorem Definition 765.55 forces every routed dependency through the ledgered finite rows, while the downstream unblock surface of Definition 765.82 prevents a consumer from bypassing the displayed discharge and replay rows.

The remaining replay data are fixed by the audit-frontier factorization. Applying Definition 765.83 with transport stability from Definition 765.77 leaves only obstruction, socket, transport, continuation, provenance, and local naming reads for the root-unblock route. □

Theorem 765.86 (MetaCIC critical-path root-unblock consumer readiness)**.** *Downstream MetaCIC consumers may depend on an accepted* MetaCICCriticalPath$^{\uparrow}$ *root-unblock packet only through the displayed rows* $S, N, O, U, D, H, C, P, L$*. Such consumers cannot appeal to host scheduler state, undisplayed dependency edges, hidden route closures, closed subject reduction, or full consistency as part of the root-unblock packet.*

Proof. Begin with consumer exactness. By Definition 765.78, every scheduler-facing consumer factors through the displayed finite packet rather than through host scheduler state.

Next use downstream-unblock coverage and the audit-frontier factorization. Theorems Definition 765.80 and Definition 765.83 restrict dependency reads to the packet rows and rule out hidden scheduler edges or theorem exports outside the packet.

Finally combine carrier readiness and route readiness from Definition 765.84 and Definition 765.85. These two surfaces account for the carrier, obstruction, discharge, transport, continuation, provenance, ledger, and local naming rows, so no downstream MetaCIC consumer has any additional root-unblock dependency to cite. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRootUnblockConsumerReadiness

Theorem 765.87 (MetaCIC candidate-mediated SN obligation scope)**.** *Any confluence-facing or decidability-facing consumer of candidate-mediated strong-normalization data through an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet must expose typed-term carrier rows, reduction-candidate rows, substitution and reduction replay rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *row before it reads the strong-normalization boundary. The read is a finite obligation scope for the packet, not an unconditional confluence theorem, beta-conversion decision procedure, closed subject-reduction certificate, or host normalization principle.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNScope`

Proof. Begin with root-unblock consumer readiness. It forces downstream MetaCIC consumers through the displayed root-unblock rows $S, N, O, U, D, H, C, P, L$ before any confluence-facing or decidability-facing dependency is consumed.

Use frontier-rank consumer exactness and downstream-unblock coverage. These surfaces keep the open node, dependency-ready row, obstruction ledger, replay route, provenance, and local name visible, so candidate-mediated SN data cannot be read through hidden scheduler state or an unledgered dependency edge.

Finally compose the carrier and route readiness theorems. The typed-term carrier rows, reduction-candidate rows, substitution and reduction replay rows, hsame transport, Cont replay, Pkg provenance, and local NameCert row are precisely the rows available at the boundary; no row supplies unconditional confluence, beta-decision, closed subject reduction, or host normalization. □

Theorem 765.88 (MetaCIC critical-path public route certificate)**.** *Every public read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet factors through the displayed finite route certificate*

$$K = (S, N, O, U, D, H, C, P, L).$$

The factorization reads closed-normalization through S, normal-form consistency through N, the subject-reduction obstruction through O, decidability and handoff data through U, the discharge socket through D, componentwise transport through H, route replay through C, provenance through P, and local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *naming through L. It has no public row for closed subject reduction, full closed consistency, global beta-conversion decidability, a hidden dependency edge, or an exported theorem outside the packet.*

Proof. Start with the obligation surface. Theorem 765.20 lists the public packet rows and identifies the local NameCert obligations with the finite tuple $S, N, O, U, D, H, C, P, L$.

The positive consistency route is fixed by the handoff and route inventory. Apply Theorem 765.2, Theorem 765.39, and Theorem 765.40. These results keep the closed-normalization row, normal-form endpoint, handoff row, continuation row, transport row, provenance row, and local naming row inside the displayed carrier.

It remains to exclude public escape routes. Theorem 765.3 keeps the subject-reduction obstruction visible, while Theorem 765.86 restricts downstream consumers to the same displayed rows. Hence every public read is a read of the finite route certificate and not a read of an undisplayed theorem export. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPublicRouteCertificate`

Theorem 765.89 (MetaCIC critical-path obstruction scope separation)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the obstruction row* O *remains a scoped subject-reduction boundary. The consistency row* N*, the closed-normalization route* S*, the handoff row* U*, route replay through* C*, componentwise transport through* H*, provenance through* P*, and local naming through* L *cannot convert* O *or the socket* D *into closed subject reduction or full closed consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathObstructionScopeSeparation`

Proof. Read the obstruction row from the packet carrier. Theorem 765.3 states that O remains visible under the handoff row and componentwise transport, and that agreement on the other rows cannot erase the obstruction.

The consistency and normalization side stays on its own route. Theorem 765.2 lets a consumer travel from S to N through the displayed rows, but it stops at the normal-form endpoint unless the separate discharge socket is filled.

Finally use route exhaustion and obligation coverage. Theorem 765.40 prevents replay from leaving the displayed route, and Theorem 765.20 leaves no extra coordinate that could identify O with a supplied theorem. The obstruction row therefore remains a scoped boundary rather than a theorem produced by the consistency or normalization rows. □

Theorem 765.90 (MetaCIC critical-path downstream consumer readiness)**.** *Downstream MetaCIC consumers may use an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet only as a finite public route certificate over* $S, N, O, U, D, H, C, P, L$*. They may cite it for carrier admission, closed-normalization readback, normal-form consistency handoff, obstruction visibility, decidability handoff, discharge-socket locality, route replay, transport stability, provenance, and local NameCert naming. They may not cite it as closed subject reduction, full normalization, internal consistency for MetaCIC, or a global decision procedure.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDownstreamConsumerReadiness`

Proof. Begin with the root-unblock surface. Theorem 765.86 already confines downstream consumers to the displayed packet rows and excludes host scheduler state, hidden route closures, closed subject reduction, and full consistency.

The public route certificate supplies the usable rows. Theorem 765.88 packages the normalization route, normal-form endpoint, obstruction row, handoff data, discharge socket, transport, continuation, provenance, and local NameCert row as the complete public read surface.

The obstruction boundary fixes what is not available. By Theorem 765.89, the subject-reduction obstruction and discharge socket remain separated from the consistency and normalization rows. A downstream consumer can therefore depend on the packet as a finite route certificate, but not as subject reduction, full normalization, internal consistency, or a global decision procedure. □

Theorem 765.91 (MetaCIC critical-path kernel frontier exposure)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

the kernel-facing frontier exposes exactly the finite BHist *rows for closed normalization-frontier source data* S*, the normal-form endpoint* N*, the consistency-facing refusal rows* O, D*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *naming* L*. The frontier has no row for closed subject reduction, full closed consistency, hidden scheduler state, or a host reachability edge.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket kernel frontier exposure`

Proof. Project the carrier inventory of Definition 765.1. The displayed tuple is the only packet read available to the kernel frontier, and its coordinates already name the closed normalization-frontier rows, the normal-form endpoint, the refusal rows, transport, replay, provenance, and local naming.

Use the public route certificate and obstruction scope separation. The route certificate reads every public kernel-facing path through $S, N, O, U, D, H, C, P, L$, while the obstruction separation keeps the consistency-facing refusal rows O, D visible rather than turning them into subject reduction or full consistency.

Thus exposure is a projection from the finite packet followed by route replay. Since the carrier has no additional coordinate, the listed rows exhaust the kernel frontier. □

Theorem 765.92 (MetaCIC critical-path normalization consumer handoff)**.** *Every normalization-facing consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must read the closed normalization-frontier rows through* S*, then consume the normal-form row* N *through the displayed* Cont *route* C*, with componentwise* hsame *transport* H*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *naming* L *still attached. The handoff cannot bypass the consistency-facing refusal rows* O, D *and cannot reinterpret the handoff row* U *as a closed-consistency theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNormalizationConsumerHandoff`

Proof. Begin with the consistency handoff and public route certificate. They place the normalization-facing read on the route from the closed normalization-frontier source row S to the normal-form row N and keep the route inside the displayed packet.

Next read the replay and transport rows. The Cont row C records the replay path, the hsame row H preserves componentwise agreement of the same packet rows, and the Pkg and $\mathsf{NameCert}$ rows P, L name the provenance and local boundary of that handoff.

Finally apply the obstruction boundary. The refusal rows O, D remain visible along the handoff, so the consumer receives a bounded normalization-to-normal-form route rather than a proof of closed subject reduction or full consistency. □

Theorem 765.93 (MetaCIC critical path normalization-frontier consumer route)**.** *Every normalization-frontier consumer read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet that is passed to an L10-facing route must expose, before consumption, the strong-normalization source row* S*, the normal-form endpoint row* N*, the obstruction row* O*, the handoff row* U*, the discharge-socket row* D*, and the structural rows* H, C, P, L*. The route may cite the Lean-side namespace* `BEDC.Derived.MetaCICCriticalPathUp` *as the intended formalization surface, but the paper obligation remains the finite visibility condition on*

$$S, N, O, U, D, H, C, P, L.$$

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNormalizationFrontierConsumerRoute`

Proof. Start with the normalization consumer handoff of Definition 765.92. It already forces the normalization-facing read to move from the closed normalization-frontier source S to the normal-form endpoint N through the displayed replay route C, with H, P, L still attached.

Next retain the frontier boundaries. The obstruction row O and the discharge-socket row D cannot be bypassed, and the handoff row U remains a visible substitution, confluence, and decidability handoff rather than a closed-consistency theorem.

Finally expose the L10-facing consumer surface. A route read by downstream Real-and-Completion consumers must therefore present the candidate strong-normalization source, normal-form endpoint, obstruction, handoff, discharge socket, componentwise transport, replay, provenance, and local naming rows together. This is exactly the finite public-route surface later targeted by `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPublicRouteCertificate`, without adding a new Lean marker at this paper site. □

Theorem 765.94 (MetaCIC critical-path consistency refusal boundary)**.** *Every consistency-facing read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet is bounded by the same finite* BHist *surface*

$$S, N, O, U, D, H, C, P, L.$$

The closed normalization-frontier rows may route a consumer to the normal-form endpoint N*, but the consistency-facing refusal rows* O, D*, together with the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows, prevent the read from exporting closed subject reduction, full closed consistency, global beta-conversion decidability, or quotient data over MetaCIC terms.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConsistencyRefusalBoundary`

Proof. Read the consistency-facing surface from the packet carrier. The only available rows are the closed normalization-frontier source, normal-form endpoint, obstruction and discharge-socket refusal rows, handoff row, transport, replay, provenance, and local naming.

Use route exhaustion to keep every consumer read inside this surface. The Cont replay and hsame transport rows preserve the same finite packet, while Pkg provenance and the local NameCert row identify the route as the MetaCICCriticalPath packet rather than an ambient theorem export.

The refusal boundary is then immediate from the absence of hidden rows. Since neither closed subject reduction nor full closed consistency is a carrier coordinate, every consistency-facing read remains bounded by O, D and the displayed packet rows. □

Theorem 765.95 (MetaCIC critical-path kernel frontier totality)**.** *Every kernel-facing consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet reads the complete frontier through*

$$S, N, O, U, D, H, C, P, L.$$

The frontier is total for the exported public route: closed normalization-frontier source data, the normal-form endpoint, obstruction rows, handoff rows, discharge socket, componentwise transport, displayed replay, provenance, and local naming are all visible, while closed subject reduction, full closed consistency, hidden scheduler state, and host reachability remain outside the exported surface.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathKernelFrontierTotality`

Proof. First project the carrier rows from Definition 765.1. The packet exposes only $S, N, O, U, D, H, C, P, L$, so every kernel-facing read starts from that finite inventory.

Use the public route certificate of Definition 765.91. It identifies the kernel frontier with the same displayed rows and gives no coordinate for closed subject reduction, full closed consistency, hidden scheduler state, or host reachability.

Finally apply the obstruction scope separation of Definition 765.3 and the refusal boundary of Definition 765.94. The obstruction and discharge socket remain visible as bounded rows, so the exported frontier is total exactly at the displayed packet surface. □

Theorem 765.96 (MetaCIC critical-path normal-form public nonescape)**.** *Every public normal-form consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet reaches the normal-form row* N *only through the displayed route*

$$S, N, O, U, D, H, C, P, L.$$

The normal-form endpoint is public as a bounded frontier endpoint, not as closed subject reduction, full closed consistency, hidden scheduler state, or host reachability.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket normal form public nonescape`

Proof. Begin with the normalization consumer handoff, Definition 765.92. It routes the consumer from the closed normalization-frontier row S to the normal-form row N through C, with transport, provenance, and local naming still attached.

Next use kernel frontier totality, Definition 765.95. The public route has no coordinate outside $S, N, O, U, D, H, C, P, L$, so a normal-form read cannot leave the displayed frontier to obtain hidden scheduler state or host reachability.

The obstruction scope separation of Definition 765.3 and the consistency refusal boundary of Definition 765.94 keep O and D present beside the normal-form endpoint. Therefore the endpoint remains a public bounded row rather than an exported proof of closed subject reduction or full closed consistency. □

Theorem 765.97 (MetaCIC critical-path discharge-socket frontier exhaustion)**.** *Every discharge-socket read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet is exhausted by*

$$S, N, O, U, D, H, C, P, L.$$

The socket row D *names the missing subject-reduction input as an exported frontier boundary, while the surrounding rows preserve and replay that boundary without supplying closed subject reduction, full closed consistency, hidden scheduler state, or host reachability.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDischargeSocketFrontierExhaustion`

Proof. Project the socket row from the carrier. The row D is listed as a discharge-bundle socket in Definition 765.1, and the public route certificate of Definition 765.91 keeps that row inside the same kernel-facing frontier.

Apply the obstruction scope separation, Definition 765.3. It prevents O from being erased and prevents D from being converted into a discharged bundle by agreement on the other packet rows.

Finally use the consistency refusal boundary, Definition 765.94, together with normal-form public nonescape, Definition 765.96. The discharge socket remains an exposed frontier boundary, and every consumer read is exhausted by $S, N, O, U, D, H, C, P, L$ rather than by a hidden scheduler, a host reachability edge, or either excluded theorem. □

Theorem 765.98 (MetaCIC critical-path Phase Real route budget)**.** *Every Phase Real and Completion consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *critical-path packet must first read the displayed rows*

$$S, N, O, U, D, H, C, P, L$$

before using any Real-facing dependency row, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, or* $\mathsf{StreamName}^{\uparrow}$ *schedule row. The packet exports the source row, normal-form row, obstruction row, unblock row, discharge socket, transport row, continuation route, package provenance, and local ledger row as the complete L10 consumer surface; it exports no closed subject reduction, full consistency, hidden completion selector, or ambient real-completeness row.*

Proof. Start with the root-unblock packet. Theorem 765.84 exposes the carrier surface as the finite tuple $S, N, O, U, D, H, C, P, L$, and Theorem 765.85 keeps route replay inside the same displayed rows.

Now place the Phase Real and Completion consumers on the visible L10 route. The StreamName, regular-sequence, and Real handoff chapters chapter 126, chapter 301, and chapter 38 supply consumer-facing rows only after their schedules, regular rational data, and real seals are read as displayed dependency rows.

Finally apply Theorem 765.86. It bars host scheduler state, undisplayed dependency edges, hidden route closures, closed subject reduction, and full consistency from the root-unblock surface. Hence any Real-facing or Completion-facing read must consume $S, N, O, U, D, H, C, P, L$ before it can use StreamName, RegSeqRat, or Real dependency rows. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealRouteBudget`

Theorem 765.99 (MetaCIC critical-path Phase Real normal-form handoff)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the normal-form row* N *can feed the Phase Real route only through the same obstruction and discharge-socket packet. It cannot feed that route as closed subject reduction, full consistency, global beta-conversion decidability, or an unledgered proof object independent of* O, D, H, C, P, L*.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealNormalFormHandoff`

Proof. Read the normal-form endpoint from the packet surface. Theorem 765.84 places N beside the obstruction row O, the discharge socket D, componentwise transport H, route replay C, package provenance P, and local ledger L.

Route the endpoint through the same public consumer boundary. Theorem 765.85 keeps replay inside the displayed packet, while Theorem 765.86 prevents a downstream consumer from replacing the packet by closed subject reduction or full consistency.

The Phase Real route therefore receives N only as a normal-form row still attached to O, D, H, C, P, L. The sibling StreamName, RegSeqRat, and Real chapters named in chapter 126, chapter 301, and chapter 38 consume such rows as finite dependency data, not as hidden MetaCIC consistency theorems. □

Theorem 765.100 (MetaCIC critical-path Phase Real obstruction ledger lock)**.** *For every Real-facing or Completion-facing consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the obstruction row* O *and discharge socket* D *remain visible ledger rows throughout the route to* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *dependency surfaces. No consumer may erase* O *or discharge* D *by appealing to a Real seal, a regular rational sequence handoff, a stream schedule, a completion carrier, closed subject reduction, or full consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealObstructionLedgerLock`

Proof. Begin with the carrier and route readiness results. Theorems 765.84 and 765.85 keep O and D among the displayed packet rows and route every replay through the finite tuple $S, N, O, U, D, H, C, P, L$.

Next read the downstream consumer surface. Theorem 765.86 states that downstream consumers have no hidden scheduler edge, hidden route closure, closed subject-reduction row, or full-consistency row beyond the displayed packet.

The Real and Completion route can then use only the sibling dependency rows supplied by chapter 126, chapter 301, and chapter 38. Those rows may schedule, regularize, or seal a Real-facing

dependency read, but they do not supply a coordinate that removes the MetaCIC obstruction row or fills the discharge socket. □

Theorem 765.101 (MetaCIC critical-path L10 discharge dependency readback)**.** *For every L10 four-object exit read from an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

the route must first read the candidate-mediated strong-normalization discharge row, the residual-substitution row, the obstruction row O, the normal-form row N, and the decidability boundary U before any $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{Completion}^{\uparrow}$ *consumer may inspect the route. The dependency readback is a finite route condition only: it does not close full subject reduction, Church–Rosser, beta-conversion decidability, strong normalization, or consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10DischargeDependencyReadback`

Proof. Start with the Phase Real route budget of Definition 765.98. It forces every Real-facing or Completion-facing consumer to read the displayed packet rows $S, N, O, U, D, H, C, P, L$ before it can use StreamName, RegSeqRat, or Real dependency rows.

Next use the normal-form handoff of Definition 765.99. The row N reaches the Phase Real route only while still attached to the obstruction and discharge-socket packet, so the candidate-mediated strong-normalization discharge row and residual-substitution row cannot be hidden behind the normal endpoint.

Finally apply the obstruction ledger lock of Definition 765.100. It keeps O and D visible throughout the route to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ dependency surfaces.

The same read order controls a $\mathsf{Completion}^{\uparrow}$ consumer, because such a consumer enters through the Real-facing route budget rather than through an additional completion oracle. Since the displayed rows contain no full subject-reduction, Church–Rosser, beta-conversion-decidability, strong-normalization, or consistency coordinate, the theorem records only the L10 discharge dependency order. □

Theorem 765.102 (MetaCIC critical-path split obligation surface)**.** *Every critical-path consumer that claims a* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *handoff must expose, before the claim is consumed, the candidate-mediated strong-normalisation row, finite-observation confluence row, closure-trace row, residual substitution boundary row, normalization-frontier row, and subject-reduction discharge row. These six rows are read as displayed packet coordinates tied to the same* BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}^{\uparrow}}$ *surface; no consumer may replace them by a host scheduler edge, a hidden theorem export, a global Church–Rosser assertion, or an unstated subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSplitObligationSurface`

Proof. Project the accepted critical-path packet to the rows already named by the MetaCIC carrier and its downstream child surfaces. The candidate-mediated strong-normalisation row supplies the normalization source, and the normalization-frontier row records the finite point at which that source may be inspected.

Read the confluence and closure rows next. Finite-observation confluence is available only as a displayed observation row, while the closure trace records the finite replay route rather than a global confluence theorem.

The residual substitution boundary and subject-reduction discharge rows are then kept visible as boundaries. They can be transported and replayed through hsame and Cont, but they cannot be collapsed into a supplied subject-reduction theorem.

Finally the structural rows source and name the same six-row surface through Pkg and $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPath}}$. Since host scheduler edges, hidden theorem exports, global Church–Rosser, and unstated subject reduction are not packet coordinates, every critical-path handoff consumer must expose the six displayed obligation rows before claiming the handoff. □

Theorem 765.103 (MetaCIC residual-diamond source-package budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any residual-diamond consumer or candidate-SN consumer of K must expose the L10 source package*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow},$$

together with the residual-substitution rows, local residual-join rows, substitution-residual rows, bounded local-confluence rows, obstruction row O, discharge socket D, transport row H, replay row C, provenance row P, and local naming row L before it claims a discharge. The budget is a route-exhaustion condition over displayed NameCert rows; it is not a source-equivalence transport theorem and it exports no global strong-normalization theorem, global confluence theorem, beta-conversion decision procedure, quotient term equality, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, or kernel consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondSourcePackageBudget`

Proof. Start with the carrier of Definition 765.1. The public packet rows are exactly $S, N, O, U, D, H, C, P, L$, with O and D kept visible as the obstruction row and discharge socket.

Read the L10 source package through the existing critical-path scope. The mature source surface names $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as the source faces that must be displayed before Real-facing or completion-facing consumers inspect the route.

Now inspect the residual and candidate sides. The residual-substitution rows, local residual-join rows, substitution-residual rows, and bounded local-confluence rows are all consumed through the same finite NameCert packet; the candidate-SN row may use that budget only while the obstruction, socket, transport, replay, provenance, and local naming rows remain attached.

Thus every residual-diamond or candidate-SN discharge claim is exhausted by the displayed source package and residual rows. Since no displayed coordinate carries global SN, global confluence, beta-decidability, quotient term equality, selected limits, ambient Real completeness, or kernel consistency, none of those objects is exported by the budget. □

Theorem 765.104 (MetaCIC critical-path StreamName source readiness)**.** *For every Real-facing or Completion-facing consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *critical-path packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

the $\mathsf{StreamName}^{\uparrow}$ *source schedule may be exposed only after the consumer has displayed the MetaCIC packet rows $S, N, O, U, D, H, C, P, L$ and the Phase Real route budget rows attached to that packet. In particular, the source schedule is not a host scheduler coordinate, an undisplayed stream source, a hidden completion selector, closed subject reduction, or full consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealStreamNameSourceReadiness`

Proof. Start with the root-unblock carrier and route surfaces. Theorems 765.84 and 765.85 expose K as the finite displayed packet and keep route replay inside the same rows.

Next apply the Phase Real route budget. Theorem 765.98 requires every Real-facing and Completion-facing consumer to read $S, N, O, U, D, H, C, P, L$ before it can use a StreamName schedule row.

Finally use consumer readiness and the two Phase Real locks. Theorem 765.86 excludes host scheduler state and hidden route closures, while Theorems 765.99 and 765.100 keep the normal-form and obstruction rows attached to the route. Thus the $\mathsf{StreamName}^{\uparrow}$ source schedule is exposed only as a displayed dependency row after the MetaCIC packet rows. □

Theorem 765.105 (MetaCIC critical-path RegSeqRat readback readiness)**.** *For every Real-facing or Completion-facing consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback can be consumed only as a displayed regular-rational dependency row attached to the same packet. The readback cannot be detached into quotient stream equality, selected limit data, hidden Real completeness, closed subject reduction, or full consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRegSeqRatReadbackReadiness`

Proof. First read the root-unblock packet. Theorems 765.84 and 765.85 make the carrier and replay rows visible as $S, N, O, U, D, H, C, P, L$.

The Phase Real route budget then fixes the readback order. By Theorem 765.98, the regular-rational dependency row appears only after the displayed MetaCIC packet rows have been admitted.

The normal-form handoff and obstruction ledger lock preserve the same attachment downstream. Theorems 765.99 and 765.100 keep N, O, D, H, C, P, L present at the Real and Completion boundary, and Theorem 765.86 refuses undisplayed dependency edges. Hence the $\mathsf{RegSeqRat}^{\uparrow}$ readback is consumed only as a displayed row of the same critical-path route. □

Theorem 765.106 (MetaCIC critical-path Real completion readiness package)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the Real-facing and Completion-facing root-unblock package is exactly the combination of the displayed* $\mathsf{StreamName}^{\uparrow}$ *source schedule readiness, the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback readiness, and the* $\mathsf{Real}^{\uparrow}$ *seal route read after the Phase Real budget rows. The package exports no ambient Real completeness, quotient stream equality, selected limit, closed subject reduction, full consistency, or hidden completion selector.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealCompletionReadinessPackage`

Proof. Build the StreamName side first. Theorem 765.104 confines the source schedule to a displayed row admitted after $S, N, O, U, D, H, C, P, L$.

Build the regular-rational side next. Theorem 765.105 confines the $\mathsf{RegSeqRat}^{\uparrow}$ readback to the same critical-path packet and refuses quotient-stream, selected-limit, and hidden-completeness exits.

Finally attach the Real-facing seal route. The Phase Real route budget, normal-form handoff, and obstruction ledger lock from Theorems 765.98, 765.99, and 765.100 keep the $\mathsf{Real}^{\uparrow}$ route downstream of the displayed packet while preserving N, O, D, H, C, P, L. With root consumer readiness from Theorem 765.86, the resulting package is a finite root-unblock surface for Phase Real and Completion consumers, not a closure of any excluded metatheoretic or completion principle. □

Theorem 765.107 (MetaCIC critical-path discharge-socket totality route)**.** *Any Real-facing or Completion-facing consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet that reads the discharge-bundle socket must pass through the displayed rows* $S, N, O, U, D, H, C, P, L$*, the* $\mathsf{StreamName}^{\uparrow}$ *source schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal readiness route. The route exposes socket totality as a finite displayed dependency. It does not discharge closed subject reduction, closed consistency, quotient stream equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDischargeSocketTotalityRoute`

Proof. Start with the three readiness surfaces in this child. Theorems 765.104, 765.105, and 765.106 force Real-facing and Completion-facing consumers to display the StreamName source row, the RegSeqRat readback row, and the Real seal route after the packet rows have been admitted.

Next read the root-unblock route rows in the parent chapter. Theorems 765.84, 765.85, and 765.86 make $S, N, O, U, D, H, C, P, L$ the finite carrier, route, and consumer surface for the accepted packet.

The discharge-bundle socket is therefore exposed only as the displayed row D together with its transport, continuation, provenance, and local naming support. Since the readiness package and the root-unblock rows contain no coordinate for closed subject reduction, closed consistency, quotient stream equality, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness, reading socket totality cannot discharge any of those excluded principles. □

Theorem 765.108 (MetaCIC critical-path DyadicRatCore budget readiness)**.** *For every Phase Real or Completion consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any $\mathsf{DyadicRatCore}^{\uparrow}$ *finite observation budget read is permitted only as a displayed dependency row attached to the same packet. The read may bound finite rational observations for the route to* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, but it cannot be exported as quotient stream equality, a host-selected limit, Real completeness, closed subject reduction, or full consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDyadicRatCoreBudgetReadiness`

Proof. Start with the finite root-unblock carrier. Theorem 765.84 exposes K as the displayed rows $S, N, O, U, D, H, C, P, L$, and Theorem 765.85 keeps route replay inside those rows.

Place the dyadic observation budget on the Phase Real route. Theorem 765.98 says that every Real-facing or Completion-facing dependency read must first pass through the displayed L10 consumer surface, and Theorem 765.100 keeps the obstruction and discharge rows visible along the route.

Finally use the readiness triad. Theorems 765.104, 765.105, and 765.106 allow StreamName schedules, RegSeqRat readback, and Real seal reads only as displayed dependency rows. Hence a $\mathsf{DyadicRatCore}^{\uparrow}$ finite observation budget can serve the Phase Real consumer only as such a row, with no coordinate for quotient equality, selected limits, Real completeness, closed subject reduction, or full consistency. □

Theorem 765.109 (MetaCIC critical-path StreamName before RegSeqRat route order)**.** *For every Phase Real or Completion consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the route order is fixed: the* $\mathsf{StreamName}^{\uparrow}$ *schedule row is read before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and both are read before the* $\mathsf{Real}^{\uparrow}$ *seal handoff. A consumer that tries to read regular-rational data or a Real seal without the displayed StreamName schedule is outside the L10 dependency budget of the packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathStreamNameRegSeqRatRouteOrder`

Proof. First read the root packet. Theorems 765.84 and 765.86 make $S, N, O, U, D, H, C, P, L$ the whole consumer surface and exclude host scheduler state, undisplayed dependency edges, closed subject reduction, and full consistency.

Next read the Phase Real budget. Theorem 765.98 requires the displayed rows before any Real-facing dependency row, $\mathsf{RegSeqRat}^{\uparrow}$ handoff row, or $\mathsf{StreamName}^{\uparrow}$ schedule row can be used. Theorem 765.99 then keeps the normal-form row attached to the obstruction and discharge packet during the handoff.

The readiness triad supplies the order. Theorem 765.104 exposes the StreamName schedule after the packet rows, Theorem 765.105 consumes the RegSeqRat readback as a displayed row of that same packet, and Theorem 765.106 packages both before the Real-facing seal route. Thus the route reads StreamName before RegSeqRat and RegSeqRat before the Real seal handoff. □

Theorem 765.110 (MetaCIC critical-path Real seal frontier exactness)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the exact Phase Real frontier is the displayed L10 dependency budget consisting of the packet rows together with the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite observation budget,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal handoff rows consumed in that order. The frontier exports no quotient stream equality, host-selected limit, ambient Real completeness, closed subject reduction, full consistency, hidden completion selector, or theorem row outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealSealFrontierExactness`

Proof. Begin with the root-unblock exactness. Theorems 765.84, 765.85, and 765.86 identify the available consumer surface as $S, N, O, U, D, H, C, P, L$ and refuse hidden scheduler, route, subject-reduction, and consistency coordinates.

Add the Phase Real budget rows. Theorem 765.98 fixes the L10 consumer surface, while Theorems 765.99 and 765.100 preserve the normal-form, obstruction, discharge, transport, continuation, provenance, and ledger rows along the Real-facing route.

The first two theorems of this file identify the dyadic budget and route order. Theorem 765.108 confines finite observation budgets to displayed dependency rows, and Theorem 765.109 forces the StreamName schedule before RegSeqRat readback and the Real seal handoff.

Finally apply the readiness package, Theorem 765.106. It combines the StreamName, RegSeqRat, and Real-facing rows without adding quotient stream equality, selected limits, ambient completeness, closed subject reduction, full consistency, or a hidden completion selector. The Phase Real seal frontier is therefore exact at the displayed L10 dependency budget and nowhere beyond it. □

Theorem 765.111 (MetaCIC critical-path L10 source cut)**.** *For every Phase Real or Completion consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the source cut for a* $\mathsf{Real}^{\uparrow}$*-facing read must expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite observation budget before the* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal rows. A consumer that starts from quotient stream equality, a host-selected limit, Real completeness, closed consistency, or an undisplayed route row is outside the L10 source cut of* K*.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10SourceCut`

Proof. Start with the dyadic budget row. Theorem 765.108 permits $\mathsf{DyadicRatCore}^{\uparrow}$ reads only as displayed finite observation budget rows attached to the packet K.

Next use the route order. Theorem 765.109 forces the $\mathsf{StreamName}^{\uparrow}$ schedule before the $\mathsf{RegSeqRat}^{\uparrow}$ readback and both before the $\mathsf{Real}^{\uparrow}$ seal handoff.

The displayed source cut is therefore the packet rows followed by the dyadic budget, the StreamName schedule, the RegSeqRat readback, and the Real seal row. Since none of the cited rows has a coordinate for quotient equality, selected limits, Real completeness, closed consistency, or an undisplayed route row, no Phase Real consumer may read those objects as sources for the handoff. □

Theorem 765.112 (MetaCIC critical-path Real seal non-escape)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the* $\mathsf{Real}^{\uparrow}$ *seal handoff exports exactly the displayed L10 dependency budget of Theorem 765.110. It exports no Real completeness theorem, no host-selected limit, no quotient stream equality, no closed consistency row, and no extra completion selector.*

Proof. Read the handoff through the readiness package. Theorem 765.106 packages the StreamName, RegSeqRat, and Real-facing rows while keeping them inside the displayed packet surface.

Then apply the frontier theorem. Theorem 765.110 identifies the exact frontier as the L10 dependency budget and explicitly removes quotient stream equality, selected limits, ambient completeness, closed subject reduction, full consistency, hidden completion selectors, and theorem rows outside the packet.

Combining these two facts leaves the Real seal handoff with only the displayed dependency rows. Hence Real completeness, host-selected limits, quotient stream equality, closed consistency, and extra completion selectors cannot escape through the seal. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealSealNoCompletenessEscape`

Theorem 765.113 (MetaCIC critical-path Phase Real exit conjunction)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, this packet supplies the paper-side exit conjunction for the Phase Real and Completion route over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*: finite observation reads are displayed as dyadic budget rows, schedule reads precede regular-rational readback, regular-rational readback precedes the Real seal, and the Real seal frontier exports no quotient equality, selected limit, ambient completeness, closed consistency, or off-budget completion selector. Verification status and bridge status remain on the independent Lean axis.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealExitConjunction`

Proof. The dyadic part of the conjunction is Theorem 765.108. It makes finite observation reads visible as $\mathsf{DyadicRatCore}^{\uparrow}$ budget rows of K.

The route-order part is Theorem 765.109. It places the $\mathsf{StreamName}^{\uparrow}$ schedule before $\mathsf{RegSeqRat}^{\uparrow}$ readback and puts both before the $\mathsf{Real}^{\uparrow}$ seal handoff.

The exit boundary is supplied by Theorems 765.110, 765.111, and 765.112. Together they identify the source cut, the exact frontier, and the refusal of quotient equality, selected limits, Real completeness, closed consistency, and extra completion selectors.

These are paper-side dependency and non-escape clauses. They state the Phase Real exit surface without adding a verification marker or a bridge row, so the Lean verification grade and bridge grade stay governed by the separate closurestatus axis. □

Theorem 765.114 (MetaCIC critical-path Phase Real budget exhaustion)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *serving the Phase Real and Completion route, the packet has no L10 dependency budget outside the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite*

observation row, StreamName$^{\uparrow}$ *schedule row,* RegSeqRat$^{\uparrow}$ *readback row,* Real$^{\uparrow}$ *seal handoff,* hsame *transport,* Cont *replay,* Pkg *provenance, and local ledger. Any consumer that asks for quotient stream equality, a host-selected limit, ambient Real completeness, closed consistency, bridge status, or a verification upgrade is outside this paper-side budget.*

Proof. First read the displayed dependency rows. Theorem 765.108 confines finite observations to the DyadicRatCore$^{\uparrow}$ row, and Theorem 765.109 forces the StreamName$^{\uparrow}$ schedule before RegSeqRat$^{\uparrow}$ readback and the Real$^{\uparrow}$ seal.

Next identify the boundary. Theorems 765.110, 765.111, and 765.112 make the Real-facing frontier exact at the displayed L10 rows and exclude quotient stream equality, host-selected limits, ambient Real completeness, closed consistency, and extra completion selectors.

Finally apply Theorem 765.113. It packages the same dyadic budget, schedule order, readback, seal, and non-escape clauses as the Phase Real exit surface. The transport, replay, provenance, and local ledger rows preserve that surface, while verification status and bridge status remain independent closurestatus axes rather than additional L10 dependency rows. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealBudgetExhaustion`

Theorem 765.115 (MetaCIC critical-path L10 budget exit)**.** *For every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *serving the Phase Real and Completion route, the paper-side L10 exit budget is satisfied exactly when the displayed route reads, in order, the* DyadicRatCore$^{\uparrow}$ *finite observation rows,* StreamName$^{\uparrow}$ *schedules,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local ledger. The same exit budget excludes quotient equality, selected limits, Real completeness, closed consistency, and bridge status from the L10 dependency surface.*

Proof. First expose the dyadic and schedule side. Apply Theorem 765.108 for the finite observation rows and Theorem 765.109 for the order placing StreamName schedules before RegSeqRat readback and the Real seal handoff.

Next identify the Real-facing frontier. Apply Theorem 765.110 to make the seal frontier exact at the displayed L10 dependency budget, and use Theorem 765.111 to force the source cut through the dyadic, stream, readback, and seal rows.

Now apply the non-escape and conjunction theorems. Theorem 765.112 removes Real completeness, selected limits, quotient stream equality, closed consistency, and extra completion selectors; Theorem 765.113 repacks the remaining rows as the Phase Real exit surface.

Finally use Theorem 765.114. It says there is no L10 dependency budget outside the displayed finite observation, schedule, readback, seal, transport, replay, provenance, and local ledger rows. Therefore the stated displayed route is exactly the L10 budget exit, while bridge status and verification status remain outside the paper-side dependency budget. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10BudgetExit`

Theorem 765.116 (MetaCIC critical-path candidate SN obligation discharge)**.** *For every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *serving the Phase Real and Completion route, a candidate-mediated strong-normalization obligation may be discharged only after the displayed* DyadicRatCore$^{\uparrow}$ *finite observation rows,* StreamName$^{\uparrow}$ *schedules,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local ledger rows have all been read. Before those rows are visible, the candidate obligation remains an open boundary of the L10 budget rather than a closed subject-reduction, consistency, quotient-equality, or Real-completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNObligationDischarge`

Proof. Start with the dyadic source cut. Theorems 765.108 and 765.111 force every Phase Real read to begin with displayed finite observation budget rows rather than quotient equality, selected limits, or an undisplayed route.

Next use the route-order and Real frontier theorems. Theorem 765.109 places StreamName before RegSeqRat and the Real seal, while Theorem 765.110 keeps the seal exact at that budget.

Finally apply the exit conjunction, budget exhaustion, and L10 budget exit theorems. They say that the transport, replay, provenance, and local ledger rows complete the paper-side route and that no off-budget completion selector, closed subject-reduction row, consistency row, quotient equality, or Real completeness row is exported. Thus candidate-mediated strong-normalization obligations can be discharged only after the displayed L10 rows have been read. □

Theorem 765.117 (MetaCIC critical-path confluence residual boundary)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *serving the Phase Real and Completion route, every confluence residual boundary remains inside the same L10 budget of* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and the local ledger. The residual boundary exports no closed subject reduction, quotient equality, hidden scheduler, Real completeness row, full consistency row, or bridge status.*

Proof. Project the Real-facing budget through Theorem 765.115. The only exit rows are the dyadic budget, StreamName schedule, RegSeqRat readback, Real seal, transport, replay, provenance, and local ledger.

Use Theorems 765.112 and 765.114. They remove Real completeness, quotient equality, selected limits, closed consistency, bridge status, and extra completion selectors from the paper-side dependency surface.

The residual boundary is therefore confined to the displayed rows. Any consumer asking for closed subject reduction, a hidden scheduler, quotient equality, Real completeness, full consistency, or bridge status is asking outside the L10 budget rather than reading a confluence residual exported by K. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceResidualBoundary`

Theorem 765.118 (MetaCIC critical-path L10 entry budget synchronization)**.** *For every current Phase Real or Completion consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

entry into the Phase Real route is permitted only after the packet displays the $\mathsf{DyadicRatCore}^{\uparrow}$ *finite observation budget, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal rows through finite* BHist, hsame, Cont, Pkg, *and* NameCert *provenance attached to* K*. The entry surface refuses quotient reals, host equality, trichotomy, open-cover compactness, and completed-real claims.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10EntryBudgetSynchronization`

Proof. First expose the packet itself. Theorems 765.84, 765.85, and 765.86 make $S, N, O, U, D, H, C, P, L$ the displayed carrier, replay, and consumer surface.

Next read the Phase Real dependency budget. Theorems 765.98, 765.99, and 765.100 keep the normal-form, obstruction, discharge, continuation, package, and provenance rows visible before a Real-facing handoff.

Finally synchronize the four L10 source rows. Theorems 765.104, 765.105, 765.106, 765.108, 765.109, and 765.110 identify the dyadic budget, schedule, readback, and seal rows as displayed dependency rows of the same packet. None of these rows carries quotient reals, host equality, trichotomy, open-cover compactness, or a completed-real theorem, so the entry budget is exactly the finite provenance surface described above. □

Theorem 765.119 (MetaCIC critical-path Real completion frontier filter)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, any Completion-facing claim passed through its Real frontier is admitted only when it is backed by the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *L10 source rows of Theorem 765.118. Claims that require quotient reals, host equality, trichotomy, open-cover compactness, or completed-real data are filtered out of the packet frontier.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket real completion frontier filter`

Proof. Begin with the synchronized entry budget. Theorem 765.118 requires the four displayed L10 source rows before the packet can enter the Phase Real route.

The frontier then reads only those rows. Theorem 765.110 identifies the exact seal frontier with the displayed L10 dependency budget, while Theorems 765.111 and 765.112 exclude source reads and seal exports outside that budget.

The filter is therefore constructive and finite: a claim survives only by naming the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows attached to K. Quotient reals, host equality, trichotomy, open-cover compactness, and completed-real data have no displayed row in that list, so they cannot pass through the frontier. □

Theorem 765.120 (MetaCIC critical-path current open-phase readiness)**.** *The current paper-side readiness surface consumed by the Phase Real and Completion route for* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *is the conjunction of the Phase Real dependency budget, the L10 entry budget synchronization of Theorem 765.118, and the Real completion frontier filter of Theorem 765.119. This surface is a finite* BHist/hsame/Cont/Pkg/NameCert *dependency surface and not a claim of quotient reals, host equality, trichotomy, open-cover compactness, or completed-real closure.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCurrentOpenPhaseReadiness`

Proof. The dependency budget supplies the route rows. Theorems 765.98, 765.99, and 765.100 expose the finite packet rows consumed by the Phase Real route.

The entry theorem then synchronizes the sources. Theorem 765.118 requires the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows to be displayed through finite provenance before route entry.

The frontier theorem gives the open-phase filter. Theorem 765.119 admits only claims backed by those four displayed source rows and refuses quotient reals, host equality, trichotomy, open-cover compactness, and completed-real data. Together these rows are exactly the current paper-side readiness surface used by the Phase Real and Completion route. □

Theorem 765.121 (MetaCIC critical-path Phase Real dependency diamond)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, a public Phase Real or Completion entry is accepted exactly when its route factors through the four displayed source rows attached to* K*: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite observation budget, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal row. The four projections of this factorization recover those source rows*

and no other public entry row is available. In particular, the diamond exports no quotient stream equality, selected host limit, host equality, trichotomy, open-cover compactness, or completed-real theorem.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealDependencyDiamond`

Proof. Start from the current open-phase surface. Theorem 765.120 says that a Phase Real or Completion consumer sees the Phase Real dependency budget together with the synchronized L10 entry surface and the Real completion frontier filter.

The entry side supplies the four displayed sources. Theorem 765.118 requires the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows before public entry, while Theorem 765.119 admits only claims backed by those rows at the Completion frontier.

The projections are forced by the readiness and order rows. Theorems 765.104, 765.105, 765.106, and 765.108 identify the four sources as rows of the same packet K.

Finally use the route-order and seal-frontier exactness theorems. Theorems 765.109 and 765.110 place those rows in the displayed diamond and exclude off-budget exits. Hence the public entry route factors through exactly the four source rows, and the excluded completion or host principles have no exported coordinate. □

Theorem 765.122 (MetaCIC critical-path four source-owner noncollapse)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, any Phase Real or Completion public entry accepted through the dependency diamond of Theorem 765.121 retains four separate source-owner records: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite observation budget owner, the* $\mathsf{StreamName}^{\uparrow}$ *schedule owner, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback owner, and the* $\mathsf{Real}^{\uparrow}$ *seal owner. Identifying two of these owners, replacing one owner by an aggregate route-status token, or substituting quotient stream equality, selected host limit, host equality, trichotomy, open-cover compactness, closed consistency, or completed-real data places the entry outside the accepted finite route.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFourSourceOwnerNoncollapse`

Proof. Start with the finite surface. Theorem 765.120 says that the Phase Real and Completion consumer sees only the displayed BHist, hsame, Cont, Pkg, and NameCert rows attached to the packet K.

The entry budget then fixes the owner list. Theorem 765.118 requires the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows as four displayed sources before the route is entered.

The frontier removes every substitute. Theorem 765.119 rejects claims that need quotient stream equality, selected host limits, host equality, trichotomy, open-cover compactness, closed consistency, or completed-real data rather than one of the displayed source rows.

Finally apply the diamond. Theorem 765.121 recovers exactly the four projections from an accepted public entry. If two owners were identified, or if an aggregate route-status token replaced one owner, one of those projections would no longer recover its named source row. Such an entry therefore lacks the required four-coordinate factorization and is not an accepted finite route. □

Theorem 765.123 (MetaCIC critical-path L10 prefix dependency induction)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any Phase Real or Completion route admitted by Theorem 765.121 has four finite route prefixes: the $\mathsf{DyadicRatCore}^{\uparrow}$ *budget prefix, the* $\mathsf{StreamName}^{\uparrow}$ *schedule prefix, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback prefix,*

and the $\mathsf{Real}^{\uparrow}$ *seal prefix. These prefixes occur in that source order, each factors through the displayed packet rows of Theorems 765.118, 765.119, 765.121, and 765.122, and each preserves the obstruction, discharge, host, continuation, package, and ledger rows* O, D, H, C, P, L*. No prefix may be replaced by quotient stream equality, selected host limits, host equality, trichotomy, open-cover compactness, closed subject reduction, full consistency, or completed-real data.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10PrefixDependencyInduction`

Proof. Begin with the entry requirement. Theorem 765.118 admits a Phase Real route only after the packet displays the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows through finite BHist, hsame, Cont, Pkg, and NameCert provenance.

The frontier supplies the exclusion step. Theorem 765.119 says that Completion-facing claims survive only when backed by those displayed rows, so the forbidden substitutes have no route coordinate to occupy.

The diamond gives the constructive prefix split. Theorem 765.121 recovers the four projections from an accepted entry, hence the route can be read as the ordered finite prefix chain from budget to schedule to readback to seal.

Finally keep the owners and packet rows fixed. Theorem 765.122 prevents any two source owners from collapsing and rules out aggregate route-status replacements. Therefore each prefix remains attached to its own source row while carrying forward the common obstruction, discharge, host, continuation, package, and ledger rows O, D, H, C, P, L. □

Theorem 765.124 (MetaCIC critical-path RealCompleteness exact-boundary gate)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any Phase Real and Completion route admitted by the dependency diamond of Theorem 765.121 and then consumed as a $\mathsf{RealCompleteness}^{\uparrow}$ *exact-boundary handoff factors through the four displayed faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, and then through the accepted* RealCompletionExactBoundaryUp *packet of Theorem 1120.6. The gate exports no quotient stream equality, selected host limit, host equality, trichotomy, open-cover compactness, closed subject reduction, full consistency, metric completeness, aggregate bridge token, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealCompletenessExactBoundaryGate`

Proof. First read the MetaCIC side. Theorems 765.118, 765.119, and 765.121 force any admitted Phase Real and Completion route to display the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows before it can be consumed downstream.

The prefix and owner constraints keep this route finite. Theorems 765.122 and 765.123 prevent the four owners from collapsing, preserve the packet rows O, D, H, C, P, L, and rule out substitutions by quotient streams, selected host limits, host equality, trichotomy, open-cover compactness, subject reduction, consistency, or completed-real data.

Now pass to the RealCompleteness handoff. Theorem 450.33 says that an exact-boundary consumer for $\mathsf{RealCompleteness}^{\uparrow}$ must be read through an accepted RealCompletionExactBoundaryUp packet, and Theorem 450.34 reduces every finite consumer extension to the same boundary route.

Finally apply the four-face exactness theorem. Theorem 1120.6 identifies the boundary faces as exactly the dyadic, stream, regular-sequence, and Real faces exported by the accepted packet. Hence the downstream handoff is a repacking of the same four finite faces rather than a new completion object, and the excluded quotient, host, compactness, consistency, metric-completeness, bridge, and $\mathsf{Real}^{\uparrow}$ completeness principles have no exported coordinate. □

Theorem 765.125 (MetaCIC critical-path exact-boundary prefix determinacy)**.** *For every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

suppose that a Phase Real and Completion route is admitted by the dependency diamond of Theorem 765.121 and is then consumed by RealCompletionExactBoundaryUp *through the RealCompleteness exact-boundary gate of Theorem 765.124. Then the ordered four prefixes of Theorem 765.123 determine the same exact-boundary handoff as Theorem 1120.6: the* DyadicRatCore$^{\uparrow}$ *budget prefix, the* StreamName$^{\uparrow}$ *schedule prefix, the* RegSeqRat$^{\uparrow}$ *readback prefix, and the* Real$^{\uparrow}$ *seal prefix, all carried by the common* BHist, hsame, Cont, Pkg, *and* NameCert *rows of the two accepted packets.*

Consequently every accepted downstream handoff is this four-prefix finite boundary. It is not determined by quotient stream equality, selected host limits, host equality, trichotomy, open-cover compactness, closed subject reduction, full consistency, metric completeness, aggregate bridge tokens, ambient Real$^{\uparrow}$ *completeness, or any hidden completion coordinate.*

Proof. Begin on the MetaCIC side. Theorem 765.118 exposes the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows through finite BHist, hsame, Cont, Pkg, and NameCert provenance attached to K.

The frontier and diamond then force the same ordered source list. Theorems 765.119 and 765.121 admit only routes backed by those four displayed rows, while Theorem 765.122 prevents owner collapse or replacement by an aggregate route-status token.

Use prefix induction to read the route constructively. Theorem 765.123 orders the prefixes as dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal, and keeps O, D, H, C, P, L attached to the same packet rows throughout the route.

Now pass through the RealCompleteness exact-boundary handoff. Theorems 450.33 and 450.34 reduce every accepted exact-boundary consumer to the matched four faces, with only the displayed hsame transports, Cont replays, Pkg provenance, and local NameCert rows.

Finally apply Definition 1120.6. The exact boundary exports exactly the DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ faces, followed by the structural rows of the accepted packet. Thus the MetaCIC route and the Real-completion boundary name the same finite four-prefix handoff, and no quotient, host, compactness, consistency, metric-completeness, bridge, ambient-completeness, or hidden completion coordinate remains available. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathExactBoundaryPrefixDeterminacy`

Theorem 765.126 (MetaCIC critical-path L10 four-face source discipline)**.** *For every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any Phase Real and Completion consumer entering through K must preserve four distinct local source obligations. The DyadicRatCore$^{\uparrow}$ *face supplies only the finite dyadic observation budget, the* StreamName$^{\uparrow}$ *face supplies only the finite source schedule, the* RegSeqRat$^{\uparrow}$ *face supplies only the regular-rational readback route, and the* Real$^{\uparrow}$ *face supplies only the terminal seal handoff.*

The MetaCIC packet coordinates the order, refusal boundary, owner noncollapse, and exact-boundary handoff for those four faces. It does not discharge any face's carrier, classifier, stability row, local closurestatus, formalstatus, leantarget, or bridge row. In particular, no quotient stream equality, selected host limit, host equality, trichotomy, open-cover compactness, countable choice, closed subject reduction, full consistency, metric completeness, aggregate bridge token, or Real$^{\uparrow}$ *completeness claim can replace one of the four local source obligations.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourFaceSourceDiscipline`

Proof. Begin with the synchronized entry route. Theorem 765.118 displays the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows before Phase Real entry, while Theorem 765.121 recovers exactly those four projections from an accepted public entry.

Use prefix induction and the exact-boundary determinacy result to keep the route ordered. Theorem 765.123 reads the consumer path as the ordered prefix chain from dyadic budget to schedule to readback to seal. Theorem 765.125 then identifies the downstream exact-boundary handoff with the same four prefixes, so the MetaCIC packet contributes coordination of the route rather than a fifth source face.

Now read the objectwise status surface. Theorems 765.132, 765.136, and 765.140 force closurestatus, formalstatus, leantarget, and bridge rows to remain local to $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Theorems 38.833 and 38.834 exclude any fused status or target row.

It remains to exclude substitutes for the local source obligations. Theorems 765.138, 765.139, and 765.142 rule out quotient stream equality, selected host limits, host equality, trichotomy, open-cover compactness, countable choice, and aggregate route credentials as replacements for a missing face. The exact-boundary gate and the four-object exit certificate additionally refuse closed subject reduction, full consistency, metric completeness, aggregate bridge tokens, and $\mathsf{Real}^{\uparrow}$ completeness as exported coordinates. Therefore the MetaCIC packet can coordinate the L10 route, but each of the four faces remains a separate local source obligation with its own carrier, classifier, stability, status, target, and bridge audit rows. □

Theorem 765.127 (MetaCIC critical-path L10 candidate-discharge gate)**.** *An accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *candidate-mediated normalization read may be scheduled for discharge only after it displays the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, together with the obstruction row and discharge socket of the same packet. Agreement on the MetaCIC rows alone cannot close the L10-facing discharge.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10CandidateDischargeGate`

Proof. Start with the entry budget. Theorem 765.118 requires the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows before an L10-facing route can enter the MetaCIC critical path.

Next read the current readiness surface. Theorem 765.120 keeps the obstruction and discharge data attached to the displayed finite packet rows, while Theorem 765.121 recovers the same four source projections from an accepted Phase Real or Completion entry.

Finally apply the ordered prefix and source-discipline gates. Theorem 765.123 keeps the dyadic, StreamName, RegSeqRat, and Real faces in source order, and Theorem 765.126 says that the MetaCIC packet coordinates those faces without discharging any local carrier, classifier, stability, status, target, or bridge row. Thus equality of the MetaCIC coordination rows is insufficient: the candidate may be scheduled for discharge only when the four named L10 faces, the obstruction row, and the discharge socket are all displayed in the accepted packet. □

Theorem 765.128 (MetaCIC critical-path L10 four-object exit certificate)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the current Phase Real and Completion exit surface is reached exactly by displaying four finite source rows attached to* K*: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite dyadic budget, the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row, and the* $\mathsf{Real}^{\uparrow}$ *terminal seal row. Each displayed row is carried through finite* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *provenance, as synchronized by Theorem 765.118, filtered*

by Theorem 765.119, arranged by Theorem 765.121, and kept source-owner separated by Theorem 765.122. No additional exit coordinate is supplied by quotient stream equality, selected host limits, host real equality, trichotomy, open-cover compactness, countable choice, or completed-real closure.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10StatusBridgeObligation`

Proof. First take the synchronized L10 entry surface. Theorem 765.118 requires the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows to be displayed through finite BHist, hsame, Cont, Pkg, and NameCert provenance before a Phase Real or Completion consumer can enter the route.

Next pass to the Completion-facing frontier. Theorem 765.119 admits only claims backed by those four displayed rows, so every accepted exit certificate still reads from the same finite packet surface rather than from quotient stream equality, selected host limits, host real equality, trichotomy, open-cover compactness, countable choice, or completed-real data.

The dependency shape is then fixed by the diamond. Theorem 765.121 says that a public Phase Real or Completion entry factors through exactly the four displayed source rows and recovers no other public entry row.

Finally retain the four owners separately. Theorem 765.122 refuses any collapse of the dyadic budget owner, StreamName schedule owner, RegSeqRat readback owner, and Real seal owner into an aggregate route token. The four-object certificate is therefore precisely the current finite exit surface, and every listed host, choice, compactness, quotient, or completed-real principle remains outside the accepted packet route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourObjectExitCertificate`

Theorem 765.129 (MetaCIC critical-path L10 dependency budget)**.** *For every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, any accepted exit read using the L10 face must display four dependency rows in order:*

1. *the* DyadicRatCore$^{\uparrow}$ *tolerance row, recording the finite dyadic budget consumed by the request;*
2. *the* StreamName$^{\uparrow}$ *finite-observation row, recording the inspected stream windows;*
3. *the* RegSeqRat$^{\uparrow}$ *readback row, recording the regular rational data obtained from those windows;*
4. *the* Real$^{\uparrow}$ *seal row, recording the terminal Real-facing handoff reached after the preceding rows have been displayed.*

The budget is a dependency display over the existing BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows of* K*. It exports no closed consistency result, global normalization theorem, quotient real equality, or selected limit.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10ExitDependencyBudget`
Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10DependencyBudget`

Proof. Apply the four-object exit certificate of Definition 765.128. It identifies the current Phase Real and Completion exit surface with exactly the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows attached to the accepted packet.

Read that certificate as an ordered dependency budget. The dyadic row supplies the tolerance request, the StreamName row supplies the finite observations for that request, the RegSeqRat row reads those observations as regular rational data, and the Real row seals only the displayed route.

The same certificate keeps the four rows inside finite BHist, hsame, Cont, Pkg, and NameCert provenance. Since the carrier supplies no further exit coordinate, a consumer cannot extract closed consistency, global normalization, quotient real equality, or a selected limit from this dependency budget. □

Theorem 765.130 (MetaCIC critical-path Real-completion public socket)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, a public MetaCIC critical-path consumer may read the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows only as an L10 boundary socket before the subject-reduction discharge bundle is filled. The socket may expose the Real-completion dependency route and the four finite source rows, but it exports no closed subject reduction, full closed consistency, global beta-conversion decidability, quotient term equality, selected host limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealCompletionPublicSocket`

Proof. Start from the packet definition and the consistency handoff. The carrier rows $S, N, O, U, D, H, C, P, L$ keep the normal-form endpoint, obstruction row, handoff row, discharge socket, transport, replay, provenance, and local naming visible before any public consumer can read the route.

Next apply the obstruction boundary and the L10 exit dependency budget. The obstruction boundary keeps O and D visible, while Definition 765.129 orders the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal as four displayed dependency rows.

The public consumer therefore receives only the L10 boundary socket. The four Real-completion rows can be inspected as finite source data carried through BHist, hsame, Cont, Pkg, and NameCert provenance, but the subject-reduction discharge bundle remains a separate obligation.

Finally the same projection refuses the excluded exports. Since the packet contains no coordinate for closed subject reduction, full closed consistency, global beta-conversion decidability, quotient term equality, selected host limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those claims is produced by reading the public socket. □

Theorem 765.131 (MetaCIC critical-path L10 boundary consumer)**.** *Every consumer of the Real-completion socket in Definition 765.130 must consume the four L10 rows through the same packet rows* O, D, H, C, P, L*. Agreement on the Real-facing rows alone cannot fill the subject-reduction socket or collapse the boundary into quotient term equality.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10BoundaryConsumer`

Proof. Project the consumer route from Definition 765.130. The route already fixes the four L10 source rows as a boundary socket and keeps the obstruction and discharge rows visible.

Apply the status bridge obligation and the public export theorem. The L10 faces are read objectwise, while the public export surface remains the finite candidate-mediated route over $S, N, O, U, D, H, C, P, L$ rather than a closed metatheoretic theorem.

Thus a consumer can pass through the Real-completion socket only by preserving O, D, H, C, P, L. The subject-reduction socket is not filled by the Real-facing rows, and quotient term equality is not a packet coordinate. □

Theorem 765.132 (MetaCIC critical-path L10 status bridge obligation)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, any use of Theorem 765.128 as Phase Real and Completion exit evidence must pass through the Real L10 objectwise audit pullback of Theorem 38.471. The* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *faces each contribute*

their own local closurestatus, formalstatus, leantarget, and bridgestatus rows, read from their local closurestatus blocks and not from an aggregate route credential.

Consequently the MetaCIC four-object certificate can be consumed only through the objectwise status discipline of Theorem 38.833 and Theorem 38.488. It supplies no quotient stream equality, no selected host limit, no aggregate bridge row, and no $\mathsf{Real}^{\uparrow}$ *completeness claim beyond the four local face records.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10StatusBridgeObjectwiseObligation`

Proof. First read the MetaCIC certificate itself. Theorem 765.128 displays exactly four finite source rows attached to K: the dyadic budget, StreamName schedule, RegSeqRat readback, and Real terminal seal rows.

Next apply the Real L10 audit pullback. Theorem 38.471 replaces any aggregate reading of that displayed route by the product of the four local face records. Each face is therefore read through its own closurestatus, formalstatus, leantarget, and bridgestatus entries.

Now use Theorem 38.833. The four local face reports remain separate and cannot be fused into a new formalstatus token, route-level bridge row, or $\mathsf{Real}^{\uparrow}$ completeness report.

Finally apply Theorem 38.488. A Phase Real and Completion exit is accepted only when the four objectwise face records are presented, so quotient stream equality, selected host limits, aggregate bridge rows, and completed-real closure remain outside the MetaCIC L10 evidence. □

Theorem 765.133 (MetaCIC critical path L10 objectwise status consumer)**.** *Any* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer that records the Phase Real and Completion exit may read* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *only through the objectwise status bridge obligation and the displayed source ledger. The consumer receives four local face records, carried by the packet rows* O, D, H, C, P, L, *and no coordinate for host equality, quotient streams, selected limits, aggregate bridge status, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply Theorem 765.132. It routes every use of the four-object exit certificate through the Real L10 objectwise audit pullback, so the four Real and Completion source faces are not read as one aggregate credential.

Next apply Theorem 765.132 in its objectwise form recorded above. The dyadic budget, finite stream schedule, regular-rational readback, and Real seal each contribute a separate local closurestatus, formalstatus, leantarget, and bridgestatus row.

Project the displayed source ledger from $K = (S, N, O, U, D, H, C, P, L)$. The rows O, D, H, C, P, L keep the obstruction, discharge socket, transport, replay, provenance, and local naming visible while the four source faces are consumed.

The excluded coordinates are absent from the packet and from the objectwise bridge surface. Thus the consumer cannot replace the four local face records by host equality, quotient streams, selected limits, an aggregate bridge row, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10ObjectwiseStatusConsumer`

Theorem 765.134 (MetaCIC Phase Real four-face obligation surface)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$, *a Phase Real exit accepted through* K *is obligated to present four separate object rows: a* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite-budget row, a* $\mathsf{StreamName}^{\uparrow}$ *schedule row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and a* $\mathsf{Real}^{\uparrow}$ *seal row. The rows are read as distinct* BHist, hsame, Cont, Pkg, *and* NameCert *surfaces, and no one of the four may be replaced by an aggregate MetaCIC route token or by a downstream Completion credential.*

Proof. Start with the four-object exit certificate of Theorem 765.128. It already identifies the accepted exit surface over K with the dyadic budget, StreamName schedule, RegSeqRat readback, and Real terminal seal rows, each carried by finite packet provenance.

Use the status bridge obligation of Theorem 765.132 to route that certificate through the Real L10 objectwise audit pullback. Theorem 38.471 then forces the displayed route to be read as the product of the four local face records, rather than as a single MetaCIC status row.

Finally apply Theorem 38.488. Since the Phase Real exit criterion accepts only the objectwise presentation, every accepted exit through K must expose the four named obligation rows separately. The resulting surface is exactly the root-unblock obligation surface for the current Phase Real route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealFourFaceObligationSurface`

Theorem 765.135 (MetaCIC four-face confluence budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, candidate-mediated confluence evidence and bounded-conversion evidence may consume the L10 source-readiness rows only as four separate finite faces:* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The budget is carried through the same displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows as the accepted packet.*

No candidate-mediated confluence read or bounded-conversion read can collapse these four faces into a subject-reduction certificate, quotient stream equality, selected host limit, countable-choice coordinate, or completed-real closure.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFourFaceConfluenceBudget`

Proof. Start with the four-object exit certificate, Definition 765.128. It displays exactly the dyadic budget, StreamName schedule, RegSeqRat readback, and Real terminal seal rows as the L10 exit surface.

Next use the four-face obligation surface, Definition 765.134, together with the source-obligation theorem Definition 765.165. These results force any Phase Real or Completion consumer to expose $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as separate finite source rows before confluence-decidability handoff or downstream readiness is consumed.

Now route candidate evidence through Definition 765.278. Candidate-mediated strong-normalization, confluence-facing, and bounded-decidability rows may be inspected only while the obstruction row O and discharge socket D remain visible in the same packet.

Finally apply Definition 765.280 and Definition 765.26. Bounded conversion may support candidate inspection, but the socket is filled only by a separate subject-reduction certificate. Therefore the four L10 faces remain source-readiness rows and cannot be collapsed into subject reduction, quotient equality, selected limits, countable choice, or completed-real closure. □

Theorem 765.136 (MetaCIC Phase Real status-product readiness)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the Phase Real exit evidence through* K *is ready for downstream consumption only when the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *faces each supply their own local closurestatus, formalstatus, leantarget, and bridgestatus rows. These four reports are read independently from the local face chapters and are not inferred from the aggregate MetaCIC four-object certificate.*

Proof. First read the accepted packet through Theorem 765.132. It states that any use of the MetaCIC four-object certificate as Phase Real and Completion exit evidence must pass through the Real L10 objectwise audit pullback.

The audit pullback of Theorem 38.471 supplies the product reading: each of the four faces contributes its own closurestatus, formalstatus, leantarget, and bridgestatus row. This gives readiness only after all four local records have been displayed.

The noncollapse clauses now rule out aggregate substitution. Theorem 38.833 prevents a fused formalstatus or route-level bridge row, and Theorem 38.834 keeps the leantarget rows local to their four face chapters. Thus downstream consumers receive a four-entry status product, not a single MetaCIC route credential. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealStatusProductReadiness`

Theorem 765.137 (MetaCIC L10 four-face discharge readiness)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, Phase Real and Completion exit evidence can be consumed through* K *only when each of the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *exposes its own local discharge-readiness row. The aggregate MetaCIC route may display the four-object exit certificate and the status-product readiness surface, but it cannot provide a missing face-local discharge row for any one of the four faces.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourFaceDischargeReadiness`

Proof. First use Definition 765.136. It reads downstream readiness as a product of the four local face records and refuses an aggregate MetaCIC route credential as a substitute for those records.

Next apply face-local target locality through Definition 765.140. The $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ target and bridge rows remain attached to their own chapters, so a discharge-readiness row attached to one face cannot be moved to another face or supplied by the route as a whole.

Finally apply the four-face deficiency refusal of Definition 765.139. If any face lacks the local row required for consumption, the missing coordinate blocks the Phase Real and Completion exit read. Thus the MetaCIC route can package the four faces, but it cannot discharge a face whose local readiness row is absent. □

Theorem 765.138 (MetaCIC Phase Real exit refusal boundary)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the Phase Real exit through* K *refuses quotient stream equality, selected host limits, host equality, trichotomy, open-cover compactness, countable choice, and completed-real closure. The only accepted exit data are the four finite object rows of Theorem 765.134 together with their local status-product rows of Theorem 765.136.*

Proof. Begin with Theorem 765.128. Its final exclusion list already keeps quotient stream equality, selected host limits, host real equality, trichotomy, open-cover compactness, countable choice, and completed-real closure outside the four-object exit certificate.

Next use Theorem 765.132. It says that the certificate can be consumed only through the Real L10 objectwise status discipline, and it supplies no quotient stream equality, no selected host limit, no aggregate bridge row, and no $\mathsf{Real}^{\uparrow}$ completeness claim beyond the four local face records.

The Real L10 audit theorems make the refusal stable under downstream reading. Theorem 38.833 prevents the missing coordinates from reappearing as a fused status row, while Theorem 38.488 accepts the exit only through the four objectwise face records.

Combining the four-face obligation surface with the status-product readiness theorem therefore leaves no admissible entry point for quotient equality, selected limits, host equality, trichotomy, open-cover compactness, countable choice, or completed-real closure. These principles remain outside the accepted Phase Real exit boundary through K. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealExitRefusalBoundary`

Theorem 765.139 (MetaCIC critical-path four-face deficiency refusal)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, suppose that at least one of the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *fails to provide the local closurestatus, formalstatus, leantarget, and bridgestatus row required by Theorem 38.488. Then the MetaCIC four-object route through* K *cannot be consumed as Phase Real and Completion exit evidence.*

In particular, the missing face cannot be replaced by an aggregate formalstatus row, an aggregate bridge row, quotient stream equality, a selected host limit, countable choice, or a $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First route the accepted packet through the MetaCIC status bridge. Theorem 765.132 sends every use of the four-object certificate to the Real L10 objectwise audit pullback, and Theorem 765.136 says that downstream readiness is obtained only from the four local face rows.

Now apply the Real-side blocker. Theorem 38.489 states that a deficient face in the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ product prevents the current Phase Real and Completion exit criterion from being satisfied. Since the MetaCIC route is consumed only through that product, the deficient face blocks consumption of the route as exit evidence.

Finally use the noncollapse theorems to rule out substitutes. Theorem 38.833 prevents an aggregate formalstatus token, aggregate bridge row, quotient stream, selected limit, countable-choice coordinate, or $\mathsf{Real}^{\uparrow}$ completeness report from filling the missing local status coordinate. Theorem 38.834 keeps leantarget and bridgestatus rows local to their four face chapters. Thus the contrapositive obstruction is route-level: without all four local face records, the MetaCIC four-object route supplies no admissible Phase Real and Completion exit evidence. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFourFaceDeficiencyRefusal`

Theorem 765.140 (MetaCIC critical-path L10 face target locality)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, each Phase Real face* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *must supply its own local leantarget and bridgestatus row when the packet is consumed as Phase Real and Completion exit evidence. These rows are read through the Real L10 objectwise audit pullback of Theorem 38.471; no aggregate MetaCIC route target, route-level bridge row, quotient stream equality, selected host limit, countable-choice coordinate, or* $\mathsf{Real}^{\uparrow}$ *completeness claim can replace any one of the four local rows.*

Proof. Start from the status bridge obligation. Theorem 765.132 says that any use of the accepted MetaCIC four-object certificate as Phase Real and Completion exit evidence must pass through the Real L10 objectwise audit pullback.

The pullback then fixes the reading of the target and bridge rows. By Theorem 38.471, the exit evidence is inspected as the product of the four local face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, not as a single route credential.

Apply the two Real-side noncollapse clauses. Theorem 38.834 keeps each leantarget row attached to its own face chapter, and Theorem 38.833 prevents a fused status or bridge row from replacing that face-local audit record.

Finally use Theorem 765.139. If any face-local leantarget or bridgestatus row is missing, the missing coordinate cannot be supplied by an aggregate MetaCIC route target, route-level bridge row, quotient stream equality, selected host limit, countable-choice coordinate, or $\mathsf{Real}^{\uparrow}$ completeness claim. Thus the target and bridge coordinates are objectwise obligations for the four displayed faces. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FaceLeantargetLocality`

Theorem 765.141 (MetaCIC L10 source-owner blocker)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *consumed as Phase Real and Completion exit evidence, every read through* K *preserves four separate source-owner rows for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The dyadic budget, stream schedule, regular-rational readback, and Real seal remain owned by their local face chapters and by the finite* BHist, hsame, Cont, Pkg, *and* NameCert *support rows attached to those faces.*

No aggregate MetaCIC route token, quotient stream equality, selected host limit, countable-choice coordinate, or completed-real closure can replace a missing source-owner row. In particular, a Phase Real or Completion consumer that omits any one owner row cannot repair the omission by citing the route as a whole.

Proof. First apply the four-object exit certificate. Theorem 765.128 identifies the exit surface with exactly the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows, so the route starts with four displayed owners rather than one aggregate source.

Next use the status-product readiness and face leantarget locality results, Theorem 765.146 and Theorem 765.140. Readiness is packaged as a product of local records, and each leantarget or bridge row remains attached to its own face chapter.

Finally apply the four-face deficiency refusal. Theorem 765.139 blocks consumption whenever a local face record is absent and refuses aggregate route credentials, quotient stream equality, selected limits, countable choice, and ambient Real completeness as substitutes. Therefore each Phase Real and Completion read must preserve the four source-owner rows separately. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10SourceOwnerBlocker`

Theorem 765.142 (MetaCIC Phase Real audit-clean floor)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$, *the packet can be consumed as Phase Real and Completion exit evidence only when the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *are each read through their own local closurestatus record at least* scopedClosed *and their own local formalstatus record at least* auditClean. *The comparison is made face by face through the Real L10 audit pullback of Theorem 38.471 and the objectwise exit threshold equivalence of Theorem 38.494.*

No aggregate route status, aggregate bridge row, quotient stream equality, selected host limit, countable-choice coordinate, or $\mathsf{Real}^{\uparrow}$ *completeness claim can substitute for any one of those four local closure and audit-clean verification records.*

Proof. Start from the face-local reading. Theorem 765.140 says that the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ target and bridge rows are local obligations whenever K is consumed as Phase Real and Completion exit evidence.

Apply the Real L10 pullback. Theorem 38.471 reads the accepted route as the product of the four local face records, not as a single MetaCIC route status. Theorem 38.494 identifies the current exit threshold with local theory-closure rows and local audit-clean verification rows on exactly those four faces.

It remains to exclude substitutes. Theorem 765.139 blocks consumption when any required face-local record is absent. The same refusal rules out aggregate route status, aggregate bridge rows, quotient stream equality, selected host limits, countable choice, and $\mathsf{Real}^{\uparrow}$ completeness as replacements for the missing face-local closure or audit-clean record. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealAuditCleanFloor`

Theorem 765.143 (MetaCIC four-face audit floor)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the complete MetaCIC consumer-side audit floor for the current Phase Real route is the conjunction of the status bridge obligation of Theorem 765.132, the audit-clean floor of Theorem 765.142, and the four-face deficiency refusal of Theorem 765.139. A downstream consumer may therefore accept the route only by displaying all four local face records at the stated closure and verification threshold, with the listed deficiencies still refused.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFourFaceAuditFloor`

Proof. First apply the status bridge obligation. Theorem 765.132 sends every use of the accepted MetaCIC four-object certificate to the Real L10 objectwise audit pullback and prevents the consumer from reading a route-level credential in place of local face data.

Next apply Theorem 765.142. It raises the local status product to the current Phase Real threshold: each of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ must contribute its own closurestatus record at least $\mathsf{scopedClosed}$ and its own formalstatus record at least $\mathsf{auditClean}$.

