Now use route determinacy and the diagonal consumer boundary, Definition 782.7 and Definition 782.10. They prevent a second route from inserting another seal, hidden selector, or ambient completion step between W and E. Thus reading the window before the seal or reading it as the window coordinate of the public route gives the same displayed surface. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier window seal commutation`

Theorem 782.17 (Finite observation-budget selector budget-ledger minimality)**.** *Let $F = (B, S, W, D, R, E, H, C,$ be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Any finite ledger surface that serves the same Real-completion, diagonal-limit, selected-tail, and schedule consumers without exporting quotient streams, host real equality, countable choice, hidden selectors, or ambient completeness must contain the displayed budget row B, schedule row S, window row W, dyadic ledger D, regular readback R, Real seal E, and structural rows H, C, P, N up to the recorded* hsame *transports.*

Proof. Begin with the carrier and NameCert obligations. The carrier of Definition 782.1 lists $B, S, W, D, R, E, H, C, P, N$, and Definition 782.2 assigns these rows the budget, window, dyadic, readback, seal, transport, route, provenance, and naming roles.

Use route determinacy. By Definition 782.7, deleting any of B, S, W, D, R, E breaks the displayed path from finite budget to seal.

Use dyadic-window exhaustion and the diagonal consumer boundary. By Definition 782.9 and Definition 782.10, the named consumers need the window and dyadic ledger rows specifically, not merely an unnamed analytic substitute.

Finally apply public export and non-escape, Definition 782.14 and Definition 782.6. Since stronger ambient objects are excluded, the only available ledger surface is the displayed packet, up to the componentwise transports already recorded by H. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.BudgetLedgerMinimality.FiniteObservationBudgetSe`
`budget ledger minimality`

Theorem 782.18 (Finite observation-budget selector shared-tail-modulus pullback)**.** *Let* $F = (B, S, W, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let*

$$T = (X_0, X_1, M_0, M_1, \tau, D_T, W_0, W_1, Q_0, Q_1, E_T, H_T, C_T, P_T, N_T)$$

be an accepted $\mathsf{CauchySharedTailModulus}^{\uparrow}$ *packet. Suppose the selector window, dyadic ledger, regular readback, and seal rows are identified with the shared-tail rows by componentwise* hsame *transports*

$$W\,\mathsf{hsame}\,W_0, \qquad D\,\mathsf{hsame}\,D_T, \qquad R\,\mathsf{hsame}\,Q_0, \qquad E\,\mathsf{hsame}\,E_T.$$

Then every common $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of* F *and* T *factors through one finite pullback route from the selector budget to the shared-tail seal:*

$$B \to S \to W \to D \to R \to E \qquad \text{and} \qquad M_0, M_1, \tau, D_T, W_0, W_1, Q_0, Q_1, E_T.$$

The route uses only the displayed transports, continuations, package provenance, and local naming rows $H, H_T, C, C_T, P, P_T, N, N_T$*. It exports no quotient stream, host real equality, countable choice, hidden selector, independent threshold replacement, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier`
`shared tail modulus pullback`

Proof. Start with the selector route. By Definition 782.7, the rows of F determine the finite path $B \to S \to W \to D \to R \to E$. By Definition 782.9, the dyadic ledger row D is exhausted by the selected finite windows W.

Read the shared-tail packet next. The tail synchronization theorem, Definition 983.3, forces both Cauchy tail requests through the single displayed threshold route $M_0, M_1, \tau, D_T, W_0, W_1, Q_0, Q_1$. The Real seal handoff theorem, Definition 983.4, exposes the seal only after that shared finite route has been replayed.

Use the displayed hsame transports to identify the common rows. The hypotheses identify the selector window with W_0, the selector dyadic ledger with D_T, the selector readback with Q_0, and the selector seal with E_T. Thus a consumer of both packets sees one finite window, one dyadic ledger, one regular readback row, and one Real seal row on the selected side.

Finally apply Definition 782.14 and the non-escape clauses already attached to the two packets. Neither carrier inventory contains quotient streams, host real equality, countable choice, hidden selectors, independent threshold replacement, or ambient completeness data. The common consumer therefore factors through the finite pullback route and cannot obtain any stronger object outside the displayed rows. □

Theorem 782.19 (Finite observation-budget selector CauchyLimitSeal pullback)**.** *Let* $F = (B, S, W, D, R, E, H, C$
be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let*

$$L = (X, S_L, D_L, G, E_L, T_L, P_L, N_L)$$

be an accepted $\mathsf{CauchyLimitSeal}^{\uparrow}$ *public-route packet. Suppose the selector's finite window, dyadic ledger, regular handoff, and Real seal rows are identified with the seal packet's schedule, dyadic ledger, regular source, and seal rows by displayed* hsame *transports*

$$W\mathsf{hsame}S_L, \qquad D\mathsf{hsame}D_L, \qquad R\mathsf{hsame}G, \qquad E\mathsf{hsame}E_L.$$

Then every common $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of* F *and* L *factors through the pullback of the selector route*

$$B \to S \to W \to D \to R \to E$$

and the seal public route

$$X \to S_L \to D_L \to G \to E_L,$$

together with the visible transport, continuation, package, and local naming rows $H, C, P, N, T_L, P_L, N_L$*. The pullback exports no quotient stream, host real equality, selected external limit, countable choice, hidden selector, or ambient completeness theorem.*

Proof. Start with the selector route. By Definition 782.7, the accepted packet F has only the displayed finite path from B through S, W, D, R to E. By Definition 782.9, the dyadic ledger read is already exhausted by the finite window row W.

Read the seal packet through its public boundary. The CauchyLimitSeal public route boundary of Definition 386.8 confines any seal-facing read to $X, S_L, D_L, G, E_L, T_L, P_L, N_L$. The non-escape theorem Definition 386.4 removes quotient streams, selected host limits, uniqueness principles, and ambient completeness from the seal inventory.

Use the displayed hsame transports componentwise. The window row of the selector is identified with the schedule row of the seal packet, the dyadic ledger with the seal ledger, the regular handoff with the regular source row, and the selector seal with the seal endpoint row. Therefore a common consumer reads one finite window, one dyadic ledger, one regular source or handoff surface, and one Real-facing seal.

Finally combine the two visible row inventories. The selector non-escape and public-export rows exclude host real equality, countable choice, hidden selectors, and ambient completeness, while the seal non-escape rows exclude quotient streams and selected external limits. The common consumer therefore factors through the stated pullback and cannot export any coordinate outside those displayed routes. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.CauchyLimitSealPullback.FiniteObservationBudgetS`
`cauchy limit seal pullback`

Theorem 782.20 (Finite observation-budget selector UniformCauchyCriterion pullback)**.** *Let* $F = (B, S, W, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let*

$$U = (I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet. Suppose the selector window, dyadic ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal rows are identified with the uniform Cauchy shared-window, tolerance-ledger, regular consumer, and seal rows by componentwise* hsame *transports*

$$W\mathsf{hsame}W_U, \qquad D\mathsf{hsame}Q_U, \qquad R\mathsf{hsame}T_U, \qquad E\mathsf{hsame}E_U.$$

Then every common $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or completion-facing consumer of* F *and* U *factors through the finite pullback surface formed by the selector route*

$$B \to S \to W \to D \to R \to E$$

and the uniform Cauchy route

$$I \to W_U \to M_U \to Q_U \to T_U \to E_U,$$

together with the displayed rows $H, H_U, C, C_U, P, P_U, N, N_U$. *The pullback exports no quotient streams, host real equality, countable choice, hidden selectors, selected limits, host metrics, or ambient completeness coordinate.*

Proof. Start with the selector side. By Definition 782.7, the rows of F determine the finite route $B \to S \to W \to D \to R \to E$. By Definition 782.9, every dyadic observation in D is already exhausted by the selected finite windows in W.

Read the uniform Cauchy packet through its public route. The RegSeqRat tail equivalence theorem, Definition 435.11, identifies the shared-window tail ledger I, W_U, M_U, Q_U, T_U with the finite-window $\mathsf{RegSeqRat}^{\uparrow}$ consumer whose seal is E_U. The public export theorem, Definition 435.20, then exposes only the surface $I, W_U, M_U, Q_U, T_U, E_U, H_U, C_U, P_U, N_U$ to downstream regular, real, or completion-facing consumers.

Use the displayed hsame transports to form the common surface. The hypotheses identify the selector window with the uniform shared-window row, the selector dyadic ledger with the uniform tolerance ledger, the selector handoff with the uniform regular consumer row, and the selector seal with the uniform seal row. Thus a consumer of both packets sees one finite window surface, one dyadic tolerance ledger, one regular handoff, and one real-facing seal.

Finally apply Definition 782.14 together with the uniform public export. Since both packets expose only the displayed routes and rows, any common $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or completion-facing consumer factors through the finite pullback surface above. The excluded objects are absent from the carrier inventories and from the public export surfaces, so the pullback cannot supply quotient streams, host real equality, countable choice, hidden selectors, selected limits, host metrics, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier uniform cauchycriterion pullback`

Theorem 782.21 (Finite observation-budget selector terminal budget nonempty)**.** *Any accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet used by a* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or completion-facing consumer exposes a nonempty displayed finite budget route*

$$B \to S \to W \to D \to R \to E.$$

The endpoint E *is reached only through the selected budget row* B, *schedule row* S, *finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W, *dyadic ledger* D, *and regular handoff row* R *of the same packet.*

Proof. Start with Definition 782.7. It identifies the displayed path from B through S, W, D, R to E as the selector route available to downstream consumers.

Use Definition 782.9. The dyadic observations in D are already read from the finite windows in W, so the route cannot skip the displayed window row or replace it by an ambient stream.

Apply Definition 782.14 and Definition 782.19. These keep Real-facing, regular, seal-facing, and completion-facing reads on the same visible selector route, with E as the displayed terminal seal. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal budget nonempty`

Theorem 782.22 (Finite observation-budget selector window index scope)**.** *Every window index read by a* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*, or completion-facing consumer of an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet is scoped by the displayed finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W *and dyadic ledger* D*. It is not scoped by quotient streams, host equality, countable choice, hidden selectors, selected limits, host metrics, or ambient completeness.*

Proof. Read the selector packet through Definition 782.21. Any consumer-visible index occurs on the displayed route $B \to S \to W \to D \to R \to E$.

Use Definition 782.9 to localize dyadic observations to the finite window row W and ledger row D. No additional index source is introduced by the dyadic side.

Finally apply Definition 782.6, Definition 782.14, and the seal pullback of Definition 782.19. The excluded host and quotient objects are absent from the carrier inventory and from the public export surface, so they cannot scope a displayed window index. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.WindowIndexScope.FiniteObservationBudgetSelector window index scope`

Theorem 782.23 (Finite observation-budget selector terminal selector synchronization)**.** *Let* $F = (B, S, W, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{UniformCauchyCriterion}^{\uparrow}$*, or completion-facing consumer reads the same terminal selector route*

$$B \to S \to W \to D \to R \to E.$$

The route is synchronized with the CauchyLimitSeal and UniformCauchyCriterion pullback surfaces, and it exports no quotient stream, host real equality, selected external limit, countable choice, hidden selector, host metric, or ambient completeness theorem.

Proof. Start with Definition 782.7. It identifies $B \to S \to W \to D \to R \to E$ as the selector route available to any consumer of the accepted packet.

Use Definition 782.19. A CauchyLimitSeal-facing read identifies the selector window, dyadic ledger, regular handoff, and Real seal with the corresponding public seal rows, so the seal consumer sees the same terminal selector route rather than a separate limit stream.

Use Definition 782.20 for the uniform-Cauchy side. The shared-window, tolerance-ledger, regular-consumer, and seal rows are pulled back to W, D, R, E, so the UniformCauchyCriterion consumer is synchronized with the same terminal route.

Finally apply Definition 782.21 and Definition 782.22. The terminal route is nonempty, every visible index is scoped by W and D, and ledger exhaustion leaves no quotient stream, host real equality, selected external limit, countable choice, hidden selector, host metric, or ambient completeness theorem to export. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal selector synchronization`

Theorem 782.24 (Finite observation-budget selector RealTailAgreementSeal pullback)**.** *Let* $F = (B, S, W, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let* $Q = (R_0, S_0, W_Q, D_Q, A_Q, H_Q, C_Q, P_Q, N_Q)$ *be an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet. Suppose* $W\mathsf{hsame}W_Q$*,* $D\mathsf{hsame}D_Q$*,* $R\mathsf{hsame}R_0$*, and* E *is the* $\mathsf{Real}^{\uparrow}$*-facing seal row reached after the agreement row* A_Q*. Then every common* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer factors through the finite pullback of*

$$B \to S \to W \to D \to R \to E$$

with the seal route R_0, S_0, W_Q, D_Q, A_Q, together with the visible hsame *transport,* Cont *continuation,* Pkg *provenance, and* NameCert *rows of the two accepted packets.*

The pullback exports no quotient stream equality, selected host limit, host convergence theorem, countable choice, hidden selector, second budget gate, or ambient completeness principle.

Proof. Begin with Definition 782.7. It fixes the selector-side path from B through S, W, D, R to the terminal seal row E.

Apply Definition 782.23. Any Real-facing, regular, uniform, seal-facing, or completion-facing read of F is already synchronized with that same terminal selector route.

On the seal side, use Definition 699.10. The accepted $\mathsf{RealTailAgreementSeal}^{\uparrow}$ packet places its paired tail request on the displayed budget and agreement rows R_0, S_0, W_Q, D_Q, A_Q before the Real-facing seal can be consumed.

Finally apply Definition 699.36. Since the shared rows satisfy $W\mathsf{hsame}W_Q$, $D\mathsf{hsame}D_Q$, and $R\mathsf{hsame}R_0$, every common Real or completion consumer is forced through the displayed finite pullback, and the absent quotient, host-limit, host-convergence, choice, hidden-selector, second-budget, and completeness objects cannot be projected from either packet. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.RealTailAgreementSealPullback.FiniteObservationB`
`realtailagreementseal pullback`

Theorem 782.25 (Finite observation-budget selector tail-agreement limit-seal triangle)**.** *Let $F = (B, S, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, let $Q = (R_Q, S_Q, W_Q, D_Q, A_Q$ be an accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *packet, and let $L = (X, S_L, D_L, G, E_L, T_L, P_L, N_L)$ be an accepted* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packet. Suppose the selector rows are identified with the tail-agreement and limit-seal rows by displayed transports*

$$W\mathsf{hsame}W_Q, \quad D\mathsf{hsame}D_Q, \quad R\mathsf{hsame}R_Q, \quad E\mathsf{hsame}A_Q, \quad X\mathsf{hsame}R, \quad S_L\mathsf{hsame}W, \quad D_L\mathsf{hsame}D, \quad E_L\mathsf{hsame}E.$$

Then every common $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of these packets factors through the single finite triangle*

$$B \to S \to W \to D \to R \to E, \qquad R_Q, S_Q, W_Q, D_Q, A_Q, \qquad X \to S_L \to D_L \to G \to E_L.$$

The factorization uses only the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows of F, Q, and L. It exports no quotient stream, selected host limit, host real equality, hidden family limit, countable choice, second selector route, or ambient completeness principle.*

Proof. Begin with the selector side. The route determinacy theorem Definition 782.7, public export theorem Definition 782.14, and pullback theorem Definition 782.24 place every accepted selector consumer on the displayed route $B \to S \to W \to D \to R \to E$.

Use the RealTailAgreementSeal side next. The budget-source lock Definition 699.10 and downstream route exhaustion Definition 699.36 identify the shared tail-agreement rows R_Q, S_Q, W_Q, D_Q, A_Q with the same finite budget, window, dyadic, regular, and seal surface.

Finally attach the CauchyLimitSeal side. The public route boundary Definition 386.8 and root completion consumer non-escape theorem Definition 386.94 force the limit-seal read through X, S_L, D_L, G, E_L and exclude every undisplayed completion coordinate. With the stated hsame transports, the three routes are one finite triangle over the displayed history, continuation, provenance, and naming rows. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier`
`tail agreement limit seal triangle`

Theorem 782.26 (Finite observation-budget selector budget-seal cut)**.** *Let* $F = (B, S, W, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, *or completion-facing consumer of* F *factors through the unique displayed cut at the dyadic and regular handoff:*

$$B \to S \to W \to D \qquad | \qquad D \to R \to E.$$

The lower segment $B \to S \to W \to D$ *supplies all finite observation and dyadic ledger data, while the upper segment* $D \to R \to E$ *supplies all regular-sequence and* $\mathsf{Real}^{\uparrow}$*-seal data.*

Any shared pullback with $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, *or* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *preserves this cut by displayed* hsame *transports. Such a pullback cannot move quotient streams, host real equality, countable choice, hidden selectors, selected limits, host metrics, or ambient completeness across the cut.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier budget seal cut`

Proof. Start with the selector route itself. The route determinacy theorem Definition 782.7 fixes the single displayed path $B \to S \to W \to D \to R \to E$, while Definition 782.9 makes the finite windows and dyadic ledger exhaust the lower observation segment.

The public export theorem Definition 782.14 then exposes that route to downstream regular, real, schedule, and completion-facing consumers without adding any alternate selector. Therefore the only handoff from finite observation to seal-facing data occurs at the displayed dyadic ledger row D.

For seal consumers, apply the three pullback theorems separately. The CauchyLimitSeal pullback Definition 782.19, the UniformCauchyCriterion pullback Definition 782.20, and the RealTailAgreementSeal pullback Definition 782.24 identify the shared rows only by displayed hsame transports, so each consumer preserves the same lower and upper segments.

Finally use the terminal tail-agreement limit-seal triangle Definition 782.25. It shows that even the combined tail-agreement and limit-seal consumer remains on the displayed finite triangle. Since the cited public and pullback surfaces contain no quotient streams, host real equality, countable choice, hidden selectors, selected limits, host metrics, or ambient completeness coordinates, none of those objects can cross the dyadic and regular handoff cut. □

Theorem 782.27 (Finite observation-budget selector RealCompletionSelectorSeal pullback)**.** *Let* $F = (B, S, W, D, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let*

$$S' = (B', W', R', L', E', H', C', P', N')$$

be an accepted $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *packet. Suppose the selector budget, selected window, regular readback, and terminal seal rows are identified with the selector-seal rows by displayed componentwise transports*

$$B\mathsf{hsame}B', \qquad W\mathsf{hsame}W', \qquad R\mathsf{hsame}R', \qquad E\mathsf{hsame}E'.$$

Then every common $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer factors through the single finite selector-to-seal pullback formed by the* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *route*

$$B \to S \to W \to D \to R \to E$$

and the RealCompletionSelectorSeal$^{\uparrow}$ *route*

$$B' \to W' \to R' \to L' \to E',$$

together with only the visible hsame *transport,* Cont *continuation,* Pkg *provenance, and* NameCert *rows* $H, H', C, C', P, P', N, N'$*. The pullback exports no quotient stream equality, host real equality, countable choice, hidden selector, detached completion limit, second selector budget, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier realcompletionselectorseal pullback`

Proof. Begin with the finite observation-budget side. The budget-seal cut of Definition 782.26 confines every Real, regular, seal, and completion-facing read of F to the displayed path $B \to S \to W \to D \to R \to E$ and preserves the dyadic-to-regular handoff under all visible pullbacks.

Attach the selector-seal side. By Definition 1081.5, an accepted RealCompletionSelectorSeal$^{\uparrow}$ packet occupies exactly the L10 selector-to-seal route through the selected window, regular readback, CauchyLimitSeal handoff, and terminal Real endpoint. By Definition 1081.6, that route is unreadable until the selector-budget row B' has been exposed.

Use the displayed transports to identify the shared surface. The hypotheses identify B with B', W with W', R with R', and E with E'. The CauchyLimitSeal pullback of Definition 782.19 supplies the seal-facing handoff through the visible limit-seal row, so the two routes meet at the same finite budget, window, readback, handoff, and endpoint surface.

Finally apply terminal exhaustion, Definition 1081.10. Every terminal Real or Completion read of the selector-seal packet is exhausted by B', W', R', L', E' and the structural rows H', C', P', N'. Since the selector side exposes only H, C, P, N beyond its displayed route, the common consumer factors through the stated pullback and cannot project any undisplayed quotient, host-equality, choice, hidden-selector, detached-limit, second-budget, or completeness coordinate. □

Theorem 782.28 (Finite observation-budget selector terminal route no-branching)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. If two Real-completion or diagonal consumers expose the same displayed rows* $B, S, W, D, R, E, H, C, P, N$*, then they determine the same terminal route*

$$B \to S \to W \to D \to R \to E.$$

In particular, no second terminal route can pass through quotient streams, host real equality, countable choice, hidden selectors, side-channel completion, or ambient completeness.

Proof. The displayed rows first determine the budget-to-window spine. By Definition 782.7, any consumer that reads $B, S, W, D, R, E, H, C, P, N$ is confined to the route from the budget row through the selected schedule, finite window family, dyadic ledger, regular handoff, and terminal seal.

The terminal endpoint is inhabited only on that same displayed surface. The nonemptiness statement of Definition 782.21 supplies the terminal budget witness, while Definition 782.22 keeps every window index inside the same finite observation rows.

It remains to rule out an alternate Real-completion exit. Apply the pullback of Definition 782.27: a Real-completion or diagonal consumer sharing the displayed rows factors through

the same finite selector-to-seal pullback. Since the pullback exports no quotient stream, host real equality, countable choice, hidden selector, side-channel completion, or ambient-completeness coordinate, the two consumers have no available coordinate from which to form a distinct terminal route. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal route no branching`

Theorem 782.29 (Finite observation-budget selector terminal route endpoint exactness)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-completion, diagonal-limit,* $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, *or* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *consumer that reaches a terminal endpoint through* F *reaches the displayed endpoint* E *through the route*

$$B \to S \to W \to D \to R \to E.$$

Moreover, any endpoint with the same displayed budget, schedule, window, dyadic, regular, seal, transport, continuation, package, and local NameCert *rows is identified with* E *by the recorded componentwise* hsame *transports.*

Proof. Begin with budget-route determinacy. By Definition 782.7, every consumer of the displayed rows $B, S, W, D, R, E, H, C, P, N$ is confined to the route from the budget row through the selected schedule, finite window family, dyadic ledger, regular handoff, and terminal Real seal.

The endpoint is then present on exactly that route. The terminal budget nonemptiness theorem Definition 782.21 supplies the terminal budget witness, while the budget-seal cut Definition 782.26 keeps the lower finite-observation segment and upper regular-seal segment attached at D and R.

Next handle the named downstream consumers. The CauchyLimitSeal, UniformCauchyCriterion, and RealTailAgreementSeal pullbacks identify their shared rows with the selector rows by displayed hsame transports, and Definition 782.27 does the same for RealCompletionSelectorSeal consumers.