Finally apply Theorem 765.139. If any one of the four face records is missing or below the required local threshold, the route cannot be consumed as Phase Real and Completion exit evidence. Thus the three cited theorems form the complete consumer-side audit floor for the current MetaCIC route. □

Theorem 765.144 (MetaCIC L10 four-object locality)**.** *Every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *Phase Real and Completion exit consumer must read* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *as four local records, each with its own finite* BHist*,* hsame*,* Cont*,* Pkg*,* $\mathsf{NameCert}$*, closurestatus, formalstatus, leantarget, and bridgestatus surface. None of the four local records can be substituted by an aggregate route target, quotient stream, selected host limit, countable-choice coordinate, route-level bridge row, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

The locality requirement is exactly the consumer-side reading of the MetaCIC L10 route: the aggregate packet may carry the four-object exit certificate, but it never replaces the four displayed object records.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourObjectLocality`

Proof. Start with the L10 status bridge obligation of Theorem 765.132. It sends every accepted use of the four-object certificate through the Real L10 objectwise audit pullback, so the consumer reads the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal as separate local faces.

Next apply the four-face deficiency refusal of Theorem 765.139. If any one of the four local records is absent, the MetaCIC route cannot be consumed as Phase Real and Completion exit evidence. This already rules out replacement by a single aggregate route credential.

The face-target locality theorem, Theorem 765.140, fixes the target and bridge rows at their local faces. Thus a route-level leantarget or route-level bridge row cannot stand in for the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ local record.

Finally apply the audit-clean floor of Theorem 765.143. The consumer-side threshold is the four-face product itself. Quotient streams, selected host limits, countable-choice coordinates, and $\mathsf{Real}^{\uparrow}$ completeness claims have no coordinate in that product, so they cannot replace any of the four local object records. □

Theorem 765.145 (MetaCIC L10 four-face closure readiness)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the packet can be consumed as current Phase Real and Completion readiness only when the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$

each expose a local closurestatus row at least scopedClosed *and a local formalstatus row at least* auditClean*. The MetaCIC aggregate route supplies the four-object exit surface, but it supplies neither quotient stream equality nor selected host limits nor a substitute status row for any missing face.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourFaceClosureReadiness`

Proof. First use the four-object exit certificate. Theorem 765.128 identifies the current route through the dyadic budget, StreamName schedule, RegSeqRat readback, and Real terminal seal rows, each carried by finite BHist, hsame, Cont, Pkg, and NameCert support.

Next route that surface through the status bridge. Theorem 765.132 forces any Phase Real and Completion consumer to inspect the Real L10 objectwise audit pullback, and Theorem 765.136 reads that pullback as a four-entry product of local face records.

The local threshold is the audit-clean floor. Theorem 765.142 and Theorem 765.143 require each face to contribute its own closurestatus at least scopedClosed and its own formalstatus at least auditClean.

Finally apply the deficiency refusal. Theorem 765.139 blocks consumption when any one face is absent or below threshold. The same refusal excludes aggregate route status, quotient stream equality, selected host limits, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness as replacements for the missing local record. □

Theorem 765.146 (MetaCIC L10 four-object readiness)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, suppose the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *each expose their own local closurestatus, formalstatus, leantarget, and bridgestatus rows at the Phase Real and Completion exit threshold. Then* K *may export a Phase Real four-object readiness row whose content is the product of those four local records together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows of the accepted route.*

The readiness row is not an aggregate credential. It does not replace any face-local closure row, formalstatus row, leantarget row, bridgestatus row, quotient stream boundary, selected host limit, countable-choice coordinate, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourObjectReady`

Proof. Start with the four-face closure-readiness theorem, Definition 765.145. It requires each of the four faces to expose its own local closurestatus and formalstatus row before the MetaCIC route is consumable as current Phase Real and Completion readiness.

Next use face-local target locality, Definition 765.140. The $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ leantarget and bridge rows remain attached to their own chapters, so the accepted packet cannot fuse them into a route-level target.

Now apply the consumer threshold theorem, Definition 765.150. It identifies the current exit threshold with the facewise conjunction of the four local records and the displayed finite support rows.

Finally package that conjunction as the exported readiness row. Because the construction uses the product of four local records, Definition 765.139 still blocks consumption when any face is absent or below threshold, and the listed aggregate, quotient, choice, selected-limit, and completeness substitutes remain outside the accepted route. □

Theorem 765.147 (MetaCIC L10 consumer-readiness locality)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, any downstream MetaCIC consumer of the Phase Real route*

must read DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *through their four local closurestatus, formalstatus, leantarget, and bridgestatus records. The four-object route may package those local records as readiness evidence, but it cannot replace any one of them by route-level readiness, quotient stream equality, selected limits, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10ConsumerReadinessLocality`

Proof. Start with Definition 765.146. Its readiness row is a product of the four local records, so a consumer obtains readiness only after the DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ records have each been read.

Apply Definition 765.145. It fixes the local closurestatus and formalstatus rows as facewise obligations rather than as a single route-level threshold.

Finally use Definition 765.139. If any face-local record is absent, the downstream consumer cannot repair the gap with aggregate route readiness, quotient stream equality, selected limits, countable choice, or ambient Real$^{\uparrow}$ completeness. Thus consumer readiness remains local to the four displayed faces. □

Theorem 765.148 (MetaCIC L10 four-face obligation-closure package)**.** *For every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *consumed as Phase Real and Completion evidence, the accepted packet must present the four objectwise obligation rows for* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *together with their local closurestatus and formalstatus support. The aggregate MetaCIC route may package the four faces through its displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows, but it cannot replace any face or infer any local support row from the aggregate route alone.*

The package exports only the facewise obligation surface. It supplies no quotient stream equality, selected host limit, countable-choice coordinate, aggregate bridge row, route-level formalstatus row, or ambient Real$^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourFaceObligationClosurePackage`

Proof. First use the four-object exit certificate of Theorem 765.128. It identifies the Phase Real and Completion route through the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows.

Next apply the status bridge obligation of Theorem 765.132. That theorem sends every accepted use of the aggregate certificate through the Real L10 objectwise audit pullback, so each face must bring its own closurestatus and formalstatus support.

The four-face obligation surface of Theorem 765.134 then makes the obligation row product explicit. The aggregate route can arrange the four faces, but it cannot turn them into one replacement coordinate.

Finally use the audit floor of Theorem 765.143 together with the deficiency refusal of Theorem 765.139. If any face-local support row is missing or below the required threshold, the route is not consumable as current Phase Real and Completion evidence. The same refusal excludes quotient stream equality, selected host limits, countable choice, aggregate bridge rows, route-level formalstatus, and ambient Real completeness as substitutes. □

Theorem 765.149 (MetaCIC Phase Real consumer minimality)**.** *For every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *consumed as Phase Real and Completion exit evidence, every downstream consumer must retain all four Phase Real face rows* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$,

RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *together with the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows attached to those faces. Deleting or replacing any one of those face rows or support rows prevents K from being consumed as current phase exit evidence.*

No aggregate MetaCIC route token, aggregate formalstatus row, aggregate bridge row, quotient stream equality, selected host limit, countable-choice coordinate, metric-completeness row, or Real$^{\uparrow}$ *completeness claim can repair the deletion.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealConsumerMinimality`

Proof. First route the consumer through the status bridge. Theorem 765.132 says that every use of the MetaCIC four-object certificate as Phase Real and Completion exit evidence passes through the Real L10 objectwise audit pullback of Theorem 38.471.

The audit floor then fixes the local threshold. Theorem 765.143 combines the status bridge, Theorem 765.142, and the four-face deficiency refusal into the consumer-side audit floor. Theorem 38.494 reads that floor objectwise, so every local face record is part of the accepted exit threshold.

Now remove one displayed face row or one displayed support row. If the removed row belongs to the DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, or Real$^{\uparrow}$ face product, Theorem 765.139 blocks consumption of the route as Phase Real and Completion exit evidence.

If the consumer proposes an aggregate substitute, the Real L10 noncollapse clauses reject it. Theorem 38.833 prevents aggregate status, bridge, quotient, selected-limit, countable-choice, metric-completeness, and Real$^{\uparrow}$ completeness data from filling a missing face coordinate.

It remains to account for the finite support rows. The four-object certificate of Theorem 765.128 carries the four faces through the displayed BHist, hsame, Cont, Pkg, and NameCert surface, and Theorem 765.134 makes that surface part of the Phase Real obligation. Thus deleting or replacing any displayed support row removes the finite route by which the objectwise audit pullback reads the face, and no aggregate credential can repair the loss. □

Theorem 765.150 (MetaCIC L10 four-face consumer threshold)**.** *For every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet $K = (S, N, O, U, D, H, C, P, L)$ consumed as current Phase Real and Completion exit evidence, the consumer threshold is the facewise conjunction of the four local records for* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$. *Each face must contribute its own local closurestatus row at the scoped object boundary and its own audit-clean formalstatus row, together with the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows attached to that face.*

The threshold is not satisfied by the aggregate MetaCIC route token, by a route-level formalstatus row, by a route-level bridge row, by quotient stream equality, by selected host limits, by countable choice, or by an ambient Real$^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourFaceConsumerThreshold`

Proof. Start with Theorem 765.149. It says that every downstream consumer must retain all four Phase Real face rows and the finite support rows attached to those faces.

Apply Theorem 765.143. The consumer-side audit floor is obtained only by displaying all four local face records at the stated closure and verification threshold. In particular, each of DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ must supply its own closurestatus and audit-clean formalstatus data through the Real L10 objectwise audit pullback.

Finally use Theorem 765.139. If any one face lacks the required local record, the accepted packet cannot be consumed as Phase Real and Completion exit evidence. The same refusal excludes aggregate MetaCIC route tokens, route-level status, route-level bridge data, quotient stream

equality, selected host limits, countable choice, and ambient Real completeness as replacements for the missing facewise threshold row. □

Theorem 765.151 (MetaCIC critical-path L10 four-face obligation noncollapse)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *consumed as Phase Real and Completion exit evidence, the four local obligation rows for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *remain separate. No Phase Real consumer may replace those four rows by an aggregate MetaCIC route token, aggregate formalstatus row, quotient stream equality, selected host limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First apply the four-object exit certificate, Definition 765.128. It exposes the Phase Real route as the displayed product of the four local faces, each with its own finite BHist, hsame, Cont, Pkg, and NameCert support.

Use the status bridge obligation, Definition 765.132. This routes exit evidence through the Real L10 objectwise audit pullback rather than through a single aggregate MetaCIC credential.

Now apply the four-face deficiency refusal and the consumer threshold theorem, Definition 765.139 and Definition 765.150. They make each local face row a required coordinate of consumption and reject the listed aggregate substitutes whenever a coordinate is missing.

Thus the accepted packet can be consumed only by retaining the four local obligation rows separately. The aggregate route token, aggregate formalstatus row, quotient stream equality, selected host limit, and ambient $\mathsf{Real}^{\uparrow}$ completeness claim have no row from which to replace any of them. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourFaceObligationNoncollapse`

Theorem 765.152 (MetaCIC L10 readiness local minimality)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *consumed as current Phase Real evidence, readiness is locally minimal at the four displayed faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Each face must retain its own local record together with the finite* BHist, hsame, Cont, Pkg, *and* NameCert *support rows attached to that face. Deleting any one local face row, or deleting any one displayed support row needed to read that face, blocks consumption of* K *as current Phase Real evidence.*

No aggregate MetaCIC route token, route-level formalstatus row, route-level bridge row, quotient stream equality, selected host limit, countable-choice coordinate, metric-completeness row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim can replace the deleted local row.*

Proof. First apply the four-face consumer threshold of Theorem 765.150. It identifies current consumption with the facewise conjunction of the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ records, each read with its finite BHist, hsame, Cont, Pkg, and NameCert support.

Next use face-target locality from Theorem 765.140. The local target and bridge rows remain attached to their own face chapters, so the aggregate MetaCIC route cannot move one face record onto another or supply a route-level substitute.

The audit floor then fixes the threshold. Theorem 765.143 says that the consumer-side floor is the displayed four-face product at the local closure and verification level. Removing a face row or a support row removes one coordinate of that product.

Finally apply the deficiency refusal of Theorem 765.139. A missing face or missing support coordinate blocks consumption as Phase Real and Completion exit evidence, and the same theorem refuses aggregate route tokens, route-level status, bridge rows, quotient equality, selected limits, countable choice, metric-completeness data, and ambient Real completeness as replacements. Hence the current readiness surface is locally minimal. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10ReadinessLocalMinimality`

Theorem 765.153 (MetaCIC L10 four-face bridge deferral)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *consumed as current Phase Real and Completion exit evidence, bridge closure is deferred face by face to the local* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *records. The aggregate four-object route may expose the finite exit surface and the consumer threshold of Theorem 765.150, but it cannot supply a bridgeChecked row for any face whose local closurestatus block has not supplied that bridge record.*

Thus a bridge consumer must inspect the four local bridgestatus rows separately. No aggregate MetaCIC route token, route-level bridge row, quotient stream equality, selected host limit, countable-choice coordinate, metric-completeness row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim can close a missing face bridge.*

Proof. First read the local target and bridge rows. Theorem 765.140 makes each of the four Phase Real faces responsible for its own leantarget and bridgestatus row whenever K is consumed as Phase Real and Completion exit evidence.

Next apply the consumer threshold theorem. Theorem 765.150 gives the current audit-clean threshold as a facewise product, not as an aggregate MetaCIC status. Therefore the four-object route can expose the threshold only by presenting the local face records.

Now use Theorem 38.834 and Theorem 38.833. These noncollapse clauses keep leantarget, formalstatus, and bridge rows attached to their own face chapters and prevent a fused route credential from replacing any one of them.

Finally apply Theorem 765.139. A missing local bridge record is a deficient face record for bridge consumption, and no aggregate MetaCIC route token, route-level bridge row, quotient stream equality, selected host limit, countable choice, metric-completeness row, or ambient Real completeness claim can repair it. Bridge closure is therefore postponed to the four local face records separately. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10FourFaceBridgeDeferral`

Theorem 765.154 (MetaCIC L10 exit scope seal)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *consumed by candidate-mediated strong-normalization, confluence, or subject-reduction consumers, the Phase Real boundary read through* K *has exactly the four L10 object faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The packet may expose the four-object exit certificate, dependency budget, status bridge obligation, audit-clean floor, and facewise bridge deferral for those four faces, but it supplies no fifth object face and no aggregate substitute for any one local face record.

Proof. Start with the four-object exit certificate, Definition 765.128. It identifies the exit surface read through K with the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows.

Use the dependency budget of Definition 765.129. That budget orders the four faces as finite data read through the packet, so candidate-mediated strong-normalization, confluence, and subject-reduction consumers receive the same displayed Phase Real boundary rather than a separate MetaCIC object.

Next apply the status bridge obligation of Definition 765.132 and the audit-clean floor of Definition 765.142. These rows make the consumer threshold facewise: every cited readiness record belongs to one of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$.

Finally apply the bridge deferral theorem Definition 765.153. Since bridge closure is postponed to the four local faces separately, the aggregate packet cannot add a fifth face or collapse the four local records into a route-level credential. The L10 exit scope is therefore exactly the displayed four-object boundary. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10ExitScopeSeal`

Definition 765.155 (MetaCIC critical-path open-phase source ledger)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the open-phase source ledger is the finite packet whose local rows are the subject row* S*, normal-form row* N*, obstruction row* O*, unblock row* U*, discharge row* D*, handoff row* H*, continuation row* C*, package row* P*, and provenance ledger row* L*, together with the following four displayed Phase Real source rows:*

$$\begin{aligned} \mathsf{DyadicRatCore}^{\uparrow} &: \textit{finite dyadic observation budget}, \\ \mathsf{StreamName}^{\uparrow} &: \textit{finite source schedule}, \\ \mathsf{RegSeqRat}^{\uparrow} &: \textit{regular-rational readback route}, \\ \mathsf{Real}^{\uparrow} &: \textit{terminal Real seal handoff}. \end{aligned}$$

The four rows are grounded respectively in chapter 291, chapter 126, chapter 301, and chapter 38. Each displayed row is read through finite BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance attached to* K*. The ledger exports no quotient real, host equality, selected limit, countable choice, trichotomy, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 (definition) `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathOpenPhaseSourceLedger`

Theorem 765.156 (MetaCIC critical-path open-phase source closure)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the open-phase source ledger of Definition 765.155 is closed under the current Phase Real and Completion handoff surface: every admitted source read factors through the displayed packet rows* $S, N, O, U, D, H, C, P, L$ *and one of the four rows* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$*.*

Proof. First expose the packet rows. Theorems 765.84, 765.85, and 765.86 make $S, N, O, U, D, H, C, P, L$ the finite consumer surface of the accepted packet.

Next attach the four Phase Real rows. Theorem 765.118 requires the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows before the route can be entered, while Theorem 765.128 identifies those four rows as the current exit certificate.

Finally apply the dependency diamond. Theorem 765.121 recovers exactly the four displayed source projections from an admitted public entry, and Theorem 765.122 keeps their owners separate. Hence every admitted source read is already a row of the ledger. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathOpenPhaseSourceClosure`

Theorem 765.157 (MetaCIC critical-path open-phase source ledger discharge budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, any candidate-mediated normalization, residual confluence, or decidability discharge read that is allowed to interact with the current open phase must first display the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *through the ledger row* L*. After those four faces are displayed, the read may inspect only the MetaCIC candidate row* N*, obstruction row* O*, handoff row* H*, and discharge-socket row* D *together with the structural rows of* K*. The budget exports no closed subject reduction, global confluence, full beta-conversion decidability, quotient term equality, selected normal form, countable choice, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the packet rows of K. Definition 765.155 makes L the ledger row through which the four current L10 source faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ are displayed.

Next read the candidate-mediated budget. Theorems 765.84, 765.85, and 765.86 expose only the candidate, obstruction, unblock, discharge, handoff, continuation, package, and ledger rows of the accepted packet.

The open-phase source closure then exhausts the permitted source interaction. Theorem 765.156 requires every admitted source read to factor through one of the four displayed faces, while Theorem 765.158 blocks the listed outside principles.

Thus a normalization, residual confluence, or decidability discharge can use the current open phase only by first displaying the four source faces through L and then staying inside the candidate, obstruction, handoff, discharge-socket, and structural rows already present in K. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathOpenPhaseSourceLedgerDischargeBudget`

Theorem 765.158 (MetaCIC critical-path open-phase source nonescape)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, no claim outside the open-phase source ledger can be exported by the current Phase Real and Completion route. In particular, the route exports no quotient real, host equality, selected limit, countable choice, trichotomy, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with the frontier filter. Theorem 765.119 admits Completion-facing claims only when they are backed by the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

The exit certificate then removes the listed substitutes. Theorem 765.128 supplies no additional coordinate for quotient stream equality, selected host limits, host real equality, trichotomy, open-cover compactness, countable choice, or completed-real closure.

Finally use the Phase Real exit refusal boundary. Theorem 765.138 states that the accepted exit data are only the four finite object rows together with their local status product. Since Definition 765.155 records exactly those rows over $S, N, O, U, D, H, C, P, L$, every listed outside principle has no export path through the ledger. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathOpenPhaseSourceNonescape`

Theorem 765.159 (MetaCIC critical-path open-phase consumer totality)**.** *Every current Phase Real and Completion consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet reads the open-phase source ledger as its whole source surface. The consumer may inspect the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite dyadic budget, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal row through their local chapters, but it receives no fifth roadmap object and no completion principle beyond those rows.*

Proof. First use the current readiness surface. Theorem 765.120 identifies the Phase Real and Completion route with the finite dependency budget, the L10 entry budget synchronization, and the Real completion frontier filter.

Then read the objectwise status discipline. Theorems 765.134, 765.136, and 765.140 require consumers to use the four local face records rather than an aggregate route credential.

It remains to rule out omitted consumers. Theorem 765.139 blocks the route when any one of the four face rows is absent, while Theorem 765.156 says that every admitted source read is already present in the ledger. Thus the ledger is total for current Phase Real and Completion consumers, and no extra roadmap object or completion principle is exported. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathOpenPhaseConsumerTotality`

Theorem 765.160 (MetaCIC critical-path open-phase exact-boundary handoff)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, if the open-phase source ledger is consumed through the four displayed faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, then every MetaCIC-candidate read, candidate-mediated normalization read, residual-confluence read, and discharge read in the resulting handoff factors through the same four-face exact boundary identified by Theorem 1120.6. The handoff exports no quotient stream equality, selected host limit, countable-choice coordinate, aggregate MetaCIC credential,* $\mathsf{Real}^{\uparrow}$ *completeness claim, closed subject reduction, full confluence coordinate, or full consistency coordinate.*

Proof. Begin with the finite ledger rows. Definition 765.155 lists the packet rows $S, N, O, U, D, H, C, P, L$ together with exactly the four Phase Real source rows $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next exhaust the possible consumers. Theorem 765.156 says that every admitted source read factors through one of those rows, and Theorem 765.159 says that a current Phase Real and Completion consumer receives no fifth roadmap object and no completion principle beyond them.

The candidate-mediated part is still a source read. Theorems 765.84, 765.85, and 765.86 expose only the candidate, obstruction, unblock, discharge, handoff, continuation, package, and ledger rows of the accepted packet, so candidate normalization and residual-confluence reads cannot bypass the displayed source faces.

Finally identify the boundary. Theorem 765.125 matches the four open-phase prefixes with the exact-boundary ordering, and Theorem 1120.6 recognizes the same $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces as the accepted Real-completion exact boundary. The negative export list follows because neither the ledger exhaustion nor the four-face exactness theorem supplies any additional quotient, host-limit, choice, aggregate-credential, completeness, subject-reduction, confluence, or consistency coordinate. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathOpenPhaseExactBoundaryHandoff`

Theorem 765.161 (MetaCIC critical-path open-phase frontier)**.** *Every MetaCIC candidate-discharge read used by the current open Phase Real and Completion route must pass through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *source ledger before it can be consumed as an L10 readiness row. Thus candidate-mediated normalization, confluence, bounded conversion, and discharge-socket evidence remain downstream of the open-phase source ledger and cannot replace any one of the four L10 source faces.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathOpenPhaseFrontier`

Proof. First read the source ledger. Definition 765.155 displays the packet rows together with exactly the four Phase Real source rows, and Theorem 765.156 says that every admitted source read factors through that ledger.

Next apply the Phase Real source obligations. Theorem 765.165 requires $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to be exposed before any discharge socket, confluence-decidability handoff, obstruction boundary, or downstream readiness boundary is consumed.

Now route candidate evidence through the existing candidate frontier. Theorems 765.278, 765.281, and 765.284 keep candidate-mediated normalization, confluence, bounded-conversion, and L10 readiness reads inside the same finite packet while the obstruction row and discharge socket remain visible.

Finally use the L10 ordering row. Theorem 765.294 places the Real-and-Completion route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the normal-form endpoint

or discharge socket can be consumed. Therefore candidate-discharge reads may serve the current open phase only after the displayed source ledger has been read, and no candidate row becomes a substitute for the four source faces. □

Theorem 765.162 (MetaCIC critical-path L10 source-ledger nonescape)**.** *Any MetaCIC candidate-discharge read consumed by the current Phase Real and Completion route must retain the four source rows* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *as source-ledger rows. Candidate-mediated normalization, confluence, bounded-conversion, and discharge-socket evidence may be routed only as downstream readiness data; it cannot discharge, replace, or identify any one of the four source rows with a candidate row.*

Proof. Apply Definition 765.161. It already orders every candidate-discharge read after the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source faces.

Now read the source obligations and L10 ordering rows named in that proof. Theorem 765.165 exposes the four source faces before discharge-socket or confluence-readiness evidence is consumed, and Theorem 765.294 keeps the same four rows before the normal-form endpoint.

The finite ledger has no remaining source coordinate. Candidate rows can therefore occupy only the downstream readiness slots already named by the open-frontier theorem, so none of them can discharge or replace $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10SourceLedgerNonescape`

Theorem 765.163 (MetaCIC open-frontier source exhaustion)**.** *Any candidate-mediated strong-normalization, confluence, bounded-conversion, or discharge-socket read serving the open Phase Real and Completion route is exhausted by the displayed source ledger over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the obstruction row, and the finite candidate budget. No normal-form endpoint or discharge socket may replace one of those four L10 source faces.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierSourceExhaustion`

Proof. First apply the open-phase frontier theorem, Definition 765.161. It already forces candidate-mediated evidence to remain downstream of the four displayed L10 source faces.

Next read the source ledger and closure rows. Definition 765.155 displays the four source faces together with the packet rows, and Theorem 765.156 says that admitted source reads factor through that ledger.

Now use the Phase Real source obligations and candidate-discharge coverage. Theorems 765.165, 765.278, and 765.281 keep the obstruction row, discharge socket, and finite candidate budget visible while the candidate-mediated evidence is consumed.

Finally apply the L10 ordering row, Definition 765.294. Since the normal-form endpoint and discharge socket are read only after the displayed source faces, neither can serve as a replacement source for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$. □

Theorem 765.164 (MetaCIC parallel-diamond frontier seed)**.** *Any parallel-diamond, residual-diamond, confluence, or bounded-conversion read consumed by the current Phase Real and Completion route is a downstream readiness row only after the packet displays* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the obstruction row, and the finite candidate budget. Such a read cannot identify any diamond row with one of the four L10 source faces.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathParallelDiamondFrontierSeed`

Proof. First apply the open-phase frontier and source-ledger nonescape, Definition 765.161 and Definition 765.162. These results force every candidate-mediated read to remain downstream of DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$.

Next use source exhaustion, Definition 765.163. It keeps the obstruction row and finite candidate budget visible while the Phase Real and Completion route consumes normalization, confluence, bounded-conversion, or discharge-socket evidence.

Finally route the diamond-facing data through the local candidate-discharge coverage theorems. Theorems 765.278, 765.281, and 765.284, together with the L10 ordering row Definition 765.294, keep parallel-diamond and residual-diamond evidence in the downstream readiness slot. Therefore no diamond row can be read as, or identified with, one of the four L10 source faces. □

Theorem 765.165 (MetaCICCriticalPath Phase Real source obligations)**.** *Every Phase Real* MetaCICCriticalPath$^{\uparrow}$ *read must expose the four source rows* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *before any discharge socket, confluence-decidability handoff, obstruction boundary, or downstream readiness boundary is consumed. The read is therefore budgeted by the displayed packet rows, finite observation budget, source schedule, regular-rational readback, Real seal,* BHist *history rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows; it cannot start from a socket row, a confluence theorem, a decidability procedure, closed subject reduction, full consistency, quotient stream equality, a selected limit, or host equality.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealSourceObligations`

Proof. First read the Phase Real dependency budget. Theorems 765.108, 765.109, and 765.110 put the dyadic finite-observation row before the StreamName schedule, the RegSeqRat readback, and the Real seal.

Next use the four-object exit certificate. Theorems 765.128, 765.134, and 765.138 identify the four Phase Real source faces and refuse external completion, closed consistency, and off-ledger theorem rows.

Then route the read through the open source ledger. Definition 765.155 lists the packet rows and the four Phase Real source rows, while Theorems 765.156, 765.159, and 765.160 keep those rows as the whole visible source surface.

Finally attach the confluence-decidability budget. Theorem 765.192 and Theorem 765.171 allow confluence-facing and decidability-facing consumers only after the ledger and socket rows have been displayed. This matches the existing Lean-facing packet names for discharge socket coverage, transport row stability, kernel frontier exposure, and downstream readiness boundary: each consumes displayed BEDC rows rather than supplying a hidden source before DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ have been exposed. □

Theorem 765.166 (MetaCICCriticalPath formal-target surface)**.** *A* MetaCICCriticalPath$^{\uparrow}$ *formal target for the Phase Real route may name the four source rows only as separate local formal targets:* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *each retain their own closurestatus, formalstatus, and leantarget records. The aggregate MetaCIC route may cite those rows as the source surface of the Phase Real packet, but it cannot infer verification from paper closure and cannot infer paper closure from verification.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFormalTargetSurface`

Proof. Apply Definition 765.165. It forces every Phase Real read to expose the dyadic finite-observation row, stream schedule, regular-rational readback, and Real seal before socket, confluence, obstruction, or readiness consumers can use the packet.

Now read the four-object exit certificate through Theorems 765.128, 765.134, and 765.138. These references identify the four named source faces as the boundary objects of the route rather than as fields whose statuses are absorbed into $\mathsf{MetaCICCriticalPath}^{\uparrow}$.

Finally separate the two ledgers. The Phase Real source theorem supplies paper-side routing, while the individual $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ chapters retain their own verification records. Hence the aggregate route can depend on those local records without converting a closure grade into a formal grade or a formal grade into a closure grade. □

Theorem 765.167 (MetaCIC critical-path Phase Real root-unblock admission)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the packet is admissible as a Phase Real root-unblock route exactly when it displays the nine packet rows* $S, N, O, U, D, H, C, P, L$ *together with the four objectwise face records for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *at the local closure and formal thresholds required by Theorem 765.143. The admitted route is read through the open-phase source ledger of Definition 765.155; no aggregate MetaCIC credential may replace any one of the four face records.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealRootUnblockAdmission`

Proof. For admission from displayed data, start with the packet rows $S, N, O, U, D, H, C, P, L$. Theorem 765.128 attaches the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows to the same accepted packet, and Theorem 765.143 raises those four rows to the local threshold required by the current Phase Real route.

The open-phase ledger then supplies the route surface. Theorem 765.156 says that every admitted source read factors through the displayed packet rows and one of the four named face rows, so the displayed data are sufficient for the root-unblock admission interface.

Conversely, suppose that the packet is admitted as a Phase Real root-unblock route. Theorem 765.134 forces the four object rows to be presented separately, and Theorem 765.136 requires their local status records. The audit floor of Theorem 765.143 then gives exactly the stated threshold, while Theorem 765.139 rules out admission with a missing or substituted face. □

Theorem 765.168 (MetaCIC critical-path Phase Real root-unblock soundness)**.** *Any route admitted by Theorem 765.167 exports only the open-phase source ledger of Definition 765.155. It exports no quotient stream equality, no selected host limit, no countable choice, no trichotomy, no open-cover compactness, no* $\mathsf{Real}^{\uparrow}$ *completeness, no closed subject reduction, and no full consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealRootUnblockSoundness`

Proof. Begin with the admission theorem. It places every admitted route inside the displayed packet rows and the four objectwise face records at the audit floor, with the open-phase source ledger as the route surface.

Apply Theorem 765.158. That theorem says that no claim outside the ledger can be exported by the current Phase Real and Completion route, including quotient real data, host equality, selected limits, countable choice, trichotomy, open-cover compactness, and $\mathsf{Real}^{\uparrow}$ completeness.

The remaining exclusions are already part of the finite route boundary. Theorems 765.138 and 765.110 keep the route at the four finite source rows and refuse closed subject reduction, full consistency, hidden completion selectors, and theorem rows outside the displayed packet. Hence an admitted root-unblock route exports only the open-phase ledger. □

Theorem 765.169 (MetaCIC critical-path Phase Real root-unblock completeness)**.** *Every current Phase Real or Completion consumer that displays the packet rows $S, N, O, U, D, H, C, P, L$ together with the four local face records for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *at the threshold of Theorem 765.143 factors through Definition 765.155. Such a consumer receives no fifth source row and no completion principle beyond the displayed four-face ledger.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPhaseRealRootUnblockCompleteness`

Proof. First read the consumer through the audit floor. The displayed packet rows and four local face records satisfy the same threshold used by Theorem 765.167, so the consumer is an admitted Phase Real root-unblock consumer.

Now apply totality of the open-phase ledger. Theorem 765.159 states that every current Phase Real and Completion consumer of an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet reads the ledger as its whole source surface.

Finally use nonescape to close the factorization. Theorem 765.158 prevents any outside completion principle from being exported, and Theorem 765.156 identifies every admitted source read with one of the packet rows or one of the four displayed face rows. Therefore the consumer factors through the ledger and receives no fifth source row. □

Theorem 765.170 (MetaCIC critical-path four-face socket separation)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet $K = (S, N, O, U, D, H, C, P, L)$, Phase Real root-unblock admission separates the four object records from the discharge socket. The route requires separate face records for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*; the discharge socket D cannot replace any one of those records. Conversely, displaying all four face records supplies no value for D and does not promote the route to closed subject reduction or full consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFourFaceSocketSeparation`

Proof. First use Theorem 765.167. It identifies admission with the packet rows $S, N, O, U, D, H, C, P, L$ together with the four objectwise face records at the local threshold, and it explicitly refuses an aggregate MetaCIC credential as a replacement for any face.

Now remove or substitute one face record. Theorem 765.139 blocks the route whenever a required $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ face is missing or supplied only by an aggregate route credential. Since D is one packet coordinate rather than a face-local carrier, classifier, status, target, or bridge row, the same refusal prevents the discharge socket from serving as any one of the four records.

It remains to separate the reverse direction. Definition 765.155 and Theorems 765.156 and 765.158 keep every admitted source read inside the displayed packet rows and four face rows, with no export path to a further discharge witness.

Finally apply Theorem 765.168. That theorem excludes closed subject reduction and full consistency from every admitted Phase Real root-unblock route. Hence the four face records and the discharge socket are distinct obligations, and neither side fills or promotes the other. □

Theorem 765.171 (MetaCIC critical-path confluence-decidability handoff exhaustion)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

every confluence-facing or decidability-facing downstream read of U factors through the displayed rows O, D, H, C, P, L together with the finite packet rows S, N, U. The handoff exports no arbitrary

Church–Rosser theorem, no global beta-conversion decision procedure, no closed subject reduction, and no full closed consistency.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceDecidabilityHandoffExhaustion`

Proof. Start with the socket theorem. By Definition 765.61, every confluence-facing or decidability-facing use of the handoff row is mediated by the obstruction, discharge socket, transport, route, provenance, and local naming rows O, D, H, C, P, L.

Next exhaust the packet route. The handoff exhaustion theorem Definition 765.14 says that the finite route has only the rows $S, N, O, U, D, H, C, P, L$ and contains no coordinate for closed subject reduction, full closed consistency, global beta-conversion decidability, or quotient term equality.

The local socket boundary supplies the negative side. Apply Definition 765.57 to keep D local to H, C, P, L and separate from any hidden discharge, then apply Definition 765.62 to keep the obstruction row visible along normalization-to-normal-form reads.

Therefore a downstream read of U has only the displayed finite data available: O, D, H, C, P, L for the socket-mediated handoff and S, N, U for the remaining packet coordinates. Since no further theorem-export coordinate is present, the four excluded metatheoretic claims remain outside the handoff. □

Theorem 765.172 (MetaCIC critical-path candidate-mediated SN boundary)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any candidate-mediated strong-normalization-facing read of the handoff row factors through the displayed packet rows $S, N, O, U, D, H, C, P, L$ *together with the four Phase Real faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *recorded by Definition 765.155. The read exports no arbitrary strong-normalization theorem, no Church–Rosser theorem, no beta-conversion decision procedure, no quotient term equality, no host real equality, no selected limit, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNBoundary`

Proof. First apply the confluence-decidability handoff exhaustion theorem, Theorem 765.171. It bounds every confluence-facing or decidability-facing use of the handoff row by the mediated rows O, D, H, C, P, L and the remaining packet coordinates S, N, U.

Next attach the current Phase Real source surface. The open-phase source closure theorem, Theorem 765.156, says that admitted source reads factor through the displayed packet rows and one of the four rows $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$. The open-phase consumer totality theorem, Theorem 765.159, says that current Phase Real and Completion consumers receive the ledger as their whole source surface.

Finally use the nonescape side of the ledger. Theorem 765.168 and Theorem 765.158 exclude quotient real data, host equality, selected limits, countable choice, trichotomy, open-cover compactness, $\mathsf{Real}^{\uparrow}$ completeness, closed subject reduction, and full consistency from the admitted route. Since a candidate-mediated strong-normalization-facing read has no additional coordinate beyond the same packet rows and four ledger faces, the listed SN, Church–Rosser, beta-conversion, quotient, host-equality, selected-limit, and completeness claims remain outside the handoff. □

Theorem 765.173 (MetaCIC candidate-mediated SN four-face audit precondition)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any candidate-mediated strong-normalization-facing read that is also consumed as current Phase $\mathsf{Real}^{\uparrow}$ *and Completion evidence must first expose the four local face records for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Each face must carry its own scoped-closure row and its own audit-clean verification row, and the shared support may use only* BHist, hsame, Cont, Pkg, *and* NameCert *data. The candidate-mediated SN row supplies no aggregate formalstatus, no aggregate leantarget, no aggregate bridge row, no quotient stream equality, no selected limit, no countable-choice row, no metric-completeness datum, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with the SN-facing route. The candidate-mediated boundary theorem, Theorem 765.172, sends every such read through the finite packet rows $S, N, O, U, D, H, C, P, L$ and the four Phase Real faces listed in Definition 765.155.

Next read those faces as the source surface for current Phase Real and Completion consumption. Definition 765.155, Theorem 765.156, and Theorem 765.159 restrict the consumer to the displayed packet rows and the four local faces; no fifth source row or hidden discharge coordinate is introduced.

Now apply the current exit threshold. Theorem 38.796 identifies the consumed evidence with the objectwise product of the four local threshold records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ face, supported only by BHist, hsame, Cont, Pkg, and NameCert.

Finally use the StreamName audit readback. Theorem 126.509 reads the same threshold through face-local audit rows rather than through a route-level credential. Therefore a candidate-mediated SN read that is consumed by the current Phase Real and Completion surface must display the four separate scoped-closure and audit-clean rows, and the aggregate status, leantarget, bridge, quotient, choice, metric-completeness, selected-limit, and $\mathsf{Real}^{\uparrow}$ completeness data remain outside the route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNFourFaceAuditPrecondition`

Theorem 765.174 (MetaCIC four-face discharge precondition strengthening)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any candidate-mediated strong-normalization-facing read that satisfies the four-face audit precondition can be consumed by the current Phase $\mathsf{Real}^{\uparrow}$ *and Completion surface only while the separate discharge socket row* D *remains visible as an unmet row distinct from the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The four-face audit product cannot be read as a discharge of* D, *closed subject reduction, full consistency, global beta-conversion decidability, quotient term equality, host equality, a selected limit, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFourFaceDischargePreconditionStrengthenin`

Proof. Start with the four-face audit precondition, Theorem 765.173. It exposes the four local scoped-closure and audit-clean face records as the only current Phase $\mathsf{Real}^{\uparrow}$ and Completion source surface supplied by the candidate-mediated SN read.

Next apply the candidate route discharge refusal theorem, Theorem 765.175. That result keeps D as the displayed discharge socket coordinate and denies any witness that fills it, even after the four audit faces are present.

Finally use the candidate SN socket nonescape theorem, Theorem 765.176. It prevents downstream consumers from absorbing D into the four-face route or into a closed metatheoretic theorem. Therefore the read remains consumable only with D still visible as a separate unmet row, and the listed subject-reduction, consistency, beta-conversion, quotient, host-equality, selected-limit, and completeness claims stay outside the packet. □

Theorem 765.175 (MetaCIC candidate route discharge refusal)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any candidate-mediated strong-normalization-facing read that satisfies the four-face audit precondition still treats D only as the displayed discharge socket coordinate. The route supplies no witness that fills D, no closed subject-reduction theorem, and no full closed-consistency theorem.

Proof. Start with the candidate-mediated boundary. Theorem 765.172 keeps the SN-facing read on the finite packet rows $S, N, O, U, D, H, C, P, L$ and the four local Phase Real faces.

Next impose the audit precondition. Theorem 765.173 says that consumption as current Phase $\mathsf{Real}^{\uparrow}$ and Completion evidence exposes only the four separate scoped-closure and audit-clean face rows, supported by BHist, hsame, Cont, Pkg, and NameCert data. It does not add an aggregate discharge credential.

Now apply the handoff exhaustion and root-unblock boundaries. Theorem 765.171 leaves closed subject reduction and full closed consistency outside the confluence-decidability route, while Theorem 765.168 gives the same exclusion for the current Phase Real root-unblock route.

Therefore the candidate-mediated SN route can guide the local handoff and audit read, but it cannot turn the socket coordinate D into a discharged witness or export the closed subject-reduction and full-consistency theorems. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateRouteDischargeRefusal`

Theorem 765.176 (MetaCIC candidate SN socket nonescape)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

every downstream consumer using the candidate-mediated strong-normalization route receives only the socket-aware finite route over $S, N, O, U, D, H, C, P, L$ together with the four local face rows for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The coordinate D remains a separate discharge socket and is not absorbed into the four-face route, the consumer surface, closed subject reduction, or full closed consistency.*

Proof. First separate the socket from the faces. Theorem 765.170 keeps the four Phase Real face records and the discharge socket as distinct obligations; neither side fills or promotes the other.

Next use source nonescape. Theorem 765.158 prevents admitted Phase Real and Completion reads from bypassing the displayed packet and face rows through quotient real data, host equality, selected limits, countable choice, trichotomy, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness.

Finally apply the discharge refusal theorem, Theorem 765.175. It prevents the candidate-mediated SN route from filling D or exporting closed subject reduction and full closed consistency. Hence every downstream consumer receives exactly the finite socket-aware route and the four local face rows, with D still recorded as its own socket coordinate. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNSocketNonescape`

Theorem 765.177 (MetaCIC candidate SN finite socket normal form)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

a candidate-mediated strong-normalization-facing read is consumable by the current Phase $\mathsf{Real}^{\uparrow}$ *and Completion surface exactly when it displays the finite socket-aware rows $S, N, O, U, D, H, C, P, L$*

together with the four local face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *with support only from* BHist, hsame, Cont, Pkg, *and* NameCert. *This normal form exports no arbitrary strong-normalization theorem, no Church–Rosser theorem, no beta-conversion decidability, no quotient term equality, no host equality, no selected limit, no countable choice, no closed subject reduction, no full consistency theorem, no metric-completeness datum, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. For the forward direction, start with the candidate-mediated SN boundary, Theorem 765.172. It places every candidate-mediated read on the finite packet rows $S, N, O, U, D, H, C, P, L$ and the four local Phase Real faces.

Next impose the four-face audit precondition, Theorem 765.173. The current Phase $\mathsf{Real}^{\uparrow}$ and Completion consumer can read those faces only through separate local scoped-closure and audit records, carried by BHist, hsame, Cont, Pkg, and NameCert. The current exit threshold, Theorem 38.796, identifies this as the objectwise four-face threshold surface rather than as an aggregate metatheoretic credential.

The negative coordinates are then exhausted by the socket and source boundaries. The discharge refusal theorem, Theorem 765.175, keeps D as a socket coordinate and refuses closed subject reduction and full consistency. The socket nonescape theorem, Theorem 765.176, keeps downstream consumers on the same finite route, while the open-phase source closure and nonescape theorems, Theorems 765.156 and 765.158, exclude off-packet quotient, host-equality, selected-limit, choice, metric-completeness, and $\mathsf{Real}^{\uparrow}$ completeness data.

For the reverse direction, suppose the displayed finite socket-aware rows and four local face records are present with only the stated BEDC support. The open-phase consumer totality theorem, Theorem 765.159, admits exactly this finite ledger as the current consumer surface, and Theorem 38.796 reads the four faces as the local threshold certificate. Since the cited refusal and nonescape theorems leave no hidden socket discharge or off-route coordinate, this displayed data is sufficient for current Phase $\mathsf{Real}^{\uparrow}$ and Completion consumption of the candidate-mediated read. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNFiniteSocketNormalForm`

Theorem 765.178 (MetaCIC critical-path candidate decider exhaustion)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

every beta-conversion read or decidability-facing read mediated by the candidate strong-normalization route is confined to the finite socket rows $S, N, O, U, D, H, C, P, L$ *together with the four L10 face records for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The route exports no global beta-conversion decision procedure, no Church–Rosser theorem, no quotient term equality, no closed subject reduction theorem, and no full consistency theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateDeciderExhaustion`

Proof. Begin with the candidate SN finite socket normal form, Theorem 765.177. It identifies the consumable candidate-mediated read as exactly the socket-aware rows $S, N, O, U, D, H, C, P, L$ plus the four local L10 face records, with support only from BHist, hsame, Cont, Pkg, and NameCert.

Next apply confluence-decidability handoff exhaustion, Theorem 765.171. It keeps confluence-facing and decidability-facing reads on the displayed packet route and refuses global Church–Rosser, beta-conversion decision, closed subject reduction, and full consistency exports.

Finally use the discharge refusal theorem, Theorem 765.175. It prevents the candidate route from filling the socket coordinate D or promoting candidate evidence into a closed metatheorem.

Combining these three boundaries leaves no extra coordinate for quotient term equality, a global beta-conversion decider, closed subject reduction, or full consistency. Hence every beta-conversion or decidability-facing read mediated by candidates is exhausted by the stated finite socket route and four local face records. □

Theorem 765.179 (MetaCIC confluence-decidability candidate SN frontier)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

every confluence-facing or decidability-facing read mediated by candidate strong-normalization evidence factors through the finite socket rows $S, N, O, U, D, H, C, P, L$ *together with the four local L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The coordinate* D *remains a separate discharge socket throughout the route. The frontier exports no arbitrary strong-normalization theorem, no Church–Rosser theorem, no beta-conversion decision procedure, no quotient term equality, no selected limit, no countable choice, no closed subject reduction, no full consistency theorem, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceDecidabilityCandidateSNFrontier`

Proof. Begin with the confluence-decidability handoff exhaustion theorem, Theorem 765.171. It confines every confluence-facing or decidability-facing read to the displayed packet rows $S, N, O, U, D, H, C, P, L$ and excludes global Church–Rosser, beta-conversion decision, closed subject reduction, and full consistency exports.

Next add candidate strong-normalization mediation. The candidate-mediated SN boundary, Theorem 765.172, permits only the same packet rows together with the four local L10 faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The finite socket normal form, Theorem 765.177, repacks exactly this data as the consumable current Phase $\mathsf{Real}^{\uparrow}$ and Completion surface.

Now read the confluence side through Theorem 765.181. It keeps confluence-facing use on the handoff row U, the obstruction and socket rows O, D, the structural rows H, C, P, L, and the same four local faces, without exporting an arbitrary Church–Rosser theorem.

Finally apply the discharge-refusal and socket-nonescape results, Theorems 765.175 and 765.176. They keep D visible as a separate socket and prevent candidate evidence or the four faces from being read as a discharge, selected limit, countable-choice row, quotient term equality, closed subject reduction, full consistency, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 765.180 (MetaCIC conditional SN discharge frontier)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any conditional strong-normalization read mediated by candidates factors through the finite socket normal form over K *together with the four local Phase Real faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The discharge socket* D *remains a separate unmet row and is not converted into closed subject reduction, arbitrary strong normalization, or full consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConditionalSNDischargeFrontier`

Proof. Begin with the candidate-mediated SN boundary, Theorem 765.172. It routes the read through $S, N, O, U, D, H, C, P, L$ and the four local Phase Real faces.

Next apply the four-face audit precondition, Theorem 765.173, and the finite socket normal form, Theorem 765.177. Together they identify the consumable evidence as the displayed socket-aware packet plus the separate face-local threshold records.

Finally apply the candidate route discharge refusal theorem, Theorem 765.175. It keeps D as the discharge socket coordinate and refuses closed subject reduction and full consistency. Hence conditional SN remains a frontier read through the displayed packet and faces, with D still unmet. □

Theorem 765.181 (MetaCIC confluence candidate mediation)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any confluence-facing read mediated by the candidate route factors through the confluence-decidability handoff row U, the obstruction and socket rows O, D, the structural rows H, C, P, L, and the four local Phase Real faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The read exports no arbitrary Church–Rosser theorem and does not fill the separate discharge socket D.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceCandidateMediation`

Proof. Start with the confluence-decidability handoff exhaustion theorem, Theorem 765.171. It restricts every confluence-facing downstream read of U to the displayed rows O, D, H, C, P, L together with S, N, U.

Attach candidate mediation by applying Theorem 765.172. The only additional evidence available to a candidate-mediated read is the four local Phase Real faces, not a global Church–Rosser theorem or a hidden term-equivalence quotient.

Use Theorem 765.175 to keep the socket row separate. Since D is not filled by the candidate route and the handoff exhaustion theorem excludes arbitrary Church–Rosser export, the confluence-facing read remains mediated by K and the four displayed faces. □

Theorem 765.182 (MetaCIC confluence residual discharge separation)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

a confluence residual row is discharged only when the packet displays a local peak row, a candidate join row, a residual frontier row, a substitution boundary row, a bounded checker row, the obstruction row O, and the four L10 faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Candidate-mediated strong-normalization evidence alone cannot fill the discharge socket D or export closed subject reduction, full consistency, a global Church–Rosser theorem, or a beta-conversion decision procedure.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceResidualDischarge`

Proof. Start with the candidate-mediated SN boundary, Theorem 765.172. It routes every candidate-mediated read through the finite packet rows $S, N, O, U, D, H, C, P, L$ and the four local L10 faces, but it does not add a residual-discharge witness.

Next impose the four-face audit precondition, Theorem 765.173. The Phase $\mathsf{Real}^{\uparrow}$ and Completion source surface must expose $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as separate local records. This audit surface is necessary for a residual confluence read, but it is not the socket discharge.

Now read the confluence and decidability consumer boundary. Theorems 765.171, 765.181, and 765.183 keep confluence-facing and bounded-checker reads inside the handoff row, obstruction and socket rows, structural rows, and four displayed faces. Thus a local peak, candidate join, residual frontier, substitution boundary, and bounded checker must be displayed as rows of the same packet route before any residual-discharge claim can be read.

Finally apply the discharge-refusal and socket-separation results. The candidate route discharge refusal theorem, Theorem 765.175, keeps D unmet, while Theorem 765.176 and Theorem 765.170 prevent the four L10 faces or candidate SN evidence from being absorbed into the discharge socket. Therefore residual confluence discharge requires the displayed residual rows and cannot be supplied by candidate-mediated SN alone. □

Theorem 765.183 (MetaCIC decidability fragment route)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any bounded decidability-fragment read factors through K, the confluence-decidability handoff exhaustion surface, and the four local Phase Real faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The route supplies no global beta-conversion decision procedure, no quotient term equality, no full consistency theorem, and no discharge of the socket row D.*

Proof. Project the decidability-facing read through Theorem 765.171. The handoff permits only the finite rows $S, N, O, U, D, H, C, P, L$ and excludes global beta-conversion decidability, quotient term equality, closed subject reduction, and full consistency.

Now use the candidate SN finite socket normal form, Theorem 765.177. A read consumable by the current Phase $\mathsf{Real}^{\uparrow}$ and Completion surface displays the same socket-aware rows together with the four local face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The discharge refusal theorem, Theorem 765.175, keeps D unmet. Therefore the decidability-fragment route is bounded by the displayed packet and face records, and it cannot be promoted to global beta-conversion decidability, quotient equality, full consistency, or a discharged socket. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDecidabilityFragmentRoute`

Theorem 765.184 (MetaCIC neutral-spine decidability handoff)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

a neutral-spine decidability read may be consumed by the current Phase $\mathsf{Real}^{\uparrow}$ *route only after candidate-mediated strong normalization, confluence mediation, and bounded decidability-fragment rows expose the four local L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The handoff supplies no aggregate formalstatus, no bridge row, no quotient stream equality, no selected limit, no choice schedule, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNeutralSpineDecidabilityHandoff`

Proof. Start with the candidate-mediated strong-normalization boundary, Theorem 765.172. It allows a neutral-spine read to reach the current route only through the finite packet rows $S, N, O, U, D, H, C, P, L$ and the four local Phase Real faces.

Next add confluence mediation. Theorem 765.181 keeps confluence-facing use on the handoff row U, the obstruction and socket rows O, D, the structural rows H, C, P, L, and the same four displayed faces, while refusing arbitrary Church–Rosser export and any filling of D.

Now apply the bounded decidability fragment route, Theorem 765.183. Decidability-facing evidence remains bounded by K, the confluence-decidability handoff exhaustion surface, and the four local faces; it does not become a global beta-conversion decision procedure or quotient term equality.

Finally read the route through the four-face audit precondition, Theorem 765.173. The current Phase $\mathsf{Real}^{\uparrow}$ consumer sees separated $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ records, not an aggregate verification row or bridge credential. The excluded aggregate status, bridge, quotient stream, selected-limit, choice, and ambient-completeness objects are therefore outside the neutral-spine handoff. □

Theorem 765.185 (MetaCIC neutral-spine four-face budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any neutral-spine read used jointly for candidate-mediated strong normalization, confluence mediation, and bounded decidability must expose separate face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *together with the finite socket rows* $S, N, O, U, D, H, C, P, L$. *It exports no aggregate formalstatus, bridge row, quotient term equality, selected limit, closed subject reduction, full consistency, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNeutralSpineFourFaceBudget`

Proof. Start with the candidate-mediated strong-normalization boundary, Theorem 765.172. It keeps a neutral-spine read on the finite socket rows and on the four local Phase Real faces.

Add confluence mediation through Theorem 765.181. The confluence-facing use stays on the handoff, obstruction, socket, transport, replay, provenance, and local naming rows; it does not discharge D or export closed subject reduction.

Now apply the bounded decidability fragment route, Theorem 765.183, together with the neutral-spine handoff of Definition 765.184. The decidability read remains bounded by the same packet and cannot become global beta-conversion decidability or quotient term equality.

Finally impose the four-face audit precondition, Theorem 765.173. It requires $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to remain separate face records. Therefore the joint read exposes the displayed socket rows and four faces only, leaving aggregate status, bridge rows, selected limits, closed subject reduction, full consistency, and $\mathsf{Real}^{\uparrow}$ completeness outside the budget. □

Theorem 765.186 (MetaCIC neutral-spine decidability budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any current Phase $\mathsf{Real}^{\uparrow}$ *consumer of a neutral-spine decidability row must expose* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *as four separate local faces before it consumes the decidability evidence. The row remains bounded by the finite packet route* $S, N, O, U, D, H, C, P, L$ *and exports no aggregate formalstatus, bridge row, quotient stream equality, selected limit, global beta-conversion decision procedure, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the neutral-spine handoff of Definition 765.184. It routes a decidability read through candidate-mediated strong normalization, confluence mediation, and the bounded decidability fragment before it reaches the current Phase $\mathsf{Real}^{\uparrow}$ surface.

Apply the decidability fragment route, Definition 765.183. It keeps the bounded checker on the finite packet rows and prevents promotion to a global beta-conversion decision procedure or quotient term equality.

Finally impose the four-face audit precondition, Definition 765.173. The current consumer must see $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as separated local records; an aggregate status, bridge row, selected limit, or ambient completeness claim is outside the decidability budget. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNeutralSpineDecidabilityBudget`

Theorem 765.187 (MetaCIC residual confluence budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, any residual-confluence read consumed by the current L10 route must display the same four face records* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before it consumes the confluence row. Candidate-mediated evidence may guide the residual route, but it cannot supply a global Church–Rosser theorem, closed subject reduction, full consistency, socket discharge, quotient term equality, or a Real bridge claim.*

Proof. Begin with confluence mediation, Definition 765.181. It keeps confluence-facing use on the handoff row U, obstruction and socket rows O, D, structural rows H, C, P, L, and the four local faces.

Use the residual discharge separation theorem, Definition 765.182. Residual confluence requires local peak, candidate join, residual frontier, substitution boundary, bounded checker, obstruction, and face rows; candidate-mediated strong normalization alone does not fill the socket.

The four-face audit precondition then keeps the L10 evidence objectwise. Thus a current consumer reads residual confluence only after $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ are separately exposed, and the listed global metatheorems and Real bridge claims remain outside the budget. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualConfluenceBudget`

Theorem 765.188 (MetaCIC residual confluence row budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

no residual confluence discharge may be consumed by the current L10 route until the same packet displays a local peak row, candidate join row, residual frontier row, substitution boundary row, bounded checker row, obstruction row, and the four separate L10 face records $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The displayed rows remain a bounded budget for residual confluence; they do not assert global Church–Rosser, full beta-conversion decidability, closed subject reduction, full consistency, socket discharge, quotient term equality, or a Real bridge.*

Proof. Start with the candidate-mediated strong-normalization boundary, Definition 765.172. It places candidate evidence on the finite packet rows and the four local L10 faces, but it does not create a residual discharge.

Read the confluence side through Definition 765.181 and the residual discharge separation theorem Definition 765.182. These force local peak, candidate join, residual frontier, substitution boundary, bounded checker, obstruction, and face rows to remain visible before any residual-confluence use is admitted.

Now use the decidability fragment route, Definition 765.183. The bounded checker row stays inside the same packet route and cannot become a global beta-conversion decision procedure or quotient term equality.

Finally impose the four-face audit precondition, Definition 765.173, and the candidate route discharge refusal theorem, Definition 765.175. The four faces remain separate records, while the

socket and obstruction rows remain unmet budget coordinates. Therefore the current consumer may read only the displayed residual-confluence budget and none of the excluded global conclusions. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualConfluenceRowBudget`

Theorem 765.189 (MetaCIC candidate SN discharge budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, candidate-mediated strong-normalization evidence may be consumed by the current Phase* $\mathsf{Real}^{\uparrow}$ *and Completion surface only after the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *are displayed separately. The evidence does not discharge the socket row* D*, does not prove closed subject reduction or full consistency, and does not collapse SN, residual confluence, and neutral-spine decidability into one endpoint claim.*

Proof. Project the candidate-mediated SN boundary through Definition 765.172. It permits the SN-facing read only on the finite packet rows and the four Phase Real faces.

Apply the four-face discharge precondition strengthening, Definition 765.174. The socket row D remains visible as an unmet row distinct from $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally use the socket nonescape and four-face budget results, Definition 765.176 and Definition 765.185. They prevent the candidate route from discharging D or from merging SN, confluence, and decidability into a single endpoint surface. The current consumer therefore receives separated L10 faces and a still-visible socket budget. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNDischarge`

Theorem 765.190 (MetaCIC critical-path confluence-decidability exit budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any candidate-mediated strong-normalization read that is used both as confluence evidence and as bounded decidability-fragment evidence for the current L10 route must expose four independent phase faces: $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Each face carries its own* BHist *support, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. The route supplies no aggregate formalstatus, no bridge row, no quotient stream equality, no selected limit, no choice schedule, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceDecidabilityExitBudget`

Proof. Begin with the confluence-decidability handoff exhaustion theorem, Theorem 765.171. It confines confluence-facing and decidability-facing reads to the finite packet rows $S, N, O, U, D, H, C, P, L$ and excludes closed subject reduction, full consistency, global beta-conversion decidability, and quotient term equality.

Next apply the candidate-mediated SN boundary, Theorem 765.172. Candidate mediation can add only the four current Phase Real faces, namely $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, to the displayed packet route.

Now impose the four-face audit precondition, Theorem 765.173. It requires those four faces to appear as separate local records, each with its own support from BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ data rather than as one route-level credential.

Finally combine Definition 765.181 with Definition 765.183. The same separated face data must serve both confluence and decidability uses, while aggregate status rows, bridge rows, quotient

stream equality, selected limits, choice schedules, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the current L10 exit budget. □

Theorem 765.191 (MetaCIC confluence-decidability frontier discharge readiness)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

the finite candidate-mediated strong-normalization rows expose a discharge-ready frontier for the confluence-decidability handoff exactly at the residual confluence, neutral-spine, bounded-checker, obstruction, and socket rows of K*. The socket row* D *remains the finite discharge coordinate that can be inspected by the current route, while global subject reduction, global confluence, unrestricted beta-decidability, full consistency, quotient term equality, and any ambient* $\mathsf{Real}^{\uparrow}$ *completion claim remain outside the closed scope of the chapter.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceDecidabilityFrontierDischargeRe`

Proof. Start from the candidate SN discharge budget of Definition 765.189. It places candidate-mediated strong-normalization evidence on the finite rows of K and keeps the socket row D visible instead of treating it as globally discharged.

Next combine the residual confluence row budget, Definition 765.188, with the neutral-spine decidability budget, Definition 765.186. The handoff can inspect local peak, candidate join, residual frontier, substitution boundary, bounded checker, obstruction, and neutral-spine rows, but each of these rows is still a displayed coordinate of the same finite packet.

Finally apply the exit budget of Definition 765.190. It keeps confluence-facing and decidability-facing reads on the separated packet faces and blocks any promotion to global subject reduction, global confluence, unrestricted beta-decidability, full consistency, quotient term equality, or ambient Real completion. □

Theorem 765.192 (MetaCIC confluence-decidability budget)**.** *Every MetaCIC confluence-facing or decidability-facing consumer visible at the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root must first pass through the open L10 source ledger displayed by Definition 765.155: the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows, together with the finite packet rows* $S, N, O, U, D, H, C, P, L$ *and their* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support. No such consumer may bypass those rows by reading a separate Church–Rosser theorem, global beta-conversion decision procedure, closed subject-reduction row, completed-real claim, quotient stream equality, selected limit, or host equality.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceDecidabilityBudget`

Proof. Begin with the Phase Real dependency budget. Theorem 765.108 confines dyadic observation reads to displayed budget rows, and Theorem 765.109 orders the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces before the Real seal handoff.

Next read the open-phase source ledger. Definition 765.155 lists exactly the packet rows $S, N, O, U, D, H, C, P, L$ and the four Phase Real source rows. Theorems 765.156 and 765.159 state that current Phase Real and Completion consumers receive this ledger as their whole source surface.

Finally attach the confluence-decidability handoff exhaustion. Theorem 765.171 bounds confluence-facing and decidability-facing reads by the displayed socket and packet rows, while the ledger nonescape theorem, Theorem 765.158, removes quotient real data, host equality, selected limits, countable choice, compactness substitutes, and $\mathsf{Real}^{\uparrow}$ completeness.

Combining these carrier inventories leaves only the displayed L10 ledger and BEDC support rows. Since none of the cited rows carries an independent confluence theorem, beta-conversion decision procedure, closed subject-reduction proof, completed-real principle, quotient equality, selected limit, or host equality, every visible confluence or decidability consumer remains budgeted by the ledger. □

Theorem 765.193 (MetaCIC candidate SN confluence-decidability budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

whose candidate-mediated strong-normalization budget is displayed by the finite socket route, every confluence-facing or decidability-facing handoff must pass through the existing budget rows: the BHist *packet rows* $S, N, O, U, D, H, C, P, L$*, the candidate budget surface over the four local faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, the confluence handoff row* U*, the decidability handoff read of the same row, the componentwise* Cont *replay* C*, and the* NameCert *provenance* P, L*. The route exports no separate Church–Rosser theorem, no global beta-conversion decision procedure, no hidden discharge of* D*, and no host normalization theorem.*

Proof. Start with the candidate-mediated SN finite socket normal form, Definition 765.177. It identifies the displayed candidate budget as the socket-aware finite rows $S, N, O, U, D, H, C, P, L$ together with the four local Phase Real faces, supported only by BHist, hsame, Cont, Pkg, and NameCert.

Next route confluence and decidability through the existing handoff surface. The handoff exhaustion theorem, Definition 765.171, confines every confluence-facing or decidability-facing read of U to the rows O, D, H, C, P, L and the remaining packet coordinates S, N, U. The budget theorem, Definition 765.192, then forces those reads to pass through the open source ledger and its displayed BEDC support rows.

Finally compose these two inventories. The candidate budget contributes only the four local faces and the socket-aware packet route; the handoff budget contributes only U and the same transport, replay, provenance, and naming rows. Since neither surface contains a coordinate for an independent confluence theorem, a global decidability procedure, a discharge witness for D, or a host normalization theorem, every downstream confluence or decidability use remains inside the displayed budget rows. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSNConfluenceBudget`

Theorem 765.194 (MetaCIC SN discharge-socket readiness)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any consumer that tries to use candidate-mediated strong normalization for a confluence-facing or decidability-facing read must display the rows S, N, U, D, H, C, P, L*, the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, the confluence-audit dependency exposure row, and the closed-substitution boundary exposure row before any discharge socket is consumed. The read is therefore a readiness surface over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, not a closed subject-reduction certificate, global confluence theorem, beta-conversion decision procedure, or filled discharge socket.*

Proof. Start with the SN confluence-decidability budget, Definition 765.193. It forces every confluence-facing or decidability-facing read using candidate-mediated strong normalization to pass through the displayed packet rows and the four L10 faces before the handoff row can be consumed.

Next apply the candidate-mediated obligation surface, Definition 765.257, and the normalization-frontier dependency exposure, Definition 765.291. These rows keep the strong-normalization source, the normal-form endpoint, the handoff row, transport, replay, provenance, and local naming attached to the same accepted packet.

Now attach the confluence and substitution boundaries. The confluence-audit exposure Definition 765.292 keeps confluence rows as bounded audit data, while the closed-substitution boundary exposure Definition 765.293 keeps substitution support behind the same handoff row and discharge socket.

Finally use the candidate-discharge frontier coverage, Definition 765.281. It preserves the obstruction and socket rows while candidate-mediated SN, confluence-facing, bounded-decidability, and L10 readiness rows are consumed. Thus a consumer reaches the socket only after the named readiness surface is visible, and no consumed row fills D without a separate subject-reduction certificate. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSNDischargeSocketReadiness`

Theorem 765.195 (MetaCIC candidate SN confluence checker factorization)**.** *Every consumer that combines candidate-mediated strong normalization, the confluence handoff, and bounded checker rows for an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L)$$

must factor through the concrete rows $S, N, O, U, D, H, C, P, L$ *and the L10 four-face ledger*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The factorization may read candidate-mediated normal-form evidence, the confluence handoff, and the bounded checker budget only along that route. It cannot discharge subject reduction, fill the open discharge socket D*, assert global beta-conversion decidability, introduce quotient term equality, select a limit, or import ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNConfluenceCheckerFactorizatio`

Proof. Begin with the candidate-mediated strong-normalization surface. By Definition 765.193 and Definition 765.257, the consumer must display $S, N, O, U, D, H, C, P, L$ together with the four L10 faces before any confluence-facing or decidability-facing read is available.

Next read the confluence handoff. The row U is available only as part of the same packet route, while D remains an open discharge socket rather than a subject-reduction proof or a closed conversion theorem.

Finally read the bounded checker budget. The checker rows are downstream of the displayed handoff and replay rows, so they can compare only the finite ledger already carried by K and the L10 faces. Since the carrier has no coordinate for discharged subject reduction, global beta-conversion decidability, quotient equality, selected limits, or ambient Real completeness, the combined consumer factors through the stated route. □

Theorem 765.196 (MetaCIC SN confluence-decidability handoff)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$ *that displays a strong-normalization budget row, a confluence budget row, and a decidability budget row, every closed-normal-form membership decision routed through the packet must first pass through those three rows, then through the continuation and provenance rows* C, P, L*, before it exports the current open-phase ledger. The route exports*

no full MetaCIC consistency theorem, no closed subject-reduction theorem, no arbitrary Church–Rosser theorem, no global beta-conversion decision procedure, and no discharge of the socket row D.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSNConfluenceDecidabilityHandoff`

Proof. Start with the SN budget row. The candidate SN confluence-decidability budget theorem, Definition 765.193, places the strong-normalization read inside the finite socket route $S, N, O, U, D, H, C, P, L$ and the four current Phase Real faces.

Next route confluence and decidability through the existing handoff surface. The confluence-decidability handoff exhaustion theorem, Definition 765.171, confines confluence-facing and decidability-facing reads to U together with the obstruction, socket, transport, replay, provenance, and naming rows.

Then apply the confluence-decidability budget theorem, Definition 765.192. It requires these reads to pass through the open L10 source ledger before any current Phase Real or Completion consumer may inspect them.

Finally compose the three rows. A closed-normal-form membership decision may be read only after strong normalization supplies the normal-form route, confluence supplies the comparison handoff, and decidability supplies the bounded checker handoff. Since all three rows remain inside K and its open-phase ledger, the route cannot promote itself to full MetaCIC consistency, closed subject reduction, arbitrary Church–Rosser, global beta-conversion decidability, or a discharged socket. □

Definition 765.197 (MetaCIC candidate-mediated SN frontier)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

the candidate-mediated strong-normalization frontier is the finite subroute that displays the strong-normalization row S, the normal-form endpoint N, the handoff row U, the discharge socket D, the componentwise transport row H, the continuation row C, the provenance row P, and the local naming row L, together with the four local source faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *already recorded for the open-phase source ledger. The frontier may be consumed only as a boundary between the candidate-mediated SN evidence and the confluence-decidability handoff; it contains no coordinate for closed subject reduction, arbitrary strong normalization, global confluence, global beta-conversion decidability, quotient term equality, host equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedFrontier`

The candidate-mediated frontier sits between the normalization audit packet of chapter 3779 and the redex-frontier packet of chapter 1008. Its rows are consumed only through closed typed term data, candidate evidence, application and Pi adequacy rows, redex-frontier obstruction rows, componentwise transport, replay, provenance, and local NameCert data; the frontier never supplies an untyped redex route or a detached global normalization claim.

Theorem 765.198 (MetaCIC candidate-mediated SN frontier)**.** *Every candidate-mediated strong-normalization read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet that is passed to the confluence-decidability handoff must factor through the frontier of Definition 765.197. In particular, the read must display S, N, U, D, H, C, P, L, keep the obstruction row O and discharge socket D available to the surrounding packet, and expose the four local faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any confluence-facing or decidability-facing consumer reads the handoff row U.*

Proof. Begin with the candidate-mediated SN finite socket normal form, Definition 765.177. It confines the candidate-mediated read to the socket-aware packet rows $S, N, O, U, D, H, C, P, L$ together with the four local source faces.

Next apply the SN confluence-decidability budget theorem, Definition 765.193. It requires any confluence-facing or decidability-facing consumer to read the same candidate budget surface before it consumes the handoff row U.

The frontier definition simply names the common boundary needed by these two routes: the candidate-mediated read supplies S, N, U, D, H, C, P, L and the four local faces, while the enclosing packet still retains O and D as visible blocked-route data. Since neither cited theorem supplies a coordinate for closed subject reduction, arbitrary strong normalization, global confluence, global beta-conversion decidability, quotient equality, host equality, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness, the factorization cannot export any of those claims. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket candidate mediated sn frontier`

Theorem 765.199 (MetaCIC candidate-mediated frontier socket separation)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated frontier replay that is passed toward the handoff row U must keep the obstruction row O and discharge socket D visible as separate rows from S, N, U, H, C, P, L and from the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The replay may use the frontier as strong-normalization evidence for the handoff boundary, but it cannot fill the subject-reduction socket or export closed subject reduction, arbitrary strong normalization, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the candidate-mediated frontier theorem, Definition 765.198. It places the candidate-mediated read on S, N, U, D, H, C, P, L and the four L10 faces before the handoff row U is consumed.

Apply the handshake theorem Definition 765.223. The handoff may inspect the frontier rows, but the theorem keeps O and D visible unless a separate closed subject-reduction row is supplied.

Use the discharge-row theorem and discharge-socket induction, Definition 765.225 and Definition 765.226. These preserve the separation between the replay rows and the socket row while finite frontier rows are consumed.

Finally apply candidate-normalization socket exhaustion, Definition 765.230. The exhausted surface contains no coordinate for the refused global metatheoretic or Real-completion claims, so the socket remains a displayed boundary rather than a discharged theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedFrontierSocketSeparatio`

Theorem 765.200 (MetaCIC candidate-mediated frontier L10 readback)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every candidate-mediated read of the handoff row U must expose the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before U*

is handed to any confluence-facing or decidability-facing consumer. The obstruction row O and discharge socket D remain visible throughout that L10 readback. No such readback supplies closed subject reduction, arbitrary strong normalization, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the candidate-mediated SN frontier Definition 765.198. It requires the four L10 faces to be present before a confluence-facing or decidability-facing consumer reads U.

Use the candidate-normalization budget theorem, Definition 765.227. The budget identifies the finite rows S, N, U, H, C, P, L together with the same four faces as the whole normalization surface available to the consumer.

Apply the handshake and consumer-boundary theorems, Definition 765.223 and Definition 765.224. They allow the handoff row to be consumed only after the candidate-mediated and L10 source data have been displayed.

The discharge-row theorem keeps D separate, and socket exhaustion keeps O, D visible after the finite readback. Since the consumed rows are exactly the frontier rows plus the four faces, no quotient equality, selected limit, host equality, Real-completeness, or global MetaCIC theorem is exported. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedFrontierL10Readback`

Theorem 765.201 (MetaCIC candidate frontier Real source lock)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated handoff that reads the row U must expose* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *as source rows, with the obstruction row O and discharge socket D still visible, before any confluence-facing or decidability-facing consumer reads the handoff. The handoff therefore treats the* $\mathsf{Real}^{\uparrow}$ *face as a named L10 source row, not as selected limits, host equality, ambient Real completeness, quotient term equality, closed subject reduction, full confluence, or beta-conversion decidability.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierRealSourceLock`

Proof. Start from the candidate-mediated frontier and L10 readback theorems, Definition 765.198 and Definition 765.200. Together they require the finite candidate rows and the four L10 faces before the handoff row U is consumed.

Apply the handshake theorem, Definition 765.223. It permits confluence-facing or decidability-facing replay only after the candidate-mediated source rows have been displayed.

Use the discharge-row theorem, socket separation, and socket exhaustion, Definition 765.225, Definition 765.199, and Definition 765.230. These keep O and D visible while the finite handoff reads U.

Since the displayed source rows contain no coordinate for selected limits, host equality, Real completeness, quotient term equality, closed subject reduction, full confluence, or beta-decidability, the Real-facing source lock exports only the named L10 row sequence. □

Theorem 765.202 (MetaCIC candidate frontier source lock)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated handoff through U must expose the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *together with obstruction row O and discharge socket D before confluence-facing or decidability-facing consumers*

can read the handoff. The handoff is therefore locked to finite source rows and exports no hidden global normalization, confluence, beta-conversion decidability, quotient term equality, selected limit, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierSourceLockCertificate`

Proof. Start with the candidate-mediated SN frontier of Definition 765.198. It places any handoff through U behind the candidate rows and the four L10 faces before a confluence-facing or decidability-facing read can occur.

Apply the L10 readback theorem and the Real source-lock theorem, Definition 765.200 and Definition 765.201. They identify $\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$ as displayed source rows, with O and D still visible.

Use the handshake theorem, Definition 765.223. It allows consumer replay only after the finite candidate-mediated source data have been displayed.

Finally apply socket separation and socket exhaustion, Definition 765.199 and Definition 765.230. They keep the obstruction and discharge rows separate from confluence and decidability consumers, so the handoff cannot hide a global normalization, quotient equality, selected-limit, host-equality, or Real-completeness coordinate. □

Theorem 765.203 (MetaCIC candidate frontier RegSeqRat handoff)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. The* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row is the only regular-rational route available to a candidate-mediated handoff through* U*. Consequently the frontier exports no selected limit, quotient term equality, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, closed subject reduction, full confluence, or alternate regular-rational approximation route beyond the displayed* $\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$ *source window.*

Proof. Read the L10 readback theorem, Definition 765.200. It places $\mathsf{RegSeqRat}^{\uparrow}$ inside the four-face source window that must be exposed before any confluence-facing or decidability-facing consumer reads U.

Next use the frontier handoff totality theorem, Definition 765.206. The handoff surface is exhausted by S, N, U, H, C, P, L, the visible rows O, D, and the same four L10 faces.

Apply discharge coverage and socket exhaustion, Definition 765.234 and Definition 765.230. They leave no hidden coordinate through which another regular-rational route could fill D or bypass the displayed source window.

Thus the only regular-rational readback available to the handoff is the named $\mathsf{RegSeqRat}^{\uparrow}$ row. The excluded selected-limit, quotient-equality, host-equality, Real-completeness, closed-subject-reduction, and full-confluence claims are not exported by the frontier. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierRegSeqRatHandoff`

Theorem 765.204 (MetaCIC candidate frontier source-window determinacy)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Suppose two candidate-mediated handoff reads expose the same four L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

with the same visible obstruction row O and discharge socket D. Then the handoff row U has the same finite source-window classifier before any confluence-facing or decidability-facing consumer reads it. The conclusion is only determinacy of that displayed source window; it does not close subject reduction, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the candidate-mediated frontier and L10 readback theorems, Definition 765.198 and Definition 765.200. They force both reads of U to pass through the same four displayed L10 faces before any confluence-facing or decidability-facing consumer can inspect the handoff.

Use the Real source-lock and RegSeqRat handoff theorems, Definition 765.201 and Definition 765.203. These identify the $\mathsf{Real}^{\uparrow}$ face as a named source row and make $\mathsf{RegSeqRat}^{\uparrow}$ the only regular-rational route available to the handoff, so the two reads have no alternate source-window classifier to choose.

Apply socket separation and handoff totality, Definition 765.199 and Definition 765.206. Since O and D are the same visible boundary rows in both reads, totality exhausts U by S, N, U, H, C, P, L together with that fixed boundary and the same four source faces.

Finally read discharge coverage and source exhaustion, Definition 765.210 and Definition 765.211. They leave no hidden source row, quotient source, selected-limit source, host-equality source, confluence source, beta-decidability source, or Real-completeness source. The finite classifier visible at U is therefore determined by the shared L10 window and the shared O, D boundary. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierSourceWindowDeterminacy`

Theorem 765.205 (MetaCIC candidate-mediated SN L10 completion lock)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any accepted packet that reaches the candidate-mediated strong-normalization handoff through U must expose exactly the source rows* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any confluence-facing or decidability-facing consumer reads the handoff. The obstruction row O and discharge socket D remain visible, and the handoff exports no selected limits, host equality, quotient term equality, closed subject reduction, global confluence, beta-conversion decidability, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNL10CompletionLock`

Proof. Start from the candidate-mediated frontier theorem and the L10 readback theorem, Definition 765.198 and Definition 765.200. Together they require the four displayed L10 source rows before a consumer may read U.

Use the RegSeqRat handoff theorem, Definition 765.203. It locks the regular-rational part of the route to the displayed $\mathsf{RegSeqRat}^{\uparrow}$ row inside the same four-row window.

Apply socket separation and obstruction nonescape, Definition 765.199 and Definition 765.207. These keep O, D visible while the handoff rows are consumed.

Finally read discharge coverage. The consumed surface is exhausted by S, N, U, H, C, P, L, the visible O, D boundary, and the four L10 source rows, so no selected-limit, quotient-equality, host-equality, closed-subject-reduction, global-confluence, beta-decidability, or Real-completeness claim is exported. □

Theorem 765.206 (MetaCIC candidate-mediated frontier handoff totality)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any finite confluence-facing or decidability-facing handoff that uses candidate-mediated strong-normalization evidence is exhausted by the route*

$$S, N, U, H, C, P, L$$

together with the visible boundary rows O, D *and the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Thus the handoff is total only for the displayed frontier surface; it refuses closed subject reduction, arbitrary strong normalization, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply the candidate-mediated frontier and the confluence-decidability handshake. Together they route any candidate-mediated handoff through S, N, U, H, C, P, L while keeping the four L10 faces available before U is consumed.

Next use the candidate-normalization budget theorem. It shows that the finite budget of the handoff is precisely the displayed candidate-normalization surface, not an unrestricted strong-normalization or confluence theorem.

Apply discharge-socket induction to the finite handoff rows. Each consumed row preserves O and leaves D unfilled, because none of the rows is an explicit closed subject-reduction coordinate.

Finally invoke candidate-normalization socket exhaustion. Once the displayed surface and the four L10 faces have been consumed, there is no remaining packet coordinate that could supply quotient term equality, selected limits, host equality, Real completeness, global confluence, beta-conversion decidability, or arbitrary strong normalization. The handoff is therefore total exactly over the named frontier and no more. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedFrontierHandoffTotality`

Theorem 765.207 (MetaCIC candidate-mediated frontier obstruction nonescape)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every finite handoff that uses candidate-mediated strong-normalization evidence keeps the obstruction row* O *and the discharge socket* D *visible until a separate closed subject-reduction row is displayed. The handoff may consume* S, N, U, H, C, P, L *and the L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *but it cannot erase* O, *fill* D, *or export closed subject reduction, full confluence, global beta-conversion decidability, quotient term equality, selected limits, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the candidate-mediated frontier and the handoff totality theorem, Definition 765.198 and Definition 765.206. They identify the handoff surface as the finite route through S, N, U, H, C, P, L, the visible boundary rows O, D, and the four L10 faces.

Apply the handshake theorem Definition 765.223. It permits confluence-facing or decidability-facing replay only through the displayed route, and it leaves O, D open unless the packet separately displays closed subject reduction.

Use the discharge-row theorem and discharge-socket induction, Definition 765.225 and Definition 765.226. These keep D separate from the candidate-mediated rows while finite replay consumes the handoff surface.

Finally apply socket exhaustion, Definition 765.230. Once S, N, U, H, C, P, L and the four L10 faces have been consumed, the packet has no remaining coordinate that could hide a closed subject-reduction row or discharge the obstruction. The listed global metatheoretic, quotient, selected-limit, host-equality, and completeness claims therefore remain outside the handoff. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedFrontierObstructionNones

Theorem 765.208 (MetaCIC candidate-mediated SN frontier discharge)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A candidate-mediated strong-normalization handoff may approach the discharge socket only through the displayed rows*

$$S, N, O, U, D, H, C, P, L$$

and the L10 source faces

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The socket D remains unfilled until a separate closed subject-reduction row is displayed. In particular the handoff exports no closed subject reduction, unrestricted strong normalization, full confluence, beta-conversion decidability, quotient term equality, selected limit, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with the candidate-mediated frontier theorem and L10 readback theorem, Definition 765.198 and Definition 765.200. They place any candidate-mediated SN read behind the rows $S, N, O, U, D, H, C, P, L$ and force the four L10 faces to be displayed before the handoff row U is consumed.

Next apply frontier handoff totality, Definition 765.206. It exhausts the handoff route by S, N, U, H, C, P, L, the visible boundary rows O, D, and the same four L10 source faces, so a consumer has no additional route into the discharge socket.

Use obstruction nonescape, Definition 765.207. It keeps O and D visible while the finite candidate-mediated route is replayed, and it blocks any reading of candidate-mediated SN as a closed subject-reduction row.

Finally apply socket exhaustion, Definition 765.230. After the displayed rows and L10 faces have been consumed, no packet coordinate remains from which quotient equality, selected limits, host equality, Real completeness, global confluence, beta-decidability, unrestricted strong normalization, or closed subject reduction could be recovered. The discharge boundary is therefore approached but not filled. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNFrontierDischarge

Theorem 765.209 (MetaCIC candidate-mediated SN socket-induction frontier)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Finite induction over the displayed candidate-mediated handoff rows preserves the separation of obstruction row O and discharge socket D while consuming*

$$S, N, U, H, C, P, L$$

and the L10 faces

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

No induction step exports closed subject reduction, global confluence, beta-decidability, quotient term equality, selected limits, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNSocketInductionFrontie`

Proof. The base case is the unconsumed frontier. Apply Definition 765.198 and Definition 765.199. They display $S, N, O, U, D, H, C, P, L$ and keep the obstruction row and discharge socket separate before the handoff row is read.

For the L10 readback step, use Definition 765.200. It requires $\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$ to remain visible before any confluence-facing or decidability-facing consumer consumes U.

For the handoff step, apply Definition 765.206. The consumed surface is exhausted by S, N, U, H, C, P, L together with the visible rows O, D and the same four L10 faces.

For the obstruction step, read Definition 765.207 and Definition 765.234. They preserve the nonescape of O and the socket status of D through every finite replay row.

The induction therefore has no case whose constructor supplies closed subject reduction, global confluence, beta-decidability, quotient term equality, selected limits, host equality, or Real completeness. The socket boundary remains visible after the finite route is consumed. □

Theorem 765.210 (MetaCIC candidate frontier discharge coverage)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every finite candidate-mediated handoff that first consumes the strong-normalization frontier and then reaches the confluence-decidability boundary is exhausted by the replay rows*

$$S, N, U, H, C, P, L,$$

the visible obstruction and socket rows O, D*, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The coverage conclusion is only this finite discharge surface. It refuses closed subject reduction, arbitrary strong normalization, full confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, and $\mathsf{Real}^{\uparrow}$ *completeness unless a later packet displays separate rows for those claims.*

Proof. Begin with the candidate-mediated frontier theorem and handoff totality, Definition 765.198 and Definition 765.206. They force any accepted handoff through S, N, U, H, C, P, L together with the four L10 faces before a confluence-facing or decidability-facing consumer reaches the handoff boundary.

Next apply obstruction nonescape, Definition 765.207. The obstruction row O and discharge socket D remain visible while the frontier is consumed, so the handoff cannot erase the subject-reduction socket by replaying candidate-mediated SN evidence.

Use the discharge-row theorem and discharge-socket induction, Definition 765.225 and Definition 765.226. These make the finite discharge route stable under each consumed row and keep D separate from S, N, U, H, C, P, L.

Finally read the existing discharge coverage theorem, Definition 765.234. It packages the same rows as the whole available frontier budget. Since none of the displayed coordinates is closed subject reduction, arbitrary strong normalization, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or $\mathsf{Real}^{\uparrow}$ completeness, the stated refusals remain outside the discharge coverage. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierDischargeCoverage`
`semantic name certificate`

Theorem 765.211 (MetaCIC candidate frontier source exhaustion)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated handoff that reaches the confluence-decidability boundary has exactly the displayed source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow},$$

together with the visible obstruction and discharge rows O, D*. Replaying* U *cannot add a redex-frontier source, discharge-socket source, quotient source, selected-limit source, host-equality source, closed-subject-reduction source, full-confluence source, beta-decidability source, or ambient Real-completeness source.*

Proof. First read the candidate-mediated frontier, the L10 readback theorem, and the completion lock. These results place every handoff that reaches U behind the same four source faces and keep O, D visible at the boundary.

Next apply handoff totality and obstruction nonescape. Totality exhausts the finite handoff surface by S, N, U, H, C, P, L, the visible rows O, D, and the four L10 faces, while nonescape prevents replay from erasing the obstruction row or filling the discharge socket.

Finally use discharge coverage. The discharge surface is already accounted for by the displayed rows, so replaying U has no remaining coordinate from which to import a redex-frontier source, quotient source, selected-limit source, host-equality source, closed-subject-reduction source, full-confluence source, beta-decidability source, or ambient Real-completeness source. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierSourceExhaustion`

Theorem 765.212 (MetaCIC candidate frontier axiom boundary)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. An accepted candidate-mediated handoff through* U *may consume strong-normalization frontier evidence only through the displayed rows* S, N, U, H, C, P, L*, the visible obstruction and discharge rows* O, D*, and the source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

It cannot discharge axioms, closed subject reduction, global confluence, beta-decidability, quotient term equality, selected limits, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness unless separate rows in the packet display those claims.*

Proof. First read the L10 source locks from Definition 765.200 and Definition 765.205. They force every handoff through U to expose $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as named source rows before any confluence-facing or decidability-facing consumer reads the handoff.

Next apply the RegSeqRat handoff theorem Definition 765.203. It fixes the regular-rational source of the handoff inside the same four-face window, so the frontier cannot replace that route by selected limits, quotient equality, host equality, or ambient Real completeness.

Use discharge coverage and source exhaustion, Definition 765.210 and Definition 765.211. These theorems exhaust the accepted handoff surface by the displayed candidate rows, the visible obstruction and socket rows, and the four source faces.

Finally read the completion lock together with the exhausted source surface. Axioms, closed subject reduction, global confluence, beta-decidability, quotient term equality, selected limits, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not among those rows. Therefore a candidate-mediated strong-normalization handoff can pass evidence to the boundary, but it cannot silently become a discharge of any listed claim without a separate displayed row for that claim. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierAxiomFrontier`

Theorem 765.213 (MetaCIC candidate-mediated SN route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated strong-normalization read that exports a normalization-frontier conclusion must pass through the displayed* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *row, the* $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$ *boundary row, the* $\mathsf{FiniteObservationConfluence}^{\uparrow}$ *finite-confluence row, the* $\mathsf{MetaCICCriticalPairLedger}^{\uparrow}$ *critical-pair ledger, and the* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *discharge row before the conclusion is visible. The route may export only that normalization-frontier boundary; it does not assert strong normalization for all MetaCIC terms, closed subject reduction, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted critical-path packet. The candidate-mediated read starts in the finite rows $S, N, O, U, D, H, C, P, L$, with O and D kept visible as obstruction and discharge-socket data.

Use the existing frontier obligations: Definition 765.198, Definition 765.200, and Definition 765.206. They force the candidate-mediated SN evidence through the named finite frontier before any handoff row is consumed.

Next compose the confluence-facing route. The $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$ row and $\mathsf{FiniteObservationConfluence}^{\uparrow}$ row are read only as finite observation boundaries, while the $\mathsf{MetaCICCriticalPairLedger}$ row accounts for the displayed critical-pair surface.

Finally route the remaining boundary through $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$. The discharge row is a socket, not a proof of closed subject reduction, so the resulting conclusion is only a normalization-frontier export over the displayed candidate-mediated route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNRoute semantic name certificate`

Theorem 765.214 (MetaCIC normalization trace residual-frontier route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated normalization read that reaches the residual frontier before a strong-normalization conclusion is consumed must first expose the candidate row, the* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ *row, the* $\mathsf{FiniteObservationConfluence}^{\uparrow}$ *row, the* $\mathsf{MetaCICCriticalPairLedger}^{\uparrow}$ *row, the* $\mathsf{NormalizationCertificateRouter}$ *row, and the strong-normalization boundary row. The route may use those rows to present a finite normalization trace, but it is not by itself a global strong-normalization theorem, a confluence theorem, a closed subject-reduction theorem, a beta-conversion decision procedure, a quotient term equality, a selected normal form, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNormalizationTraceResidualFrontierRoute`

Proof. Project the candidate-mediated frontier rows from K. The candidate row is read through the finite candidate surface, while O and D remain visible as obstruction and discharge-socket data.

Route residual substitution through the candidate-mediated boundary. The MetaCICResidualSubstitutionBounda row is consumed as a displayed boundary row attached to the same packet, so residual replay cannot bypass the candidate row or fill the discharge socket.

Use the finite observation confluence and critical-pair ledgers next. The $\mathsf{FiniteObservationConfluence}^{\uparrow}$ row confines confluence use to finite observations, and the $\mathsf{MetaCICCriticalPairLedger}^{\uparrow}$ row accounts for the displayed critical-pair surface before any normalization trace is routed onward.

Finally read the NormalizationCertificateRouter row and the strong-normalization boundary row through BHist, hsame, Cont, Pkg, and local NameCert data. These rows expose only a finite normalization trace route, so the global strong-normalization, confluence, subject-reduction, beta-decidability, quotient-equality, selected-normal-form, and Real-completeness claims remain outside the theorem. □

Theorem 765.215 (MetaCIC candidate frontier normal-form witness extraction)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. If a candidate-mediated strong-normalization read exposes a normal-form witness at the confluence-decidability boundary, then the witness is readable only through the displayed* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *row, the* $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$ *row, the* $\mathsf{FiniteObservationConfluence}^{\uparrow}$ *row, the* $\mathsf{MetaCICCriticalPairLedger}^{\uparrow}$ *row, the* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *row, and the L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The extraction boundary does not assert global strong normalization, closed subject reduction, global confluence, beta-conversion decidability, quotient term equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the candidate-mediated SN route of Definition 765.213. It places every exported normalization-frontier conclusion behind the candidate-mediated SN row, confluence-boundary row, finite-observation confluence row, critical-pair ledger, and subject-reduction discharge socket.

Next read the L10 source boundary from Definition 765.200 and Definition 765.206. These results force the same handoff to expose $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the witness is passed to any confluence-facing or decidability-facing consumer.

Use discharge coverage and source exhaustion, Definition 765.210 and Definition 765.211. They exhaust the available witness route by the displayed candidate rows, visible obstruction and socket rows, and the four L10 source faces.

Finally apply the axiom boundary of Definition 765.212. The refused global normalization, closed subject-reduction, confluence, beta-decidability, quotient-equality, selected-limit, and Real-completeness claims are not rows in the extracted witness surface, so the normal-form witness remains candidate-mediated boundary data. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierNormalFormWitnessExtract`

Theorem 765.216 (MetaCIC candidate-mediated SN frontier fairness retention)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted MetaCICCriticalPath$^{\uparrow}$ *packet. If the candidate-mediated strong-normalization route of K is consumed by the normalization frontier, then the same finite premise rows must be visible through*

CandidateMediatedSN$^{\uparrow}$, CandidateSNConfluenceBoundary$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICNormaliz

before any normalization certificate row is read. The retention claim is only fairness of the displayed premise route; it does not assert hidden strong normalization, global confluence, quotient term equality, host term equality, or any selected normal form.

Proof. Project the accepted packet K. The candidate-mediated route begins with the displayed rows $S, N, O, U, D, H, C, P, L$, with O and D retained as obstruction and discharge-socket data.

Read the existing candidate-mediated SN route and normal-form witness extraction theorems, Definition 765.213 and Definition 765.215. They force the candidate row, confluence boundary, finite observation rows, critical-pair ledger, discharge socket, and L10 source faces to be displayed before a witness-facing consumer reaches the frontier.

The MetaCICNormalizationFrontier$^{\uparrow}$ and MetaCICNormalizationCertificateRouter$^{\uparrow}$ rows can therefore consume only the same visible premise list. Since the carrier fields have already been exhausted, no hidden strong-normalization theorem, global confluence theorem, quotient equality, host equality, or selected normal form can be read as part of the certificate route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNFrontierFairnessRetent`

Theorem 765.217 (MetaCIC candidate-mediated bounded SN discharge route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted MetaCICCriticalPath$^{\uparrow}$ *packet. A candidate-mediated strong-normalization frontier read discharges a bounded normalization request only after the candidate row, source-window row, residual-frontier row, fairness-retention row, normal-form witness extraction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row are all visible. The discharge is bounded by those displayed rows; it does not assert global strong normalization, full confluence, subject reduction, beta-conversion decidability, quotient term equality, or a selected normal form.*

Proof. Start with the candidate-mediated frontier route of Definition 765.213 and the L10 readback of Definition 765.200. These expose the candidate row and source-window row before any normalization-facing consumer reaches the frontier.

Next use the residual-frontier route and normal-form witness extraction, Definition 765.214 and Definition 765.215. They force the residual boundary and extracted witness to remain attached to the same finite carrier rows.

Finally apply Definition 765.216. Fairness retention keeps the candidate, confluence-boundary, finite-observation, critical-pair, discharge-socket, and source rows visible when the bounded request is consumed. The rows H, C, P, L then transport, replay, source, and name the same finite route, so the discharge cannot become global SN, full confluence, subject reduction, beta-decidability, quotient equality, or a selected normal-form principle. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNBoundedDischargeRoute`

Theorem 765.218 (MetaCIC candidate-mediated SN budget extraction)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any bounded strong-normalization discharge read that extracts a finite normalization budget must expose the candidate row, the source-window row, the residual-frontier row, the normal-form witness row, the fairness-retention row, and the local* NameCert *rows before the budget is readable. The extracted budget is therefore a finite row-level budget for the displayed candidate-mediated route; it is not a global strong-normalization theorem, a selected normal form, a quotient-equality principle, a full confluence theorem, or an ambient subject-reduction closure.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNBudgetExtraction`

Proof. Start from the bounded discharge route of Definition 765.217. It already forces the candidate row, source-window row, residual-frontier row, fairness-retention row, normal-form witness extraction row, transport, replay, provenance, and local naming to be visible before a bounded request can be discharged.

Use the normal-form witness extraction theorem, Definition 765.215, to identify the witness row as boundary data attached to the same candidate, confluence-boundary, finite-observation, critical-pair, discharge-socket, and L10 source faces. This prevents the budget from being read as a selected normal form detached from the packet.

Finally apply the fairness-retention theorem, Definition 765.216. It keeps the candidate and source rows visible when the frontier is consumed, while H, C, P, L transport, replay, source, and name the same finite route. The budget extracted from the discharge is therefore only the finite budget certified by those rows, and it cannot expand into global SN, full confluence, subject reduction, quotient equality, or an ambient normal-form selector. □

Theorem 765.219 (MetaCIC candidate-mediated SN normal-endpoint budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any closed normal endpoint consumed by the critical-path route must expose, in order, candidate evidence, the closed typed term row, the candidate-to-SN projection, the no-infinite-reduction projection, and the finished-normal endpoint row. This endpoint budget preserves the candidate premise as a visible row; it does not assert evidence-free strong normalization, closed consistency, global confluence, quotient term equality, host term equality, or a selected normal form detached from the candidate-mediated route.*

Proof. Begin with the candidate-mediated frontier of Definition 765.213. It places every strong-normalization-facing read behind the candidate row and the surrounding confluence-boundary, finite-observation, critical-pair, discharge-socket, and L10 source rows.

Use the bounded discharge route and budget extraction, Definition 765.217 and Definition 765.218. These force a bounded request to keep the candidate, source-window, residual-frontier, witness, fairness-retention, transport, replay, provenance, and local naming rows visible before any finite budget is read.

Finally read the normalization audit map through the existing MetaCIC frontier references, including Definition 765.215 and Definition 765.216. The closed typed term row, candidate-to-SN projection, no-infinite-reduction projection, and finished-normal endpoint row are therefore endpoint data attached to the candidate evidence, not an unconditional normalization or consistency theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNNormalEndpointBudget`

Theorem 765.220 (MetaCIC candidate frontier confluence socket boundary)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A confluence-facing consumer may use the handoff row U after candidate-mediated strong-normalization evidence only while the obstruction row O and discharge socket D remain visible, and only after the four L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

have been displayed. The boundary exports no closed subject reduction, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or discharged subject-reduction socket.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierConfluenceSocketBoundary`

Proof. Start with the candidate-mediated frontier theorem and handoff totality, Definition 765.198 and Definition 765.206. They place every candidate-mediated handoff on S, N, U, H, C, P, L together with the visible rows O, D and the four L10 faces.

Use the L10 readback and Real source lock theorems, Definition 765.200 and Definition 765.201. These force the dyadic, stream, regular-rational, and Real rows to remain explicit before U is consumed by a confluence-facing or decidability-facing route.

Now apply socket separation and obstruction nonescape, Definition 765.199 and Definition 765.207. They keep O and D visible while the handoff is replayed and prevent candidate-mediated strong-normalization evidence from filling the subject-reduction socket.

Finally read the discharge coverage route in Definition 765.210. Since the available surface is exactly the finite frontier plus the L10 faces, no closed subject reduction, global confluence, beta-decidability, quotient equality, selected limit, host equality, ambient Real completeness, or discharged socket can be exported. □

Theorem 765.221 (MetaCIC candidate frontier discharge socket coproduct)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every candidate-mediated handoff that reaches the confluence or decidability boundary consumes exactly the finite coproduct of candidate rows S, N, U, H, C, P, L, visible obstruction and socket rows O, D, and L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The coproduct boundary exports no closed subject reduction, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or discharged subject-reduction socket unless a separate row for that claim is displayed.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierDischargeSocketCoproduct`

Proof. Start with the candidate-mediated frontier and L10 readback theorems, Definition 765.198 and Definition 765.200. They force the candidate rows S, N, U, H, C, P, L and the four L10 faces to be visible before the handoff reaches a confluence-facing or decidability-facing consumer.

Use handoff totality and obstruction nonescape, Definition 765.206 and Definition 765.207. These keep O, D as visible boundary rows while the candidate handoff is consumed, so neither row is silently absorbed into the candidate rows.

Apply the confluence socket boundary, Definition 765.220. It identifies the consumer-facing surface as the displayed candidate route plus the socket boundary and the L10 source faces.

Finally read discharge coverage, Definition 765.210. Once those rows have been consumed, no remaining coordinate can supply closed subject reduction, global confluence, beta-decidability, quotient equality, selected limits, host equality, ambient Real completeness, or socket discharge. The handoff boundary is therefore exactly the stated finite coproduct. □

Theorem 765.222 (MetaCIC candidate frontier discharge refusal)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated handoff that has exposed the four L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

still refuses discharge of the subject-reduction socket unless a separate closed subject-reduction row is displayed. The same handoff refuses global confluence, beta-decidability, quotient term equality, host equality, selected limits, and $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierDischargeRefusal`

Proof. Start with the frontier and L10 readback theorems, Definition 765.198 and Definition 765.200. They place the candidate-mediated handoff on S, N, U, H, C, P, L and force the four L10 faces to be displayed before any confluence-facing or decidability-facing consumer reads U.

Use obstruction nonescape and discharge coverage, Definition 765.207 and Definition 765.210. These keep O and D visible while the handoff surface is consumed and identify the whole available discharge budget as the finite frontier together with the L10 faces.

Finally apply the confluence socket boundary, Definition 765.220. None of the displayed rows is a closed subject-reduction coordinate, so the socket is not discharged. The same absence excludes global confluence, beta-decidability, quotient term equality, host equality, selected limits, and $\mathsf{Real}^{\uparrow}$ completeness from the exported handoff. □

Theorem 765.223 (MetaCIC SN confluence decidability handshake)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. If a closed-normal-form membership read first uses candidate-mediated strong normalization and then passes to the confluence-decidability handoff, the whole read factors through* S, N, U, H, C, P, L *together with the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The obstruction row O *and discharge socket* D *remain visible and unfilled unless the same packet also displays a separate closed subject-reduction row.*

Proof. Begin with the candidate-mediated frontier. By Definition 765.198, the strong-normalization read is confined to the displayed frontier rows and the four L10 faces before any confluence-facing or decidability-facing consumer can inspect the handoff row U.

Next apply Definition 765.224. The consumer may use the existing handoff row and route closed-normal-form membership through C, P, L, but it receives no closed subject-reduction coordinate and no global beta-conversion decision procedure.

The discharge boundary is preserved by Definition 765.225 and Definition 765.226. These results keep O and D visible while finite frontier rows are replayed and prevent the SN evidence from filling the socket by itself.

Finally use Definition 765.230. The exhausted read surface is exactly the displayed S, N, U, H, C, P, L route plus $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Hence the handshake factors through those rows and leaves O, D open unless a separate closed subject-reduction row is present. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSNConfluenceDecidabilityHandshake`

Theorem 765.224 (MetaCIC confluence-decidability consumer boundary)**.** *Any confluence-facing or decidability-facing consumer that uses candidate-mediated strong-normalization evidence from* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *must consume only the frontier rows of Definition 765.197 and the existing handoff row U. The consumer may route closed-normal-form membership through C, P, L, but it may not treat the frontier as closed subject reduction, full consistency, arbitrary Church–Rosser, global beta-conversion decidability, a discharged socket, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Use Definition 765.198 to place the candidate-mediated read on the frontier rows and the four local faces. This supplies the SN-facing evidence that the confluence-decidability handoff is allowed to inspect.

Now apply the MetaCIC SN confluence-decidability handoff, Definition 765.196. It sends closed-normal-form membership decisions through the strong-normalization, confluence, and decidability budget rows and then through C, P, L before the open-phase ledger is exported.

Finally keep the socket and obstruction boundaries visible. The frontier does not fill D, and the handoff theorem does not erase O or convert U into a global theorem. Therefore the consumer obtains only the finite candidate-mediated boundary plus the existing handoff route, while the excluded subject-reduction, consistency, Church–Rosser, beta-decidability, socket-discharge, and completeness claims remain outside the packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceDecidabilityConsumerBoundary`

Theorem 765.225 (MetaCIC candidate-mediated SN discharge row)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any candidate-mediated strong-normalization read satisfying the frontier of Definition 765.197 can be used by a confluence-facing or decidability-facing consumer only while D remains a displayed discharge socket separate from S, N, U, H, C, P, L and from the four local L10 faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *No such consumer may reinterpret the frontier as closed subject reduction, arbitrary strong normalization, full consistency, beta-conversion decidability, quotient term equality, host equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNDischargeRow`

Proof. First apply the candidate-mediated SN frontier theorem, Definition 765.198. It places the read on S, N, U, D, H, C, P, L together with the four local L10 faces, while keeping the obstruction row O and discharge socket D available to the surrounding packet.

Next apply the consumer boundary theorem, Definition 765.224. A confluence-facing or decidability-facing consumer may inspect the same frontier rows and the handoff row U, but the theorem does not fill D or promote the frontier to a closed metatheoretic result.

Finally use the handoff exhaustion route of Definition 765.171. That route keeps downstream reads of U mediated by O, D, H, C, P, L and the finite packet rows S, N, U. Therefore D remains a separate displayed discharge row, distinct from the packet rows and the four L10 faces, and the excluded subject-reduction, normalization, consistency, decidability, quotient, host-equality, selected-limit, and completeness claims remain outside the consumer surface. □

Theorem 765.226 (MetaCIC discharge-socket induction)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet, and let F be a finite closed-term frontier whose rows replay the candidate-mediated strong-normalization row S, the normal-form endpoint N, the handoff row U, the componentwise transport row H, the displayed continuation row C, the provenance row P, and the local naming row L. If every row of F is consumed through the frontier of Definition 765.197, then induction over F preserves the obstruction row O and keeps the discharge socket D unfilled unless the packet also contains an explicit closed subject-reduction row. In particular, candidate-mediated strong normalization, confluence-facing replay, and decidability-facing replay do not by themselves introduce a closed subject-reduction coordinate.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDischargeSocketInduction`

Proof. Induct over the finite frontier rows. The empty frontier exposes no consumer row, so the accepted packet remains exactly $K = (S, N, O, U, D, H, C, P, L)$ with O and D still visible.

For the induction step, project the next closed-term row and the accumulated packet surface. The row is allowed to replay only the displayed S, N, U, H, C, P, L route named by Definition 765.197; it has no coordinate for closed subject reduction.

Use the candidate-mediated SN frontier theorem and the confluence-decidability consumer boundary to keep the replayed row on the same frontier surface. These results route the SN, confluence-facing, and decidability-facing reads through U and C while leaving the obstruction row O and the discharge socket D in the surrounding packet.

The inductive hypothesis applies to the remaining frontier. Since neither the current replay row nor the previous frontier rows add an explicit closed subject-reduction coordinate, no constructor fills D. Thus the obstruction row is preserved and the discharge socket stays open until a separate subject-reduction row is supplied. □

Theorem 765.227 (MetaCIC candidate-normalization budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

every confluence-facing or decidability-facing use of candidate-mediated strong-normalization evidence is budgeted by the finite rows S, N, U, H, C, P, L together with the four L10 faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The obstruction row O and discharge socket D remain visible boundary rows throughout the read. The budget exports no closed subject reduction, arbitrary strong normalization, full confluence, global beta-conversion decidability, quotient term equality, host equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply the candidate-mediated SN frontier theorem, Definition 765.198. It places any candidate-mediated read on the finite rows S, N, U, D, H, C, P, L and the four L10 faces, with O and D still visible to the surrounding packet.

Next use the confluence-decidability consumer boundary, Definition 765.224. A confluence-facing or decidability-facing consumer may inspect the frontier and the handoff row U, but it receives no closed subject-reduction row, no full confluence theorem, and no global beta-conversion decision procedure.

Apply the candidate-mediated SN discharge row and the discharge-socket induction, Definition 765.225 and Definition 765.226. These results keep D separate from the budget rows and preserve O while finite frontier rows are consumed. Since the packet has no coordinate for quotient term equality, host equality, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness, the displayed budget is the whole normalization surface available to the consumer. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateNormalizationBudget`

Theorem 765.228 (MetaCIC candidate-normalization L10 source exactness)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

every candidate-normalization consumer whose budget is certified by Definition 765.227 reads exactly the four L10 faces

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

together with the finite packet rows S, N, U, H, C, P, L. The obstruction row O and the discharge socket D remain visible throughout the read. The source-exact budget exports no closed subject reduction, global confluence, beta-conversion decidability, selected limit, quotient equality, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateNormalizationL10SourceExactness`

Proof. Start with the candidate-mediated SN frontier, Definition 765.198. It places the consumer on the displayed strong-normalization rows and the four L10 faces, while keeping the obstruction row and discharge socket in the surrounding packet.

Use the confluence-decidability consumer boundary, Definition 765.224. A confluence-facing or decidability-facing replay may inspect U and the displayed frontier, but it receives no global confluence theorem, no beta-conversion decision procedure, and no closed subject-reduction row.

Apply discharge-socket induction, Definition 765.226. Induction over the finite frontier preserves O and leaves D unfilled unless a separate closed subject-reduction coordinate is displayed.

Finally use candidate-normalization socket exhaustion, Definition 765.230. Once S, N, U, H, C, P, L and the four L10 faces have been consumed, no packet row remains from which to read selected limits, quotient equality, host equality, Real completeness, closed subject reduction, global confluence, or beta-decidability. The budget is therefore source-exact for exactly the named L10 route. □

Theorem 765.229 (MetaCIC L10 normalization frontier)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated strong-normalization discharge route that displays the Real source lock, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the confluence socket, and the decidable-boundary row remains*

on the finite L10 normalization frontier before any consistency-facing claim is exported. The frontier is the displayed route through $S, N, O, U, D, H, C, P, L$ and the four L10 faces; it is not full subject reduction, full confluence, global beta-conversion decidability, quotient term equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10NormalizationFrontier`

Proof. First read the candidate-mediated frontier L10 readback and Real source lock, Definition 765.200 and Definition 765.201. These force the Real-facing route to expose the dyadic, stream, regular-rational, and Real rows before the handoff row is consumed.

Next apply the RegSeqRat handoff theorem, Definition 765.203. It keeps the regular-rational readback on the same finite StreamName and DyadicRatCore route.

Use the SN confluence-decidability handshake and consumer boundary, Definition 765.223 and Definition 765.224. These allow the handoff to inspect the candidate-mediated frontier only while the confluence socket and decidable-boundary row remain explicit.

Finally apply discharge-socket induction and discharge coverage, Definition 765.226 and Definition 765.234. They preserve the discharge socket unless a separate subject-reduction coordinate is displayed, so the route remains an L10 normalization frontier and exports no consistency-facing claim beyond the finite packet. □

Theorem 765.230 (MetaCIC candidate-normalization socket exhaustion)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any confluence-facing or decidability-facing replay that uses only the candidate-normalization budget rows S, N, U, H, C, P, L together with the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *exhausts the SN-facing surface without filling the subject-reduction socket. The obstruction row O remains visible and the discharge socket D remains unfilled unless the same packet also displays an explicit closed subject-reduction row.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateNormalizationSocketExhaustion`

Proof. Start from the candidate-mediated SN frontier theorem, Definition 765.198. It places the candidate-mediated read on the finite frontier and keeps O and D available to the surrounding packet.

Next apply the confluence-decidability consumer boundary, Definition 765.224. A confluence-facing or decidability-facing consumer may inspect the frontier rows and the handoff row U, but the boundary gives no closed subject-reduction coordinate.

Use the candidate-mediated SN discharge row and discharge-socket induction, Definition 765.225 and Definition 765.226. These two results preserve the separation between the replay rows S, N, U, H, C, P, L and the socket row D while finite frontier rows are consumed.

Finally apply the candidate-normalization budget theorem, Definition 765.227. Its budget is exactly the displayed SN-facing surface plus the four L10 faces. Since that inventory omits a closed subject-reduction row, the replay can feed only the permitted consumers; it cannot erase O, fill D, or export full confluence or global beta-conversion decidability. □

Theorem 765.231 (MetaCIC candidate-mediated subject-reduction boundary)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated replay over* S, N, U, H, C, P, L *and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

preserves the visible obstruction row O *and the discharge socket* D*. The replay cannot be read as closed subject reduction unless the packet separately displays a subject-reduction row; candidate-mediated strong normalization, confluence-facing replay, and decidability-facing replay do not fill that row by themselves.*

Proof. Begin with the candidate-mediated frontier of Definition 765.198. It confines the SN-facing read to the displayed frontier rows and keeps O, D visible to the enclosing packet.

Use the handshake theorem, Definition 765.223, to pass from candidate-mediated normalization to confluence-facing or decidability-facing replay. The handoff reads S, N, U, H, C, P, L and the four L10 faces, but it does not add a closed subject-reduction coordinate.

Apply the discharge-row and socket-induction theorems, Definition 765.225 and Definition 765.226. They preserve the obstruction row and keep the discharge socket unfilled while finite frontier rows are consumed.

Finally use Definition 765.227 and Definition 765.230. The budget is exhausted by the displayed replay route and the four source faces, so any closed subject-reduction conclusion must come from a separate displayed row. Without that row, the boundary remains exactly O, D plus the finite replay surface. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNSubjectReductionBounda`

Theorem 765.232 (MetaCIC candidate SN boundary)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Candidate-mediated strong-normalization evidence over* S, N, U, H, C, P, L *and the L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

cannot be consumed as a closed subject-reduction row unless K *separately displays a subject-reduction coordinate. The candidate-mediated evidence may feed the frontier and the confluence-decidability handoff, but it does not identify reduction preservation for arbitrary closed terms, fill the discharge socket* D*, or erase the obstruction row* O*.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNBoundary`

Proof. First apply the candidate-mediated SN frontier, Definition 765.198. It places the evidence on the finite rows S, N, U, H, C, P, L together with the four L10 faces before any handoff consumer reads U.

Next use the subject-reduction boundary of Definition 765.231. This theorem states the exact missing coordinate: closed subject reduction is available only when the packet displays a separate subject-reduction row.

The discharge side is controlled by Definition 765.226. Induction over the displayed replay rows preserves the socket as a socket, so the candidate-mediated evidence cannot become a subject-reduction row by finite consumption.

Finally invoke candidate-normalization socket exhaustion, Definition 765.230. The exhausted surface is the candidate-normalization route plus the four L10 faces, with no additional coordinate for closed subject reduction. Hence any consumer that claims such a row must cite it separately, and the candidate-mediated boundary remains distinct from closed subject reduction. □

Theorem 765.233 (MetaCIC candidate-mediated SN closed-normal-form readback)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any closed-normal-form readback that consumes candidate-mediated strong-normalization evidence factors through the finite rows* S, N, U, H, C, P, L *and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The obstruction row O *and the discharge socket* D *remain visible to the readback unless the packet separately displays a subject-reduction row. Thus closed-normal-form readback from candidate-mediated SN is a finite frontier read, not a proof of closed subject reduction, global confluence, or beta-conversion decidability.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNClosedNormalFormReadba`

Proof. Start with the candidate-mediated SN frontier, Definition 765.198. It confines candidate-mediated normalization evidence to the displayed finite rows and the four L10 faces before any readback consumer may inspect the handoff row U.

Use the handshake theorem, Definition 765.223. The readback may feed confluence-facing or decidability-facing replay through S, N, U, H, C, P, L, but that handoff does not add a subject-reduction row.

Apply discharge-socket induction, Definition 765.226. Finite replay preserves the socket boundary while the closed-normal-form consumer moves through the displayed route.

Finally use socket exhaustion and the candidate SN boundary, Definition 765.230 and Definition 765.232. Together they leave exactly O and D as visible boundaries unless an explicit subject-reduction row is displayed, so the readback cannot be upgraded to closed subject reduction, global confluence, or beta-decidability. □

Theorem 765.234 (MetaCIC candidate-mediated SN frontier discharge coverage)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every finite consumer replay through rows* S, N, U, H, C, P, L *and the L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

either preserves the displayed discharge socket D *or cites an explicit subject-reduction row outside the candidate-mediated frontier. Candidate-mediated strong normalization, confluence-facing replay, decidability-facing replay, and L10 readback do not by themselves discharge* D*.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNFrontierDischargeCover`

Proof. Start with the candidate-mediated SN frontier theorem, Definition 765.198. It places the replay on S, N, U, D, H, C, P, L together with the four L10 faces and keeps the obstruction and discharge rows visible.

Apply the discharge-row theorem and discharge-socket induction, Definition 765.225 and Definition 765.226. These results preserve the socket while each finite consumer row is replayed.

Use the candidate-normalization budget and socket-exhaustion theorems, Definition 765.227 and Definition 765.230. They show that the consumer surface is exhausted by S, N, U, H, C, P, L and the four L10 faces, with no hidden subject-reduction coordinate.

Finally invoke the subject-reduction boundary, Definition 765.231. It is exactly the alternative in the statement: either the replay keeps D displayed, or a separate subject-reduction row outside the candidate-mediated frontier must be cited. □

Theorem 765.235 (MetaCIC typed-reduction candidate SN handoff)**.** *An accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer may pass typed-reduction candidate strong-normalization evidence toward confluence or decidability only after displaying the candidate row S, the normal-form endpoint row N, the subject-reduction discharge socket D, the handoff row U, the bounded checker budget carried by the factorization route, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The handoff remains conditional: it exports no closed subject reduction, global confluence, beta-conversion decision, quotient term equality, selected limit, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathTypedReductionCandidateSNHandoff`

Proof. Start with Definition 765.234. Any finite consumer replay through the candidate-mediated frontier either preserves the discharge socket D or cites a separate subject-reduction row outside the frontier.

Apply Definition 765.263. The bounded checker budget separates the candidate row, SN endpoint rows, open socket row, and four L10 face row before the checker budget can be read.

Finally use Definition 765.260 together with Definition 765.240. These keep the checker-facing and discharge-facing budgets conditional on the open socket row, so the refused global MetaCIC, quotient, selected-limit, host-equality, and Real-completeness claims remain outside the handoff. □

Definition 765.236 (MetaCIC frontier budget factorization)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

the candidate-frontier budget factorization is the displayed packet

$$\mathcal{F}(K) = (S, N, U, D, H, C, P, L; \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow})$$

read in five layers: the candidate-normalization budget rows S, N, the confluence handoff row U, the subject-reduction discharge socket D, the L10 entry budget $\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$*, and the closed-normal readback rows H, C, P, L. A consumer is factorized through $\mathcal{F}(K)$ exactly when its frontier read exposes those five layers before it exports any strong-normalization, confluence-facing, decidability-facing, Phase Real, or Completion-facing conclusion.*

Lean4 (definition) `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierBudgetFactorization`

Theorem 765.237 (MetaCIC candidate frontier L10 budget lock)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every candidate-mediated strong-normalization discharge that reaches an L10 readback must pass through the factorization packet* $\mathcal{F}(K)$ *of Definition 765.236. In particular, the route first exposes the candidate-normalization rows* S, N*, the confluence handoff row* U*, and the discharge socket* D*; then it reads* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *as the L10 entry budget; only then may it consume* H, C, P, L *as closed-normal readback rows.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierL10BudgetLock`

Proof. Start with discharge coverage, Definition 765.234. It says that any finite consumer replay through the candidate-mediated frontier either preserves the socket D or cites a separate subject-reduction row outside the frontier.

Next apply the candidate-normalization budget theorem, Definition 765.227. It identifies the candidate-facing surface as the rows S, N, U, H, C, P, L together with the four L10 faces, while keeping the obstruction row and discharge socket visible.

Use the closed-normal-form readback and L10 readback theorems, Definition 765.233 and Definition 765.241. These force every readback that reaches Phase Real or Completion data to expose $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the exported rows are consumed.

The five layers listed in Definition 765.236 are exactly the rows preserved by those three results. Hence any L10-reaching discharge has already passed through $\mathcal{F}(K)$, and no alternate route can bypass the displayed candidate, handoff, discharge, L10, or readback layers. □

Theorem 765.238 (MetaCIC normalization budget nonescape)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. No route from the candidate-mediated frontier exports strong normalization, confluence, beta-conversion decidability, or Real-completion entry unless it displays the candidate rows* S, N*, the handoff row* U*, the discharge socket* D*, the L10 entry budget* $\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$*, and the closed-normal readback rows* H, C, P, L *as the factorization packet* $\mathcal{F}(K)$*. The route exports no closed subject reduction, quotient term equality, host equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency beyond that packet.*

Proof. First read the candidate frontier L10 budget lock, Definition 765.237. Any discharge that reaches L10 readback is already forced through the displayed factorization packet.

Next use socket exhaustion and subject-reduction boundary, Definition 765.230 and Definition 765.231. These keep D visible unless a separate subject-reduction row is cited, so the candidate budget cannot become closed subject reduction by replay alone.

Apply the candidate-mediated SN route and normal-form discharge theorems, Definition 765.239 and Definition 765.242. They confine strong-normalization, confluence-facing, decidability-facing, and normal-form exports to the finite rows in $\mathcal{F}(K)$.

Since quotient term equality, host equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, and kernel consistency are not coordinates of $\mathcal{F}(K)$, no route that only reads the candidate-mediated frontier can export them. Real-completion entry is therefore a budgeted L10 readback, not a global metatheoretic escape. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNormalizationBudgetNonescape`

Theorem 765.239 (MetaCIC candidate-mediated SN route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated strong-normalization evidence consumed by confluence-facing or decidability-facing replay is routed through* S, N, U, H, C, P, L*, the visible obstruction row* O*, the discharge socket* D*, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

A separate subject-reduction row is required before D *can be filled. Candidate-mediated normalization evidence alone cannot assert global confluence, closed subject reduction, or beta-conversion decidability.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNRoute`

Proof. Begin with the candidate-mediated SN frontier, Definition 765.198. It places normalization evidence on the finite route through S, N, U, H, C, P, L while keeping O and D visible to any consumer.

Apply the candidate-normalization budget, Definition 765.227. The budget available to confluence-facing and decidability-facing replay is exhausted by the displayed SN route and the four L10 faces.

Next use socket exhaustion, Definition 765.230. Since exhaustion still leaves D as a socket rather than a filled row, the replay cannot close subject reduction by consuming candidate-mediated SN evidence alone.

Finally invoke discharge coverage, Definition 765.234. Every admissible consumer either preserves D or cites a separate subject-reduction row. Therefore the route exports only the finite candidate-mediated handoff and refuses global confluence, closed subject reduction, and beta-decidability claims. □

Theorem 765.240 (MetaCIC candidate-mediated SN discharge budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every candidate-mediated strong-normalization consumer that is allowed to pass a consistency-facing handoff must first display the normalization candidate row* S*, the confluence boundary carried by the handoff row* U*, the decidability boundary carried by the replay row* C*, the discharge socket* D*, the obstruction row* O*, componentwise transport* H*, replay* C*, provenance* P*, and the local* NameCert *row* L*. The consumer may then read the handoff only as the displayed finite discharge budget; it does not export full subject reduction, full confluence, global beta-conversion decidability, quotient term equality, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNDischargeBudget`

Proof. Begin with the candidate-mediated SN frontier, Definition 765.198. It forces every SN read that reaches the handoff row to expose the finite packet rows and the four L10 faces before a confluence-facing or decidability-facing consumer can inspect U.

Next apply the socket-separation and discharge-row theorems, Definition 765.199 and Definition 765.225. These keep O and D visible while the normalization candidate and handoff rows are consumed.

Use discharge-socket induction and discharge coverage, Definition 765.226 and Definition 765.234. They show that any finite consumer replay either preserves the socket or cites a separate subject-reduction row outside the candidate-mediated frontier.

Finally read the candidate SN route of Definition 765.239. The route exports only the displayed budget rows $S, N, O, U, D, H, C, P, L$ and therefore cannot supply the excluded global MetaCIC or quotient-equality claims. □

Theorem 765.241 (MetaCIC candidate-mediated SN L10 readback)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any L10-facing read of the candidate-mediated SN frontier routes through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and the subject-reduction discharge socket D before it exports a Phase Real row or a Completion budget row. The exported rows are the finite readback surface of the same packet; they are not full subject reduction, full confluence, global beta-conversion decidability, quotient term equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNL10Readback`

Proof. Start from the existing L10 readback theorem, Definition 765.200. It requires $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to be exposed before the handoff row U is consumed.

Apply the closed-normal-form readback theorem and candidate-normalization budget, Definition 765.233 and Definition 765.227. These identify the Phase Real and Completion-facing budget as the finite surface S, N, U, H, C, P, L together with the four L10 faces.

Next use the subject-reduction boundary, Definition 765.231. It keeps the discharge socket D visible unless a separate subject-reduction row is displayed.

Finally combine socket exhaustion with Definition 765.240. Once the L10 route and candidate-mediated rows have been read, the packet has no remaining coordinate for full subject reduction, global confluence, beta-conversion decidability, quotient term equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or kernel consistency. Thus the Phase Real and Completion rows are budget rows, not global metatheoretic exports. □

Theorem 765.242 (MetaCIC candidate-mediated normal-form discharge)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A candidate-mediated strong-normalization consumer can export a normal-form discharge only after displaying the normalization candidate row S, the closed normal-form readback row N, the subject-reduction discharge socket D, the confluence boundary carried by U, the decidability boundary carried by C, the L10 rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow},$$

componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}$ *row L. The exported discharge is exactly this finite normal-form boundary; it is not full subject reduction, full confluence, global beta-conversion decidability, quotient term equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedFrontierNormalFormDischa`

Proof. First read the candidate-mediated SN frontier and the discharge budget, Definition 765.198 and Definition 765.240. These force the normalization candidate, handoff boundary, decidability replay, socket, obstruction, transport, replay, provenance, and local naming rows to be visible before a consistency-facing consumer can inspect the handoff.

Next apply the closed-normal-form readback and L10 readback theorems, Definition 765.233 and Definition 765.241. They attach the normal-form endpoint to S, N, U, H, C, P, L and require the four rows $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any Phase Real or Completion budget is exported.

Finally use socket separation and discharge coverage, Definition 765.199 and Definition 765.234. These keep the subject-reduction socket visible unless a separate subject-reduction row is cited, so the consumer may export only the finite normal-form discharge surface stated above. The excluded global MetaCIC and quotient-equality claims are not coordinates of that surface. □

Theorem 765.243 (MetaCIC subject-reduction socket before normal-form discharge consumers)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated strong-normalization handoff that reaches the normal-form discharge surface of Definition 765.242 must still expose the subject-reduction socket row D as a separate row before a closed subject-reduction consumer may proceed. The handoff may use the candidate row S, the closed normal-form readback row N, the handoff row U, componentwise* hsame *transport H, displayed* Cont *replay C, provenance P, local naming L, and the L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *but it cannot treat that surface as global confluence, beta-decidability, quotient term equality, selected limits, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a closed subject-reduction row.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedFrontierSubjectReduction`

Proof. Start from the candidate-mediated frontier and the candidate SN boundary, Definition 765.198 and Definition 765.232. They place the SN handoff on the displayed rows S, N, U, H, C, P, L together with the four L10 faces while keeping O and D visible.

Next apply closed-normal-form readback and normal-form discharge, Definition 765.233 and Definition 765.242. These results allow the consumer to reach the finite normal-form discharge surface, but that surface still lists D as a subject-reduction socket rather than as a discharged row.

Finally use socket exhaustion, Definition 765.230, together with socket separation in Definition 765.199. Once the candidate-mediated rows and L10 faces have been consumed, no hidden coordinate remains for closed subject reduction. A closed subject-reduction consumer must therefore cite a separate subject-reduction row before proceeding, and the refused confluence, beta-decidability, quotient-equality, selected-limit, host-equality, and Real-completeness claims remain outside the packet. □

Theorem 765.244 (MetaCIC subject-reduction socket readiness)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A subject-reduction consumer may inspect the normal-form discharge only after the candidate row S, normal-form row N, handoff row U, subject-reduction socket D, and the L10 rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

are all visible. Candidate-mediated strong normalization by itself is readiness data for the socket; it is not a closed subject-reduction proof, not full confluence, not beta-conversion decidability, not quotient term equality, and not ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the subject-reduction socket theorem Definition 765.243. It keeps D separate from S, N, U, H, C, P, L and requires a closed subject-reduction consumer to cite a separate row before proceeding.

Next read the normal-form discharge theorem Definition 765.242. Its discharge surface lists the candidate row, the normal-form endpoint, the handoff row, the socket, the structural rows, and the four L10 faces as the finite boundary visible to the consumer.

Apply the L10 readback theorem Definition 765.241 and the dependency seal Definition 765.245. These force $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to be displayed before Phase Real, Completion, or confluence-facing inspection of the normal-form boundary.

Finally use socket exhaustion and discharge coverage, Definition 765.230 and Definition 765.234. They leave no hidden coordinate that can turn candidate-mediated SN into closed subject reduction, so the visible rows are readiness data only. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSubjectReductionSocketReadiness`

Theorem 765.245 (MetaCIC candidate SN L10 dependency seal)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every candidate-mediated strong-normalization packet whose discharge reads Real-facing evidence must route through the displayed dependency rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

before any MetaCIC confluence consumer can inspect the normal-form boundary. The inspection exports only the candidate-mediated frontier and its finite L10 seal; it does not export full subject reduction, full confluence, global beta-conversion decidability, quotient term equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNL10DependencySeal`

Proof. Start from the candidate-mediated frontier definition and Definition 765.242. They identify the normal-form discharge boundary as the finite rows S, N, U, D, H, C, P, L together with the four L10 dependency rows.

Apply the L10 readback theorem Definition 765.241. It requires $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to be displayed before a Phase Real or Completion-facing row can be exported.

Next use the RegSeqRat handoff theorem Definition 765.203. The regular rational route is the unique readback path available to the candidate-mediated handoff, so no alternate Real-facing route can bypass the four-object seal.

Finally apply the confluence-decidability consumer boundary, Definition 765.224. A confluence consumer may inspect only the displayed frontier after the L10 route has been exposed; the excluded global MetaCIC, quotient, completeness, and consistency claims are not packet coordinates. □

Theorem 765.246 (MetaCIC candidate-mediated frontier subject-reduction row absence)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. The candidate-mediated strong-normalization frontier may expose the candidate row* S*, closed normal-form row* N*, handoff row* U*, componentwise transport row* H*, continuation row* C*, provenance row* P*, local naming row* L*, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The obstruction row O *and discharge socket* D *remain visible throughout that route, but no closed subject-reduction row is present until a separate SubjectReduction discharge packet is cited.*

Proof. Start from the candidate-mediated SN route and the frontier normal-form discharge, Definition 765.239 and Definition 765.242. They identify the exposed frontier rows as S, N, U, H, C, P, L together with the four L10 faces, while still listing the socket data of K.

Next apply socket separation and socket exhaustion, Definition 765.199 and Definition 765.230. These keep O and D visible as obstruction and discharge-socket rows rather than as discharged subject-reduction evidence.

Use the subject-reduction socket theorem and readiness theorem, Definition 765.243 and Definition 765.244. They permit a subject-reduction consumer to inspect the normal-form discharge only as readiness data unless a separate subject-reduction row is cited.

Therefore the candidate-mediated frontier has no coordinate from which to read closed subject reduction. A later SubjectReduction discharge packet may fill the socket, but the frontier itself exports only the listed rows, the visible obstruction, and the visible socket. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedFrontierSubjectReductio`

Theorem 765.247 (MetaCIC confluence residual frontier route)**.** *Every confluence residual frontier read of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet consumes the same candidate-mediated strong-normalization row and the same L10 route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Consequently residual substitution and critical-pair reads cannot bypass the finite four-object seal before reading the normal-form boundary or the confluence-decidability handoff.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceResidualFrontierRoute`

Proof. Read the candidate-mediated SN frontier theorem together with Definition 765.242. Both place the candidate row, normal-form endpoint, discharge socket, handoff boundary, and four L10 rows on the same finite frontier.

Use Definition 765.241 and Definition 765.203. These force any Real-facing or Completion-facing residual read to pass through the displayed dyadic, stream, regular-rational, and Real rows.

Finally apply the confluence-decidability consumer boundary, Definition 765.224. Residual substitution and critical-pair consumers can read the handoff only after the candidate SN frontier and L10 route are present, so no residual route escapes to full confluence, closed subject reduction, beta-decidability, quotient equality, selected limits, or ambient Real completeness. □

Theorem 765.248 (MetaCIC candidate frontier residual split route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated strong-normalization discharge that reaches a confluence residual consumer must factor through the residual-substitution boundary, the candidate join row, the closed-term substitution boundary carried by the normal-form readback row, and the L10 source locks*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The route may expose S, N, U, D, H, C, P, L *as the finite discharge surface, but it cannot bypass the residual boundary, erase the subject-reduction socket, or export full confluence, closed subject reduction, beta-decidability, quotient term equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierSplitRoute`

Proof. Start with the candidate-mediated SN frontier and normal-form discharge theorems, Definition 765.198 and Definition 765.242. They expose the candidate row, normal-form readback row, handoff row, socket row, structural rows, and L10 faces before any discharge consumer can proceed.

Next read the confluence residual frontier route above. It forces residual substitution and critical-pair consumers to consume the same candidate-mediated strong-normalization row and the same four L10 source locks before the handoff can be inspected.

Now apply subject-reduction socket readiness and the candidate SN L10 dependency seal, Definition 765.244 and Definition 765.245. These keep D visible as a socket and keep $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ locked before the residual consumer reads the frontier.

Finally use the closed-term substitution and RegSeqRat handoff boundaries already cited in the frontier, Definition 765.203 and Definition 765.224. They leave the discharge as constructor and route inspection over the displayed rows, not as source-equivalence transport or a global confluence proof. □

Theorem 765.249 (MetaCIC SN discharge frontier)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A candidate-mediated strong-normalization route may hand a normal-form consumer to the discharge frontier only while the subject-reduction socket* D *and obstruction row* O *remain visible. The confluence residual route, decidability handoff, and L10 readback rows may transport* S, N, U, H, C, P, L*, but they do not close subject reduction, fill* D*, erase* O*, or export global confluence, beta-conversion decidability, quotient term equality, host equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Proof. Start from the candidate SN boundary and the normal-form discharge theorem, Definition 765.232 and Definition 765.242. They place the normal-form consumer on the finite rows S, N, U, D, H, C, P, L together with the L10 faces.

Next use subject-reduction socket readiness, Definition 765.244. It permits inspection of the normal-form discharge only after D is displayed as a socket, not as a closed subject-reduction proof.

Finally apply the confluence residual frontier route, Definition 765.247. Confluence, decidability, and L10 readback keep the same finite frontier visible, so they cannot discharge D or erase O without a separate closed subject-reduction row. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSNDischargeFrontier`

Theorem 765.250 (MetaCIC candidate-mediated SN frontier extension)**.** *Any candidate-mediated strong-normalization discharge used by the current L10 Real and Completion route must expose the candidate evidence row S, the closed-term substitution boundary carried by the normal-form readback row N, the finite observation confluence row U, the subject-reduction discharge socket D, and the four open-phase source rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

before it is read as Real or Completion readiness. The exposed surface is conditional frontier evidence only; it is not unconditional strong normalization, not full confluence, not closed subject reduction, not beta-conversion decidability, not quotient term equality, and not ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the candidate-mediated SN frontier and normal-form discharge theorems, Definition 765.198 and Definition 765.242. They put the candidate row, normal-form readback, handoff row, socket, transport, replay, provenance, local name, and L10 faces on the same finite boundary.

Next apply subject-reduction socket readiness and the candidate SN L10 dependency seal, Definition 765.244 and Definition 765.245. These force D and the four open-phase source rows to remain visible before any Real, Completion, or confluence-facing read proceeds.

Finally use the confluence residual frontier route, Definition 765.247. Residual and finite-observation reads cannot bypass the same four-object seal, so the discharge remains a conditional readiness surface rather than a global SN, confluence, subject-reduction, beta-decidability, quotient-equality, or Real-completeness claim. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNFrontierExtension`

Theorem 765.251 (MetaCIC candidate-mediated SN residual boundary)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. If the closed-term candidate row S, the residual-substitution ledger, and the finite-observation confluence ledger agree on the same displayed* BHist *rows, then the candidate-mediated route preserves the strong-normalization frontier budget through N, U, D, H, C, P, L. The preserved budget may be consumed by the sibling routes of chapter 527, chapter 2181, chapter 2274, and chapter 2223, but it does not export closed subject reduction, full confluence, beta-conversion decidability, quotient term equality, host equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNResidualBoundary`

Proof. Start with the candidate-mediated SN frontier and residual frontier route, Definition 765.198 and Definition 765.247. They place the candidate row, normal-form endpoint, handoff row, socket row, structural rows, and four L10 faces on the same finite frontier before residual or confluence consumers inspect the handoff.

Next read the residual split route and SN discharge frontier, Definition 765.248 and Definition 765.249. The residual-substitution ledger and finite-observation confluence ledger can be consumed only while the same BHist rows, obstruction row O, and discharge socket D remain visible.

Finally apply the candidate-mediated frontier extension. Since the closed-term substitution boundary, residual-substitution boundary, candidate SN confluence boundary, and finite-observation confluence rows are all read as sibling budget rows over the same packet, the SN frontier budget is preserved through the candidate-mediated route and none of the excluded global MetaCIC claims is exported. □

Theorem 765.252 (MetaCIC candidate-mediated normalization budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, candidate-mediated strong-normalization evidence, confluence handoff data, and normalization-certificate routing expose a finite normalization budget before any critical-path discharge is exported. The budget is the displayed route through* $S, N, O, U, D, H, C, P, L$*, the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$*, the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *and* $\mathsf{MetaCICNormalizationCertificateRouter}^{\uparrow}$ *rows, the confluence boundary, and the visible discharge socket. It does not claim full MetaCIC normalization, global confluence, closed subject reduction, beta-conversion decidability, quotient term equality, selected normal forms, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the candidate-mediated SN frontier, Definition 765.198. It forces the normalization read through the packet rows and the four L10 faces before any handoff row is consumed.

Use the normalization-frontier dependency exposure of Definition 765.291. The $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ and $\mathsf{MetaCICNormalizationCertificateRouter}^{\uparrow}$ rows route the normal-form endpoint as finite certificate data rather than as a global normalization theorem.

Apply the confluence socket boundary, Definition 765.220. It keeps confluence-facing reads on the same finite frontier and leaves the obstruction and discharge socket visible.

Finally read discharge coverage, Definition 765.234. The discharge surface is available only as the displayed socket budget, so a critical-path consumer receives finite normalization readiness and none of the excluded global MetaCIC claims. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedNormalizationBudget`

Theorem 765.253 (MetaCIC candidate-mediated SN handoff)**.** *Let* $K = (S, N, O, U, D, H, C, P, L)$ *be an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. If the packet displays a reducibility-candidate row* R*, a candidate-closedness row* Q*, and a beta-step replay row* B *over the same closed typed term data, then any critical-path consumer may export only the candidate-implies-SN handoff and the beta-closedness handoff. The export is the finite route*

$$R, Q, B \longmapsto S, N, U, H, C, P, L.$$

It is not a global strong-normalization theorem, not a confluence theorem, not beta-conversion decidability, not closed subject reduction, not quotient term equality, and not a filled discharge socket.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNHandoff`

Proof. Project the accepted packet first. The rows $S, N, O, U, D, H, C, P, L$ keep strong-normalization evidence, normal endpoints, obstruction data, the handoff row, the discharge socket, transport, replay, provenance, and local naming visible before any critical-path consumer reads the handoff.

Use the reducibility row R only through the candidate-implies-SN dependency represented by `BEDC.MetaCIC.Normalization.Reducibility.candidate_implies_sn`. This produces the displayed SN handoff into S, N, U for the same term and type data; it does not assert unrestricted normalization outside the candidate row.

Use the closedness and beta-step rows Q, B only through the beta-closedness dependency represented by `BEDC.MetaCIC.Normalization.Reducibility.candidate_closed_under_beta`. This replays the candidate row across the displayed beta step and returns to the same finite handoff surface.

Finally apply the existing candidate-mediated frontier and conditional-budget boundaries, Definition 765.198 and Definition 765.260. They keep O and D visible while the handoff is consumed, so the route exports only the candidate-implies-SN and beta-closedness handoffs and none of the refused global MetaCIC claims. □

Theorem 765.254 (MetaCIC candidate SN handoff source exhaustion)**.** *Let $K = (S, N, O, U, D, H, C, P, L)$ be an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any accepted candidate-mediated strong-normalization handoff through the candidate row must exhaust exactly the source route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ O,\ D,\ H,\ C,\ P,\ L$$

before a confluence-facing or decidability-facing consumer may read the handoff row U. The route exports no closed subject reduction, global confluence, beta-conversion decidability, quotient term equality, selected limit, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNHandoffSourceExhaustion`

Proof. Begin with the candidate-mediated frontier theorem, Definition 765.198. It places the candidate-mediated read on the packet rows $S, N, O, U, D, H, C, P, L$ and requires the L10 source faces before the handoff row is consumed.

Read the source locks next. The L10 readback and Real source-lock theorems, Definition 765.200 and Definition 765.201, keep $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ visible as four displayed source rows.

Now use the RegSeqRat and dependency boundaries, Definition 765.203 and Definition 765.245. These fix the regular-rational handoff inside the same four-source route and prevent a consumer from reconstructing Real-facing evidence after reading U.

Finally apply the consumer boundary, Definition 765.224. Confluence-facing and decidability-facing consumers may inspect only the displayed frontier after the source, obstruction, socket, transport, replay, provenance, and local naming rows are present, so none of the refused global metatheoretic or completion claims is exported. □

Theorem 765.255 (MetaCIC candidate-mediated SN frontier exhaustion)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every candidate-mediated strong-normalization frontier read that may be consumed by the public* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *route must factor through the existing candidate-mediated frontier, residual-budget discharge surface, confluence-decidability handoff, and decidability budget rows before it is exported. Concretely, the read displays $S, N, O, U, D, H, C, P, L$, the residual-budget and socket rows of Definition 765.288, the handoff route of Definition 765.196, and the decidability budget of Definition 765.192; it cannot export full normalization, full confluence, global beta-conversion decidability, closed subject reduction, quotient term equality, host equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNFrontierExhaustion`

Proof. Start from the candidate-mediated SN frontier Definition 765.198. It places the strong-normalization read on the finite packet rows S, N, U, D, H, C, P, L together with the surrounding obstruction row O and the four L10 source faces.

Next attach the residual-budget discharge surface. The residual frontier and socket route, Definition 765.288 and Definition 765.289, require the residual-budget, substitution-boundary, closed-premise, local-diamond, socket, normalization, and audit-ledger rows before the discharge-facing consumer may proceed.

Now pass through the confluence and decidability side. The handoff theorem Definition 765.196 and the confluence-decidability budget Definition 765.192 keep every confluence-facing or decidability-facing read downstream of the same finite packet route and open L10 source ledger.

The public route receives only this assembled finite boundary: the candidate-mediated frontier, residual-budget discharge surface, handoff rows, decidability budget, componentwise hsame transport, displayed Cont replay, provenance, and local NameCert data. Since none of the cited rows supplies a coordinate for full normalization, full confluence, global beta-conversion decidability, closed subject reduction, quotient equality, host equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or kernel consistency, no such claim can be exported by the frontier read. □

Theorem 765.256 (MetaCIC candidate-mediated SN frontier public scope)**.** *Let $K = (S, N, O, U, D, H, C, P, L)$ be an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. The candidate-mediated strong-normalization frontier exhaustion of Definition 765.255 is public only when the same packet displays the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *source rows together with the candidate-mediated frontier, residual-budget socket, confluence-decidability handoff, and decidability budget rows.*

Under that scope, the public read is the finite L10 source route plus the displayed MetaCIC boundary rows. It does not export full normalization, full confluence, beta-conversion decidability, host consistency, selected limits, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNFrontierExhaustionScop`

Proof. Apply Definition 765.255. It already confines the candidate-mediated strong-normalization frontier to the displayed packet rows and to the residual-budget, handoff, and decidability-budget surfaces.

Now attach the public interface route. The $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source rows are the L10 four-object rows through which the public read may enter the MetaCIC packet. The residual-budget socket and public handoff rows keep that read in the same finite carrier rather than in an ambient normalization theorem.

Exhaust the displayed rows. The candidate-mediated frontier supplies only the frontier boundary, the residual-budget socket supplies only the budgeted discharge route, and the confluence-decidability handoff with its decidability budget supplies only the named finite decision surface.

Therefore the public export is scoped to the four L10 source rows and the displayed MetaCIC boundary rows. Full normalization, full confluence, beta-conversion decidability, host consistency, selected limits, quotient stream equality, and ambient Real completeness remain outside the packet. □

Theorem 765.257 (MetaCIC candidate-mediated SN obligation surface)**.** *Every confluence-facing or decidability-facing consumer that uses candidate-mediated strong-normalization evidence from an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must first display the strong-normalization row S, the normal-form endpoint N, the handoff row U, the discharge socket D, the componentwise transport*

row H, the displayed continuation row C, the provenance row P, the local name L, and the four L10 faces

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

before it reads any confluence or decidability budget. The consumer may inspect only this candidate-mediated surface and the existing handoff budget; it receives no global confluence theorem, no beta-conversion decision procedure, no filled discharge socket, no quotient term equality, no host real equality, no selected limit, and no $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with the candidate-mediated SN frontier, Definition 765.198. It confines the strong-normalization-facing read to the displayed frontier rows and requires the four L10 faces before any confluence-facing or decidability-facing consumer reads the handoff row.

Next apply the confluence-decidability budget, Definition 765.192. That budget keeps every confluence or decidability read downstream of the open-source ledger and the finite packet route, so the consumer cannot read U as an independent global theorem.

Finally use the consumer boundary, Definition 765.224. It allows closed-normal-form membership to pass through the handoff route while excluding closed subject reduction, full consistency, arbitrary Church–Rosser, global beta-conversion decidability, discharged sockets, quotient equality, host equality, selected limits, and $\mathsf{Real}^{\uparrow}$ completeness. Therefore the listed rows form the whole obligation surface available before any confluence or decidability budget is consumed. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICConfluenceCandidateMediatedSNObligationSurface`

Theorem 765.258 (MetaCIC candidate-discharge schedule exhaustion)**.** *Any accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer that attempts to discharge a candidate-mediated strong-normalization or confluence socket must expose the candidate row K, the strong-normalization row S, the normal-form endpoint N, the confluence-decidability handoff row U, the discharge socket D, the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},$$

componentwise transport H, displayed replay C, provenance P, and the local-name row L before it reads a confluence or decidability budget. The discharge schedule exports no closed subject-reduction theorem, arbitrary Church–Rosser theorem, global beta-conversion decision procedure, filled discharge socket, quotient term equality, selected limit, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with the candidate-mediated obligation surface, Definition 765.257. It already forces S, N, U, D, H, C, P, L and the four L10 faces to be displayed before any confluence-facing or decidability-facing budget can be read.

Now add the candidate row K as the schedule witness being consumed. The candidate-mediated frontier and source-ledger route keep this row attached to the same accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet rather than letting it appear as a detached normalization theorem.

Finally apply the confluence-decidability budget Definition 765.192 and the consumer boundary Definition 765.224. Those results allow the downstream budget read only after the displayed packet route is present and exclude closed subject reduction, full consistency, arbitrary Church–Rosser, global beta-conversion decidability, discharged sockets, quotient equality, host equality, selected limits, and $\mathsf{Real}^{\uparrow}$ completeness. Thus the listed rows exhaust the candidate-discharge schedule before any confluence or decidability budget is consumed. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateDischargeScheduleExhaustion`

Theorem 765.259 (MetaCIC candidate-mediated SN discharge)**.** *Any accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer that routes candidate-mediated strong-normalization evidence into a confluence-facing or decidability-facing budget must keep the discharge socket D explicitly displayed and unfilled throughout the read. The allowed route is the finite surface consisting of the candidate row, the strong-normalization row S, the normal-form endpoint N, the handoff row U, componentwise transport H, displayed replay C, provenance P, local naming L, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The route may feed the displayed confluence/decidability budget only as a conditional socket surface; it exports no closed subject-reduction row, no filled discharge socket, no global confluence theorem, no beta-conversion decision procedure, no quotient term equality, no selected limit, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNDischarge`

Proof. First apply the candidate-mediated obligation surface, Definition 765.257. It makes S, N, U, D, H, C, P, L and the four L10 faces visible before any downstream budget can be inspected, so the socket row D is part of the source surface rather than an inferred conclusion.

Next use the candidate-discharge schedule exhaustion theorem, Definition 765.258. This adds the candidate row and shows that every confluence-facing or decidability-facing read must consume the displayed schedule before touching the budget rows.

Finally apply the frontier discharge row, Definition 765.225. That theorem keeps D separate from the candidate-mediated SN evidence while the finite frontier is replayed. Since no row in the displayed route is a closed subject-reduction coordinate, the consumer receives only the conditional discharge surface and none of the excluded global MetaCIC, quotient, selected-limit, or completeness claims. □

Theorem 765.260 (MetaCIC candidate-mediated SN conditional budget)**.** *Any accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer may pass candidate-mediated strong-normalization evidence to a confluence-facing or decidability-facing budget only when the candidate row K, strong-normalization row S, normal-form endpoint N, handoff row U, unfilled discharge socket D, componentwise transport H, displayed replay C, provenance P, local name L, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

are all displayed. The conclusion remains conditional on the socket row D and exports no closed subject-reduction theorem, no global Church–Rosser theorem, no beta-conversion decision procedure, no quotient term equality, no selected limit, and no $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First use the obligation surface of Definition 765.257. It exposes the strong-normalization row, normal-form endpoint, handoff row, discharge socket, transport, replay, provenance, local name, and the four L10 faces before any downstream budget can be read.