Finally apply terminal route no-branching, Definition 782.28. Since any endpoint with the same displayed rows determines the same route $B \to S \to W \to D \to R \to E$, the endpoint is the displayed E up to the recorded componentwise hsame transports, and no quotient, choice, hidden selector, side-channel completion, or ambient completeness coordinate can supply a different terminal endpoint. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal route endpoint exactness`

Theorem 782.30 (Finite observation-budget selector terminal diagonal pullback functoriality)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. The terminal route endpoint exactness, finite-approximation pullback, cofinal readback, and diagonal-consumer boundary determine a functorial pullback surface for every* $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *and diagonal-completion consumer of* F.

The consumer receives only the displayed $B, S, W, D, R, E, H, C, P, N$ *rows and their recorded* hsame, Cont, Pkg, *and* NameCert *structure. It receives no quotient stream, host real equality, hidden selector, countable choice, host metric, or ambient completeness row.*

Proof. Begin with the route. The budget-route determinacy theorem Definition 782.7 fixes the single path $B \to S \to W \to D \to R \to E$ for every accepted consumer of the displayed selector rows.

Attach the diagonal boundary. By Definition 782.10, any diagonal-completion read of the selector must use the displayed budget, selected schedule, finite windows, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and local naming rows.

Use the finite pullback and readback surfaces next. The finite-approximation pullback Definition 782.11 and cofinal readback theorem Definition 782.12 identify the common $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and diagonal-completion reads by displayed componentwise transports, so each consumer acts on the same finite surface.

Finally apply endpoint exactness, Definition 782.29. Since the terminal endpoint is the displayed E along the same route, the pullback is functorial in the permitted consumers and has no coordinate from which to read quotient streams, host real equality, hidden selectors, countable choice, host metrics, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal diagonal pullback functoriality`

Theorem 782.31 (Finite observation-budget selector Real-seal window saturation)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Any Real-completion or diagonal consumer that reaches the same terminal row E through the same budget, schedule, dyadic, regular, transport, continuation, provenance, and local naming rows B, S, D, R, H, C, P, N must use the displayed finite* $\mathsf{StreamName}^{\uparrow}$ *window family W. Adding or replacing a window without changing the budget or schedule is not a refinement of the same selector packet; it is a different accepted packet with a different window row.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier real seal window saturation`

Proof. Start with the route into the terminal Real seal. By Definition 782.4, every Real-facing read of E is reached only after the finite budget, schedule, selected window family, dyadic ledger, and regular handoff have been exposed.

Use window exhaustion for the lower observation segment. By Definition 782.9, the dyadic observations in D are already covered by the displayed finite windows W, so a diagonal or completion consumer has no independent dyadic source outside that family.

Now apply route determinacy. The theorem Definition 782.7 fixes the displayed route from B through S, W, D, R to E whenever the structural rows H, C, P, N are preserved.

Finally use the terminal theorems to exclude a hidden selector. By Definition 782.28 and Definition 782.29, a consumer reaching the same endpoint through the same displayed rows cannot pass through a second window source. A changed window family therefore changes the accepted selector packet rather than refining the original one. □

Theorem 782.32 (Finite observation-budget selector terminal window minimality)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Every terminal* $\mathsf{Real}^{\uparrow}$*-facing read of F factors through exactly the displayed finite budget row B, selected* $\mathsf{StreamName}^{\uparrow}$ *window family W,*

DyadicRatCore$^{\uparrow}$ *ledger* D, RegSeqRat$^{\uparrow}$ *handoff* R, *componentwise* hsame *transports* H, *displayed* Cont *route* C, Pkg *provenance* P, *and local* NameCert *row* N, *with the selected schedule row* S *mediating the route*

$$B \to S \to W \to D \to R \to E.$$

If any one of the displayed budget, schedule, window, dyadic ledger, regular handoff, seal, transport, continuation, provenance, or local naming rows is dropped, the remaining rows no longer determine the terminal endpoint exactness of Definition 782.29.

Proof. First identify the only route available to a terminal consumer. The budget-route determinacy theorem Definition 782.7 fixes the path from B through S, W, D, R to E, and terminal selector synchronization Definition 782.23 keeps the selected schedule and window rows attached to that path.

Next remove terminal branching. By Definition 782.28, two consumers exposing the same displayed rows determine the same terminal route, so there is no alternate endpoint route through quotient streams, host real equality, countable choice, hidden selectors, side-channel completion, or ambient completeness.

It remains to record sufficiency and minimality. Sufficiency is exactly endpoint exactness from Definition 782.29: the displayed rows identify the terminal endpoint with E by componentwise hsame transport. For minimality, each listed row is used by one segment of the displayed route or by its transport, continuation, provenance, and naming certificate. Dropping such a row removes the corresponding segment or certificate witness, so the endpoint can no longer be recovered by the cited exactness theorem. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal window minimality`

Theorem 782.33 (Finite observation-budget selector diagonal-tail coverage)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. The terminal window inventory of Definition 782.32 covers every diagonal-tail consumer route used by* RegularCauchyTailSelector$^{\uparrow}$, RealDiagonalCompletion$^{\uparrow}$, *and* RealCompletionSelectorSeal$^{\uparrow}$*: such a consumer reads its terminal* Real$^{\uparrow}$ *handoff only through the finite route*

$$B \to S \to W \to D \to R \to E$$

and through the displayed H, C, P, N *rows. The coverage imports no quotient stream, countable choice operation, host real equality, hidden selector, detached completion limit, or independent completeness oracle.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier diagonal tail coverage`

Proof. Begin with the tail-facing side. The tail-meet seal compatibility theorem Definition 782.5 places every selected-tail or seal consumer on the displayed finite chain, and the diagonal consumer boundary Definition 782.10 keeps diagonal-limit and Real-completion consumers inside the same rows.

Now attach the selector-seal consumer. The RealCompletionSelectorSeal pullback Definition 782.27 identifies the shared budget, selected window, regular readback, and terminal seal rows with the selector-seal route using only displayed hsame, Cont, Pkg, and NameCert data.

Finally apply terminal window minimality, Definition 782.32. Its inventory is sufficient for the terminal endpoint and loses exactness when a displayed row is removed. Therefore the diagonal-tail consumers named in the statement are covered by the same finite terminal window, while the excluded quotient, choice, host-equality, hidden-selector, detached-limit, and completeness coordinates remain absent. □

Theorem 782.34 (Finite observation-budget selector terminal section exactness)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Every terminal Real-completion or diagonal-tail section whose displayed rows agree with* $B, S, W, D, R, E, H, C, P, N$ *is exactly the finite section pulled back along* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The section exports no quotient stream, host real equality, countable choice, hidden selector, detached completion limit, metric-completeness row, or ambient completeness oracle.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal section exactness`

Proof. First use terminal window minimality, Definition 782.32. It supplies the full selector inventory $B, S, W, D, R, E, H, C, P, N$ and says that dropping any one of those rows loses terminal endpoint determination.

Next apply terminal route endpoint exactness, Definition 782.29. Since the displayed rows agree with the accepted packet, the terminal section reaches the same $\mathsf{Real}^{\uparrow}$ endpoint E through the same componentwise hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

For diagonal-tail consumers, use Definition 782.33. It keeps the $\mathsf{RegularCauchyTailSelector}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, and $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ reads on the same finite route

$$B \to S \to W \to D \to R \to E.$$

Finally identify that route with the existing four-face finite-section pullback. By Definition 126.586, agreement of the finite $\mathsf{StreamName}^{\uparrow}$ windows with the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and current $\mathsf{Real}^{\uparrow}$ seal determines exactly the same terminal section and exports none of the excluded quotient, host-equality, choice, hidden-selector, detached-limit, metric-completeness, or ambient-completeness coordinates. □

Theorem 782.35 (Finite observation-budget selector terminal section pullback uniqueness)**.** *Let*

$$F_0 = (B, S, W, D, R, E, H, C, P, N)$$

and

$$F_1 = (B, S, W, D, R, E, H, C, P, N)$$

be accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packets with the same displayed budget, schedule, window, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and local naming rows. Suppose that the terminal sections of* F_0 *and* F_1 *both satisfy the finite-section pullback along* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Then the two terminal sections determine the same budget-to-seal route*

$$B \to S \to W \to D \to R \to E$$

and the same $\mathsf{Real}^{\uparrow}$ *seal up to the recorded componentwise* hsame *transports. No quotient stream, host real equality, choice row, hidden selector, metric-completeness row, or ambient-completeness oracle can distinguish the two terminal sections.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal section pullback uniqueness`

Proof. First apply terminal section exactness, Definition 782.34, to each accepted packet. Since both displayed rows are $B, S, W, D, R, E, H, C, P, N$, both terminal sections are the finite section pulled back through the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces.

Next identify the endpoint route. Terminal route endpoint exactness, Definition 782.29, fixes the endpoint at the displayed seal E, while terminal window minimality, Definition 782.32, keeps every route segment attached to the same rows $B, S, W, D, R, E, H, C, P, N$.

Finally use the four-face pullback exactness Definition 126.586. The shared finite windows, dyadic ledger, regular readback, and Real seal determine one pulled-back section, so the two terminal sections induce the same displayed chain and the same $\mathsf{Real}^{\uparrow}$ seal under the componentwise hsame transports. The non-escape clauses in the cited exactness and minimality theorems exclude quotient streams, host equalities, choice rows, hidden selectors, metric-completeness rows, and ambient-completeness oracles as possible distinguishing data. □

Theorem 782.36 (Finite observation-budget selector terminal cofinal-window coverage)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Every cofinal terminal consumer compatible with the displayed selector rows factors through the same finite window route*

$$B \to S \to W \to D \to R \to E.$$

Compatibility with $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$*,* $\mathsf{RealDiagonalCompletion}^{\uparrow}$*, and* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *is therefore mediated only by the displayed budget, schedule, window, dyadic ledger, regular handoff, Real seal, componentwise* hsame *transports,* Cont *route,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. The exported terminal surface contains no quotient stream, countable choice operation, host real equality, hidden selector, detached completion limit, or ambient completeness oracle.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal cofinal window coverage`

Proof. First fix the finite terminal inventory. Terminal window minimality, Definition 782.32, says that every terminal $\mathsf{Real}^{\uparrow}$-facing read of F uses exactly the displayed rows $B, S, W, D, R, E, H, C, P, N$ with S mediating the route through the finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

Next attach the diagonal-tail consumers. By Definition 782.33, the $\mathsf{RegularCauchyTailSelector}^{\uparrow}$, $\mathsf{RealDiagonalCompletion}^{\uparrow}$, and $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ reads of the packet all remain on the same finite route and import none of the excluded quotient, choice, host-equality, hidden-selector, detached-limit, or completeness coordinates.

Now pass from a compatible terminal section to the displayed section. Terminal section exactness, Definition 782.34, identifies any section agreeing with the displayed rows as the finite section pulled back along $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally use pullback uniqueness. The uniqueness theorem Definition 782.35, together with Definition 126.586, leaves only the chain $B \to S \to W \to D \to R \to E$ as the cofinal terminal route. Hence every compatible cofinal consumer factors through that route and exports only the displayed structural rows. □

Theorem 782.37 (Finite observation-budget selector terminal cofinal-window transport invariance)**.** *Let*

$$F_0 = (B, S, W, D, R, E, H, C, P, N)$$

and

$$F_1 = (B, S, W, D, R, E, H, C, P, N)$$

be accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packets whose terminal rows agree componentwise in the budget row* B*, schedule row* S*, finite* $\mathsf{StreamName}^{\uparrow}$ *window family* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *transports* H*, displayed* Cont *route* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N*. Then every cofinal terminal consumer compatible with* F_0 *is compatible with* F_1*, and conversely, and both compatibilities factor through the same displayed route*

$$B \to S \to W \to D \to R \to E.$$

No quotient stream, host real equality, choice operation, hidden selector, detached completion limit, or ambient completeness oracle can distinguish the two packets at a cofinal terminal consumer.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal cofinal window transport invariance`

Proof. First apply terminal cofinal-window coverage, Definition 782.36, to F_0 and to F_1. Since the two packets expose the same displayed rows $B, S, W, D, R, E, H, C, P, N$, every compatible cofinal terminal consumer on either side is already forced onto the same finite route through the selected $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and terminal $\mathsf{Real}^{\uparrow}$ seal.

Next identify the terminal sections. The terminal section exactness theorem Definition 782.34 turns compatibility with the displayed rows into the finite section pulled back along $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Now use terminal section pullback uniqueness, Definition 782.35. The two sections have the same budget, schedule, window, dyadic, regular, seal, transport, continuation, provenance, and local naming rows, so they determine one route and one terminal seal under the recorded componentwise hsame transports.

Finally invoke Definition 126.586. The four-face pullback has no additional quotient, host-equality, choice, hidden-selector, detached-limit, or ambient-completeness coordinate. Thus transport along the shared rows carries cofinal terminal compatibility in either direction and leaves the route $B \to S \to W \to D \to R \to E$ invariant. □

Theorem 782.38 (Finite observation-budget selector terminal cofinal-window section decomposition)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Every cofinal terminal consumer compatible with* F *decomposes into the four displayed section faces: the finite* $\mathsf{StreamName}^{\uparrow}$ *window family* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The only transport data between these faces are the componentwise* hsame *rows* H*, displayed* Cont *route* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N*.*

Equivalently, the consumer route is the finite section

$$W \to D \to R \to E$$

inside the budget and schedule envelope B, S*. It exports no quotient stream, host real equality, choice row, hidden selector, detached limit, metric-completeness row, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal cofinal window section decomposition`

Proof. First apply terminal cofinal-window coverage, Definition 782.36. It places every compatible cofinal terminal consumer on the displayed route from the finite budget and selected schedule through W, D, R to E.

Next use terminal section exactness, Definition 782.34. This identifies the compatible terminal section with the finite section pulled back along $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Now apply terminal section pullback uniqueness, Definition 782.35. The rows $B, S, W, D, R, E, H, C, P, N$ determine a single budget-to-seal route, so any compatible consumer has the same four-face section decomposition.

Finally use Definition 126.586. Its finite-section pullback gives the displayed $\mathsf{StreamName}^{\uparrow}$ window face, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger face, $\mathsf{RegSeqRat}^{\uparrow}$ readback face, and $\mathsf{Real}^{\uparrow}$ seal face, while the non-escape clauses in the cited theorems exclude quotient streams, host real equality, choice rows, hidden selectors, detached limits, metric-completeness rows, and ambient completeness. □

Theorem 782.39 (Finite observation-budget selector terminal route status readback)**.** *Every terminal cofinal consumer of an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet reports its route status only through the displayed budget, schedule, finite window, dyadic ledger, regular-rational readback, Real seal, transport, continuation, provenance, and local naming rows*

$$B, S, W, D, R, E, H, C, P, N.$$

No quotient stream, hidden selector, host real equality, metric-completeness row, countable choice row, or ambient completeness oracle is a status coordinate for the same terminal route.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal route status readback`

Proof. First apply terminal cofinal-window coverage. It places every compatible terminal consumer on the displayed route from budget and schedule through the window, dyadic, regular, and Real-seal faces.

Next use terminal cofinal-window transport invariance. The status readback is preserved by the componentwise hsame rows, the displayed continuation row, the package provenance row, and the local naming row, so transport cannot create a second terminal status.

Finally apply terminal cofinal-window section decomposition. The route decomposes into the four displayed faces W, D, R, E inside the envelope B, S, H, C, P, N, and the four-face pullback exactness excludes quotient, hidden-selector, choice, host-equality, metric-completeness, and ambient-completeness coordinates. □

Theorem 782.40 (Finite observation-budget selector cofinal window exhaustion)**.** *For an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, the cofinal terminal route is exhausted by the rows* $B, S, W, D, R, E, H, C, P, N$*. No quotient stream, hidden selector, countable choice row, host real equality, metric-completeness row, or ambient completeness oracle can refine the same route while preserving the displayed terminal window.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier cofinal window exhaustion`

Proof. Begin with terminal window minimality. Removing a displayed row loses terminal endpoint determination, so a refinement of the same route must preserve the visible budget, schedule, window, dyadic, regular, seal, transport, continuation, provenance, and naming rows.

Use terminal route status readback. Any compatible terminal consumer reports status through those rows alone, so a hidden selector, quotient stream, or choice row would be an extra status coordinate rather than a refinement of the same route.

Finally invoke terminal cofinal-window section decomposition and the four-face pullback exactness. The four faces W, D, R, E already determine the terminal section over B, S, H, C, P, N, leaving no host real equality, metric-completeness row, or ambient completeness oracle to refine the cofinal window. □

Theorem 782.41 (Finite observation-budget selector terminal-window nonescape)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Every terminal Real-completion consumer that preserves the displayed budget, schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *window, dyadic ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, Real seal,* hsame *transport,* Cont *route,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row has no additional status coordinate for quotient streams, hidden selectors, host real equality, metric-completeness data, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal window nonescape`

Proof. First use terminal-window minimality, Definition 782.32. It says that the displayed rows $B, S, W, D, R, E, H, C, P, N$ are sufficient for terminal endpoint determination and that dropping any displayed row loses that determination.

Next apply terminal route status readback, Definition 782.39. A compatible terminal consumer reports status only through the same rows, so any quotient stream, hidden selector, host equality, metric-completeness row, choice row, or ambient-completeness oracle would be an additional status coordinate.

Use cofinal-window exhaustion, Definition 782.40, to rule out refinements of the same terminal route. The route is already exhausted by the displayed packet.

Finally apply the four-face terminal correspondence, Definition 782.42. The section faces W, D, R, E assemble the terminal consumer over B, S, H, C, P, N, leaving no further terminal-window escape coordinate. □

Theorem 782.42 (Finite observation-budget selector four-face terminal correspondence)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. A terminal consumer is compatible with* F *exactly when it is given by the four displayed terminal section faces* W, D, R, E *together with the shared budget, schedule, transport, continuation, provenance, and local naming rows* B, S, H, C, P, N*. Thus the public terminal route is precisely the finite observation-budget passage*

$$B, S \to W \to D \to R \to E$$

and the correspondence exports no quotient stream, host real equality, choice row, detached completion limit, metric-completeness row, or ambient completeness oracle.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier four face terminal correspondence`

Proof. Start with terminal cofinal-window section decomposition, Definition 782.38. It sends every compatible terminal consumer to the four displayed faces W, D, R, E inside the shared envelope B, S, H, C, P, N.

For the reverse direction, apply terminal section exactness, Definition 782.34. A section assembled from W, D, R, E and the shared rows is already a terminal section over the accepted packet, so it gives a compatible terminal consumer.

The two constructions are inverse on the displayed rows by terminal section pullback uniqueness, Definition 782.35. No second terminal section can have the same budget, schedule, window, dyadic, regular, seal, transport, continuation, provenance, and naming rows.

Finally use Definition 126.586. The underlying finite $\mathsf{StreamName}^{\uparrow}$ section has no additional quotient, host-equality, choice, detached-limit, metric-completeness, or ambient-completeness coordinate, so the four faces are exactly the terminal route. □

Theorem 782.43 (Finite observation-budget selector terminal cofinal-window route reflection)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Any terminal consumer whose four displayed terminal faces are the same* W, D, R, E *reflects to the same finite public route*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Any claimed terminal read outside the displayed faces W, D, R, E *is not a refinement of the same packet.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal cofinal window route reflection`

Proof. Apply terminal cofinal-window coverage, Definition 782.36. The accepted packet exhausts the terminal finite observation window through the displayed $\mathsf{StreamName}^{\uparrow}$ row and its dyadic, regular-sequence, and Real-seal faces.

Next use terminal cofinal-window section decomposition, Definition 782.38. A terminal consumer over the packet decomposes into exactly the four faces W, D, R, E inside the shared envelope B, S, H, C, P, N.

Route status readback, Definition 782.39, identifies every terminal status claim with those same displayed rows. Terminal-window nonescape, Definition 782.41, then excludes any additional terminal coordinate.

Finally apply the four-face terminal correspondence, Definition 782.42. The common faces W, D, R, E determine the same $\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ route, while any read outside those faces asks for quotient streams, hidden selectors, host real equality, metric-completeness rows, countable choice, or ambient completeness rather than a refinement of F. □

Theorem 782.44 (Finite observation-budget selector terminal budget exhaustion)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. No terminal consumer route reaching the displayed* Real$^{\uparrow}$ *seal* E *can read outside the budget row* B*, selected schedule row* S*, finite* StreamName$^{\uparrow}$ *window family* W*,* DyadicRatCore$^{\uparrow}$ *ledger* D*,* RegSeqRat$^{\uparrow}$ *handoff* R*, componentwise* hsame *transports* H*, displayed* Cont *route* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. Thus the terminal budget is exhausted exactly by the route*

$$B, S \to W \to D \to R \to E.$$

The exhausted surface has no quotient stream, host real equality, countable choice row, hidden selector, detached completion limit, metric-completeness row, or ambient completeness oracle.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal budget exhaustion`

Proof. First apply terminal window minimality, Definition 782.32. It identifies the complete terminal inventory of an accepted packet and says that dropping any displayed row removes the endpoint exactness supplied by the terminal route.

Next attach diagonal-tail coverage, Definition 782.33. This keeps every Real-completion and diagonal consumer on the same finite chain through B, S, W, D, R, E and the same transport, continuation, provenance, and local naming rows.

Now use terminal section exactness, Definition 782.34. A consumer that reaches the terminal seal through the displayed rows is exactly the finite section pulled back along StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$.

Finally combine terminal section pullback uniqueness with the four-face terminal correspondence, Definition 782.35 and Definition 782.42. These results leave no second terminal route with the same rows and no additional quotient, host-equality, choice, hidden-selector, detached-limit, metric-completeness, or ambient-completeness coordinate. □

Theorem 782.45 (Finite observation-budget selector cofinal route choice freeness)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. Every cofinal terminal route compatible with* F *is determined by the displayed budget, schedule, finite window, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and local naming rows. In particular, cofinal compatibility requires no independent choice of terminal route, no choice of a hidden tail selector, and no choice of an external completion witness beyond the four faces* W, D, R, E *inside the envelope* B, S, H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier cofinal route choice freeness`

Proof. Start from terminal cofinal-window coverage, Definition 782.36. It forces any compatible cofinal consumer onto the displayed finite route from the selected budget and schedule through W, D, R to E.

Next decompose the route by Definition 782.38. The consumer is exactly the four-face section with StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ faces and with transport supplied only by H, C, P, N.

The forward and reverse readings of compatibility are supplied by the four-face terminal correspondence, Definition 782.42. A consumer compatible with F gives the displayed four faces, and the displayed four faces with the shared rows give a compatible terminal consumer.

Finally use terminal section pullback uniqueness, Definition 782.35. Since no second section can carry the same displayed rows, there is no remaining route-choice parameter, hidden selector, external completion witness, quotient stream, host equality, or ambient completeness oracle. □

Theorem 782.46 (Finite observation-budget selector terminal readiness correspondence)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. The following terminal-readiness data are equivalent as public Real-and-Completion handoff surfaces:*

1. *a terminal consumer route compatible with* F*;*
2. *the exhausted finite budget route* $B, S \to W \to D \to R \to E$ *together with the displayed* H, C, P, N *rows;*
3. *the four-face terminal section* W, D, R, E *inside the same budget, schedule, transport, continuation, provenance, and local* $\mathsf{NameCert}$ *envelope.*

Under this correspondence, later $\mathsf{Real}^{\uparrow}$*, diagonal-completion, and selector-seal consumers receive exactly the displayed budget-readiness rows and no quotient stream, host real equality, countable choice operation, hidden selector, detached completion limit, metric-completeness row, or ambient completeness oracle.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal readiness correspondence`

Proof. First pass from a compatible terminal consumer to the exhausted route. By Definition 782.44, any terminal route reaching E is already confined to the displayed budget, schedule, window, dyadic, regular, seal, transport, continuation, provenance, and local naming rows.

Next pass from the exhausted route to the four-face section. The terminal cofinal-window section decomposition theorem, Definition 782.38, rewrites the route as the four faces W, D, R, E inside the envelope B, S, H, C, P, N.

For the converse direction, use the four-face terminal correspondence, Definition 782.42. The four displayed faces together with the shared rows assemble exactly a compatible terminal consumer.

It remains to show that the correspondence is the handoff surface seen by downstream consumers. Terminal section exactness and pullback uniqueness, Definition 782.34 and Definition 782.35, identify all three descriptions with the same finite section pulled back along $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally, cofinal route choice freeness, Definition 782.45, removes any extra route parameter. Hence $\mathsf{Real}^{\uparrow}$, diagonal-completion, and selector-seal consumers inherit only the displayed budget-readiness rows and none of the excluded quotient, host-equality, choice, hidden-selector, detached-limit, metric-completeness, or ambient-completeness data. □

Theorem 782.47 (Finite observation-budget selector terminal four-face pullback lock)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. The terminal Real-and-Completion consumer surface of* F *is locked by the four displayed faces* W, D, R, E *in the following sense:*

1. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-section pullback reads exactly the selected finite window family* W*;*

2. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger face reads exactly* D*;*

3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback face reads exactly* R*;*

4. *the* $\mathsf{Real}^{\uparrow}$ *terminal seal face reads exactly* E*.*

Every $\mathsf{UniformCauchyCriterion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, diagonal-completion, or selector-seal consumer compatible with the selector must factor through exactly this route*

$$B, S \to W \to D \to R \to E$$

with transport, continuation, provenance, and local naming supplied only by H, C, P, N*. The locked surface contains no quotient stream, host real equality, countable choice operation, hidden tail selector, detached completion witness, metric-completeness row, or ambient completeness oracle.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal four face pullback lock`

Proof. First identify the public readiness surface. The terminal readiness correspondence, Definition 782.46, equates a compatible terminal consumer, the exhausted route $B, S \to W \to D \to R \to E$, and the four-face section W, D, R, E inside the shared H, C, P, N envelope.

Now pin the four faces as a pullback rather than as a loose list. Terminal section exactness, Definition 782.34, identifies any compatible terminal section with the finite section pulled back along $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Terminal section pullback uniqueness, Definition 782.35, leaves no second section with the same displayed rows.

Next read the StreamName-facing side through the ambient finite-section theorem. By Definition 126.586, the selected finite windows, dyadic ledger, regular readback, and Real seal determine one four-face pullback. Therefore the first face reads W, the second reads D, the third reads R, and the fourth reads E.

Finally attach the open Real-and-Completion consumers. The UniformCauchyCriterion pullback, Definition 782.20, places any compatible uniform-Cauchy read on the same finite observation route, while the readiness correspondence already covers the $\mathsf{Real}^{\uparrow}$, diagonal-completion, and selector-seal handoff surfaces. Thus every such consumer factors through the displayed route and can export only $B, S, W, D, R, E, H, C, P, N$, with the quotient, host-equality, choice, hidden-selector, detached-witness, metric-completeness, and ambient-completeness coordinates absent. □

Theorem 782.48 (Finite observation-budget selector terminal cofinal schedule lock)**.** *Let*

$$F_0 = (B, S, W, D, R, E, H, C, P, N)$$

and

$$F_1 = (B, S', W, D, R, E, H, C, P, N)$$

be accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packets. Suppose both packets are compatible with the same terminal cofinal-window route and with the same four-face pullback through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Then every terminal consumer reads the same budget-to-seal surface from* F_0 *and* F_1*:*

$$B \to W \to D \to R \to E$$

with transport, continuation, provenance, and local naming supplied only by H, C, P, N*. In particular, the terminal consumer can read no distinction between* S *and* S'*. Any actual schedule*

separation must alter the displayed route before the terminal seal, not only a hidden scheduling coordinate behind the common four-face surface.

The locked surface contains no quotient stream, countable choice operation, hidden selector, detached completion limit, metric-completeness row, or ambient completeness oracle.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal cofinal schedule lock`

Proof. First apply terminal cofinal-window coverage, Definition 782.36, to F_0 and to F_1. Each compatible terminal consumer is forced onto the displayed finite route through the $\mathsf{StreamName}^{\uparrow}$ window family W, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, $\mathsf{RegSeqRat}^{\uparrow}$ handoff R, and $\mathsf{Real}^{\uparrow}$ seal E.

Next use terminal cofinal-window transport invariance, Definition 782.37, on the rows shared by the two packets. The only row not literally shared is the schedule coordinate, and the hypothesis says that both schedules feed the same terminal cofinal-window route and the same four-face pullback. Transport therefore carries terminal compatibility from F_0 to F_1 and back without creating a second terminal read.

Now exhaust the terminal budget. By Definition 782.44, any terminal consumer that reaches E is already confined to the displayed budget, finite window, dyadic ledger, regular handoff, seal, transport, continuation, provenance, and local naming rows. Cofinal route choice freeness, Definition 782.45, removes any independent route choice or hidden selector that could record a separate schedule decision.

Finally apply the terminal four-face pullback lock, Definition 782.47. Since both packets present the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces, the terminal consumer sees the same locked surface. Thus a real schedule separation must appear before the terminal seal as a displayed route change; it cannot be stored only in a hidden scheduling coordinate.

The non-escape clauses in the cited theorems exclude quotient streams, countable choice, hidden selectors, detached completion limits, metric-completeness rows, and ambient completeness oracles from the terminal surface. □

Theorem 782.49 (Finite observation-budget selector terminal tail-meet synchronization)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Any terminal consumer that is compatible both with the* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *cofinal-window route and with either a* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *shared-tail route or a* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *cofinal schedule must read the same L10 terminal route*

$$B, S \to W \to D \to R \to E.$$

Equivalently, the tail-meet consumer, the cofinal-schedule consumer, and the terminal selector consumer all factor through the same four displayed faces W, D, R, E, with transport, continuation, provenance, and local naming supplied only by H, C, P, N. The synchronized surface cannot introduce a second tail-meet threshold, hidden cofinal schedule, quotient stream, host real equality, choice row, detached limit, metric-completeness row, or ambient completeness oracle.

Proof. First place the selector-side consumer on the terminal route. Terminal cofinal-window coverage, Definition 782.36, forces every compatible terminal read through the displayed finite window, dyadic ledger, regular-rational readback, and Real seal faces. The terminal four-face pullback lock, Definition 782.47, then identifies those faces as exactly W, D, R, E over the route $B, S \to W \to D \to R \to E$.

Next attach the schedule side. The terminal cofinal schedule lock, Definition 782.48, says that two accepted schedules with the same terminal cofinal-window route and the same four-face pullback give the terminal consumer no visible schedule distinction. Thus a $\mathsf{TailCofinalitySchedule}^{\uparrow}$ consumer compatible with F reads the same schedule-facing route rather than a hidden cofinal schedule behind it.

Now attach the shared-tail side. The RegularCauchyTailMeet budget-selector handoff, Definition 560.89, requires every $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ consumer of an accepted shared-tail packet to consume the displayed TailMeet route before selecting a downstream budget. The root budget route lock, Definition 560.91, leaves no second downstream budget or independent tail oracle available to the same consumer.

Combining these route locks gives determinacy at the terminal selector surface. Both the TailMeet-compatible read and the cofinal-schedule-compatible read reach the same selector packet F, and F has only the four terminal faces W, D, R, E after B, S. Therefore the common consumer factors through the displayed route $B, S \to W \to D \to R \to E$.

The non-escape clauses in the cited selector and TailMeet results remove every unlisted resource. Hence no second tail-meet threshold, hidden cofinal schedule, quotient stream, host real equality, choice row, detached limit, metric-completeness row, or ambient completeness oracle can be added at the synchronized terminal surface. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal tail meet synchronization`

Theorem 782.50 (Finite observation-budget selector terminal window seal inversion)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. Any terminal consumer exposing the same four faces* W, D, R, E *and the same budget, schedule, transport, continuation, provenance, and local naming rows* B, S, H, C, P, N *determines the same Real seal route*

$$B, S \to W \to D \to R \to E.$$

Conversely, any accepted terminal Real-seal route from B, S *to* E *decomposes into those four displayed faces* W, D, R, E *inside the same envelope. The correspondence exports no quotient stream, host real equality, countable choice operation, detached limit, metric-completeness row, or ambient completeness oracle.*

Proof. For the forward direction, begin with terminal cofinal-window coverage. Definition 782.36 places every compatible terminal consumer on the displayed finite route through the window, dyadic, regular, and Real-seal faces.

Terminal section exactness and terminal section pullback uniqueness then remove any second route. By Definition 782.34, the compatible consumer is the finite section pulled back along $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; by Definition 782.35, the shared rows $B, S, W, D, R, E, H, C, P, N$ determine a single terminal section.

For the reverse direction, read an accepted Real-seal route through the four-face surface. The terminal four-face pullback lock, Definition 782.47, pins the four displayed faces as W, D, R, E, and terminal tail-meet synchronization, Definition 782.49, keeps tail-meet and cofinal-schedule consumers on the same L10 route.

Thus terminal routes and compatible terminal windows determine one another over the displayed packet. The non-escape clauses in the cited theorems exclude quotient streams, host real

equality, countable choice, detached limits, metric-completeness rows, and ambient completeness from either direction of the correspondence. □

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal window seal inversion`

Theorem 782.51 (Finite observation-budget selector terminal window choice-free section)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. Every terminal cofinal-window section accepted by F is determined by the displayed finite selector row S, the shared tail-meet route, and the Real-seal route*

$$B, S \to W \to D \to R \to E.$$

It is not determined by a hidden choice of subsequence, a host-selected limit, a quotient stream, host real equality, a detached completion point, a metric-completeness row, or an ambient completeness oracle.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier terminal window choice free section`

Proof. Start with terminal cofinal-window coverage, Definition 782.36. It places every compatible terminal consumer on the displayed finite route through the window, dyadic ledger, regular handoff, and Real seal.

Apply the pullback lock, Definition 782.47. The four terminal faces are exactly W, D, R, E, so the terminal section is already read through the packet rows $B, S, W, D, R, E, H, C, P, N$.

Next use the cofinal schedule lock and tail-meet synchronization, Definition 782.48 and Definition 782.49. These results identify the schedule-facing consumer and the shared-tail consumer with the same route rather than with a hidden subsequence choice.

Finally invoke window seal inversion, Definition 782.50. The Real-seal route and the terminal cofinal window determine one another over the displayed packet. Therefore the terminal section is choice-free in the stated sense: it is fixed by S, the tail-meet route, and the Real-seal route, and it has no hidden subsequence, host limit, quotient, host equality, detached completion, metric-completeness, or ambient-completeness coordinate. □

Theorem 782.52 (Finite observation-budget selector budget-prefix pullback inversion)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. Suppose a terminal four-face section is compatible with F, its finite budget prefix and selected-schedule prefix agree with the displayed rows B, S, and its terminal seal agrees with E through the displayed transport, continuation, provenance, and local naming rows H, C, P, N. Then that terminal section is forced to be the finite route*

$$B \to S \to W \to D \to R \to E.$$

Conversely, a section that passes through the displayed rows $B, S, W, D, R, E, H, C, P, N$ is exactly a compatible terminal four-face section for F.

This inversion exports only the accepted budget prefix, selected schedule, window family, dyadic ledger, regular readback, Real seal, componentwise hsame *transports,* Cont *route,* Pkg *provenance, and local* NameCert *row. It excludes quotient streams, host real equality, choice rows, hidden selectors, detached completion limits, metric-completeness rows, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier budget prefix pullback inversion`

Proof. For the forward direction, begin with the agreed budget and schedule prefix. Terminal budget exhaustion, Definition 782.44, confines any compatible terminal route reaching E to the displayed packet rows, so the prefix inventory cannot be enlarged beyond B, S and the rows they expose.

Next bind the four terminal faces. The terminal four-face pullback lock, Definition 782.47, identifies the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces as W, D, R, E inside the same H, C, P, N envelope.

Now recover the window from the seal-facing read. Terminal window seal inversion, Definition 782.50, says that the Real-seal route and the terminal cofinal window determine one another over the displayed packet. Since the seal agrees with E through H, C, P, N, the window-facing section is the displayed W rather than a detached completion-side choice.

Finally remove hidden selection. Terminal window choice-free section, Definition 782.51, fixes the terminal cofinal-window section from S, the shared tail-meet route, and the Real-seal route. The forward section is therefore the finite route $B \to S \to W \to D \to R \to E$, with no quotient stream, host real equality, choice row, hidden selector, detached completion limit, metric-completeness row, or ambient completeness coordinate.

For the converse direction, read the displayed route as a terminal consumer surface. The four-face terminal correspondence, Definition 782.42, assembles the four displayed faces W, D, R, E together with the agreed rows B, S, H, C, P, N into a compatible terminal consumer for F.

The same correspondence identifies that consumer with the terminal four-face section it exposes. Hence any route through the displayed rows is exactly the compatible terminal four-face section, and the excluded quotient, host-equality, choice, hidden-selector, detached-limit, metric-completeness, and ambient-completeness data have no coordinate in either direction. □

Theorem 782.53 (Finite observation-budget selector selected-tail terminal pullback)**.** *Let*

$$F = (B_F, S_F, W_F, D_F, R_F, E_F, H_F, C_F, P_F, N_F)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, and let*

$$T = (Q, E_T, A_T, W_T, K_T, S_T, R_T, H_T, C_T, P_T, N_T)$$

be an accepted $\mathsf{SelectedTailSeed}^{\uparrow}$ *packet. Suppose the selected finite-tail admission, window, readback, dyadic, and Real rows* A_T, W_T, K_T, S_T, R_T *agree with the terminal four faces* W_F, D_F, R_F, E_F *of* F *through the displayed componentwise* hsame *rows, the same* Cont *replay route, the same* Pkg *provenance, and the compatible local* $\mathsf{NameCert}_{\mathsf{FiniteObservationBudgetSelector}^{\uparrow}}$ *and* $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ *rows. Then every terminal consumer compatible with both packets factors through the single finite selector route*

$$B_F, S_F \to W_F \to D_F \to R_F \to E_F$$

and, under the selected-tail identification, through the finite-tail-to-Real route

$$A_T, W_T, K_T, S_T, R_T.$$

This pullback exposes only the accepted finite budget, selected schedule, terminal window, dyadic ledger, regular readback, Real seal, selected finite-tail admission, componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows. It excludes quotient streams, host real equality, countable choice, detached completion limits, metric-completeness rows, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier selected tail terminal pullback`

Proof. Start on the terminal selector side. By terminal cofinal-window coverage, Definition 782.36, every compatible terminal consumer of F is already routed through the displayed finite terminal surface.

Now apply budget-prefix pullback inversion, Definition 782.52. Since the shared consumer agrees with the finite budget prefix B_F, S_F and the seal-facing row E_F through the displayed structural rows, the terminal selector section is forced to be the route $B_F, S_F \to W_F \to D_F \to R_F \to E_F$.

Turn to the selected-tail side. The finite-tail Real-boundary scope theorem, Definition 1207.20, identifies A_T, W_T, K_T, S_T, R_T as the exact finite-tail-to-Real boundary supplied by T. The Real-completion boundary theorem, Definition 1207.13, keeps that boundary finite and prevents it from being enlarged into an ambient completion principle.

The hypotheses identify the selected-tail rows with the terminal four faces through hsame, Cont, Pkg, and the two local NameCert rows. Therefore a consumer compatible with both packets has no second route: the selector route and the selected-tail boundary are the same finite BEDC handoff. The cited nonescape clauses remove quotient streams, host real equality, countable choice, detached completion limits, metric-completeness rows, and ambient completeness from the pullback surface. □

Theorem 782.54 (Finite observation-budget selector bounded-monotone diagonal synchronization)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. Let M be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet whose convergence-seal route is terminal-compatible with F, and let L be an accepted* DiagonalLimitCompatibility$^{\uparrow}$ *packet reading the same terminal* Real$^{\uparrow}$ *and* CauchyLimitSeal$^{\uparrow}$ *surface. Then every downstream* Real$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, RegularCauchyTailSelector$^{\uparrow}$, *or diagonal-completion consumer compatible with F, M, and L factors through the single finite terminal route*

$$B, S \to W \to D \to R \to E$$

together with the common BHist, hsame, Cont, Pkg, *and* NameCert *support rows.*

The synchronized surface exports no quotient stream, selected host limit, host real equality, trichotomy, countable choice, hidden selector, detached completion limit, metric-completeness row, open-cover compactness, or ambient completeness oracle.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier bounded monotone diagonal synchronization`

Proof. First bind the terminal surface supplied by F. Terminal cofinal-window coverage, Definition 782.36, places every compatible terminal read on the displayed finite window route, and the terminal four-face pullback lock, Definition 782.47, identifies the four terminal faces as W, D, R, E inside the same H, C, P, N envelope.

Next apply the budget-prefix inversion above. Since the compatible reads agree on the budget prefix B, S and the terminal seal E, Definition 782.52 forces the section to be exactly the route $B \to S \to W \to D \to R \to E$ rather than a route selected from outside the accepted packet.

Now attach the bounded-monotone consumer. The bounded-monotone selector terminal pullback and Real-seal route exhaustion, Definition 535.68 and Definition 535.70, route the convergence-seal and limit-seal consumers through the displayed witness rows and then through the same

StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert support rows.

Finally read the diagonal packet as a compatibility consumer of that same surface. The diagonal-limit bounded-monotone handoff and the existing compatibility pullback allow L to inspect only the terminal Real and limit-seal rows already exposed by F and M. It therefore adds no second terminal route and no independent completion-side coordinate.

Combining these route locks, every named downstream consumer factors through the single displayed terminal surface. The non-escape clauses in the finite-selector and bounded-monotone theorems exclude quotient streams, selected host limits, host real equality, trichotomy, countable choice, hidden selectors, detached completion limits, metric-completeness rows, open-cover compactness, and ambient completeness from the synchronized route. □

Theorem 782.55 (Finite observation-budget selector bounded-monotone diagonal Lean handoff)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. Let M be an accepted* BoundedMonotoneCauchyWitness$^{\uparrow}$ *packet, and let L be an accepted* DiagonalLimitCompatibility$^{\uparrow}$ *packet. Suppose F, M, and L satisfy the terminal compatibility hypotheses of Definition 782.54: the bounded-monotone witness reads the terminal convergence-seal route of F, and the diagonal packet reads the same terminal* Real$^{\uparrow}$ *and* CauchyLimitSeal$^{\uparrow}$ *surface.*

Then the later Lean target may be stated as one BEDC route handoff over exactly the displayed finite-selector rows $B, S, W, D, R, E, H, C, P, N$, the bounded-monotone selector and real-seal rows, and the diagonal seal and readback rows. The handoff consumes no quotient stream, selected host limit, host real equality, countable choice, metric-completeness row, ambient completeness oracle, hidden selector, detached completion limit, or independent diagonal completion coordinate.

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier bounded monotone diagonal synchronization lean handoff`

Proof. First read the selector side. Terminal route status readback and terminal budget exhaustion, Definition 782.39 and Definition 782.44, force every compatible terminal read of F onto the displayed rows $B, S, W, D, R, E, H, C, P, N$.

Next attach the bounded-monotone witness. The bounded-monotone selector terminal pullback and Real-seal public route exhaustion identify the convergence-seal consumer of M with the same selector surface, so its selector and real-seal rows do not introduce a second host limit, quotient stream, or countable-choice coordinate.

Finally attach the diagonal packet. The diagonal-limit compatibility four-face terminal pullback and synchronized budget terminality theorems, Definition 646.135 and Definition 646.151, make L a reader of the same terminal seal and readback rows rather than a supplier of an independent completion oracle.

Combining the three route locks gives a single formalization-ready BEDC obligation: Lean must consume the finite-selector rows, the bounded-monotone seal rows, and the diagonal seal/readback rows as one route handoff, with every excluded host, quotient, choice, metric-completeness, ambient-completeness, and detached-limit coordinate absent from the statement. □

Theorem 782.56 (Finite observation-budget selector UniformCauchy Real readiness)**.** *Let*

$$F = (B, S, W, D, R, E, H, C, P, N)$$

be an accepted FiniteObservationBudgetSelector$^{\uparrow}$ *packet. Any Real-and-Completion consumer simultaneously compatible with the* UniformCauchyCriterion$^{\uparrow}$ *pullback, the bounded-monotone diagonal synchronization hypotheses, and the terminal four-face pullback lock factors through the same finite route*

$$B, S \to W \to D \to R \to E.$$

The public readiness surface exposes only the StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows carried by that route. It excludes quotient streams, host real equality, countable choice, hidden selectors, detached limits, metric-completeness rows, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.FiniteObservationBudgetSelectorUp.FiniteObservationBudgetSelectorCarrier uniform cauchy real readiness`

Proof. First place the uniform-Cauchy read on the selector route. The UniformCauchyCriterion pullback, Definition 782.20, identifies the shared-window, tolerance-ledger, regular-consumer, and seal rows with W, D, R, E over the finite selector path from B, S.

Next bind the terminal surface. The terminal readiness correspondence and terminal four-face pullback lock, Definition 782.46 and Definition 782.47, force every compatible terminal consumer to expose exactly the four faces W, D, R, E inside the displayed H, C, P, N envelope.

Now attach the bounded-monotone and diagonal side. The bounded-monotone diagonal synchronization theorem, Definition 782.54, makes the bounded-monotone witness and diagonal packet readers of the same Real$^{\uparrow}$ and CauchyLimitSeal$^{\uparrow}$ surface rather than suppliers of an independent completion coordinate.