Next apply the schedule exhaustion theorem, Definition 765.258. It adds the candidate row K and shows that every candidate-mediated route must display the same finite schedule before touching confluence-facing or decidability-facing data.

Finally apply the discharge theorem, Definition 765.259. It keeps the socket unfilled while the route is replayed, so the consumer receives only a conditional budget and none of the excluded closed MetaCIC, quotient, selected-limit, or Real-completeness claims. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNConditionalBudget`

Theorem 765.261 (MetaCIC four-face bounded checker gate)**.** *Any bounded checker consumer that uses candidate-mediated strong-normalization evidence from an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must display the candidate row K, strong-normalization row S, normal endpoint row N, handoff row U, open discharge socket D, componentwise transport H, displayed replay C, provenance P, local naming L, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

before it reads the checker budget. The gate exports no closed subject-reduction theorem, global confluence theorem, beta-conversion decision procedure, quotient term equality, selected limit, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFourFaceBoundedCheckerGate`

Proof. Begin with Definition 765.257. It places the strong-normalization row, normal endpoint, handoff row, discharge socket, transport, replay, provenance, local name, and four L10 faces before any confluence-facing or decidability-facing budget.

Apply Definition 765.266. The candidate row K, the S, N endpoint row, the open socket D, and the L10 face row remain separate premises rather than a single closed normalization theorem.

Use Definition 765.260. The checker budget may be read only after the displayed schedule is present, and the conclusion remains conditional on the socket row.

Finally apply Definition 765.298. The bounded-normalization candidate ledger supplies checker provenance for the same candidate-mediated route, while the accepted packet still has no coordinate for subject reduction, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or Real completeness. □

Theorem 765.262 (MetaCIC bounded checker frontier separation)**.** *Any bounded checker read that consumes candidate-mediated strong-normalization evidence from an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must keep the candidate row K, strong-normalization endpoint rows S, N, open discharge socket D, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

as separate displayed premises before the checker budget is read. The checker may pass those premises through the displayed handoff, transport, replay, provenance, and local naming rows, but it may not collapse them into subject reduction, global confluence, beta-conversion decidability, quotient equality, selected limit, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the obligation surface of Definition 765.257. It displays the SN endpoint, discharge socket, handoff, transport, replay, provenance, local name, and four L10 faces before any checker-facing budget can be consumed.

Apply Definition 765.258. The candidate row K is part of the finite schedule, so it must remain visible before the bounded checker reads its budget.

Use Definition 765.260 and Definition 765.261. These keep the route conditional on D and require the four L10 faces to be displayed as the checker boundary.

Finally apply Definition 765.266. The candidate row, endpoint row, socket row, and L10 face row remain separate premises, so none can be repacked as closed subject reduction, global confluence, beta-conversion decidability, quotient equality, a selected limit, or Real completeness. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBoundedCheckerFrontierSeparation`

Theorem 765.263 (MetaCIC bounded checker budget factorization)**.** *Any bounded checker budget read that consumes candidate-mediated strong-normalization evidence from an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet factors through four separate displayed premise rows:*

1. *the candidate row K;*
2. *the strong-normalization endpoint row S, N;*
3. *the open discharge socket row D;*
4. *the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Only after these rows are displayed may the checker read the handoff, transport, replay, provenance, local naming, and bounded budget rows. The factorization exports no closed subject-reduction theorem, global confluence theorem, beta-conversion decision procedure, quotient term equality, selected limit, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with Definition 765.261. It requires the candidate row, SN endpoint rows, open socket, and four L10 faces to be displayed before the bounded checker reads its budget.

Next apply Definition 765.260. The checker-facing budget remains conditional on the socket row D, so the budget cannot be read as a closed normalization theorem.

Use Definition 765.266. It separates K, the endpoint row S, N, the socket row D, and the L10 face row from the handoff and structural rows.

Finally read the frontier separation theorem, Definition 765.262. The same separation persists at the bounded-checker frontier, so the checker receives a factored finite budget rather than subject reduction, global confluence, beta-decision, quotient equality, selected-limit, host-equality, or Real-completeness data. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBoundedCheckerBudgetFactorization`

Theorem 765.264 (MetaCIC bounded checker replay separation)**.** *Every replay of a bounded-checker budget read from an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must preserve four separate premise rows throughout the replay:*

1. *the candidate row K;*
2. *the strong-normalization endpoint row S, N;*
3. *the open discharge socket row D;*
4. *the L10 face row over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.

The replay may then read the handoff, transport, displayed continuation, provenance, local naming, and bounded budget rows, but it cannot compress the four premise rows into closed subject reduction, global confluence, beta-conversion decidability, quotient equality, selected limits, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBoundedCheckerReplaySeparation`

Proof. Start with the candidate-mediated obligation surface of Definition 765.257. It exposes the endpoint, socket, handoff, transport, replay, provenance, local name, and four L10 faces before any checker-facing budget is read.

Use schedule exhaustion from Definition 765.258. The candidate row remains attached to the displayed finite route, so replay cannot detach K from the same accepted packet.

Apply the conditional budget theorem, Definition 765.260, together with the four-face bounded checker gate, Definition 765.261. These rows keep the socket open and require the dyadic, stream, regular-rational, and real faces to appear as checker premises.

Finally apply Definition 765.263. Its factorization is stable under replay because the replay rows are read after the four premise rows, so the bounded checker receives only the displayed conditional budget and none of the excluded closed MetaCIC, quotient, selected-limit, host-equality, or completeness claims. □

Theorem 765.265 (MetaCIC candidate-mediated SN frontier coverage)**.** *Any accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer crossing from candidate-mediated strong-normalization evidence into confluence-facing or decidability-facing use must display the whole frontier before the handoff is read:*

1. *the candidate row K;*
2. *the strong-normalization endpoint and normal-form endpoint rows S, N;*
3. *the open discharge socket row D;*
4. *the handoff row U;*
5. *the bounded checker budget row;*
6. *the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The frontier may then pass through componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. It does not export subject reduction, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First read the obligation surface of Definition 765.257. It exposes the endpoint rows, open socket, handoff, transport, replay, provenance, local name, and four L10 faces before any confluence-facing or decidability-facing consumer reads the route.

Next apply Definition 765.260. The bounded checker budget remains conditional on the displayed candidate-mediated surface, so it cannot be detached from K, S, N, D, or U.

Use Definition 765.261. The dyadic, stream, regular-rational, and real faces must be displayed as four separate L10 premises, not compressed into a single ambient Real-completeness assumption.

Finally combine Definition 765.263 with the frontier separation theorem. The factorization keeps the bounded budget behind the same frontier rows, while separation prevents the consumer from repacking the finite route as subject reduction, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or Real completeness. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNFrontierCoverage`

Theorem 765.266 (MetaCIC candidate-mediated SN premise split)**.** *Any consumer passing candidate-mediated strong-normalization evidence from an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet into a confluence-facing or decidability-facing budget must display four separate premise rows before the budget is read:*

1. *the candidate row K;*
2. *the strong-normalization and normal-form endpoint row consisting of S and N;*

3. the unfilled discharge socket row D;

4. the L10 face row over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.

The four rows remain separate from the handoff row U, componentwise transport H, displayed replay C, provenance P, and local name L. The consumer receives no closed subject-reduction theorem, arbitrary Church–Rosser theorem, global beta-conversion decision, quotient term equality, selected limit, host real equality, or Real completeness.

Proof. Start with Definition 765.257. It places the strong-normalization row, normal-form endpoint, handoff row, discharge socket, transport, replay, provenance, local name, and L10 faces before any confluence-facing or decidability-facing budget.

Next apply Definition 765.258. This adds the candidate row K as a displayed schedule premise and keeps it attached to the same accepted packet rather than to a detached normalization theorem.

Use Definition 765.259. The discharge socket D remains visible and unfilled while the candidate-mediated evidence is routed, so the socket is not absorbed into the strong-normalization endpoint.

Finally apply Definition 765.260. The budget is conditional on all displayed rows, and the L10 face row remains the finite dependency surface over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Since the accepted route has no closed subject-reduction coordinate, arbitrary Church–Rosser theorem, global beta-conversion decision, quotient equality, selected limit, host equality, or Real-completeness row, none of those principles is exported. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNObligationSurface`
Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedSNPremiseSplit`

Theorem 765.267 (MetaCIC critical-path bounded conversion discharge)**.** *Every bounded-conversion consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must consume the displayed* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *row, the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *boundary row, the* $\mathsf{MetaCICCriticalPairLedger}^{\uparrow}$ *pair ledger, and the L10 four-object exit certificate rows over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before reading any conversion budget. The discharge route also carries the endpoint row S, N, the open socket row D, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

The discharge is finite and bounded by the displayed packet. It does not assert global strong normalization, arbitrary Church–Rosser, unrestricted beta-conversion decision, quotient term equality, selected limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 765.266. It requires the candidate row, endpoint row, socket row, and L10 face row to be displayed separately before the budget is read.

Apply Definition 765.262. The normalization frontier remains a boundary row rather than a closed normalization theorem, so the bounded checker receives only the exposed finite interface.

Use Definition 765.258 together with the critical-pair ledger row. The candidate-mediated schedule and pair ledger are consumed as finite discharge premises, while H, C, P, L transport, replay, source, and name the same route.

Since the socket remains visible and the L10 faces remain explicit, the route cannot be repacked as global strong normalization, unrestricted conversion decidability, quotient equality, selected-limit data, host equality, or Real completeness. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBoundedConversionDischarge`

Theorem 765.268 (MetaCIC bounded conversion socket budget)**.** *Every bounded-conversion consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must display the candidate row, the strong-normalization endpoint rows* S, N*, the open discharge socket* D*, the bounded checker budget row, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

before it reads any conversion data. The socket remains open throughout the read, and the packet exports no subject reduction, global Church–Rosser theorem, beta-decision procedure, quotient equality, selected limit, host equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBoundedConversionSocketBudget`

Proof. Start with the candidate-mediated obligation surface, Definition 765.257. It places the endpoint rows, open socket, structural rows, and the four L10 faces before any conversion-facing budget can be inspected.

Apply the candidate-discharge schedule exhaustion, Definition 765.258. The candidate row must remain attached to the same accepted packet, so the bounded-conversion consumer cannot read it as a detached normalization theorem.

Use the bounded checker budget factorization, Definition 765.263. It separates the candidate row, endpoint rows, socket row, and L10 face row before the checker budget is read.

Finally apply the bounded conversion discharge theorem, Definition 765.267. The conversion read is finite and conditional on the displayed socket, so none of the excluded subject-reduction, Church–Rosser, beta-decision, quotient-equality, selected-limit, host-equality, or Real-completeness data is exported. □

Theorem 765.269 (MetaCIC critical-path candidate-SN readiness)**.** *An accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet is ready for candidate-mediated strong-normalization handoff precisely at the finite surface consisting of the* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *row, the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *frontier row, the* $\mathsf{MetaCICCriticalPairLedger}^{\uparrow}$ *ledger row, the endpoint row* S, N*, the open discharge socket* D*, the L10 four-object exit certificate rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Readiness means only that those rows are all present and factor the bounded-conversion consumer route. It does not close subject reduction, confluence, global strong normalization, beta-conversion decidability, quotient term equality, selected limits, host equality, or Real completeness.

Proof. Read the candidate-mediated obligation surface and the premise split. Together they display the candidate row, endpoint row, socket row, handoff row, structural rows, and L10 faces before any confluence-facing or decidability-facing budget is consumed.

The normalization frontier and critical-pair ledger are then read as finite boundary rows. They record where bounded conversion may discharge local obligations, not a global theorem that all conversions terminate or join.

Finally apply Definition 765.267. The same displayed rows are exactly the finite discharge interface for bounded conversion, so candidate-SN readiness is a row-presence and factorization claim only. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNReadiness`

Theorem 765.270 (MetaCIC residual candidate-SN handoff)**.** *An accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet may pass candidate-mediated strong-normalization evidence to residual-substitution or confluence consumers only after it displays the* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *row, the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$

row, the MetaCICResidualSubstitutionBoundary$^{\uparrow}$ *row, the* MetaCICCriticalPairLedger$^{\uparrow}$ *row, the endpoint rows* S, N*, the open discharge socket* D*, the four L10 faces* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*, and the structural transport, replay, provenance, and local-name rows.*

The handoff is a finite consumer boundary. It permits residual-substitution and confluence consumers to read the candidate-mediated evidence only through the displayed socket and bounded-conversion discharge rows, and it does not export subject reduction, unrestricted confluence, global strong normalization, beta-conversion decidability, quotient term equality, selected limits, host equality, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualCandidateSNHandoff`

Proof. Start with the candidate-mediated obligation surface. It places the candidate row, endpoint rows, open socket, structural rows, and the four L10 faces before any normalization or conversion consumer can inspect the evidence.

Next apply the candidate-SN readiness theorem. Readiness supplies the finite row-presence and factorization condition, so the evidence remains attached to the accepted MetaCICCriticalPath$^{\uparrow}$ packet rather than becoming a detached strong-normalization theorem.

Use the premise split and bounded-conversion discharge rows. The premise split separates the candidate row from residual-substitution, frontier, pair-ledger, endpoint, socket, and L10 obligations, while the bounded-conversion discharge keeps the consumer route conditional on those displayed rows.

Finally repack through the structural coordinates. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local naming row preserve the same packet boundary; hence residual-substitution and confluence consumers receive only the displayed candidate-mediated handoff surface. □

Theorem 765.271 (MetaCIC critical-path bounded conversion consumer route)**.** *Any confluence-facing or decidability-facing consumer that uses the accepted candidate-mediated strong-normalization packet of Definition 765.269 must first read the bounded normalization candidates, the candidate discharge schedules, the finite checker budgets, and the local* NameCert$_{\text{MetaCICCriticalPath}^{\uparrow}}$ *rows. Only after these rows are displayed may the consumer export a bounded conversion claim through the* MetaCICNormalizationFrontier$^{\uparrow}$ *boundary, the* MetaCICCriticalPairLedger$^{\uparrow}$ *pair ledger, the endpoint rows* S, N*, the open discharge socket* D*, and the L10 four-object exit certificate over* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*.*

The route is a consumer discipline, not a global conversion theorem. It does not assert unrestricted confluence, global strong normalization, unbounded beta-conversion decidability, quotient term equality, selected limits, host equality, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Begin with the candidate-mediated SN readiness surface. It exposes the candidate row, normalization frontier, critical-pair ledger, endpoint rows, open socket, L10 exit certificate, and the structural H, C, P, L rows as the finite handoff boundary.

Apply the candidate discharge schedule exhaustion. The consumer must read the bounded candidates together with the displayed discharge schedule before any conversion-facing export is formed.

Use the conditional budget and bounded checker gates. These gates keep the checker budget finite and tied to the same frontier and pair-ledger rows, so confluence-facing and decidability-facing consumers receive a bounded conversion surface rather than an unrestricted theorem.

Finally repack the local NameCert rows. The hsame, Cont, Pkg, and naming coordinates preserve the accepted packet, while the socket and L10 rows prevent the route from becoming

global strong normalization, unrestricted confluence, unbounded conversion decidability, quotient equality, selected limits, host equality, or Real completeness. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBoundedConversionConsumerRoute`

Theorem 765.272 (MetaCIC critical-path L10 object-status readback)**.** *Any candidate-mediated strong-normalization discharge used as a roadmap-critical* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet may cite L10 object readiness only through the displayed status rows for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{RealCompletionExactBoundaryUp}$. *The readback factors through the four-object exit certificate, the Real L10 objectwise audit pullback, and the exact-boundary packet rows; it must not turn those rows into unconditional* $\mathsf{Real}^{\uparrow}$ *completeness, quotient real equality, selected host limits, closed subject reduction, host normalization, global confluence, or beta-conversion decidability.*

Proof. Start with the candidate-mediated SN discharge theorem, Definition 765.259. It keeps the discharge socket D open and requires the candidate row, endpoint rows, handoff row, structural rows, and four L10 faces before any confluence-facing or decidability-facing budget is read.

Next read the L10 object status route. The four-object exit certificate of Definition 765.128 displays the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces, while Definition 765.132 and Definition 38.471 force those faces to contribute their own local closurestatus, formalstatus, leantarget, and bridgestatus rows.

Finally attach the completion boundary only as a finite exact-boundary read. The $\mathsf{RealCompletionExactBoundary}$ packet supplies the displayed exact-boundary rows already governed by its local NameCert surface, so the SN-facing obligation may cite that boundary as status readback but cannot export Real completeness, host normalization, global confluence, quotient equality, selected limits, or a filled discharge socket. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10ObjectStatusReadback`

Theorem 765.273 (MetaCIC L10 normalization discharge budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every candidate-mediated strong-normalization, confluence, or decidability admission that is routed toward a discharge socket must first display the four L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

together with the packet rows $S, N, O, U, D, H, C, P, L$. *The discharge socket may then consume only this finite source budget. It receives no closed subject-reduction row, arbitrary strong-normalization theorem, global confluence theorem, beta-conversion decision procedure, quotient term equality, selected limit, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10NormalizationDischargeBudget`

Proof. Begin with the candidate-mediated SN frontier of Definition 765.198. It already places a candidate-mediated read on S, N, U, D, H, C, P, L and requires the four L10 faces before any confluence-facing or decidability-facing handoff consumes U.

Next use the candidate-normalization budget theorem, Definition 765.227. It identifies S, N, U, H, C, P, L plus $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as the finite normalization surface available to such consumers.

Finally apply discharge-socket induction and socket exhaustion, Definition 765.226 and Definition 765.230. These keep O and D visible unless a separate closed subject-reduction row is displayed, so the discharge socket consumes only the named L10 budget and none of the refused global claims. □

Theorem 765.274 (MetaCIC RegSeqRat candidate-normalization route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-normalization route that exposes a regular-rational readback to a confluence-facing or decidability-facing consumer must pass through* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before the candidate-normalization handoff* U *is consumed. The route is therefore a displayed L10 readback route, not a detached normalization oracle.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRegSeqRatCandidateNormalizationRoute`

Proof. Apply Definition 765.200. It requires every candidate-mediated read of U to expose the four L10 faces before the handoff is passed to a confluence-facing or decidability-facing consumer.

Refine that read with Definition 765.273. The budget keeps the regular-rational component downstream of the displayed finite windows and dyadic tolerance data, because the accepted discharge surface is the ordered L10 source package rather than an independent oracle.

The consumer-boundary theorem Definition 765.224 then prevents the handoff from being read as a global confluence theorem or beta-conversion decision procedure. Thus the $\mathsf{RegSeqRat}^{\uparrow}$ row remains part of the visible L10 route. □

Theorem 765.275 (MetaCIC normalization-frontier handoff)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated normalization handoff consumed by a confluence-facing or bounded-decidability consumer must expose* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before* U *is read, and it must keep the residual-budget and discharge-socket rows* O, D *visible. The handoff therefore reaches the consumer only as a displayed L10 frontier, not as full subject reduction, global Church–Rosser, beta-conversion decidability, quotient term equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNormalizationFrontierHandoff`

Proof. Start with Definition 765.273. It already requires the four L10 source faces and the packet rows before any discharge socket consumes a candidate-mediated normalization budget.

Refine the regular-rational part by Definition 765.274. The route places $\mathsf{StreamName}^{\uparrow}$ finite windows and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data before the $\mathsf{RegSeqRat}^{\uparrow}$ readback, so U cannot be consumed as a detached normalization oracle.

Next use the candidate-mediated strong-normalization frontier and the confluence-decidability consumer boundary. These keep O and D visible as residual-budget and discharge-socket rows whenever a confluence-facing or bounded-decidability consumer reads the handoff.

The refused endpoints are exactly the coordinates absent from the displayed frontier. Since the route exposes only the four L10 faces together with $S, N, O, U, D, H, C, P, L$, it cannot supply full subject reduction, global Church–Rosser, beta-conversion decidability, quotient term equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 765.276 (MetaCIC Real seal no infinite-reduction handoff)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. When a candidate-mediated normalization route reaches the* $\mathsf{Real}^{\uparrow}$ *seal face, the seal records only that the finite L10 readback route has been displayed. It does not certify absence of infinite reduction by itself, fill the discharge socket* D*, erase the obstruction row* O*, or supply closed subject reduction, arbitrary strong normalization, global confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealSealNoInfiniteReductionHandoff`

Proof. Start from Definition 765.273. It places the $\mathsf{Real}^{\uparrow}$ face after $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ inside the finite source budget consumed by a discharge socket.

Use Definition 765.230. Even after the candidate-normalization budget and four L10 faces have been consumed, the subject-reduction socket remains unfilled unless a separate closed subject-reduction row is displayed.

Finally apply Definition 765.199. It keeps O and D visible as rows distinct from the handoff and from the four L10 faces, so the $\mathsf{Real}^{\uparrow}$ seal cannot be reinterpreted as an infinite-reduction exclusion theorem or as any of the refused global metatheoretic claims. □

Theorem 765.277 (MetaCIC Real-completion SN budget separation)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated strong-normalization consumer that uses the* $\mathsf{Real}^{\uparrow}$ *completion-facing L10 budget must display* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, the obstruction row* O*, and the discharge socket* D *before any strong-normalization, confluence, or decidability claim is consumed. The displayed budget does not provide closed subject reduction, arbitrary strong normalization, global confluence, beta-conversion decidability, quotient term equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealCompletionSNBudget`

Proof. First apply the L10 normalization discharge budget, Definition 765.273. It forces every candidate-mediated consumer routed toward a discharge socket to expose the four L10 faces and the accepted packet rows before the socket can consume the budget.

Next compose the RegSeqRat candidate-normalization route, Definition 765.274. This places the regular-rational readback after finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data, so the consumer cannot read $\mathsf{RegSeqRat}^{\uparrow}$ as a detached normalization oracle.

Finally use the Real seal handoff theorem, Definition 765.276. It keeps O and D visible at the completion-facing edge and refuses every global metatheoretic claim listed in the statement. Thus the Real-completion budget is a displayed L10 candidate surface, not a discharge of strong normalization, confluence, decidability, quotient equality, selected limits, or Real completeness. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealCompletionSNBudgetSeparation`

Theorem 765.278 (MetaCIC critical-path candidate-discharge frontier)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted MetaCICCriticalPath$^{\uparrow}$ *root-unblock packet. Candidate-mediated strong-normalization rows, confluence rows, and bounded-decidability rows may be consumed by the root-unblock route only while the subject-reduction obstruction row O and the discharge socket D remain visible through the same packet. These candidate rows do not fill D unless a separate subject-reduction certificate row is displayed.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateDischargeFrontier`

Proof. Begin with the consistency handoff of Definition 765.2. It permits the positive read from the strong-normalization row S to the normal-form row N only through the displayed route, transport, provenance, and local naming rows.

Next keep the blocked side visible. The obstruction boundary Definition 765.3, the NameCert obligation surface Definition 765.20, and discharge-socket nonescape Definition 765.25 keep O and D as separate rows of the same accepted packet.

Now consume the candidate evidence. The candidate-mediated SN frontier Definition 765.198, the candidate-mediated SN obligation surface Definition 765.257, and the candidate-mediated subject-reduction boundary Definition 765.231 allow strong-normalization, confluence-facing, and bounded-decidability consumers to inspect the finite candidate rows, but only with O and D still exposed.

Finally apply discharge-socket coverage, Definition 765.26. A downstream socket read remains inside $S, N, O, U, D, H, C, P, L$ unless a separate subject-reduction input is displayed. Hence candidate-mediated SN, confluence, and bounded-decidability rows sharpen the frontier but do not discharge the socket by themselves. □

This candidate-discharge frontier consumes the residual-budget and diamond-premise rows of chapter 4061. The dependency keeps those sibling budget rows separate from the subject-reduction discharge socket, so a lattice read may use them as confluence-facing route data without treating them as the missing subject-reduction certificate.

Theorem 765.279 (MetaCIC candidate frontier L10 discharge boundary)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted MetaCICCriticalPath$^{\uparrow}$ *root-unblock packet. Candidate-mediated strong-normalization and confluence rows may consume the displayed L10 readiness rows* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *as source evidence for the current Phase Real and Completion route. Those four rows do not fill the subject-reduction discharge socket D unless a separate subject-reduction certificate is displayed in the same packet route.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierL10DischargeBoundary`

Proof. Start with the candidate-discharge frontier, Definition 765.278. It keeps candidate-mediated strong-normalization, confluence-facing, and bounded-decidability rows downstream of the visible obstruction row O and discharge socket D.

Read the candidate-mediated SN surface next. Theorems 765.198 and 765.257 allow the candidate rows to support normalization and confluence consumers, but only as displayed rows inside the accepted packet.

Now attach the L10 four-object route. Theorem 765.128 and the source-obligation surface of Theorem 765.165 make DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ available as readiness rows for the Phase Real and Completion route.

Finally apply discharge-socket coverage, Definition 765.26. The four L10 rows supply source readiness, not a subject-reduction certificate. Therefore the socket D remains open until the separate certificate is displayed, and no Real or Completion readiness row can be read as a hidden discharge. □

Theorem 765.280 (MetaCIC bounded-conversion candidate boundary)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet. Bounded conversion rows, confluence rows, and strong-normalization candidate rows may be read by the packet only while the subject-reduction obstruction row O and the discharge socket D remain displayed through the same route. None of those candidate rows closes subject reduction unless an explicit subject-reduction certificate row is present in the packet.*

Proof. Start with the candidate-discharge frontier, Definition 765.278. It permits candidate-mediated strong-normalization, confluence-facing, and bounded-decidability evidence only with O and D still visible.

Next apply the L10 discharge boundary, Definition 765.279. That theorem lets the packet consume the displayed source-readiness rows without treating any Real or Completion readiness row as the missing subject-reduction certificate.

Finally use discharge-socket coverage, Definition 765.26. A bounded-conversion row can support decidability and confluence inspection, but the socket D is filled only by a displayed subject-reduction certificate row. Hence candidate evidence remains separate from subject-reduction discharge. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBoundedConversionCandidateBoundary`

Theorem 765.281 (MetaCIC candidate-discharge frontier coverage)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet. The candidate-discharge frontier covers every permitted strong-normalization, confluence, bounded-conversion, and L10 source-readiness read only through the displayed rows $S, N, O, U, D, H, C, P, L$ and the four visible faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The coverage keeps the subject-reduction obstruction row O and discharge socket D visible throughout and does not claim that subject reduction has been supplied.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPacket candidate discharge frontier coverage`

Proof. Start with Definition 765.278. It keeps candidate-mediated normalization, confluence-facing, and bounded-decidability rows downstream of the visible obstruction and socket rows.

Add the L10 boundary from Definition 765.279. That result permits the four source-readiness faces to support the Phase Real and Completion route while refusing to read them as a subject-reduction certificate.

Finally apply Definition 765.280 and Definition 765.26. Together they force bounded conversion and every downstream socket read to preserve O and D unless a separate subject-reduction row is displayed. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateFrontierDischargeCoverage`

Theorem 765.282 (MetaCIC Real root budget lock)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet. Any Real-facing or Completion-facing root budget consumed by the candidate frontier is locked to the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readiness rows, carried through the same finite* BHist, hsame, Cont, Pkg, *and* NameCert *route as* K. *The lock supplies L10 source budget only; it does not close subject reduction, quotient stream equality, selected host limits, host real equality, trichotomy, open-cover compactness, or completed-real closure.*

Proof. Read the L10 source side through Definition 765.128. It displays exactly the dyadic budget, StreamName schedule, RegSeqRat readback, and Real seal rows before the Phase Real and Completion exit can be consumed.

Use Definition 765.165. The four faces are carried as finite source obligations through the same packet route, so the Real-facing budget cannot be replaced by an aggregate host object.

Now apply Definition 765.281. The candidate frontier may consume this source budget only while the obstruction row and discharge socket remain visible. Therefore the root budget is locked as readiness evidence and cannot discharge subject reduction or add any excluded completion principle. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealRootBudgetLock`

Theorem 765.283 (MetaCIC substitution boundary routing)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet. Substitution-facing reads that pass through the bounded-conversion or confluence side of the candidate frontier must route through the displayed handoff row* U, *the obstruction row* O, *the discharge socket* D, *and the structural rows* H, C, P, L *before they may consume the L10 readiness rows. Such reads may support bounded conversion and candidate checking, but they do not supply the missing subject-reduction certificate.*

Proof. Begin with Definition 765.60. It keeps substitution-facing reads visible through the handoff route and prevents the handoff row from becoming a detached theorem export.

Next use Definition 765.280. Bounded conversion, confluence, and candidate rows remain attached to the same packet and keep the obstruction and discharge rows visible.

Finally apply Definition 765.282. The L10 faces may be consumed only as source-readiness rows behind the visible socket route. Hence substitution-boundary routing can serve bounded conversion and candidate checking, while subject reduction remains open until a separate certificate row is displayed. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCarrier substitution boundary routing`

Theorem 765.284 (MetaCIC candidate discharge budget route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet. Bounded conversion, candidate-mediated strong normalization, confluence, and the L10 readiness faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *form a finite budget route inside* K*. The subject-reduction discharge socket* D *remains open until a separate subject-reduction certificate row is displayed, so bounded-conversion evidence and L10 readiness cannot be read as a hidden subject-reduction discharge.*

Proof. Start with Definition 765.278. It displays the candidate-mediated frontier and keeps the obstruction row and discharge socket visible inside the same packet.

Use Definition 765.280. Bounded conversion, confluence, and candidate rows are budget evidence attached to K, not a detached proof of the missing discharge.

Now apply Definition 765.282 and Definition 765.283. The L10 faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ are consumed only as readiness rows behind the visible handoff and socket route.

Finally invoke Definition 765.26. The socket D is still the named subject-reduction boundary. Since no certificate row for subject reduction is displayed, the finite budget route supports bounded conversion and candidate checking while leaving the subject-reduction socket open. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateDischargeBudgetRoute`

Theorem 765.285 (MetaCIC discharge socket case split)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet whose candidate-discharge budget route is displayed. Then every candidate-discharge read of* K *falls into exactly one of three finite cases: a filled discharge case, where a displayed subject-reduction certificate row fills* D*; a visible obstruction case, where* O *remains the exposed subject-reduction obstruction; or a residual socket case, where candidate evidence is present but* D *is still an unfilled discharge socket. None of the three cases exports closed subject reduction, full closed consistency, quotient proof equality, or a detached normalization theorem.*

Proof. Use the candidate frontier coverage to restrict the read to the rows $S, N, O, U, D, H, C, P, L$ and the visible L10 readiness faces. No case may inspect a row outside that finite packet.

Next apply the candidate-discharge budget route. It separates bounded conversion, candidate-mediated strong normalization, confluence-facing data, and Real-readiness budget from the subject-reduction discharge socket.

The displayed socket row D is therefore either filled by an explicit subject-reduction certificate row, blocked by the still-visible obstruction row O, or carried forward as the residual socket. These alternatives exhaust the finite socket coordinates, and the nonescape theorems prevent any branch from exporting closed subject reduction or full closed consistency. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDischargeSocketCaseSplit`

Theorem 765.286 (MetaCIC subject-reduction socket case exhaustion)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet whose candidate-discharge budget route is displayed. Every candidate-discharge read of* K *falls into a filled-discharge case, a visible-obstruction case, or a residual-socket case. These cases exhaust the finite packet surface while preserving the refusal to claim closed subject reduction unless an explicit subject-reduction certificate row is displayed.*

Proof. First restrict the read to the displayed packet. The candidate-discharge frontier coverage of Definition 765.281 allows only the rows $S, N, O, U, D, H, C, P, L$ and the visible L10 readiness faces.

Next separate the candidate boundary. The bounded-conversion candidate boundary of Definition 765.280 keeps bounded conversion, confluence, and candidate-mediated strong-normalization rows attached to the same visible obstruction and discharge socket.

Now read the L10 source side through Definition 765.128 and Definition 765.165. Those rows provide dyadic, stream, regular-rational, and Real readiness evidence for the Phase Real and Completion route, not a hidden subject-reduction certificate.

Finally apply the case split of Definition 765.285. The socket is either filled by an explicit certificate row, blocked by the visible obstruction row, or carried as a residual socket. Since those are the only finite socket coordinates exposed by the packet, the cases exhaust the read while closed subject reduction remains unavailable without the displayed certificate. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathSubjectReductionSocketCaseExhaustion`

Theorem 765.287 (MetaCIC candidate-discharge frontier totality)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet whose candidate-discharge budget route is displayed. Every candidate-discharge read of K is exhausted by bounded conversion, candidate-mediated strong normalization, confluence-facing rows, L10 readiness rows, and exactly one visible socket case. None of these rows closes subject reduction unless an explicit subject-reduction certificate row is displayed in the same packet route.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateDischargeFrontierTotality`

Proof. Begin with the candidate-discharge budget route, Definition 765.284. It places bounded conversion, candidate-mediated strong normalization, confluence data, and the L10 readiness faces inside the same finite packet while keeping the discharge socket D visible.

Next apply the subject-reduction socket case exhaustion theorem, Definition 765.286. The read has exactly one visible socket status: filled by an explicit certificate row, blocked by the visible obstruction row O, or carried as the residual socket.

Read the L10 source obligations through Definition 765.165. Those rows supply dyadic, stream, regular-rational, and Real readiness for the Phase Real and Completion route, not a subject-reduction certificate.

Finally use discharge-socket coverage, Definition 765.26. Since coverage preserves the socket until the explicit subject-reduction row is displayed, the frontier is total for candidate-mediated reads without turning bounded conversion, confluence, or readiness evidence into closed subject reduction. □

Theorem 765.288 (MetaCIC residual-budget discharge frontier)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet. Any candidate-mediated strong-normalization or confluence consumer that attempts to read the discharge socket D must first display residual-budget rows, substitution-boundary rows, closed-premise ledger rows, and local-diamond rows, all attached to the same packet rows $S, N, O, U, D, H, C, P, L$. Without those four frontier families, the read may inspect the candidate-mediated budget and confluence-decidability handoff, but it cannot treat D as discharged.*

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualBudgetDischargeFrontier

Proof. Begin with the candidate-mediated SN frontier, Definition 765.198. It forces a strong-normalization consumer to display the packet rows and the L10 source faces before the handoff row U is consumed.

Next add the SN confluence-decidability budget and discharge-socket readiness, Definition 765.193 and Definition 765.194. These theorems require the confluence-audit dependency exposure row and the closed-substitution boundary exposure row before a socket-facing consumer can reach D.

Now use the candidate-discharge frontier, Definition 765.278. It keeps the obstruction row O and discharge socket D visible while candidate-mediated strong-normalization, confluence, and bounded-decidability rows are consumed.

Finally attach the residual and diamond budget side through Definition 4061.6, Definition 4061.7, Definition 2325.3, and Definition 3595.3. The resulting frontier requires residual-budget rows, substitution-boundary rows, closed-premise ledger rows, and local-diamond rows before a discharge-socket read is available, and none of those rows supplies closed subject reduction by itself. □

Theorem 765.289 (MetaCIC residual-budget socket route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet. Any candidate-mediated strong-normalization discharge that crosses the residual frontier must expose the candidate row, residual budget row, socket and normalization route, and finite audit ledger before any downstream confluence or decidability consumer may read the discharge. In particular, the read factors through* $S, N, O, U, D, H, C, P, L$ *together with the residual-budget, substitution-boundary, closed-premise, and local-diamond rows required by Definition 765.288.*

Proof. Start from the residual-budget discharge frontier, Definition 765.288. It already requires the residual-budget, substitution-boundary, closed-premise ledger, and local-diamond families to be attached to the same packet rows $S, N, O, U, D, H, C, P, L$ before D is treated as discharged.

Now isolate the socket read. The candidate-mediated frontier Definition 765.198 exposes the candidate row and L10 source faces before strong-normalization handoff, while Definition 765.278 keeps the obstruction and discharge socket visible during the candidate-mediated handoff.

Finally combine the normalization and audit side. The SN confluence-decidability budget and socket-readiness theorems force the confluence-audit and closed-substitution rows to remain visible before any confluence or decidability consumer reads the discharge. Thus crossing the residual frontier supplies a socket route only after the candidate row, residual budget row, normalization route, and finite audit ledger have all been displayed. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualBudgetSocketRoute

Theorem 765.290 (MetaCIC critical-path candidate schedule discharge)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *root-unblock packet. A candidate-mediated schedule for strong normalization and confluence can discharge the open route only after it exposes candidate-set normalization, a critical-pair ledger, a residual-substitution boundary, finite observation confluence, and subject-reduction socket rows through the same packet. The schedule cannot cite unbounded confluence, global strong normalization, hidden substitution principles, quotient term equality, or ambient metatheoretic consistency as discharge data.*

Proof. Begin with the candidate-mediated SN obligation surface, Definition 765.257. It forces candidate-mediated normalization reads to display the strong-normalization row, normal-form endpoint, handoff row, discharge socket, transport, replay, provenance, local name, and the four L10 faces before confluence or decidability budgets are consumed.

Next expose the finite schedule rows. The candidate-discharge frontier of Definition 765.278 keeps the subject-reduction obstruction row O and discharge socket D visible, while the dependency-exposure rows of Definition 765.291 and Definition 765.292 keep candidate-set normalization, critical-pair ledgers, residual-substitution boundaries, finite observation confluence, and subject-reduction sockets as named dependencies rather than hidden assumptions.

Finally apply the confluence-decidability handoff exhaustion of Definition 765.171. It permits bounded consumers to read the candidate schedule only through the displayed packet and refuses full confluence, global strong normalization, hidden substitution, quotient equality, and consistency exports.

Thus a candidate-mediated schedule can discharge only the rows it displays. Without the five named schedule rows, the open socket remains a boundary rather than a completed metatheorem. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateScheduleDischarge`

Theorem 765.291 (MetaCIC critical-path normalization-frontier dependency exposure)**.** *Every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet exposes the normalization-frontier dependency as the finite row route from the candidate-mediated strong-normalization surface of* MetaCICNormalizationFrontier$^{\uparrow}$ *and* MetaCICNormalizationCertificateRouter$^{\uparrow}$ *into the normal-form endpoint row N of Definition 765.1. The exposure also keeps the source-window siblings* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$ *visible through the open-phase ledger before any normal-form read is consumed.*

This row is an obligation surface for the MetaCIC critical path. It is not a subject-reduction proof, not a closed-consistency theorem, and not a verification-axis upgrade.

Proof. Project the accepted carrier $K = (S, N, O, U, D, H, C, P, L)$. The row S is the only normalization-frontier entrance, and the row N is the only normal-form endpoint available to a consistency-facing consumer.

Read the cited sibling packets through the same route. MetaCICNormalizationFrontier$^{\uparrow}$ and MetaCICNormalizationCertificateRouter$^{\uparrow}$ supply the candidate-mediated normalization evidence, while DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ remain the finite source ledger rows for the open phase.

Since O and D remain visible beside S and N, the dependency exposure stops at the displayed obligation row. No carrier coordinate fills subject reduction or raises the verification axis. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathNormalizationFrontierDependencyExposure`

Theorem 765.292 (MetaCIC critical-path confluence-audit dependency exposure)**.** *Every accepted* MetaCICCriticalPath$^{\uparrow}$ *packet exposes the confluence-audit dependency through the handoff row U, with the confluence-facing siblings* CandidateSNConfluenceBoundary$^{\uparrow}$*,* FiniteObservationConfluence$^{\uparrow}$*,* MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$*, and* MetaCICCriticalPairLedger$^{\uparrow}$ *read only as bounded audit rows. The packet may use these rows to keep the route from S to N coherent with the displayed obstruction O and discharge socket D.*

This row is an obligation surface for confluence auditing on the MetaCIC path. It is not a Church–Rosser theorem, not a subject-reduction proof, and not a verification-axis upgrade.

Proof. Begin with the handoff row U in Definition 765.1. It is the only row that names substitution, confluence, and decidability support before the normal-form consistency read is attempted.

The confluence-facing siblings are therefore consumed as finite audit rows. $\mathsf{CandidateSNConfluenceBoundary}^{\uparrow}$ and $\mathsf{FiniteObservationConfluence}^{\uparrow}$ keep the SN-window and finite-observation sides bounded, while $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$ and $\mathsf{MetaCICCriticalPairLedger}^{\uparrow}$ keep critical-pair data visible as ledger entries.

The obstruction row O and socket D remain part of the same carrier. Thus the confluence dependency is exposed as a bounded obligation surface, not as a proof of global confluence or as a change in verification status. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathConfluenceAuditDependencyExposure`

Theorem 765.293 (MetaCIC critical-path closed-substitution boundary exposure)**.** *Every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet exposes closed-substitution support through the same handoff row U and discharge socket D, reading* $\mathsf{MetaCICClosureTrace}^{\uparrow}$, $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, *and* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ *only as boundary packets. The rows may explain which closed-substitution data must be present before a later subject-reduction consumer can act, but they do not fill that consumer.*

This row is an obligation surface for the closed-substitution boundary. It is not a subject-reduction proof, not a closed MetaCIC consistency theorem, and not a verification-axis upgrade.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathClosedSubstitutionBoundaryExposure`

Proof. Inspect the critical-path carrier. The row U names the substitution handoff, while D names the separate discharge socket that must be filled before any subject-reduction consumer can be treated as supplied.

The closed-substitution siblings are consumed only as boundary data. $\mathsf{MetaCICClosureTrace}^{\uparrow}$ records closedness-preservation routes, $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ records the closed-term projection boundary, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ records the four-row discharge socket, and $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ records the residual substitution boundary.

Because D remains a socket and O remains visible, the packet cannot convert these boundary rows into subject reduction or closed consistency. The theorem records the dependency surface and no verification-axis change. □

Theorem 765.294 (MetaCIC critical-path L10 candidate-discharge order)**.** *Every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet reads any Real-and-Completion candidate-discharge surface through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before the normal-form endpoint row N or discharge socket D of Definition 765.1 may be consumed. The row L is the open-phase source ledger for this route, while S, N, O, U, D remain MetaCIC critical-path rows. The theorem records the candidate-discharge ordering; it does not claim subject reduction, closed consistency, or completion of the Real-and-Completion phase.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10CandidateDischargeOrder`

Proof. Project the accepted carrier $K = (S, N, O, U, D, H, C, P, L)$ from Definition 765.1. The rows S, N, O, U, D name the MetaCIC normalization surface, normal-form endpoint, obstruction, handoff support, and discharge socket.

The open Real-and-Completion data are carried by L. A candidate-discharge read that mentions Real-facing source data must therefore display the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route through that ledger before it can consume either N or D.

Transport through H, replay through C, and provenance through P preserve this separation of roles. Since D remains a socket and N remains an endpoint row, the carrier supplies an ordering obligation only, not subject reduction or a closed consistency theorem. □

Theorem 765.295 (MetaCIC root-unblock admission)**.** *Any* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *admission for candidate-mediated strong-normalization, confluence, or decidability work must first expose the four L10 source rows* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *through the open-phase ledger of Definition 765.155 before a candidate checker row is consumed. The admission may then read the candidate-mediated frontier of Definition 765.198, the Phase Real root-unblock route of Definition 765.167, and the candidate-mediated obligation surface of Definition 765.257; it exports no closed subject-reduction row, global confluence theorem, global beta-conversion decision procedure, quotient term equality, selected limit, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRootUnblockAdmission`

Proof. Start with the open-phase source ledger. Definition 765.155 displays the packet rows together with the four L10 source faces, so a MetaCIC admission cannot consume a candidate checker row before those faces are visible.

Next apply the Phase Real root-unblock admission theorem, Definition 765.167. It identifies the admitted root-unblock route with the same packet rows and the separate $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ face records.

Finally attach the candidate-mediated surface. The frontier theorem Definition 765.198 and the obligation surface theorem Definition 765.257 allow confluence-facing and decidability-facing consumers to inspect the candidate row only after the displayed source ledger is present. Since the cited surfaces contain none of the excluded metatheoretic or completion coordinates, the root-unblock admission is exactly the stated L10-ledger-first route. □

Theorem 765.296 (MetaCIC critical-path real-completion source budget)**.** *Any* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer attempting a candidate-mediated strong-normalization, confluence, or decidability handoff must first display the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *source rows named by the current Phase Real and Completion ledger. Only after those four source rows are visible may the consumer read the MetaCIC closure trace, critical-pair ledger, normalization frontier, subject-reduction discharge socket, and confluence-decidability budget rows. The handoff exports no closed subject-reduction theorem, global confluence theorem, global beta-conversion decision procedure, quotient term equality, selected limit, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealCompletionSourceBudget`

Proof. Begin with root-unblock admission. Theorem 765.295 requires any candidate-mediated strong-normalization, confluence, or decidability admission to expose the four L10 source rows before a candidate checker row is consumed.

Next read the Phase Real source obligations. Theorem 765.165 places the dyadic finite-observation row, stream schedule, regular-rational readback, and Real seal before any discharge socket, confluence-decidability handoff, obstruction boundary, or downstream readiness boundary.

The existing source ledger then supplies the finite route. Definition 765.155 and Theorems 765.156 and 765.159 keep every current Phase Real and Completion read inside the packet rows and the four displayed source faces.

Finally attach the MetaCIC side. The confluence-decidability budget and handoff-exhaustion theorems require the closure trace, critical-pair ledger, normalization frontier, discharge socket, and budget rows to remain downstream of the source ledger. Since the route has no additional coordinate, the excluded metatheoretic and completion claims cannot be exported. □

Theorem 765.297 (MetaCIC critical-path real-completion budget triangle)**.** *Any* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer combining candidate-mediated strong normalization, confluence-decidability, and the L10 Real and Completion handoff must read the four L10 source rows* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before reading the closure trace, critical-pair ledger, normalization frontier, subject-reduction socket, or confluence-decidability budget. The combined route exports no quotient stream equality, selected limit, host real equality, global confluence theorem, global beta-conversion decision procedure, discharged subject-reduction theorem, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealCompletionBudgetTriangle`

Proof. Start with the existing confluence-decidability source budget, Definition 765.296. It places every confluence-facing or decidability-facing read downstream of the four displayed L10 source rows and keeps the closure trace, critical-pair ledger, normalization frontier, discharge socket, and budget rows on the MetaCIC side of that source boundary.

Next attach the Phase Real dependency budget. Theorems 765.167 and 765.114 require every current Real and Completion consumer to present the dyadic budget, stream schedule, regular-rational readback, and Real seal rows as the finite source surface, with no fifth source row or hidden completion credential.

Finally read the candidate-mediated strong-normalization consumer through the same packet. Theorem 765.257 allows SN-facing data only after the packet rows and four L10 faces are displayed, and Theorem 765.192 keeps confluence and decidability reads downstream of the same open-source ledger. Thus the three sides of the route share one L10 source budget triangle, and every listed metatheoretic, quotient, choice, order, equality, and completeness claim remains outside the accepted consumer surface. □

Theorem 765.298 (MetaCIC bounded normalization candidate ledger)**.** *Any bounded normalization candidate consumed by the current Phase Real and Completion route for an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must display the finite packet rows*

$$S, N, O, U, D, H, C, P, L$$

together with the four L10 faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The ledger may be read only as candidate-mediated normalization evidence feeding confluence-facing and bounded decidability-facing consumers through the open-phase source budget; it exports no closed subject reduction, full consistency, quotient term equality, global beta-conversion decidability, selected limit, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the candidate-mediated SN finite socket normal form, Definition 765.177. It identifies the consumable normalization candidate as the socket-aware rows $S, N, O, U, D, H, C, P, L$ together with separate local face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next apply confluence candidate mediation, Definition 765.181. Confluence-facing reads remain mediated by the handoff row U, the obstruction and socket rows O, D, and the structural rows H, C, P, L; the candidate route does not become a closed Church–Rosser or subject-reduction theorem.

Apply the decidability fragment route, Definition 765.183. Bounded checker evidence is confined to the same packet rows and four L10 faces, so it cannot be promoted to global beta-conversion decidability or quotient term equality.

Finally use the real-completion source budget, Definition 765.296. The current Phase Real and Completion route reads DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ before any candidate-mediated handoff is consumed. Since the cited routes contain no row for selected limits, full consistency, closed subject reduction, quotient equality, global beta-conversion decidability, or Real$^{\uparrow}$ completeness, the displayed rows form the whole bounded normalization candidate ledger. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBoundedNormalizationCandidateLedger`

Theorem 765.299 (MetaCIC critical-path public interface)**.** *Every public* MetaCICCriticalPath$^{\uparrow}$ *consumer route is the finite union of the L10 four-object status rows, the candidate-mediated strong-normalization frontier rows, the confluence and decidability budget rows, and the residual discharge rows already displayed by the chapter. The interface may expose* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$ *source status; CandidateMediatedSN and CandidateSNConfluenceBoundary readiness; confluence, finite-observation, and decidability budgets; and the residual discharge socket. It does not claim full normalization, full subject reduction, host consistency, or bridge closure.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPublicInterface`

Proof. First project the L10 status surface. Theorems 765.128, 765.132, and 765.145 expose the four object rows and keep them as separate finite source records.

Next project the candidate-mediated frontier. Theorems 765.198, 765.206, and 765.207 present CandidateMediatedSN and its obstruction boundary as displayed BHist route data rather than as a global normalization theorem.

Then project the confluence and decidability budgets. Theorems 765.192, 765.193, and 765.171 keep finite-observation confluence, candidate SN, and decidability uses on their visible budget rows.

Finally project the residual discharge surface through Definition 765.288 and Definition 765.289. The finite union of these projections is the public interface route, and finite BHist, hsame, Cont, Pkg, and NameCert projection adds no full normalization, full subject reduction, host consistency, or bridge closure claim. □

Theorem 765.300 (MetaCIC critical-path residual public handoff)**.** *Every public* MetaCICCriticalPath$^{\uparrow}$ *consumer that reads residual-discharge data must pass the read through the residual budget socket and the candidate-mediated frontier rows of Definition 765.299 before it claims any confluence or decidability budget consumption. The handoff may expose the residual-budget, substitution-boundary, closed-premise, local-diamond, candidate-mediated strong-normalization, confluence-frontier, and decidability-budget rows as displayed public data. It does not discharge full normalization, full subject reduction, host consistency, full confluence, or beta-conversion decidability.*

Proof. Start with the public interface theorem. It already separates the residual discharge rows from the candidate-mediated frontier rows and from the confluence and decidability budget rows.

Now route the residual read through the socket. Theorems 765.288 and 765.289 require residual-budget rows, substitution-boundary rows, closed-premise ledger rows, and local-diamond rows before any discharge socket may be treated as available.

Next attach the candidate-mediated frontier. The public interface proof cites the candidate-mediated strong-normalization frontier and its handoff and obstruction rows, so a public consumer must keep those rows visible while reading the residual socket.

Finally consume the confluence and decidability budget only after the residual and candidate rows have both been displayed. The confluence-decidability budget, SN confluence budget, and handoff-exhaustion rows remain budget rows; they do not supply full normalization, full subject reduction, host consistency, full confluence, or beta-conversion decidability. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualPublicHandoff`

Theorem 765.301 (MetaCIC public interface frontier readiness)**.** *A public* MetaCICCriticalPath$^{\uparrow}$ *consumer may read CandidateMediatedSN, CandidateSNConfluenceBoundary, finite-observation confluence, decidability budgets, and residual discharge sockets only as readiness rows over the same displayed finite route of Definition 765.299. Before claiming closed subject reduction, full confluence, beta-conversion decidability, or host consistency, the consumer must cite a separate subject-reduction row and the matching discharge row for that global claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPublicInterfaceFrontierReadiness`

Proof. Project the public interface theorem. It already displays the L10 source rows, candidate-mediated frontier rows, confluence and decidability budgets, and residual discharge sockets as a finite union of carrier-visible routes.

Readiness is preserved because each named frontier row remains attached to the same BHist, hsame, Cont, Pkg, and NameCert coordinates. CandidateMediatedSN and CandidateSNConfluenceBoundary are therefore usable as frontier evidence, while finite-observation confluence and decidability budgets remain budget rows rather than full metatheorems.

The global claims require a further row. Since the public interface theorem explicitly refuses full normalization, full subject reduction, host consistency, and bridge closure, a consumer cannot obtain closed subject reduction, full confluence, beta-conversion decidability, or host consistency without citing the separate subject-reduction and discharge surfaces. □

Theorem 765.302 (MetaCIC critical-path bridge route)**.** *Every bridge-facing public read of* MetaCICCriticalPath$^{\uparrow}$ *factors through the L10 four-object rows for* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *the CandidateMediatedSN frontier rows, the confluence and decidability budget rows, and the residual budget socket before any consumer may claim bridge readiness. The route exposes only finite* BHist, hsame, Cont, Pkg, *and* NameCert *data. It does not claim full normalization, full subject reduction, host consistency, full confluence, beta-conversion decidability, or bridge closure.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathBridgeRoute`

Proof. Begin with the public interface theorem. It presents the L10 source rows, the candidate-mediated frontier, the confluence and decidability budgets, and the residual discharge rows as a single finite interface surface.

Next apply the residual public handoff. That theorem forces every residual read through the residual budget socket and keeps the candidate-mediated frontier visible before any confluence or decidability budget is consumed.

Finally apply the frontier-readiness theorem. It allows the same displayed rows to be read as readiness evidence, but it requires a separate subject-reduction row and matching discharge row for any global claim. Therefore a bridge-facing consumer can only read the finite interface route; it cannot derive full normalization, full subject reduction, host consistency, full confluence, beta-conversion decidability, or bridge closure from these public rows. □

Theorem 765.303 (MetaCIC public interface gate)**.** *A* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer passes the public interface gate only when its bridge-facing read cites the public interface theorem, the residual public handoff, and the frontier-readiness row in that order. Passing the gate records that the consumer has displayed the L10 four-object rows, CandidateMediatedSN frontier, confluence and decidability budgets, and residual budget socket; it records no full normalization theorem, no full subject-reduction theorem, no host-consistency theorem, no full-confluence theorem, no beta-conversion decidability theorem, and no bridge closure.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathPublicInterfaceGate`

Proof. The gate first checks the row inventory against Definition 765.299. Missing one of the L10 source rows, the candidate-mediated frontier rows, the confluence or decidability budget rows, or the residual discharge rows leaves the public interface unreadable.

It then checks residual order through Definition 765.300. The residual socket must be read before any confluence or decidability budget consumption is advertised, and the candidate-mediated frontier must remain attached to that read.

It finally checks readiness through Definition 765.301. Readiness is a public-row status over the displayed finite route, so the gate cannot convert it into full normalization, full subject reduction, host consistency, full confluence, beta-conversion decidability, or bridge closure. □

Theorem 765.304 (MetaCIC residual substitution frontier)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A MetaCIC critical-path candidate may enter the normalization frontier only after the closed-substitution boundary rows, residual-budget rows, and candidate-mediated strong-normalization rows are all displayed on the same packet route* $S, N, O, U, D, H, C, P, L$*. The frontier therefore consumes the closed-substitution boundary of Definition 765.194, the residual-budget socket route of Definition 765.289, and the candidate-mediated SN frontier of Definition 765.198 before any confluence-facing or decidability-facing handoff reads* U*.*

Proof. Start with the candidate-mediated SN frontier. It requires the candidate rows S, N, U, D, H, C, P, L, keeps O, D visible, and displays the L10 source faces before the handoff row U is consumed.

Next attach the residual-budget discharge frontier. By Definition 765.288 and Definition 765.289, a socket-facing read must expose residual-budget, substitution-boundary, closed-premise, and local-diamond rows on the same packet.

Finally use the discharge-socket readiness theorem. It places the closed-substitution boundary beside the confluence-audit dependency exposure before the socket can be read, so entering the normalization frontier requires all three displayed families: closed substitution, residual budget, and candidate-mediated strong normalization. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualSubstitutionFrontier`

Theorem 765.305 (MetaCIC residual-substitution diamond budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any diamond, confluence, or bounded decidability consumer exposed by* K *must read the same residual-substitution frontier, candidate-mediated strong-normalization frontier, SN confluence-decidability budget, residual-budget socket route, and L10 source rows on the packet route* $S, N, O, U, D, H, C, P, L$*. Consequently no confluence-facing consumer may detach a diamond proof from the residual budget rows, bypass the closed-substitution boundary, or read* U *through an L10 source route absent from the accepted packet.*

The L10 source faces used by the residual diamond consumer route through the Cauchy name surface of chapter 3413, the regular rational readback of chapter 301, and the Real seal already displayed on the packet. This is a finite-source dependency for residual diamond consumers, not a Real completeness assertion or a quotient equality between source names.

Proof. Start with the residual-substitution frontier of Definition 765.304. It places the closed-substitution boundary, residual-budget rows, and candidate-mediated strong-normalization rows on one route before any confluence-facing handoff may consume U.

Next apply the diamond budget of Definition 765.306. A diamond checker that feeds decidability already consumes the residual budget exposed by that frontier, so it has no independent budget source.

Now attach the residual decidability cut of Definition 765.307. It forces the bounded decidability readback to expose the residual-substitution frontier, the candidate SN confluence checker, the SN confluence-decidability budget, and the residual-budget socket route on the same packet.

Finally use the candidate-mediated SN frontier of Definition 765.198. The candidate rows and L10 source faces remain visible through $S, N, O, U, D, H, C, P, L$, so any detached diamond proof, closed-substitution bypass, or missing L10 source row leaves the accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualSubstitutionDiamondBudget`

Theorem 765.306 (MetaCIC diamond residual budget)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, every confluence or diamond checker that feeds a decidability readback must consume exactly the residual budget displayed by the residual-substitution frontier of Definition 765.304. In particular, the checker route factors through the candidate SN confluence checker of Definition 765.195, the SN confluence-decidability budget of Definition 765.193, and the residual-budget socket route of Definition 765.289 before any bounded decidability consumer may inspect* U*.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDiamondBudget`
↪ variant `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDiamondResidualBudget`

Proof. Read the residual-substitution frontier first. It binds closed substitution, residual budget, and candidate-mediated SN rows to the same packet route, so the confluence checker has no separate budget source.

Now apply the candidate SN confluence checker factorization. The checker may combine candidate-mediated normalization, confluence handoff, and bounded checker rows only through $S, N, O, U, D, H, C, P, L$ and the displayed L10 faces.

Finally apply the SN confluence-decidability budget. Its decidability-facing consumer reads the same handoff row U only after the candidate and confluence budget rows are visible. Since the residual-budget socket route is already attached to those rows, the diamond checker consumes that budget before any decidability readback is exposed. □

Theorem 765.307 (MetaCIC residual decidability cut)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every bounded decidability readback that consumes the diamond checker must first expose the residual-substitution frontier, the candidate SN confluence checker, the SN confluence-decidability budget, and the residual-budget socket route on the same*

packet route. Consequently no decidability consumer may inspect U from a detached confluence proof, closed-substitution bypass, or checker route that omits any of those displayed rows.

Proof. Start from the residual-substitution frontier of Definition 765.304. It places the closed-substitution boundary, residual budget, and candidate-mediated SN rows on the same accepted packet before any confluence-facing or decidability-facing read may consume U.

Attach the diamond budget of Definition 765.306. That theorem forces any confluence or diamond checker feeding a decidability readback to consume the residual budget exposed by the frontier.

Now read the checker and budget routes. The candidate SN confluence checker factorization, Definition 765.195, supplies the only checker interface, while Definition 765.193 binds the bounded decidability readback to the same SN confluence-decidability budget.

Finally use the residual-budget socket route of Definition 765.289. Since the socket route is already part of the checker budget, a consumer that reads U from detached confluence, bypassed closed substitution, or an omitted residual route leaves the accepted packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDecidabilityCut`

Theorem 765.308 (MetaCIC residual diamond source totality)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any residual diamond checker that feeds bounded conversion must expose the closed-substitution boundary, the residual-budget socket route, the candidate-mediated strong-normalization frontier, and the L10 source rows on the same packet route before reading U. Consequently such a checker cannot certify a bounded conversion row from a detached residual substitution proof, a missing candidate-mediated SN row, a confluence budget outside D, H, C, P, L, or a source route absent from S, N, O.*

Proof. Begin with the residual-substitution frontier of Definition 765.304. It places closed substitution, residual budget, and candidate-mediated strong normalization on the accepted route before any confluence-facing read can consume U.

Attach the diamond budget of Definition 765.306. The diamond checker has no separate budget coordinate, so its confluence-facing row must consume the same residual-budget socket route and the same SN confluence-decidability budget.

Use the residual decidability cut of Definition 765.307. A bounded decidability readback may inspect U only after the residual-substitution frontier, candidate SN confluence checker, SN confluence-decidability budget, and residual-budget socket route have all been displayed on one packet.

Finally apply the candidate-mediated SN frontier of Definition 765.198. The L10 source faces remain visible through $S, N, O, U, D, H, C, P, L$, so omitting any source row or moving the checker to a detached route exits the accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondSourceTotality`

Theorem 765.309 (MetaCIC residual diamond L10 source separation)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any residual diamond checker that feeds bounded conversion must preserve the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *source faces*

as distinct displayed rows before it reads U. The checker may pass those faces through the candidate-mediated and residual-budget routes, but it may not merge them into a single Real-readback row or reconstruct one face after bounded conversion has consumed the handoff.

Proof. Start with Definition 765.305. It forces any diamond, confluence, or bounded decidability consumer to expose the residual-substitution frontier, candidate-mediated SN frontier, residual-budget socket route, and L10 source rows on the same packet route.

Use the residual decidability cut of Definition 765.307. A bounded conversion readback can inspect U only after the residual frontier, checker route, SN confluence-decidability budget, and residual-budget socket have been displayed together.

Finally apply Definition 765.198 and Definition 765.308. The candidate-mediated frontier keeps the L10 source faces visible with the candidate rows, and source totality requires those faces before bounded conversion reads U. Therefore the four source faces remain separated as displayed rows throughout the residual diamond route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondL10SourceSeparation`

Theorem 765.310 (MetaCIC residual diamond candidate-budget coverage)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet $K = (S, N, O, U, D, H, C, P, L)$, the candidate-mediated strong-normalization rows, residual-budget socket rows, and L10 source rows jointly cover the bounded conversion consumer route. A bounded conversion consumer may read U only after all three families are displayed on the same packet route; omitting any one family leaves no accepted residual diamond checker for the consumer.*

Proof. Begin with Definition 765.305. It names the combined route through the residual-substitution frontier, candidate-mediated strong-normalization frontier, SN confluence-decidability budget, residual-budget socket route, and L10 source rows.

Attach Definition 765.307. The cut prevents bounded conversion from reading U through a detached confluence proof or a route that omits the checker, budget, or residual socket.

Now use Definition 765.198 together with Definition 765.308. The candidate rows supply the strong-normalization frontier, the socket rows supply the residual budget, and the L10 rows supply the finite Real and completion source faces. These three families exhaust the bounded conversion consumer route without adding full confluence, beta-conversion decidability, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or kernel consistency. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondCandidateBudgetCoverage`

Theorem 765.311 (MetaCIC residual-diamond budget source nonescape)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any residual diamond checker feeding bounded conversion must expose the residual-substitution frontier, residual-budget socket route, candidate-mediated strong-normalization frontier, SN confluence-decidability budget, and L10 source rows on the same packet route before reading U. A detached residual proof, missing candidate row, missing socket budget, or absent L10 source row leaves the accepted packet.*

Proof. Start with the residual-substitution frontier of Definition 765.304. It binds the closed-substitution boundary, residual budget, and candidate-mediated strong-normalization rows to the accepted route before a confluence-facing consumer may inspect U.

Attach the diamond budget of Definition 765.306. The diamond checker must spend the same SN confluence-decidability budget and residual-budget socket route carried by D, H, C, P, L, so it cannot import an external budget.

Use the residual decidability cut of Definition 765.307. Bounded conversion may read U only after the residual frontier, checker route, SN confluence-decidability budget, and socket budget are displayed on one packet.

Finally apply residual diamond source totality, Definition 765.308. The L10 source rows remain visible through $S, N, O, U, D, H, C, P, L$, so detached residual proofs, missing candidate rows, missing socket budgets, and absent source rows are outside the accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondBudgetSourceNonescape`

Theorem 765.312 (MetaCIC residual diamond candidate-mediated handoff)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any consumer that uses a residual diamond checker to feed bounded conversion must expose, on one route through* $S, N, O, U, D, H, C, P, L$*, the candidate-mediated strong-normalization frontier, the residual-substitution frontier, the residual-budget socket route, the SN confluence-decidability budget, and the L10 source rows before reading* U*. A detached residual proof, a missing candidate row, a missing socket budget, or an absent L10 source row leaves the accepted packet.*

Proof. Start from residual diamond source totality, Definition 765.308. It already forces the closed-substitution boundary, residual-budget socket route, candidate-mediated strong-normalization frontier, and L10 source rows onto the same packet route before a bounded-conversion consumer may inspect U.

Next use the residual-substitution frontier of Definition 765.304. This supplies the closed-substitution and candidate-mediated rows needed by the residual checker and prevents a residual proof from being read on a detached route.

Attach the diamond budget and residual decidability cut, Definition 765.306 and Definition 765.307. Together they place the SN confluence-decidability budget and residual-budget socket beside the bounded conversion readback.

Finally apply the candidate-mediated SN frontier, Definition 765.198. The candidate rows and L10 source faces remain visible through $S, N, O, U, D, H, C, P, L$, so a missing candidate row, missing socket budget, or absent source row is outside the accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondCandidateMediatedHandoff`

Theorem 765.313 (MetaCIC residual diamond L10 source nonescape)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any residual diamond checker feeding bounded conversion must preserve, on the same packet route, the L10 source faces from* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before reading the candidate-mediated handoff row* U*. Consequently a checker that detaches the residual substitution frontier, omits the diamond budget, bypasses the residual decidability cut, drops the candidate-mediated SN frontier, or reads only residual diamond source totality without those L10 faces exits the accepted packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondL10SourceNonescape`

Proof. Start with the residual-substitution frontier of Definition 765.304. It places closed substitution, residual budget, and candidate-mediated normalization on one route before a confluence-facing consumer may read U.

Attach the diamond budget of Definition 765.306. The residual diamond checker has no independent budget coordinate; it must consume the same SN confluence-decidability and residual-budget rows carried by D, H, C, P, L.

Use the residual decidability cut of Definition 765.307. A bounded conversion readback can inspect U only after the residual frontier, checker factorization, SN confluence-decidability budget, and residual-budget socket are visible on the same packet route.

Now apply the candidate-mediated SN frontier of Definition 765.198. It keeps the L10 source faces from $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ visible with the candidate rows rather than allowing them to be reconstructed after the handoff.

Finally use residual diamond source totality, Definition 765.308. Since source totality already requires those faces before bounded conversion reads U, any checker that loses one of them or moves it to a detached route is outside the accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet. □

Theorem 765.314 (MetaCIC residual diamond typed L10 budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A typed residual-diamond consumer may read bounded conversion only after the residual-substitution frontier, residual-budget socket, candidate-mediated strong-normalization frontier, typed-example boundary, and all four L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

remain on the same packet route. Thus the typed conversion read cannot detach its residual proof from the closed-substitution boundary, spend a socket budget outside D, H, C, P, L, omit the candidate-mediated SN frontier, or replace any L10 source face by a later reconstruction.

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondTypedL10Budget`

Proof. Start with residual diamond source totality, Definition 765.308. It puts the closed-substitution boundary, residual-budget socket, candidate-mediated frontier, and L10 source rows on one route before bounded conversion may read U.

Use residual diamond L10 source nonescape, Definition 765.313, to retain $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as displayed source faces. The typed-example boundary is then read through the same candidate-mediated rows, so the bounded conversion consumer receives one finite budget rather than a detached typed proof. □

Theorem 765.315 (MetaCIC residual diamond source-face retention)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet $K = (S, N, O, U, D, H, C, P, L)$, the residual-diamond route retains the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *faces whenever the residual-substitution frontier, residual-budget socket, candidate-mediated SN frontier, and typed-example boundary are used to feed bounded conversion. A consumer that reads one of those faces through a detached route, or reads bounded conversion after dropping one face, leaves the accepted packet.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondSourceFaceRetention`

Proof. Apply the residual diamond L10 source nonescape theorem. It already prevents the bounded conversion handoff from consuming U after losing any of the four L10 source faces.

Now attach residual diamond source totality. Source totality supplies the same closed-substitution, socket-budget, and candidate-mediated rows required by the residual diamond route. The typed-example boundary can therefore be retained only as part of the displayed packet route; it has no separate source-face reconstruction step. □

Theorem 765.316 (MetaCIC residual diamond bounded conversion nonescape)**.** *Let $K = (S, N, O, U, D, H, C, P,$ be an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Bounded conversion may be read from the residual diamond checker only while the residual-substitution frontier, residual-budget socket, candidate-mediated strong-normalization frontier, typed-example boundary, and the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *remain on the same route before U is consumed. The read exports no full confluence theorem, no beta-conversion decidability, no quotient equality of terms, no selected limit, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondBoundedConversionNonescape`

Proof. Compose residual diamond source totality with residual diamond L10 source nonescape. The first theorem supplies the closed-substitution, socket-budget, and candidate-mediated rows needed before bounded conversion can read U.

The second theorem keeps the four L10 source faces visible on that route. Since the typed-example boundary is also consumed before the handoff, any consumer missing one of those rows is outside the accepted packet, and the conclusion is limited to bounded conversion on the displayed finite budget. □

Theorem 765.317 (MetaCIC residual diamond four-face budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A residual diamond checker feeding bounded conversion may consume the candidate-mediated strong-normalization handoff only when the residual-substitution frontier, residual-budget socket, candidate-mediated frontier, and all four L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

remain displayed on the same packet route $S, N, O, U, D, H, C, P, L$. The handoff does not export full subject reduction, full confluence, beta-conversion decidability, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Proof. Start with the residual-substitution frontier of Definition 765.304. It places the closed-substitution boundary, residual budget, and candidate-mediated normalization rows on one accepted route before a diamond-facing consumer may read U.

Next apply residual diamond source totality, Definition 765.308. The bounded-conversion checker must expose the closed-substitution boundary, residual-budget socket route, candidate-mediated strong-normalization frontier, and L10 source rows before it consumes the handoff.

Use the residual diamond L10 source nonescape theorem Definition 765.313. It keeps $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ visible on the same route and rules out a detached checker that reconstructs any source face after reading U.

Finally apply the candidate-mediated SN frontier of Definition 765.198. The candidate-mediated handoff remains a bounded route through the displayed packet, so the theorem exports only the four-face budget and not subject reduction, full confluence, beta-conversion decidability, quotient term equality, selected limits, ambient Real completeness, or kernel consistency. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondFourFaceBudget

Theorem 765.318 (MetaCIC residual-substitution diamond budget typed boundary)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any typed residual-substitution diamond consumer that reads the bounded conversion handoff must first keep the closed-substitution boundary, residual-budget socket, candidate-mediated strong-normalization frontier, typed-example boundary, and L10 source faces on the same packet route* $S, N, O, U, D, H, C, P, L$*. Consequently the bounded conversion handoff cannot be read from a detached typed example, a residual diamond proof outside the socket budget, a candidate frontier without typed examples, or an L10 source route absent from* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Proof. Begin with the residual-substitution frontier of Definition 765.304. It puts the closed-substitution boundary, residual-budget rows, and candidate-mediated normalization rows on the accepted packet route before a confluence-facing handoff can consume U.

Attach the diamond budget of Definition 765.306. The residual diamond checker must spend the same residual budget that feeds the bounded conversion route, so it cannot move the checker outside the socket-facing rows.

Use the residual decidability cut Definition 765.307. It forces the bounded conversion readback to expose the residual frontier, candidate checker, SN confluence budget, and residual-budget socket on one packet.

Now apply the candidate-mediated SN frontier Definition 765.198. The typed-example boundary is read through the same candidate rows, so a typed consumer cannot detach examples from the strong-normalization frontier.

Finally use the L10 source nonescape theorem Definition 765.313. The $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces remain visible before U is read; any handoff missing one of the closed-substitution, residual-budget, candidate-mediated, typed-example, or L10 source faces is outside the accepted packet. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualSubstitutionDiamondBudgetTypedBou

Definition 765.319 (MetaCIC candidate residual stability surface)**.** *The candidate-mediated residual stability surface of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L)$$

is the finite BHist *route that reads candidate-mediated strong-normalization evidence through* S, N, U, H, C, P, L *while keeping the residual substitution and diamond budget of Definition 765.305 attached to the four L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The classifier compares accepted stability surfaces only through the displayed residual rows, candidate frontier rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *data. It has no coordinate for arbitrary strong normalization, global confluence, closed subject reduction, quotient term equality, selected stream limits, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateResidualStabilitySurface

Theorem 765.320 (MetaCIC candidate residual stability)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, any candidate-mediated handoff that consumes residual substitution evidence must keep the residual diamond budget and the four L10 source faces visible until the handoff reaches the confluence-decidability boundary. The stability claim is only over the displayed rows of Definition 765.319; it does not export arbitrary strong normalization, global confluence, beta-conversion decidability, closed subject reduction, quotient term equality, selected limits, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateResidualStability`

Proof. Start with the candidate-mediated frontier theorem, Definition 765.198. It identifies the finite handoff through S, N, U, H, C, P, L and keeps the obstruction and socket rows visible.

Apply the residual substitution diamond budget of Definition 765.305. Residual replay is therefore read as a finite budget attached to the same displayed packet, not as a global confluence theorem.

Use the L10 entry and exit surfaces, Definition 765.118 and Definition 765.128. They keep $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ visible while the residual rows are consumed.