Finally use the bounded-monotone diagonal Lean handoff, Definition 782.55, to package the three compatibility requirements as one route obligation. The only remaining public rows are the finite selector faces together with BHist, hsame, Cont, Pkg, and NameCert support. The non-escape clauses in the cited pullback, terminal, and synchronization results remove quotient streams, host real equality, countable choice, hidden selectors, detached limits, metric-completeness rows, and ambient completeness from the readiness surface. □

Closure status for NameCert$_{\text{FiniteObservationBudgetSelector}^{\uparrow}}$.

Constructive story: A FiniteObservationBudgetSelector$^{\uparrow}$ packet is generated from a precision budget row B, selected schedule row S, finite StreamName$^{\uparrow}$ window family W, DyadicRatCore$^{\uparrow}$ ledger D, RegSeqRat$^{\uparrow}$ handoff row R, Real$^{\uparrow}$ seal row E, componentwise hsame transports H, displayed Cont routes C, Pkg provenance P, and a local NameCert row N.

Formal verification: FormalStatus(NameCert$_{\text{FiniteObservationBudgetSelector}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Origin: human

Not claimed: This chapter does not close quotient streams, host real equality, countable choice, hidden limit selectors, ambient completeness, or checked Lean verification.

Upgrade path: The theory closure is mature; remaining work is Lean verification and bridge checking for the same finite budget-to-seal surface.

Chapter 783

A Concrete Naming Certificate for $\mathsf{SubjectReductionBundleTrace}^{\uparrow}$

The $\mathsf{SubjectReductionBundleTrace}^{\uparrow}$ packet concretizes the explicit bundle discharge route of chapter 9374 as a finite BEDC trace. It reads the explicit discharge surface of chapter 718, the ledger discipline of chapter 720, and the finite continuation route shape of chapter 469. The chapter names the route packet; it does not inhabit the dependent-codomain discharge for the present closed-CIC substrate.

Definition 783.1 (SubjectReduction bundle trace carrier)**.** *A* $\mathsf{SubjectReductionBundleTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, E, L, H, C, P, N)$$

with the following visible coordinates:

1. *B is the four-field subject-reduction discharge bundle row, naming the same obligation surface read by* $\mathsf{SubjectReductionDischarge}^{\uparrow}$*;*
2. *E is the explicit extraction row that records direct bundle consumption;*
3. *L is the finite discharge ledger inherited from* $\mathsf{SubjectReductionDischargeLedger}^{\uparrow}$*, with one row for each required subject-reduction discharge hypothesis;*
4. *H is the componentwise* hsame *transport comparing bundle fields, extraction rows, and ledger rows;*
5. *C is the displayed* Cont *route from the chosen discharge carrier to the subject-reduction theorem consumer, in the finite trace style of* $\mathsf{ContinuationTrace}^{\uparrow}$*;*
6. *P is the* Pkg *provenance over* BHist*,* hsame*,* Cont*,* $\mathsf{NameCert}$*,* $\mathsf{SubjectReductionDischarge}^{\uparrow}$*,* $\mathsf{SubjectReductionDischargeLedger}^{\uparrow}$*, and the bundle route object;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionBundleTrace}^{\uparrow}}$ *row.*

The carrier exports only these finite rows. It contains no dependent-codomain proof, no host evaluator, and no second subject-reduction principle.

Lean4 (definition) `BEDC.Derived.SubjectReductionBundleTraceUp.SubjectReductionBundleTraceUp`

Theorem 783.2 (SubjectReduction bundle trace NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{SubjectReductionBundleTra}}$ *surface for Definition 783.1 consists of five finite obligations: carrier admission for the displayed*

packet, classifier stability under componentwise hsame *transport of* B, E, L, H, C, P, N*, route readback for direct bundle consumers, non-escape from dependent-codomain discharge evidence not present in the packet, and public export as the finite BEDC route packet for subject-reduction consumers.*

Proof. Carrier admission is the tuple displayed in Definition 783.1. Each coordinate is a finite BEDC row or a local package and naming row.

Classifier stability is componentwise. A transported packet may compare the bundle row, extraction row, discharge ledger, transport row, continuation route, provenance, and local name only through the displayed hsame and Cont data.

The remaining obligations are supplied by the route readback, non-escape, and public export theorems below. Together they account for every consumer read while keeping the packet on the bundle discharge surface described in chapter 9374. □

Theorem 783.3 (SubjectReduction bundle trace route readback)**.** *Every subject-reduction consumer of an accepted* SubjectReductionBundleTrace$^{\uparrow}$ *packet reads the bundle row* B *directly and consumes the four discharge rows in* L*. The public route factors through* H, C, P, N *and does not introduce a second discharge surface.*

Lean4 ✓ `BEDC.Derived.SubjectReductionBundleTraceUp.SubjectReductionBundleTraceCarrier route readback`

Proof. Project the carrier. The only discharge-bearing rows are the bundle row B, the extraction row E, and the finite ledger L.

For the direct route, the consumer reads B and then reads the four required discharge rows from L. The rows H and C only transport and route the displayed data, while P, N record provenance and local naming.

Thus the route terminates at the finite bundle ledger. No additional subject-reduction principle is available beyond the displayed packet. □

Theorem 783.4 (SubjectReduction bundle trace non-escape)**.** *An accepted* SubjectReductionBundleTrace$^{\uparrow}$ *packet cannot be used to construct a dependent-codomain discharge for the present closed-CIC substrate, a host evaluator, a termination predicate, a quotient of reduction behaviours, or a second subject-reduction theorem. Its public reads are exhausted by* B, E, L, H, C, P, N*.*

Proof. Read the carrier inventory. None of the displayed rows is a dependent-codomain proof, a host evaluator, a termination predicate, a quotient object, or a second theorem.

Apply the route readback theorem. The consumer follows the direct bundle route, which ends in the same four-row discharge ledger L and the same BEDC route and provenance data.

The obstruction boundary from chapter 9374 remains external to this packet. Since the carrier contains no row discharging that boundary for the present substrate, no public read can escape the finite route packet. □

Theorem 783.5 (SubjectReduction bundle trace public export)**.** *The public* SubjectReductionBundleTrace$^{\uparrow}$ *export is the finite packet of Definition 783.1 together with the NameCert obligations of Definition 783.2, the route readback of Definition 783.3, and the non-escape boundary of Definition 783.4. Downstream subject-reduction work may consume it as a BEDC-native route packet for bundle discharge, but not as an inhabitant of any discharge hypothesis not listed in* L*.*

Proof. The carrier supplies the finite rows B, E, L, H, C, P, N. The NameCert obligations bind carrier admission, classifier stability, route readback, non-escape, and public export to those rows.

The readback theorem accounts for direct bundle consumption. The non-escape theorem excludes the structures that would make the packet stronger than a route packet.

Repacking these clauses yields the public export. It is the concrete BEDC route packet for the bundle discharge interface, with the same four discharge rows visible and no hidden subject-reduction evidence outside the finite ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionBundleTrace}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionBundleTrace}^{\uparrow}$ packet is generated from a carrier row, explicit NameCert obligations, route readback, non-escape, and public export over the finite bundle discharge trace.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionBundleTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 783.1, Definition 783.2, Definition 783.3, Definition 783.4, and Definition 783.5 bind the carrier, NameCert obligations, route readback, non-escape, and public export theorems.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionBundleTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close dependent-codomain discharge evidence, host evaluators, termination predicates, quotients, second subject-reduction principles, Lean verification, or a public bridge schema.

Upgrade path: Obligation closure requires checked carrier admission, route readback, non-escape, public export, componentwise transport, provenance, and local naming for the same finite bundle-trace packet.

Chapter 784

A Concrete Naming Certificate for $\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}$

The $\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}$ packet gives the route vision of chapter 9374 a finite BEDC landing. It reads the socket rows of chapter 719 and sits beside the classifier packet of chapter 785: the classifier names the explicit bundle route being used, while the equivalence packet records that every accepted consumer-facing discharge read terminates at that bundle surface.

Definition 784.1 (Subject-reduction route equivalence carrier)**.** *A* $\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, D, H, C, P, N)$$

with the following displayed rows:

1. *B is the bundle-route row, recording explicit construction of the four-field subject-reduction discharge bundle;*
2. *D is the bundle-consumption row, recording the finite handoff from the bundle row B to the socket surface;*
3. *H gives componentwise* hsame *transport for the four discharge coordinates, the bundle row, the consumer route, provenance, and local naming;*
4. *C gives the displayed* Cont *consumer routes through which downstream packets read the route agreement;*
5. *P gives* Pkg *provenance over* BHist, Ext, Cont, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, $\mathsf{SubjectReductionRouteClassifie}$ *the bundle route, componentwise* hsame, *and* $\mathsf{NameCert}$ *rows;*
6. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}}$ *row.*

The carrier contains no inhabitant of the four discharge hypotheses, no closed subject-reduction theorem, and no route equality outside the displayed finite rows.

Definition 784.2 (Subject-reduction route equivalence classifier)**.** *The* $\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}$ *classifier compares only the rows displayed in Definition 784.1. Two accepted packets agree exactly when their bundle rows B, consumption rows D, componentwise* hsame *ledgers H, consumer-route rows C, provenance rows P, and local naming rows N agree through the displayed* BHist *coordinates.*

The classifier has no coordinate for host definitional equality between route implementations, no proof that the route is inhabited for the closed-CIC substrate, and no hidden discharge witness. Its entire comparison surface is the finite packet $S = (B, D, H, C, P, N)$.

Theorem 784.3 (SubjectReductionRouteEquivalence bundle-socket handoff)**.** *For every accepted* $\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}$ *carrier* $S = (B, D, H, C, P, N)$*, the bundle route* B *feeds the* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *surface through* D*. A consumer reaching the socket through* B *reads the four displayed discharge coordinates in bundle order through the componentwise transport rows in* H*.*

Proof. Project the carrier rows. The row B already has the bundle-shaped socket order.

Read the consumption row D. It is the only permitted route from B to the socket-facing bundle shape, so any consumer must enter the socket through that displayed handoff.

Finally use the transport rows H and the consumer routes C. They identify the four coordinates componentwise and replay them to the socket surface. Since the packet has no further route coordinate, every read terminates at the same displayed socket rows. □

Theorem 784.4 (SubjectReductionRouteEquivalence NameCert obligations)**.** *For the carrier of Definition 784.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the finite packet* $S = (B, D, H, C, P, N)$*;*
2. *row classification for the bundle row* B *and consumption row* D*;*
3. *componentwise stability through the* hsame *transport ledger* H*;*
4. *consumer exactness through the displayed* Cont *routes* C*;*
5. *package provenance and local naming through* P *and* N*.*

Proof. Carrier admission is the first projection of the displayed packet S. The next projection reads the route rows B, D and therefore supplies the complete classifier surface for bundle coordinates.

The transport obligation is exactly the row H. It compares the four discharge coordinates and the route metadata componentwise, without adding another discharge source.

The remaining public obligations are the consumer routes and provenance rows. The row C gives the only consumer reads, while P and N bind package origin and local naming. These five groups exhaust the carrier coordinates. □

Theorem 784.5 (SubjectReductionRouteEquivalence consumer non-escape)**.** *Every consumer read of an accepted* $\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}$ *carrier receives route agreement only as the finite rows*

$$B, T, D, H, C, P, N.$$

The consumer may use these rows to compare bundle-route reads at the $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *surface. It cannot infer an inhabited discharge bundle, a closed subject-reduction theorem, host equality of route implementations, or any discharge evidence not present in the packet.*

Proof. Apply the NameCert-obligation theorem to identify every accepted read with one of the displayed carrier rows.

For a permitted route-agreement read, the consumer follows B directly to the socket or follows T through D to the same socket surface. The rows H and C transport and replay that finite comparison, and P, N record provenance and local naming.

For every stronger request, the packet has no coordinate to answer it. In particular, no row proves any of the four discharge hypotheses or exports a closed subject-reduction theorem. The consumer therefore remains confined to finite route agreement. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}$ packet is generated from bundle, consumption, componentwise hsame, displayed Cont, Pkg, and local NameCert rows over the subject-reduction discharge socket.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 784.1, Definition 784.2, Definition 784.3, Definition 784.4, and Definition 784.5 bind finite route agreement for the bundle subject-reduction discharge route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionRouteEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not inhabit the discharge bundle, provide a closed subject-reduction theorem, verify the packet in Lean, or bridge it to a public schema.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, socket handoff, NameCert obligations, consumer non-escape, provenance, and local naming for the same finite route-equivalence packet.

Chapter 785

A Concrete Naming Certificate for $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$

The $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ packet realizes the route distinction of chapter 9374 as finite NameCert data. It reads the shared discharge rows from chapter 719 and makes them available to compiler consumers such as chapter 625 through an explicit route-kind ledger rather than through prose about explicit bundle invocation style.

Definition 785.1 (Subject-reduction route classifier carrier)**.** *A* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, A, L, P, K, I, U, H, C, Q, N)$$

with the following displayed rows:

1. *B is the beta-substitution preservation discharge row;*
2. *A is the application-argument stability discharge row;*
3. *L is the lambda-domain subject-reduction discharge row;*
4. *P is the Pi-domain subject-reduction discharge row;*
5. *K is the route-kind row with the accepted classifier value* bundle*;*
6. *I is the invocation row, recording explicit bundle construction from B, A, L, P;*
7. *U is the consumer row, recording the downstream read that consumes the classified route as a subject-reduction discharge handoff;*
8. *H records componentwise* hsame *transports for the four discharge rows, the route-kind row, the invocation row, the consumer row, provenance, and the local naming row;*
9. *C records the displayed* Cont *routes by which consumers read the discharge rows, route-kind classifier, invocation evidence, consumer handoff, provenance, and naming coordinates;*
10. *Q is the* Pkg *provenance ledger over* BHist, Ext, Cont, $\mathsf{SubjectReduction}^{\uparrow}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, $\mathsf{TypePreservingCompiler}^{\uparrow}$*, the bundle route, componentwise* hsame*, and* $\mathsf{NameCert}$ *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteClassifier}^{\uparrow}}$ *row.*

The carrier contains no proof of any discharge row, no closed subject-reduction theorem, no host conversion rule, no erased derivation semantics, and no unrecorded route outside the displayed packet.

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteClassifierUp.SubjectReductionRouteClassifierTasteGate single carrier alignment`

Theorem 785.2 (SubjectReductionRouteClassifier NameCert obligations)**.** *For the carrier of Definition 785.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteClassifier}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$R = (B, A, L, P, K, I, U, H, C, Q, N),$$

the four discharge rows B, A, L, P*, the route-kind classifier* K*, the invocation row* I*, the consumer row* U*, componentwise transport through* H*, displayed continuation reads through* C*, package provenance through* Q*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteClassifierUp.SubjectReductionRouteClassifierCarrier namecert obligations`

Proof. Project the displayed packet R. The first four coordinates are exactly the discharge rows already exposed by the socket chapter, so the classifier receives no extra MetaCIC premise.

Read K, I, U next. The route-kind row chooses the accepted route class, the invocation row records the corresponding construction of the same four-field bundle, and the consumer row records the downstream handoff.

Finally inspect H, C, Q, N. These rows provide transport, route replay, provenance, and local naming for the displayed coordinates. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 785.3 (SubjectReductionRouteClassifier canonical-bundle correspondence)**.** *In every accepted* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *carrier, the* bundle *route kind classifies explicit invocation for the same four-row discharge packet* B, A, L, P*. The* bundle *row reads* I *as explicit construction of the four-field bundle. No route read changes the discharge payload.*

Proof. Start with the carrier projection. The four discharge rows B, A, L, P are fixed before the route-kind row is read.

For the bundle case, I records direct construction of the bundle from those four displayed rows. The consumer row U therefore receives exactly B, A, L, P through the explicit packet.

The route-kind row K has no third accepted classifier value, and the carrier has no coordinate for replacing B, A, L, P. Hence the accepted route kind terminates at the same discharge payload. □

Theorem 785.4 (SubjectReductionRouteClassifier consumer non-escape)**.** *Every consumer read of an accepted* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *carrier factors through*

$$B, A, L, P, K, I, U, H, C, Q, N.$$

The consumer may inspect the four discharge rows, the route-kind classifier, invocation evidence, consumer handoff, componentwise hsame *transports, displayed* Cont *routes, package provenance, and local* NameCert *row. It cannot read a closed subject-reduction theorem, a proof of any missing discharge row, host conversion, erased derivation semantics, quotient equality of MetaCIC terms, or a route not named by* K*.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteClassifierUp.SubjectReductionRouteClassifierCarrier consumer nonescape`

Proof. Apply the NameCert-obligation theorem to identify the accepted carrier with the finite rows $B, A, L, P, K, I, U, H, C, Q, N$.

For a permitted route read, the consumer first reads K, then follows I to the bundle-facing form of the same four discharge rows, and finally reads the handoff recorded by U. The transport and route rows H, C preserve that path without creating another route kind.

For a request outside the classifier, the packet has no coordinate to satisfy it. In particular, no row supplies a closed subject-reduction theorem, proves a missing discharge premise, or exports host semantics. The consumer is therefore confined to the displayed classifier packet. □

Theorem 785.5 (SubjectReductionRouteClassifier public export)**.** *The public export of an accepted* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *carrier is exactly the finite route-classifier packet*

$$B, A, L, P, K, I, U, H, C, Q, N.$$

Downstream compiler and audit chapters may cite this export as a named classifier for choosing explicit bundle invocation over the same socket-level discharge rows, but not as an inhabitant of those rows and not as a closed subject-reduction theorem.

Proof. The carrier definition gives the complete public inventory. The NameCert-obligation theorem binds carrier admission, discharge-row reads, route classification, invocation evidence, consumer handoff, transport, routing, provenance, and local naming to that inventory.

The canonical-bundle correspondence theorem identifies accepted route reads as presentations of B, A, L, P. The consumer non-escape theorem then prevents any public read from leaving the displayed rows.

Thus the export is a finite classifier over the socket-level discharge surface. It can guide compiler and audit consumers to the chosen invocation style, while leaving discharge proofs and closed subject reduction outside the packet. □

Theorem 785.6 (SubjectReductionRouteClassifier vision concretization)**.** *The explicit bundle discharge route of chapter 9374 are realized by the finite* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *carrier of Definition 785.1. The realization consists of the four shared discharge rows* B, A, L, P*, the route-kind classifier* K*, the invocation row* I*, the consumer row* U*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Proof. The route chapter identifies one way to deliver the same subject-reduction discharge payload: explicit bundle passing. The carrier records the invocation in K and records the corresponding invocation evidence in I.

The socket chapter supplies the finite shape of the shared discharge rows, while the compiler chapter supplies a downstream consumer of subject-reduction handoffs. The row U connects the classified invocation to that consumer-facing handoff.

The public-export theorem then packages the result as a finite NameCert classifier. The chapter therefore has a concrete BEDC landing: route prose is replaced by a displayed packet whose accepted public reads are exactly the rows of R. □

Theorem 785.7 (SubjectReductionRouteClassifier primitive scope)**.** *The primitive scope of an accepted* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *packet is exactly the displayed* BHist*,* Ext*,* Cont*,* hsame*,* Pkg*,* NameCert*,* $\mathsf{SubjectReduction}^{\uparrow}$*,* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$*, and* $\mathsf{TypePreservingCompiler}^{\uparrow}$ *rows of*

$$B, A, L, P, K, I, U, H, C, Q, N.$$

The classifier introduces no host conversion rule, erased derivation semantics, quotient equality of MetaCIC terms, hidden route kind, or proof of any discharge row outside that primitive surface.

Proof. Start from Definition 785.1. Its displayed coordinates are the four discharge rows, the route-kind classifier, invocation evidence, consumer handoff, componentwise transport, continuation, package provenance, and local naming.

Apply Definition 785.2. The local NameCert surface reads carrier admission, the four discharge rows, route kind, invocation evidence, consumer row, transport, continuation, provenance, and name through those same coordinates.

Use Definition 785.3, Definition 785.4, and Definition 785.5. These identify explicit bundle invocation, keep public consumers on the displayed packet, and rule out any route outside the listed primitive rows.

Thus the primitive scope is exactly the finite BEDC surface named in the statement. □

Theorem 785.8 (SubjectReductionRouteClassifier scoped consumer exactness)**.** *Every compiler or audit consumer of an accepted* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *packet reads exactly the displayed route rows*

$$B, A, L, P, K, I, U, H, C, Q, N$$

over BHist, Ext, Cont, hsame, Pkg, $\mathsf{NameCert}$, $\mathsf{SubjectReduction}^{\uparrow}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, *and* $\mathsf{TypePreservingCompiler}^{\uparrow}$. *The classifier may route the four discharge rows as bundle data, but it cannot treat itself as a proof of those four discharge rows.*

Proof. Begin with the local NameCert obligations and primitive scope. The obligation surface displays the carrier, route-kind row, invocation row, consumer handoff, transport, continuation, provenance, and local naming rows, while Definition 785.7 identifies these rows as the primitive packet surface.

Next use the canonical-bundle correspondence Definition 785.3. It says that the accepted route reads are presentations of the same payload B, A, L, P, not new discharge proofs.

Finally apply consumer non-escape and public export, Definition 785.4 and Definition 785.5. These theorems force every compiler or audit read to remain on the displayed public packet. Thus scoped consumers receive exactly the listed route rows and no proof of subject reduction, preservation, lookup, or substitution beyond the rows already supplied by the discharge socket. □

Theorem 785.9 (SubjectReductionRouteClassifier socket scope)**.** *The four discharge rows* B, A, L, P *in an accepted* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *packet are consumed from chapter 719. This classifier records how those rows are invoked and handed to consumers; it does not prove beta-substitution preservation, application-argument stability, lambda-domain subject reduction, or Pi-domain subject reduction.*

Proof. Project the carrier of Definition 785.1. The rows B, A, L, P are present as already supplied discharge rows, and the remaining rows classify and route them.

Apply Definition 785.2. The certificate obligations expose the four rows and then read K, I, U, H, C, Q, N as classifier, invocation, consumer, transport, continuation, provenance, and naming data.

Use Definition 785.4. Since no coordinate supplies proofs of missing discharge premises or closed subject reduction, the classifier cannot discharge the four rows on its own.

Therefore the rows are consumed from the socket chapter and only routed by this classifier. □

Theorem 785.10 (SubjectReductionRouteClassifier type-preserving scope)**.** *Every* $\mathsf{TypePreservingCompiler}^{\uparrow}$ *consumer of an accepted* $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ *packet may read the packet only as an invocation-style handoff for the shared rows* B, A, L, P. *The consumer may inspect whether the route is* bundle *and may follow* I *and* U *to the same discharge payload, but it receives no compiler correctness proof, erased operational semantics, host conversion rule, or additional subject-reduction discharge.*

Proof. Begin with Definition 785.3. The bundle route presents one four-row payload, so a compiler consumer cannot obtain different discharge data by changing route notation.

Apply Definition 785.5. The public surface exported to downstream chapters is exactly $B, A, L, P, K, I, U, H, C,$

Now use Definition 785.7 and Definition 785.9. These pin the primitive rows and record that the four discharge rows are consumed from the socket rather than proved by the classifier.

The type-preserving compiler read is therefore an invocation-style handoff only. No carrier coordinate remains from which compiler correctness, erased semantics, host conversion, or an additional subject-reduction discharge could be projected. □

Theorem 785.11 (SubjectReductionRouteClassifier audit handoff)**.** *Every audit or compiler consumer reading an accepted* SubjectReductionRouteClassifier$^{\uparrow}$ *packet receives only the classified invocation handoff over the same four socket rows B, A, L, P. The handoff may use the* bundle *presentation, but it cannot be read as a proof of subject reduction, preservation, lookup, substitution, erased semantics, or host conversion.*

Proof. Begin with the canonical-bundle correspondence theorem, Definition 785.3. It identifies the accepted presentation as invocation styles for the same four socket rows B, A, L, P.

Apply consumer non-escape and public export, Definition 785.4 and Definition 785.5. These confine every downstream read to $B, A, L, P, K, I, U, H, C, Q, N$ and prevent any public consumer from projecting a closed proof or host semantic row.

Finally use socket scope and type-preserving scope, Definition 785.9 and Definition 785.10. They identify B, A, L, P as socket-supplied discharge rows and restrict compiler-facing use to the classified handoff, so audit and compiler consumers receive no proof of subject reduction, preservation, lookup, substitution, erased semantics, or host conversion. □

Theorem 785.12 (SubjectReductionRouteClassifier route-kind coverage)**.** *In every accepted* SubjectReductionRout *packet, each route-kind row K consumed by the classifier is exactly* bundle*. A downstream route read cannot consume a second route kind, because the carrier has no coordinate, invocation row, continuation route, or package provenance row for any classifier value outside that case.*

Proof. Project the carrier of Definition 785.1. The row K is displayed with exactly one accepted classifier value, and the row I is displayed as the corresponding invocation evidence for that value.

For the bundle case, use Definition 785.3. The invocation row reads the four discharge rows B, A, L, P as an explicit bundle.

Finally apply Definition 785.7. Since the primitive surface has no hidden route-kind coordinate and no provenance row for another route, no third route can be consumed. □

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteClassifierUp.SubjectReductionRouteClassifierCarrier route kind coverage`

Theorem 785.13 (SubjectReductionRouteClassifier invocation payload inversion)**.** *Let I be the invocation row of an accepted* SubjectReductionRouteClassifier$^{\uparrow}$ *packet. Reading I along the* bundle *route reconstructs the displayed discharge rows B, A, L, P by explicit bundle projection. Thus invocation inversion never changes the discharge payload consumed from the socket chapter.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteClassifierUp.SubjectReductionRouteClassifierCarrier invocation payload inversion`

Proof. Start with the socket scope theorem, Definition 785.9. It records that B, A, L, P are already consumed from chapter 719 before this classifier routes them.

In the bundle branch, the invocation row is the explicit construction of the bundle over the displayed rows. Projecting that bundle returns B, A, L, P.

The inversion therefore reconstructs the same four socket rows in the accepted branch. It cannot produce another discharge row, because Definition 785.12 rules out any additional route kind. □

Theorem 785.14 (SubjectReductionRouteClassifier audit-handoff totality)**.** *Every audit consumer or* TypePreservingCompiler$^{\uparrow}$ *consumer of an accepted* SubjectReductionRouteClassifier$^{\uparrow}$ *packet reads exactly*

$$B, A, L, P, K, I, U, H, C, Q, N.$$

The handoff exposes the four socket discharge rows, the route-kind classifier, invocation row, consumer row, componentwise transports, continuation replay, package provenance, and local name; it exposes no additional proof row for the discharged subject-reduction premises.

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteClassifierUp.SubjectReductionRouteClassifierCarrier audit handoff totality`

Proof. Start from Definition 785.4. It confines every consumer read to the displayed classifier packet and rules out compiler correctness, erased semantics, host conversion, and unnamed routes.

Apply Definition 785.9 and Definition 785.10. These identify B, A, L, P as socket-supplied discharge rows and restrict compiler-facing use to invocation-style handoff data.

Now use Definition 785.12 and Definition 785.13. The route-kind row has only the accepted branch, and that branch reconstruct the same socket payload.

Finally, the primitive-scope theorem Definition 785.7 accounts for K, I, U, H, C, Q, N as the remaining displayed classifier, invocation, consumer, transport, continuation, provenance, and naming rows. No coordinate remains for another discharge proof. □

Theorem 785.15 (SubjectReductionRouteClassifier invocation row non-escape)**.** *In an accepted* SubjectReductionRouteClassifier$^{\uparrow}$ *packet, the invocation row I selects the* bundle *presentation of the same socket payload B, A, L, P. The row I never proves beta-substitution preservation, application-argument stability, lambda-domain subject reduction, Pi-domain subject reduction, or any discharge payload beyond those four socket rows.*

Proof. The canonical-bundle correspondence theorem Definition 785.3 gives the meaning of I: explicit bundle construction in the bundle branch.

Use Definition 785.13. The reading returns exactly B, A, L, P, so the selected presentation does not change the payload.

Apply Definition 785.12. Since no second route kind is admitted, I cannot select a branch whose payload is a discharge proof rather than a presentation of the socket rows.

The remaining non-escape clause follows from Definition 785.9. The four named preservation obligations belong to the socket surface, and this classifier records how they are invoked rather than proving them. □

Theorem 785.16 (SubjectReductionRouteClassifier socket-payload coverage)**.** *The four discharge rows consumed by every accepted* SubjectReductionRouteClassifier$^{\uparrow}$ *packet are exactly the beta-substitution, application-argument, lambda-domain, and Pi-domain rows supplied by* SubjectReductionDischargeSock *The classifier creates none of those four rows; it only routes its bundle presentation to audit and* TypePreservingCompiler$^{\uparrow}$ *consumers.*

Proof. Begin with the socket scope theorem Definition 785.9. It states that B, A, L, P are consumed from chapter 719 and that this classifier does not prove the four preservation clauses.

Next apply Definition 785.10. A compiler consumer may inspect route style and follow I and U to the same payload, but it receives no additional subject-reduction discharge.

The route-kind coverage theorem and invocation-row non-escape theorem then close the coverage argument. The only accepted route choices are the bundle presentation, and the invocation row selects presentation style without manufacturing any socket row. □

Theorem 785.17 (SubjectReductionRouteClassifier consumer route totality)**.** *Every* TypePreservingCompiler$^{\uparrow}$ *or audit consumer handoff of an accepted* SubjectReductionRouteClassifier$^{\uparrow}$ *packet factors through*

$$B, A, L, P, K, I, U, H, C, Q, N.$$

The consumer receives the four socket discharge rows, the route-kind decision, invocation evidence, the handoff row, componentwise transport, continuation replay, provenance, and local naming data, and it receives no proof of a missing discharge premise.

Proof. First apply Definition 785.4. It confines every consumer read to the displayed rows $B, A, L, P, K, I, U, H, C, Q$ and excludes closed subject-reduction proofs, host conversion, erased derivation semantics, and routes not named by K.

Next use Definition 785.5. The public export is exactly the finite route-classifier packet, so any compiler or audit handoff has to pass through the displayed rows rather than through an external certificate.

The route-kind coverage and invocation payload inversion theorems identify all accepted route reads. When the consumer follows the bundle branch, the invocation row reconstructs the same socket payload B, A, L, P.

Finally invoke Definition 785.9 and Definition 785.10. The four discharge rows are consumed from the socket chapter and then handed to the compiler as invocation-style data, so no missing discharge premise becomes available to the consumer. □

Theorem 785.18 (SubjectReductionRouteClassifier obstruction-projection boundary)**.** *Every consumer of an accepted* SubjectReductionRouteClassifier$^{\uparrow}$ *packet that attempts to read a raw-relation subject-reduction bundle must also expose the checked no-bundle obstruction row. Projecting application-argument stability, lambda-domain preservation, or Pi-domain preservation from the raw relation lands in the obstruction ledger, not in a discharge proof. The classifier route may present the socket payload B, A, L, P through K, I, U, H, C, Q, N, but it never manufactures the four discharge fields and never converts the raw MetaCIC relation into* SubjectReductionDischargeBundle *data.*

Proof. Start with the consumer route totality theorem. It confines every compiler or audit read to $B, A, L, P, K, I, U, H, C, Q, N$ and states that no missing discharge premise is exported by the carrier.

Use route-kind coverage and invocation payload inversion. The route-kind row admits only the bundle presentation, and following that branch reconstructs the same socket payload. Thus changing the projection syntax cannot introduce a raw-relation discharge field.

Now apply socket-payload coverage. The four rows consumed by the classifier are exactly the rows supplied by SubjectReductionDischargeSocket$^{\uparrow}$. They are routed as finite payload data, not derived from the raw MetaCIC subject-reduction relation.

Finally read the MetaCIC obstruction ledger: the checked rows named by `not_appArgTypeStable`, `not_lamDomainSubjectReduction`, `not_piDomainSubjectReduction`, and `not_subjectReductionDischargeBun`

record that those raw projections do not yield the discharge interface on the present substrate. Therefore any raw-relation consumer must expose that no-bundle row, and the classifier remains a route over supplied socket rows rather than a source of discharge proofs. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteClassifier}\uparrow}$.

Constructive story: A $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$ packet is generated from four subject-reduction discharge rows, a bundle route-kind classifier, invocation and consumer rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionRouteClassifier}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: Definition 785.5, Definition 785.14, Definition 785.16, and Definition 785.17 bind the public route-classifier carrier, audit handoff, mature consumer-coverage surface, and finite consumer route for the packet $B, A, L, P, K, I, U, H, C, Q, N$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionRouteClassifier}\uparrow}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.SubjectReductionRouteClassifierUp.SubjectReductionRouteClassifierCarrier\_audit\_handof`

Bridge status: none

Origin: human

Not claimed: This chapter does not prove any of the four MetaCIC discharge rows, construct a closed subject-reduction theorem, verify the classifier in Lean, or bridge the packet to a public schema.

Upgrade path: No higher theory-closure grade remains; bridge checking remains on the verification axis.

Chapter 786

A Concrete Naming Certificate for $\mathsf{ClosurePreservationAuditWitness}^{\uparrow}$

The $\mathsf{ClosurePreservationAuditWitness}^{\uparrow}$ packet realizes the closedness-preservation chain of chapter 9381 as finite BEDC NameCert data. It sits beside the main closed-normal consistency boundary of chapter 764, the confluence audit witness of chapter 745, and the beta-step boundary of chapter 754: those chapters consume closed endpoints, confluence rows, and beta-step rows, while this packet records how the five closedness-preservation theorems remain visible as a single replayable carrier.

Definition 786.1 (ClosurePreservationAuditWitness carrier)**.** *A* $\mathsf{ClosurePreservationAuditWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, V, F, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the shift-one closedness-preservation row;*
2. *V is the variable-substitution closedness-preservation row;*
3. *F is the full-substitution closedness-preservation row;*
4. *B is the beta-step closedness-preservation row;*
5. *R is the finite beta-star closedness-preservation row;*
6. *H records componentwise* hsame *transports for the five theorem rows, replay routes, provenance, and local naming;*
7. *C records the displayed* Cont *routes by which consumers replay the shift, substitution, beta-step, and beta-star rows without leaving the closedness classifier;*
8. *P is the* Pkg *provenance over* BHist, hsame, Cont, $\mathsf{NameCert}$, *the closure-preservation audit map, the closed-normal consistency main packet, the MetaCIC confluence audit witness, and the beta-step boundary;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditWitness}^{\uparrow}}$ *row.*

The carrier contains no subject-reduction theorem, no typing transport, no host conversion rule, no quotient equality of MetaCIC terms, and no route from closedness preservation to full closed consistency.

Theorem 786.2 (ClosurePreservationAuditWitness NameCert obligations)**.** *For the carrier of Definition 786.1, the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditWitness}\uparrow}$ *surface consists exactly of carrier admission for*

$$W = (S, V, F, B, R, H, C, P, N),$$

readback of the shift-one row S, variable-substitution row V, full-substitution row F, beta-step row B, and beta-star row R, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.

Proof. Project the displayed packet W. The first five coordinates are the theorem rows named by the closure-preservation audit map, so carrier admission exposes exactly the closedness-preservation chain and no typing premise.

Read H and C next. Transport keeps each theorem row componentwise stable, while continuation replay lets a consumer reach the shift, substitution, beta-step, and beta-star rows in the same finite packet.

Finally inspect P and N. Provenance anchors the packet in the source audit map and in the sibling closed-normal, confluence, and beta-boundary chapters, while the local naming row names the carrier itself. Since no other coordinate is present, these rows exhaust the NameCert surface. □

Lean4 ✓ `BEDC.Derived.ClosurePreservationAuditWitnessUp.ClosurePreservationAuditWitness namecert obligations`

Theorem 786.3 (ClosurePreservationAuditWitness beta-step row)**.** *In every accepted* ClosurePreservationAuditWit *carrier, the beta-step row B is read only as closedness preservation for a single MetaCIC beta contraction. Its permitted inputs are the closedness rows supplied by the shift and substitution coordinates S, V, F, transported through H and replayed through C. It does not export typing preservation for the contracted redex.*

Proof. Project W and isolate the beta-step coordinate B. The carrier places B after the shift and substitution rows, so the displayed read of B depends only on closedness budgets already present in the packet.

The transport row H preserves those coordinates componentwise, and the replay row C exposes the beta-step theorem through the same closedness classifier. Neither row contains a typing derivation or a codomain transport.

Thus B certifies the closedness boundary for one beta contraction and nothing stronger. □

Theorem 786.4 (ClosurePreservationAuditWitness beta-star row)**.** *In every accepted* ClosurePreservationAuditWit *carrier, the beta-star row R is the finite-path replay of the beta-step closedness row B. A consumer may cite R to keep the endpoint of a finite beta path inside the same closedness classifier, but may not cite it as Church–Rosser, normalization, subject reduction, or closed consistency.*

Proof. The carrier exposes B and R as separate rows. The beta-star row is consumed after the single-step row has been made available, and its replay route is recorded in C.

Componentwise hsame transport through H preserves the finite-path row without altering its classifier. The provenance row P points to the confluence and consistency siblings only as consumers of closed endpoints, not as consequences of the beta-star row.

Therefore R is exactly a finite beta-chain closedness row. It cannot be repacked as a confluence theorem, a normalization theorem, a typing-preservation theorem, or a consistency theorem. □

Lean4 ✓ `BEDC.Derived.ClosurePreservationAuditWitnessUp.ClosurePreservationAuditWitness beta star row`

Theorem 786.5 (ClosurePreservationAuditWitness substitution row)**.** *In every accepted* ClosurePreservationAuditW *carrier, the substitution surface consists of the variable-substitution row V and full-substitution row F together with the shift-one row S needed under binders. The packet exposes these rows as closedness-preservation data for MetaCIC syntax and does not add a typing-substitution lemma, dependent codomain transport, or host-level substitution semantics.*

Proof. Project the substitution coordinates of W. The shift row S supplies the binder-index motion, the variable-substitution row V supplies the local variable case, and the full-substitution row F supplies the recursive substitution read.

The transport and replay rows H, C keep these three rows available as closedness facts. They do not introduce a typing context, a displayed codomain, or a semantic substitution relation.

Hence the substitution surface is exactly the closedness-preservation surface named by S, V, F. □

Lean4 ✓ `BEDC.Derived.ClosurePreservationAuditWitnessUp.ClosurePreservationAuditWitness substitution row`

Theorem 786.6 (ClosurePreservationAuditWitness non-escape)**.** *Every consumer read of an accepted* ClosurePreservationAuditWitness$^{\uparrow}$ *carrier factors through*

$$S, V, F, B, R, H, C, P, N.$$

The consumer may inspect the five closedness-preservation theorem rows, their componentwise hsame *transports, displayed* Cont *replay routes,* Pkg *provenance, and local* NameCert *naming. It cannot extract a subject-reduction theorem, a typing conversion rule, a confluence diamond, a normalization theorem, a closed-consistency theorem, or any row not displayed by the carrier.*

Proof. Apply the NameCert-obligation theorem to identify the accepted carrier with the finite tuple $S, V, F, B, R, H, C, P, N$.

The beta-step theorem, beta-star theorem, and substitution theorem above describe the only theorem rows with downstream computational content. Each remains a closedness-preservation row and is replayed only through C after componentwise transport through H.

For every stronger request, inspect the carrier inventory. No coordinate supplies a typing derivation, a conversion rule, a confluence proof, a normalization proof, or a consistency proof. The consumer is therefore confined to the displayed closedness-preservation witness packet. □

Closure status for NameCert$_{\text{ClosurePreservationAuditWitness}^{\uparrow}}$.

Constructive story: A ClosurePreservationAuditWitness$^{\uparrow}$ packet is generated from shift-one preservation, variable substitution, full substitution, beta-step preservation, beta-star preservation, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ClosurePreservationAuditWitness}^{\uparrow}}$, seed)

Scope closed: Definition 786.1, Definition 786.2, Definition 786.3, Definition 786.4, Definition 786.5, and Definition 786.6 bind the finite closedness-preservation audit witness packet.

Formal verification: FormalStatus(NameCert$_{\text{ClosurePreservationAuditWitness}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not prove subject reduction, typing substitution, confluence, normalization, closed consistency, Lean verification of the witness packet, or a public schema bridge.

Upgrade path: Obligation closure requires checked carrier admission, theorem-row readback, beta-step exactness, beta-star exactness, substitution exactness, replay routes, provenance, local naming, and non-escape for the same finite packet.

Chapter 787

A Concrete Naming Certificate for $\mathsf{SubjectReductionRoute}^{\uparrow}$

The $\mathsf{SubjectReductionRoute}^{\uparrow}$ packet turns the explicit bundle discharge route of chapter 9374 into one finite naming surface. It reads the socket-level discharge rows of chapter 719 and keeps the obstruction boundary of chapter 731 visible: the packet names the route by which a discharge would be handed to a consumer, but it does not manufacture any missing MetaCIC discharge premise.

Definition 787.1 (Subject-reduction route carrier)**.** *A* $\mathsf{SubjectReductionRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, A, L, P, E, I, U, H, C, Q, N)$$

with the following displayed rows:

1. *B is the beta-substitution preservation discharge row;*
2. *A is the application-argument stability discharge row;*
3. *L is the lambda-domain subject-reduction discharge row;*
4. *P is the Pi-domain subject-reduction discharge row;*
5. *E is the explicit bundle row whose coordinates are exactly B, A, L, P;*
6. *I is the invocation row recording that the consumer reads E directly;*
7. *U is the consumer handoff row for the downstream subject-reduction use site;*
8. *H records componentwise* hsame *transports for the discharge rows, bundle row, invocation row, consumer row, provenance row, and local naming row;*
9. *C records the displayed* Cont *routes by which the consumer reaches the same four discharge rows through the explicit invocation route;*
10. *Q is the* Pkg *provenance ledger over* BHist, Ext, Cont, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, $\mathsf{SubjectReductionRoute}$ $\mathsf{TypePreservingCompiler}^{\uparrow}$, *componentwise* hsame, *and local* $\mathsf{NameCert}$ *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRoute}^{\uparrow}}$ *row.*

The carrier has no coordinate for closed subject reduction, host conversion, erased derivation semantics, quotient equality of terms, or an additional route outside the displayed bundle pair.

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteUp.SubjectReductionRouteTasteGate single carrier alignment`

Theorem 787.2 (SubjectReductionRoute NameCert obligations)**.** *For the carrier of Definition 787.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRoute}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$R = (B, A, L, P, E, I, U, H, C, Q, N),$$

the four discharge rows B, A, L, P*, explicit bundle packaging through* E*, invocation selection through* I*, consumer handoff through* U*, componentwise transport through* H*, displayed continuation reads through* C*, package provenance through* Q*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteUp.SubjectReductionRouteNameCertObligations`

Proof. Project the displayed tuple R. The first four coordinates are the socket-level subject-reduction discharge rows, while E is the presentation of that same four-row packet.

Read the invocation and consumer rows. The row I records direct bundle use, and U records the downstream handoff that consumes the chosen presentation.

Finally read H, C, Q, N. These rows supply transport, route replay, provenance, and local naming for the displayed coordinates. Since the carrier exposes no further coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 787.3 (SubjectReductionRoute bundle correspondence)**.** *In every accepted* $\mathsf{SubjectReductionRoute}^{\uparrow}$ *carrier, the explicit bundle row* E *determines the discharge packet* B, A, L, P*. Bundle invocation changes none of the discharge rows, adds no new discharge premise, and removes no row required by the subject-reduction consumer.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteUp.SubjectReductionRouteBundleCorrespondence`

Proof. The carrier definition fixes B, A, L, P before the public route is inspected. The bundle row E packages those four rows directly.

The invocation row I records the route the consumer follows, and the consumer row U records the handoff after that route has reached B, A, L, P. There is no coordinate in the packet where the route can alter the discharge payload. □

Theorem 787.4 (SubjectReductionRoute obstruction non-escape)**.** *Every accepted* $\mathsf{SubjectReductionRoute}^{\uparrow}$ *carrier preserves the obstruction boundary of chapter 731. A consumer may read the finite bundle route packet, but cannot extract a closed MetaCIC subject-reduction theorem, a proof of any missing discharge row, a host conversion principle, erased semantics, or quotient equality of terms from that packet.*

Proof. Apply the NameCert-obligation theorem to identify every permitted read with one of the displayed rows of R.

Rows B, A, L, P are discharge placeholders exposed through the socket surface, and rows E, I, U only determine how those rows are handed to a consumer. The transport, continuation, provenance, and naming rows certify this finite route; they do not add a theorem-producing coordinate.

The obstruction chapter remains untouched by this packet because the carrier contains no row for closing the dependent-codomain obstruction. Therefore no accepted read can escape from route naming into a closed subject-reduction result. □

Theorem 787.5 (SubjectReductionRoute public handoff)**.** *The public handoff of an accepted* $\mathsf{SubjectReductionRoute}^{\uparrow}$ *carrier is exactly the finite route packet*

$$B, A, L, P, E, I, U, H, C, Q, N.$$

Downstream compiler and audit chapters may cite this handoff as a named route from bundle presentation to the same four discharge rows. They may not cite it as an inhabitant of those rows, as a closed subject-reduction proof, or as a bridge to host semantics.