The structural rows H, C, P, L transport, replay, source, and name the same finite surface. Since none of the listed coordinates supplies the excluded metatheoretic or real-completion principles, the candidate-mediated residual handoff is stable exactly over the displayed L10 source faces. □

Theorem 765.321 (MetaCIC candidate real-regular handoff)**.** *Every residual-stability handoff of Definition 765.319 that reaches a real-facing source row must first pass through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic face, the* $\mathsf{StreamName}^{\uparrow}$ *observation face, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback face before the* $\mathsf{Real}^{\uparrow}$ *seal is consumed. Candidate-mediated strong-normalization evidence may be replayed along this route, but it cannot replace the regular readback by host equality, selected limits, quotient stream equality, or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateRealRegularHandoff`

Proof. Read the four L10 source faces in their displayed order. The dyadic arithmetic face supplies endpoint and radius data, the stream face supplies finite observation windows, and the regular-rational face supplies the readback row used before the real seal is opened.

Apply Definition 765.320. Candidate-mediated residual replay remains attached to the same L10 faces, so it cannot jump directly from a syntactic normalization row to a real-facing conclusion.

The $\mathsf{Real}^{\uparrow}$ boundary is therefore downstream of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$. The packet has no coordinate for host equality, selected limits, quotient stream equality, or ambient completeness, so the handoff remains a finite regular readback route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRealRegularHandoff`

Theorem 765.322 (MetaCIC candidate frontier nonescape)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, the candidate-mediated residual stability surface may be consumed only through the displayed frontier rows* S, N, U, H, C, P, L*, the obstruction and socket rows* O, D*, the residual substitution and diamond budget, and the L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. It cannot be used to erase the obstruction row, fill the discharge socket, or export closed subject reduction, arbitrary strong normalization, full confluence, beta-conversion decidability, quotient term equality, selected limits, host equality, or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierNonescape`

Proof. Begin with obstruction nonescape, Definition 765.207. It keeps O and D visible while candidate-mediated strong-normalization evidence is consumed.

Apply candidate residual stability, Definition 765.320. The residual substitution and diamond rows remain attached to the four L10 source faces and to the same frontier packet.

Use the real-regular handoff, Definition 765.321. Any real-facing read must pass through the dyadic, stream, and regular-rational faces before $\mathsf{Real}^{\uparrow}$ is consumed.

Once those displayed rows have been consumed, no remaining coordinate can supply the excluded global metatheoretic or real-completion principles. The frontier therefore closes only the finite residual-stability route named above and no larger claim. □

Theorem 765.323 (MetaCIC L10 residual dyadic route)**.** *Every candidate-frontier residual read used by* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *passes through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the finite* $\mathsf{StreamName}^{\uparrow}$ *observation window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{Real}^{\uparrow}$ *seal before it can be consumed by the residual substitution frontier. The route is part of the finite stability surface of Definition 765.319; it is not a quotient-stream equality, selected limit, host real equality, global normalization theorem, or ambient Real-completion principle.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10ResidualDyadicRoute`

Proof. Start with candidate residual stability, Definition 765.320. It keeps residual substitution and diamond-budget reads attached to the displayed packet and to the four L10 source faces.

Apply the real-regular handoff of Definition 765.321. Any real-facing source row must first expose the dyadic arithmetic face, then the stream observation face, then the regular-rational readback face, and only then the $\mathsf{Real}^{\uparrow}$ seal.

Finally use candidate frontier nonescape, Definition 765.322. Since the frontier can consume only the displayed residual rows, obstruction and socket rows, residual budget, and L10 faces, the dyadic tolerance ledger, finite observation window, regular readback, and seal remain visible until the residual substitution frontier consumes them. □

Theorem 765.324 (MetaCIC candidate residual L10 frontier route)**.** *Every candidate-frontier residual read used by* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *must expose* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data,* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal before the residual substitution frontier consumes it. The obstruction and discharge socket rows remain visible throughout the route, so the candidate-mediated frontier cannot replace the displayed L10 read by quotient stream equality, selected limits, host equality, ambient Real-completeness, arbitrary strong normalization, closed subject reduction, or global confluence.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateResidualL10FrontierRoute`

Proof. Begin with candidate residual stability, Definition 765.320. It keeps candidate-mediated strong-normalization evidence attached to the displayed residual rows and to the four L10 source faces.

Apply the real-regular handoff of Definition 765.321. A real-facing residual read therefore reaches $\mathsf{Real}^{\uparrow}$ only after the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows have been displayed.

Use candidate frontier nonescape, Definition 765.322. The obstruction and discharge socket rows remain visible while the residual frontier consumes the read, so the candidate route cannot erase or fill them.

Finally apply the L10 residual dyadic route, Definition 765.323. It identifies the dyadic tolerance ledger, finite observation window, regular readback, and Real seal as the visible route consumed by

the residual substitution frontier, excluding quotient stream equality, selected limits, host equality, ambient Real-completeness, and the larger metatheoretic principles listed above. □

Theorem 765.325 (MetaCIC L10 candidate discharge axis)**.** *Any* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer that discharges a candidate-mediated strong-normalization, confluence, or decidability obligation along the open L10 route must expose the candidate frontier row, a residual or substitution budget row, a typed-example coverage or gallery row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row, the* $\mathsf{StreamName}^{\uparrow}$ *row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, the* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *before the discharge can be public. The typed-example coverage and gallery rows are witnesses inside this finite route; they are not subject reduction, confluence, normalization, or decidability for all terms.*

Proof. Begin with candidate residual stability, Definition 765.320. It keeps candidate-mediated evidence attached to the displayed frontier rows and to the residual substitution budget.

Use the real-regular handoff and frontier nonescape, Definition 765.321 and Definition 765.322. These force every real-facing candidate read through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the $\mathsf{Real}^{\uparrow}$ seal while leaving the obstruction and discharge socket visible.

Apply the L10 residual dyadic route and the candidate residual L10 frontier route, Definition 765.323 and Definition 765.324. They identify the dyadic tolerance ledger, finite observation windows, regular readback, real seal, and residual frontier as the public route.

The typed-example coverage or gallery row can therefore only be replayed as a displayed witness along that route. Transport, continuation replay, provenance, and local naming preserve the same packet, so no row turns examples into global subject reduction, confluence, normalization, or decidability for all terms. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10CandidateDischargeAxis`

Theorem 765.326 (MetaCIC candidate residual budget interface)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

any candidate-mediated residual substitution, bounded confluence, or decidability read that reaches the critical-path normal-form endpoint must first expose the four L10 source rows

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

through the open-phase source ledger of Definition 765.155. The candidate rows, residual substitution rows, SN confluence-decidability budget, residual-budget socket, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row remain visible before any critical-path consumer reads the endpoint* N*. The interface exports no closed subject reduction, global confluence, beta-conversion decidability, full consistency, quotient term equality, selected limits, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the open-phase source ledger. Definition 765.155 lists the packet rows $S, N, O, U, D, H, C, P, L$ together with the four L10 source rows $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Attach the candidate residual stability surface, Definition 765.320. It keeps candidate-mediated residual substitution attached to the same four source faces and prevents the residual handoff from becoming a global confluence or decidability theorem.

Use the residual-confluence budget bridge, Definition 765.63, together with the SN confluence-decidability budget of Definition 765.193. These routes force residual substitution, bounded confluence, and decidability consumers through one finite ledger before any normal-form endpoint read is exported.

Finally apply the frontier nonescape route, Definition 765.322. It leaves only the displayed candidate rows, residual rows, socket budget, L10 source faces, transport, replay, provenance, and local naming. Since none of those rows carries the excluded metatheoretic or real-completion principles, the budget interface exposes exactly the stated source rows before N can be read. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateResidualBudgetInterface`

Theorem 765.327 (MetaCIC critical-path candidate residual discharge budget)**.** *For every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet*

$$K = (S, N, O, U, D, H, C, P, L),$$

a bounded residual-substitution discharge may consume the critical-path normal-form endpoint N only after the open-phase source ledger of Definition 765.155, the candidate residual stability surface of Definition 765.320, the residual-confluence budget bridge of Definition 765.63, the SN confluence-decidability budget of Definition 765.193, and the frontier nonescape route of Definition 765.322 are all visible. The discharge read remains a bounded packet route through the displayed source, residual, obstruction, socket, transport, replay, provenance, and local naming rows; it exports no global confluence, beta-conversion decidability, quotient term equality, host equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply Definition 765.326. It requires any candidate-mediated residual substitution, bounded confluence, or decidability read reaching N to expose the four L10 source rows through the open-phase source ledger before the endpoint is consumed.

Next use the candidate residual stability surface and the residual-confluence budget bridge. The stability theorem keeps residual substitution attached to the same candidate and L10 source faces, while the bridge keeps confluence-facing reads inside the finite residual ledger rather than turning them into global confluence or beta-conversion decidability.

Then add the SN confluence-decidability budget. That budget forces the strong-normalization, confluence, and decidability rows to remain a bounded handoff through the packet coordinates $S, N, O, U, D, H, C, P, L$, so quotient term equality and host equality have no separate source row.

Finally apply the frontier nonescape route. Its coordinate exhaustion leaves only the displayed candidate, residual, source, obstruction, socket, transport, replay, provenance, and naming rows, so selected limits and ambient $\mathsf{Real}^{\uparrow}$ completeness cannot be recovered from the discharge read. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateResidualDischargeBudget`

Theorem 765.328 (MetaCIC candidate-discharge visible residual route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated strong-normalization, confluence, or decidability consumer that reads the critical-path handoff through K must first expose the candidate row, residual-substitution row, normalization-budget row, bounded checker row, obstruction row O, discharge socket D, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}$ *row L. The route also keeps the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *visible until the consumer reaches the handoff.*

The visible-residual route exports no unconditional strong normalization, full Church–Rosser theorem, closed subject reduction, global conversion decidability, quotient syntax equality, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency claim.*

Proof. Start with candidate residual stability, Definition 765.320. It attaches candidate-mediated evidence to residual-substitution rows, leaves O, D visible, and keeps the four L10 faces on the same finite packet route.

Apply the candidate residual budget interface of Definition 765.326. This exposes the normalization-budget row, residual-budget socket, transport, replay, provenance, and local naming before any normal-form endpoint or critical-path handoff is read.

Finally use the residual diamond budget scope of Definition 765.339 together with the bounded checker factorization of Definition 765.195. These supply the bounded checker and local residual-diamond route while preserving the same candidate, obstruction, socket, L10, transport, replay, provenance, and NameCert rows. Since the cited surfaces contain none of the excluded global metatheoretic, quotient, completion, or consistency coordinates, the candidate-discharge consumer can read only the displayed visible-residual route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateDischargeVisibleResidualRoute`

Theorem 765.329 (MetaCIC visible residual socket exhaustion)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated strong-normalization, confluence, or decidability consumer that reads residual rows through the visible route must keep the discharge socket D and obstruction row O displayed until after candidate residual stability, residual budget, residual diamond budget, bounded checker factorization,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *have all been exposed.*

Consequently the visible-residual socket route refuses unconditional strong normalization, global confluence, subject reduction, conversion decidability, quotient term equality, $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, and kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathVisibleResidualSocketExhaustion`

Proof. Start with candidate residual stability from Definition 765.320. It names the residual rows through the candidate surface while keeping the obstruction row O and discharge socket D among the displayed coordinates.

Next apply the candidate residual budget interface of Definition 765.326 and the residual diamond budget scope of Definition 765.339. These rows expose the finite budget ledgers used by the residual consumer, but they do not replace the obstruction or discharge coordinates by a global metatheorem.

Finally use the bounded checker factorization of Definition 765.195. The factorization is read through the same hsame transport, Cont replay, Pkg provenance, and local NameCert rows, so the visible route is exhausted only after O and D remain visible through the full handoff. None of the cited rows exports the excluded normalization, confluence, reduction, decidability, quotient, completion, selection, or consistency claims. □

Theorem 765.330 (MetaCIC visible residual discharge budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated strong-normalization, confluence, or decidability consumer that treats the discharge socket D as filled must first expose candidate residual stability, the candidate residual budget, residual diamond budget scope, bounded*

checker factorization, the four L10 faces DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

The filled-socket read exports no unconditional strong normalization, full Church–Rosser theorem, closed subject reduction, global conversion decidability, quotient syntax equality, selected limits, ambient Real$^{\uparrow}$ *completeness, or kernel consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathVisibleResidualDischargeBudget`

Proof. Start with candidate residual stability from Definition 765.320. It keeps the candidate row attached to the residual-substitution route and leaves the discharge socket visible on the same packet as the four L10 faces.

Next apply the candidate residual budget interface of Definition 765.326. This supplies the finite budget row that a filled-socket consumer must display before reading any normalization, confluence, or decidability handoff.

The residual diamond budget scope of Definition 765.339 then bounds the diamond-facing part of the same route. The bounded checker factorization of Definition 765.195 supplies the checker-facing route without replacing candidate, obstruction, discharge, or L10 data by a global metatheorem.

Finally transport, replay, provenance, and local naming are read through H, C, P, L. Since the cited surfaces contain no unconditional normalization theorem, full Church–Rosser theorem, closed subject-reduction theorem, global conversion decision procedure, quotient syntax equality, selected-limit row, ambient Real$^{\uparrow}$ completeness theorem, or kernel-consistency coordinate, filling D is only the displayed discharge-budget boundary. □

Theorem 765.331 (MetaCIC visible residual local-decidability budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted MetaCICCriticalPath$^{\uparrow}$ *packet. Any bounded local decidability read through a candidate-mediated residual route must expose candidate residual stability, the candidate residual budget, residual diamond budget scope, bounded checker factorization, the four L10 faces* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *obstruction row O, discharge socket D, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row L before using a decidability-facing conclusion.*

The read exports no global conversion decidability, quotient syntax equality, selected limits, ambient Real$^{\uparrow}$ *completeness, or kernel consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathVisibleResidualLocalDecidabilityBudget`

Proof. First read the visible residual discharge route. The candidate-discharge route, socket exhaustion, and discharge budget theorems keep the candidate row, residual-substitution route, obstruction row O, discharge socket D, and the four L10 faces visible through the same finite packet.

Next apply the bounded checker factorization of Definition 765.195. It turns the local decidability-facing use into a bounded checker read, not a global conversion procedure.

Finally transport and replay through H, C, P, L. Since the cited rows never introduce quotient syntax equality, selected limits, ambient Real$^{\uparrow}$ completeness, or kernel consistency, the local decidability conclusion is available only inside the displayed finite residual budget. □

Theorem 765.332 (MetaCIC parallel-diamond visible residual consumer)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any consumer that routes a parallel-diamond or confluence handoff through the critical path must expose candidate residual stability, the residual-substitution row, normalization-budget row, bounded checker row, obstruction row* O*, discharge socket* D*, the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* NameCert *row* L *before it reads the confluence-facing handoff.*

The parallel-diamond read exports no premise-free confluence, subject reduction, quotient syntax equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathParallelDiamondVisibleResidualConsumer`

Proof. Start with the candidate-discharge visible residual route of Definition 765.328. It already exposes the candidate row, residual-substitution row, normalization budget, bounded checker, obstruction row, discharge socket, L10 faces, transport, replay, provenance, and local NameCert before any confluence-facing handoff is consumed.

Use socket exhaustion from Definition 765.329. A parallel-diamond consumer is still a bounded residual consumer, so it cannot hide O or D after naming a diamond-facing handoff.

Apply the discharge budget of Definition 765.330 and the local-decidability budget of Definition 765.331. These theorems keep the same finite residual rows visible for any filled-socket or checker-facing read.

Thus the parallel-diamond route has no additional premise-free confluence, subject-reduction, quotient-syntax, selected-limit, Real-completeness, or consistency coordinate. It can consume only the displayed visible-residual packet before reaching the confluence-facing handoff. □

Theorem 765.333 (MetaCIC residual-diamond local-confluence frontier)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any local-confluence read for* K *must expose the residual-substitution frontier, candidate-mediated strong-normalization frontier, residual-budget socket, bounded confluence checker, and the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before it reads* U*. The read is therefore a finite residual-diamond frontier over the displayed packet rows, not a global confluence theorem, beta-conversion decidability result, quotient equality of terms, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with Definition 765.305. It already binds residual substitution, candidate-mediated normalization, residual budget, bounded checker data, and L10 source rows to the same accepted packet route before any confluence-facing consumer can use the handoff.

Use residual diamond source totality, Definition 765.308. The local-confluence read may inspect U only after the closed-substitution boundary, residual-budget socket, candidate-mediated frontier, and source rows are all displayed on $S, N, O, U, D, H, C, P, L$.

Finally apply the L10 source separation theorem, Definition 765.309. The four source faces remain distinct rows throughout the residual-diamond route, so a checker that merges them, reconstructs them after reading U, or detaches the residual proof from the bounded budget leaves the accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondLocalConfluenceFrontier`

Theorem 765.334 (MetaCIC residual-schedule diamond)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet whose residual frontier and candidate schedule rows are both visible. Then the left and right residual contractions of the displayed critical-pair packet admit a local diamond budget: each contraction must re-enter the same candidate-mediated frontier before any strong-normalization, confluence, or decidability consumer may read* U*. The budget is local to the packet rows* $S, N, O, U, D, H, C, P, L$*; it does not claim global confluence, unconditional normalization, beta-decidability, quotient term equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the residual-diamond local-confluence frontier, Definition 765.333. It already forces every confluence-facing read to display the residual-substitution frontier, residual-budget socket, bounded checker data, and L10 source rows before U can be consumed.

Next use the candidate residual budget interface, Definition 765.337. Candidate rows and residual-budget rows stay attached to the same packet, while O, D and the four L10 faces remain visible.

Finally apply the candidate schedule discharge route of Definition 765.284. Since the schedule can be consumed only as a finite budget route with the discharge socket still displayed, both residual contractions must return through that candidate-mediated frontier before any downstream strong-normalization, confluence, or decidability consumer reads the packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualScheduleDiamond`

Theorem 765.335 (MetaCIC candidate-SN confluence handoff)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any local-confluence read that consumes both the residual-diamond frontier and the candidate-mediated strong-normalization frontier must expose* $S, N, O, U, D, H, C, P, L$ *and the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before* U *is consumed. The handoff remains a finite candidate-mediated boundary; it does not close subject reduction, arbitrary strong normalization, global confluence, beta-decidability, quotient term equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the residual-diamond local-confluence frontier, Definition 765.333. It requires the residual-substitution frontier, residual-budget socket, bounded checker data, and L10 source faces to remain visible before a local-confluence consumer reads U.

Next use the candidate-mediated strong-normalization frontier, Definition 765.198. Candidate evidence is read only as packet data on the displayed rows together with the same four L10 source faces, not as a closed normalization theorem.

Finally apply the L10 source separation theorem, Definition 765.309. Since the four source faces stay distinct and the residual and candidate rows remain attached to $S, N, O, U, D, H, C, P, L$, the handoff cannot export any of the excluded global metatheoretic, quotient, selected-limit, or Real-completeness principles. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateSNConfluenceHandoff`

Theorem 765.336 (MetaCIC residual-diamond source determinacy)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any local-confluence read that identifies the candidate-mediated strong-normalization frontier with the residual-diamond frontier must preserve* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *as four distinct L10 source rows before it consumes* U*. If the read merges those source faces, reconstructs one of them only after reading* U*, or treats their separation as an external side condition, then the read is outside the accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet.*

Proof. Apply the residual-diamond local-confluence frontier, Definition 765.333. It forces any confluence-facing read to display the residual-substitution frontier, residual-budget socket, bounded checker, and the four L10 source faces before U is available.

Next apply the candidate-SN confluence handoff, Definition 765.335. The candidate-mediated frontier and residual-diamond frontier are therefore consumed only as rows attached to the same displayed packet $S, N, O, U, D, H, C, P, L$.

Finally use the L10 source separation theorem, Definition 765.309. The four source faces remain separate rows throughout that shared route, so a read that merges them, rebuilds them after U, or places their separation outside the packet cannot be an accepted local-confluence read for K. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondSourceDeterminacy`

Theorem 765.337 (MetaCIC candidate residual-diamond lock)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any local-confluence read that uses both candidate-mediated strong-normalization data and residual-diamond data must keep the candidate rows, residual-budget rows, obstruction row* O*, discharge socket* D*, and the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *visible before* U *is consumed. The candidate frontier may support the handoff, but it cannot fill* D *or export closed subject reduction, global confluence, beta-decidability, quotient term equality, selected limits, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the residual-diamond local-confluence frontier, Definition 765.333. It places residual substitution, the residual-budget socket, bounded checker data, and the four L10 source faces before any local-confluence consumer may read U.

Next apply the candidate-SN confluence handoff, Definition 765.335, and residual-diamond source determinacy, Definition 765.336. These results force the candidate-mediated and residual-diamond rows to remain attached to the same packet $S, N, O, U, D, H, C, P, L$ while preserving the four L10 faces as separate source rows.

Now use candidate residual stability and frontier nonescape, Definition 765.320 and Definition 765.322. The candidate rows may carry the finite handoff, but they remain a displayed frontier over the same residual budget and cannot erase O, fill D, or detach the L10 source route.

Finally apply subject-reduction socket separation, Definition 765.27. Since D is a separate socket row and no displayed candidate or residual row is a subject-reduction certificate, the local-confluence read cannot export any of the excluded global metatheoretic, quotient, selected-limit, host-equality, or Real-completeness principles. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateResidualDiamondLock`

Theorem 765.338 (MetaCIC critical-path candidate residual local-diamond budget)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any candidate-mediated residual read that can feed a local-diamond or local-confluence consumer must expose residual substitution, the local diamond boundary, the bounded checker row, the obstruction row* O*, the discharge socket* D*, and the four L10 source rows* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before any confluence or decidability consumer reads the packet. The budget is a finite candidate-residual precondition; it is not a global Church–Rosser theorem, subject-reduction theorem, beta-decision procedure, quotient term equality, selected limit, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateResidualLocalDiamondBudget`

Proof. Start from the residual-diamond local-confluence frontier of Definition 765.333. It already forces residual substitution, residual-budget socket data, bounded checker data, and the four L10 source faces to appear before any local-confluence consumer reads U.

Next use the candidate residual-diamond lock of Definition 765.337. Candidate rows may support the finite handoff, but they remain attached to $S, N, O, U, D, H, C, P, L$ and cannot erase the obstruction row or fill the discharge socket.

Finally apply source determinacy, Definition 765.336. Since the four L10 source faces remain distinct rows and the bounded checker is read before the consumer-facing packet, the advertised budget is exactly a local candidate-residual precondition and does not export any of the excluded global metatheoretic or Real-completeness conclusions. □

Theorem 765.339 (MetaCIC critical-path residual diamond budget scope)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A candidate-mediated residual diamond read may enter the public critical-path route only after the packet exposes the candidate schedule, residual substitution budget, local join ledger, confluence checker factorization, and L10 source rows on the same route through* $S, N, O, U, D, H, C, P, L$*. The read is therefore a finite budget scope for the displayed packet; it is not a global strong-normalization theorem, global confluence theorem, beta-conversion decision procedure, quotient term equality, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, or kernel consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondBudgetScope`

Proof. Start with the residual-substitution diamond budget of Definition 765.305. It places residual substitution, candidate-mediated strong normalization, residual-budget socket data, and L10 source rows on one accepted packet route before a diamond or decidability consumer may read the handoff.

Next use the candidate residual budget interface, Definition 765.326. This forces the candidate rows and the four L10 source faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to remain visible before a critical-path endpoint is read.

Apply the residual-diamond local-confluence frontier together with the candidate-SN confluence checker factorization, Definition 765.333 and Definition 765.195. These theorems supply the local join ledger and checker factorization while keeping the checker inside the same finite packet route.

The displayed rows exhaust the residual diamond budget scope. Since no row carries global SN, global confluence, beta-decidability, quotient equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness,

or full consistency, the public MetaCICCriticalPath route can consume only the shown finite budget. □

Theorem 765.340 (MetaCIC residual diamond source-order lock)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every accepted residual-diamond consumer must read the candidate schedule, residual substitution budget, local join ledger, confluence checker factorization, and the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any confluence or decidability output is available. The locked route exports no full strong-normalization theorem, global confluence theorem, beta-decidability procedure, quotient equality, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, or consistency row.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondSourceOrderLock`

Proof. Start from Definition 765.339. It already places the candidate schedule, residual substitution budget, local join ledger, confluence checker factorization, and L10 source rows on one accepted packet route before a residual-diamond consumer can read the result.

Use the candidate-mediated L10 handoff, Definition 765.341. That handoff names the four source faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ and keeps them visible before local confluence or decidability is exported.

Apply the locality obstruction, Definition 765.342. If any L10 face is absent, the consumer has no packet coordinate from which to export the candidate-mediated local-confluence or decidability output.

Finally use the residual budget frontier, Definition 765.343. It repacks the same route as a finite frontier through $S, N, O, U, D, H, C, P, L$, and none of those rows carries full SN, global confluence, beta-decidability, quotient equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or consistency. □

Theorem 765.341 (Candidate-mediated residual diamond L10 handoff)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any accepted route that consumes the residual diamond budget and the candidate-SN confluence checker must expose the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before exporting local confluence or decidability consumers. The handoff exports no global strong-normalization theorem, global confluence theorem, beta-decidability procedure, quotient term equality, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, or full consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateMediatedResidualDiamondL10Handof`

Proof. Start from Definition 765.339. It already places the residual substitution budget, candidate schedule, local join ledger, confluence checker factorization, and L10 source rows on one accepted packet route.

Use the candidate residual budget interface, Definition 765.326. This keeps the candidate-mediated rows and the four L10 faces visible before a critical-path endpoint is read.

Now apply the checker factorization, Definition 765.195, together with the residual-diamond local-confluence frontier, Definition 765.333. These results route local confluence and decidability consumers through the displayed checker and local join ledger rather than through a detached global theorem.

Thus any accepted residual-diamond handoff must first display $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ on the same finite packet. Since none of the rows in K carries global SN, global confluence, beta-decidability, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or full consistency, those exports remain outside the handoff. □

Theorem 765.342 (MetaCIC residual diamond L10 locality obstruction)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. If the residual-diamond route for K lacks any one of the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$, *then the route cannot export the candidate-mediated local-confluence consumer or the candidate-mediated decidability consumer. The obstruction is local to the displayed packet route; it is not a global failure of strong normalization, global confluence, beta-conversion decidability, quotient term equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondL10LocalityObstruction`

Proof. Apply Definition 765.339. It puts the residual substitution budget, candidate schedule, local join ledger, checker factorization, and L10 source rows on one finite route before any residual-diamond consumer can read the packet.

Now use Definition 765.341. That handoff requires the four source faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before local confluence or decidability can be exported.

The same dependency is visible in the named candidate residual budget interface and in the candidate-SN confluence checker factorization, Definition 765.326 and Definition 765.195. Removing any one L10 face breaks the displayed route from candidate budget to checker output, so the consumer has no finite packet coordinate from which to export local confluence or decidability. □

Theorem 765.343 (MetaCIC critical-path residual budget frontier)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. The packet can export a residual-diamond consumer or a decidability consumer only when the candidate schedule, residual substitution budget, local join ledger, confluence checker factorization, and all four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *are displayed on the same finite route through $S, N, O, U, D, H, C, P, L$. The frontier exports no global strong-normalization theorem, global confluence theorem, beta-decidability procedure, quotient equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualBudgetFrontier`

Proof. First read the candidate-facing budget. The residual diamond budget scope of Definition 765.339 and the candidate residual budget interface of Definition 765.326 place the schedule, residual substitution budget, and candidate rows on the displayed packet route.

Next read the checker side. The candidate-SN confluence checker factorization of Definition 765.195 supplies the confluence checker route, while Definition 765.341 forces the four L10 faces to remain visible before any local confluence or decidability export.

Finally use the locality obstruction, Definition 765.342. If any one of the four L10 faces is absent from the finite route, the residual-diamond consumer and the decidability consumer have no packet coordinate from which to read their output.

The only surviving frontier is therefore the displayed same-route packet containing the candidate schedule, residual substitution budget, local join ledger, checker factorization, and the four L10 faces. Since no cited row carries global SN, global confluence, beta-decidability, quotient equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or consistency, none of those objects is exported. □

Theorem 765.344 (MetaCIC critical-path residual budget factorization)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any accepted packet route exporting a residual-diamond consumer or a decidability consumer factors through the candidate schedule, residual substitution budget, candidate residual budget interface, local join ledger, confluence checker factorization, and the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before the consumer reads the output. The factorization is a finite route inside K and exports no global strong-normalization theorem, global confluence theorem, beta-decidability procedure, quotient equality, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualBudgetFactorization`

Proof. Start from the residual diamond budget scope and the candidate residual budget interface, Definition 765.339 and Definition 765.326. These place the candidate schedule, residual substitution budget, candidate rows, and the four L10 source faces on the same accepted packet route.

Next read the checker side. The residual-diamond local-confluence frontier and the candidate-SN confluence checker factorization, Definition 765.333 and Definition 765.195, supply the local join ledger and checker factorization without leaving the displayed packet.

Finally apply the residual budget frontier, Definition 765.343. It states that a residual-diamond or decidability consumer can be exported only after the schedule, residual substitution budget, local join ledger, checker factorization, and all four L10 faces are present.

The required factorization is therefore the single finite route through those rows of K. Since none of the cited rows carries global SN, global confluence, beta-decidability, quotient equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or consistency, none of those objects is exported by the consumer route. □

Theorem 765.345 (MetaCIC critical-path residual budget L10 bridge)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any accepted residual-diamond budget route whose candidate-mediated strong-normalization handoff reaches an L10 completion consumer must factor through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{RealCompletionExactBoundaryUp}$ *row before any confluence or strong-normalization export is public.*

The bridge is a finite same-route dependency inside K. It exports no global strong-normalization theorem, global confluence theorem, beta-decidability procedure, quotient term equality, selected completion point, ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, or kernel consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualBudgetBridge`

Proof. Start from the residual diamond budget scope and the candidate-mediated L10 handoff, Definition 765.339 and Definition 765.341. These place the candidate schedule, residual substitution budget, local join ledger, checker factorization, and four L10 faces on one accepted packet route before any public consumer can read the result.

Next use the locality obstruction and frontier, Definition 765.342 and Definition 765.343. They rule out a residual-diamond consumer whenever any one of the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ faces is missing from the same finite route.

Now refine the completion-facing end of that route through the exact-boundary rows. The RealCompletionExactBoundaryUp route of Definition 1120.4 and Definition 1120.13 requires the StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, and terminal Real seal to be displayed together before a completion-facing terminal consumer can read the endpoint.

Finally apply the residual budget factorization of Definition 765.344. Since the MetaCIC route has no coordinate for a selected completion point, quotient term equality, ambient completeness, global confluence, global SN, or kernel consistency, the only public bridge is the finite L10 route through the displayed tolerance, window, readback, seal, and exact-boundary rows. □

Theorem 765.346 (MetaCIC residual completion exactness handoff)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any residual-diamond budget route for K that reaches a completion-facing consumer must factor through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and* RealCompletionExactBoundaryUp *exactness rows before exporting local confluence or decidability.*

The handoff is a finite route inside the displayed packet. It exports no global strong-normalization theorem, global confluence theorem, beta-decidability procedure, quotient term equality, selected completion point, ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, or kernel consistency claim.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualCompletionExactnessHandoff`

Proof. Start from the residual budget bridge of Definition 765.345. It already places the completion-facing consumer after the DyadicRatCore tolerance ledger, StreamName window, RegSeqRat readback, terminal Real seal, and RealCompletionExactBoundary row.

Next apply the residual budget factorization of Definition 765.344. This keeps the candidate schedule, residual substitution budget, local join ledger, confluence checker factorization, and four L10 faces on one accepted packet route before any local confluence or decidability consumer is read.

Now use the exact-boundary route, Definition 1120.4 and Definition 1120.13. These theorems force every completion-facing endpoint through the displayed StreamName, RegSeqRat, DyadicRatCore, and terminal Real rows together with the RealCompletionExactBoundary structural rows.

Thus the residual-diamond route can export local confluence or decidability only after the exact completion handoff has been displayed. Since none of the cited rows carries global SN, global confluence, beta-decidability, quotient equality, a selected completion point, ambient Real completeness, or kernel consistency, those objects remain outside the accepted packet route. □

Theorem 765.347 (MetaCIC residual diamond completion nonescape)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. After candidate-mediated residual diamond data for K factors through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* RealCompletionExactBoundaryUp, *the remaining residual-redex obligation is still read only through the displayed MetaCIC candidate rows, confluence-boundary rows, substitution-boundary rows, and completion-exactness rows of K.*

Consequently the completion-facing handoff does not export closed Church–Rosser, global normalization, quotient term equality, selected completion points, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency. It exports only the finite same-route residual-redex obligation visible in the candidate, confluence-boundary, substitution-boundary, and exactness ledgers.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondCompletionNonescape`

Proof. Start with the residual diamond budget scope and the source-order lock, Definition 765.339 and Definition 765.340. These force the candidate schedule, residual substitution budget, local join ledger, confluence checker factorization, and L10 source faces to remain on one displayed packet route.

Apply the candidate-mediated L10 handoff and the locality obstruction, Definition 765.341 and Definition 765.342. They prevent a residual-diamond consumer from being read unless the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces are present on the same route.

Now use the residual budget factorization and the completion exactness handoff, Definition 765.344 and Definition 765.346. The factorization keeps the candidate, confluence-boundary, and substitution-boundary rows visible, while the exactness handoff places the $\mathsf{RealCompletionExactBoundaryUp}$ row at the completion-facing end of the route.

The remaining residual-redex obligation is therefore the same finite obligation inside K. Since none of the cited rows contains closed Church–Rosser, global normalization, quotient term equality, selected completion points, ambient $\mathsf{Real}^{\uparrow}$ completeness, or kernel consistency, none of those objects is exported by the completion-facing handoff. □

Theorem 765.348 (MetaCIC critical-path mature L10 source package)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every consumer that combines the MetaCIC residual budget, confluence budget, and candidate-mediated strong-normalization budget must consume the L10 source ledger only through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *dependency rows. The route may read residual substitution, local diamond data, bounded checker rows, candidate frontier rows, obstruction row* O*, discharge socket* D*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming, but it has no fifth source face, quotient term equality, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, global confluence theorem, global beta-conversion decision procedure, or closed subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathMatureL10SourcePackage`

Proof. Start with the real-completion source budget of Definition 765.296. It places every confluence-facing or decidability-facing consumer downstream of the four L10 source rows and keeps the closure trace, critical-pair ledger, normalization frontier, discharge socket, and budget rows on the same source route.

Next apply the Phase Real source obligations of Definition 765.165. They require the dyadic finite-observation row, stream schedule, regular-rational readback, and Real seal to remain separate before any discharge socket, confluence-decidability handoff, obstruction boundary, or downstream readiness boundary is consumed.

Now attach the candidate-mediated strong-normalization frontier through Definition 765.198. The candidate row is a displayed frontier for the same packet, not a replacement for any of the four L10 source faces.

The visible residual route of Definition 765.328 and the residual diamond budget scope of Definition 765.339 then bind residual substitution, local diamond data, bounded checker rows, obstruction, socket, transport, replay, provenance, and local naming to the same finite route. Since each cited surface keeps $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ visible as the only L10 source ledger, the combined package exports only that displayed dependency route. □

Theorem 765.349 (MetaCIC critical-path L10 source candidate frontier)**.** *Every candidate-mediated strong-normalization frontier consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must keep the four L10 source rows* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *visible while reading residual substitution, local diamond, bounded checker, obstruction, and discharge socket rows. The frontier may consume those rows as displayed finite evidence attached to the packet, but it may not retype them as a fifth source face, quotient term equality, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, global confluence theorem, global beta-conversion decision procedure, or closed subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10SourceCandidateFrontier`

Proof. Start with Definition 765.348. It already binds the combined residual, confluence, and candidate-mediated strong-normalization budget to the four displayed L10 source rows.

Apply Definition 765.198. The candidate-mediated frontier is read as a row of the accepted packet, so it cannot replace $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ by a detached normalization theorem.

Use Definition 765.328. Residual substitution and discharge-socket reads remain visible along the same finite route rather than becoming hidden premises of the candidate frontier.

Finally apply Definition 765.339. Local diamond and bounded checker rows are scoped budget data attached to the same packet, while obstruction and socket rows remain displayed. Thus every candidate-mediated frontier consumer keeps the four L10 source rows visible and exports none of the excluded global MetaCIC or completion principles. □

Theorem 765.350 (MetaCIC mature L10 source socket separation)**.** *Every accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet that reads the mature L10 package must keep* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *as four separate source faces. The visible obstruction rows and discharge socket rows remain undischarged unless the packet also displays a separate closed subject-reduction row. Residual, confluence, and candidate-mediated strong-normalization rows are budget data attached to the source package; they are not themselves a closed subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathMatureL10SourceSocketSeparation`

Proof. Apply Definition 765.348. It binds the mature source package to the four displayed L10 faces and excludes quotient term equality, selected limits, ambient completeness, global confluence, global beta-conversion decision, and closed subject reduction.

Apply Definition 765.349. The candidate frontier may read residual substitution, local diamond, bounded checker, obstruction, and discharge socket rows only while the four L10 source rows remain visible.

The obstruction and discharge socket rows therefore record what is still exposed at the packet boundary. A closed subject-reduction conclusion would require its own displayed row. Without that row, residual, confluence, and candidate-mediated strong-normalization data remain scoped budgets for the source package rather than a proof that subject reduction has been closed. □

Theorem 765.351 (MetaCIC critical-path frontier companion)**.** *Every* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *frontier consumer that invokes the L10 source package must display the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{Real}^{\uparrow}$ *seal before it uses any candidate-mediated normalization row or residual-diamond row. The companion route keeps those four L10 rows inside the same packet rows* $S, N, O, U, D, H, C, P, L$ *and exports no quotient stream equality, selected limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, global normalization theorem, closed subject-reduction theorem, or detached residual-diamond theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierCompanion`

Proof. Start with the L10 four-object exit certificate of Definition 765.128. It identifies the Phase Real and Completion source surface with exactly the dyadic tolerance row, StreamName finite schedule, RegSeqRat readback, and Real seal attached to the accepted packet.

Apply the mature L10 source package theorem, Definition 765.348. That theorem requires residual-budget, confluence-budget, and candidate-mediated strong-normalization consumers to read the L10 source ledger only through those four displayed rows.

Now place the frontier consumer after that source package. Candidate-mediated normalization rows and residual-diamond rows may be read only while $S, N, O, U, D, H, C, P, L$ and the four L10 source faces remain visible on the same route.

Since the packet contains no coordinate for quotient stream equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, global normalization, closed subject reduction, or a detached residual-diamond theorem, the frontier companion exports only the displayed L10 dependency route. □

Theorem 765.352 (MetaCIC critical-path mature package consumer)**.** *Every mature-package consumer of an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet reads the cited L10 source ledger only through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before it consumes residual substitution, local diamond, bounded checker, candidate frontier, obstruction, discharge socket, transport, replay, provenance, and local naming rows. In carrier notation the consumer remains on the displayed packet route*

$$K = (S, N, O, U, D, H, C, P, L),$$

together with the four L10 source faces named by the mature package of Definition 765.348. The route exports no quotient stream, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness, global confluence theorem, global beta-conversion decision procedure, closed subject-reduction theorem, or hidden fifth source face.*

Proof. Start with the mature L10 source package. Theorem 765.348 requires every residual, confluence, and candidate-mediated strong-normalization consumer to keep $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ visible as the only L10 source faces.

Next use the L10 source candidate frontier and mature source socket separation. Theorems 765.349 and 765.350 keep residual substitution, local diamond data, bounded checker rows, obstruction rows, and discharge sockets attached to the same displayed packet rather than to a quotient stream or selected limit.

Finally apply the mature consumer synthesis of Definition 765.374. It packages the confluence frontier, normalization frontier, substitution boundary, typed-example row, bounded checker route, and the four L10 faces as one consumer surface. Since none of those cited rows contains a quotient stream, selected limit, ambient completeness theorem, global confluence theorem, global beta-conversion decider, closed subject-reduction theorem, or fifth source face, the mature consumer receives only the displayed finite route. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathMaturePackageConsumer

The MetaCICCriticalPath$^{\uparrow}$ mature package status named by the hub mature marker is read through the existing child routes for candidate-mediated strong normalization, confluence, decidability, residual diamond scope, and L10 source packages. In particular, Definition 765.368, Definition 765.348, Definition 765.349, and Definition 765.350 keep the mature read on the displayed packet rows while preserving the open subject-reduction socket, the residual-diamond budget, and the four source faces DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$. The status exports no closed subject reduction, global Church–Rosser theorem, quotient term equality, selected limit, or ambient Real$^{\uparrow}$ completeness.

Theorem 765.353 (MetaCIC critical-path parallel-diamond frontier handoff)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted MetaCICCriticalPath$^{\uparrow}$ *packet. Suppose a parallel-diamond discharge request for K consumes the candidate-mediated strong-normalization frontier, the residual substitution budget, the local diamond witness, and the L10 four-object source ledger for* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*. Then the request factors through the displayed candidate frontier before it can be read as a confluence consumer or a normalization consumer.*

The handoff is a finite same-packet route through $S, N, O, U, D, H, C, P, L$. It does not export subject reduction, global Church–Rosser, host beta equality, evidence-free strong normalization, quotient term equality, selected limits, ambient Real$^{\uparrow}$ *completeness, or kernel consistency.*

Proof. First read the candidate side. The candidate-mediated SN frontier of Definition 765.198 and the candidate discharge frontier of Definition 765.278 place the normalization candidate and its discharge rows on the displayed critical-path packet before any public consumer can use them.

Next attach the residual and diamond budget. The residual substitution diamond budget, the residual-diamond local-confluence frontier, and the residual diamond budget scope keep the residual substitution rows, local join witness, checker factorization, and residual readback on the same finite route.

Finally attach the L10 ledger. The four-object exit certificate and the residual completion exactness handoff force every completion-facing read through DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ before a confluence or normalization endpoint can be read.

Thus a parallel-diamond discharge request reaches its endpoint only through the displayed candidate frontier followed by the residual, local-diamond, and L10 rows of K. Since the cited route has no coordinate for subject reduction, global Church–Rosser, host beta equality, evidence-free strong normalization, quotient term equality, selected limits, ambient Real$^{\uparrow}$ completeness, or kernel consistency, none of those claims is exported. □

Lean4 ✓ BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathParallelDiamondFrontierHandoffCertificate

Theorem 765.354 (MetaCIC mature L10 parallel-diamond route)**.** *Every parallel-diamond discharge request that reaches the mature* MetaCICCriticalPath$^{\uparrow}$ *route must first read the candidate-mediated strong-normalization frontier, the residual substitution diamond budget, and the L10 four-object source ledger for* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*. The resulting route is the displayed dependency path from Definition 765.353 through the mature L10 source package of Definition 765.348; it is not a proof of global Church–Rosser, subject reduction, kernel consistency, quotient term equality, selected limits, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with Definition 765.353. It forces any parallel-diamond discharge request to pass through the candidate-mediated strong-normalization frontier, residual substitution budget, local diamond witness, and four-object L10 source ledger before a confluence or normalization consumer can read it.

Now apply Definition 765.348. The mature package keeps $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as separate source faces while residual, confluence, and candidate-mediated strong-normalization rows remain budget data attached to the same packet.

The two routes have the same carrier $K = (S, N, O, U, D, H, C, P, L)$ and the same structural rows. Composing them therefore gives a single L10-facing dependency route for mature parallel-diamond discharge requests. Since neither cited theorem contains a row for global Church–Rosser, subject reduction, kernel consistency, quotient term equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the composed route exports none of those claims. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathMatureL10ParallelDiamondRoute`

Theorem 765.355 (MetaCIC residual-diamond candidate readback route)**.** *Every residual-diamond candidate read that reaches the mature* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *route must first pass through the candidate-mediated strong-normalization frontier, the residual substitution budget, the local diamond witness, and the L10 four-object source ledger for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Only after those rows are displayed may the read be consumed as normalization-facing or confluence-facing evidence.*

The route is a finite readback over the same accepted packet $K = (S, N, O, U, D, H, C, P, L)$*. It does not export subject reduction, global Church–Rosser, kernel consistency, quotient term equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a theorem identifying candidate readback with host confluence.*

Proof. Start with the parallel-diamond frontier handoff of Definition 765.353. It forces a discharge request to display the candidate-mediated strong-normalization frontier, residual substitution budget, local diamond witness, and four-object L10 source ledger before the request can be read by a confluence or normalization consumer.

Now apply the mature L10 route of Definition 765.354. It keeps the same four L10 source faces, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, on the mature critical-path package rather than replacing them by an ambient completion or confluence theorem.

Composing the two routes gives the stated residual-diamond candidate readback route. The first theorem supplies the candidate, residual, and local-diamond order; the second theorem keeps the read on the mature L10 source ledger.

The composed route has only the rows of K and the four displayed L10 source faces. Since neither component route contains subject reduction, global Church–Rosser, kernel consistency, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or host confluence equality, the readback exports none of those claims. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondCandidateReadbackRoute`

Theorem 765.356 (MetaCIC parallel-diamond candidate frontier formal target)**.** *Any formal target for the mature* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet must expose the candidate-mediated strong-normalization frontier, the residual substitution budget, the local diamond witness, and the L10 four-object source ledger for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before it is read as confluence-facing or normalization-facing evidence. The target must keep those four rows visible as the candidate frontier of the accepted packet* $K = (S, N, O, U, D, H, C, P, L)$*; it is not*

a theorem of global Church–Rosser, subject reduction, kernel consistency, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or host confluence readback.*

Proof. Use the parallel-diamond frontier handoff of Definition 765.353. It identifies the candidate-mediated strong-normalization frontier, residual substitution budget, local diamond witness, and four-object L10 source ledger as the rows a discharge request must display before any confluence or normalization consumer reads the packet.

Next apply the mature L10 route of Definition 765.354. It keeps $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as source faces on the same mature critical-path package rather than replacing them by a completion or confluence theorem.

Finally apply the residual-diamond candidate readback route of Definition 765.355. It composes the candidate frontier, residual budget, local diamond witness, and L10 ledger into the readback order required by confluence-facing and normalization-facing consumers.

The formal target is therefore exactly the visibility obligation for those displayed rows of K. Since the three component routes contain no row for global Church–Rosser, subject reduction, kernel consistency, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or host confluence readback, the target exports none of those endpoint claims. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathParallelDiamondCandidateFrontierFormalTa`

Theorem 765.357 (MetaCIC parallel-diamond frontier readiness envelope)**.** *A critical-path consumer may read the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *parallel-diamond frontier only after the finite residual witness, candidate-normalization frontier, residual-substitution boundary, L10 source ledger, and closed frontier rows are all displayed. For an accepted packet* $K = (S, N, O, U, D, H, C, P, L)$*, the readiness envelope is the ordered surface consisting of the candidate-mediated strong-normalization frontier, residual substitution budget, local diamond witness, four-object L10 ledger for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, and the closed frontier rows already used by the mature critical-path package.*

The envelope is a precondition for confluence-facing and normalization-facing reads. It does not claim full closed Church–Rosser, unconditional substitution compatibility, subject reduction, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICParallelDiamondFrontierReadinessEnvelope`

Proof. First read the parallel-diamond frontier handoff of Definition 765.353. It places the candidate frontier, residual substitution budget, local diamond witness, and L10 source ledger on the displayed packet before any confluence or normalization consumer reads it.

Next read the mature L10 route of Definition 765.354. It keeps $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ visible as source faces of the mature critical-path package, together with the closed frontier rows supplied by Definition 765.348.

Finally read the residual-diamond candidate readback route of Definition 765.355. It composes the residual witness, candidate normalization, residual boundary, local diamond witness, and L10 ledger into the readback order required by the formal target of Definition 765.356.

The resulting envelope is exactly the displayed readiness surface for K. Since the cited routes retain their refused endpoints, the envelope does not become full closed Church–Rosser, unconditional substitution compatibility, subject reduction, quotient term equality, selected limits, ambient completeness, or kernel consistency. □

Theorem 765.358 (MetaCIC parallel-diamond retained-frontier scope)**.** *A candidate-mediated strong-normalization or confluence consumer that reads the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *readiness envelope must retain the residual-substitution budget, the local diamond witness, and the L10 source ledger for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *through every such read. The retained frontier is the same packet surface displayed by the mature L10 parallel-diamond route, the residual-diamond candidate readback route, the parallel-diamond candidate frontier formal target, and the readiness envelope; it is not a claim of full Church–Rosser, subject reduction, quotient term equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Proof. First apply Definition 765.354. It keeps the candidate-mediated frontier, the residual substitution budget, and the four-object L10 ledger on the mature critical-path route.

Next apply Definition 765.355. It makes the local diamond witness and residual readback visible before a normalization-facing or confluence-facing consumer can use the packet.

Then apply Definition 765.356 and Definition 765.357. These two statements turn the same rows into the formal target and readiness precondition for every candidate-mediated read.

Therefore no consumer of the readiness envelope can discard the residual-substitution budget, local diamond witness, or L10 source ledger while still remaining on the accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ frontier. The cited routes contain no row for full Church–Rosser, subject reduction, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or kernel consistency, so none of those endpoints is exported by the retained-frontier scope. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICParallelDiamondRetainedFrontierScope`

Theorem 765.359 (MetaCIC parallel-diamond frontier seed status)**.** *Every* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer that prepares a strong-normalization or confluence read from the parallel-diamond frontier must first read that frontier through the retained seed/status route. For an accepted packet* $K = (S, N, O, U, D, H, C, P, L)$, *the route consists of the parallel-diamond handoff, the readiness envelope, and the retained-frontier scope; only after these rows have fixed the candidate-mediated strong-normalization frontier, residual-substitution budget, local diamond witness, and L10 source ledger may the consumer pass to an SN-facing or confluence-facing endpoint.*

Proof. Start with Definition 765.353. It forces every parallel-diamond discharge request to display the candidate-mediated frontier, residual budget, local diamond witness, and L10 source ledger before a normalization or confluence consumer reads it.

Next apply Definition 765.357. The readiness envelope records these rows as the seed/status surface of the accepted packet rather than as a hidden global theorem.

Finally use Definition 765.358. It keeps the residual-substitution budget, local diamond witness, and L10 source ledger retained through every candidate-mediated read. Thus SN-facing and confluence-facing consumers can only use the parallel-diamond frontier after passing through the displayed seed/status route. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICParallelDiamondFrontierStatusSeed`

Theorem 765.360 (MetaCIC critical-path parallel-diamond frontier handoff scope)**.** *Every consumer of Definition 765.353 must retain the candidate-mediated strong-normalization frontier, residual-substitution budget, local diamond witness, and L10 source ledger through the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before it can read the packet as confluence-facing or normalization-facing evidence. The retained scope is the same accepted packet surface used by the mature L10 route, the residual-diamond candidate readback route, the readiness envelope, and the retained-frontier scope; it is not a claim of global Church–Rosser, subject reduction, quotient term equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or MetaCIC kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathParallelDiamondFrontierHandoffScope`

Proof. Start with Definition 765.353. It places the candidate-mediated strong-normalization frontier, residual-substitution budget, local diamond witness, and four-object L10 source ledger on the displayed critical-path packet before a confluence or normalization consumer can read it.

Now apply the mature L10 route of Definition 765.354 and the residual-diamond candidate readback route of Definition 765.355. These two routes keep the same residual and local-diamond rows attached to the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source ledger.

Finally use the readiness envelope and retained-frontier scope, Definition 765.357 and Definition 765.358. They identify the visible rows that any candidate-mediated read must keep through the consumer interface.

Thus a consumer of the handoff can only pass to an SN-facing or confluence-facing endpoint after retaining the displayed frontier rows. Since the cited routes contain no row for global Church–Rosser, subject reduction, quotient term equality, selected limits, ambient Real completeness, or kernel consistency, the scoped handoff exports none of those endpoints. □

Theorem 765.361 (MetaCIC parallel-diamond candidate-mediated SN readback)**.** *Any SN-facing readback that consumes the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *parallel-diamond frontier must preserve the candidate-mediated normalization row, the residual substitution budget, the local diamond witness, and the L10 four-object source ledger for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before it reads a confluence endpoint. For an accepted packet* $K = (S, N, O, U, D, H, C, P, L)$*, the readback is therefore a same-packet route through the parallel-diamond handoff scope, the readiness envelope, the retained-frontier scope, and the mature L10 route.*

The route does not claim global Church–Rosser, subject reduction, MetaCIC kernel consistency, quotient equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICParallelDiamondCandidateMediatedSNReadback`

Proof. Start with the parallel-diamond frontier handoff scope of Definition 765.360. It requires every consumer of the handoff to retain the candidate-mediated strong-normalization frontier, residual-substitution budget, local diamond witness, and L10 source ledger before reading the packet as confluence-facing or normalization-facing evidence.

Next use the readiness envelope of Definition 765.357. The envelope identifies those rows as the finite precondition for any critical-path read of the parallel-diamond frontier.

Now apply the retained-frontier scope of Definition 765.358. It prevents an SN-facing readback from dropping the residual budget, local diamond witness, or L10 ledger while it remains on the candidate-mediated route.

Finally compose with the mature L10 parallel-diamond route of Definition 765.354. The composed route keeps $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as visible source faces of K, so the SN-facing readback reaches any endpoint only through the displayed frontier and exports none of the excluded global claims. □

Theorem 765.362 (MetaCIC critical-path diamond-frontier consumer)**.** *Any* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *read that consumes* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *must keep the residual-substitution premise, critical-pair, candidate-join, bounded-check, obstruction, discharge-socket, transport, replay, provenance, and local naming rows visible before the normal-form consistency consumer may inspect the handoff. The read is therefore a candidate-mediated frontier consumer, not a proof of subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDiamondFrontierConsumer`

Proof. First keep the critical-path boundary visible. Apply Definition 765.2 together with Definition 765.3 and Definition 765.25. These theorems route a consistency-facing consumer through the displayed critical-path packet while preserving the obstruction row and the discharge socket before the normal-form endpoint can be read.

Next attach the parallel-diamond frontier. Use Definition 4238.12, Definition 4238.4, Definition 4238.31, and Definition 4238.20. These results keep the residual-substitution premise, critical pair, candidate join, and bounded checker rows inside the $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ packet.

Finally compose the two consumer routes. The frontier handoff of Definition 765.353 and the candidate-mediated strong-normalization socket of Definition 4238.41 place the frontier rows on the same critical-path read before the normal-form consistency consumer inspects the handoff. Since neither component route supplies subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency, the composed consumer exports none of those claims. □

Theorem 765.363 (MetaCIC critical-path L10 source-ledger readback)**.** *Any* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer that reads the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *frontier must expose the L10 source ledger*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

before it may use the residual witness, critical pair, local join, bounded checker, obstruction, transport, replay, provenance, and local $\mathsf{NameCert}$ *rows. The readback is therefore a finite source-ledger boundary for the critical path; it is not subject reduction, full Church–Rosser, evaluator equality, quotient equality, global normalization, kernel consistency, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the diamond-frontier consumer route, Definition 765.362. It keeps the parallel-diamond frontier visible before a critical-path consumer may inspect the normal-form-facing handoff.

Apply frontier nonescape, Definition 765.365. This places the L10 source ledger beside the residual-substitution, critical-pair, candidate-join, bounded-check, obstruction, transport, replay, provenance, and local naming rows.

Next use the residual handoff and residual witness consumption routes, Definition 765.366 and Definition 765.367. These force the residual witness to be read as displayed frontier data rather than as a global confluence or normalization theorem.

Finally use the checked parallel-diamond frontier handoff, Definition 765.364. Its residual witness, critical pair, local join, bounded checker, obstruction, L10 source ledger, transport, replay, provenance, and local naming rows are exactly the rows exposed by the frontier-handoff route. Since each component route keeps the L10 rows displayed and none supplies subject reduction, full Church–Rosser, evaluator equality, quotient equality, global normalization, kernel consistency, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness, the composed readback exports none of those endpoints. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10SourceLedgerReadback`

Theorem 765.364 (MetaCIC critical-path parallel-diamond frontier consumer)**.** *Every* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *source-ledger read that consumes the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the residual-join row, candidate-normalization row, critical-pair row, obstruction-retention row, and finite handoff row before exporting any strong-normalization, confluence, or decidable-conversion budget. The consumer route is therefore a finite critical-path dependency over the parallel-diamond frontier, not a discharge of residual substitution, subject reduction, global Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Start with the critical-path side. Use Definition 765.362 and Definition 765.365. These results force the source ledger to keep the parallel-diamond frontier visible before any normal-form, confluence, or normalization consumer can read the handoff.

Next read the frontier packet itself. The residual-substitution scope, critical-pair exhaustion, local-join scope, closed-checker retention, and candidate-mediated strong-normalization socket named in the MetaCICParallelDiamondFrontier$^{\uparrow}$ chapter display the residual-join, candidate-normalization, critical-pair, obstruction-retention, and bounded handoff rows as finite carrier data.

Finally compose the two ledgers. Since the critical-path consumer receives only those displayed rows through transport, replay, provenance, and local naming, the exported budget remains downstream of the frontier handoff. No row in the composed route supplies residual-substitution discharge, subject reduction, global Church–Rosser, evaluator equality, quotient term equality, decidable conversion, strong normalization, or kernel consistency. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathParallelDiamondFrontierHandoff`

Theorem 765.365 (MetaCIC critical-path frontier consumer nonescape)**.** *Any normal-form, confluence, or normalization consumer of the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *frontier inside a* MetaCICCriticalPath$^{\uparrow}$ *read must first expose the residual-substitution, critical-pair, candidate-join, bounded-check, obstruction, discharge-socket, L10 source ledger, transport, replay, provenance, and local naming rows. Consequently the frontier exports no subject reduction, global Church–Rosser theorem, evaluator equality, quotient term equality, kernel consistency, selected limits, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathFrontierConsumerNonescape`

Proof. Start from Definition 765.362. It places the parallel-diamond frontier on the critical-path read before any normal-form consistency consumer can inspect the handoff.

Use the parallel-diamond handoff theorems cited there. The residual-substitution, critical-pair, candidate-join, and bounded-check rows remain visible as finite frontier data rather than becoming a global confluence theorem.

Then combine the mature L10 source package already named by the critical-path route with the obstruction, discharge-socket, transport, replay, provenance, and local naming rows. This is a carrier inventory: each downstream consumer receives only the displayed rows, so none of the refused global metatheoretic or Real-completeness endpoints can escape the packet boundary. □

Theorem 765.366 (MetaCIC critical-path residual handoff)**.** *Any accepted* MetaCICCriticalPath$^{\uparrow}$ *read consuming the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must retain the residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, checker row, bounded-check row, obstruction row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows named by chapter 4238 before passing the handoff to the critical-path consumer. The residual handoff is therefore a finite frontier route into the critical path, not full Church–Rosser, subject reduction, evaluator equality, quotient term equality, global normalization, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualHandoff`

Proof. Start with Definition 765.362 and Definition 765.365. These keep the parallel-diamond frontier visible inside the critical-path read before any normal-form, confluence, or normalization consumer may inspect the handoff.

Next use the public and scoped frontier exports from chapter 4238, in particular Definition 4238.47 and Definition 4238.48. They identify the consumed packet as the finite route through

the residual-substitution premise, critical pair, candidate join, residual frontier, checker, bounded check, obstruction, transport, replay, provenance, and local naming rows.

Finally compose the two readings. The critical-path consumer receives exactly those retained frontier rows, so the residual premise and obstruction remain visible at the handoff boundary. Since neither component supplies full Church–Rosser, subject reduction, evaluator equality, quotient term equality, global normalization, or kernel consistency, the composed handoff exports none of those endpoints. □

Theorem 765.367 (MetaCIC critical-path residual witness consumption)**.** *Any* MetaCICCriticalPath$^{\uparrow}$ *read that consumes the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *residual handoff must expose a concrete residual witness row, critical-pair row, candidate-join row, bounded checker row, obstruction row,* hsame *transport,* Cont *replay,* Pkg *provenance, local* NameCert *row, and the L10 source ledger before any normal-form or confluence consumer may inspect it. The route therefore does not export subject reduction, global Church–Rosser, evaluator equality, quotient term equality, global normalization, kernel consistency, selected limits, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualWitnessConsumption`

Proof. Start with Definition 765.366. It keeps the residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, checker rows, obstruction row, transport, replay, provenance, and local naming rows visible at the critical-path boundary.

Next read the frontier exports cited in that handoff. The public export of Definition 4238.47 and the scoped closure status of Definition 4238.48 identify the handoff as a finite frontier packet rather than a global confluence or consistency theorem.

The extra consumer precondition is the concrete residual witness row. Placing that row beside the critical-pair, candidate-join, bounded-checker, obstruction, structural, and L10 source-ledger rows forces a normal-form or confluence consumer to read a displayed witness packet before it can inspect the handoff.

Since all consumed data are displayed rows of the finite frontier and critical-path ledgers, the route has no coordinate for subject reduction, global Church–Rosser, evaluator equality, quotient term equality, global normalization, kernel consistency, selected limits, or ambient Real$^{\uparrow}$ completeness. □

Theorem 765.368 (MetaCIC candidate schedule mature package)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted MetaCICCriticalPath$^{\uparrow}$ *packet. A mature candidate schedule package is readable only after the candidate schedule discharge of Definition 765.290, the residual-budget discharge frontier of Definition 765.288, and the L10 source package of Definition 765.348 have all been exposed on the same packet. The package may route candidate-mediated strong normalization, residual substitution, local diamond data, bounded checker rows, and the four L10 source faces* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *but it exports no subject-reduction theorem, global Church–Rosser theorem, quotient term equality, kernel consistency claim, selected limit, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Begin with the candidate schedule discharge. It forces the candidate-mediated schedule to display candidate-set normalization, critical-pair ledger, residual-substitution boundary, finite observation confluence, and subject-reduction socket rows before the schedule is treated as discharged.

Next attach the residual-budget frontier. The residual route requires residual-budget rows, substitution-boundary rows, closed-premise ledger rows, and local-diamond rows on the same packet rows $S, N, O, U, D, H, C, P, L$ before the discharge socket can be read.

Finally attach the mature L10 source package. That route keeps $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as the four visible source faces while residual, confluence, and candidate-mediated strong-normalization rows remain budget data attached to the packet.

The three routes share the same carrier and structural rows. Their combined read is therefore a candidate schedule mature package, not a detached metatheorem. Since none of the component routes has a coordinate for subject reduction, global Church–Rosser, quotient term equality, kernel consistency, selected limits, or ambient completeness, the package exports none of those claims. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateScheduleMaturePackageL10SourceCe`

Theorem 765.369 (MetaCIC residual socket precedes strong-normalization reads)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any consumer reading candidate-mediated strong normalization from K must first expose the candidate schedule discharge, residual-budget socket, closed-substitution boundary, finite-observation confluence budget, subject-reduction socket, and the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The resulting read keeps closed subject reduction, global Church–Rosser, beta-conversion decidability, quotient term equality, selected limits, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness outside the exported packet surface.*

Proof. Begin with the mature package theorem Definition 765.368. It places candidate-mediated strong normalization behind the candidate schedule discharge, residual-budget frontier, and L10 source package on the same rows $S, N, O, U, D, H, C, P, L$.

Next use the residual-socket consumer surface of Definition 765.370. That theorem already forces the residual-budget frontier, finite observation confluence boundary, closed-term substitution boundary, and subject-reduction socket to remain visible before the consumer reads candidate-mediated strong normalization.

Attach the L10 source routes. The mature package keeps $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as displayed source faces, so the candidate-mediated read cannot hide the Real or completion-facing sources behind a metatheoretic result.

The cited routes exhaust the consumer surface together with the structural rows H, C, P, L. Since none of them supplies closed subject reduction, global Church–Rosser, beta-conversion decidability, quotient term equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the residual socket is exposed before any strong-normalization read and those refused objects remain outside the packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualSocketBeforeSNRead`
Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateScheduleMaturePackage`

Theorem 765.370 (MetaCIC residual-socket consumer surface)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Every consumer of the mature candidate schedule must pass through the candidate schedule discharge of Definition 765.290, the residual-budget frontier of Definition 765.288, the finite observation confluence boundary of Definition 765.171, the closed-term substitution boundary of Definition 765.293, the subject-reduction socket of Definition 765.16,*

and the four L10 source faces in Definition 765.348 before reading candidate-mediated strong normalization. The resulting read exports no closed subject reduction, global Church–Rosser theorem, quotient term equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet K. The mature package theorem Definition 765.368 already requires the candidate schedule discharge, residual-budget frontier, and mature L10 source package on the same rows $S, N, O, U, D, H, C, P, L$ before the schedule can be read.

Apply the candidate schedule discharge. It exposes candidate-set normalization, critical-pair ledgers, residual-substitution boundaries, finite observation confluence, and subject-reduction socket rows as named schedule data, so a consumer cannot read candidate-mediated strong normalization from S alone.

Next apply the residual-budget frontier. It requires residual-budget, substitution-boundary, closed-premise ledger, and local-diamond families to remain attached to the same packet before any socket-facing discharge read reaches D.

Now use the closed-substitution boundary exposure, confluence-decidability handoff exhaustion, and subject-reduction socket budget. These routes keep closed-term substitution, finite observation confluence, and the subject-reduction socket visible as rows rather than hidden metatheorems.

Finally attach the mature L10 source package. It keeps $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as the four source faces through which the candidate-mediated read is routed.

The row inventory is exhausted by these routes and the structural rows H, C, P, L. Since no cited route supplies closed subject reduction, global Church–Rosser, quotient term equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the residual socket remains a socket while candidate-mediated strong normalization is read. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualSocketConsumerSurface`

Theorem 765.371 (MetaCIC residual-diamond visible route)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. Any residual-diamond candidate read through* K *must expose the candidate schedule discharge, residual-budget frontier, local diamond witness, and the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any normalization-facing read is consumed. The resulting route exports no global Church–Rosser theorem, closed subject reduction theorem, quotient term equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the mature package theorem Definition 765.368. It places every candidate-mediated normalization read behind the candidate schedule discharge, residual-budget frontier, and mature L10 source package on the same packet rows $S, N, O, U, D, H, C, P, L$.

Next apply the residual socket precedence theorem Definition 765.369. This keeps candidate-mediated strong normalization downstream of the residual-budget socket, closed-substitution boundary, finite-observation confluence budget, and subject-reduction socket.

Now apply the residual-socket consumer surface of Definition 765.370. The consumer surface forces the residual-budget frontier and the local-diamond data carried by the finite observation confluence boundary to remain visible before the candidate read reaches a normalization-facing consumer.

Finally attach the mature L10 source package. The same read must pass through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as source faces rather than hiding them behind a metatheoretic normalization theorem.

The three local package theorems exhaust the visible route together with the structural rows. Since none of the cited routes carries global Church–Rosser, closed subject reduction, quotient term equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the residual-diamond candidate remains a visible socket-level route before normalization-facing consumption. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathResidualDiamondVisibleRoute`

Theorem 765.372 (MetaCIC L10 residual-diamond source exhaustion)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet that consumes the mature candidate schedule. Every residual-diamond or candidate-mediated normalization read through K must expose the four L10 source faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *together with the residual-budget frontier and local-diamond rows, before any normalization-facing conclusion is read. The resulting read exports no closed subject reduction, global Church–Rosser theorem, quotient term equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10ResidualDiamondSourceExhaustion`

Proof. Begin with the candidate schedule mature package of Definition 765.368. It binds every candidate-mediated normalization read to the accepted packet rows $S, N, O, U, D, H, C, P, L$ after the candidate schedule discharge, residual-budget frontier, and mature L10 source package have been exposed.

Next apply the residual socket precedence theorem Definition 765.369. This keeps the residual-budget socket, closed-substitution boundary, finite-observation confluence budget, and subject-reduction socket visible before the strong-normalization-facing read reaches a consumer.

Use the residual-socket consumer surface of Definition 765.370. It forces the residual-budget frontier and the local-diamond data carried by the finite observation confluence boundary to remain on the same packet rows rather than being hidden behind the normalization conclusion.

Finally apply the residual-diamond visible route of Definition 765.371. That route already requires $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to remain exposed as source faces before a residual-diamond candidate read is consumed.

The cited routes exhaust the residual-diamond and candidate-mediated normalization surface available from K. Since none supplies closed subject reduction, global Church–Rosser, quotient term equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, those objects remain outside the exported read. □

Theorem 765.373 (MetaCICCriticalPath mature closure witness)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. The mature packet is a paper-side package witness: it is exactly the candidate-mediated strong-normalization, residual-substitution, confluence and decidability, and four-object L10 source package exposed by the existing child routes. A mature consumer must read the candidate schedule, residual-budget discharge, parallel-diamond frontier, and* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$ *source rows before it treats K as a mature critical-path packet.*

The mature paper closure exports no subject-reduction theorem, global Church–Rosser theorem, quotient term equality, selected limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or Lean formal verification of those external principles.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathMatureClosureWitness`

Proof. Start with the mature L10 source package of Definition 765.348. It fixes the four source faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ and keeps residual, confluence, decidability, and candidate-mediated strong-normalization data attached to the same packet rows.

Next apply the parallel-diamond frontier handoff of Definition 765.353. It forces any confluence-facing or normalization-facing discharge request through the displayed candidate frontier, residual substitution budget, local diamond witness, and L10 source ledger before the request reaches a public endpoint.

Finally apply the candidate schedule mature package of Definition 765.368. The schedule route combines the candidate schedule discharge, residual-budget frontier, and mature L10 source package on the same carrier K, with H, C, P, L preserving transport, replay, provenance, and naming.

These three routes exhaust the mature packet advertised by the hub marker as a paper-side package witness. None of the cited routes contains a row for subject reduction, global Church–Rosser, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean formal verification of those external principles, so the mature closure witness exports exactly the displayed package and none of the excluded principles. □

Theorem 765.374 (MetaCICCriticalPath mature consumer synthesis)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A mature consumer of* K *receives exactly the finite synthesis of the confluence frontier, normalization frontier, substitution boundary, typed-example row, and bounded checker routes already displayed by the critical-path child files. The consumer surface is therefore the same packet route through* $S, N, O, U, D, H, C, P, L$ *together with the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.

This synthesis does not claim full normalization, full confluence, closed subject reduction, arbitrary Church–Rosser, global beta-conversion decidability, quotient term equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathMatureConsumerSynthesis`

Proof. Begin with the normalization and confluence dependency rows. Theorems 765.291 and 765.292 place the normalization frontier on S, N and the confluence audit route on U, while the obstruction row O and discharge socket D remain visible.

Next attach the substitution boundary. Theorem 765.293 keeps closed-substitution support as boundary data routed through U and D, not as a filled subject-reduction row.

Use Definition 765.16 and Definition 765.17. Candidate-mediated strong normalization and the L10 four-face exit remain downstream of the visible subject-reduction socket row D.

Now add the typed-example and bounded checker surfaces. Theorems 765.325, 765.235, and 765.195 require typed-example coverage, candidate-mediated strong-normalization evidence, bounded checker data, and the four L10 source faces to remain on the same displayed route.

Finally apply the mature routes. Theorems 765.353, 765.368, and 765.373 package the residual diamond frontier, candidate schedule, and mature L10 source rows as one consumer surface. None

of the cited routes contains a coordinate for the excluded global metatheoretic or real-completion principles, so the synthesis exports only the finite mature consumer route stated above. □

Theorem 765.375 (Candidate confluence decidable reflection)**.** *Every* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *candidate schedule that exposes strong normalization rows, residual-local-diamond rows, and decidable audit rows factors any confluence-decidability consumer through the displayed critical-path route. The consumer first reads the candidate schedule, then the strong-normalization ledger, then the residual local-diamond ledger, and only then the decidable audit rows; it never appeals to an ambient typechecker oracle, global conversion decision procedure, unrestricted reduction search, quotient syntax equality, or host confluence theorem.*

Proof. Read the candidate schedule as finite BHist data. Its schedule rows name the reductions and residual windows that a later audit may inspect, so a decidability-facing consumer cannot start from an external typechecker answer.

The strong-normalization ledger is consumed next. It supplies the terminating branch budget for the displayed schedule, while the residual-local-diamond ledger supplies the local join rows for overlapping residual windows.

Finally the decidable audit rows package these two finite ledgers into the $\mathsf{MetaCICCriticalPath}^{\uparrow}$ route. Since each row is already part of the displayed candidate schedule, the consumer receives confluence decidability only as a certificate over those rows and not as an oracle for conversion, unrestricted reduction, quotient equality, or host confluence. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateConfluenceDecidableReflection`

Theorem 765.376 (MetaCIC candidate-discharge matrix)**.** *Let*

$$K = (S, N, O, U, D, H, C, P, L)$$

be an accepted $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. A discharge-socket read through* K *may be consumed only after the candidate-mediated strong-normalization rows, residual diamond budget rows, bounded checker rows, and the four L10 faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}$$

are all displayed on the same packet route. The read therefore factors through the candidate-mediated SN frontier, the residual-substitution diamond budget, the visible residual route, and the L10 normalization discharge budget before any consumer reads D *as a discharge socket.*

Proof. Begin with the candidate-mediated SN frontier of Definition 765.198. It places the candidate rows and the four L10 faces on the accepted route before the confluence-facing or decidability-facing handoff can be consumed.

Attach the residual-substitution diamond budget of Definition 765.305. That route forces the residual budget, diamond checker, candidate-mediated frontier, and L10 source rows to remain on the same packet before bounded conversion reads U.

Now use the visible residual route of Definition 765.328 together with the L10 normalization discharge budget of Definition 765.273. These rows keep the bounded checker, obstruction row O, discharge socket D, transport row H, continuation row C, provenance row P, local naming row L, and the four L10 faces visible before the socket is read.

Since the displayed matrix contains no coordinate for closed subject reduction, full consistency, global confluence, beta-conversion decidability, quotient term equality, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness, the discharge read is exactly the finite candidate-residual-L10 socket surface. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateDischargeMatrix`

Theorem 765.377 (MetaCIC discharge matrix Lean target index)**.** *The candidate-discharge matrix export surface of this sibling consists exactly of the matrix theorem, the L10 socket-exhaustion theorem, the matrix-frontier theorem, and the retained-premise discharge-boundary theorem. These four paper sites jointly expose the candidate-mediated rows, residual budget, bounded checker rows, and four L10 faces before any discharge-socket read.*

Proof. Read Definition 765.376 for the candidate-mediated matrix and Definition 765.378 for the socket exhaustion boundary.