Proof. The carrier definition lists the entire public inventory. The NameCert-obligation theorem binds carrier admission and every permitted read to that inventory.

The bundle correspondence theorem shows that the public route reaches the four-row discharge packet. The obstruction non-escape theorem then excludes reads that would turn the route packet into a closed MetaCIC theorem or host-semantic bridge.

Thus the public handoff is a finite naming certificate for route delivery only. It supplies a stable consumer-facing packet while keeping discharge inhabitation and bridge checking on their own axes. □

Theorem 787.6 (SubjectReductionRoute finite route surface)**.** *Every accepted* $\mathsf{SubjectReductionRoute}^{\uparrow}$ *carrier binds the subject-reduction route classifier, compiler handoff, and discharge socket rows on the single finite path*

$$\mathsf{SubjectReductionRouteClassifier}^{\uparrow} \longmapsto \mathsf{TypePreservingCompiler}^{\uparrow} \longmapsto \mathsf{SubjectReductionDischargeSocket}^{\uparrow} \longmapsto (B, A, L,$$

The route first names the classifier row that selects the explicit bundle presentation, then names the type-preserving compiler handoff row through which the consumer reaches that bundle, and finally exposes the socket-level discharge rows B, A, L, P*. It exports no closed subject-reduction theorem, no additional discharge inhabitant, no host conversion principle, no erased semantics, and no bridge status.*

Proof. Project the carrier $R = (B, A, L, P, E, I, U, H, C, Q, N)$. The package provenance row Q names the $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$, $\mathsf{TypePreservingCompiler}^{\uparrow}$, and $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ sources before the local naming row is read.

Apply Definition 787.3. The explicit bundle row E determines exactly the four discharge rows B, A, L, P, so the classifier can select only that displayed presentation.

Apply Definition 787.5. The compiler-facing consumer reaches the same four-row bundle through I and U, while H, C, Q, N transport, replay, source, and name the route. Since Definition 787.4 excludes closed discharge, host conversion, erased semantics, and bridge data, the stated finite path is the whole scoped surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionRoute}^{\uparrow}$ packet is generated from four subject-reduction discharge rows, an explicit bundle row, an invocation row, a consumer handoff row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionRoute}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 787.1, Definition 787.2, Definition 787.3, Definition 787.4, Definition 787.5, and Definition 787.6 bind the carrier, NameCert obligations, bundle correspondence, obstruction non-escape, public handoff, and classifier–compiler–socket route surface for the finite route packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionRoute}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.SubjectReductionRouteUp.SubjectReductionRouteTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove any MetaCIC discharge row, construct closed subject reduction, provide Lean verification, or bridge the packet to a public schema.

Upgrade path: Public export and bridge work require a public SubjectReductionRouteUp schema surface and a checked standard bridge for the same finite route packet.

Chapter 788

A Concrete Naming Certificate for MetaCICClosurePreservation$^{\uparrow}$

The MetaCICClosurePreservation$^{\uparrow}$ packet turns the ClosurePreservation audit map of chapter 9381 into a finite naming surface. It reads the substitution rows of chapter 779, the closed seal of chapter 531, the beta-redex handoff of chapter 716, the generator classifier of chapter 486, and the subject-reduction consumer boundary of chapter 483. The packet records closure-preservation data; it does not turn closedness into typing preservation.

Definition 788.1 (MetaCIC ClosurePreservation carrier)**.** *A* MetaCICClosurePreservation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, V, U, B, F, A, C, G, R, H, Q, P, N)$$

with the following displayed rows:

1. *S is the one-step shift closedness row for* `shift_one_preserves_closed_succ`*;*
2. *V is the variable-substitution closedness row for* `substitute_var_preserves_closed_at`*;*
3. *U is the full substitution closedness row for* `substitute_preserves_closed_at`*;*
4. *B is the one-step beta closedness row for* `betaStep_preserves_closed`*;*
5. *F is the finite beta-chain closedness row for* `betaStarStep_preserves_closed`*;*
6. *A is the* SubstitutionAuditMap$^{\uparrow}$ *row through which shift and substitution are read;*
7. *C is the* ClosedSubstitutionSeal$^{\uparrow}$ *row that keeps the closed substitution boundary visible;*
8. *G is the* GeneratorClosure$^{\uparrow}$ *classifier row for the authorized shift, substitution, beta-step, and beta-chain moves;*
9. *R is the downstream* SubjectReduction$^{\uparrow}$ *consumer row that may cite closedness preservation but still requires its own typing-discharge rows;*
10. *H stores componentwise* hsame *transports for the preservation rows, audit row, closed seal, generator classifier, consumer row, provenance row, and local naming row;*
11. *Q stores displayed* Cont *routes for reading each preservation row through the audit and generator-classifier surface;*
12. *P is the* Pkg *provenance over* `Term`*,* `ClosedAt`*, shift, substitution, beta-step, beta-chain,* SubstitutionAuditMap$^{\uparrow}$*,* ClosedSubstitutionSeal$^{\uparrow}$*,* BetaSubstitutionPreservation$^{\uparrow}$*,* GeneratorClosure$^{\uparrow}$*,* SubjectReduction$^{\uparrow}$*,* hsame*,* Cont*, and* NameCert *rows;*

13. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservation}^{\uparrow}}$ *row.*
The carrier has no coordinate for `HasType` *preservation, conversion soundness, confluence, normalization, closed consistency, or an unlisted substitution calculus.*

Lean4 ✓ `BEDC.Derived.MetaCICClosurePreservationUp.MetaCICClosurePreservationTasteGate single carrier alignment`

Theorem 788.2 (MetaCIC ClosurePreservation NameCert obligations)**.** *For every accepted* MetaCICClosurePreserv *carrier*

$$M = (S, V, U, B, F, A, C, G, R, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservation}^{\uparrow}}$ *surface consists exactly of carrier admission, the five displayed closedness-preservation rows S, V, U, B, F, the substitution audit row A, the closed-substitution seal C, the generator-closure classifier G, the subject-reduction consumer row R, componentwise transport through H, displayed continuation through Q, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 788.1. The rows S, V, U, B, F are the five closure-preservation rows named by chapter 9381.

Read the dependency rows next. The substitution row A forces every shift or substitution read through chapter 779, the seal row C keeps closed substitution inside chapter 531, and the classifier row G records the authorized generator-closure surface.

Finally read R, H, Q, P, N. These rows identify the downstream subject-reduction consumer boundary, transport the displayed packet, replay its finite routes, record provenance, and name the local certificate. Since the carrier lists no further coordinate, the local NameCert obligations are exhausted by the displayed packet. □

Theorem 788.3 (Shift and substitution classifier handoff)**.** *In an accepted* $\mathsf{MetaCICClosurePreservation}^{\uparrow}$ *carrier, the shift row S, variable-substitution row V, and full-substitution row U are read only through the audit row A and the generator-classifier row G. A consumer cannot detach those rows from the* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *and* $\mathsf{GeneratorClosure}^{\uparrow}$ *surfaces or read them as an unrestricted substitution calculus.*

Proof. The carrier places S, V, U beside the audit row A and classifier row G. Thus every displayed continuation route for the syntactic movement rows is one of the routes recorded in Q from the same packet.

The audit row A gives the substitution readback boundary, while G supplies the generator-closure classifier for authorized movement under `ClosedAt`. Transport through H preserves those coordinates componentwise and cannot create a new movement rule.

An unrestricted substitution calculus would require a row outside $S, V, U, A, G, H, Q, P, N$. The carrier has no such row, so the handoff remains the displayed classifier handoff. □

Lean4 ✓ `BEDC.Derived.MetaCICClosurePreservationUp.MetaCICClosurePreservationCarrier shift substitution classifier handoff`

Theorem 788.4 (Beta-chain non-escape)**.** *For every accepted* $\mathsf{MetaCICClosurePreservation}^{\uparrow}$ *carrier, the beta-step row B and beta-chain row F export only closedness preservation under* `ClosedAt`*. They do not export* `HasType` *preservation, beta-substitution preservation for codomains, confluence, normalization, or closed consistency.*

Proof. Read B as the one-step closedness row and F as the finite beta-chain closedness row. Both rows are part of the same `ClosedAt` packet fixed in Definition 788.1.

The beta redex side may cite the sibling $\mathsf{BetaSubstitutionPreservation}^{\uparrow}$ packet through provenance, but the carrier records it only as a dependency boundary for the subject-reduction route. The actual exported rows remain B and F over closedness.

Confluence, normalization, typed preservation, and consistency would each require a separate row not present in M. Therefore the beta-chain surface preserves closedness without escaping into those stronger claims. □

Theorem 788.5 (ClosurePreservation ledger exactness)**.** *The public ledger of an accepted* MetaCICClosurePreservat *packet is exactly*

$$S, V, U, B, F, A, C, G, R, H, Q, P, N.$$

Downstream closed-normal and subject-reduction route work may cite this ledger for finite closedness preservation, but must separately supply any typing, conversion, confluence, normalization, or bridge rows it consumes.

Proof. The first theorem fixes the NameCert obligation surface for the packet. The shift-substitution theorem fixes the syntactic movement rows behind the audit and generator-classifier boundary.

The beta-chain theorem fixes the one-step and finite-chain rows as closedness-preservation data only. Thus the accepted public ledger is the carrier inventory itself.

Any downstream use that needs typing, conversion, confluence, normalization, or bridge data must cite a separate packet for that data. The $\mathsf{MetaCICClosurePreservation}^{\uparrow}$ ledger contributes the closedness-preservation side and no additional coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetaCICClosurePreservation}^{\uparrow}$ packet is generated from shift, variable-substitution, full-substitution, beta-step, and beta-chain closedness rows, a substitution audit row, a closed-substitution seal, a generator-closure classifier, a subject-reduction consumer row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 788.1, Definition 788.2, Definition 788.3, Definition 788.4, and Definition 788.5 bind the finite ClosurePreservation packet and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close type preservation, conversion soundness, confluence, normalization, closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shift and substitution classifier handoff, beta-chain non-escape, ledger exactness, provenance, transport, continuation, and local naming for the same finite packet.

Chapter 789

A Concrete Naming Certificate for $\mathsf{SrDischargeRouteAudit}^{\uparrow}$

The $\mathsf{SrDischargeRouteAudit}^{\uparrow}$ packet realizes the route discipline of chapter 9374 as a finite NameCert audit surface. It sits beside the discharge socket of chapter 719, the discharge packet of chapter 718, the obstruction packet of chapter 731, and the MetaCIC critical-path packet of chapter 765. Those sibling chapters name the payload and the blocked edge; the present chapter records how explicit bundle discharge is audited without turning the route into a closed subject-reduction proof.

Definition 789.1 (SrDischargeRouteAudit carrier)**.** *A* $\mathsf{SrDischargeRouteAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (B, S, L, P, R, O, H, C, Q, N)$$

with the following displayed rows:

1. *B is the beta-substitution preservation discharge row;*
2. *S is the application-argument stability discharge row;*
3. *L is the lambda-domain subject-reduction discharge row;*
4. *P is the Pi-domain subject-reduction discharge row;*
5. *R is the route-audit row, recording the public read as explicit* $\mathsf{SubjectReductionDischargeBundle}$ *consumption;*
6. *O is the obstruction row inherited from the MetaCIC subject-reduction obstruction packet;*
7. *H records componentwise* hsame *transport for the four discharge rows, the route-audit row, the obstruction row, provenance, and local naming;*
8. *C records the displayed* Cont *reads from each admitted route to the same four-row discharge payload and to the obstruction boundary;*
9. *Q is the* Pkg *provenance over* BHist, hsame, Cont, $\mathsf{NameCert}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, $\mathsf{SubjectReductionDischarge}^{\uparrow}$, $\mathsf{MetaCICSubjectReductionBoundaryUp}$, $\mathsf{SubjectReductionBundleTrace}^{\uparrow}$, $\mathsf{SubjectReductionRouteClassifier}^{\uparrow}$*, and the MetaCIC critical-path packet of chapter 765;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SrDischargeRouteAudit}^{\uparrow}}$ *row.*

The carrier contains no fifth discharge row, no proof of the obstruction row, no erased derivation semantics, and no closed subject-reduction theorem.

Theorem 789.2 (SrDischargeRouteAudit bundle coherence)**.** *For an accepted* SrDischargeRouteAudit$^{\uparrow}$ *carrier, the explicit bundle route is coherent exactly when its public read terminates at the four discharge rows B, S, L, P and the obstruction row O. The route-audit row R records direct* SubjectReductionDischargeBu *consumption, but it cannot change the payload consumed by* subject_reduction_from_bundle*.*

Proof. Project the carrier A. The rows B, S, L, P are fixed before the route-audit row is inspected, and the obstruction row O is a separate displayed coordinate.

The route row R records consumption of a SubjectReductionDischargeBundle whose four fields are exactly B, S, L, P. The displayed Cont rows in C replay those fields to the consumer, while H only transports the named rows componentwise.

The obstruction row O remains present in the read. Since the carrier has no coordinate for replacing B, S, L, P or for dropping O, the route is coherent only as a route into the same finite audit packet. □

Theorem 789.3 (SrDischargeRouteAudit non-escape)**.** *Every public read of an accepted* SrDischargeRouteAudit$^{\uparrow}$ *carrier factors through*

$$B, S, L, P, R, O, H, C, Q, N.$$

The reader may inspect the four discharge rows, the bundle route audit, the obstruction row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It cannot extract a missing discharge proof, a closed subject-reduction theorem, host conversion semantics, quotient equality of MetaCIC terms, or an unrecorded route around the obstruction row.*

Proof. Begin with the carrier inventory. The only discharge-bearing coordinates are B, S, L, P, and the only route coordinate is R.

Apply the bundle coherence theorem. A permitted consumer follows R through direct bundle consumption, and that route ends at the same four discharge rows and preserves the obstruction row O.

Now inspect H, C, Q, N. These rows provide transport, replay, provenance, and local naming for the displayed packet. None of them introduces a discharge proof, a host conversion relation, quotient equality, or another route around O.

Therefore every public read stays inside the finite audit packet and the obstruction boundary remains visible at the point where the route is consumed. □

Theorem 789.4 (SrDischargeRouteAudit NameCert obligations)**.** *The local* NameCert$_{\text{SrDischargeRouteAudit}^{\uparrow}}$ *surface for Definition 789.1 consists exactly of carrier admission for $A = (B, S, L, P, R, O, H, C, Q, N)$, four-row discharge payload exposure, route-audit coherence for explicit bundle reads, obstruction-row preservation, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming. These obligations certify the finite audit packet as a sibling lattice node for the subject-reduction discharge route relationship.*

Proof. Carrier admission is the tuple displayed in Definition 789.1. It names the four discharge rows, the route-audit row, the obstruction row, transport rows, continuation rows, provenance, and local naming.

Payload exposure follows by projecting B, S, L, P. The bundle coherence theorem binds accepted route reads to those same four rows and keeps O attached to the route boundary.

Stability and replay are supplied by H and C. The package row Q records the neighboring socket, discharge, obstruction, route-classifier, bundle-trace, and critical-path chapters from which the audit packet is read.

Finally, the non-escape theorem excludes every stronger consumer request. Hence the listed rows are not merely sufficient for the local NameCert surface; they exhaust it. □

Closure status for $\mathsf{NameCert}_{\mathsf{SrDischargeRouteAudit}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{SrDischargeRouteAudit}^{\uparrow}$ packet is generated from finite BHist rows for the four subject-reduction discharge payloads, a route-audit row for bundle consumption, an obstruction row, transports, continuations, provenance, and local naming. The route row is replayed by Cont through the explicit bundle, exposing the same four payload rows and keeping the obstruction visible. Componentwise hsame preserves the payload, route, and obstruction rows, while Pkg records neighboring discharge and audit dependencies. The packet certifies route coherence without discharging subject reduction.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SrDischargeRouteAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the SrDischargeRouteAudit carrier, payload exposure, bundle-typeclass coherence, obstruction preservation, non-escape theorem, and NameCert obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SrDischargeRouteAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim a missing discharge proof, closed subject reduction, host conversion semantics, quotient equality of MetaCIC terms, or an unrecorded route around the obstruction.

Upgrade path: Obligation closure requires Lean encodings of the audit carrier, route-coherence theorem, obstruction preservation, and non-escape theorem.

Chapter 790

A Concrete Naming Certificate for $\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}$

The $\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}$ packet turns the explicit discharge route of chapter 9374 into a finite NameCert carrier. It sits between the socket packet of chapter 719 and the subject-reduction packet of chapter 483: the socket names the four discharge obligations, the subject-reduction packet names the consumed typing-preservation read, and this route certificate records how bundle access exposes exactly that same four-row payload.

Definition 790.1 (SubjectReductionDischargeRouteCert carrier)**.** *A* $\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, V, O, H, C, P, N)$$

with the following displayed rows:

1. *B is the explicit bundle row, naming the four-field* SubjectReductionDischargeBundle *packet;*
2. *V is the bundle-consumption row for the subject-reduction theorem obtained from the explicit packet;*
3. *O is the checked no-bundle obstruction row for the present raw relation;*
4. *H records componentwise* hsame *transports for the bundle, bundle-consumption, obstruction, socket, provenance, and naming rows;*
5. *C records the displayed* Cont *routes by which consumers read the explicit bundle route, the obstruction ledger, the discharge socket, and the subject-reduction packet;*
6. *P is the* Pkg *provenance over chapter 9374, chapter 719, and chapter 483;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}}$ *row.*

The carrier contains no inhabitant of the four discharge hypotheses for the closed-CIC substrate, no closed subject-reduction theorem, no host conversion rule, and no alternate subject-reduction route outside the displayed bundle row.

Lean4 (definition) `BEDC.MetaCIC.SubjectReductionDischargeBundle`

Theorem 790.2 (SubjectReductionDischargeRouteCert NameCert obligations)**.** *For the carrier of Definition 790.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$R = (B, V, O, H, C, P, N),$$

route visibility for the explicit bundle row B, bundle-consumption row V, and obstruction row O, componentwise transport through H, displayed continuation reads through C, provenance through P, and local naming through N.

Lean4 ✓ `BEDC.MetaCIC.subject reduction from bundle`

Proof. Project the displayed packet R. The explicit route is the bundle row B consumed by V, and the obstruction row O records why the raw relation does not inhabit the bundle.

Read H and C next. Transport preserves the named route rows componentwise, while continuation replay exposes only the displayed bundle, obstruction, socket, and subject-reduction reads.

Finally inspect P and N. Provenance ties the route certificate to the vision chapter, the discharge socket, and the subject-reduction packet. Since no carrier coordinate supplies a closed-CIC inhabitant of the four hypotheses, the listed rows exhaust the NameCert obligations without closing the obstruction boundary. □

Theorem 790.3 (SubjectReductionDischargeRouteCert socket consumption)**.** *Every downstream consumer of an accepted* $\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}$ *packet that reads a* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *row must consume the socket through the displayed route rows B, V, O, transported by H, replayed through C, and accounted for by P, N. The consumer may use the explicit bundle route only after the four discharge rows are supplied, and that route does not export a closed subject-reduction theorem for the present closed-CIC substrate.*

Proof. Start with the accepted route certificate. Its only subject-reduction route coordinates are the explicit bundle row and the corresponding consumption row.

Apply the socket chapter through provenance. The socket supplies the four discharge rows as a finite obligation surface, and the route certificate records that those rows are carried explicitly by B.

The subject-reduction packet is reached only after the displayed route has been replayed through C. Because the carrier has no coordinate for a closed-CIC inhabitant of the four hypotheses, socket consumption remains a route-certificate read and cannot become an unparameterised closed theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}$ packet is generated from an explicit bundle route, a subject-reduction consumption row, an obstruction row, componentwise hsame transports, displayed Cont routes, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 790.1, Definition 790.2, and Definition 790.3 bind the finite bundle route certificate and its socket-consumption boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionDischargeRouteCert}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close the four MetaCIC discharge obligations, construct an inhabited discharge bundle for the closed-CIC substrate, prove closed subject reduction, give Lean verification of the route certificate, or bridge check it.

Upgrade path: Obligation closure requires checked carrier admission, bundle route exactness, socket consumption, route replay, provenance, local naming, and non-escape for the same finite packet.

Chapter 791

A Concrete Naming Certificate for $\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}$

The $\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}$ packet realizes the closure-preservation audit map of chapter 9381 as a finite NameCert surface. It sits beside the kernel admission packet of chapter 557, the substitution audit packet of chapter 779, the normalization audit seal of chapter 777, and the preservation-facing packet of chapter 483. Those siblings expose admission, substitution, closed-normal, and typed-preservation boundaries; this packet records only the closedness-preserving route from shift and substitution through one-step and finite beta movement.

Definition 791.1 (MetaCIC closure preservation audit carrier)**.** *A* $\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, G, S, H, C, P, N)$$

with the following visible rows:

1. *T is the five-row theorem ledger for* `shift_one_preserves_closed_succ`*,* `substitute_var_preserves_closed` `substitute_preserves_closed_at`*,* `betaStep_preserves_closed`*, and* `betaStarStep_preserves_closed`*;*
2. *G is the generator-closure ledger for the closed-under-shift and closed-under-substitute classifier rows named in section 9381.5;*
3. *S is the handoff ledger that records how the substitution rows feed the beta-step row and how the beta-step row feeds the finite beta-chain row;*
4. *H records componentwise* hsame *transport for theorem rows, generator-closure rows, handoff rows, continuation rows, provenance rows, and local naming rows;*
5. *C records the displayed* Cont *routes for reading shift closedness, variable substitution closedness, full substitution closedness, one-step beta closedness, and beta-chain closedness in dependency order;*
6. *P is the* Pkg *provenance over chapter 9381, chapter 557, chapter 779, chapter 777, and chapter 483;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for typing preservation, conversion typing, closed subject reduction, host reduction semantics, quotient equality of terms, or an external proof oracle.

Theorem 791.2 (MetaCIC closure preservation audit NameCert obligations)**.** *For the carrier of Definition 791.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}}$ *surface consists exactly of carrier*

admission for $Q = (T, G, S, H, C, P, N)$, theorem-ledger readback through T, generator-closure readback through G, substitution-to-beta handoff readback through S, componentwise transport through H, displayed route replay through C, package provenance through P, and local naming through N.

Proof. Project the accepted carrier. The five theorem rows in T are the complete checked closedness-preservation chain named by chapter 9381.

Read G and S next. The generator rows authorize shift and substitution only relative to the closedness classifier, while the handoff row orders the substitution endpoint before beta-step and beta-chain reads.

The structural rows H, C, P, N transport, replay, locate, and name the same packet. Since no further coordinate is present, these rows exhaust the local NameCert obligations. □

Theorem 791.3 (MetaCIC closure preservation substitution-to-beta handoff)**.** *Every accepted* MetaCICClosurePreservationAudit$^{\uparrow}$ *carrier routes closedness preservation from substitution to beta movement through the ordered ledger*

$$\texttt{substitute_preserves_closed_at} \longrightarrow \texttt{betaStep_preserves_closed} \longrightarrow \texttt{betaStarStep_preserves_closed}.$$

The route may read the shift and variable-substitution rows as prerequisites of the full substitution row, but it cannot bypass the displayed substitution row when certifying the beta-redex case or bypass the one-step row when certifying a finite beta chain.

Proof. Start with the handoff coordinate S. Its first dependency records that the full substitution theorem is obtained from the shift and variable-substitution rows in the theorem ledger.

The beta-step read then consumes that substitution row only at the beta-redex boundary. Congruence cases stay inside the same theorem ledger and do not create a typing or conversion route.

Finally the finite beta-chain read consumes the one-step beta row. The continuation row C preserves this order for downstream consumers, so the packet exposes a dependency chain rather than an unstructured collection of theorem names. □

Theorem 791.4 (MetaCIC closure preservation subject-reduction boundary)**.** *An accepted* MetaCICClosurePreserva *packet may be consumed by the subject-reduction surface of chapter 483 only as closedness-stability data. It exports the displayed rows T, G, S, H, C, P, N and no row for* HasType *preservation, dependent-codomain transport, binder-domain preservation, beta-substitution typing, conversion typing, or closed subject reduction.*

Proof. Inspect the carrier rows. The theorem ledger T is stated over the closedness classifier, and G records generator closure for that classifier rather than for typing membership.

The handoff row S reaches beta-step and beta-chain closedness, not target typing. Its routes are therefore usable around the preservation-facing packet of chapter 483 without supplying any of the typed discharge rows named there.

The exclusion follows from the missing coordinates. The transport, continuation, provenance, and naming rows replay T, G, S componentwise, so they cannot introduce a hidden subject-reduction theorem. □

Closure status for NameCert$_{\text{MetaCICClosurePreservationAudit}^{\uparrow}}$.

Constructive story: A MetaCICClosurePreservationAudit$^{\uparrow}$ packet is generated from five closedness-preservation theorem rows, two generator-closure rows, a substitution-to-beta handoff ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICClosurePreservationAudit}^{\uparrow}}$, seed)

Scope closed: Definition 791.1, Definition 791.2, Definition 791.3, and Definition 791.4 bind the finite closure-preservation audit packet and its subject-reduction boundary.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICClosurePreservationAudit}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close typing preservation, conversion typing, closed subject reduction, dependent-codomain transport, host reduction semantics, quotient equality of terms, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, theorem-ledger exactness, generator-closure exactness, substitution-to-beta route ordering, transport, route replay, provenance, and non-escape for the same finite packet.

Chapter 792

A Concrete Naming Certificate for $\mathsf{ClosurePreservationAuditTrace}^{\uparrow}$

The $\mathsf{ClosurePreservationAuditTrace}^{\uparrow}$ packet realizes the closure-preservation audit map of chapter 9381 as finite NameCert data. It sits beside the route classifier of chapter 785, the substitution audit map of chapter 779, and the normalization audit seal of chapter 777: those siblings expose discharge routes, closed substitution rows, and candidate-mediated normalization reads, while this packet records the closedness-preservation theorem chain as one replayable audit trace.

Definition 792.1 (Closure-preservation audit trace carrier)**.** *A* $\mathsf{ClosurePreservationAuditTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, V, U, B, F, H, C, P, N)$$

with the following visible rows:

1. *S is the shift-one closedness row for* shift_one_preserves_closed_succ*;*
2. *V is the variable-substitution row for* substitute_var_preserves_closed_at*;*
3. *U is the full-substitution row for* substitute_preserves_closed_at*;*
4. *B is the beta-step closedness row for* betaStep_preserves_closed*;*
5. *F is the finite beta-star preservation row for* betaStarStep_preserves_closed*;*
6. *H records componentwise* hsame *transport across the five closedness-preservation rows, provenance, routes, and local naming;*
7. *C records the displayed* Cont *routes by which a consumer replays the shift, variable-substitution, full-substitution, beta-step, and beta-star rows in order;*
8. *P is the* Pkg *provenance over* Term*,* ClosedAt*,* shift*,* substitute*, one-step beta reduction, finite beta-star chains,* BHist*,* hsame*,* Cont*, and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditTrace}^{\uparrow}}$ *row.*

The carrier exports no typing preservation theorem, no dependent codomain transport, no normalization proof, no confluence theorem, no quotient equality over reductions, and no host semantic equality coordinate.

Lean4 ✓ `BEDC.Derived.ClosurePreservationAuditTraceUp.ClosurePreservationAuditTraceTasteGate`
`single carrier alignment`

Theorem 792.2 (Closure-preservation audit trace NameCert obligations)**.** *The carrier of Definition 792.1 satisfies the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditTrace}^{\uparrow}}$ *obligation surface. Its obligations are carrier admission for*

$$T = (S, V, U, B, F, H, C, P, N),$$

shift-one readback through S*, variable-substitution readback through* V*, full-substitution readback through* U*, beta-step readback through* B*, beta-star readback through* F*, componentwise transport through* H*, displayed continuation through* C*, provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from the displayed finite packet. The rows S, V, U expose the shift-one, variable-substitution, and full-substitution closedness facts described by the audit map.

Project B and F next. The beta-step row consumes the substitution row at a contraction boundary, and the finite beta-star row records repeated consumption of the beta-step row along the displayed chain.

Finally inspect H, C, P, N. These rows transport, replay, locate, and name the same finite packet. Since the carrier has no coordinate for typing preservation, dependent codomain transport, normalization, confluence, quotient equality, or host semantic equality, the listed rows exhaust the local NameCert surface. □

Theorem 792.3 (Closure-preservation audit trace beta-star coverage)**.** *Every accepted* ClosurePreservationAuditTra *packet covers the closedness-preservation route from one-step beta contraction to finite beta-star chains. A consumer that reads the beta-star row* F *must reach it through the displayed beta-step row* B*, the full-substitution row* U*, the variable-substitution row* V*, the shift-one row* S*, and the route and provenance rows* C, P, N*, with componentwise transport supplied by* H*.*

Proof. Start with an accepted carrier $T = (S, V, U, B, F, H, C, P, N)$. The finite packet orders the closedness rows so that the beta-star coordinate is not a standalone theorem name; it is a row read through the same trace as the one-step beta coordinate.

The beta-step row B depends on the full-substitution row U at the contraction boundary. The full-substitution row in turn is supported by the variable-substitution row V and the shift-one row S, matching the theorem chain recorded in chapter 9381.

The replay route C and provenance row P keep that chain visible to consumers, while H transports the displayed rows componentwise and N names the local certificate. Because no additional coordinate is available, beta-star coverage is exactly the finite trace through $S, V, U, B, F, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditTrace}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosurePreservationAuditTrace}^{\uparrow}$ packet is generated from shift-one closedness, variable substitution, full substitution, beta-step preservation, beta-star preservation, componentwise transport, displayed continuation routes, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditTrace}^{\uparrow}}$, seed)

Scope closed: Definition 792.1, Definition 792.2, and Definition 792.3 bind the finite closure-preservation trace and its beta-star coverage boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditTrace}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close typing preservation, dependent codomain transport, subject reduction, normalization, confluence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exact readback of the five closedness-preservation rows, transport, route replay, provenance, local naming, and beta-star non-escape for the same finite trace.

Chapter 793

A Concrete Naming Certificate for $\mathsf{SubjectReductionRouteAudit}^{\uparrow}$

The $\mathsf{SubjectReductionRouteAudit}^{\uparrow}$ packet is the finite audit surface for the explicit bundle discharge route described in chapter 9374. It keeps the obstruction boundary of chapter 9377 visible while consuming the socket rows of chapter 719. The packet records route handoff data only; it does not inhabit the four MetaCIC discharge hypotheses and does not close subject reduction.

Definition 793.1 (Subject-reduction route-audit carrier)**.** *A* $\mathsf{SubjectReductionRouteAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (B, E, I, U, S, H, C, P, N)$$

with the following displayed rows:

1. *B is the explicit bundle row naming the four subject-reduction discharge hypotheses as one* SubjectReductionDischargeBundle *packet;*
2. *E is the route-exactness row comparing accepted bundle reads with the socket payload;*
3. *I is the invocation row recording downstream explicit-bundle consumption;*
4. *U is the socket handoff row through which the consumer reaches the displayed discharge socket surface;*
5. *S is the* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *row carrying the four named discharge sockets;*
6. *H records componentwise* hsame *transports for the bundle row, exactness row, invocation row, socket row, handoff row, provenance row, and local name;*
7. *C records the displayed* Cont *routes from route exactness to socket handoff and downstream subject-reduction consumption;*
8. *P is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, *and the bundle route;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteAudit}^{\uparrow}}$ *row.*

The carrier classifier compares only the displayed route rows, socket rows, transports, continuations, provenance, and local naming data. It has no coordinate for closed subject reduction, host conversion, quotient equality of terms, erased semantics, or an inhabitant of any missing discharge hypothesis.

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteAuditUp.SubjectReductionRouteAuditTasteGate single carrier alignment`

Theorem 793.2 (SubjectReductionRouteAudit NameCert obligations)**.** *For the carrier of Definition 793.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteAudit}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$A = (B, E, I, U, S, H, C, P, N),$$

bundle-route visibility through B*, route-exactness comparison through* E*, invocation through* I*, socket handoff through* U, S*, componentwise transport through* H*, displayed continuation reads through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the displayed packet A. The bundle row B is the public route presentation, while E records exactness against the socket payload.

Read the invocation row I. It records that the explicit bundle path is used, but it does not add a fifth discharge row and does not alter the four-row socket payload.

The handoff rows U, S place the route in the socket surface. The transports H and continuations C replay only the displayed route and socket coordinates, and P, N record provenance and local naming. These rows exhaust the finite NameCert obligations. □

Theorem 793.3 (SubjectReductionRouteAudit socket handoff)**.** *Every downstream consumer of an accepted* $\mathsf{SubjectReductionRouteAudit}^{\uparrow}$ *packet reaches the subject-reduction discharge socket only through*

$$B, E, I, U, S, H, C, P, N.$$

The explicit bundle route hands off the socket payload without exporting a closed subject-reduction theorem, a proof of the four discharge hypotheses, a host conversion rule, or any route outside the displayed bundle comparison.

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteAuditUp.SubjectReductionRouteAudit socket handoff`

Proof. Start with the carrier and the NameCert-obligation theorem. They identify every permitted consumer read with one of the displayed rows of A.

The bundle route reaches the socket through B, U, S. The comparison row E records that this path exposes the same four-row payload named by the socket.

Transport and replay are then forced through H and C. Since the packet has no coordinate for an inhabited discharge hypothesis, host conversion, closed subject reduction, or an alternate route, the socket handoff remains a finite audit row for bundle-route consumption alone. □

Theorem 793.4 (SubjectReductionRouteAudit obligation surface)**.** *Every accepted* $\mathsf{SubjectReductionRouteAudit}^{\uparrow}$ *packet exposes exactly its bundle route comparison row, socket handoff row, nonescape ledger, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row before any MetaCIC discharge consumer can inspect it. The exposed surface remains an audit packet and does not prove subject reduction, closed subject reduction, or a public schema bridge.*

Proof. Project the carrier of Definition 793.1. The comparison row is E, the socket handoff is read through U, S, the nonescape information is the absence of any discharge-hypothesis coordinate beyond the displayed route rows, and H, C, P, N supply transport, replay, provenance, and naming.

Apply the NameCert obligations of Definition 793.2. They identify the accepted packet with exactly those carrier, comparison, handoff, transport, replay, provenance, and local naming rows.

Finally use the socket handoff theorem, Definition 793.3. It permits downstream inspection only through the displayed bundle comparison and socket rows, while explicitly withholding closed subject reduction, the missing discharge hypotheses, host conversion, and any route outside the displayed bundle comparison. Hence the obligation surface supports MetaCIC discharge work without asserting subject reduction, closed subject reduction, or a public schema bridge. □

Theorem 793.5 (SubjectReductionRouteAudit discharge boundary)**.** *Every accepted* SubjectReductionRouteAudit$^{\uparrow}$ *packet exposes the explicit bundle row, route-exactness row, invocation row, socket handoff row, discharge-socket row, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row before any MetaCIC consumer may inspect it. The same packet still does not inhabit any of the four discharge hypotheses and does not prove closed subject reduction.*

Proof. Project the carrier of Definition 793.1. The coordinates $B, E, I, U, S, H, C, P, N$ are respectively the explicit bundle, exactness, invocation, handoff, socket, transport, replay, provenance, and local naming rows.

Apply Definition 793.2. It forces every accepted inspection route to pass through exactly those displayed rows before a downstream MetaCIC consumer can read the packet.

Apply Definition 793.3. The socket handoff exposes the discharge-socket payload through U, S while preserving the absence of coordinates for the four hypothesis inhabitants, host conversion, closed subject reduction, or an alternate route. Thus the discharge boundary is a finite audit surface and not a proof of subject reduction. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteAudit}^{\uparrow}}$.

Constructive story: A SubjectReductionRouteAudit$^{\uparrow}$ packet is generated from an explicit bundle row, route-exactness comparison, an invocation row, a socket handoff, the discharge socket row, componentwise hsame transports, displayed Cont routes, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SubjectReductionRouteAudit}^{\uparrow}}$, seed)

Scope closed: Definition 793.1, Definition 793.2, and Definition 793.3 bind the finite route-audit packet between bundle comparison and subject-reduction socket handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SubjectReductionRouteAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not prove any MetaCIC discharge hypothesis, construct closed subject reduction, provide Lean verification, or bridge the packet to a public schema.

Upgrade path: Obligation closure requires checked carrier admission, bundle route comparison, socket handoff exactness, non-escape, provenance, and local naming for the same finite route-audit packet.

Chapter 794

A Concrete Naming Certificate for $\mathsf{ClosurePreservationTrace}^{\uparrow}$

The $\mathsf{ClosurePreservationTrace}^{\uparrow}$ packet realizes the closedness-preservation audit map of chapter 9381 as finite NameCert data. It sits alongside the subject-reduction carrier of chapter 483, the closed-term substitution carrier of chapter 537, and the beta-substitution preservation carrier of chapter 716. Its scope is the unconditional ClosedAt chain for shift, substitution, one-step beta, and finite beta paths; it does not discharge the dependent typing obligations carried by subject-reduction chapters.

Definition 794.1 (ClosurePreservationTrace carrier)**.** *A* $\mathsf{ClosurePreservationTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, V, U, B, R, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the shift-preservation row for the one-step successor boundary;*
2. *V is the variable-substitution preservation row at the selected closedness boundary;*
3. *U is the full substitution preservation row, linking the body budget and payload budget to the receiving* ClosedAt *boundary;*
4. *B is the one-step beta-preservation row;*
5. *R is the finite beta-star preservation row;*
6. *D is the displayed* ClosedAt *boundary row, recording the source depth, target depth, body budget, payload budget, and endpoint boundary consumed by S, V, U, B, R;*
7. *H records componentwise* hsame *transports for the shift, substitution, beta-step, beta-star, boundary, provenance, and local naming rows;*
8. *C records the displayed* Cont *routes by which a consumer reads the preservation chain in the order shift, variable substitution, substitution, beta step, and beta-star closure;*
9. *P is the* Pkg *provenance over chapter 9381, chapter 537, chapter 716, chapter 483,* BHist, hsame, Cont, ClosedAt, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationTrace}^{\uparrow}}$ *row.*

The carrier contains no typing derivation, no subject-reduction theorem, no conversion rule, no confluence or normalization theorem, and no route for changing the classifier from ClosedAt *to* HasType.

Theorem 794.2 (ClosurePreservationTrace NameCert obligations)**.** *For the carrier of Definition 794.1, the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationTrace}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$T = (S, V, U, B, R, D, H, C, P, N),$$

visibility of the five preservation rows S, V, U, B, R*, boundary accounting through* D*, componentwise transport through* H*, displayed route replay through* C*, provenance through* P*, and local naming through* N*. The surface classifies a finite closedness trace and not a typing-preservation package.*

Proof. Project the displayed packet T. The first five coordinates are precisely the preservation chain listed in chapter 9381: shift preservation, variable substitution preservation, full substitution preservation, beta-step preservation, and beta-star preservation.

Read the boundary row D next. It keeps the successor boundary for shift, the source and receiving boundaries for substitution, and the endpoint boundary for beta movement in one visible row, so consumers cannot silently change the closedness index while following the chain.

Finally inspect H, C, P, N. These rows provide transport, route replay, provenance, and local naming for the displayed coordinates. Since the carrier has no typing coordinate and no host conversion coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 794.3 (ClosurePreservationTrace closedness route)**.** *Every accepted* $\mathsf{ClosurePreservationTrace}^{\uparrow}$ *carrier exposes a single closedness-preservation route from the source* ClosedAt *boundary through shift, substitution, one-step beta reduction, and finite beta-star closure. A consumer that starts with a displayed closed source term and follows* C *reaches only the transported* ClosedAt *endpoint named by* D *and cannot obtain a* HasType *endpoint from this packet.*

Proof. Start with the carrier projection of Definition 794.1. The continuation route C first reads the shift row S and the variable-substitution row V, then uses the full substitution row U to account for the beta-redex contractum boundary.

The one-step beta row B reads the same substitution boundary, while the beta-star row R composes finitely many such one-step reads. The boundary row D is shared by those rows, so the source and endpoint closedness claims remain on the displayed boundary route.

No step in this route reads the subject-reduction carrier as a proof payload. The references to chapter 483, chapter 537, and chapter 716 are provenance anchors and neighboring consumers, not hidden typing evidence. □

Theorem 794.4 (ClosurePreservationTrace non-escape)**.** *Every public read of an accepted* ClosurePreservationTrace *carrier factors through*

$$S, V, U, B, R, D, H, C, P, N.$$

The read may inspect the closedness preservation rows, the ClosedAt *boundary ledger, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row. It cannot read a typing derivation, a subject-reduction discharge row, a conversion theorem, a confluence theorem, a normalization theorem, quotient equality of terms, or a host semantic model.*

Proof. Apply the NameCert-obligation theorem to identify any accepted carrier with the finite packet $T = (S, V, U, B, R, D, H, C, P, N)$.

For an admitted closedness read, the consumer follows the displayed route through C and transports rows componentwise through H. The package provenance P records where the chain is cited, but it does not add another payload coordinate.

For any request outside the closedness route, the carrier has no row to satisfy it. In particular, subject-reduction and beta-substitution chapters may consume or compare the closedness trace, but this packet does not inhabit their typing-preservation obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosurePreservationTrace}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosurePreservationTrace}^{\uparrow}$ packet is generated from finite shift, substitution, beta-step, beta-star, ClosedAt boundary, transport, continuation, package, and naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosurePreservationTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 794.1, Definition 794.2, Definition 794.3, and Definition 794.4 bind the finite closedness-preservation trace over the audit-map chain.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosurePreservationTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove typing preservation, confluence, normalization, conversion soundness, Lean verification of the trace carrier, or a public bridge.

Upgrade path: Obligation closure requires checked carrier admission, closedness-route exactness, transport stability, continuation replay, provenance, local naming, and non-escape for the same finite trace packet.

Chapter 795

A Concrete Naming Certificate for MetaCICClosureTrace$^{\uparrow}$

The MetaCICClosureTrace$^{\uparrow}$ packet gives the ClosurePreservation audit map of chapter 9381 a finite BEDC landing. It sits beside the audit-gate packet of chapter 552 and the kernel trace packet of chapter 557: the former records admission discipline, the latter records accepted declarations, and this packet records the closedness-preservation rows that downstream MetaCIC routes may replay.

Definition 795.1 (MetaCICClosureTrace carrier)**.** *A* MetaCICClosureTrace$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, U, V, B, R, G, K, H, C, P, N)$$

with the following displayed rows:

1. *S is the shift closedness row, naming the theorem row for* `shift_one_preserves_closed_succ`*;*
2. *U is the variable-substitution closedness row, naming the theorem row for* `substitute_var_preserves_closed_`
3. *V is the full-substitution closedness row, naming the theorem row for* `substitute_preserves_closed_at`*;*
4. *B is the one-step beta closedness row, naming the theorem row for* `betaStep_preserves_closed`*;*
5. *R is the finite beta-chain closedness row, naming the theorem row for* `betaStarStep_preserves_closed`*;*
6. *G records the generator-closure rows for* `closed_under_shift_classifier` *and* `closed_under_substitute_cl`
7. *K records the kernel-acceptance trace rows for the accepted MetaCIC ClosurePreservation declarations and their displayed dependency ledger;*
8. *H records componentwise* hsame *transports for theorem rows, generator rows, kernel trace rows, provenance rows, and local naming rows;*
9. *C records the displayed* Cont *routes by which downstream subject-reduction, closed-normal, and conversion-facing packets read the closure trace;*
10. *P is the* Pkg *provenance over chapter 9381, chapter 552, chapter 557, the MetaCIC ClosurePreservation module, generator-closure rows, componentwise* hsame*, and* NameCert *rows;*
11. *N is the local* NameCert$_{\text{MetaCICClosureTrace}^{\uparrow}}$ *row.*

The carrier contains no typing preservation theorem, no subject-reduction discharge inhabitant, no confluence theorem, no normalization theorem, no hidden kernel soundness premise, and no generator outside the displayed shift, substitution, beta-step, and finite beta-chain rows.

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceTasteGate single carrier alignment`

Theorem 795.2 (MetaCICClosureTrace substitution and shift generator package)**.** *For every accepted* MetaCICClosureTrace$^{\uparrow}$ *carrier* $T = (S, U, V, B, R, G, K, H, C, P, N)$*, the rows* S, U, V, G *form a finite generator package for the closedness classifier. The shift row* S *authorizes the one-step lift at the successor boundary, the variable row* U *and full-substitution row* V *authorize substitution at the receiving boundary, and the generator row* G *records exactly those two generator-closure classifier witnesses as the package exported to downstream closure consumers.*

Proof. Project the displayed packet T. The shift row and the two substitution rows are already separated as S, U, V, so the carrier has a finite inventory before any downstream consumer is considered.

Read the generator row G. Its shift coordinate is backed by the same closedness-preservation theorem named by S, and its substitution coordinate is backed by the variable and full-substitution theorem rows U, V.