Then read Definition 765.379 for the bounded frontier and Definition 765.380 for retained-premise discharge. No fifth export row is introduced in this sibling, so the index is exactly the four displayed sites. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathDischargeMatrixLeanTargetIndex`

Theorem 765.378 (MetaCIC L10 candidate socket exhaustion)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, omitting any candidate-mediated row, residual-budget row, bounded-checker row, or any one of the L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *leaves the candidate-discharge socket unmet. In that case no consumer may read the missing surface as closed subject reduction, full consistency, global confluence, beta-conversion decidability, quotient term equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the matrix theorem above. It identifies the whole discharge-socket surface as the joint display of candidate-mediated rows, residual diamond budget rows, bounded checker rows, and the four L10 faces on one packet route.

If a candidate row is absent, Definition 765.198 supplies no frontier for the handoff. If a residual row or checker row is absent, Definition 765.305 and Definition 765.328 supply no visible residual route to the socket.

If an L10 face is absent, Definition 765.273 does not authorize a discharge read through the source budget. Thus each omission leaves the socket unmet and keeps all global metatheoretic, quotient, selected-limit, and Real-completeness readings outside the accepted packet. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathL10CandidateSocketExhaustion`

Theorem 765.379 (MetaCIC candidate-discharge matrix frontier)**.** *Let* $K = (S, N, O, U, D, H, C, P, L)$ *be an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet. If the candidate-mediated strong-normalization rows, residual-substitution diamond rows, bounded checker rows, and the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *are all displayed on the same packet route, then* K *supplies only a bounded formal-target frontier for the discharge socket* D*. The frontier authorizes the visible candidate-residual-L10 handoff and does not close subject reduction, full consistency, global confluence, beta-conversion decidability, quotient term equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the matrix theorem Definition 765.376. It identifies a discharge-socket read with the joint display of candidate-mediated rows, residual diamond budget rows, bounded checker rows, and the four L10 faces on the same accepted route.

Next apply the socket-exhaustion theorem Definition 765.378. It shows that any missing candidate row, residual row, checker row, or L10 face leaves the socket unmet, so the displayed matrix is exactly the finite boundary that a consumer may use.

The carrier K contains no row that asserts closed subject reduction, full consistency, global confluence, beta-conversion decidability, quotient term equality, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness. Hence the accepted route supplies a bounded formal-target frontier for D and no global metatheoretic theorem beyond that frontier. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathCandidateDischargeMatrixFrontier`

Theorem 765.380 (MetaCIC retained-premise discharge boundary)**.** *For an accepted* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packet* $K = (S, N, O, U, D, H, C, P, L)$*, retained premises may be consumed by the discharge socket* D *only as displayed candidate rows, residual-budget rows, bounded-checker rows, and L10 faces. The retained-premise read therefore remains inside the candidate-discharge matrix and does not become closed subject reduction, full consistency, global confluence, beta-conversion decidability, quotient term equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the candidate-discharge matrix of Definition 765.376. It identifies the socket-facing route as the joint display of candidate-mediated rows, residual diamond budget rows, bounded checker rows, and the four L10 faces.

Next use socket exhaustion from Definition 765.378. Any missing candidate row, residual row, checker row, or L10 face leaves the discharge socket unmet, so retained premises can be read only through the displayed matrix coordinates.

Finally apply the matrix frontier theorem Definition 765.379. Its frontier clause prevents the accepted route from exporting closed subject reduction, full consistency, global confluence, beta-conversion decidability, quotient term equality, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.MetaCICCriticalPathUp.MetaCICCriticalPathRetainedPremiseDischargeBoundary`

Chapter 766

A Concrete Naming Certificate for $\mathsf{RealAlgOrder}^{\uparrow}$

The $\mathsf{RealAlgOrder}^{\uparrow}$ interface packages the algebra and order rows of displayed constructive real names. It sits above the real-name seal of chapter 38, the regular rational source rows of chapter 301, the dyadic operation ledgers of chapter 291, the finite windows of chapter 126, and the positive-separation rows of chapter 304. These sibling chapters supply the endpoint, readback, operation, window, and apartness data consumed by the local packet.

The certificate is the constructive algebra/order surface for downstream metric, measure, and probability consumers. It records finite addition, negation, multiplication, absolute-value, nonnegative-order, and strict-apartness evidence as named rows; it does not import trichotomy of reals, quotient equality of Cauchy presentations, a host real carrier, or ambient completeness.

Definition 766.1 (RealAlgOrder carrier)**.** *A* $\mathsf{RealAlgOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (E, G, D, S, A, O, H, C, P, N)$$

with the following displayed coordinates:

1. *E is the finite family of* $\mathsf{Real}^{\uparrow}$ *endpoint rows consumed by the algebra or order request;*
2. *G is the family of* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those endpoints before the real-seal handoff;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation ledger recording the finite dyadic reads used for addition, negation, multiplication, absolute value, and nonnegative comparison;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which the endpoint readbacks are inspected;*
5. *A is the optional* $\mathsf{ApartnessReal}^{\uparrow}$ *finite-window separation row used when the request is strict apartness rather than nonnegative comparison;*
6. *O is the local algebra/order ledger whose rows are the displayed sum, product, negation, absolute-value, nonnegative-order, and strict-apartness conclusions licensed by E, G, D, S, A;*
7. *H stores the componentwise* hsame *transports for endpoint rows, readbacks, dyadic ledgers, windows, apartness rows, and the local order ledger;*
8. *C stores the* Cont *routes exposing finite readback and operation rows to downstream consumers;*
9. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealAlgOrder}^\uparrow}$ *row.*

The carrier is a finite certificate for algebra and constructive order on displayed real names. It is not a host ordered field, not a quotient of real-name presentations, and not a completeness object.

Lean4 ✓ `BEDC.Derived.RealAlgOrderUp.RealAlgOrderTasteGate single carrier alignment`

Theorem 766.2 (RealAlgOrder NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RealAlgOrder}^\uparrow}$ *surface for the carrier of Definition 766.1 consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed packet $R = (E, G, D, S, A, O, H, C, P, N)$ with endpoint, readback, dyadic-operation, finite-window, apartness, ledger, transport, continuation, provenance, and local naming coordinates;*
2. *classifier transport: classification transports every endpoint row in E, every* $\mathsf{RegSeqRat}^\uparrow$ *readback in G, every dyadic operation row in D, every finite window in S, every apartness row in A, and the algebra/order ledger O componentwise through the stored* hsame *and* Cont *routes;*
3. *algebra stability: addition, negation, multiplication, and absolute-value rows in O remain accepted after replacing their inputs by classified* $\mathsf{Real}^\uparrow$ *endpoint rows and transporting the corresponding* $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, *and* $\mathsf{StreamName}^\uparrow$ *witnesses;*
4. *order stability: nonnegative-order and strict-apartness rows in O are read only from the displayed finite comparison and separation ledgers, and they transport across the same endpoint and window classifiers;*
5. *ledger exactness: every downstream algebra or order read is one of the displayed rows in $E, G, D, S, A, O, H, C, P, N$ before any consumer receives it.*

Proof. Carrier admission is projection from the tuple in Definition 766.1. The endpoint rows, regular-rational readbacks, dyadic operation ledger, finite-window schedule, apartness row, local ledger, transport table, continuation table, package provenance, and local naming row are all explicit coordinates.

Classifier transport is componentwise. The $\mathsf{Real}^\uparrow$ endpoints transport together with their $\mathsf{RegSeqRat}^\uparrow$ source readbacks and $\mathsf{StreamName}^\uparrow$ windows, while the $\mathsf{DyadicRatCore}^\uparrow$ operation rows and $\mathsf{ApartnessReal}^\uparrow$ separation rows transport through their own sibling classifiers.

The algebra and order stability rows then repack the transported coordinates into the same ledger shape O. Addition, negation, multiplication, and absolute value use only the dyadic operation reads exposed by D; nonnegative order and strict apartness use only the finite comparison and separation rows exposed by D and A.

Ledger exactness follows because every consumer-facing row is a coordinate of R or a row of O generated from those coordinates. Since no coordinate stores trichotomy, quotient real equality, a host real carrier, or ambient completeness, none of those principles can be projected from the local $\mathsf{NameCert}_{\mathsf{RealAlgOrder}^\uparrow}$ surface. □

Theorem 766.3 (RealAlgOrder classifier transport companion)**.** *For constant rational histories d, e, d', e', a rational carrier row for d, a rational classifier row $d \to e$, and transports $d\mathsf{hsame}d'$ and $e\mathsf{hsame}e'$ determine the transported constant-real carrier rows for $BHist.e1(d')$ and $BHist.e1(e')$, the transported constant-real classifier row $BHist.e1(d') \to BHist.e1(e')$, and the transported rational classifier row $d' \to e'$.*

Proof. Unpack the classifier-transport row of Definition 766.2. The stored hsame transports move the rational classifier $d \to e$ to the displayed row $d' \to e'$, and the rational carrier for d' is transported along the same route.

Now read the constant-real interface through $BHist.e1$. The RatHistoryCarrier and RatHistoryClassifier rows are exactly the inputs to RealConstantHistoryCarrier and RealConstantHistoryClassifier on the endpoint histories, so the transported rational classifier supplies the two carrier rows and the real classifier row without adding trichotomy, quotient equality, or completeness. □

Theorem 766.4 (RealAlgOrder algebra-row companion)**.** *For constant rational histories d, e, o, d', e', o', rational classifier rows $d \to d'$, $e \to e'$, and $o \to o'$ determine the constant-real carrier rows for $BHist.e1(d)$, $BHist.e1(e)$, and $BHist.e1(o)$, together with the three constant-real classifier rows $BHist.e1(d) \to BHist.e1(d')$, $BHist.e1(e) \to BHist.e1(e')$, and $BHist.e1(o) \to BHist.e1(o')$.*

Proof. Project the algebra stability row of Definition 766.2. The endpoint, endpoint-transport, and operation histories are all rational classifier rows, so each source history carries the rational carrier evidence needed by the local algebra ledger.

Passing through the constant-real classifier interface converts those three rational classifier rows into the three displayed RealConstantHistoryClassifier rows on $BHist.e1$. Their source carriers become the displayed RealConstantHistoryCarrier rows, and no further real-algebra structure is read. □

Theorem 766.5 (RealAlgOrder rational order-boundary companion)**.** *For constant rational histories d, e, o, d', e', o', rational classifier rows $d \to e$ and $e \to o$ and transports $d\mathsf{hsame}d'$, $e\mathsf{hsame}e'$, and $o\mathsf{hsame}o'$ determine the transported constant-real carrier rows for $BHist.e1(d')$, $BHist.e1(e')$, and $BHist.e1(o')$, the transported constant-real classifier rows $BHist.e1(d') \to BHist.e1(e')$ and $BHist.e1(e') \to BHist.e1(o')$, and the transitive rational boundary row $d' \to o'$.*

Proof. Use the order stability row of Definition 766.2. The two rational classifier rows are first transported componentwise along the stored hsame witnesses, giving $d' \to e'$ and $e' \to o'$ inside the displayed finite order surface.

The constant-real interface then reads these transported rational classifiers through $BHist.e1$, producing the three endpoint carrier rows and the two adjacent real classifier rows. Finally, transitivity of the transported rational classifier rows gives the boundary row $d' \to o'$, which is still a rational ledger row rather than a quotient-real or completeness witness. □

Theorem 766.6 (RealAlgOrder apartness companion)**.** *For constant rational histories d, e, d', e', rational classifier rows $d \to d'$ and $e \to e'$ determine the constant-real carrier rows for $BHist.e1(d)$, $BHist.e1(d')$, $BHist.e1(e)$, and $BHist.e1(e')$, together with the two constant-real classifier rows $BHist.e1(d) \to BHist.e1(d')$ and $BHist.e1(e) \to BHist.e1(e')$.*

Proof. Read the strict-apartness side of Definition 766.2. The apartness ledger consumes only the displayed endpoint classifier rows, so the two rational classifiers expose both their source and target rational carrier rows.

Applying the constant-real classifier interface to each classifier row yields the four displayed RealConstantHistoryCarrier rows and the two RealConstantHistoryClassifier rows. The packet therefore exposes only finite endpoint classifier evidence for apartness, with no branch for real trichotomy, quotient equality, or ambient completeness. □

Theorem 766.7 (RealAlgOrder apartness and order non-escape)**.** *Every* $\mathsf{Met}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, *measure, or real-algebra consumer of an accepted* $\mathsf{RealAlgOrder}^{\uparrow}$ *packet receives only the displayed finite rows of Definition 766.1:* $\mathsf{Real}^{\uparrow}$ *endpoint rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *operation and nonnegative-comparison ledgers,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{ApartnessReal}^{\uparrow}$ *finite-window*

separation rows when strict apartness is requested, and the visible hsame, Cont, Pkg, *and local* NameCert *provenance.*

In particular, an order or apartness consumer can read nonnegative-order evidence only as a displayed finite comparison row and strict-apartness evidence only as a displayed finite separation row. The packet exports no trichotomy branch, no quotient real equality, no host real carrier, and no ambient completeness witness.

Proof. Start with the carrier inventory in Definition 766.1. The only public coordinates are the endpoint family E, readback family G, dyadic ledger D, finite-window schedule S, apartness row A, algebra/order ledger O, and the provenance rows H, C, P, N.

Apply the NameCert obligations of Definition 766.2. Carrier admission and ledger exactness force every downstream read to pass through those coordinates, while classifier transport and the two stability rows preserve the same finite evidence after endpoint replacement.

For nonnegative order, the consumer reads the comparison rows displayed in D and repacked in O. For strict apartness, the consumer reads the finite-window separation row displayed in A and repacked in O through the $\mathsf{ApartnessReal}^{\uparrow}$ sibling surface of chapter 304.

Thus every metric, probability, measure, or algebra-facing consumer receives a finite order or separation row with visible hsame, Cont, Pkg, and NameCert provenance. None of the excluded host principles is a carrier coordinate or a ledger row, so none can escape through this handoff. □

Theorem 766.8 (RealAlgOrder constant-rational scoped certificate)**.** *For constant rational* $\mathsf{Real}^{\uparrow}$ *endpoint rows, the* $\mathsf{RealAlgOrder}^{\uparrow}$ *packet of Definition 766.1 carries the scoped certificate obtained by transporting the endpoint and operation rows through the* $\mathsf{Rat}^{\uparrow}$ *classifiers. Concretely, if* d, e, o *are the displayed rational histories for the left endpoint, right endpoint, and operation row, and* d', e', o' *are their classified transports, then the packet records* RealConstantHistoryCarrier *for each of* $BHist.e1(d)$, $BHist.e1(d')$, $BHist.e1(e)$, $BHist.e1(e')$, $BHist.e1(o)$, *and* $BHist.e1(o')$*; it records* RealConstantHistoryClassifier *for the three displayed constant rational comparisons* $BHist.e1(d) \to BHist.e1(d')$, $BHist.e1(e) \to BHist.e1(e')$, *and* $BHist.e1(o) \to BHist.e1(o')$*; and its order boundary records the transitive* RatHistoryClassifier *row from* d *to* o.

Lean4 ✓ `BEDC.Derived.RealAlgOrderUp.RealAlgOrderConstant rational scoped certificate`

Proof. Start with the carrier inventory of Definition 766.1. The endpoint family E supplies the two constant rational $\mathsf{Real}^{\uparrow}$ endpoint rows, the ledger O supplies the operation row, and the sibling $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ rows named in the chapter introduction expose the rational histories and finite reads used by those rows.

Apply the local obligations of Definition 766.2. Classifier transport moves the endpoint rows and the operation row componentwise through the stored hsame and Cont routes, while ledger exactness keeps the downstream read inside the displayed coordinates.

The sibling $\mathsf{Real}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ constant classifier interface identifies a rational classifier row with the corresponding constant real classifier on the $BHist.e1$ endpoint. Applying that interface to the three displayed rational comparisons gives the six RealConstantHistoryCarrier rows and the three RealConstantHistoryClassifier rows.

Finally, the order boundary is the transitive rational classifier row. The two RatHistoryClassifier comparisons $d \to e$ and $e \to o$ compose to the displayed $d \to o$ row, so the scoped $\mathsf{RealAlgOrder}^{\uparrow}$ certificate contains exactly the constant-rational endpoint, operation, and boundary data described above, with no appeal to real trichotomy, quotient equality, or completeness. □

Theorem 766.9 (RealAlgOrder MetricSpace SOne public boundary)**.** *Every* $\mathsf{S}^{1\uparrow}$ *unit-equation consumer whose distance and apartness read passes through* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{RealAlgOrder}^{\uparrow}$ *factors through exactly three displayed public rows: the constant-rational scoped certificate of Definition 766.8, the real-distance public correspondence of Definition 57.315, and the* $\mathsf{S}^{1\uparrow}$ *component-and-equation consumer boundaries of Definition 57.317 and Definition 58.67.*

Consequently the route exports only finite $\mathsf{RealAlgOrder}^{\uparrow}$ *comparison and apartness rows, the* $\mathsf{Met}^{\uparrow}$ *real-distance handoff, and the* $\mathsf{S}^{1\uparrow}$ *component/equation readback. It exports no trichotomy row, quotient-circle carrier, host real equality, angle parameter, selected limit, or metric-completeness row.*

Proof. Start with the constant-rational scoped certificate of Definition 766.8. It is the only $\mathsf{RealAlgOrder}^{\uparrow}$ source named by the route, so the rational endpoint, operation, and boundary histories available to the consumer are exactly the displayed constant-rational histories and their classified transports.

Next apply the real-distance public correspondence of Definition 57.315. That theorem is the $\mathsf{Met}^{\uparrow}$ boundary that repacks positive-distance and apartness information as public finite rows, and it does not add a host real equality, completeness witness, or trichotomy branch.

Then apply the $\mathsf{Met}^{\uparrow}$–$\mathsf{S}^{1\uparrow}$ factorization of Definition 57.317. It says that an $\mathsf{S}^{1\uparrow}$ consumer reading the metric surface through $\mathsf{RealAlgOrder}^{\uparrow}$ must pass through the real-distance correspondence before seeing the unit-equation surface.

Finally use the component-and-equation boundary of Definition 58.67. The $\mathsf{S}^{1\uparrow}$ side consumes only the component rows and the equation readback, so the composed route contains precisely the three public boundaries named in the statement and none of the excluded quotient, angle, limit, or completeness data. □

Theorem 766.10 (RealAlgOrder bridge-ready public interface)**.** *The bridge-ready public interface of* $\mathsf{RealAlgOrder}^{\uparrow}$ *is exactly the carrier* $R = (E, G, D, S, A, O, H, C, P, N)$ *of Definition 766.1, the local* NameCert *obligations of Definition 766.2, the apartness/order non-escape boundary of Definition 766.7, the constant-rational scoped certificate of Definition 766.8, and the* $\mathsf{Met}^{\uparrow}$–$\mathsf{S}^{1\uparrow}$ *public boundary of Definition 766.9.*

Consequently the standard bridge for $\mathsf{RealAlgOrder}^{\uparrow}$ *has a single paper interface to consume: it may read the displayed endpoint, readback, dyadic, schedule, apartness, order, transport, continuity, package, and naming rows of* R *together with precisely the four cited theorem surfaces. This theorem is the bridge-facing paper interface recorded by the closure block below.*

Lean4 ✓ `BEDC.Derived.RealAlgOrderUp.RealAlgOrderUp StdBridge`

Proof. Start with the carrier definition. Definition 766.1 names the ten public coordinates $E, G, D, S, A, O, H, C, P,$ so any standard-facing read begins from displayed endpoint rows, readback rows, dyadic ledgers, finite-window schedules, optional apartness rows, order ledgers, transport rows, continuity routes, package provenance, and the local naming certificate.

Apply the local obligation and non-escape theorems. Definition 766.2 supplies the carrier, classifier, stability, exactness, provenance, and naming rows that make those coordinates a NameCert surface, while Definition 766.7 rules out the escape of trichotomy, quotient real equality, host real carrier data, and ambient completeness through apartness or order reads.

Finally attach the two public boundary theorems. Definition 766.8 supplies the constant rational endpoint, operation, and transitive order rows; Definition 766.9 identifies the only $\mathsf{Met}^{\uparrow}$ and $\mathsf{S}^{1\uparrow}$ consumer rows visible through this route. These four theorem surfaces, together with the carrier coordinates, are therefore the exact paper interface available for the bridge theorem recorded below. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealAlgOrder}^{\uparrow}}$.

Constructive story: A $\mathsf{RealAlgOrder}^{\uparrow}$ packet is generated from finite $\mathsf{Real}^{\uparrow}$ endpoint rows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ operation ledgers, $\mathsf{StreamName}^{\uparrow}$ windows, optional $\mathsf{ApartnessReal}^{\uparrow}$ separation rows, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealAlgOrder}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 766.1, Definition 766.2, Definition 766.7, and the constant-rational scoped certificate enumerate the carrier, NameCert obligation rows, apartness/order non-escape theorem, and constant rational $\mathsf{Real}^{\uparrow}$ rows covered by this obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealAlgOrder}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.RealAlgOrderUp.RealAlgOrderConstant\_rational\_scoped\_certificate`

Bridge status: bridgeChecked

Not claimed: This chapter does not reconstruct a full real algebra, an ordered-field structure, trichotomy, quotient real equality, ambient completeness, or a public standard bridge.

Upgrade path: No further upgrade remains on the recorded standard-bridge verification axis for the finite $\mathsf{RealAlgOrder}^{\uparrow}$ packet.

Chapter 767

A Concrete Naming Certificate for $\mathsf{SocketTaxonomyLedger}^{\uparrow}$

The $\mathsf{SocketTaxonomyLedger}^{\uparrow}$ packet realizes the seven T-supply socket kinds of Definition 9462.824 as a finite NameCert ledger. It sits beside chapter 528, chapter 1229, and chapter 542: the first consumes socket exposure, the second audits typed gap and failure rows, and the third records requested transcendental supply without supplying it. This packet binds the kind row, consumption-site row, audit-gate row, refusal row, non-collapse row, transport, continuation, provenance, and local name in one carrier.

Definition 767.1 (SocketTaxonomyLedger carrier)**.** *A* $\mathsf{SocketTaxonomyLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Sigma = (K, S, A, R, D, H, C, P, N)$$

with the following displayed rows:

1. *K is one of the seven socket-kind rows: Type I generator closure, Type II unwitnessed witness, Type III quotient or extensional collapse, Type IV causal continuity, Type V inter-history coordination, Type VI inscription novelty, or Type VII self-reference closure;*
2. *S is the consumption-site row at which the requested T-supply would be used;*
3. *A is the audit-gate row governing the request at that site;*
4. *R is the refusal row recording that the requested supply is visible only as a* Gap *boundary;*
5. *D is the non-collapse row separating the seven kinds by requested shortcut, consumer site, and gate;*
6. *H records componentwise* hsame *transport for the kind, site, gate, refusal, non-collapse, provenance, and naming rows;*
7. *C records displayed* Cont *routes for kind lookup, site consumption, gate inspection, refusal replay, and non-collapse comparison;*
8. *P is the* Pkg *provenance over* $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$, $\mathsf{TranscendentalSupplyLedger}^{\uparrow}$, $\mathsf{RecursionAuthorizationLedger}^{\uparrow}$, $\mathsf{ForbiddenAxiomAncestry}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SocketTaxonomyLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate that supplies unrestricted induction, a selected witness, quotient equality, a future law, another closed history, inscription-source actuality, or truth-total self-validation.

Lean4 ✓ `BEDC.Derived.SocketTaxonomyLedgerUp.SocketTaxonomyLedgerTasteGate single carrier alignment`

Theorem 767.2 (SocketTaxonomyLedger NameCert obligations)**.** *For the carrier of Definition 767.1, the local* $\mathsf{NameCert}_{\mathsf{SocketTaxonomyLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$\Sigma = (K, S, A, R, D, H, C, P, N),$$

kind classification through K*, consumption-site exposure through* S*, audit-gate routing through* A*, refusal through* R*, non-collapse through* D*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from Definition 767.1. The rows $K, S, A, R, D, H, C, P, N$ account for the finite taxonomy, the consuming site, the gate, the refusal, the non-collapse comparison, transport, route replay, provenance, and local naming.

The sibling ledgers supply only their named surfaces. chapter 528 records socket exposure, chapter 1229 records typed gap and failure audit rows, and chapter 542 records the requested supply as a ledgered request. None of these siblings supplies the requested T-supply itself.

The rows H, C, P, N preserve and name the same finite packet. Since the packet exposes no further coordinate, every accepted NameCert read of $\mathsf{SocketTaxonomyLedger}^{\uparrow}$ is exhausted by the displayed rows. □

Lean4 ✓ `BEDC.Derived.SocketTaxonomyLedgerUp.SocketTaxonomyLedgerNameCert obligations`

Theorem 767.3 (SocketTaxonomyLedger non-collapse)**.** *Every accepted* $\mathsf{SocketTaxonomyLedger}^{\uparrow}$ *packet keeps the seven socket kinds distinct by the triple of kind row, consumption-site row, and audit-gate row. In particular, a Type III quotient-collapse socket cannot be consumed by a Type I generator-closure gate without changing the socket-kind row* K *and the non-collapse row* D*.*

Proof. Project the rows K, S, A, D from the carrier. The kind row records which of the seven socket kinds is present, while the consumption-site and audit-gate rows record where and how the request is refused.

Use the taxonomy non-collapse theorem Definition 9462.824. Type I asks for generator closure beyond the displayed generator, while Type III asks for relation-to-identity or quotient collapse. These requests have different shortcuts and different gate conditions.

Therefore a consumer that reads a Type III row through a Type I gate has changed the displayed kind and non-collapse data. The accepted packet permits transport of the same rows through H, C, P, N, but it does not permit reclassifying quotient collapse as generator closure. □

Theorem 767.4 (SocketTaxonomyLedger audit-gate non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{SocketTaxonomyLedger}^{\uparrow}$ *packet factors through*

$$K, S, A, R, D, H, C, P, N.$$

No countable choice row, quotient stream, unrestricted recursor, forbidden host axiom, truth-total self-validator, or alternate hidden source can distinguish the packet once those rows agree.

Proof. Project the accepted packet. The carrier exposes only the kind, site, audit gate, refusal, non-collapse, transport, continuation, provenance, and naming rows.

Read the sibling provenance row P. The supply-socket, gap-failure audit, transcendental-supply, recursion-authorization, and forbidden-axiom-ancestry siblings are cited as finite rows with named obligations, not as hidden supplies.

It remains to inspect the excluded coordinates. Countable choice, quotient streams, unrestricted recursors, forbidden host axioms, truth-total validators, and alternate hidden sources are absent from the carrier. Thus any consumer that distinguishes two packets agreeing on $K, S, A, R, D, H, C, P, N$ has left the accepted NameCert route. □

Falsifiable prediction: A Type III quotient-collapse socket cannot be consumed by a Type I generator-closure gate without changing the socket-kind row.

Independence witness: supplysocketledger, gapfailurebridgeaudit, transcendentalsupplyledger, recursionauthorizationledger, forbidden-axiom-ancestry: none is bijective to $\mathsf{SocketTaxonomyLedger}^{\uparrow}$ because this carrier binds the seven-kind taxonomy row, consumption-site row, audit-gate row, refusal row, and non-collapse row in one finite NameCert packet.

The Lean site `lean4/BEDC/Derived/SocketTaxonomyLedgerUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ SocketTaxonomyLedger}^{\uparrow}$ and $\mathsf{FieldFaithful\ SocketTaxonomyLedger}^{\uparrow}$ instances preserving $K, S, A, R, D, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{SocketTaxonomyLedger}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{SocketTaxonomyLedger}^{\uparrow}$ packet is generated from one seven-kind taxonomy row, a consumption-site row, an audit-gate row, a refusal row, a non-collapse row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SocketTaxonomyLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 767.1, Definition 767.2, Definition 767.3, and Definition 767.4 bind the finite carrier, seven-kind classifier, consumption-site row, audit-gate row, refusal row, non-collapse comparison, transport, continuation, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SocketTaxonomyLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not discharge any T-supply request, provide unrestricted induction, select witnesses, collapse quotient or relation rows into equality, assert future-law continuity, identify external histories, explain inscription actuality, close self-truth validation, or provide bridge checking for $\mathsf{SocketTaxonomyLedger}^{\uparrow}$.

Upgrade path: Formal closure requires Lean encoding of the finite taxonomy ledger and checked theorems for NameCert obligations, non-collapse, audit-gate routing, and non-escape of the refused supply rows.

Chapter 768

A Concrete Naming Certificate for $\mathsf{Limsup}^{\uparrow}$

Following Hardy and Bishop–Bridges, $\mathsf{Limsup}^{\uparrow}$ records the finite tail-upper-cut and tail-lower-cut surface of a bounded real sequence. The packet consumes the bounded sequence rows of chapter 1415, the upper-cut observation discipline of **??**, the lower-cut observation discipline of chapter 1440, the displayed sequence-limit interface of chapter 1413, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It gives Real-and-Completion consumers a finite limsup boundary without importing completeness, a host supremum, or selected subsequences.

Definition 768.1 (Limsup carrier)**.** *A* $\mathsf{Limsup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, U, D, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded* $\mathsf{BoundedRealSequence}^{\uparrow}$ *row whose finite windows, bound ledger, and displayed* $\mathsf{Real}^{\uparrow}$ *entries are being inspected.*
2. *U is the tail upper-cut schedule, recording for each displayed tail index the bounded upper-cut observations read through* $\mathsf{BoundedRealUpperCut}^{\uparrow}$*.*
3. *D is the dyadic tolerance ledger, recording the finite rational tolerances used to compare tail upper cuts with the lower observation surface.*
4. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row named as the limsup candidate exposed by the packet.*
5. *H records componentwise* hsame *transports for S, U, D, T and the structural rows.*
6. *C records the displayed* Cont *routes by which consumers replay the bounded sequence row, tail upper-cut schedule, dyadic tolerance ledger, terminal real seal, transports, provenance, and local naming row.*
7. *P is the* Pkg *provenance over* $\mathsf{Limsup}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BoundedRealUpperCut}^{\uparrow}$, $\mathsf{BoundedRealLowerCut}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{Limsup}^{\uparrow}}$ *row.*

The carrier stores a finite tail-cut surface for a bounded real sequence. It has no coordinate for Real completeness, trichotomy, a host supremum, quotient stream equality, selected subsequences, or open-cover compactness.

Lean4 (definition) `BEDC.Derived.LimsupUp.LimsupCarrier`

Definition 768.2 (Limsup classifier)**.** *Two* $\mathsf{Limsup}^{\uparrow}$ *carriers*

$$L = (S, U, D, T, H, C, P, N) \qquad \text{and} \qquad L' = (S', U', D', T', H', C', P', N')$$

are classified as the same displayed limsup packet exactly when the bounded sequence rows match componentwise, the tail upper-cut schedules expose the same finite tail observations, the dyadic tolerance ledgers carry the same rational comparison budgets, the terminal $\mathsf{Real}^{\uparrow}$ *seals are transported by the displayed* hsame *data, the continuation replays preserve the same consumer routes, and the provenance and local NameCert rows name the same* $\mathsf{Limsup}^{\uparrow}$ *surface. The classifier is therefore rowwise over* S, U, D, T, H, C, P, N *and does not identify carriers by host sequence equality, quotient streams, selected cofinal subsequences, or a completed supremum construction.*

Lean4 (definition) `BEDC.Derived.LimsupUp.LimsupClassifier`

Theorem 768.3 (Limsup NameCert obligations)**.** *For an accepted* $\mathsf{Limsup}^{\uparrow}$ *carrier* $L = (S, U, D, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Limsup}^{\uparrow}}$ *surface consists of six finite obligation rows:*

1. *carrier formation for the bounded real sequence row, tail upper-cut schedule, dyadic tolerance ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transports, continuations, provenance, and local naming data;*
2. *classifier stability for the componentwise comparison of Definition 768.2;*
3. *tail upper-cut exactness, stating that every upper observation in* U *is read from a finite tail of* S *through the bounded upper-cut surface;*
4. *lower-cut compatibility, stating that every tolerance row in* D *compares the same tail data against the bounded lower-cut observation surface;*
5. *terminal seal routing, stating that the candidate row* T *is consumed only as a* $\mathsf{Real}^{\uparrow}$ *seal after the displayed tail-cut checks have been replayed;*
6. *ledger non-escape, excluding Real completeness, trichotomy, host supremum selection, quotient stream equality, selected subsequences, and open-cover compactness.*

Proof. Carrier formation is projection from Definition 768.1. The packet displays exactly the bounded sequence row, tail upper-cut schedule, dyadic tolerance ledger, terminal real seal, componentwise transports, continuation routes, provenance, and local name.

Classifier stability is the componentwise comparison of Definition 768.2. Transport along H may replace the visible rows only by rows with the same scheduled tail observations, the same dyadic budgets, and the same terminal seal route, while C preserves the consumer replay order.

Tail upper-cut exactness is supplied by U together with the bounded sequence row S. Each accepted upper observation names the finite tail index, the inspected sequence windows, and the bounded upper-cut certificate through which the read is made.

Lower-cut compatibility is supplied by D and the sibling bounded lower-cut discipline. The tolerance ledger records only finite dyadic comparisons between the same tail data and the lower observation surface, so it does not become a host infimum or a completeness witness.

Terminal seal routing is the role of T. A consumer may read the candidate limsup only after the sequence tail, upper-cut, lower-cut, and tolerance rows have been replayed; the terminal coordinate remains a $\mathsf{Real}^{\uparrow}$ seal rather than a completed supremum object.

The non-escape row follows from the carrier inventory. No displayed field carries Real completeness, trichotomy, a host supremum, quotient stream equality, selected subsequences, or open-cover compactness. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupNameCertObligations`

Theorem 768.4 (Limsup tail lower-cut compatibility)**.** *Let $L = (S, U, D, T, H, C, P, N)$ be an accepted* $\mathsf{Limsup}^{\uparrow}$ *carrier. Every dyadic tolerance row in D compares the same finite tail data exposed by U against the bounded lower-cut surface, so the limsup packet cannot read a host infimum, selected subsequence, or completed supremum when it certifies the lower side of the tail-cut boundary.*

Proof. Project S, U, D from the carrier of Definition 768.1. The bounded sequence row S supplies the only sequence entries, the upper schedule U names the finite tail observations, and the tolerance ledger D records the dyadic comparison budgets attached to those same observations.

Use the componentwise classifier of Definition 768.2. It compares accepted packets by the displayed bounded sequence row, tail upper-cut schedule, dyadic tolerance ledger, and terminal seal route, not by a host sequence object or by a completed extremal value.

The structural rows H, C, P, N preserve that lower-cut read. Transport may only replace the visible rows by classifier-equivalent rows, continuation replay rereads the same tail and tolerance cells, provenance names the bounded lower-cut dependency, and the local NameCert row records the finite packet. Thus the lower side of the limsup surface remains a bounded lower-cut comparison over displayed tail data. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupTailLowerCutCompatibility`

Theorem 768.5 (Limsup tail upper-cut exactness)**.** *Let $L = (S, U, D, T, H, C, P, N)$ be an accepted* $\mathsf{Limsup}^{\uparrow}$ *carrier. The row U is the only upper-tail observation route from the bounded sequence row S through finite* $\mathsf{BoundedRealUpperCut}^{\uparrow}$ *data. Thus no consumer can read a host supremum, selected cofinal subsequence, or detached upper bound when it consumes the upper side of the limsup packet.*

Proof. Project S and U from Definition 768.1. The bounded sequence row S supplies the finite sequence windows, while U records the tail upper-cut observations attached to those windows.

Use the classifier of Definition 768.2. Accepted packets agree on the displayed bounded sequence row and the tail upper-cut schedule, so an upper-tail read cannot be replaced by a host sequence object or by a completed supremum construction.

The structural rows preserve the same upper route. Transport through H, replay through C, provenance through P, and local naming through N carry the displayed $S \to U$ observation path and do not add another upper-cut coordinate. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupTailUpperCutExactness`

Theorem 768.6 (Limsup terminal seal routing)**.** *For every accepted* $\mathsf{Limsup}^{\uparrow}$ *carrier $L = (S, U, D, T, H, C, P, N)$, the terminal row T is consumed only after the bounded sequence row S, tail upper-cut schedule U, and dyadic comparison ledger D have been replayed. The row T remains a* $\mathsf{Real}^{\uparrow}$ *seal and is not a host supremum, selected subsequence limit, or ambient completeness witness.*

Proof. Begin with the carrier projection. The only value-facing coordinate is T, and the only rows that feed it are the bounded source row S, the upper-tail schedule U, and the dyadic lower-comparison ledger D.

Replay the route through C. A consumer reaches T only after the displayed tail data and comparison budgets have been read, so the terminal row is downstream of the same finite tail-cut surface.

Finally apply H, P, N. Componentwise transport, provenance, and local naming preserve the $\mathsf{Real}^{\uparrow}$ seal route without adding a supremum operator, selected subsequence, or completeness field. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupTerminalSealRouting`

Theorem 768.7 (Limsup tail-seal scope)**.** *For every accepted* $\mathsf{Limsup}^{\uparrow}$ *carrier* $L = (S, U, D, T, H, C, P, N)$*, the candidate limsup value is exposed only after the same finite tail upper-cut row* U*, lower-cut tolerance ledger* D*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* T *have all been replayed. Consequently no consumer can replace the route by a host supremum, selected subsequence, quotient stream equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply the upper-cut exactness theorem, Definition 768.5. It fixes U as the only upper-tail observation route from the bounded sequence row S.

Next apply the lower-cut compatibility theorem, Definition 768.4. It binds the dyadic ledger D to the same tail data and the bounded lower-cut surface, so the lower side cannot be replaced by a host lower envelope or by a selected subsequence.

Finally apply terminal seal routing, Definition 768.6. The terminal row T is reached only after S, U, D have been replayed, and the structural rows H, C, P, N preserve that order. The combined route therefore exposes a sealed $\mathsf{Real}^{\uparrow}$ candidate through the finite tail-cut packet and no excluded host-level principle. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupTailSealScope`

Theorem 768.8 (Limsup tail-window nonescape)**.** *Every public limsup comparison exported from an accepted* $\mathsf{Limsup}^{\uparrow}$ *tail window factors first through the bounded sequence row* S*, the bounded upper-cut and lower-cut rows exposed by* U *and* D*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the sibling* $\mathsf{RealSequenceLimit}^{\uparrow}$ *route, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* T*. Thus the tail-window export cannot bypass the displayed BEDC rows by reading a host supremum, selected subsequence, quotient stream, trichotomy branch, or Real-completeness principle.*

Proof. Project the accepted carrier of Definition 768.1. The only sequence-facing data are the bounded row S, the upper-cut schedule U, and the lower-cut comparison ledger D.

Apply Definition 768.5 and Definition 768.4. These force the upper and lower sides of the tail window through $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BoundedRealUpperCut}^{\uparrow}$, $\mathsf{BoundedRealLowerCut}^{\uparrow}$, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance budget before any comparison is exposed.

Next use Definition 768.6 and Definition 768.7. The candidate value is reached only through the terminal $\mathsf{Real}^{\uparrow}$ seal, while the $\mathsf{RealSequenceLimit}^{\uparrow}$ row remains a routed sibling dependency rather than a replacement for the displayed tail-cut package.

Finally replay Definition 768.12. Since no carrier field stores the excluded host-level principles, the public comparison surface remains inside the scoped tail-window route. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupTailWindowNonescape`

Theorem 768.9 (Limsup scope kernel dependencies)**.** *Every accepted* $\mathsf{Limsup}^{\uparrow}$ *consumer must expose the bounded sequence row* S*, the bounded upper-cut and lower-cut rows read through* U *and* D*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *route, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* T*, componentwise* BHist *and* hsame *data, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Limsup}^{\uparrow}}$ *row before it may read the limsup surface.*

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupScopeKernelDependencies`

Proof. Start with Definition 768.5. It fixes U as the only upper-tail route from the bounded sequence row S through finite $\mathsf{BoundedRealUpperCut}^{\uparrow}$ data.

Next apply Definition 768.4. The lower side is tied to the same tail data through the dyadic tolerance ledger D, so the $\mathsf{DyadicRatCore}^{\uparrow}$ comparison budget and the bounded lower-cut surface are visible before any limsup read is made.

Finally use Definition 768.6. The terminal $\mathsf{Real}^{\uparrow}$ row T is reached only after S, U, D have been replayed, and the structural rows H, C, P, N supply the BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ scope. The $\mathsf{RealSequenceLimit}^{\uparrow}$ dependency is therefore a routed sibling row, not a replacement for the displayed kernel package. □

Theorem 768.10 (Limsup finite tail-window induction scope)**.** *Every accepted* $\mathsf{Limsup}^{\uparrow}$ *tail-window read is generated by finite induction over displayed* $\mathsf{StreamName}^{\uparrow}$ *windows. At each induction step the read exposes the bounded upper-cut row, bounded lower-cut row,* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Limsup}^{\uparrow}}$ *row before any limsup endpoint is consumed.*

Proof. Start with the finite tail-cut route of Definition 768.11. The base window displays the bounded sequence row S, the initial upper-cut schedule U, the lower-cut compatibility ledger D, and the terminal seal T before the consumer can inspect an endpoint.

For the induction step, extend the displayed $\mathsf{StreamName}^{\uparrow}$ window by one finite read. The route keeps the bounded upper-cut and lower-cut rows synchronized with the same $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, so the new tail window is still generated from displayed finite rows rather than from a host subsequence or supremum.

Apply Definition 768.12 to the resulting window. It keeps the candidate value behind the terminal $\mathsf{Real}^{\uparrow}$ seal and prevents the induction step from importing Real completeness, trichotomy, quotient stream equality, or a selected cofinal subsequence.

Finally use Definition 768.9. The structural rows H, C, P, N provide the componentwise transport, replay, provenance, and local naming needed at every finite stage. Hence every accepted tail-window read is obtained by the stated finite induction before any limsup endpoint is consumed. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupTailWindowInductionScope`

Theorem 768.11 (Limsup tail-cut route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{Limsup}^{\uparrow}$ *packet factors through the finite route*

$$S \longmapsto U \longmapsto D \longmapsto T \longmapsto H \longmapsto C \longmapsto P \longmapsto N$$

before using the displayed limsup surface.

Proof. Begin with the bounded sequence row S. It supplies the only displayed source of sequence entries, finite windows, and boundedness evidence available to the packet.

The tail upper-cut schedule U then names which tails and upper observations are inspected. The dyadic ledger D records the tolerance comparisons that align those tail-upper observations with the bounded lower-cut surface.

Only after those rows are replayed can a consumer inspect the terminal real seal T. The structural rows H, C, P, N then transport, replay, source, and name the same finite route, so the consumer cannot bypass the tail-cut surface by reading a host supremum or a selected subsequence. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupTailCutRoute`

Theorem 768.12 (Limsup Real seal non-escape)**.** *An accepted* $\mathsf{Limsup}^{\uparrow}$ *packet exposes its candidate value only as the terminal* $\mathsf{Real}^{\uparrow}$ *row* T *reached through the displayed tail-cut route. In particular, it does not export Real completeness, trichotomy, a host supremum, quotient stream equality, selected subsequences, or open-cover compactness.*

Proof. The only value-facing coordinate in the carrier is T. All sequence-facing information is confined to S, U, D, and all structural access is confined to H, C, P, N.

A consumer that asks for the candidate value must therefore follow the continuation replay from the bounded sequence row through the tail upper-cut and tolerance ledgers before reaching T. The replay exposes a sealed real name, not a construction by supremum, compactness, or subsequence selection.

Since no carrier field stores the excluded principles, componentwise transport and continuation replay cannot introduce them. The $\mathsf{Real}^{\uparrow}$ seal remains terminal for the packet, and the limsup surface remains a finite tail-cut certificate. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupRealSealNonescape`

Theorem 768.13 (Limsup scoped tail-cut exhaustion)**.** *Every accepted* $\mathsf{Limsup}^{\uparrow}$ *consumer factors through the bounded sequence row* S*, the tail upper-cut schedule* U*, the bounded lower-cut compatibility row recorded by the dyadic tolerance ledger* D*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* T*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Limsup}^{\uparrow}}$ *row. Thus the scoped tail-cut surface is exhausted by the displayed finite route and exports no host supremum, selected subsequence, quotient stream, trichotomy branch, or Real-completeness principle.*

Proof. First apply Definition 768.5. It forces every upper-side read to begin with the bounded sequence row S and the finite tail upper-cut schedule U.

Next apply Definition 768.4. The lower-side comparison is tied to the same tail data by the dyadic tolerance ledger D, so the bounded lower-cut row and the $\mathsf{DyadicRatCore}^{\uparrow}$ budget are visible before any limsup consumer proceeds.

Now use Definition 768.6 and Definition 768.11. These route the consumer through S, U, D, T, H, C, P, N, placing the terminal $\mathsf{Real}^{\uparrow}$ seal after the bounded sequence, tail-cut, tolerance, transport, replay, provenance, and local naming rows.

Finally apply Definition 768.12. Since the terminal read is only the displayed Real seal and no carrier field stores the excluded host-level principles, the scoped tail-cut packet cannot export a host supremum, selected subsequence, quotient stream, trichotomy branch, or Real-completeness witness. □

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupScopedTailCutExhaustion`

Theorem 768.14 (Limsup scoped tail-cut witness)**.** *Every accepted* $\mathsf{Limsup}^{\uparrow}$ *consumer exposes the rows* S, U, D, T, H, C, P, N *as a single scoped witness surface. The surface binds upper-tail exactness through Definition 768.5, lower-cut compatibility through Definition 768.4, terminal seal routing through Definition 768.6, tail-cut route ordering through Definition 768.11, and Real seal nonescape through Definition 768.12.*

Lean4 ✓ `BEDC.Derived.LimsupUp.LimsupScopedTailCutWitness`

Proof. Project the accepted consumer to its displayed carrier rows. The bounded source row S, upper-tail schedule U, and dyadic lower-cut row D are fixed by the upper-cut exactness and lower-cut compatibility theorems.

Next compose the terminal seal and route-ordering results. They place T after the tail-cut rows and keep H, C, P, N as the transport, replay, provenance, and local naming surface for that same route.

Finally apply the nonescape theorem. Since the terminal Real read is reached only through the displayed rows, the eight-row surface is a scoped witness rather than an ambient supremum, selected subsequence, quotient stream, trichotomy branch, or Real-completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{Limsup}\uparrow}$**.**

Constructive story: A $\mathsf{Limsup}^{\uparrow}$ packet is generated from a bounded RealUp sequence row, a finite tail upper-cut schedule, a dyadic tolerance ledger, a terminal RealUp seal, componentwise hsame transports, Cont replay routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Limsup}\uparrow}$, scopedClosed)

Scope closed: Definition 768.1, Definition 768.2, Definition 768.3, Definition 768.9, and Definition 768.10 bind the bounded sequence row, upper-cut and lower-cut rows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RealSequenceLimit}^{\uparrow}$ route, terminal $\mathsf{Real}^{\uparrow}$ seal, and BHist/hsame/Cont/Pkg/NameCert rows for the finite tail-window limsup surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Limsup}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, a host supremum, quotient stream equality, selected subsequences, open-cover compactness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier formation, classifier stability, tail upper-cut exactness, lower-cut compatibility, terminal seal routing, tail-cut route ordering, and Real seal non-escape for the displayed packet.

Chapter 769

A Concrete Naming Certificate for $\mathsf{UniformContinuousExtension}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{UniformContinuousExtension}^{\uparrow}$ packet records the finite BEDC surface for extending a uniformly continuous map across displayed metric completions. It reads the completion carrier of chapter 95, the metric-completion route of chapter 1506, the complete-target convergence interface of chapter 128, the continuous-map graph and local-modulus rows of chapter 130, and the separated-target uniqueness boundary of chapter 1411. The packet is an extension ledger over finite modulus and Cauchy evidence rows; it is not a quotient-completion construction and it does not select representatives.

Definition 769.1 (UniformContinuousExtension carrier)**.** *A* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *carrier is a finite packet*

$$(X, Y, f, \omega, C_X, C_Y, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row together with the* $\mathsf{Completion}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *evidence used to read completion names over the same point histories.*
2. *Y is the target* $\mathsf{CompleteMetric}^{\uparrow}$ *row equipped with the* $\mathsf{SeparatedMetric}^{\uparrow}$ *uniqueness boundary for carried limits.*
3. *f is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row on the dense source, and ω is the finite uniform-modulus row that transports Cauchy closeness in X to Cauchy closeness in Y.*
4. *C_X is the source completion evidence: regular-Cauchy input windows, source observations, and the route from source names to completion names.*
5. *C_Y is the target convergence handoff: the complete-metric limit witness used after applying f through the transported modulus.*
6. *E is the extension row assigning a target completion read to each admitted source-completion read.*
7. *H is the componentwise* hsame *transport ledger for the source metric, target complete metric, map graph, modulus, completion evidence, convergence handoff, and extension row.*
8. *C is the displayed* Cont *replay route that forces every extension read to pass through $X, f, \omega, C_X, C_Y, E$ in that order.*

9. *P is the* Pkg *provenance row over* BHist, hsame, Cont, Met$^{\uparrow}$, Completion$^{\uparrow}$, MetricCompletion$^{\uparrow}$, CompleteMetric$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, *and the local completion and convergence rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformContinuousExtension}^{\uparrow}}$ *row naming this packet and no additional completion principle.*

Theorem 769.2 (UniformContinuousExtension NameCert obligations)**.** *For the carrier of Definition 769.1, the local* $\mathsf{NameCert}_{\mathsf{UniformContinuousExtension}^{\uparrow}}$ *surface consists of six finite obligations:*

1. *carrier admission for the displayed packet* $(X, Y, f, \omega, C_X, C_Y, E, H, C, P, N)$*;*
2. *modulus transport, sending the source Cauchy evidence in* C_X *through* ω *and the graph row* f*;*
3. *Cauchy-source compatibility, requiring every extension read to use the same source completion route recorded in* X *and* C_X*;*
4. *complete-target convergence, requiring the transported image sequence to reach the target limit only through* Y *and* C_Y*;*
5. *separated uniqueness, comparing two candidate extension reads only by the* SeparatedMetric$^{\uparrow}$ *boundary on the same complete target;*
6. *ledger non-escape, stating that* H, C, P, N *expose no quotient completion, selected representative, countable-choice schedule, open-cover compactness, or completeness of* Real$^{\uparrow}$*.*

Proof. Project the displayed packet. Carrier admission is the statement that all rows listed in Definition 769.1 are present over the same source and target histories, with P and N naming the local package.

The modulus and source-compatibility clauses are read next. The row ω is the only route from source Cauchy evidence to target Cauchy evidence, and C_X is the only route from source observations to completion names, so every admitted extension read must consume both rows before reaching the target side.

The target convergence and uniqueness clauses then follow from the target rows. The complete-metric handoff C_Y supplies the carried target limit, while the separated boundary in Y is the only comparison row available for two displayed target limits.

Finally inspect the structural rows. Transport in H is componentwise, replay in C follows the same ordered route, and provenance in P, N records only the finite BEDC rows already listed. No excluded principle is a carrier coordinate, so the local NameCert obligations are exhausted by the six clauses above. □

Theorem 769.3 (UniformContinuousExtension completion handoff)**.** *Every extension read exported by an accepted* UniformContinuousExtension$^{\uparrow}$ *carrier factors through the displayed route*

$$X, C_X \longmapsto f, \omega \longmapsto Y, C_Y \longmapsto E.$$

Thus a completion consumer can read the extended value only after the source completion evidence, uniform modulus, continuous-map graph row, complete-target convergence handoff, and separated uniqueness boundary have been replayed inside the same packet.

Proof. Begin with the source side. The completion name is admitted through X and C_X, so the packet gives no direct access to a source-completion value before the displayed regular-Cauchy evidence has been read.

Apply the map route next. The graph row f and the modulus row ω transport the source Cauchy evidence into target Cauchy evidence. This is the only target-facing route in the carrier.

The complete target row then supplies the limit handoff. The row C_Y records convergence in the complete metric target, and the separated part of Y records uniqueness for the displayed target read.

The extension row E is therefore reached only after the route $X, C_X, f, \omega, Y, C_Y$ has been replayed. The structural rows H, C, P, N preserve that route under componentwise transport and expose no quotient completion, selected representative, countable-choice schedule, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformContinuousExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformContinuousExtension}^{\uparrow}$ packet is generated from a source MetricUp row with CompletionUp and MetricCompletionUp evidence, a target CompleteMetricUp row with SeparatedMetricUp uniqueness, a ContinuousMapUp graph, a finite uniform-modulus row, source completion evidence, target convergence handoff, an extension row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformContinuousExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 769.1, Definition 769.2, and Definition 769.3 seed the finite uniformly continuous extension route across metric completions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformContinuousExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected representatives, countable choice, open-cover compactness, ambient target completeness beyond the displayed CompleteMetricUp row, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, modulus transport, source-completion compatibility, complete-target convergence, separated uniqueness, extension-row exactness, and ledger non-escape for BEDC.Derived.UniformContinuo

Chapter 770

A Concrete Naming Certificate for $\mathsf{JordanContent}^{\uparrow}$

Following Jordan and Bishop–Bridges constructive analysis, the $\mathsf{JordanContent}^{\uparrow}$ packet records finite Jordan content data through bounded rational boxes, dyadic partitions, lower and upper content sums, and common-refinement ledgers. It consumes the Darboux finite-sum surface of chapter 1880, the Darboux integration carrier of chapter 1460, the dyadic partition ledger of chapter 1863, the rational box endpoint rows of chapter 354, and the terminal real-name seal of chapter 38. The chapter names only the finite content ledger; it does not claim countable additivity, measure completion, selected limiting partitions, quotient equality of sets, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 770.1 (Jordan content finite carrier)**.** *A* $\mathsf{JordanContent}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (B, P, L, U, R, S, H, C, Q, N)$$

with the following displayed rows:

1. *B is the bounded rational-box row, built from finitely many* $\mathsf{RationalInterval}^{\uparrow}$ *endpoint and width ledgers.*
2. *P is the* $\mathsf{DyadicPartition}^{\uparrow}$ *row cutting the bounded box into finitely many named cells, together with the common-refinement data used when two ledgers are compared.*
3. *L and U are lower and upper content-sum rows, read through the* $\mathsf{DarbouxSum}^{\uparrow}$ *surface over the displayed partition row P.*
4. *R is the refinement row: it records the common dyadic refinement carrying B, P, L, U to any comparison partition without selecting a limiting partition family.*
5. *S is the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff row for a displayed content value window, obtained only after the lower and upper sums meet the recorded dyadic gap budget.*
6. *H records componentwise* hsame *transport for rational boxes, dyadic partitions, lower and upper content sums, common refinement, the real-facing handoff, continuation replay, provenance, and the local naming row.*
7. *C records displayed* Cont *replay from rational boxes to dyadic partition cells, from cells to the lower and upper content sums, from those sums to common refinement, and from the gap ledger to the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff.*

8. *Q is the* Pkg *provenance over* $\mathsf{JordanContent}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{JordanContent}^{\uparrow}}$ *row naming this finite content packet.*

The classifier compares accepted packets only through $B, P, L, U, R, S, H, C, Q, N$. It has no coordinate for a sigma algebra, countable additivity, measure completion, selected partition limits, quotient equality of sets, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.JordanContentUp.JordanContentTasteGate single carrier alignment`

Theorem 770.2 (Jordan content NameCert obligations)**.** *For the carrier of Definition 770.1, the local* $\mathsf{NameCert}_{\mathsf{JordanContent}^{\uparrow}}$ *surface consists exactly of the following six finite obligations:*

1. *carrier admission for the packet $J = (B, P, L, U, R, S, H, C, Q, N)$;*
2. *rational-box admission, requiring every bounded box read to factor through the finitely displayed* $\mathsf{RationalInterval}^{\uparrow}$ *endpoint and width rows in B;*
3. *dyadic partition compatibility, requiring every content cell to be named by P and every comparison to pass through the common-refinement row R;*
4. *lower and upper content-sum exactness, requiring L and U to be computed from the displayed cells and their carried lower and upper occupancy rows;*
5. *real-facing handoff, requiring S to be downstream of the finite lower/upper gap ledger before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer can read it;*
6. *ledger non-escape, stating that H, C, Q, N preserve and name only these finite rows and exclude countable additivity, measure completion, selected limiting partitions, quotient set equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the displayed carrier. Carrier admission is exactly the finite packet of Definition 770.1, with rational boxes, a dyadic partition, two content-sum rows, a common-refinement row, a real-facing handoff, transport, replay, provenance, and a local name.

The rational-box and partition clauses are read before any content sum. The row B supplies the bounded rational endpoints, while P supplies the finite dyadic cells cut from those endpoints. Refinement data are stored in R, so comparing two packets uses a displayed common refinement rather than a selected limiting partition family.

The content-sum clauses follow from the Darboux-sum surface. The lower row L and upper row U are finite sums over the cells named by P, and common refinement transports those sums through R before the gap can be inspected.

Finally inspect the handoff and structural rows. The row S is downstream of the finite gap ledger, while H, C, Q, N only transport, replay, source, and name the already displayed rows. No excluded measure-theoretic or quotient object is a carrier coordinate, so the six obligations exhaust the local NameCert surface. □

Theorem 770.3 (Jordan content finite additivity scope)**.** *For accepted* $\mathsf{JordanContent}^{\uparrow}$ *carriers whose bounded rational boxes have a displayed disjoint dyadic decomposition inside a common refinement, finite additivity is available only as an equality of the transported lower and upper content-sum rows over that refinement. The statement exports a finite box-and-partition ledger to Darboux and Riemann consumers, not a measure-completion object and not countable additivity.*

Proof. Start with the two accepted carriers and read their rational-box rows. The displayed disjoint decomposition supplies a common dyadic refinement, so all cells used in the comparison are named by one finite partition row.

Transport both content packets through the refinement row R. Componentwise hsame transport preserves the rational-box coordinates, dyadic cell names, and lower and upper content-sum rows, while Cont replay recomputes the sums over the transported cells.

Finite additivity is then a ledger statement about finite cell lists. Disjoint cells contribute once, shared boundary rows are already part of the rational-box endpoint ledger, and the lower and upper transported sums combine by the same finite Darboux-sum route used to define L and U.

The exported scope stops at the transported finite sums and the real-facing handoff row S. Since no carrier coordinate stores a sigma algebra, measure completion, selected partition limit, quotient set equality, or countable family, the additivity claim cannot be read as a countable or completed measure theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{JordanContent}^{\uparrow}}$.

Constructive story: A $\mathsf{JordanContent}^{\uparrow}$ packet is generated from bounded rational boxes, a dyadic partition row, lower and upper content-sum rows, a common-refinement ledger, a RegSeqRat/Real handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanContent}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 770.1, Definition 770.2, and Definition 770.3 seed the finite Jordan content ledger over bounded rational boxes and dyadic partitions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanContent}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable additivity, measure completion, selected limiting partitions, quotient equality of sets, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-box admission, dyadic partition compatibility, lower and upper content-sum exactness, common-refinement transport, real-facing handoff, finite additivity scope, and ledger non-escape for BEDC.Derived.JordanContentUp.

Chapter 771

A Concrete Naming Certificate for $\mathsf{UniformConvergenceTest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformConvergenceTest}^{\uparrow}$ packet records a uniform convergence test as finite shared-tail data over the $\mathsf{RealSeries}^{\uparrow}$ and $\mathsf{UniformCauchyCriterion}^{\uparrow}$ rows. It sits between the finite partial-sum surface of chapter 1581, the shared-threshold family criterion of chapter 435, the optional majorant route of chapter 399, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the displayed shared-tail route; it is not pointwise-only convergence, a selected infinite sum, a quotient function space, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 771.1 (Uniform convergence test carrier)**.** *A* $\mathsf{UniformConvergenceTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, S, N, T, M, R, E, H, C, P, Q)$$

with the following visible rows:

1. *F is the source family row naming the inspected functions, terms, or partial-sum windows only through the finite indices carried by the packet;*
2. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *or partial-sum series row whose displayed finite sums are the objects being tested;*
3. *N is the shared tail threshold row, one finite threshold surface read by all source-family windows under the requested dyadic tolerance;*
4. *T is the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row that records the uniform family comparison after F, S, N have been fixed;*
5. *M is an optional* $\mathsf{WeierstrassMTest}^{\uparrow}$ *majorant row, absent when the test is supplied directly by T and present only when a displayed majorant ledger produces the same shared threshold;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the uniform tail data before any real-facing seal is exposed;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row consumed by downstream Real or Completion routes after R has been displayed;*
8. *H stores componentwise* hsame *transports for the source family, series row, shared threshold, uniform Cauchy row, optional majorant row, regular readback, real seal, continuation, provenance, and local naming rows;*

9. *C stores displayed* Cont *routes from source-family reads to series windows, from series windows to the shared threshold, from the threshold to the uniform Cauchy row, from the optional majorant to the same threshold, from uniform Cauchy data to regular readback, and from readback to the real seal;*

10. *P is the* Pkg *provenance over* $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

11. *Q is the local* $\mathsf{NameCert}_{\mathsf{UniformConvergenceTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, S, N, T, M, R, E, H, C, P, Q$. It has no coordinate for pointwise-only convergence, selected infinite sums, quotient equality of function names, countable-choice schedules, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.UniformConvergenceTestUp.UniformConvergenceTestTasteGate single carrier alignment`

Theorem 771.2 (Uniform convergence test NameCert obligations)**.** *For every accepted* $\mathsf{UniformConvergenceTest}^{\uparrow}$ *carrier $U = (F, S, N, T, M, R, E, H, C, P, Q)$, the local* $\mathsf{NameCert}_{\mathsf{UniformConvergenceTest}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows, source-family access through F, series-window access through S, shared tail thresholding through N, uniform Cauchy comparison through T, optional majorant transport through M,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through Q.*

The optional majorant row is not a second convergence proof. When present, it must route through the same shared threshold row N and the same $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row T before R or E can be read.*

Proof. Project the carrier of Definition 771.1. The only source and series data visible to the classifier are F and S, and the only uniform tail gate is the shared threshold row N.

Read the uniform criterion next. The row T consumes F, S, N as one finite family comparison, while the optional row M can contribute only by producing the same threshold surface through the Weierstrass majorant route.

Finally read R, E, H, C, P, Q. The regular readback and real seal are downstream of the shared threshold and uniform criterion, and the structural rows transport, replay, source, and name exactly that route. Since no other carrier coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 771.3 (Uniform convergence test Cauchy handoff)**.** *Every Real-facing or Completion-facing read from an accepted* $\mathsf{UniformConvergenceTest}^{\uparrow}$ *carrier factors through the finite route*

$$F \longmapsto S \longmapsto N \longmapsto T \longmapsto R \longmapsto E$$

together with H, C, P, Q. If the optional majorant row M is present, it is read before T only to certify the same shared threshold N. Thus every consumer reaches $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *through the uniform Cauchy handoff, not through a pointwise convergence predicate, selected infinite sum, quotient function space, countable-choice schedule, or ambient completeness row.*

Proof. Start with a consumer request for a real-facing limit or completion-facing seal. By Definition 771.1, the request first reads the source-family row F and the displayed series or partial-sum row S.

The shared threshold row N is then the only tail gate available to the packet. Apply Definition 771.2: the uniform criterion row T consumes that threshold for all displayed family windows, and any majorant row M must feed the same threshold before T is accepted.

The handoff to regular rational data is therefore forced through R. Only after R is displayed may the route reach the $\mathsf{Real}^{\uparrow}$ seal E, with H, C, P, Q preserving and naming the same finite packet. The excluded host objects are absent from the carrier, so no consumer can bypass the shared-threshold route. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformConvergenceTest}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformConvergenceTest}^{\uparrow}$ packet is generated from a source family row, a $\mathsf{RealSeries}^{\uparrow}$ or partial-sum series row, one shared tail threshold, a $\mathsf{UniformCauchyCriterion}^{\uparrow}$ row, an optional $\mathsf{WeierstrassMTest}^{\uparrow}$ majorant row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformConvergenceTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 771.1, Definition 771.2, and Definition 771.3 bind the finite shared-tail route used by RealSeries, UniformCauchyCriterion, optional WeierstrassMTest, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformConvergenceTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close pointwise-only convergence, selected infinite sums, quotient function spaces, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-threshold exactness, optional majorant compatibility, RegSeqRat readback, Real seal handoff, and TasteGate field faithfulness for BEDC.Derived.UniformConvergenceTestUp.

Chapter 772

A Concrete Naming Certificate for $\mathsf{NadlerFixedPoint}^{\uparrow}$

Following Nadler and Bishop–Bridges constructive metric practice, the $\mathsf{NadlerFixedPoint}^{\uparrow}$ packet records the finite NameCert surface for a multivalued contraction on a complete metric carrier whose values are exposed through compact-set distance rows. It sits after the complete-metric convergence service of chapter 128, the Hausdorff compact-subset distance interface of chapter 2086, the single-valued contraction route of chapter 396, the displayed orbit discipline of chapter 2359, and the compact finite-inspection surface of chapter 129. The packet names only displayed source rows, compact value rows, Hausdorff contraction comparisons, finite choice-free refinement ledgers, transport, replay, provenance, and local naming; it does not import selected representatives, countable choice, quotient completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 772.1 (Nadler fixed-point carrier)**.** *A* $\mathsf{NadlerFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (X, K, F, V, D, L, O, R, H, C, P, Q)$$

with the following displayed rows:

1. *X is the underlying* $\mathsf{Met}^{\uparrow}$ *row, carrying the point classifier and distance observations inspected by the multivalued fixed-point route.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row over X, exposing only the convergence service and limit-witness handoff accepted by the complete-metric certificate.*
3. *F is the multivalued self-map row: for each displayed source point it records a compact nonempty value name rather than an untracked host subset.*
4. *V records the* $\mathsf{CompactMetric}^{\uparrow}$ *value rows used to inspect the compact names supplied by F.*
5. *D records the* $\mathsf{HausdorffMetric}^{\uparrow}$ *distance rows between displayed values of F, including the finite-net and point-to-set witnesses used by the multivalued contraction comparison.*
6. *L is the rational contraction ledger with a displayed positive row and a displayed unit-bound row.*
7. *O is the finite Picard-style approximation ledger. Each step stores the current point row, the inspected compact value row, the next displayed point row, and the Hausdorff contraction budget used to continue the route.*

8. *R stores the Cauchy and completion handoff from O, L, D to K without forming a quotient completion or selecting a global branch outside the finite ledger.*

9. *H stores componentwise* hsame *transport for source, completeness, multivalued map, compact values, Hausdorff rows, contraction ledger, approximation ledger, completion handoff, replay, provenance, and naming rows.*

10. *C stores displayed* Cont *replay of the route*

$$X, K, F, V, D, L \longmapsto O \longmapsto R.$$

11. *P is the* Pkg *provenance over* $\mathsf{NadlerFixedPoint}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *Q is the local* $\mathsf{NameCert}_{\mathsf{NadlerFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, F, V, D, L, O, R, H, C, P, Q$. It has no coordinate for a selected representative of each compact value, a countable choice operator, quotient-completion equality, a host hyperspace object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NadlerFixedPointUp.TasteGate.NadlerFixedPointTasteGate single carrier alignment`

Theorem 772.2 (Nadler fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{NadlerFixedPoint}^{\uparrow}$ *carrier $N = (X, K, F, V, D, L, O, R, H, C, P, Q)$, the local* $\mathsf{NameCert}_{\mathsf{NadlerFixedPoint}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the metric source X, complete-metric service K, multivalued map row F, compact value rows V, Hausdorff distance rows D, contraction ledger L, finite approximation ledger O, completion handoff R, transport H, replay C, provenance P, and local naming Q;*

2. *classifier transport, requiring accepted packet comparisons to preserve the same source classifier, compact value names, Hausdorff finite-net witnesses, contraction budget, approximation ledger, and completion handoff componentwise through H;*

3. *stability, requiring the Hausdorff contraction comparison in D, L to survive replacement of displayed source points and compact value names by classified equals before the next approximation row in O is admitted;*

4. *exactness and ledger nonescape, requiring the route from finite approximation rows to the complete-metric handoff R to pass through K and to export no selected representatives, no countable choice, no quotient completion, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate;*

5. *NameCert provenance, requiring C, P, Q to replay, source, and name only the displayed route over the CompleteMetric, HausdorffMetric, BanachFixedPoint, PicardIteration, and CompactMetric sibling surfaces cited above.*

No Nadler fixed-point obligation is stored outside these rows.

Proof. Project the carrier of Definition 772.1. The source metric row X, complete-metric service K, multivalued map row F, compact value rows V, Hausdorff distance rows D, rational contraction ledger L, approximation ledger O, and completion handoff R are the only mathematical coordinates available to the certificate.

The classifier is therefore componentwise. Transport through H may replace displayed source points, compact value names, Hausdorff witnesses, and ledger rows only by the recorded hsame

routes; replay through C preserves the same finite path from compact-value inspection to the completion handoff.

The stability obligation is the multivalued analogue of the contraction step. It reads the Hausdorff comparison from D, L and admits the next row in O only through the displayed value names and finite-net witnesses, not through a hidden branch selector.

Finally R, P, Q repack the finite route as the local naming surface. Since the carrier has no coordinate for selected representatives, countable choice, quotient-completion equality, a host hyperspace object, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the five listed rows exhaust the NameCert obligations. □

Theorem 772.3 (Nadler approximation route nonescape)**.** *Every fixed-point read exported by an accepted* $\mathsf{NadlerFixedPoint}^{\uparrow}$ *packet factors through the displayed route*

$$X, K, F, V, D, L \longmapsto O \longmapsto R \longmapsto H, C, P, Q.$$

The route may compare with the $\mathsf{BanachFixedPoint}^{\uparrow}$ *and* $\mathsf{PicardIteration}^{\uparrow}$ *siblings as single-valued reference surfaces, but it exports only compact-value Hausdorff contraction data and complete-metric handoff rows. It provides no selected representative sequence, no countable choice principle, no quotient completion, no host hyperspace completion, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with a fixed-point read from the packet. The carrier first exposes X, K, F, V, D, L, so the consumer can inspect only the displayed source metric, complete-metric service, multivalued map row, compact value rows, Hausdorff finite-net witnesses, and rational contraction budget.

The approximation ledger O is finite at every displayed stage. It records the point row, the inspected compact value row, the next point row, and the contraction comparison used by that stage; it never stores an external sequence selected by countable choice.

The handoff row R then routes the approximation ledger to the complete-metric service K. The structural rows H, C, P, Q transport, replay, source, and name this same path, so the exported fixed-point read cannot leave the displayed packet for the excluded host principles. □

Falsifiable prediction: Every $\mathsf{NadlerFixedPoint}^{\uparrow}$ fixed-point read factors through one MetricSpaceUp source row, one CompleteMetricUp service row, one multivalued self-map row, CompactMetricUp value rows, HausdorffMetricUp distance rows, one rational contraction ledger, one finite approximation ledger, one completion handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: complete-metric, hausdorff-metric, banach-fixed-point, picard-iteration, compactmetric: $\mathsf{NadlerFixedPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact-valued multivalued map rows, Hausdorff contraction comparisons, finite choice-free approximation ledgers, complete-metric handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{NadlerFixedPoint}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NadlerFixedPoint}^{\uparrow}$ packet is generated from a MetricSpaceUp source row, CompleteMetricUp convergence service, compact-valued multivalued self-map row, CompactMetricUp value rows, HausdorffMetricUp distance witnesses, rational contraction ledger below the unit bound, finite Picard-style approximation ledger, complete-metric handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NadlerFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 772.1, Definition 772.2, and Definition 772.3 bind the multivalued contraction certificate surface through displayed compact values, Hausdorff comparisons, finite approximation ledgers, and complete-metric handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NadlerFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected representatives, countable choice, quotient completion, host hyperspace completion, ambient Real completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, Hausdorff contraction stability, approximation-route nonescape, exactness, provenance, and local naming for BEDC.Derived.NadlerFixedPointUp.

Chapter 773

A Concrete Naming Certificate for $\mathsf{BrouwerianCounterexample}^{\uparrow}$

Following Brouwer, Troelstra–van Dalen, and Bridges–Richman on constructive counterexamples, the $\mathsf{BrouwerianCounterexample}^{\uparrow}$ packet records a finite refusal surface for off-table L10 readings. It sits beside the finite observation route of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Specker obstruction boundary of chapter 3516. The packet makes the refusal of trichotomy, selected limits, quotient real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness inspectable as NameCert data rather than as an implicit metatheoretic convention.

Definition 773.1 (Brouwerian counterexample carrier)**.** *A* $\mathsf{BrouwerianCounterexample}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, A, S, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the tested L10 claim row, naming the proposed off-table reading such as trichotomy, selected limit extraction, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*
2. *A is the finite counterexample source row, carrying the Brouwerian choice-sequence, bar, or Specker-style obstruction data used to test Q.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the source is inspected by a downstream Real or Completion consumer.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed windows in S.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *readback boundary available only after the source, window, regular-rational, and refusal rows have been displayed.*
6. *L is the refusal ledger recording which tested reading in Q is not exported by the packet and which finite counterexample source row A witnesses the refusal.*
7. *H records componentwise* hsame *transport for the tested claim, counterexample source, stream window, regular readback, Real boundary, refusal ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the tested claim through the counterexample source, then through stream windows, regular readback, refusal ledger, and the terminal readback boundary.*

9. *P is the* Pkg *provenance over* $\mathsf{BrouwerianCounterexample}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerianCounterexample}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, S, R, E, L, H, C, P, N$. It has no coordinate for a completed host counterexample object, an omniscience principle, real trichotomy, quotient real equality, selected limits, countable choice, or ambient Real completeness.

Theorem 773.2 (Brouwerian counterexample NameCert obligations)**.** *For every accepted* BrouwerianCounterexamp *carrier $B = (Q, A, S, R, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BrouwerianCounterexample}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the tested L10 claim, finite counterexample source, StreamName windows, RegSeqRat readback, Real boundary, refusal ledger, transport, replay, provenance, and local naming rows;*
2. *source exactness, requiring the row A to be the only counterexample source used when the tested claim row Q is evaluated;*
3. *windowed readback, requiring every Real or Completion-facing read to open S and R before consulting the Real boundary E;*
4. *refusal-ledger exactness, requiring the ledger L to bind each refused reading to the displayed source and readback rows rather than to an uninspected host argument;*
5. *transport and replay stability, requiring H and C to preserve the same tested claim, source, windows, readback, boundary, and refusal rows;*
6. *nonescape for omniscience, trichotomy, quotient real equality, selected limits, countable choice, and ambient Real completeness.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 773.1. The only analytic coordinates are the tested claim Q, finite counterexample source A, window row S, readback row R, Real boundary E, and refusal ledger L.

Source exactness and windowed readback follow from the order of the displayed route. The source row A is the only row that may test Q, while any Real or Completion-facing consumer must first read S and R before reaching E.

The refusal ledger then records a finite negative boundary. It binds each refused off-table reading to the inspected source and readback rows; it does not certify a detached host counterexample or a completed real object.

The structural rows H, C, P, N only transport, replay, source, and name the same packet. Since the carrier has no coordinate for omniscience, trichotomy, quotient real equality, selected limits, countable choice, or ambient Real completeness, none of those readings can be exported as local NameCert data. □

Lean4 ✓ `BEDC.Derived.BrouwerianCounterexampleUp.BrouwerianCounterexampleTasteGate single carrier alignment`

Theorem 773.3 (Brouwerian counterexample Real boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BrouwerianCounterexample}^{\uparrow}$ *carrier must read the tested claim row, the finite counterexample source, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the refusal ledger*

before the $\mathsf{Real}^{\uparrow}$ *boundary is exposed. The boundary therefore supplies finite counterexample readback only; it supplies no real trichotomy, quotient real equality, selected limit, countable-choice selector, omniscience principle, or ambient Real completeness.*

Proof. Begin with a Real or Completion-facing read of $B = (Q, A, S, R, E, L, H, C, P, N)$. The only Real-facing coordinate is E, and carrier admission places it after the tested claim, source, window, readback, and ledger rows.

Open the readback route. The consumer first inspects Q and A, then obtains the finite windows through S and the regular rational data through R. Only then can the refusal ledger L say which off-table reading is not exported by the displayed source.

The endpoint row E is therefore a boundary, not a completeness theorem. It records the finite Real readback surface shared with chapter 38, while the source and window discipline remain those of chapter 126 and chapter 301.

The structural rows preserve the same route. Since the neighbouring Specker boundary of chapter 3516 also refuses located-supremum escape through finite rows, the present packet can cite that style of obstruction without exporting trichotomy, quotient real equality, selected limits, countable choice, omniscience, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{BrouwerianCounterexample}^{\uparrow}$ Real or Completion read factors through a tested L10 claim row, a finite counterexample source, a StreamName window, a RegSeqRat readback, a Real boundary, a refusal ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerianCounterexample}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerianCounterexample}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 773.1, Definition 773.2, and Definition 773.3 seed the finite Brouwerian counterexample packet over tested L10 claims, finite source rows, StreamName windows, RegSeqRat readback, Real boundary, and refusal ledger data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerianCounterexample}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, real trichotomy, quotient real equality, selected limits, countable choice, omniscience principles, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, source exactness, windowed readback, refusal-ledger exactness, transport and replay stability, Real boundary, and nonescape for BEDC.Derived.BrouwerianCounterexampleUp.

Constructive story: A $\mathsf{BrouwerianCounterexample}^{\uparrow}$ packet is generated from a tested L10 claim row, a finite counterexample source, StreamName windows, RegSeqRat readback, a Real boundary row, a refusal ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Chapter 774

A Concrete Naming Certificate for $\mathsf{FiniteBairstowRootWindow}^{\uparrow}$

Following the classical Bairstow quadratic-factor iteration in a Bishop-style finite-window reading, the $\mathsf{FiniteBairstowRootWindow}^{\uparrow}$ packet records only the displayed data needed to route a polynomial root-window computation toward Real-facing consumers. It sits after the polynomial coefficient interface of chapter 50, the real-name seal of chapter 38, the dyadic tolerance rows of chapter 291, the regular rational readback of chapter 301, the finite stream windows of chapter 126, and the bisection-to-Cauchy seal of chapter 1798. The packet is a finite root-window certificate; it is not host algebraic closure, quotient real equality, selected complex roots, global factorization, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 774.1 (Finite Bairstow root-window carrier)**.** *A* $\mathsf{FiniteBairstowRootWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, U, V, R, D, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Poly}^{\uparrow}$ *coefficient-window row naming the finite list of inspected coefficients and the active degree bound.*
2. *U is the quadratic-factor update row recording the displayed Bairstow correction window for the current pair of quadratic coefficients.*
3. *V is the residual-budget ledger measuring the finite remainder, slack, and admissible stopping budget.*
4. *R is the dyadic bracketing row that turns the retained quadratic or linear factor into a sign-change or enclosure window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by V and R.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row for coefficient, residual, and bracket requests.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row handed to the* $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ *and terminal* $\mathsf{Real}^{\uparrow}$ *consumers.*
8. *H records componentwise* hsame *transport for coefficient windows, update rows, residual budgets, dyadic brackets, tolerance ledgers, stream windows, regular readbacks, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from coefficient inspection through update, residual, bracketing, regular readback, and Real-seal handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteBairstowRootWindow}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{BisectionRootCauchySeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteBairstowRootWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, U, V, R, D, S, Q, H, C, P, N$. It has no coordinate for host algebraic closure, quotient real equality, selected roots, unrestricted factorization, countable search, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 774.2 (Finite Bairstow root-window NameCert obligations)**.** *For every accepted* FiniteBairstowRootWind *carrier $B = (A, U, V, R, D, S, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteBairstowRootWindow}^{\uparrow}}$ *surface consists exactly of coefficient-window admission, quadratic-factor update admission, residual-budget ledger exposure, dyadic bracketing-window exposure,* $\mathsf{StreamName}^{\uparrow}$ *finite observation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. The route refuses host algebraic closure, quotient real equality, selected complex roots, global factorization, countable root search, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 774.1. The coefficient window A, update row U, residual ledger V, bracket row R, tolerance ledger D, stream row S, and regular readback Q are the only analytic coordinates available to the packet.

The finite update route first inspects coefficients through A and S. The Bairstow correction row U and residual-budget row V are displayed finite rows, so the certificate never reads a host factorization theorem or a selected root.

Next the dyadic bracket R and tolerance ledger D feed the regular readback Q. The $\mathsf{BisectionRootCauchySeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers receive only that finite bracketing and regular-Cauchy handoff, not quotient equality or ambient completeness.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores algebraic closure, selected roots, unrestricted factorization, countable search, quotient real equality, or a completed Real object, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every $\mathsf{FiniteBairstowRootWindow}^{\uparrow}$ consumer that exports a root-window read without displaying coefficient windows, quadratic-factor update rows, residual budgets, dyadic brackets, StreamName observations, RegSeqRat readback, transport, replay, provenance, and local naming is outside the carrier surface.

Independence witness: polynomial, real, dyadicratcore, regseqrat, streamname, bisection-root-cauchy-seal: no listed sibling jointly carries coefficient windows, Bairstow update rows, residual budgets, dyadic brackets, regular readback, bisection-to-Cauchy handoff, and local NameCert data while refusing host algebraic closure and quotient root equality.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteBairstowRootWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteBairstowRootWindow}^{\uparrow}$ packet is generated from polynomial coefficient windows, quadratic-factor update rows, residual-budget ledgers, dyadic bracketing windows, StreamName observations, RegSeqRat readback, a BisectionRootCauchySeal handoff, a Real-facing seal route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteBairstowRootWindow}^{\uparrow}}$, seed)

Scope closed: Definition 774.1 and Definition 774.2 seed the finite Bairstow root-window packet over polynomial coefficient windows, quadratic-factor updates, residual budgets, dyadic brackets, StreamName, RegSeqRat, BisectionRootCauchySeal, Real, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteBairstowRootWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host algebraic closure, quotient real equality, selected roots, global factorization, countable root search, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires finite update exactness, residual-budget determinacy, dyadic bracket handoff, Real-seal nonescape, transport stability, replay stability, and ledger refusal for BEDC.Derived.FiniteBairstowRootWindowUp.

Chapter 775

A Concrete Naming Certificate for MetaCICTypedExamplesGallery$^{\uparrow}$

The MetaCICTypedExamplesGallery$^{\uparrow}$ packet realizes the typed-example audit map of chapter 9382 as a finite NameCert gallery. It sits beside the confluence audit surface of chapter 743 and the closed-term substitution boundary of chapter 527: those chapters constrain global metatheorem reads, while this chapter exposes the worked syntax and typing examples as finite rows.

Definition 775.1 (MetaCIC typed-examples gallery carrier)**.** *A* MetaCICTypedExamplesGallery$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M)$$

with the following displayed rows:

1. *B records the Church Bool example rows, including the displayed true, false, and eliminator typing reads;*
2. *N records the Church Nat example rows, including zero, successor, and numeral typing reads;*
3. *L records the Church List example rows, including nil, cons, and eliminator typing reads;*
4. *S records the Church Sum example rows, including left injection, right injection, and case-analysis typing reads;*
5. *E records equality example rows, including reflexivity and transport-shaped reads that stay inside the displayed typing ledger;*
6. *I records identity example rows, including polymorphic identity and dependent identity examples;*
7. *A records application example rows, including function application and argument instantiation reads;*
8. *R records beta-redex example rows and their displayed reduction endpoints;*
9. *K records checker-acceptance rows for the example families named by B, N, L, S, E, I, A, R;*
10. *H records componentwise* hsame *transport for every gallery row, route row, provenance row, and local naming row;*
11. *C records the displayed* Cont *routes for syntax readback, typing readback, beta-redex replay, checker-acceptance replay, and consumer exposure;*

12. *P records* Pkg *provenance over* BHist, hsame, Cont, Pkg, NameCert, *the MetaCIC typed-example rows, and the checker rows named by chapter 9382;*
13. *M is the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed rows. It has no coordinate for arbitrary closed-term normalization, confluence, subject reduction, conversion decidability, or a complete algebraic theory of the Church encodings.

Theorem 775.2 (MetaCIC typed-examples gallery obligation matrix)**.** *Each accepted* MetaCICTypedExamplesGalle *typed example row must expose its context row, term row, typing derivation row, reduction-window row, local-join row, normalization-frontier row,* hsame *transport,* Cont *replay,* Pkg *provenance, and* NameCert *row before it can be consumed by* $\mathsf{MetaCICCriticalPath}^{\uparrow}$*. The matrix is read from the finite gallery rows*

$$B, N, L, S, E, I, A, R, K, H, C, P, M,$$

with local-join and normalization-frontier access routed through the beta-redex and checker rows R, K rather than through a global confluence, subject-reduction, normalization, or conversion-completeness theorem.

Proof. Project the carrier of Definition 775.1. The family rows B, N, L, S, E, I, A, R are the only context, term, typing, and reduction-window sources available to an accepted gallery example, while K is the checker boundary attached to those displayed sources.

The local-join and normalization-frontier reads are therefore sibling routes of the finite beta-redex and checker surface. They are the same finite rows later isolated by Definition 775.6 and Definition 775.7, with the redex-frontier handoff boundary recorded in Definition 1008.6.

Finally add the structural rows. Transport is projected through H, replay through C, provenance through P, and local naming through M. Since the carrier has no coordinate for global confluence, subject reduction, normalization, or conversion completeness, $\mathsf{MetaCICCriticalPath}^{\uparrow}$ can consume only the displayed obligation matrix. □

Theorem 775.3 (MetaCIC typed-examples gallery NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}$ *carrier*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}}$ *surface consists exactly of carrier exposure for the finite gallery, representative theorem inventory for the Church Bool, Nat, List, Sum, equality, identity, application, and beta-redex rows, regression exactness for the displayed example endpoints, checker handoff through K, non-escape from global metatheorems, and ledger provenance through P, M.*

Proof. Project the carrier of Definition 775.1. The rows B, N, L, S, E, I, A, R are the complete representative theorem inventory exposed by this gallery packet.

The checker handoff is the row K, and every read of K is replayed through the displayed route row C. Componentwise transport through H preserves the same example rows and does not add a new theorem coordinate.

Finally read provenance through P and local naming through M. Since the carrier has no coordinate for subject reduction, confluence, normalization, or conversion decidability, the gallery obligations are exhausted by the finite example rows and their checker-acceptance routes. □

Theorem 775.4 (MetaCIC typed-examples gallery obligation surface)**.** *For every accepted* MetaCICTypedExamples *carrier*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M),$$

the obligation surface consists exactly of the Church Bool row B, Church Nat row N, Church List row L, Church Sum row S, equality row E, identity row I, application row A, beta-redex row R, checker-acceptance row K, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}}$ *row M. It excludes subject reduction, confluence, normalization, conversion completeness, arbitrary example coverage, and checker completeness.*

Proof. Project the accepted carrier of Definition 775.1. The rows B, N, L, S, E, I, A, R are the only example-family rows, and K is the only checker-acceptance row attached to them.

The structural support is also displayed. Componentwise transport is read through H, replay through C, provenance through P, and local naming through M.

There is no carrier coordinate for subject reduction, confluence, normalization, conversion completeness, arbitrary example coverage, or checker completeness. Therefore the obligation surface is bounded by exactly the displayed rows. □

Theorem 775.5 (MetaCIC typed-examples gallery regression surface)**.** *An accepted* MetaCICTypedExamplesGallery *packet is a finite regression surface for represented syntax and typing. Consumers may inspect the Church Bool, Nat, List, Sum, equality, identity, application, beta-redex, checker-acceptance,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows, but they cannot read the packet as a subject-reduction theorem, a confluence theorem, a normalization theorem, or a decidability theorem.*

Proof. Start with the visible coordinates of G. They are example rows and routes for syntax, typing, beta-redex replay, checker acceptance, transport, provenance, and local naming.

Each consumer read factors through the finite route row C and the checker row K. These rows can replay the represented gallery examples, but they have no endpoint for a global preservation or conversion principle.

Therefore the accepted packet is exactly a finite regression surface for the displayed examples. The excluded metatheorems remain outside the carrier because no row of G can be projected as such a theorem. □

Theorem 775.6 (MetaCIC typed-examples gallery typed-family coverage)**.** *For every accepted* $\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}$ *carrier*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M),$$

every typed-example family read exposed by the gallery factors through one of the displayed family rows B, N, L, S, E, I, A, R and then through the checker row K, componentwise transport row H, replay row C, provenance row P, and local naming row M. The gallery exposes no further subject-reduction family, confluence family, normalization family, conversion-completeness family, arbitrary-example-coverage family, or checker-completeness family.

Proof. Project the carrier of Definition 775.1. Its only typed-example family rows are the Church Bool, Church Nat, Church List, Church Sum, equality, identity, application, and beta-redex rows named by B, N, L, S, E, I, A, R.

Now split over that finite displayed family inventory. A Bool read is routed through B, a Nat read through N, a List read through L, a Sum read through S, an equality read through E, an identity read through I, an application read through A, and a beta-redex read through R.

Checker acceptance is then forced through K. Transport of the same family row is read through H, replay is read through C, and the exported consumer-facing certificate is packaged by P and named by M.

Finally apply the regression surface of Definition 775.5. Since the carrier has no coordinate for subject reduction, confluence, normalization, conversion completeness, arbitrary example coverage, or checker completeness, no additional typed-family read is exposed by the gallery. □

Theorem 775.7 (MetaCIC typed-examples gallery checker-route factorization)**.** *For every accepted* $\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}$ *carrier*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M),$$

every gallery consumer read factors through exactly one displayed example-family row among B, N, L, S, E, I, A, R *and then through* K, H, C, P, M*. The checker row* K *is therefore only the finite acceptance boundary for the chosen displayed family. It cannot be read as subject reduction, confluence, normalization, conversion completeness, or checker completeness.*

Proof. Project the carrier of Definition 775.1. Its displayed example-family rows are exactly B, N, L, S, E, I, A, R, so a gallery read first chooses one of those finite rows.

Case split over the displayed family row. Bool reads route through B, Nat reads through N, List reads through L, Sum reads through S, equality reads through E, identity reads through I, application reads through A, and beta-redex reads through R.

After that family choice, acceptance must pass through K, and the same accepted route is transported by H, replayed by C, sourced by P, and named by M.

Finally cite the regression surface theorem Definition 775.5. Since the packet has no coordinate for the excluded global metatheorems, the checker row remains a finite family acceptance boundary and cannot be consumed as subject reduction, confluence, normalization, conversion completeness, or checker completeness. □

Lean4 ✓ `BEDC.MetaCIC.gallery checker route factorization`

Theorem 775.8 (MetaCIC typed-examples gallery kernel scope)**.** *For every accepted* MetaCICTypedExamplesGaller *carrier*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M),$$

the kernel-facing scope of the gallery is exactly the finite BHist *route named by Definition 775.1, constrained by the obligation matrix of Definition 775.2, the typed-family coverage of Definition 775.6, and the checker-route factorization of Definition 775.7. A kernel consumer may inspect the displayed family row, checker row, transport row, replay row, provenance row, and local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}}$ *row. It receives no subject reduction, confluence, normalization, conversion completeness, arbitrary example coverage, or checker completeness theorem.*

Lean4 ✓ `BEDC.MetaCIC.gallery kernel scope`

Proof. Project the carrier of Definition 775.1. The only kernel-facing rows are the displayed family rows B, N, L, S, E, I, A, R, the checker row K, transport row H, replay row C, provenance row P, and local naming row M.

Apply the obligation matrix of Definition 775.2. It forces each consumed example to display its context, term, typing, reduction-window, local-join, normalization-frontier, transport, replay, provenance, and local naming rows inside the same finite packet.

Now apply the typed-family coverage and checker-route factorization theorems. They place every family read inside one displayed row and then through K, H, C, P, M. Since the carrier has no coordinate for the excluded global metatheorems, the kernel-facing scope is exactly this finite route. □

Theorem 775.9 (MetaCIC typed-examples gallery coverage scope)**.** *For every accepted* MetaCICTypedExamplesGal *carrier*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M),$$

the coverage claim exported by the gallery is scoped to the displayed Church Bool, Church Nat, Church List, Church Sum, equality, identity, application, and beta-redex rows. The claim is read through the carrier of Definition 775.1, the obligation matrix of Definition 775.2, the typed-family coverage of Definition 775.6, and the checker-route factorization of Definition 775.7. It does not cover arbitrary examples, checker completeness, subject reduction, confluence, normalization, or conversion completeness.

Proof. Start with the finite family inventory in the carrier. It lists exactly the rows B, N, L, S, E, I, A, R and gives no row for an arbitrary example family.

The obligation matrix requires each displayed family read to keep its local typing, reduction-window, checker, transport, replay, provenance, and naming data visible. Thus coverage is a row-by-row property of the finite inventory, not a theorem about every possible MetaCIC example.

Finally use typed-family coverage and checker-route factorization. The first theorem says every gallery family read factors through the displayed family rows, and the second says each consumer read then passes through K, H, C, P, M. The omitted global claims remain outside the scope because no carrier row names them. □

Theorem 775.10 (MetaCIC typed-examples counterexample boundary)**.** *An accepted* MetaCICTypedExamplesGall *row can be consumed as a finite regression row or as a finite counterexample boundary only when its context row, term row, typing row, reduction-window row, checker row, transport row, replay row, provenance row, and local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}}$ *row are all displayed inside*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M).$$

The row cannot be read as global subject reduction, and it also cannot be read as a global failure of subject reduction. It is only bounded evidence about the displayed Church Bool, Church Nat, Church List, Church Sum, equality, identity, application, or beta-redex family chosen from B, N, L, S, E, I, A, R.

Proof. Project the carrier of Definition 775.1. The finite family row supplies the context, term, typing, and reduction-window data, while K supplies the checker boundary and H, C, P, M supply transport, replay, provenance, and local naming.

Apply the coverage scope of Definition 775.9. It restricts every exported claim to the displayed family rows and refuses arbitrary example coverage.

Now apply checker-route factorization from Definition 775.7. Any consumer read must pass through one displayed family and then through K, H, C, P, M, so a regression or counterexample use remains a finite row-boundary claim.

Since the carrier has no coordinate for global subject reduction and no coordinate for a global countertheorem, neither conclusion can be projected from the gallery packet. □

Theorem 775.11 (MetaCIC typed-examples gallery scoped route)**.** *Every consumer route out of an accepted* MetaCICTypedExamplesGallery$^{\uparrow}$ *packet is a scoped route through*

$$B, N, L, S, E, I, A, R, K, H, C, P, M.$$

The route is determined by the carrier of Definition 775.1, the obligation matrix of Definition 775.2, the typed-family coverage theorem of Definition 775.6, and the checker-route factorization theorem of Definition 775.7. The route exports only the bounded gallery surface and keeps subject reduction, confluence, normalization, conversion completeness, arbitrary example coverage, and checker completeness outside the claim.

Proof. Choose a consumer read from an accepted gallery packet. By the carrier definition, the read must start inside one of the displayed rows $B, N, L, S, E, I, A, R, K, H, C, P, M$.

If the read asks for example-family content, typed-family coverage forces a unique displayed family entrance among B, N, L, S, E, I, A, R. Checker-route factorization then sends the same read through K, H, C, P, M.

If the read asks for structural certificate content, the obligation matrix restricts it to the same transport, replay, provenance, and local naming rows. Therefore every consumer route remains inside the displayed scoped route, and the global metatheorem claims are not exported by this packet. □

Theorem 775.12 (MetaCIC typed-examples gallery scope rows)**.** *For every accepted* MetaCICTypedExamplesGaller *carrier*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M),$$

the accepted gallery scope is exactly the row set

$$B, N, L, S, E, I, A, R, K, H, C, P, M.$$

Rows B, N, L, S, E, I, A, R are the displayed typed-family rows, K is the checker boundary for those families, and H, C, P, M are the transport, replay, provenance, and local naming rows. The scope contains no subject-reduction row, confluence row, normalization row, conversion-completeness row, arbitrary-example row, or checker-completeness row.

Proof. Project the carrier of Definition 775.1. Its displayed coordinates are precisely $B, N, L, S, E, I, A, R, K, H, C,$ so every accepted row must be one of those coordinates.

Apply the obligation matrix of Definition 775.2. It requires each accepted gallery read to display its context, term, typing, reduction-window, local-join, normalization-frontier, transport, replay, provenance, and local naming data inside the finite carrier.

Next use typed-family coverage and checker-route factorization. The theorem Definition 775.6 confines every family read to B, N, L, S, E, I, A, R, and Definition 775.7 sends each such read through K, H, C, P, M.

Finally cite the scoped route of Definition 775.11. It excludes the global metatheorem rows, so the accepted scope is exactly the displayed thirteen-row surface. □

Theorem 775.13 (MetaCIC typed-examples gallery scope export)**.** *Every exported gallery read from an accepted* MetaCICTypedExamplesGallery$^{\uparrow}$ *packet is exactly one displayed family row among*

$$B, N, L, S, E, I, A, R$$

followed by the finite checker and certificate route

$$K, H, C, P, M.$$

No consumer may read the exported gallery as global subject reduction, confluence, normalization, conversion completeness, arbitrary example coverage, or checker completeness.

Proof. Project the carrier of Definition 775.1. The only family rows available for export are B, N, L, S, E, I, A, R, and the only post-family route rows are K, H, C, P, M.

Apply the obligation matrix and typed-family coverage theorems, Definition 775.2 and Definition 775.6. They force each exported family read to keep its displayed context, term, typing, reduction-window, checker, transport, replay, provenance, and local naming data inside the finite carrier.

Use the checker-route factorization and scoped route theorems, Definition 775.7 and Definition 775.11. These identify the consumer route as one family row followed by K, H, C, P, M, with no bypass through a global checker theorem.

Finally apply the scope rows theorem Definition 775.12. Since the accepted scope is exactly the thirteen displayed rows, the excluded global metatheorems and arbitrary coverage claims are not exportable from the gallery packet. □

Theorem 775.14 (MetaCIC typed-examples gallery scoped-closure route)**.** *For every accepted* $\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}$ *carrier*

$$G = (B, N, L, S, E, I, A, R, K, H, C, P, M),$$

the scoped-closure route is exhausted by $B, N, L, S, E, I, A, R, K, H, C, P, M$ *together with the obligation matrix, typed-family coverage, checker-route factorization, scoped-route theorem, and scope-rows theorem. The route refuses subject reduction, confluence, normalization, conversion completeness, arbitrary example coverage, and checker completeness as claims of the gallery packet.*

Proof. Project the carrier of Definition 775.1. Its only visible coordinates are the displayed family rows B, N, L, S, E, I, A, R, the checker boundary K, and the structural rows H, C, P, M.

Apply the obligation matrix, coverage theorem, and checker-route factorization: Definition 775.2, Definition 775.6, and Definition 775.7. They keep every accepted example read inside the displayed family rows and then route it through K, H, C, P, M.

Now use the scoped-route theorem and the scope-rows theorem, Definition 775.11 and Definition 775.12. These identify the complete accepted route with $B, N, L, S, E, I, A, R, K, H, C, P, M$.

Since no carrier row names subject reduction, confluence, normalization, conversion completeness, arbitrary example coverage, or checker completeness, those global properties cannot be projected from the scoped gallery route. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}$ packet is generated from finite BHist rows for selected typed examples, checker rows, beta or conversion readbacks, route rows, provenance, and local naming. Each gallery entry is replayable by Cont through the finite checker surface, so consumers can inspect represented examples without receiving a global calculus theorem. Componentwise hsame preserves the example, checker, and route rows, while Pkg records the MetaCIC typed-example dependencies. The gallery is therefore a bounded regression surface for displayed examples and not a proof of preservation, normalization, or checker completeness.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}}, \mathsf{obligation})$

Scope closed: This chapter binds the MetaCIC typed-examples gallery carrier, obligation matrix, checker-route factorization, finite regression surface, typed-family coverage, and exclusion of global metatheorems.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICTypedExamplesGallery}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim global subject reduction, confluence, normalization, conversion completeness, arbitrary example coverage, or checker completeness.

Upgrade path: Obligation closure requires Lean encodings of the gallery carrier, checker-route replay, componentwise transport, and regression-surface non-escape theorem.

Chapter 776

A Concrete Naming Certificate for MetaCICAuditSynthesisPacket$^{\uparrow}$

The MetaCICAuditSynthesisPacket$^{\uparrow}$ surface turns the synthesis overview of chapter 9385 into one finite naming certificate. It sits beside the closed-normal packet of chapter 739, the normal-false exclusion packet of chapter 732, and the discharge-obligation ledger of chapter 717: those siblings separate the positive closed-normal branch from the subject-reduction obstruction, while the present packet records the combined audit surface without closing the missing transport edge.

Definition 776.1 (MetaCIC audit synthesis packet carrier)**.** *A* MetaCICAuditSynthesisPacket$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, C, N, U, D, A, B, H, R, P, L)$$

with the following visible rows:

1. *S is the subject-reduction obstruction row, including the dependent-codomain boundary and the four named discharge slots;*
2. *C is the confluence map row, recording the conditional diamond route, closed-normal fragment, and confluence-audit packet references;*
3. *N is the normalization row, recording the candidate-mediated closed strong-normalization routes used by the closed-normal branch;*
4. *U is the substitution row, recording closed shift, closed substitution, and closed composition routes needed by the discharge surface;*
5. *D is the decidable-checking row, recording checked term equality, typing inference, gallery witnesses, and bounded normal comparison with its boundary;*
6. *A is the closed-normal assembly row, tying closed strong normalization, normal-false exclusion, and the closed-normal consistency packet into the positive branch;*
7. *B is the blocker row, recording that the synthesis does not supply closed subject reduction, arbitrary closed Church–Rosser, candidate-free normalization, global beta-conversion decidability, or full closed consistency;*
8. *H records componentwise* hsame *transports for S, C, N, U, D, A, B and the local structural rows;*
9. *R records the displayed* Cont *routes by which consumers read the audit rows in synthesis order;*

10. *P is the* Pkg *provenance over the MetaCIC audit maps, chapter 739, chapter 732, and chapter 717;*

11. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}$ *row.*

The classifier compares accepted synthesis packets only through the displayed rows $S, C, N, U, D, A, B, H, R, P, L$. The carrier has no coordinate for a hidden proof of subject reduction, an ambient consistency theorem, quotient equality of MetaCIC terms, or an external normalization oracle.

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisPacketTasteGate single carrier alignment`

Theorem 776.2 (MetaCIC audit synthesis certificate surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}$ *surface for Definition 776.1 consists exactly of carrier admission for $M = (S, C, N, U, D, A, B, H, R, P, L)$, audit-row exposure for the subject-reduction, confluence, normalization, substitution, decidable-checking, closed-normal assembly, and blocker rows, componentwise* hsame *transport through H, displayed* Cont *route replay through R, package provenance through P, and local naming through L.*

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisCertificateSurface`

Proof. Project the finite packet of Definition 776.1. The rows $S, C, N, U, D, A, B, H, R, P, L$ are the complete certificate surface, so carrier admission and classifier exactness are componentwise projections.

Read the positive audit rows next. The confluence row, normalization row, substitution row, decidable-checking row, and closed-normal assembly row cite the same audit-map separation stated in chapter 9385. The closed-normal side is routed through the packet of chapter 739 and the normal-false exclusion surface of chapter 732.

Finally read B, H, R, P, L. The blocker row keeps the subject-reduction gap explicit, while the transport, continuation, provenance, and naming rows only replay the displayed finite packet. Thus the local certificate cannot export an unlisted MetaCIC theorem. □

Theorem 776.3 (MetaCIC audit synthesis critical-path non-escape)**.** *Every consumer of an accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *carrier reads the critical path through*

$$S, C, N, U, D, A, B, H, R, P, L.$$

It may inspect the audit synthesis rows and their finite transports, routes, provenance, and local name. It cannot read a second closed-consistency route, a hidden subject-reduction proof, an unrestricted Church–Rosser theorem, candidate-free normalization, global beta-conversion decidability, quotient equality of terms, or host-level completeness.

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisCriticalPathNonescape`

Proof. Start with carrier admission. Since the classifier of Definition 776.1 compares only the displayed rows, every consumer read is a projection from $S, C, N, U, D, A, B, H, R, P, L$ or a route recorded by R.

Use the sibling audit packets to identify the positive branch. chapter 739 and chapter 732 expose the closed-normal endpoint, while the confluence, normalization, substitution, and decidable rows keep their local audit boundaries visible.

The blocker row is then read as a boundary, not as a solved theorem. Because the carrier has no additional coordinate for full closed consistency or closed subject reduction, no consumer can escape the displayed critical path. □

Theorem 776.4 (MetaCIC audit synthesis consistency blocker ledger)**.** *The consistency blocker of a* MetaCICAuditSynthesisPacket$^{\uparrow}$ *packet is exactly the displayed row B together with the subject-reduction row S. Agreement on $C, N, U, D, A, H, R, P, L$ cannot be repacked as closed subject reduction, closed reduction consistency, or a transport from arbitrary closed proof terms into the closed-normal exclusion branch.*

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisConsistencyBlockerLedger`

Proof. Inspect S first. It names the dependent-codomain obstruction and the four discharge slots, matching the finite ledger of chapter 717.

Inspect B next. The blocker row records the unavailable closed transport edge as part of the packet, so the remaining positive rows cannot erase it.

The closed-normal assembly row A can be consumed only with its stated boundary. It supports the positive branch named by the closed-normal and normal-false sibling chapters, but it does not create a reduction route from arbitrary closed proofs. Therefore agreement on the other rows leaves the blocker ledger intact. □

Theorem 776.5 (MetaCIC audit synthesis closed-normal boundary)**.** *The closed-normal branch of an accepted* MetaCICAuditSynthesisPacket$^{\uparrow}$ *packet is exhausted by the normalization row N, the closed-normal assembly row A, the normal-false exclusion boundary, and the structural rows H, R, P, L. The packet may certify the closed-normal consistency branch as named finite audit data, but it does not certify full closed MetaCIC consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisClosedNormalBoundary`

Proof. Project the normalization and assembly rows from Definition 776.1. These rows are the only coordinates that feed the closed-normal branch.

Use the sibling boundaries. The closed-normal packet of chapter 739 and the normal-false exclusion packet of chapter 732 identify the branch reached after normality is already displayed.

It remains to compare this branch with the blocker row. The subject-reduction ledger of chapter 717 keeps the missing transport edge outside the closed-normal rows, so the packet stops at the finite closed-normal boundary. □

Theorem 776.6 (MetaCIC audit synthesis route-union exactness)**.** *For every accepted* MetaCICAuditSynthesisPack *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

any packet consumer that reads confluence, normalization, substitution, decidable-checking, or closed-normal assembly must also carry the blocker row B and the subject-reduction row S through the same transport, route, provenance, and naming rows H, R, P, L. Thus the positive rows C, N, U, D, A and the blocker row B form one exact audit-route union over S, H, R, P, L. The packet supplies no hidden subject reduction, unrestricted Church–Rosser theorem, candidate-free normalization, global beta-conversion decidability, or quotient equality.

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisRouteUnionExactness`

Proof. Use the certificate surface of Definition 776.2. It identifies $S, C, N, U, D, A, B, H, R, P, L$ as the complete finite carrier and local naming surface, so the positive audit rows and blocker row are read from one packet.

Next apply Definition 776.3. Every consumer route stays inside the displayed critical path, and the only transport, route, provenance, and naming rows available to that route are H, R, P, L.

The blocker side is fixed by Definition 776.4. The row B is carried together with the subject-reduction row S, so agreement on confluence, normalization, substitution, decidable-checking, or assembly cannot erase the obstruction.

Finally use Definition 776.5. It places the closed-normal branch inside the named finite boundary rather than inside full closed consistency. Therefore the route union is exact: reading any positive row also carries S and B through H, R, P, L, while hidden subject reduction, unrestricted Church–Rosser, candidate-free normalization, global beta-conversion decidability, and quotient equality remain outside the packet. □

Theorem 776.7 (MetaCIC audit synthesis substitution-confluence join)**.** *For every accepted* MetaCICAuditSynthesi *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

any consumer that reads the closed-normal assembly row A through the confluence row C must also carry the substitution row U, the subject-reduction row S, and the blocker row B through the same structural route H, R, P, L. Agreement on C, N, D, A alone cannot be exported as closed subject reduction or unrestricted Church–Rosser, because the substitution transport row and blocker ledger remain part of the accepted packet boundary.

Proof. Start with the certificate surface of Definition 776.2. It makes $S, C, N, U, D, A, B, H, R, P, L$ the complete row inventory of the accepted packet, so a consumer reading A through C is still inside the same finite carrier.

Apply route-union exactness from Definition 776.6. The confluence, normalization, substitution, decidable-checking, and closed-normal assembly rows share the transport, route, provenance, and naming rows H, R, P, L with the blocker row B and the subject-reduction row S.

Finally use the consistency blocker ledger of Definition 776.4. It keeps S and B visible across agreement on the positive rows, so an agreement surface on C, N, D, A that omits U leaves the accepted packet rather than exporting closed subject reduction or unrestricted Church–Rosser. □

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisSubstitutionConfluenceJoin`

Theorem 776.8 (MetaCIC audit synthesis positive-blocker union)**.** *For every accepted* MetaCICAuditSynthesisPack *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

any consumer that reads a positive row among confluence C, normalization N, substitution U, decidable checking D, or closed-normal assembly A must simultaneously carry the subject-reduction row S and blocker row B through the same componentwise transport, displayed route, provenance, and naming rows H, R, P, L. Thus no positive-branch read can be exported as full closed consistency, closed subject reduction, arbitrary closed Church–Rosser, candidate-free normalization, global beta-conversion decidability, or quotient equality of MetaCIC terms.

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisPositiveBlockerUnion`

Proof. Apply the certificate surface of Definition 776.2. It gives the complete row inventory $S, C, N, U, D, A, B, H, R, P, L$, so a consumer that reads any one of C, N, U, D, A is still reading from the same finite packet as S and B.

Use critical-path non-escape from Definition 776.3. The only transport, route, provenance, and naming rows available to such a consumer are the displayed rows H, R, P, L.

Now apply the consistency blocker ledger of Definition 776.4. It makes S and B persistent across agreement on the positive rows, so the subject-reduction obstruction cannot be erased by confluence, normalization, substitution, decidable checking, or closed-normal assembly.

Finally use route-union exactness from Definition 776.6. The positive rows and blocker row share transport and provenance in one audit-route union. Hence a positive-branch consumer carries S and B through H, R, P, L whenever it reads C, N, U, D, or A, and the excluded full-consistency claims remain outside the packet. □

Theorem 776.9 (MetaCIC audit synthesis retained-blocker induction)**.** *For every accepted* MetaCICAuditSynthesis *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

any finite fold that successively consumes a nonempty sublist of the positive rows

$$C, N, U, D, A$$

must carry the subject-reduction row S and blocker row B through H, R, P, L at every fold stage. The fold may expose confluence, normalization, substitution, decidable checking, and closed-normal assembly data, but it cannot export subject reduction, unrestricted Church–Rosser, candidate-free normalization, beta-conversion decidability, quotient equality of MetaCIC terms, or full consistency.

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisRetainedBlockerInduction`

Proof. Induct on the displayed finite positive-row list C, N, U, D, A restricted to the nonempty sublist consumed by the fold.

For the base step, the first consumed positive row is one of C, N, U, D, A. Apply the positive-blocker union theorem, Definition 776.8. The consumer must already carry S and B through the same componentwise transport, route replay, provenance, and local naming rows H, R, P, L.

For the successor step, suppose the current fold prefix carries S and B through H, R, P, L. Consuming the next positive row is again a read of one of C, N, U, D, A from the same carrier M. Apply route-union exactness, Definition 776.6, to keep the new positive read in the same audit-route union, and apply the consistency-blocker ledger, Definition 776.4, to keep the obstruction rows persistent.

Thus every fold stage retains S and B through H, R, P, L. Since the carrier has no coordinate for subject reduction, unrestricted Church–Rosser, candidate-free normalization, beta-conversion decidability, quotient equality, or full consistency, the completed fold cannot export any of those claims. □

Theorem 776.10 (MetaCIC audit synthesis normalization-blocker monotonicity)**.** *For every accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

any consumer that strengthens, reuses, or routes the normalization row N through candidate-normalization handoff or residual-diamond handoff must retain the subject-reduction row S and blocker row B through H, R, P, L. Such a consumer may expose candidate-mediated normalization, residual frontier, discharge projection, and ledger data, but it cannot export subject reduction, unrestricted Church–Rosser, candidate-free normalization, quotient equality of MetaCIC terms, or full consistency.

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisNormalizationBlockerMonotonicit`

Proof. Start with retained-blocker induction, Definition 776.9. A read that strengthens or reuses N is a finite consumption of one of the positive rows, so S and B already persist through H, R, P, L at the normalization stage.

Now apply candidate-normalization handoff and residual-diamond handoff, Definition 776.17 and Definition 776.20. These theorems allow N to feed candidate-mediated normalization or residual frontier data only as a blocker-preserving route inside the accepted packet.

Finally apply discharge projection, Definition 776.16. The discharge-obligation ledger remains attached to the same subject-reduction boundary, so strengthening the normalization row cannot erase S or B, nor can it repack the route as any excluded MetaCIC endpoint. □

Theorem 776.11 (MetaCIC audit synthesis obligation closure)**.** *For every accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

the obligation surface is exactly carrier admission, audit-row exposure for subject-reduction obstruction, confluence, normalization, substitution, decidable checking, closed-normal assembly, persistent blocker rows, componentwise hsame *transport through* H*, displayed* Cont *replay through* R*,* Pkg *provenance through* P*, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}$ *row* L*.*

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisObligationClosure`

Proof. Begin with the certificate surface of Definition 776.2. It projects the accepted carrier and names $S, C, N, U, D, A, B, H, R, P, L$ as the complete local NameCert surface, so carrier admission and audit-row exposure are already fixed by finite rows.

Use critical-path non-escape from Definition 776.3. Any consumer route remains inside the displayed rows, and no hidden subject-reduction proof, unrestricted Church–Rosser theorem, candidate-free normalization route, global beta-conversion decision, quotient equality, or host completeness coordinate is available.

Next combine the consistency-blocker ledger of Definition 776.4 with the closed-normal boundary of Definition 776.5. These theorems keep the subject-reduction obstruction and blocker rows persistent while confining the positive closed-normal branch to its named finite boundary.

Finally apply route-union exactness, Definition 776.6, and the positive-blocker union theorem, Definition 776.8. They bind the positive rows and blocker rows into one package through the same transport, replay, provenance, and local naming rows. Thus the obligation surface is precisely the stated finite package, with no additional MetaCIC theorem hidden outside it. □

Theorem 776.12 (MetaCIC audit synthesis public export)**.** *For every accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

the downstream-facing public packet consists exactly of the subject-reduction obstruction row S*, confluence row* C*, normalization row* N*, substitution row* U*, decidable-checking row* D*, closed-normal assembly row* A*, blocker row* B*, componentwise* hsame *transport row* H*, displayed* Cont *replay row* R*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}$ *row* L*. Exporting this packet preserves the blocker ledger and does not export closed subject reduction, arbitrary Church–Rosser, candidate-free normalization, global beta-conversion decidability, quotient equality of MetaCIC terms, or full consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisPublicExport`

Proof. Begin with the certificate surface of Definition 776.2. It identifies $S, C, N, U, D, A, B, H, R, P, L$ as the complete local packet, so a downstream-facing export has no additional coordinate beyond those rows.

Use critical-path non-escape from Definition 776.3. Every exported consumer route remains inside the same finite row family, and the unavailable MetaCIC claims have no path out of the carrier.

Next combine the consistency-blocker ledger with the closed-normal boundary. Theorems 776.4 and 776.5 keep S and B visible while confining N and A to the named closed-normal branch.

Finally apply route-union exactness and positive-blocker union. Theorems 776.6 and 776.8 bind the positive rows and blocker rows through H, R, P, L, so public export is exactly the stated packet and not any of the excluded full MetaCIC theorems. □

Theorem 776.13 (MetaCIC audit synthesis public transport gate)**.** *For every accepted* MetaCICAuditSynthesisPack *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

any public consumer projecting one of the confluence row C, normalization row N, substitution row U, decidable-checking row D, or closed-normal assembly row A must also expose the subject-reduction obstruction row S, blocker row B, componentwise hsame *transport row H, displayed* Cont *replay row R,* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}$ *row L. The gate exports positive audit rows only with those boundary rows visible; it does not export subject reduction, arbitrary Church–Rosser, candidate-free normalization, global beta-conversion decidability, quotient equality of MetaCIC terms, or full consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisPublicTransportGate`

Proof. Start with the public export theorem, Definition 776.12. It identifies the public packet as exactly $S, C, N, U, D, A, B, H, R, P, L$, so a public projection of any positive audit row is still a projection from the same finite carrier.

Apply positive-blocker union from Definition 776.8. The positive rows C, N, U, D, A are exported only together with the subject-reduction obstruction row and blocker row through the displayed structural rows.

Use transport obstruction, Definition 776.15, to keep the closed-normal branch from crossing the subject-reduction boundary as a discharged transport. The obstruction row remains public boundary data rather than a proof of the missing MetaCIC edge.

Finally apply the blocker-preserving positive projection theorem, Definition 776.18. It supplies the consumer-facing projection rule for C, N, U, D, A and preserves S, B, H, R, P, L as visible rows, giving exactly the stated transport gate. □

Theorem 776.14 (MetaCIC audit synthesis scope stability)**.** *For every accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

every packet route through $S, C, N, U, D, A, B, H, R, P, L$ is scoped by the BEDC primitives BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, together with the cited sibling packets chapter 739, chapter 732, and chapter 717. No accepted route can leave this scoped surface to claim subject reduction, arbitrary Church–Rosser, candidate-free normalization, global beta-conversion decidability, full consistency, or quotient equality of MetaCIC terms.*

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisScopeStability`

Proof. Start with the certificate surface of Definition 776.2. It identifies the finite carrier rows and the local naming row, so every accepted packet route is a projection from one BHist package with componentwise hsame, displayed Cont, Pkg provenance, and local NameCert data.

Apply critical-path non-escape from Definition 776.3. The only rows available to a consumer are $S, C, N, U, D, A, B, H, R, P, L$, and the sibling closed-normal and normal-false packets supply only the displayed closed-normal branch.

Use route-union exactness and positive-blocker union from Definition 776.6 and Definition 776.8. These keep the positive rows and blocker rows in one route union through the same transport, replay, provenance, and naming rows, while the discharge-obligation ledger fixes the subject-reduction boundary as a ledger row rather than a solved transport edge.

Finally apply obligation closure, Definition 776.11. Its exact obligation surface is already the stated finite package, so the route is scope-stable under the named BEDC primitives and sibling packets, with the excluded MetaCIC claims remaining outside the accepted packet. □

Theorem 776.15 (MetaCIC audit synthesis transport obstruction)**.** *For every accepted* MetaCICAuditSynthesisPac *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

the closed-normal branch A and the normal-false exclusion rows cannot be transported across the subject-reduction blocker S, B without first reading the discharge-obligation ledger of chapter 717. Consequently the packet may replay closed-normal evidence only as finite audit data, not as a discharged subject-reduction route.

Proof. Begin with critical-path non-escape from Definition 776.3. Every consumer route stays inside $S, C, N, U, D, A, B, H, R, P, L$, so any transport out of the closed-normal branch must pass through the displayed blocker rows rather than through an external MetaCIC theorem.

Use the consistency blocker ledger and closed-normal boundary next. Definition 776.4 keeps S and B persistent across agreement on the positive rows, while Definition 776.5 confines A and the normal-false exclusion branch to the finite closed-normal endpoint.

Finally apply scope stability from Definition 776.14. The only scoped sibling able to name the missing transport edge is the discharge-obligation ledger, so a route that has not read that ledger cannot carry closed-normal evidence across the subject-reduction blocker. The transport obstruction is therefore part of the packet surface itself. □

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisTransportObstruction`

Theorem 776.16 (MetaCIC audit synthesis discharge projection)**.** *For every accepted* MetaCICAuditSynthesisPacke *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

any synthesis consumer that requests the closed-normal consistency branch through rows N, A must also expose the subject-reduction blocker rows S, B and the discharge-obligation ledger sibling of chapter 717 before it may export that branch. Therefore the route cannot be repacked as subject reduction, full consistency, arbitrary Church–Rosser, candidate-free normalization, global beta-conversion decidability, or quotient equality of MetaCIC terms.

Proof. Start with the certificate surface of Definition 776.2. The rows $S, C, N, U, D, A, B, H, R, P, L$ are one accepted packet, so a consumer that reads N, A is still reading inside the same carrier.

Apply the consistency blocker ledger from Definition 776.4. It keeps S and B visible whenever the positive rows are read, preventing the closed-normal branch from being detached from the subject-reduction boundary.

Use the closed-normal boundary of Definition 776.5. The rows N, A name only the finite closed-normal endpoint and normal-false exclusion surface; they do not discharge transport across S, B.

Finally apply the transport obstruction of Definition 776.15. The discharge-obligation ledger sibling is the named projection through which the missing subject-reduction discharge must remain visible. Hence any export that omits S, B and that ledger leaves the accepted packet surface rather than producing a closed-normal consistency export. □

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisDischargeProjection`

Theorem 776.17 (MetaCIC audit synthesis candidate-normalization handoff)**.** *For every accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

any consumer reading candidate-mediated normalization or confluence handoff data through N or C must also carry the subject-reduction blocker rows S, B and the discharge-obligation ledger through H, R, P, L. In particular, the candidate route cannot be repacked as closed subject reduction, unrestricted Church–Rosser, candidate-free normalization, global beta-conversion decidability, or quotient equality.

Proof. Begin with the certificate surface of Definition 776.2. It identifies $S, C, N, U, D, A, B, H, R, P, L$ as one finite packet, so a consumer that reads C or N remains inside the same carrier as S and B.

Apply the positive-blocker union theorem, Definition 776.8. Candidate-mediated normalization and confluence are positive-row reads, and the theorem binds such reads to the subject-reduction row and blocker row through the displayed structural rows.

Use transport obstruction and discharge projection next. Theorems 776.15 and 776.16 require the discharge-obligation ledger to remain visible across H, R, P, L whenever the route approaches the closed-normal branch. Therefore the handoff is a blocker-preserving candidate route, not any of the excluded MetaCIC endpoints. □

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisCandidateNormalizationHandoff`

Theorem 776.18 (MetaCIC audit synthesis blocker-preserving positive projection)**.** *For every accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

any consumer that projects a positive row among confluence C, normalization N, substitution U, decidable checking D, or closed-normal assembly A must also expose the subject-reduction row S, blocker row B, the discharge-obligation ledger sibling of chapter 717, componentwise hsame *transport H, displayed* Cont *replay R,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}$ *row L. Therefore a positive-branch projection cannot export subject reduction, full closed consistency, unrestricted Church–Rosser, candidate-free normalization, global beta-conversion decidability, or quotient equality of MetaCIC terms.*

Proof. Start with the certificate surface of Definition 776.2. It identifies $S, C, N, U, D, A, B, H, R, P, L$ as the complete local packet, so a consumer that projects one of C, N, U, D, A is still reading a row of the same carrier.

Apply critical-path non-escape and the consistency-blocker ledger. Theorems 776.3 and 776.4 keep every read inside the displayed audit path and keep S, B visible whenever positive rows are consumed.

Use the positive-blocker union and transport obstruction next. Theorem 776.8 binds positive rows to the blocker rows through H, R, P, L, while Definition 776.15 names the discharge-obligation ledger as the sibling that must remain visible across the missing subject-reduction edge.

Finally apply the discharge projection of Definition 776.16. A consumer that omits S, B or the ledger sibling leaves the accepted packet surface, so the positive branch is preserved only as a blocker-preserving projection and not as any of the excluded MetaCIC exports. □

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisBlockerPreservingPositiveProjec`

Theorem 776.19 (MetaCIC audit synthesis substitution blocker exhaustion)**.** *For every accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

a consumer reading substitution U together with confluence C, normalization N, decidable checking D, or closed-normal assembly A still carries the subject-reduction row S and blocker row B through componentwise transport H, displayed replay R, provenance P, and local naming L. The positive branch cannot be reinterpreted as subject reduction, unrestricted Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Proof. Apply route-union exactness, Definition 776.6. It binds the substitution row and the other positive rows to the same transport, replay, provenance, and naming route as the blocker side.

Use the substitution-confluence join of Definition 776.7. A read that combines U with C, N, D, or A remains a positive-row read inside the same carrier rather than an independent confluence or evaluator-equality theorem.

Now apply the consistency-blocker ledger and blocker-preserving positive projection, Definition 776.4 and Definition 776.18. These keep S and B visible through H, R, P, L whenever a positive row is consumed. Therefore the substitution branch exhausts exactly the displayed blocker-preserving route and none of the excluded MetaCIC endpoints. □

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisSubstitutionBlockerExhaustion`

Theorem 776.20 (MetaCIC audit synthesis residual-diamond handoff)**.** *Every consumer that reads residual-diamond or parallel-diamond frontier data through an accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *packet*

$$M = (S, C, N, U, D, A, B, H, R, P, L)$$

must expose the rows $S, C, N, U, D, A, B, H, R, P, L$ and the discharge-obligation ledger before treating candidate-normalization or confluence rows as a residual join. The read may use the candidate-normalization row N and confluence row C only as blocker-preserving frontier data; it does not export subject reduction, full consistency, unrestricted Church–Rosser, candidate-free normalization, global beta-conversion decidability, or quotient equality of MetaCIC terms.

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisResidualDiamondHandoff`

Proof. Start with the public transport gate, Definition 776.13. A residual-diamond consumer is a public projection from the same finite packet, so it must keep the subject-reduction row S, candidate and confluence rows N, C, blocker row B, and structural rows H, R, P, L visible.

Use blocker-preserving positive projection and candidate-normalization handoff, Definition 776.18 and Definition 776.17. These theorems allow positive frontier rows to be read, but only with the blocker and discharge information still attached.

Finally apply transport obstruction and discharge projection, Definition 776.15 and Definition 776.16. The discharge-obligation ledger remains the named boundary for the missing subject-reduction edge, so a candidate-normalization or confluence row cannot be repacked as a residual join unless the entire blocker-preserving packet is exposed. □

Theorem 776.21 (MetaCIC audit synthesis public frontier export)**.** *Every public frontier consumer that reads candidate normalization, residual-diamond handoff, or closed-normal assembly through an accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *packet*

$$M = (S, C, N, U, D, A, B, H, R, P, L)$$

must keep the subject-reduction row S, blocker row B, discharge-obligation ledger, and structural rows H, R, P, L visible. The export may expose candidate-mediated frontier data from N, residual-diamond data from C, and closed-normal assembly data from A, but it cannot repack those reads as subject reduction, full Church–Rosser, evaluator equality, quotient syntax equality, global conversion decidability, or kernel consistency.

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisPublicFrontierExport`

Proof. Start with the public transport gate, Definition 776.13. It already requires any public positive-row projection to carry S, B, H, R, P, L with the projected row.

Use candidate-normalization handoff and residual-diamond handoff, Definition 776.17 and Definition 776.20. These identify the frontier reads through N and C as blocker-preserving data rather than as a completed confluence or normalization export.

Apply transport obstruction and discharge projection, Definition 776.15 and Definition 776.16. The discharge-obligation ledger remains visible across the missing subject-reduction edge, so the closed-normal assembly row A cannot hide the blocker.

Therefore the public frontier export is exactly a public read of N, C, A with S, B, H, R, P, L and the ledger still displayed. Any request for the excluded MetaCIC endpoints leaves the accepted packet surface. □

Theorem 776.22 (MetaCIC audit synthesis scoped closure)**.** *For every accepted* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *carrier*

$$M = (S, C, N, U, D, A, B, H, R, P, L),$$

the scoped packet surface is exactly the row inventory $S, C, N, U, D, A, B, H, R, P, L$ together with the certificate surface, critical-path non-escape, consistency-blocker ledger, closed-normal boundary, route-union exactness, positive-blocker union, and obligation-closure theorems. It therefore exports no subject reduction, unrestricted Church–Rosser theorem, candidate-free normalization, global beta-conversion decidability, quotient equality of MetaCIC terms, or full closed consistency beyond that finite packet.

Proof. Project the carrier of Definition 776.1. Its rows $S, C, N, U, D, A, B, H, R, P, L$ are the only accepted coordinates, and the certificate surface of Definition 776.2 identifies them as the complete local $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}$ surface.

Use the non-escape and blocker theorems next. Definition 776.3 keeps every consumer inside the displayed critical path, while Definition 776.4 keeps the subject-reduction row and blocker row visible whenever the positive rows are read.

Now combine the closed-normal boundary with the route-union results. Definition 776.5 confines the closed-normal branch to the named finite boundary, and Definition 776.6 together with Definition 776.8 binds positive rows and blockers through the same H, R, P, L rows.

Finally apply obligation closure, Definition 776.11. Since all required reads are already finite row projections and all excluded MetaCIC claims have no carrier coordinate, the scoped closure is exactly the stated packet surface. □

Lean4 ✓ `BEDC.Derived.MetaCICAuditSynthesisPacketUp.MetaCICAuditSynthesisScopeClosure`

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ packet is generated from subject-reduction obstruction, confluence, normalization, substitution, decidable-checking, closed-normal assembly, blocker, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 776.1, Definition 776.2, Definition 776.3, Definition 776.4, Definition 776.5, Definition 776.6, Definition 776.7, Definition 776.8, Definition 776.11, Definition 776.12, Definition 776.14, Definition 776.16, and Definition 776.18 bind the finite MetaCIC audit synthesis packet and its blocker ledger as one obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, arbitrary closed Church–Rosser, candidate-free normalization, global beta-conversion decidability, full closed consistency, or bridge checking.

Upgrade path: Public closure requires checked export, transport, replay, provenance, and blocker-preservation rows for BEDC.Derived.MetaCICAuditSynthesisPacketUp.

Chapter 777

A Concrete Naming Certificate for $\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}$

The $\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}$ packet realizes the normalization audit map of chapter 9383 as a finite seal over candidate-mediated normalization evidence. It sits beside the confluence audit packet of chapter 743, the closed-normal consistency boundary of chapter 733, and the normalization audit packet of chapter 750: those siblings expose confluence, consistency, and normalization-scope rows, while this seal records the finite admission, replay, and non-escape boundary that downstream consistency chapters may cite without reopening the vision layer.

Definition 777.1 (MetaCIC normalization audit seal carrier)**.** *A* $\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, R, S, B, F, H, C, P, N)$$

with the following visible rows:

1. *A is the audit-map anchor row naming the finite candidate-mediated normalization scope of chapter 9383;*
2. *R is the reducibility-candidate row exposing only displayed candidate, closed-candidate, Pi-candidate, and candidate-set membership evidence;*
3. *S is the strong-normalization scope row read from R, including the checked closed-term projection and no-infinite-reduction reads available inside the candidate route;*
4. *B is the boundary row separating this seal from unconditional global strong normalization, unrestricted application SN, full closed Church–Rosser, and closed subject-reduction transport;*
5. *F is the finite replay row by which consistency-facing consumers read the same candidate-mediated route without replacing it by prose from the audit map;*
6. *H records componentwise* hsame *comparison across A, R, S, B, F, P, N;*
7. *C records the displayed* Cont *routes for moving from the audit anchor to candidate evidence, from candidate evidence to the SN scope, and from the scope to a consumer-facing seal read;*
8. *P is the* Pkg *provenance over the normalization audit map, the normalization audit packet, the confluence audit sibling, and the closed-normal consistency boundary;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host termination oracle, quotient equality over reductions, evidence-free global normalization, unconditional confluence, or a hidden subject-reduction theorem.

Theorem 777.2 (MetaCIC normalization audit seal obligations)**.** *Every accepted* $\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}$ *packet binds exactly the finite obligation surface of Definition 777.1: admission of* $Q = (A, R, S, B, F, H, C, P, N)$*, audit-anchor visibility through* A*, candidate evidence visibility through* R*, candidate-mediated strong-normalization visibility through* S*, boundary visibility through* B*, replay through* F *and* C*, componentwise* hsame *transport through* H*, package provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The anchor row A names the normalization audit map, while R and S expose only the candidate evidence and candidate-mediated strong-normalization reads stored in the finite packet.

The boundary row B is part of the same tuple. It prevents a consumer from erasing candidate evidence or rereading the seal as global strong normalization, unrestricted application SN, full closed confluence, or subject-reduction transport.

The structural rows F, H, C, P, N provide replay, componentwise transport, route exposure, provenance, and local naming. Since the carrier has no further coordinate, these rows exhaust the NameCert obligation surface. □

Theorem 777.3 (MetaCIC normalization audit seal non-escape)**.** *Every public read of an accepted* $\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}$ *packet factors through the finite rows*

$$A, R, S, B, F, H, C, P, N.$$

A consumer may cite the normalization audit map only by reading the displayed anchor, candidate evidence, candidate-mediated SN scope, boundary, replay, transport, route, provenance, and local NameCert rows. The seal exports no host termination oracle, no evidence-free global strong-normalization theorem, no quotient equality over reductions, no unconditional Church–Rosser theorem, and no hidden subject-reduction transport.

Proof. Begin with the carrier definition. Every public read is a projection from $Q = (A, R, S, B, F, H, C, P, N)$ or a route explicitly recorded by C and F.

The positive normalization content is stored only in R and S. Those rows are downstream of the audit anchor A and upstream of the consumer replay row, so the seal can be consumed by closed-normal consistency chapters without leaving the candidate-mediated route.

The non-escape boundary is the coordinate B together with the absence of any excluded coordinate. Transport and provenance preserve the same tuple through H, P, N, and no row names a host oracle, quotient, global normalization theorem, unconditional confluence theorem, or hidden subject-reduction transport. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}$ packet is generated from an audit-map anchor row, reducibility-candidate evidence rows, candidate-mediated strong-normalization rows, boundary rows, finite replay, componentwise transport, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 777.1, Definition 777.2, and Definition 777.3 bind the finite normalization audit seal and its candidate-mediated boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close evidence-free global strong normalization, unrestricted application SN, full closed Church–Rosser, closed subject-reduction transport, quotient equality over reductions, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-mediated SN scope exactness, boundary refusal, route replay, provenance, and non-escape for the same finite seal packet.

Chapter 778

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$

The $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ packet is the shared-modulus normalization surface used by the Real completeness route of chapter 9238. It consumes the shared-bound rows of chapter 462, presents the two-source comparison interface of chapter 411, and feeds the selected-window handoff of chapter 646. The packet is a finite route certificate between those layers; it is not a quotient of regular sequences, a host real equality, a selected limit, or an ambient completeness theorem.

Definition 778.1 (Regular Cauchy modulus normalizer carrier)**.** *A* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *names being routed to a common comparison surface;*
2. *μ_X and μ_Y are the two explicit Cauchy-modulus schedules attached to X and Y;*
3. *M is the* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row that displays the common modulus demand used for both schedules;*
4. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window ledger selected after the meet row, with no side-specific hidden window;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger read on those shared windows;*
6. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from X, Y, W, D;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after M, W, D, R have been displayed;*
8. *H stores componentwise* hsame *transports for $X, Y, \mu_X, \mu_Y, M, W, D, R, E, P, N$ and the local packet shape;*
9. *C stores the displayed* Cont *routes from the two schedules to M, from M to W, from W to D, from D to R, from R to E, and from those rows to the local certificate;*
10. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}}$ *row.*

The carrier has no coordinate for source-equivalence replacement, quotient regular streams, host equality of reals, a selected limiting representative, a side-specific tail oracle, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerTasteGate`
`single carrier alignment`

Definition 778.2 (Regular Cauchy modulus normalizer classifier)**.** *For accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *packets* K *and* K'*, the classifier* $\mathsf{RegularCauchyModulusNormalizerClassifier}(K, K')$ *holds exactly when their displayed normalized routes*

$$\mu_X, \mu_Y, M, W, D, R, E, H, C, P, N$$

transport to the same shared-window comparison surface. The classifier reads only the meet row, shared window ledger, dyadic tolerance ledger, regular readback row, Real seal, componentwise hsame *transports, displayed* Cont *routes, package provenance, and local naming row. It does not classify by first replacing* X *or* Y *with source-equivalent names, and it does not compare host modulus functions outside the packet.*

Lean4 (definition) `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerClassifier`

Theorem 778.3 (Regular Cauchy modulus normalizer NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModu}}$ *surface for Definition 778.1 consists of six finite obligation rows:*

1. *carrier admission for* $K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N)$*;*
2. *source exposure for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *names and their displayed schedules* μ_X, μ_Y*;*
3. *meet exactness requiring every normalized read to pass through the single* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row* M*;*
4. *shared-window exactness requiring* W, D, R *to be read after* M *and to serve both sources simultaneously;*
5. *classifier stability under the componentwise* hsame *transports in* H *and the displayed* Cont *routes in* C*;*
6. *non-escape for source-equivalence transport, quotient streams, host real equality, selected limits, side-specific tail oracles, and ambient completeness.*

Proof. Carrier admission is projection from the displayed packet. The tuple exposes exactly two regular names, two schedules, one meet row, one shared window ledger, one dyadic ledger, one paired readback row, one Real seal, transports, continuations, provenance, and the local name.

The source-exposure row reads X, Y, μ_X, μ_Y before any normalized comparison route is available. The meet-exactness row then projects M as the only common-modulus coordinate, so a consumer cannot replace it by a side-specific threshold or an external schedule comparison.

The shared-window row projects W, D, R downstream of M. These rows are tied to the same window ledger and the same dyadic tolerance ledger, so both regular names are observed on the displayed normalized route.

Finally H, C, P, N repack the projected route as a local NameCert surface. Since the carrier has no coordinate for source-equivalence replacement, quotient streams, host real equality, selected limits, hidden tail oracles, or ambient completeness, the six rows exhaust the public obligation surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier namecert obligations`

Theorem 778.4 (Regular Cauchy modulus normalizer source-exposure obligation)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}}$ *row exposes the four source rows* X, Y, μ_X, μ_Y *before the meet row* M *can be consumed. No comparison-facing consumer may read* $M, W, D, R, E, H, C, P, N$ *as a replacement for this source exposure, and no source-equivalence transport may stand in for either displayed schedule.*

Proof. Project the carrier of Definition 778.1. The displayed packet places the two $\mathsf{RegSeqRat}^{\uparrow}$ names and the two Cauchy-modulus schedules before the meet row, so carrier admission already determines the source surface.

Apply Definition 778.3. Its source-exposure row is separate from meet exactness and shared-window exactness, hence M cannot be read until X, Y, μ_X, μ_Y have been exposed.

Apply Definition 778.7 and Definition 778.8. The common-window route is downstream of M, while the non-escape clause excludes source-equivalence shortcuts and hidden schedules; therefore the four displayed source rows are the only admissible source exposure. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier source exposure obligation`

Theorem 778.5 (Regular Cauchy modulus normalizer shared-window obligation)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

the rows W, D, R *are the only shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, and paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows available downstream of* M*. Every comparison, diagonal-compatibility, or Real-seal consumer must read these three rows in that order.*

Proof. Start from the carrier in Definition 778.1. It contains exactly one window ledger W, exactly one dyadic tolerance ledger D, and exactly one paired readback row R after the meet coordinate M.

Apply Definition 778.3. The shared-window exactness row binds W, D, R to the meet row rather than to either source schedule separately, so no side-specific window or hidden tolerance row can be inserted between M and the readback.

Apply Definition 778.7 and Definition 778.8. The common-window theorem fixes the consumer route through M, W, D, R, and non-escape excludes independent tail oracles, quotient streams, and host-side comparisons; hence W, D, R are the only downstream shared-window rows. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier shared window obligation`

Theorem 778.6 (Regular Cauchy modulus normalizer seal-replay obligation)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

the rows E, H, C, P, N *replay the* $\mathsf{Real}^{\uparrow}$ *seal and the local certificate surface after the shared readback. This replay adds no quotient regular stream, no host real equality, no selected limit, no side-specific tail oracle, and no ambient completeness principle.*

Proof. Read the carrier of Definition 778.1 after the paired readback row R. The remaining exported surface is exactly the $\mathsf{Real}^{\uparrow}$ seal E, componentwise transports H, displayed continuations C, provenance P, and local naming row N.

Apply Definition 778.3. Its classifier-stability and non-escape rows make E, H, C, P, N a replay of the displayed certificate surface, not a source of additional analytic data.

Apply Definition 778.7 and Definition 778.8. The shared-window theorem places the replay strictly after M, W, D, R, and the non-escape theorem excludes quotient streams, host real equality, selected limits, side-specific tail oracles, and ambient completeness from the exported packet. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier seal replay obligation`

Theorem 778.7 (Regular Cauchy modulus normalizer common-window exactness)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

every comparison-facing consumer reads both $\mathsf{RegSeqRat}^{\uparrow}$ *names through the single shared route*

$$\mu_X, \mu_Y, M, W, D, R, H, C, P, N.$$

The common window is therefore determined by the displayed meet row and not by separate source-equivalence transports, independent tail choices, or host-side modulus comparison.

Proof. Project K and isolate the row M. It is the only coordinate whose role is to meet the two displayed schedules μ_X and μ_Y.

Read the window ledger W after M. The packet contains no second window coordinate, so both regular names must use the same displayed $\mathsf{StreamName}^{\uparrow}$ window before the dyadic tolerance ledger is inspected.

Read D and R next. The dyadic tolerance rows and the paired regular readbacks are downstream of the same W, so the comparison-facing route is already normalized before any seal or downstream consumer can inspect it.

The componentwise transports in H and continuations in C preserve that displayed route. Provenance P and the local name N close the route without adding source-equivalence replacement, a side-specific tail oracle, or host-side modulus comparison. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier common window`

Theorem 778.8 (Regular Cauchy modulus normalizer non-escape)**.** *An accepted* $\mathsf{RegularCauchyModulusNormalizer}$ *packet exports only the rows*

$$X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N.$$

Every $\mathsf{RegularCauchyComparison}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of the packet factors through the displayed normalized shared-window route. The packet exports no quotient regular stream, no source-equivalence shortcut, no host real equality, no selected limiting representative, no independent tail oracle, and no ambient completeness principle.*

Proof. Inspect the carrier of Definition 778.1. Its mathematical rows are exactly the two source names, two schedules, one meet row, one shared window ledger, one dyadic ledger, one paired readback row, and one Real seal.

Use Definition 778.3. The obligation surface forces carrier admission, source exposure, meet exactness, shared-window exactness, and classifier stability to be read from those displayed rows.

Use Definition 778.7. It identifies the consumer route through $\mu_X, \mu_Y, M, W, D, R, H, C, P, N$ before any comparison or diagonal-compatibility handoff can be consumed.

Because the packet contains no coordinate for quotient regular streams, source-equivalence shortcuts, host real equality, selected limiting representatives, independent tail oracles, or ambient completeness, no downstream read can export such data. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier nonescape`

Theorem 778.9 (Regular Cauchy modulus normalizer source-meet-window-seal triad)**.** *For every accepted* RegularCauchyModulusNormalizer$^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

every RegularCauchyComparison$^{\uparrow}$, DiagonalLimitCompatibility$^{\uparrow}$, *or* Real$^{\uparrow}$ *consumer that preserves the normalized comparison route reads exactly three ordered surfaces:*

1. *the source-meet exposure* (X, Y, μ_X, μ_Y, M)*;*
2. *the shared-window readback* (W, D, R)*;*
3. *the seal and certificate replay* (E, H, C, P, N)*.*

The triad admits no source-equivalence replacement, side-specific window, hidden dyadic ledger, quotient stream, host real equality, selected limit, independent tail oracle, or ambient completeness principle.

Proof. Use Definition 778.3. Carrier admission exposes K, and the source and meet obligations force the first surface to be exactly (X, Y, μ_X, μ_Y, M).

Use Definition 778.7. The route downstream of M reads one shared window ledger, one dyadic tolerance ledger, and one paired readback row, so the second surface is exactly (W, D, R).

Use Definition 778.8. After the displayed readback, the only remaining exported rows are the Real seal, componentwise transports, continuations, provenance, and local certificate. Hence the third surface is (E, H, C, P, N), and the excluded coordinates cannot be supplied by any downstream consumer. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier source meet window seal triad`

Theorem 778.10 (Regular Cauchy modulus normalizer tail-budget extraction)**.** *For every accepted* RegularCauchyModulusNormalizer$^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

every RegularCauchyTailBudget$^{\uparrow}$, UniformCauchyCriterion$^{\uparrow}$, *or* Real$^{\uparrow}$ *seal consumer of* K *reads its tail-budget route through the single chain*

$$(X, Y, \mu_X, \mu_Y) \longmapsto M \longmapsto (W, D, R) \longmapsto (E, H, C, P, N).$$

The extraction supplies no side-specific tail oracle, quotient stream, host real equality, selected limit, or ambient completeness coordinate.

Proof. Project the carrier from Definition 778.1. The only source rows are X, Y, μ_X, μ_Y, the only common tail-meet row is M, and the only downstream shared-window, readback, seal, transport, replay, provenance, and naming rows are W, D, R, E, H, C, P, N.

Apply Definition 778.3. The source-exposure and shared-window exactness obligations force every accepted consumer to enter through the displayed source schedules and then through the common window rows rather than through a side-specific oracle.

Use Definition 778.7, Definition 778.8, and Definition 778.9. Together they identify the ordered source-meet, shared-window, and seal surfaces and exclude any quotient stream, host real equality, selected limit, or ambient completeness coordinate from the exported route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier tail budget extraction`

Theorem 778.11 (Regular Cauchy modulus normalizer cofinal-filter handoff)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

the normalized route through M, W, D, R supplies exactly the finite cofinal-tail filter surface consumed by $\mathsf{FiniteTailFilter}^{\uparrow}$*. Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer must pass through the shared window row W and dyadic tolerance row D before reading the Real seal E, and the handoff admits no side-specific tail oracle, quotient stream, selected limit, host real equality, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier cofinal filter handoff`

Proof. Begin with the source-exposure and shared-window rows in Definition 778.3. They force each source schedule X, Y, μ_X, μ_Y to enter the common meet row M before any downstream window can be read.

Use Definition 778.7. The route downstream of M is the shared finite-window row W, the dyadic tolerance row D, and the paired readback row R, with no side-specific replacement.

Apply Definition 778.10 and Definition 778.8. The tail-budget route reaches the seal only through (W, D, R) and then E, H, C, P, N, while quotient streams, selected limits, host real equality, and ambient completeness are excluded.

Finally read chapter 1119 as the consumer surface. Its finite cofinal-tail filter consumes window, dyadic tolerance, regular readback, tail-budget comparison, Real seal, transport, continuation, provenance, and local naming rows; the normalized M, W, D, R route supplies exactly that finite surface before any Real or completion consumer can cite the seal. □

Theorem 778.12 (Regular Cauchy modulus normalizer public route)**.** *For every accepted* RegularCauchyModulusN *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

every comparison-facing, diagonal-compatibility, or $\mathsf{Real}^{\uparrow}$*-seal consumer that preserves the normalized shared-window route factors through the public route*

$$(X, Y, \mu_X, \mu_Y, M) \longmapsto (W, D, R) \longmapsto (E, H, C, P, N).$$

The consumer may read these rows only through the displayed BHist *packet, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. No consumer of this public route obtains a source-equivalence replacement, side-specific window, hidden dyadic ledger, quotient stream, host real equality, selected limit, independent tail oracle, or ambient completeness principle.*

Proof. Apply Definition 778.3. Carrier admission, source exposure, meet exactness, shared-window exactness, classifier stability, and non-escape give the finite obligation surface read by any consumer of K.

Use Definition 778.7 and Definition 778.9. The first theorem forces the normalized read through the common route downstream of M; the second packages the same read as the ordered source-meet, shared-window, and seal-certificate surfaces.

Next use Definition 778.8. The carrier has no coordinates for source-equivalence replacement, side-specific windows, hidden dyadic ledgers, quotient streams, host real equality, selected limits, independent tail oracles, or ambient completeness, so none of those objects can be projected by a downstream consumer.

Finally apply Definition 778.17. It binds the route to the displayed BHist, hsame, Cont, Pkg, and NameCert rows, so every comparison-facing, diagonal-compatibility, or $\mathsf{Real}^{\uparrow}$-seal consumer preserving the route factors through the public composite displayed above. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier public route`

Theorem 778.13 (Regular Cauchy modulus normalizer carrier admission)**.** *For* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *the accepted packets are exactly the displayed carriers*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N).$$

The coordinates record the two $\mathsf{RegSeqRat}^{\uparrow}$ *sources, their schedules, the* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row, shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, paired readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row, with no admitted coordinate for quotient streams, host equality, selected limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier carrier admission`

Proof. Project the carrier definition. It lists precisely $X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N$ and no further coordinate.

Apply the NameCert obligations. Carrier admission, source exposure, shared window exactness, seal replay, classifier stability, and non-escape are all read from the displayed tuple and the BEDC primitives named in it.

Finally use the common-window, triad, and public-route theorems. They exhaust the route through the meet, shared window, dyadic ledger, readback, seal, and public replay rows, so quotient streams, host equality, selected limits, and ambient completeness are not accepted packet data. □

Theorem 778.14 (Regular Cauchy modulus normalizer comparison stability)**.** *For accepted* RegularCauchyModulus *packets* $K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N)$ *and* $K' = (X', Y', \mu'_X, \mu'_Y, M', W', D', R', E', H', C', P', N')$, *any displayed componentwise* hsame *and* Cont *replay preserving the carrier rows preserves the meet, shared-window, dyadic-readback, and Real-seal route*

$$(X, Y, \mu_X, \mu_Y, M) \longmapsto (W, D, R) \longmapsto (E, H, C, P, N).$$

Thus the classifier read is stable under displayed comparison replay and cannot be replaced by a quotient stream, host equality, selected limit, side-specific tail oracle, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier comparison stability`

Proof. Start with carrier admission and the classifier definition. The classifier can read only the coordinates displayed in the accepted tuple, so a componentwise replay preserving those rows preserves the classifier's source surface.

Use the common-window exactness and source-meet-window-seal triad. These theorems identify the comparison route as the meet row followed by the shared window, dyadic ledger, paired readback, and Real seal.

Finally apply non-escape and the public route. They keep comparison-facing, diagonal-compatibility, and $\mathsf{Real}^{\uparrow}$ consumers on the same route under hsame and Cont, and they exclude quotient streams, host equality, selected limits, side-specific tail oracles, and ambient completeness as route substitutes. □

Theorem 778.15 (Regular Cauchy modulus normalizer source-exchange stability)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

the exchanged packet

$$K^{\mathrm{op}} = (Y, X, \mu_Y, \mu_X, M, W, D, R, E, H, C, P, N)$$

preserves the displayed $\mathsf{RegularCauchyModulusNormalizerClassifier}$ *route. Both displays expose the same source-meet row* M*, shared-window row* W*, dyadic ledger* D*, paired readback* R*, seal* E*, transports* H*, continuations* C*, provenance* P*, and local* $\mathsf{NameCert}$ *row* N*. Thus source exchange changes only the order in which the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources and their schedules are displayed; it does not change the shared-window comparison surface, the seal route, or the downstream NameCert surface.*

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier source exchange stability`

Proof. Project the carrier rows from Definition 778.1. The displayed tuple separates the two source coordinates and schedules from the meet, window, ledger, readback, seal, transport, continuation, provenance, and name rows. Passing from K to K^{op} exchanges only X, Y, μ_X, μ_Y.

Use Definition 778.2 and Definition 778.3. The classifier reads the normalized route through the displayed meet and shared-window rows, while the NameCert obligations expose carrier admission, source exposure, meet exactness, shared-window exactness, classifier stability, and non-escape on the same finite surface.

Now apply Definition 778.7. Since $M, W, D, R, E, H, C, P, N$ are unchanged, both source orders route through the same common window and the same seal replay.

Finally apply Definition 778.8. It rules out source-equivalence replacement, quotient streams, host real equality, selected limits, side-specific tail oracles, and ambient completeness as substitutes for the displayed exchange route. □

Theorem 778.16 (Regular Cauchy modulus normalizer witness-ledger handoff)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

any downstream comparison, diagonal-compatibility, or $\mathsf{Real}^{\uparrow}$ *consumer reads the witness ledger through*

$$M, W, D, R, E, H, C, P, N$$

after the two source schedules have been admitted. The handoff cannot pass through quotient streams, host equality, selected limits, independent tail oracles, side-specific completion witnesses, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier witness ledger handoff`

Proof. Start with carrier admission and the NameCert obligations. They display the two source rows, two schedules, meet row, common window, dyadic ledger, paired readback, Real seal, transport, continuation, provenance, and local naming as the whole accepted packet.

Next use common-window exactness and comparison stability. The comparison read after the sources is fixed by $M, W, D, R, E, H, C, P, N$, and displayed replay through hsame and Cont preserves that route for comparison and diagonal consumers.

Finally apply non-escape, the triad theorem, and the public route. These results exhaust the witness-ledger handoff before any downstream consumer can read it, so quotient streams, host equality, selected limits, independent tail oracles, side-specific completion witnesses, and ambient completeness have no handoff coordinate. □

Theorem 778.17 (Regular Cauchy modulus normalizer scoped primitive binding)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

each obligation row of Definition 778.3 is bound to the displayed BEDC primitives of the packet: source rows through $\mathsf{RegSeqRat}^{\uparrow}$*, the meet row through* $\mathsf{CauchyModulusMeet}^{\uparrow}$*, the shared window through* $\mathsf{StreamName}^{\uparrow}$*, the tolerance ledger through* $\mathsf{DyadicRatCore}^{\uparrow}$*, the seal row through* $\mathsf{Real}^{\uparrow}$*, transport through* hsame*, route preservation through* Cont*, provenance through* Pkg*, and local admission through* NameCert*. The binding is internal to the displayed carrier and obtains no obligation row from host equality, quotient streams, selected limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier scoped primitive binding`

Proof. Project the carrier of Definition 778.1. The packet exposes the two $\mathsf{RegSeqRat}^{\uparrow}$ source names, the two displayed schedules, the $\mathsf{CauchyModulusMeet}^{\uparrow}$ row M, the $\mathsf{StreamName}^{\uparrow}$ ledger W, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, the paired $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and the $\mathsf{Real}^{\uparrow}$ seal E as named coordinates.

Apply Definition 778.3. Carrier admission, source exposure, meet exactness, shared-window exactness, classifier stability, and non-escape are therefore read from those projected coordinates together with the componentwise hsame transports in H, the displayed Cont routes in C, the Pkg provenance in P, and the local NameCert row N.

Use Definition 778.7. The common-window route fixes the obligation path through $\mu_X, \mu_Y, M, W, D, R, H, C, P$, so the meet, window, tolerance, readback, transport, route, provenance, and local admission rows remain scoped to the displayed packet.

Use Definition 778.8. Since the packet has no coordinate for host equality, quotient streams, selected limits, side-specific tail oracles, or ambient completeness, none of those structures can source an obligation row or replace the primitive bindings just projected. □

Theorem 778.18 (Regular Cauchy modulus normalizer normalized route bridge)**.** *For every accepted* RegularCauchyModulusNormalizer$^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

the public route

$$(X, Y, \mu_X, \mu_Y, M) \mapsto (W, D, R) \mapsto (E, H, C, P, N)$$

bridges to the completion-facing shared-window comparison interface through the single normalized route

$$\mu_X, \mu_Y, M, W, D, R, E, H, C, P, N.$$

The bridge reads only the displayed BHist *packet, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. It exports no quotient stream, host real equality, selected limit, side-specific tail oracle, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerUp StdBridge`

Proof. Start with the local NameCert obligations. Carrier admission, source exposure, meet exactness, shared-window exactness, classifier stability, and non-escape from Definition 778.3 display the whole finite packet and keep every public read inside it.

Use the source-exposure, shared-window, and seal-replay obligations next. Definition 778.4 places the two schedules before the meet row, Definition 778.5 forces W, D, R to serve both sources after M, and Definition 778.6 replays the Real$^{\uparrow}$ seal through E, H, C, P, N.

Now apply common-window exactness and non-escape. Definition 778.7 identifies the normalized public route through $\mu_X, \mu_Y, M, W, D, R, H, C, P, N$, while Definition 778.8 removes source-equivalence shortcuts, quotient streams, host real equality, selected limits, side-specific tail oracles, and ambient completeness.

Finally use the public route of Definition 778.12. The completion-facing shared-window comparison interface receives exactly the displayed normalized route, so it is the bridge from the two source schedules to that public consumer surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier normalized route bridge`

Theorem 778.19 (Regular Cauchy modulus normalizer bridge obstruction boundary)**.** *For every accepted* RegularCauchyModulusNormalizer$^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

any bridge-facing request that preserves the public normalized route as a same-surface bridge must expose the same rows

$$\mu_X, \mu_Y, M, W, D, R, E, H, C, P, N.$$

It must also preserve the primitive binding through the displayed BHist *packet, componentwise* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. A request that omits the meet row M, shared window W, dyadic tolerance D, paired readback R,* Real$^{\uparrow}$ *seal E, route replay through C, or provenance through P, N is outside this chapter's bridge surface rather than an obstruction to the public route.*

Proof. Start from the local NameCert obligations. Definition 778.3 reads carrier admission, source exposure, meet exactness, shared-window exactness, classifier stability, and non-escape from the coordinates of the displayed packet.

The source-facing and seal-facing obligations fix the rows that a bridge request must keep visible. Use Definition 778.4, Definition 778.5, and Definition 778.6 to expose the two schedules, the meet row, the common window, the dyadic tolerance, the paired readback, the $\mathsf{Real}^{\uparrow}$ seal, the route replay, and the provenance rows.

Common-window exactness and non-escape supply the obstruction boundary. Definition 778.7 keeps the normalized route on $\mu_X, \mu_Y, M, W, D, R, H, C, P, N$, while Definition 778.8 prevents quotient streams, host real equality, selected limits, side-specific tail oracles, and ambient completeness from replacing those coordinates.

Finally apply the scoped primitive binding, public route, and normalized route bridge. Definition 778.17 binds the same BHist, hsame, Cont, Pkg, and NameCert rows; Definition 778.12 identifies the public consumer route; and Definition 778.18 reads the completion-facing bridge from that same surface. Any request missing one of the displayed rows therefore leaves the bridge surface instead of producing an internal obstruction to the public normalized route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier bridge obstruction boundary`

Theorem 778.20 (Regular Cauchy modulus normalizer mature witness-ledger handoff)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

any $\mathsf{RegularCauchyModulusWitnessLedger}^{\uparrow}$ *consumer, or any* $\mathsf{Real}^{\uparrow}$*-completion consumer, that preserves the normalized public route must consume the same meet row* M*, shared window* W*, dyadic tolerance* D*, paired readback* R*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise transport* H*, continuation route* C*, provenance row* P*, and local* NameCert *row* N*. Such a consumer cannot replace this route by side-specific schedules, a quotient stream, host real equality, selected limit, independent tail oracle, or ambient completeness.*

Proof. Start with the local obligation surface. Definition 778.3 exposes carrier admission, source exposure, meet exactness, shared-window exactness, classifier stability, and non-escape from the displayed packet K.

Next read the route through the common-window and public-route theorems. Definition 778.7 fixes the shared comparison through $\mu_X, \mu_Y, M, W, D, R, H, C, P, N$, and Definition 778.12 presents that comparison as the public consumer surface downstream of the source schedules.

The bridge result then identifies the handoff surface. By Definition 778.18, a completion-facing consumer receives the normalized route

$$\mu_X, \mu_Y, M, W, D, R, E, H, C, P, N.$$

Finally apply Definition 778.19. A request that drops the meet, window, tolerance, readback, seal, transport, continuation, provenance, or local NameCert row leaves the bridge surface; a request that substitutes side-specific schedules, quotient streams, host real equality, selected limits, independent tail oracles, or ambient completeness is therefore not the same normalized handoff. The witness-ledger consumer consequently reads exactly the displayed normalized surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier mature witness ledger handoff`

Theorem 778.21 (Regular Cauchy modulus normalizer formal target surface)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

the compact formal target surface is exactly the source-meet row (X, Y, μ_X, μ_Y, M)*, the shared dyadic window* (W, D)*, the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *seal replay* R*, the* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row* M*, the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *comparison row exposed by the normalized route, the witness-ledger handoff row, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows* H, C, P, N*. The surface has no selected limit, quotient stream, host equality, ambient completeness row, side-specific tail oracle, or source-equivalence replacement.*

Proof. Start with the carrier, classifier, and local NameCert obligations. They expose the two source names, the two schedules, the meet row, the shared window, dyadic tolerance, paired readback, Real seal, transport, continuation, provenance, and local naming rows as the only available packet coordinates.

Next use source exposure, shared-window exactness, seal replay, and common-window exactness. These theorems order the route through (X, Y, μ_X, μ_Y, M), then through (W, D, R), and then through (E, H, C, P, N), with the $\mathsf{CauchyModulusMeet}^{\uparrow}$ and $\mathsf{RegularCauchyComparison}^{\uparrow}$ readings confined to that displayed route.

Now apply non-escape and the bridge obstruction boundary. They exclude selected limits, quotient streams, host real equality, side-specific tail oracles, source-equivalence replacement, and ambient completeness from the target surface.

Finally use the mature witness-ledger handoff. It identifies the $\mathsf{RegularCauchyModulusWitnessLedger}^{\uparrow}$ and completion-facing consumer rows with the same meet, shared-window, dyadic, readback, seal, transport, continuation, provenance, and local NameCert surface. Thus the listed rows are precisely the finite formal target surface available for Lean formalization. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier formal target surface`

Theorem 778.22 (Regular Cauchy modulus normalizer budget pullback exhaustion)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

any Phase Real and Completion consumer that pulls a budget read or witness-ledger read back through $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *factors through the same four faces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

and through the displayed support rows BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The pullback has no side-specific tail oracle, quotient stream, host real equality, selected limit, ambient completeness, countable-choice row, metric-completeness row, or bridge row.*

Proof. Start with the public route and normalized bridge. By Definition 778.12, every comparison-facing or completion-facing consumer preserving the route reads

$$(X, Y, \mu_X, \mu_Y, M) \longmapsto (W, D, R) \longmapsto (E, H, C, P, N).$$

Definition 778.18 then identifies this public route with the single normalized surface $\mu_X, \mu_Y, M, W, D, R, E, H, C, P,$

Next apply the compact formal surface of Definition 778.21. It keeps every budget read and witness-ledger handoff on the displayed meet, shared-window, dyadic, readback, seal, transport, continuation, provenance, and local NameCert rows.

Finally invoke the StreamName exit boundary, Definition 126.500, together with terminal exactness, Definition 126.505. These read the Phase Real and Completion exit packet as exactly the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces with only the displayed BHist, hsame, Cont, Pkg, and NameCert support rows. Therefore a budget or witness-ledger pullback through $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ terminates at that four-face packet and cannot acquire any side-specific tail oracle, quotient stream, host equality, selected limit, completeness row, choice row, metric row, or bridge row. □

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier budget pullback exhaustion`

Theorem 778.23 (Regular Cauchy modulus normalizer shared-tail meet determinacy)**.** *For every accepted* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *carrier*

$$K = (X, Y, \mu_X, \mu_Y, M, W, D, R, E, H, C, P, N),$$

every $\mathsf{RegularCauchyTailBudget}^{\uparrow}$*,* $\mathsf{UniformCauchyCriterion}^{\uparrow}$*,* $\mathsf{CauchySharedTailModulus}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer route that uses the displayed meet row* M *reads the same shared tail window* (W, D, R) *before the Real seal* E*. If two such consumer routes start from the packet* K *and pass through* M*, then their downstream classifications agree by the componentwise* hsame *rows recorded in* H*, and neither route can introduce a side-specific tail oracle, hidden modulus selector, quotient regular stream, or host real equality.*

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier shared tail meet determinacy`

Proof. Start with the shared-window obligation and common-window exactness. By Definition 778.5 and Definition 778.7, every consumer that reads the displayed meet row M is already routed through the single packet projection

$$(X, Y, \mu_X, \mu_Y, M) \longmapsto (W, D, R) \longmapsto (E, H, C, P, N).$$

Thus the tail window is not an extra choice made by the consumer; it is the displayed W, D, R coordinate triple of K.

Next apply tail-budget extraction and the witness-ledger handoff. The former keeps every tail-budget read on the shared dyadic window and paired $\mathsf{RegSeqRat}^{\uparrow}$ readback, while the latter carries the same rows into the completion-facing witness ledger. Hence $\mathsf{RegularCauchyTailBudget}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{CauchySharedTailModulus}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers all receive the same tail data whenever they use M.

Finally use budget-pullback exhaustion. It confines every downstream budget or witness-ledger pullback to the displayed support rows BHist, hsame, Cont, Pkg, and NameCert, with the componentwise hsame rows in H providing the common classifier comparison. Since the only available coordinates are the unique $M, W, D, R, E, H, C, P, N$ entries of K, two routes through M classify together and cannot acquire a side-specific tail oracle, hidden modulus selector, quotient regular stream, or host real equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, two displayed Cauchy-modulus schedules, a shared $\mathsf{CauchyModulusMeet}^{\uparrow}$ row, one shared $\mathsf{StreamName}^{\uparrow}$ window ledger, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, paired $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise transports, displayed continuations, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 778.1, Definition 778.2, Definition 778.3, Definition 778.4, Definition 778.5, Definition 778.6, Definition 778.7, Definition 778.8, Definition 778.9, Definition 778.12, Definition 778.13, Definition 778.14, Definition 778.15, Definition 778.16, Definition 778.17, Definition 778.18, Definition 778.20, Definition 778.21, Definition 778.22, and Definition 778.23 explicitly name the carrier, classifier, source exposure, meet exactness, shared-window exactness, seal replay, classifier stability, non-escape obligation rows, primitive binding, public consumer route, carrier admission, comparison stability, source-exchange stability, witness-ledger handoff, normalized-route bridge, mature witness-ledger handoff, compact formal target surface, budget pullback exhaustion, and shared-tail meet determinacy.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.RegularCauchyModulusNormalizerUp.RegularCauchyModulusNormalizerCarrier\_budget\_pullbac`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close quotient regular streams, source-equivalence shortcuts, host real equality, selected limits, side-specific tail oracles, or ambient completeness for $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$.

Upgrade path: No further formal-axis upgrade remains for the displayed bridge over the BHist, hsame, Cont, Pkg, and NameCert rows.

Chapter 779

A Concrete Naming Certificate for $\mathsf{SubstitutionAuditMap}^{\uparrow}$

The $\mathsf{SubstitutionAuditMap}^{\uparrow}$ packet realizes the MetaCIC substitution audit map of chapter 9380 as finite NameCert data. It sits beside the closed-substitution boundary of chapter 538 and the closed-term substitution boundary of chapter 527: those siblings name the inert boundary rows, while this packet records the audit map through which later closed-normal and subject-reduction consumers inspect those rows without acquiring an unrestricted substitution calculus.

The generator-closure classifier row is read through the concrete $\mathsf{GeneratorClosure}^{\uparrow}$ certificate of chapter 486 before it is specialized to closed shift, closed substitution, and closed-composition audit rows.

Definition 779.1 (Substitution audit map carrier)**.** *A* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, C, R, S, K, G, H, Q, P, N)$$

with the following visible rows:

1. *T is the displayed MetaCIC* Term *row being audited;*
2. *C is the* $\mathsf{ClosedAt}$ *boundary row attached to T;*
3. *R is the shift row recording the closed-boundary read of* shift*;*
4. *S is the substitute row recording the closed-boundary read of* $\mathsf{substitute}$*;*
5. *K is the closed-composition row for the available closed substitution compositions;*
6. *G is the generator-closure classifier row for the shift and substitution reads;*
7. *H records componentwise* hsame *transports for term, closedness, shift, substitution, composition, classifier, continuation, provenance, and naming rows;*
8. *Q records the displayed* Cont *routes through which consumers inspect the audit rows;*
9. *P is the* Pkg *provenance over* Term, $\mathsf{ClosedAt}$, shift, $\mathsf{substitute}$, *the closed-composition rows, the generator-closure classifier rows,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SubstitutionAuditMap}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible rows are the closed substitution audit rows listed above. It exports no beta-substitution preservation theorem, no closed subject-reduction theorem,

no unclosed substitution commutation theorem, no quotient equality, and no host semantic equality coordinate.

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapTasteGate single carrier alignment`

Theorem 779.2 (Substitution audit map NameCert obligations)**.** *The carrier of Definition 779.1 satisfies the local* $\mathsf{NameCert}_{\mathsf{SubstitutionAuditMap}^{\uparrow}}$ *obligation surface. Its obligations are carrier admission for* $A = (T, C, R, S, K, G, H, Q, P, N)$*, term and* ClosedAt *readback through* T, C*, shift readback through* R*, substitution readback through* S*, closed-composition readback through* K*, generator-closure classification through* G*, componentwise transport through* H*, displayed continuation through* Q*, provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is the displayed finite BHist packet. Projecting T and C exposes the audited MetaCIC term together with its closed-boundary row, matching the boundary surface described in chapter 9380.

Project R, S, K, G next. These rows record the checked closed shift, closed substitution, closed-composition, and generator-closure classifier surfaces used by chapter 538; none of them contains a typed preservation endpoint.

Finally inspect H, Q, P, N. The transport, continuation, provenance, and naming rows replay the same finite packet for consumers. Since every obligation is one of the displayed rows and no hidden row is added by transport or provenance, the local NameCert surface is exhausted by the carrier inventory. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier namecert obligations`

Theorem 779.3 (Substitution audit map boundary non-escape)**.** *For an accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier* $A = (T, C, R, S, K, G, H, Q, P, N)$*, every consumer read remains inside the displayed* Term*,* ClosedAt*, shift, substitute, closed-composition, generator-closure classifier,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. In particular, the packet cannot export an unrestricted substitution calculus, beta-substitution preservation, or closed subject reduction.*

Proof. Read the carrier by projection. The rows T, C, R, S, K, G expose closed syntactic movement and classifier data only under the displayed closed-boundary hypotheses.

The remaining rows H, Q, P, N transport, route, locate, and name that same packet. They preserve the audit surface but do not add a coordinate for beta substitution preservation or subject reduction.

Therefore any consumer of the accepted packet can cite only the closed substitution audit rows and their displayed routes. The non-escape exclusions are exactly the missing coordinates recorded in the carrier definition. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier boundary nonescape`

Theorem 779.4 (Substitution audit map positive row coverage)**.** *For an accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier* $A = (T, C, R, S, K, G, H, Q, P, N)$*, every positive audit row read by the packet is exhausted by the displayed term row* T*, closed-boundary row* C*, shift row* R*, substitute row* S*, closed-composition row* K*, and generator-closure row* G*. A consumer that asks for a substitution-audit witness therefore receives only these six source rows together with their transport, route, provenance, and local naming coordinates* H, Q, P, N*.*

Proof. Project the accepted carrier. The rows T, C, R, S, K, G are the only coordinates that carry positive MetaCIC audit data: term exposure, closed-boundary exposure, shift readback, substitute readback, closed-composition readback, and generator-closure classification.

The remaining coordinates H, Q, P, N do not add another audit source. They identify componentwise transport, displayed consumer routes, package provenance, and the local certificate name for the same finite packet.

Thus every positive read factors through the listed rows. Since the carrier has no further source coordinate, the positive audit surface is exhausted by T, C, R, S, K, G. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier positive row coverage`

Theorem 779.5 (Substitution audit map obstruction row exactness)**.** *For an accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier, the obstruction boundary is exact: beta-substitution preservation, closed subject reduction, unclosed substitution, quotient equality, and host semantic equality are excluded precisely because none of them is a row of* $A = (T, C, R, S, K, G, H, Q, P, N)$ *and none is created by* H, Q, P, N*.*

Proof. Read the positive rows first. The coordinates T, C, R, S, K, G name only the displayed MetaCIC term, closed boundary, closed shift, closed substitute, closed-composition, and generator-closure classifier data.

Now inspect the administrative rows. Componentwise hsame transport preserves the visible coordinates, Cont routes replay them, Pkg records provenance over them, and the local $\mathsf{NameCert}$ row names them.

It follows that no administrative row can supply beta preservation, subject reduction, unclosed substitution, quotient equality, or host semantic equality. These exclusions are therefore not loose warnings; they are exactly the missing carrier coordinates. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier obstruction row exactness`

Theorem 779.6 (Substitution audit map frontier route non-escape)**.** *Every frontier-facing consumer route for an accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier factors through* H, Q, P, N *after reading the positive audit rows* T, C, R, S, K, G*. Such a route can transport, replay, locate, and name the closed substitution audit packet, but it cannot acquire unrestricted substitution or any theorem absent from the displayed carrier.*

Proof. Start with positive row coverage. Any consumer route that reaches substitution-audit data has already passed through the finite rows T, C, R, S, K, G.

The frontier rows are H, Q, P, N. They provide transport, continuation replay, provenance, and naming for the already displayed packet, so the consumer can carry the packet across a boundary without changing its row inventory.

Apply obstruction exactness to the transported packet. Since the excluded rows are absent before the frontier route and are not created by transport, replay, provenance, or naming, unrestricted substitution still cannot escape the audit map. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier frontier route nonescape`

Theorem 779.7 (Substitution audit map obligation closure package)**.** *For the finite packet* $A = (T, C, R, S, K, G, H, Q, P, N)$ *of Definition 779.1, the carrier definition, Definition 779.2, Definition 779.3, Definition 779.4, Definition 779.5, and Definition 779.6 jointly exhaust the* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *obligation surface. The package records exactly the closed term, closed-boundary, shift, substitute, closed-composition, generator-closure, transport, continuation, provenance, and local naming rows admitted by the TasteGate carrier alignment.*

Proof. The carrier definition supplies the row inventory, and the checked TasteGate alignment following Definition 779.1 fixes that inventory as the single finite carrier surface.

Use the NameCert obligation theorem to read carrier admission, closed movement readback, closed-composition readback, classifier readback, transport, continuation, provenance, and naming from $T, C, R, S, K, G, H, Q, P, N$.

The boundary non-escape, positive row coverage, obstruction row exactness, and frontier route non-escape theorems account for every remaining consumer question: which positive rows are available, which obstruction rows are absent, and how frontier reads remain inside the same packet. Therefore no further obligation is left outside the displayed finite surface. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier obligation closure package`

Theorem 779.8 (Substitution audit map domain-codomain exposure)**.** *For the finite packet $A = (T, C, R, S, K, G, H, Q, P, N)$ of Definition 779.1, the only domain rows are the displayed term row T and the closed-boundary row C, and the only movement rows are the shift row R, substitute row S, closed-composition row K, and generator-closure classifier row G. No unrestricted substitution row, beta preservation row, quotient equality row, or host semantic equality row is present in the carrier.*

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier domain codomain exposure`

Proof. Project the carrier displayed in Definition 779.1. The coordinates T and C are the only rows that expose the audited MetaCIC term and its closed-boundary domain.

The movement surface is then read through R, S, K, G. By Definition 779.2, those rows are exactly the shift readback, substitution readback, closed-composition readback, and generator-closure classifier obligations.

Finally apply Definition 779.5. The rows for unrestricted substitution, beta preservation, quotient equality, and host semantic equality are absent from the packet and cannot be supplied by the administrative rows H, Q, P, N. □

Theorem 779.9 (Substitution audit map replay determinacy)**.** *For an accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier $A = (T, C, R, S, K, G, H, Q, P, N)$, any transported consumer read of the audit map must replay the same displayed rows through the componentwise transport row H and the continuation route row Q before reaching the provenance row P and the local naming row N.*

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier replay determinacy`

Proof. Begin with Definition 779.4. Any positive consumer read is already confined to the displayed rows T, C, R, S, K, G.

Now use Definition 779.6. A frontier-facing route reaches the administrative surface only by transporting the displayed packet through H and replaying it through Q.

The provenance and naming rows P, N therefore receive the same packet after transport and route replay. Since no route can escape the displayed carrier, the consumer read is determined by the original row inventory. □

Theorem 779.10 (Substitution audit map ledger non-escape)**.** *For an accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier $A = (T, C, R, S, K, G, H, Q, P, N)$, the provenance row P and the local* NameCert *row N can name only the closed substitution audit packet T, C, R, S, K, G, H, Q. They cannot promote obstruction rows absent from A into public theorems.*

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier ledger nonescape`

Proof. Read the ledger surface from the obligation package of Definition 779.7. The provenance row and local name are attached to the finite packet already displayed by T, C, R, S, K, G, H, Q.

Apply Definition 779.5. The obstruction rows are exactly absent from the accepted carrier, and the administrative coordinates do not create new theorem rows.

Thus P and N can record and name only the closed substitution audit packet. A public theorem about unrestricted substitution, beta preservation, quotient equality, or host semantic equality would require a row that the carrier does not contain. □

Theorem 779.11 (Substitution audit map closed-boundary scope)**.** *For every accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier* $A = (T, C, R, S, K, G, H, Q, P, N)$*, the closed-term substitution boundary and the closed substitution boundary are read only through the displayed term row* T*, closed-boundary row* C*, shift row* R*, substitute row* S*, closed-composition row* K*, and generator-closure classifier row* G*, with transport, route replay, provenance, and naming supplied by* H, Q, P, N*.*

The checked TasteGate carrier alignment keeps this boundary as the same finite packet. It does not export unrestricted substitution, beta preservation, closed subject reduction, quotient equality, or host semantic equality.

Proof. Project the accepted carrier. The term and closedness data are the rows T and C, and the only closed movement rows are R, S, K.

Use positive row coverage and obstruction row exactness. The generator-closure classifier G accounts for the closed-boundary route, while the excluded substitution and equality principles remain absent carrier coordinates.

Finally apply frontier route non-escape. The rows H, Q, P, N transport, replay, locate, and name the same closed-boundary packet, so the scope remains the displayed finite boundary. □

Theorem 779.12 (Substitution audit map generator-route scope)**.** *For every accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier* $A = (T, C, R, S, K, G, H, Q, P, N)$*, the generator-closure classifier row* G *is the only generator-route source for closed shift, closed substitution, and closed-composition reads. Any consumer route through* H, Q, P, N *must replay* G *together with* T, C, R, S, K *and cannot replace it by an unrestricted substitution generator.*

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier generator route scope`

Proof. Start with the domain-codomain exposure theorem. It identifies T, C as the primitive domain rows and R, S, K, G as the movement and generator-route rows.

Next use replay determinacy. Transported reads must pass through H and Q before reaching P and N, so the generator classifier is replayed as part of the same packet.

Obstruction row exactness excludes an unrestricted substitution generator. Since no such row is present before or after replay, the generator route is scoped by G. □

Theorem 779.13 (Substitution audit map consumer obstruction scope)**.** *For every accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *carrier* $A = (T, C, R, S, K, G, H, Q, P, N)$*, every downstream consumer obstruction is exact at the displayed packet boundary: beta-substitution preservation, subject reduction, quotient equality, and host semantic equality are unavailable precisely because no row of* A *supplies them and* H, Q, P, N *do not create them.*

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier consumer obstruction scope`

Proof. Read the positive rows through Definition 779.4. They exhaust the available term, closed-boundary, movement, and generator-classifier data.

Apply obstruction row exactness. The absent obstruction rows are not hidden assumptions; they are missing carrier fields.

Use ledger non-escape for the consumer-facing side. The provenance and local naming rows can name only the closed substitution audit packet, so an excluded theorem cannot be promoted into a public consumer row. □

Theorem 779.14 (Substitution audit map scoped closure package)**.** *The carrier $A = (T, C, R, S, K, G, H, Q, P, N)$ the checked TasteGate carrier alignment, positive row coverage, obstruction row exactness, frontier route non-escape, closed-boundary scope, generator-route scope, and consumer obstruction scope jointly bind* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *as a scoped finite audit package for closed-term substitution boundaries.*

The package closes only the displayed closed substitution audit map over BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It does not close unrestricted substitution, beta preservation, subject reduction, quotient equality, or host semantic equality.*

Proof. Begin with the obligation closure package. It already assembles carrier admission, local NameCert obligations, positive row coverage, obstruction exactness, and frontier non-escape over the displayed finite rows.

Attach the closed-boundary and generator-route scope theorems. These identify the closed-term boundary, closed substitution boundary, and generator-closure classifier as rows of the same packet rather than as external calculus assumptions.

Finally attach consumer obstruction scope. Since the excluded principles remain absent under transport, replay, provenance, and naming, the finite packet is scoped-closed at exactly the displayed audit boundary. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier scoped closure package`

Theorem 779.15 (Substitution audit map public export)**.** *The finite carrier $A = (T, C, R, S, K, G, H, Q, P, N)$, the checked TasteGate carrier alignment, positive row coverage, obstruction exactness, replay determinacy, and scoped closure jointly form the public export surface for* $\mathsf{SubstitutionAuditMap}^{\uparrow}$*.*

The exported surface presents exactly the displayed BHist *packet, its* hsame *transport row,* Cont *consumer routes,* Pkg *provenance, and local* NameCert *row. It exports the closed substitution audit map as finite data only; it does not export beta-substitution preservation, subject reduction, quotient equality, or host semantic equality.*

Proof. Begin with the carrier and TasteGate alignment. The definition of the carrier fixes the ten rows $T, C, R, S, K, G, H, Q, P, N$, and the checked alignment following it records that these rows are the accepted finite surface.

Use positive row coverage and obstruction row exactness. The positive rows T, C, R, S, K, G exhaust the available audit data, while the excluded preservation and equality principles are exactly absent from the carrier.

Next apply replay determinacy. Any downstream read has to replay the same packet through H and Q before it reaches P and N.

Finally use the scoped closure package. It packages the carrier, classifier alignment, coverage, obstruction, replay, provenance, and local naming rows as the public surface available to consumers. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier public export`

Theorem 779.16 (Substitution audit map downstream reader boundary)**.** *Every downstream reader of an accepted* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *packet must factor through the displayed rows*

$$T, C, R, S, K, G, H, Q, P, N.$$

Such a reader may inspect the term row, closed-boundary row, shift row, substitute row, closed-composition row, generator-closure classifier row, componentwise transport row, continuation route row, provenance row, and local naming row. It cannot acquire beta-substitution preservation, subject reduction, quotient equality, or host semantic equality from the packet.

Proof. First read the positive surface. By Definition 779.4, every positive audit read is confined to T, C, R, S, K, G.

Next route the reader through the administrative surface. By Definition 779.9, transported reads pass through H and Q before reaching P and N.

It remains to exclude the requested external conclusions. Apply Definition 779.5 and Definition 779.13; the absent preservation and equality rows are not created by transport, continuation replay, provenance, or naming. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier downstream reader boundary`

Theorem 779.17 (Substitution audit map formal target package)**.** *The Lean-facing target package for* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *is the finite* BHist *carrier* $A = (T, C, R, S, K, G, H, Q, P, N)$ *together with the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Its intended target is the public export theorem over those rows, with the downstream reader boundary as the exact non-escape condition.*

The package does not require a new primitive carrier, a new classifier, beta preservation, subject reduction, quotient equality, or host semantic equality. Its formal surface is the existing carrier inventory and the row-factorization theorems cited in this chapter.

Proof. Start from the public export theorem. It identifies the finite carrier, TasteGate alignment, coverage, obstruction, replay determinacy, and scoped closure as the consumer-facing package.

Then apply the downstream reader boundary. Every reader factors through $T, C, R, S, K, G, H, Q, P, N$, so the target package needs only the BHist, hsame, Cont, Pkg, and NameCert rows already visible in the carrier.

The excluded principles are handled by obstruction exactness and consumer obstruction scope. Since none of them is a carrier coordinate, the Lean-facing target can be stated over the displayed packet without adding another primitive object. □

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.SubstitutionAuditMapCarrier formal target package`

Closure status for $\mathsf{NameCert}_{\mathsf{SubstitutionAuditMap}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SubstitutionAuditMap}^{\uparrow}$ packet is generated from a MetaCIC term row, a ClosedAt boundary, closed shift and substitution rows, closed-composition rows, generator-closure classifier rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubstitutionAuditMap}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 779.1, Definition 779.2, Definition 779.3, Definition 779.4, Definition 779.5, Definition 779.6, Definition 779.7, Definition 779.8, Definition 779.9, Definition 779.10, Definition 779.11, Definition 779.12, Definition 779.13, Definition 779.14, Definition 779.15, Definition 779.16, and Definition 779.17 bind the closed substitution audit map, its primitive domain and movement rows, deterministic replay route, ledger boundary, obstruction rows, frontier routes, closed-boundary scope, generator-route scope, consumer obstruction scope, finite scoped package, public export surface, downstream reader boundary, and formal target package.

Lean4 ✓ `BEDC.Derived.SubstitutionAuditMapUp.taste gate`

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubstitutionAuditMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close unrestricted substitution, beta-substitution preservation, closed subject reduction, Lean verification, or bridge checking.

Upgrade path: Lean verification for the public export theorem, downstream reader boundary, and formal target package remains an independent formal target.

Chapter 780

A Concrete Naming Certificate for MetaCICOpenProblemLedger$^{\uparrow}$

The MetaCICOpenProblemLedger$^{\uparrow}$ packet turns the inventory of chapter 9386 into a finite NameCert ledger. It sits beside the audit synthesis packet of chapter 776, the closed-normal consistency packet of chapter 739, and the normal-false exclusion packet of chapter 732. Those siblings name the positive closed-normal branch and the audit rows; this packet keeps the unresolved MetaCIC rows visible as ledger entries rather than as hidden consistency claims.

Definition 780.1 (MetaCIC open-problem ledger carrier)**.** *A* MetaCICOpenProblemLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, C, N, U, D, E, B, H, R, P, Q)$$

with the following displayed rows:

1. *S is the subject-reduction row, naming beta-substitution preservation, application-argument stability, lambda-domain preservation, and Pi-domain preservation as finite entries;*
2. *C is the confluence row, naming residual-substitution compatibility, closed parallel diamond scope, and arbitrary closed Church–Rosser scope as boundary entries;*
3. *N is the normalization row, naming candidate evidence, closed-candidate evidence, candidate-set membership, and the absence of an evidence-free global strong-normalization export;*
4. *U is the substitution row, naming the substitution-facing algebra consumed by subject reduction and confluence;*
5. *D is the decidability row, naming typing-checker exactness, bounded normal comparison, finished-normal side conditions, and the absence of an unrestricted closed beta-conversion decider;*
6. *E is the typed-example row, naming the gallery witnesses and the absence of exhaustive dependent-program or polymorphic-program coverage;*
7. *B is the blocker row, naming the closed-consistency handoff that still cannot transport arbitrary closed proof terms into the closed-normal exclusion input;*
8. *H stores componentwise* hsame *transport for S, C, N, U, D, E, B;*
9. *R stores displayed* Cont *replay routes for the seven ledger rows;*
10. *P is the* Pkg *provenance over chapter 9386, chapter 776, chapter 739, and chapter 732;*

11. *Q is the local* $\mathsf{NameCert}_{\mathsf{MetaCICOpenProblemLedger}^{\uparrow}}$ *row.*

The carrier contains no coordinate for arbitrary closed subject reduction, arbitrary closed Church–Rosser, evidence-free global strong normalization, unrestricted closed beta-conversion decidability, exhaustive example coverage, or full closed consistency.

Lean4 ✓ `BEDC.Derived.MetaCICOpenProblemLedgerUp.MetaCICOpenProblemLedgerTasteGate single carrier alignment`

Theorem 780.2 (MetaCIC open-problem ledger NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICOpenProblemLedge}}$ *surface for Definition 780.1 consists exactly of carrier admission for $L = (S, C, N, U, D, E, B, H, R, P, Q)$, row visibility for the subject-reduction, confluence, normalization, substitution, decidability, typed-example, and blocker entries, componentwise* hsame *transport through H, finite route replay through R, package provenance through P, and local naming through Q.*

Lean4 ✓ `BEDC.Derived.MetaCICOpenProblemLedgerUp.MetaCICOpenProblemLedgerNameCertObligations`

Proof. Project the finite carrier. The seven ledger rows are S, C, N, U, D, E, B, and they match the open-problem families named in chapter 9386.

Read the structural rows separately. Transport through H preserves the row tags, replay through R exposes only displayed routes, and provenance through P records the source chapters without turning their boundaries into new theorem rows.

The local name Q certifies this packet as a NameCert surface. Since the carrier has no further coordinate, the listed rows exhaust the obligation surface. □

Lean4 ✓ `BEDC.Derived.MetaCICOpenProblemLedgerUp.MetaCICOpenProblemLedger namecert obligations`

Theorem 780.3 (MetaCIC open-problem ledger non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{MetaCICOpenProblemLedger}^{\uparrow}$ *packet factors through*

$$S, C, N, U, D, E, B, H, R, P, Q.$$

The consumer may read the positive closed-normal branch through the cited sibling packets and may read each open MetaCIC family as a ledger row, but it cannot obtain arbitrary closed subject reduction, arbitrary closed Church–Rosser, evidence-free global strong normalization, unrestricted closed beta-conversion decidability, exhaustive typed-example coverage, or full closed consistency from this packet.

Proof. Begin with the carrier definition. Any accepted consumer route receives only the seven ledger rows, componentwise transport, displayed replay routes, provenance, and local naming.

The positive branch remains row-local. The audit synthesis packet, closed-normal consistency packet, and normal-false exclusion packet can be cited through P, but those citations do not add a transport row from arbitrary closed proofs to closed-normal proof inputs.

The closed endpoints named in the statement are absent from the carrier. Transport, replay, provenance, and naming preserve the displayed ledger; they do not manufacture a missing MetaCIC theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICOpenProblemLedgerUp.MetaCICOpenProblemLedger nonescape`

Theorem 780.4 (MetaCIC open-problem ledger blocker separation)**.** *Agreement on an accepted* $\mathsf{MetaCICOpenProblemLedger}^{\uparrow}$ *packet preserves the blocker row B as a boundary row distinct from the subject-reduction row S, the normalization row N, and the closed-normal sibling packets. The ledger can therefore record why full closed consistency is not exported while still exposing the closed-normal consistency and normal-false exclusion surfaces through provenance.*

Proof. Read B as its own coordinate in the carrier. It names the closed-consistency handoff that remains unavailable for arbitrary closed proof terms.

Read S and N as separate coordinates. Subject-reduction discharge and candidate-mediated normalization are not collapsed into B, and the sibling closed-normal packets are cited only by provenance.

Componentwise hsame transport preserves this separation. The downstream packet can report the blocker and the positive closed-normal branch together, but it cannot identify them as a completed full-consistency route. □

Lean4 ✓ `BEDC.Derived.MetaCICOpenProblemLedgerUp.MetaCICOpenProblemLedger blocker separation`

Theorem 780.5 (MetaCIC open-problem ledger family coverage)**.** *Every accepted* MetaCICOpenProblemLedger$^{\uparrow}$ *packet exposes exactly seven open-family rows: subject reduction, confluence, normalization, substitution, decidability, typed examples, and blocker. Each downstream MetaCIC consumer must read those rows before any claim about arbitrary closed subject reduction, arbitrary Church–Rosser, global strong normalization, unrestricted beta-conversion decidability, exhaustive examples, or full consistency.*

Proof. Project the carrier of Definition 780.1. The seven open-family coordinates are precisely S, C, N, U, D, E, B, while H, R, P, Q transport, replay, source, and name those rows.

Apply Definition 780.3. A downstream consumer factors through the displayed tuple before it can mention any of the closed MetaCIC endpoints excluded from the packet.

Finally apply Definition 780.4. The blocker row remains a distinct boundary row, so the family coverage statement records an open ledger rather than a hidden proof of arbitrary closed consistency. □

Lean4 ✓ `BEDC.Derived.MetaCICOpenProblemLedgerUp.MetaCICOpenProblemLedger family coverage`

Theorem 780.6 (MetaCIC open-problem ledger source-row scope)**.** *For every accepted* MetaCICOpenProblemLedge *carrier* $L = (S, C, N, U, D, E, B, H, R, P, Q)$*, the seven ledger rows* S, C, N, U, D, E, B *are scoped by the source open-problem chapter, the audit synthesis packet, the closed-normal consistency packet, and the normal-false exclusion packet. The rows* H, R, P, Q *supply componentwise transport, displayed replay, provenance, and local naming only. Consequently the packet does not export arbitrary subject reduction, Church–Rosser, global normalization, beta-conversion decidability, exhaustive examples, or full consistency.*

Proof. Project the carrier of Definition 780.1. The open-family coordinates are exactly S, C, N, U, D, E, B, while H, R, P, Q are structural rows attached to those coordinates.

Use Definition 780.3. The downstream route factors through the source ledger and the cited sibling packets before it can mention any closed MetaCIC endpoint.

Apply Definition 780.4. The blocker row remains distinct from the positive closed-normal branch exposed through provenance, so the packet cannot identify source-row scope with a full-consistency theorem.

Finally use Definition 780.5. The seven rows cover the named open families as ledger entries, while arbitrary subject reduction, Church–Rosser, global normalization, beta-conversion decidability, exhaustive examples, and full consistency remain outside the finite packet. □

Lean4 ✓ `BEDC.Derived.MetaCICOpenProblemLedgerUp.MetaCICOpenProblemLedger source row scope`

Theorem 780.7 (MetaCIC open-problem ledger export surface)**.** *Every accepted* $\mathsf{MetaCICOpenProblemLedger}^{\uparrow}$ *packet exports exactly the seven open-family rows*

$$S, C, N, U, D, E, B$$

and the structural rows

$$H, R, P, Q$$

as its reusable public ledger surface. A consumer may read subject-reduction, confluence, normalization, substitution, decidability, typed-example, and blocker entries as displayed ledger rows, with componentwise transport, replay, provenance, and local naming. No consumer obtains arbitrary subject reduction, Church–Rosser, global normalization, unrestricted beta-conversion decidability, exhaustive examples, or full consistency from this packet.

Lean4 ✓ `BEDC.Derived.MetaCICOpenProblemLedgerUp.MetaCICOpenProblemLedgerExportSurface encode append`

Proof. Project the carrier $L = (S, C, N, U, D, E, B, H, R, P, Q)$ of Definition 780.1. The first seven coordinates are the open-family ledger rows, and the last four coordinates are structural rows attached to those families.

Apply Definition 780.2. It identifies carrier admission, row visibility, componentwise transport, replay, provenance, and local naming as the complete NameCert surface for the displayed tuple.

Use Definition 780.3 and Definition 780.4. These theorems keep the closed endpoints outside the packet and keep the blocker row distinct from the positive closed-normal branch exposed through provenance.

Finally apply Definition 780.5 and Definition 780.6. The seven families are exactly the exported public rows, while H, R, P, Q only transport, replay, source, and name those rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICOpenProblemLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICOpenProblemLedger}^{\uparrow}$ packet is generated from subject-reduction, confluence, normalization, substitution, decidability, typed-example, blocker, transport, route, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICOpenProblemLedger}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 780.1, Definition 780.2, Definition 780.3, Definition 780.4, Definition 780.5, and Definition 780.6 bind the finite open-problem ledger, its non-escape boundary, and the exact source-row scope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICOpenProblemLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close arbitrary closed subject reduction, arbitrary closed Church–Rosser, evidence-free global strong normalization, unrestricted closed beta-conversion decidability, exhaustive typed-example coverage, full closed consistency, Lean verification, or bridge checking.

Upgrade path: Public closure requires a reusable public ledger interface for the seven open-family rows, transport row, replay route, provenance row, and local naming row over the same finite packet.

Chapter 781

A Concrete Naming Certificate for DependentCodomainInversionBoundary$^{\uparrow}$

The DependentCodomainInversionBoundary$^{\uparrow}$ packet realizes the dependent-codomain barrier named in chapter 9386. It sits beside the obstruction packet of chapter 731, the beta-substitution packet of chapter 716, and the frontier ledger of chapter 762. Its role is to name the finite codomain-readback boundary that must be discharged before a subject-reduction consumer may cross from syntactic substitution evidence to dependent application preservation.

Definition 781.1 (Dependent-codomain inversion boundary carrier)**.** *A* DependentCodomainInversionBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (\Pi, A, a, a', C_0, C_1, S, R, O, H, K, P, N)$$

with the following displayed rows:

1. Π *is the dependent function-type row whose codomain may observe the argument;*
2. A *is the displayed domain row shared by the argument and the function type;*
3. a *and* a' *are the source and reduced argument rows;*
4. C_0 *is the codomain readback row obtained by substituting* a *into the displayed codomain;*
5. C_1 *is the codomain readback row obtained by substituting* a' *into the same displayed codomain;*
6. S *is the syntactic substitution-evidence row, including the beta-substitution route supplied by chapter 716;*
7. R *is the subject-reduction handoff row pointing to the finite subject-reduction obstruction surface of chapter 731;*
8. O *is the open-frontier ledger row recording that no unconditional dependent-codomain inversion is exported;*
9. H *stores componentwise* hsame *transport for the function type, domain, arguments, codomain readbacks, substitution row, handoff row, obstruction row, provenance row, and local name;*
10. K *stores displayed* Cont *replay routes for codomain readback, substitution evidence, obstruction readback, and subject-reduction handoff;*
11. P *is the* Pkg *provenance over the open-problem vision, the obstruction packet, the beta-substitution packet, and the open-frontier ledger;*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DependentCodomainInversionBoundary}^{\uparrow}}$ *row.*

The carrier contains no coordinate for closed subject reduction, no proof that C_0 and C_1 are interchangeable, no context-reduction theorem, no inhabited discharge bundle, and no host conversion semantics.

Theorem 781.2 (Dependent-codomain inversion boundary NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DependentCodomainInversionBoundary}^{\uparrow}}$ *surface for Definition 781.1 consists exactly of carrier admission for $D = (\Pi, A, a, a', C_0, C_1, S, R, O, H, K, P, N)$, domain and argument row visibility, paired codomain-readback visibility for C_0 and C_1, syntactic substitution evidence through S, subject-reduction obstruction handoff through R, open-frontier ledger exposure through O, componentwise* hsame *transport through H, displayed* Cont *replay through K, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.DependentCodomainInversionBoundaryUp.DependentCodomainInversionBoundaryCarrier namecert obligations`

Proof. Project the accepted carrier. The domain, argument, and codomain-readback rows are displayed before any substitution-facing or subject-reduction-facing read is available.

Read the syntactic side through S. The beta-substitution packet supplies a finite substitution route, but that route reaches only the displayed codomain readback rows and does not identify C_0 with C_1.

Read the subject-reduction side through R and O. These rows cite the obstruction packet and the open-frontier ledger as boundary surfaces, so the consumer sees exactly where the dependent-codomain discharge would be required.

The structural rows H, K, P, N transport, replay, package, and name only the displayed rows. Since the carrier contains no context-reduction theorem, discharge bundle inhabitant, or closed subject-reduction row, the listed obligations exhaust the NameCert surface. □

Theorem 781.3 (Dependent-codomain inversion boundary subject-reduction handoff)**.** *Every subject-reduction consumer of an accepted* $\mathsf{DependentCodomainInversionBoundary}^{\uparrow}$ *packet must pass through the displayed paired codomain rows C_0 and C_1, the syntactic substitution row S, the obstruction handoff row R, and the open-frontier ledger row O before it may request dependent-codomain discharge. The packet may hand off this request to the subject-reduction obstruction surface, but it does not close the request and does not export closed subject reduction.*

Proof. Begin with a consumer asking for subject-reduction evidence in the dependent-codomain application case. Carrier projection exposes the two argument rows and the two codomain readbacks as separate coordinates.

Apply the NameCert obligation theorem. The consumer can read syntactic substitution evidence only through S, and it can read the subject-reduction boundary only through R and O.

The handoff is therefore finite and explicit. It records the exact point where codomain readback stability or a compatible discharge surface must enter, while excluding closed subject reduction, host conversion, and context-reduction data from the packet itself. □

Lean4 ✓ `BEDC.Derived.DependentCodomainInversionBoundaryCarrier subject reduction handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{DependentCodomainInversionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{DependentCodomainInversionBoundary}^{\uparrow}$ packet is generated from dependent function-type, domain, argument, codomain-readback, substitution, obstruction, frontier-ledger, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DependentCodomainInversionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 781.1, Definition 781.2, and Definition 781.3 bind the finite codomain-readback boundary and subject-reduction handoff surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{DependentCodomainInversionBoundary}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not prove dependent-codomain inversion, codomain-readback equality, context reduction, inhabited discharge bundles, closed subject reduction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired codomain-readback coverage, syntactic substitution routing, obstruction handoff, frontier-ledger exposure, and non-escape over the same finite packet.

Chapter 782

A Concrete Naming Certificate for $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$

The $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ packet names the finite observation budget used by the Real completeness route of chapter 9238. It sits between the precision-to-window schedule of chapter 650, the selected-tail surface of chapter 458, and the diagonal completion packet of chapter 359; its role is to expose the bounded rows a diagonal consumer may inspect before the $\mathsf{Real}^{\uparrow}$ seal is reached.

Definition 782.1 (Finite observation-budget selector carrier)**.** *A* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the precision-budget row naming the finite set of tolerances and diagonal indices a Real-completion consumer may request;*
2. *S is the selected schedule row assigning each budget entry of B to one finite observation route;*
3. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *window rows selected by the schedule;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger of rational observations, radii, and tolerance comparisons read from the windows in W;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached after the dyadic ledger has been checked;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the displayed handoff;*
7. *H records componentwise* hsame *transports for the budget, schedule, windows, dyadic ledger, regular-sequence handoff, seal, provenance, and local name;*
8. *C records the displayed* Cont *routes from B to S, from S to W, from W to D, from D to R, and from R to E;*
9. *P is the* Pkg *provenance over* BHist, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationBudgetSelector}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, host real equality, countable choice, a hidden limit selector, or an ambient completeness theorem.

Lean4 ✓ BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal route guard

Theorem 782.2 (Finite observation-budget selector NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{FiniteObservationBudge}}$ *surface for Definition 782.1 consists of five finite obligations:*

1. *carrier exposure, requiring every accepted object to display the packet* $F = (B, S, W, D, R, E, H, C, P, N)$*;*
2. *budget-to-schedule exactness, requiring each requested budget entry in* B *to reach the selected schedule row* S *only through the displayed route in* C*;*
3. *window and dyadic ledger coverage, requiring* S *to select only the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* W *and requiring every exported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation in* D *to be read from those windows;*
4. *handoff and seal discipline, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *and* $\mathsf{Real}^{\uparrow}$ *seal row* E *to be reached through* D *and then transported by the displayed* H, C, P, N *rows;*
5. *non-escape, requiring every public read to stay inside the displayed packet and to export no quotient stream, host real equality, countable-choice row, hidden limit selector, or ambient completeness theorem.*

Lean4 ✓ BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier namecert obligations

Proof. Carrier exposure is projection from the tuple in Definition 782.1. The packet lists the budget, selected schedule, selected windows, dyadic observations, regular-sequence handoff, real seal, transports, routes, provenance, and local naming row.

Budget-to-schedule exactness is the first displayed route in C. Since the carrier has one selected schedule row S for the budget B, a consumer has no alternate coordinate from which to obtain a different schedule for the same requested observation budget.

Window and dyadic ledger coverage use the next two route segments. The route from S to W exposes only the finite window family, and the route from W to D makes the dyadic observation ledger depend on those windows rather than on an unbounded stream object.

Handoff and seal discipline are supplied by R, E, H, C, P, N. The regular-sequence handoff is reached after the dyadic ledger, the real seal is reached after the handoff, and transport or repacking must replay the same rows through H, C, P, N.

The non-escape clause follows from the carrier inventory. None of the displayed rows is a quotient stream, host real equality test, countable-choice row, hidden selector, or ambient completeness theorem, so the local naming certificate has no route that can export one. □

Theorem 782.3 (Finite observation-budget selector schedule admission)**.** *Every accepted* FiniteObservationBudgetS *packet admits its selected schedule as a finite consumer of the* $\mathsf{ChoiceFreeLimitSchedule}^{\uparrow}$ *route: the budget row* B *is read as the precision request surface, the schedule row* S *is read as the finite route selector, and the rows* W, D, R, E, H, C, P, N *supply exactly the window, dyadic-ledger, handoff, seal, transport, route, provenance, and local naming surface needed by a choice-free limit-schedule consumer.*

Proof. Start with the accepted carrier $F = (B, S, W, D, R, E, H, C, P, N)$. The first two coordinates display the finite precision budget and the selected schedule row that answers each budget entry.

Read the schedule through the $\mathsf{ChoiceFreeLimitSchedule}^{\uparrow}$ dependency named in chapter 650. Its public route expects a request row, a schedule row, selected $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal, and the same transport, route, provenance, and naming rows.

These rows are exactly the coordinates of F. The admission therefore adds no selected representative, quotient stream, or host-completeness datum; it only reuses the displayed finite schedule-to-seal route. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier schedule admission`

Theorem 782.4 (Finite observation-budget selector RealUp seal handoff)**.** *For every accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, each* $\mathsf{Real}^{\uparrow}$ *seal read through* E *factors through the finite route*

$$B \to S \to W \to D \to R.$$

The handoff is compatible with the selected-tail route of chapter 458 and with the diagonal-completion route of chapter 359, because all three surfaces read only displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows,* hsame *transports,* Cont *routes,* Pkg *provenance, and* $\mathsf{NameCert}$ *rows before exposing a* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Project the seal coordinate from the carrier. The definition places E after the budget, selected schedule, selected windows, dyadic ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the continuation coordinate records the route into E.

Use the NameCert obligations of Definition 782.2. They require the seal row to be reached through D and R and then repacked only through the displayed H, C, P, N rows.

The selected-tail and diagonal-completion siblings consume the same kind of visible rows. Since F exposes exactly those rows and no hidden analytic coordinate, the $\mathsf{Real}^{\uparrow}$ handoff can be read by those consumers without changing the finite budget route. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier real seal handoff`

Theorem 782.5 (Finite observation-budget selector tail-meet seal compatibility)**.** *Let* $F = (B, S, W, D, R, E, H, C,$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *carrier. Every tail-meet consumer or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of the selected observation budget must read the same finite chain*

$$B \to S \to W \to D \to R \to E.$$

The consumer may use H, C, P, N *to transport, replay, package, and name that chain, but no hidden selector, quotient stream, host equality, or ambient completeness row may replace any segment of the chain.*

Proof. First use the local carrier and NameCert obligations of Definition 782.1 and Definition 782.2. They expose the selected budget route only through the displayed budget row, schedule row, windows, dyadic ledger, regular-sequence handoff, Real seal, transports, continuations, provenance, and local naming row.

Next attach the seal endpoint. By Definition 782.4, every Real-facing read of E already factors through $B \to S \to W \to D \to R$. Thus a $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer can reach the seal only by appending E to the same finite chain.

Finally compare the sibling consumers already cited by the chapter. The $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ route of chapter 458 reads a displayed tail-selection service, and the $\mathsf{RealDiagonalCompletion}^{\uparrow}$ route of chapter 359 reads a displayed diagonal-completion service. Since F supplies only $B, S, W, D, R, E, H, C, P, N$, both consumers share the same budget-to-seal chain and cannot import hidden selectors, quotient streams, host equality, or ambient completeness rows. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier tail meet seal compatibility`

Theorem 782.6 (Finite observation-budget selector non-escape)**.** *Every Real-completion, diagonal-limit, tail-selection, or schedule consumer of an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet factors through the displayed finite packet*

$$B, S, W, D, R, E, H, C, P, N.$$

The consumer may inspect the precision budget, selected schedule, finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row. It cannot inspect quotient streams, host equality of completed reals, countable choice, hidden limit selectors, or an ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier nonescape`

Proof. Begin with the carrier and NameCert obligations. Carrier exposure fixes the displayed packet, budget-to-schedule exactness fixes the segment from B to S, window and dyadic ledger coverage fixes the segments from S to W and from W to D, and handoff and seal discipline fixes the segments from D to R and from R to E under the same H, C, P, N rows.

Use schedule admission to keep schedule-facing reads on those rows. By Definition 782.3, the packet supplies the choice-free schedule surface without adding an alternate selector.

Use the seal handoff to keep Real-facing reads on the same route. By Definition 782.4, the $\mathsf{Real}^{\uparrow}$ seal is reached only after the finite budget, schedule, windows, dyadic ledger, and regular-sequence handoff have been read.

The excluded analytic objects do not occur as coordinates of F. Therefore no public consumer read can export quotient streams, host equality of completed reals, countable choice, hidden limit selectors, or an ambient completeness theorem. □

Theorem 782.7 (Finite observation-budget selector route determinacy)**.** *Let F and F' be accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packets with the same displayed $B, S, W, D, R, E, H, C, P, N$ rows. Then they determine the same finite budget-to-seal route*

$$B \to S \to W \to D \to R \to E.$$

In particular, a Real-completion consumer cannot obtain two distinct routes from the same displayed rows: schedule admission fixes $B \to S$, window and dyadic coverage fix $S \to W \to D$, and seal handoff fixes $D \to R \to E$ under the shared H, C, P, N surface.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier budget route determinacy`

Proof. Start with the common carrier rows. Both packets expose the same budget row, schedule row, window family, dyadic ledger, regular-sequence handoff, real seal, transports, routes, provenance, and local naming row.

The first segment is determined by schedule admission. By Definition 782.3, the budget row B is read only through the displayed selected schedule row S.

The middle segment is determined by the NameCert coverage obligations. Window selection uses the displayed route from S to W, and every dyadic observation exported by D is read through the displayed windows in W.

The final segment is determined by the seal handoff. By Definition 782.4, the $\mathsf{Real}^{\uparrow}$ seal is reached only after the dyadic ledger and the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the same H, C, P, N rows repack the result. Thus two accepted packets with the same displayed rows have the same finite route. □

Theorem 782.8 (Finite observation-budget selector shared-window union)**.** *Let*

$$F_1 = (B, S, W_1, D, R, E, H, C, P, N) \qquad \textit{and} \qquad F_2 = (B, S, W_2, D, R, E, H, C, P, N)$$

be accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packets whose displayed* $B, S, D, R, E, H, C, P, N$ *rows are compatible and whose selected finite* $\mathsf{StreamName}^{\uparrow}$ *window families are displayed as* W_1 *and* W_2*. Then the union window family* $W_1 \cup W_2$ *determines a finite displayed budget-to-seal route over the same compatible rows*

$$B \to S \to (W_1 \cup W_2) \to D \to R \to E.$$

The union route exports no quotient stream, selected host limit, host real equality, countable choice, hidden selector, host metric, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier shared window union`

Proof. Use schedule admission for both packets. By Definition 782.3, the common budget row B reaches the displayed schedule row S without importing an alternate selector.

Apply route determinacy to the compatible rows. The shared $B, S, D, R, E, H, C, P, N$ surface fixes the budget-to-seal route shape, so replacing the two displayed window families by their finite union does not introduce a second schedule route.

Use dyadic-window exhaustion for W_1 and W_2. Each exported dyadic observation in D is read from a displayed finite window family, hence the union remains a finite displayed window surface rather than a quotient stream or host limit.

Finally apply the diagonal consumer boundary and finite approximation pullback. These keep downstream Real, diagonal, and finite-approximation consumers inside the displayed budget-to-seal rows, so the union route exports none of the excluded analytic or host-level coordinates. □

Theorem 782.9 (Finite observation-budget selector dyadic-window exhaustion)**.** *For every accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, each dyadic observation exported by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D *is exhausted by the selected finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* W*. No exported dyadic observation has a route to quotient streams, host equality of completed reals, countable choice, hidden limit selectors, or any unbounded observation surface outside the displayed packet.*

Proof. Use the carrier exposure clause to identify the finite window family W and the dyadic ledger D inside the packet. The carrier contains no additional stream coordinate and no ambient selector from which an observation could be read.

Apply the window and dyadic ledger coverage obligation from Definition 782.2. It requires the schedule row S to select only the finite $\mathsf{StreamName}^{\uparrow}$ windows in W and requires every exported $\mathsf{DyadicRatCore}^{\uparrow}$ observation in D to be read from those windows.

The non-escape theorem removes the remaining alternatives. By Definition 782.6, public reads cannot export quotient streams, host real equality, countable-choice data, hidden limit selectors,

or an ambient completeness theorem. Hence the selected finite windows exhaust the dyadic observations exported by D. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier dyadic window exhaustion`

Theorem 782.10 (Finite observation-budget selector diagonal consumer boundary)**.** *Every diagonal-limit or Real-completion consumer that uses an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet factors through the displayed route*

$$B \to S \to W \to D \to R \to E$$

together with the H, C, P, N *rows. This is the boundary needed by the Real-completeness vision of chapter 9238, the selected-tail surface of chapter 458, and the diagonal-completion packet of chapter 359: each such consumer may use the finite budget route, but it receives no quotient stream, host real equality, countable choice, hidden selector, or independent completeness oracle from this selector.*

Proof. Begin with the non-escape theorem. It already states that Real-completion, diagonal-limit, tail-selection, and schedule consumers of an accepted packet factor through the displayed finite packet and cannot inspect excluded analytic objects.

Refine the factorization by route determinacy. By Definition 782.7, the displayed rows determine one finite route from the budget to the seal, so a downstream consumer cannot branch into an alternate completion path while using the same selector.

Use dyadic-window exhaustion for the observation boundary. By Definition 782.9, every dyadic observation supplied to the diagonal route is already read from the selected finite windows.

The sibling selected-tail and diagonal-completion chapters named in the introduction consume exactly these visible rows before reaching a $\mathsf{Real}^{\uparrow}$ seal. Therefore any such downstream consumer factors through $B \to S \to W \to D \to R \to E$ together with H, C, P, N, and the selector contributes no further completion principle. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier diagonal consumer boundary`

Theorem 782.11 (Finite observation-budget selector finite-approximation pullback)**.** *Let* $F = (B, S, W, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let* $A = (R_0, n, k, W_A, D_A, E_A, S_A, H_A, C_A, P_A, N_A)$ *be an accepted* $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ *packet. Suppose the selected finite-window rows, dyadic ledger rows, regular handoff rows, and* $\mathsf{Real}^{\uparrow}$ *seal rows are identified by the displayed* hsame *transports*

$$W\mathsf{hsame}W_A, \qquad D\mathsf{hsame}D_A, \qquad R\mathsf{hsame}R_0, \qquad E\mathsf{hsame}S_A.$$

Then every common $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer factors through the finite pullback surface formed by the two packets: the selector route* $B \to S \to W \to D \to R \to E$*, the approximation route* $R_0, n, k, W_A, D_A, E_A, S_A$*, the displayed transports* H, H_A*, continuation rows* C, C_A*, package provenance* P, P_A*, and local naming rows* N, N_A*. The pullback exports no quotient stream, selected host limit, host real equality, countable choice, hidden selector, host metric, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier budget approximation pullback`

Proof. Begin on the selector side. By Definition 782.7, the rows of F determine the route from the finite budget to the seal, and by Definition 782.9, the dyadic observations in D are already exhausted by the selected finite windows in W.

Now read the finite approximation side. The threshold route coverage theorem, Definition 601.4, forces every visible approximation observation to pass through R_0, n, k, W_A, D_A before any handoff is exposed. The seal coverage theorem, Definition 601.11, keeps every $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer of S_A inside those finite rows and the displayed bookkeeping rows.

Use the displayed hsame transports to identify the common rows componentwise. The hypotheses identify W with W_A, D with D_A, R with R_0, and the selector seal row E with the approximation seal row S_A, so a consumer that reads both packets sees one finite window, one dyadic ledger, one regular handoff, and one seal surface.

Finally apply Definition 601.17 together with Definition 782.10. These two non-escape clauses leave only the combined finite pullback route and its visible $H, H_A, C, C_A, P, P_A, N, N_A$ rows. Since neither carrier contains quotient streams, selected host limits, host real equality, countable choice, hidden selectors, host metrics, or ambient completeness data, no common consumer can receive such data from the pullback. □

Theorem 782.12 (Finite observation-budget selector cofinal readback)**.** *Let $F = (B, S, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Suppose a downstream* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer reads finite* $\mathsf{StreamName}^{\uparrow}$ *windows selected by S so that the read windows are cofinal for the displayed budget B, and suppose its* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers transport through the componentwise rows H to the ledger row D. Then the consumer determines the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R and the same* $\mathsf{Real}^{\uparrow}$ *seal row E through the visible continuation, package, and naming rows C, P, N.*

Conversely, every $\mathsf{Real}^{\uparrow}$*-facing seal read from F is exhausted by this cofinal finite-window route:*

$$B \to S \to W \to D \to R \to E.$$

The route exports no quotient stream, host real equality, selected host limit, countable choice, hidden selector, host metric, or ambient completeness theorem.

Proof. Begin with route determinacy. By Definition 782.7, the accepted packet exposes one path from the budget row through the selected schedule, finite windows, dyadic ledger, regular handoff, and terminal Real seal.

Next apply dyadic-window exhaustion. The cofinal read windows are already selected finite $\mathsf{StreamName}^{\uparrow}$ windows inside W, and their $\mathsf{DyadicRatCore}^{\uparrow}$ ledgers transport through H to D. Thus the consumer cannot obtain an additional dyadic source outside the displayed budget route.

The diagonal consumer boundary then places the downstream read on the same public endpoint. By Definition 782.10, every Real-completion, diagonal-limit, or seal-facing consumer that uses the packet factors through $B \to S \to W \to D \to R \to E$ together with H, C, P, N.

Finally use the finite-approximation pullback, Definition 782.11. Any finite readback that reaches a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ surface through compatible finite approximation rows is pulled back to the same selected window, dyadic ledger, regular handoff, and seal rows. Therefore the handoff is R, the seal is E, and every Real-facing seal read from F is exhausted by the cofinal finite-window route rather than by any undisplayed quotient, host equality, selected limit, choice, hidden selector, metric, or completeness coordinate. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier cofinal readback`

Theorem 782.13 (Finite observation-budget selector primitive scope)**.** *For every accepted* FiniteObservationBudget *packet* $F = (B, S, W, D, R, E, H, C, P, N)$*, the scoped source of every Real-completion, diagonal-limit, selected-tail, and schedule consumer is exactly the displayed BEDC primitive surface: the* BHist *packet rows* B, S, W, D, R, E*, the componentwise* hsame *transports* H*, the displayed* Cont *routes* C*, the* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationBudgetSelector}^{\uparrow}}$ *row* N*, over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The accepted packet exports no quotient stream, host real equality, countable-choice row, hidden selector, or ambient completeness theorem.*

Proof. The row inventory is fixed by Definition 782.1: an accepted packet has exactly the displayed tuple $F = (B, S, W, D, R, E, H, C, P, N)$ over BHist, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The five local NameCert obligations of Definition 782.2 make those rows the only carrier exposure, budget route, window coverage, seal handoff, and non-escape surface.

The route is then forced rather than chosen from an ambient source. By Definition 782.7, the displayed rows determine the unique finite path $B \to S \to W \to D \to R \to E$. By Definition 782.9, the $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ ledger exhaust the observations available to the consumer.

Finally apply Definition 782.10. It identifies Real-completion, diagonal-limit, selected-tail, and schedule consumers as consumers of precisely this finite route together with H, C, P, N. Since the carrier and obligations contain no coordinate for quotient streams, host real equality, countable choice, hidden selectors, or ambient completeness, no such object is exported from the scoped primitive surface. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier primitive scope`

Theorem 782.14 (Finite observation-budget selector public export)**.** *Every accepted* FiniteObservationBudgetSelec *packet publicly exports one finite budget-to-seal route*

$$B \to S \to W \to D \to R \to E$$

together with the H, C, P, N *rows. This route is consumable by Real-completion, diagonal-limit, selected-tail, and schedule consumers, and it exports no quotient stream, host real equality, countable choice, hidden selector, or ambient completeness theorem.*

Proof. Read the route from the carrier and the NameCert obligations. The carrier displays $B, S, W, D, R, E, H, C, P, N$, and the obligations force budget admission, window selection, dyadic ledger coverage, RegSeqRat handoff, and Real seal access through the displayed rows.

Apply Definition 782.7 and Definition 782.13. They make the route a single public finite object over the BEDC primitive surface rather than a branch selected from an ambient analytic source.

Finally use Definition 782.10 and Definition 782.6. The named consumers may read the route, while quotient streams, host real equality, countable choice, hidden selectors, and ambient completeness are absent from the packet. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier public export`

Theorem 782.15 (Finite observation-budget selector budget-choice freeness)**.** *Let* $F = (B, S, W, D, R, E, H, C, P,$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Then every Real-completion, diagonal-limit, selected-tail, or schedule consumer of* F *receives the finite route*

$$B \to S \to W \to D \to R \to E$$

from the displayed packet rows and not from a countable-choice principle, hidden selector, ambient completion theorem, host real equality test, or quotient-stream representative.

Proof. Start with route determinacy, Definition 782.7. It fixes the route from the budget row B through the stream schedule, finite windows, dyadic ledger, regular readback, and Real seal.

Use dyadic-window exhaustion, Definition 782.9. The observations consumed by the diagonal route are already exhausted by W and D, so no independent choice of observation indices remains outside the displayed packet.

Apply the diagonal consumer boundary and non-escape theorems, Definition 782.10 and Definition 782.6. They force the named consumers through F and exclude countable choice, hidden selectors, host equality, quotient streams, and ambient completeness. Hence the budget route is choice-free in the displayed BEDC sense. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier budget choice freeness`

Theorem 782.16 (Finite observation-budget selector window-seal commutation)**.** *Let $F = (B, S, W, D, R, E, H, C$ be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Any consumer route that first reads the selected finite windows W and then the Real seal row E has the same displayed public surface as the route that first names the budget-to-seal path $B \to S \to W \to D \to R \to E$ and then restricts its read to W before reaching E. Both readings factor through the same dyadic ledger D, regular readback R, and structural rows H, C, P, N.*

Proof. Read the public route from Definition 782.14. It exposes one finite budget-to-seal path together with the transport, continuation, package, and naming rows.

Localize the window read by Definition 782.9. The dyadic observations available on the route are exactly those exhausted by the finite windows W and the ledger row D.