Finally inspect H, C, P, N. Transport and continuation replay preserve the displayed package rows, while provenance and local naming bind them to the ClosurePreservation audit map. Since no other generator coordinate occurs in T, the exported generator package is exhausted by S, U, V, G. □

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier substitution shift generator package`

Theorem 795.3 (MetaCICClosureTrace closed-substitution route)**.** *Every closed-substitution consumer of an accepted* MetaCICClosureTrace$^{\uparrow}$ *carrier* $T = (S, U, V, B, R, G, K, H, C, P, N)$ *must read the shift row* S*, the variable-substitution row* U*, the full-substitution row* V*, the generator row* G*, and the kernel-acceptance row* K *before exporting closedness preservation. The route exports only the closure-preservation boundary for closed substitution; it exports no typing, conversion, confluence, normalization, subject-reduction, or kernel-soundness conclusion.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier closed substitution route`

Proof. Project the displayed carrier T. The rows S, U, V, G, K are separate coordinates, so a closed-substitution consumer can identify the shift, variable-substitution, full-substitution, generator, and acceptance ledger data before any beta-chain or continuation row is inspected.

Use Definition 795.2. It identifies S, U, V, G as the finite generator package for the closedness classifier, with U and V supplying the substitution coordinates and S supplying the boundary shift coordinate.

The row K then records kernel acceptance for the displayed ClosurePreservation declarations. The substitution audit-map boundary supplies the prose routing discipline: accepted closed-substitution reads stop at closedness preservation and do not acquire typing, conversion, confluence, normalization, subject-reduction, or kernel-soundness data from any hidden carrier coordinate. □

Theorem 795.4 (MetaCICClosureTrace beta-star preservation readback)**.** *Every downstream consumer that reads finite beta-chain closedness from an accepted* MetaCICClosureTrace$^{\uparrow}$ *carrier receives it through the route*

$$B, R, H, C, P, N.$$

The one-step beta row B *supplies the local preservation step, the finite beta-chain row* R *supplies the iterated readback, and the route may cite the checked MetaCIC theorem* `BEDC.MetaCIC.betaStarStep_preserves_`

as the kernel-accepted declaration recorded by K. The readback preserves only `ClosedAt`*; it exports no typing, conversion, confluence, or normalization conclusion.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier beta star preservation readback`

Proof. Begin with the beta rows. The row B names the one-step closedness preservation fact, and the row R names its finite beta-chain closure.

Use the kernel trace row K only as an acceptance ledger for the named declaration. This ledger records that the finite beta-chain theorem is part of the accepted ClosurePreservation surface; it does not add a separate semantic premise.

Now replay the consumer route through H, C, P, N. Componentwise transport keeps B and R aligned, the continuation route exposes the finite read, provenance identifies the ClosurePreservation audit map, and the local NameCert row names the packet. Because the carrier has no typing or conversion coordinate, the readback stops at closedness preservation. □

Theorem 795.5 (MetaCICClosureTrace NameCert obligations)**.** *For the carrier of Definition 795.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosureTrace}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$T = (S, U, V, B, R, G, K, H, C, P, N),$$

the five ClosurePreservation theorem rows S, U, V, B, R, generator-closure readback through G, kernel-acceptance trace accounting through K, componentwise transport through H, displayed continuation reads through C, package provenance through P, and local naming through N.

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier namecert obligations`

Proof. Carrier admission is the first projection of the displayed packet T. This projection fixes the five theorem rows before the generator, kernel trace, transport, route, provenance, or naming rows are read.

The generator and kernel obligations are then forced by G and K. The row G exposes only the shift and substitution generator-closure witnesses, while K records accepted ClosurePreservation declarations and their dependency ledger.

The remaining obligations are exactly the public routing rows. The row H supplies componentwise hsame transport, C supplies continuation replay, P supplies package provenance, and N supplies local naming. No carrier coordinate remains from which a stronger MetaCIC theorem could be exported. □

Theorem 795.6 (MetaCICClosureTrace substitution beta-chain boundary)**.** *Every accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *consumer that combines the substitution rows S, U, V, G with the beta rows B, R must still read only* `ClosedAt` *preservation through K, H, C, P, N. The combined route may replay shift, substitution, one-step beta, and finite beta-chain closedness preservation, but it cannot export typing preservation, confluence, normalization, subject reduction, conversion soundness, or kernel soundness.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier substitution beta chain boundary`

Proof. First read the substitution side through Definition 795.2 and Definition 795.3. These results identify S, U, V, G as a closedness-generator package and force the closed-substitution route to stop at `ClosedAt` preservation.

Next read the beta side through Definition 795.4. It exposes only the one-step row B and finite-chain row R as closedness preservation data.

Finally apply Definition 795.5. The only remaining public route is K, H, C, P, N, whose kernel ledger, transport, replay, provenance, and naming rows preserve the displayed ClosurePreservation declarations. Since the carrier has no coordinate for typing, confluence, normalization, subject reduction, conversion soundness, or kernel soundness, the combined consumer cannot export any of those stronger claims. □

Theorem 795.7 (MetaCICClosureTrace kernel ledger boundary)**.** *For every accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *carrier* $T = (S, U, V, B, R, G, K, H, C, P, N)$*, the kernel-acceptance row* K *is only an acceptance ledger for the displayed ClosurePreservation declarations. It cannot be used as a hidden kernel-soundness premise, a typing derivation, a confluence witness, a normalization witness, or a subject-reduction witness.*

Proof. Project the row K from the carrier. By Definition 795.5, this row accounts for accepted ClosurePreservation declarations and their displayed dependency ledger.

The substitution and beta routes do not enlarge that ledger. The route of Definition 795.3 reads K after S, U, V, G, while Definition 795.4 reads K only as acceptance evidence for the beta-chain closedness row.

Thus K remains a ledger coordinate rather than a semantic kernel premise. The stronger objects named in the statement are absent from Definition 795.1, so no accepted consumer can recover them from the packet. □

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier kernel ledger semantic name certificate`

Theorem 795.8 (MetaCICClosureTrace obligation-closure package)**.** *The substitution-shift generator package of Definition 795.2, the beta-star preservation readback of Definition 795.4, the local NameCert obligations of Definition 795.5, and the kernel-ledger boundary of Definition 795.7 jointly exhaust the obligation-closure surface for the* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *packet. The package exposes only shift, substitution, beta-step, finite beta-chain closedness, generator readback, kernel acceptance ledger, transport, replay, provenance, and local naming; it exports no typing preservation, confluence, normalization, subject reduction, conversion soundness, or kernel soundness.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier obligation closure package`

Proof. Project the carrier of Definition 795.1. The rows S, U, V, G are the substitution and shift generator package, while B, R are the one-step beta and finite beta-chain closedness rows.

Apply the substitution-shift generator theorem to bind S, U, V, G as the complete closedness-generator surface. Apply the beta-star readback theorem to bind B, R as the only finite beta-chain read available to downstream consumers.

Now use the local NameCert obligations. They account for carrier admission, ClosurePreservation theorem rows, generator readback, kernel-trace accounting, componentwise transport, continuation replay, provenance, and local naming.

Finally use the kernel-ledger boundary. The ledger row K remains acceptance accounting for displayed ClosurePreservation declarations and is not a semantic premise for stronger MetaCIC results. Since the carrier has no row for typing preservation, confluence, normalization, subject reduction, conversion soundness, or kernel soundness, the listed rows exhaust the obligation-closure package. □

Theorem 795.9 (MetaCICClosureTrace candidate-mediated SN route)**.** *Any downstream read that uses an accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *carrier* $T = (S, U, V, B, R, G, K, H, C, P, N)$ *inside a candidate-mediated normalization packet may consume from* T *only the shift, substitution, beta-step, finite beta-chain, generator, kernel-ledger, transport, replay, provenance, and local-name rows. The strong-normalization conclusion must import candidate evidence from the router or frontier before it is stated;* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *itself contributes closedness preservation and kernel acceptance accounting, never evidence-free normalization.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier candidate mediated sn route`

Proof. Begin with the closedness rows. The substitution-shift generator package identifies S, U, V, G as the shift and substitution surface, while the beta-star readback identifies B, R as the one-step and finite beta-chain closedness surface.

Next read the kernel boundary. The kernel-ledger theorem keeps K as acceptance accounting for displayed ClosurePreservation declarations rather than as a semantic proof of subject reduction, conversion, confluence, or normalization.

Now apply the obligation-closure package. It routes the remaining rows through H, C, P, N and states that the exported surface is closedness preservation only.

Therefore a candidate-mediated normalization packet may use this carrier as a closedness-preservation ledger, but the candidate evidence required for strong normalization must arrive from the candidate router or frontier. Since no such evidence is a coordinate of T, the route cannot state a strong-normalization conclusion from $\mathsf{MetaCICClosureTrace}^{\uparrow}$ alone. □

Theorem 795.10 (MetaCICClosureTrace residual frontier)**.** *Every residual-frontier consumer of an accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *carrier* $T = (S, U, V, B, R, G, K, H, C, P, N)$ *may read the ClosurePreservation rows*

$$S, U, V, B, R, G, K, H, C, P, N$$

only as closedness-preservation evidence. Any confluence, residual, candidate, strong-normalization, subject-reduction, or conversion-soundness conclusion must import the corresponding diamond, residual, and candidate data from a separate MetaCIC frontier packet before it is claimed.

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier residual frontier`

Proof. Begin with the candidate-mediated SN route. It permits downstream normalization packets to consume the closure trace only through the displayed shift, substitution, beta-step, finite beta-chain, generator, kernel-ledger, transport, replay, provenance, and local-name rows.

Use the kernel-ledger boundary next. The row K records acceptance accounting for ClosurePreservation declarations, not a hidden proof of subject reduction, confluence, normalization, residual determinacy, or conversion soundness.

Thus a residual-frontier consumer may forward $S, U, V, B, R, G, K, H, C, P, N$ as a closedness-preservation ledger. Since the carrier contains no diamond, residual, or candidate evidence row, every stronger MetaCIC conclusion must be supplied by a separate frontier packet before the consumer can claim it. □

Theorem 795.11 (MetaCICClosureTrace obligation-closure forwarder)**.** *For every accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *carrier* $T = (S, U, V, B, R, G, K, H, C, P, N)$*, the rows* $S, U, V, B, R, G, K, H, C, P, N$ *jointly form the obligation-closure surface exported to closure-preservation consumers. The exported surface*

consists only of shift closedness, variable-substitution closedness, full-substitution closedness, one-step beta closedness, finite beta-chain closedness, generator readback, kernel-trace ledger accounting, componentwise transport, replay, provenance, and local naming. It refuses typing preservation, conversion, confluence, normalization, subject reduction, and hidden kernel soundness.

Proof. First apply Definition 795.2. It identifies S, U, V, G as the displayed generator package for shift and substitution closedness.

Next apply Definition 795.4. It identifies B, R as the one-step and finite beta-chain closedness readback route and keeps that readback at `ClosedAt` preservation.

Now apply Definition 795.7. The row K remains only an acceptance ledger for displayed ClosurePreservation declarations, not a hidden semantic premise.

Finally apply Definition 795.5. The rows H, C, P, N provide componentwise transport, replay, provenance, and local naming for the same finite packet. Since no carrier coordinate stores typing, conversion, confluence, normalization, subject reduction, or kernel soundness, the forwarder exports exactly the listed obligation-closure surface. □

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier obligation closure forwarder`

Theorem 795.12 (MetaCICClosureTrace obligation-closure upgrade)**.** *The substitution-shift generator package of Definition 795.2, beta-star preservation readback of Definition 795.4, NameCert obligations of Definition 795.5, kernel-ledger boundary of Definition 795.7, and candidate frontier of Definition 795.13 jointly form the obligationClosure package for* $\mathsf{MetaCICClosureTrace}^{\uparrow}$*. The package exports only finite* `ClosedAt` *preservation across shift, substitution, beta-step, finite beta-chain, generator readback, kernel-ledger accounting, transport, replay, provenance, and local naming. It exports no typing theorem, confluence theorem, normalization theorem, subject-reduction theorem, conversion-soundness theorem, or kernel-soundness theorem.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier obligation closure upgrade`

Proof. Begin with the generator package. The substitution-shift theorem identifies S, U, V, G as the complete closedness-generator surface for shift and substitution reads.

Attach the beta route next. The beta-star preservation readback identifies B, R as the displayed one-step and finite-chain closedness rows, and the NameCert obligations bind those rows to carrier admission, transport, replay, provenance, and local naming.

Use the kernel-ledger boundary to keep K as acceptance accounting for ClosurePreservation declarations rather than as a hidden semantic premise. The candidate-frontier theorem then orders the whole route as

$$S, U, V, G \longmapsto B, R \longmapsto K \longmapsto H, C, P, N.$$

Thus the combined package reaches obligationClosure for the paper packet by preserving only `ClosedAt`. Since no carrier row stores typing, confluence, normalization, subject reduction, conversion soundness, or kernel soundness, none of those stronger claims is exported. □

Theorem 795.13 (MetaCICClosureTrace candidate frontier)**.** *Every normalization-facing, confluence-facing, or conversion-facing read of an accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *packet must pass through the displayed candidate frontier*

$$S, U, V, G \longmapsto B, R \longmapsto K \longmapsto H, C, P, N.$$

The first stage is the substitution-and-shift generator package, the second stage is the beta-star closedness chain, the third stage is the kernel ledger for accepted ClosurePreservation declarations,

and the final stage is componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. The frontier exports only finite* `ClosedAt` *preservation for the displayed trace; it exports no hidden subject-reduction hypothesis, no host reduction equality, no unrestricted strong-normalization principle, and no confluence statement outside the finite candidate trace.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier candidate frontier`

Proof. Start with the generator side. The substitution-shift generator package identifies S, U, V, G as the complete closedness-generator surface for shift and substitution reads, while the closed-substitution route forces any closed-substitution consumer to pass through those rows before using the ledger.

Next attach the beta-chain side. The beta-star preservation readback exposes B, R as the one-step and finite-chain closedness rows, and it states that the readback stops at `ClosedAt` preservation.

Now read the kernel boundary. The kernel-ledger boundary keeps K as acceptance accounting for displayed ClosurePreservation declarations rather than as a semantic subject-reduction or kernel-soundness premise.

Finally package the route through the obligation-closure theorem. The rows H, C, P, N provide transport, replay, provenance, and naming for the same finite packet. Since the carrier has no coordinate for host reduction equality, unrestricted strong normalization, full confluence, subject reduction, typing preservation, conversion soundness, or kernel soundness, every such consumer remains on the displayed candidate frontier. □

Theorem 795.14 (MetaCICClosureTrace scoped confluence audit route)**.** *Every candidate-mediated normalization consumer of an accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *packet may pass the closedness-preservation rows*

$$S, U, V, B, R, G, K, H, C, P, N$$

into a confluence-facing, conversion-facing, or strong-normalization-facing route only as scoped `ClosedAt` *evidence over the displayed carrier of Definition 795.1. Any strong-normalization, confluence, subject-reduction, or conversion-soundness conclusion must be imported from the candidate frontier or router packet rather than from* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *itself.*

Proof. Begin with the carrier of Definition 795.1. Its rows are closedness-preservation rows, generator rows, kernel-ledger accounting, transport, replay, provenance, and local naming; none is a typing, confluence, subject-reduction, conversion-soundness, or normalization coordinate.

Apply the obligation-closure package of Definition 795.8. It packages the substitution, shift, beta-step, finite beta-chain, NameCert, kernel-ledger, transport, replay, provenance, and naming rows as a finite `ClosedAt` surface.

Now use the candidate frontier of Definition 795.13. The frontier orders the same rows as the route through which normalization-facing, confluence-facing, and conversion-facing consumers may read the packet, and the checked TasteGate marker records that the carrier alignment has only this single displayed field surface.

Therefore a consumer may forward the closure trace as scoped `ClosedAt` evidence, but any strong-normalization, confluence, subject-reduction, or conversion-soundness theorem must arrive from the candidate frontier or router packet. The closure trace preserves closedness; it does not create the stronger MetaCIC conclusion. □

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier scoped confluence audit route`

Theorem 795.15 (MetaCICClosureTrace candidate-mediated closedness ledger)**.** *Every downstream closedness consumer of an accepted* MetaCICClosureTrace$^{\uparrow}$ *packet* $T = (S, U, V, B, R, G, K, H, C, P, N)$ *must read the candidate-mediated route in the order* S, U, V, G*, then* B, R*, then* K*, then* H, C, P, N*. The exported ledger is only a finite* `ClosedAt` *preservation route through substitution, shift, beta-step, finite beta-chain, kernel acceptance accounting, transport, replay, provenance, and local naming. It exports no subject reduction, no confluence, no normalization, no conversion theorem, no host reduction equality, and no kernel soundness.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier candidate mediated closedness ledger`

Proof. First read the substitution-shift generator package. It identifies S, U, V, G as the finite candidate generator surface through which closed-substitution and shift reads enter the packet.

Next use the closed-substitution route and beta-star preservation readback. The former keeps substitution reads at `ClosedAt` preservation, and the latter attaches the one-step beta row B and finite-chain row R without introducing typing or conversion data.

Now apply the kernel ledger boundary. The row K records accepted ClosurePreservation declarations and their dependency ledger only as accounting, not as a hidden semantic proof of subject reduction, confluence, normalization, conversion, host reduction equality, or kernel soundness.

Finally apply the candidate frontier nonescape route. The rows H, C, P, N transport, replay, source, and name the same finite packet, so the candidate-mediated ledger exports only `ClosedAt` preservation for the displayed trace. □

Theorem 795.16 (MetaCICClosureTrace candidate closure forwarding)**.** *Any candidate-mediated consumer forwarding* MetaCICClosureTrace$^{\uparrow}$ *rows into normalization, confluence, subject-reduction, or conversion packets may forward only the displayed* `ClosedAt` *preservation rows* $S, U, V, B, R, G, K, H, C, P, N$ *of an accepted carrier* $T = (S, U, V, B, R, G, K, H, C, P, N)$*. Strong-normalization, confluence, subject-reduction, and conversion-soundness conclusions must be supplied by the downstream candidate packet;* MetaCICClosureTrace$^{\uparrow}$ *contributes no such conclusion by itself.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier candidate closure forwarding`

Proof. First use the substitution-shift generator package of Definition 795.2. It identifies S, U, V, G as generator rows for closedness preservation, not as typing, reduction, or conversion evidence.

Next apply the beta-star preservation readback and the kernel-ledger boundary. The rows B, R replay beta-step and finite-chain closedness preservation, while K records kernel acceptance accounting only inside the same `ClosedAt` ledger.

Finally apply the candidate-mediated closedness ledger of Definition 795.15. Row exhaustion leaves H, C, P, N as transport, replay, provenance, and local naming support, so any stronger normalization, confluence, subject-reduction, or conversion-soundness theorem must enter from the downstream candidate packet. □

Theorem 795.17 (MetaCICClosureTrace candidate closedness interface)**.** *Every candidate-mediated consumer may import* MetaCICClosureTrace$^{\uparrow}$ *only as closedness evidence for shift, substitution, beta-step, finite beta-chain, kernel-ledger accounting, componentwise transport, displayed replay, provenance, and local naming. Any strong-normalization, confluence, subject-reduction, conversion-soundness, or typing conclusion must be supplied by a separate candidate frontier or router packet, not by the closure trace itself.*

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier candidate closedness interface`

Proof. Project the carrier of Definition 795.1. Its displayed rows are exactly $S, U, V, B, R, G, K, H, C, P, N$, so the only theorem rows available to a consumer are shift, substitution, beta-step, finite beta-chain, generator, ledger, transport, replay, provenance, and local-name rows.

Apply the obligation-closure package of Definition 795.8. It identifies those rows as a finite `ClosedAt` preservation surface and refuses typing, confluence, normalization, subject-reduction, conversion-soundness, and kernel-soundness conclusions.

Use the kernel-ledger boundary of Definition 795.7. The row K remains acceptance accounting for ClosurePreservation declarations rather than a hidden semantic premise.

Finally apply the candidate frontier of Definition 795.13 and the candidate-mediated closedness ledger of Definition 795.15. These theorems route candidate-facing consumers through the same closedness rows and require every stronger MetaCIC conclusion to enter from a separate frontier or router packet. □

Theorem 795.18 (MetaCICClosureTrace closed-normalization source order)**.** *Every closed-normalization-facing consumer of an accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *carrier*

$$T = (S, U, V, B, R, G, K, H, C, P, N)$$

must read the displayed source order

$$S, U, V, G \longmapsto B, R \longmapsto K \longmapsto H, C, P, N.$$

The read supplies only closedness preservation for shift, variable substitution, full substitution, one-step beta, finite beta chains, generator rows, kernel-ledger accounting, transport, replay, provenance, and local naming. It refuses subject reduction, arbitrary normalization, quotient term equality, kernel soundness, and any normalization conclusion not already supplied by the downstream candidate packet.

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier closed normalization source order`

Proof. Project the carrier row family $S, U, V, B, R, G, K, H, C, P, N$. The only normalization-facing data available from the trace are the displayed ClosurePreservation rows and their structural support.

Apply the substitution-shift generator package to order S, U, V, G. Apply the beta-star preservation readback to attach B, R as beta closedness rows, and then apply the kernel-ledger boundary to keep K as acceptance accounting rather than semantic soundness.

Finally apply the candidate closure forwarding theorem. It permits forwarding only the displayed `ClosedAt` preservation rows, so closed-normalization consumers must obtain any actual normalization theorem from the downstream candidate packet rather than from this closure trace. □

Theorem 795.19 (MetaCICClosureTrace confluence handoff boundary)**.** *Every confluence-facing handoff from an accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *carrier factors through*

$$S, U, V, B, R, G, K, H, C, P, N.$$

The handoff may cite the substitution generator package, beta-star preservation readback, kernel-ledger boundary, and candidate-mediated closedness ledger, but it exports no global confluence theorem, no subject-reduction theorem, no quotient term equality, no arbitrary normalization theorem, and no kernel-soundness premise.

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier confluence handoff boundary`

Proof. Start with a confluence-facing consumer. Carrier projection exposes only the five closure theorem rows, the generator row, the kernel ledger, and the structural rows.

Use the substitution beta-chain boundary to combine S, U, V, G with B, R while staying inside `ClosedAt` preservation. Use the obligation-closure forwarder to route the same rows through K, H, C, P, N.

The candidate closure forwarding theorem is the final boundary. It allows the closedness trace to be forwarded into a confluence packet, but it does not let the trace itself assert global confluence, quotient equality of terms, subject reduction, arbitrary normalization, or kernel soundness. □

Theorem 795.20 (MetaCICClosureTrace decidability readback frontier)**.** *Every decidability-facing readback from an accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *carrier is confined to the displayed rows*

$$S, U, V, B, R, G, K, H, C, P, N.$$

It may read closedness preservation, generator accounting, kernel acceptance accounting, componentwise transport, displayed replay, provenance, and local naming. It may not read decidable conversion, decidable typing, quotient term equality, global confluence, arbitrary normalization, subject reduction, or kernel soundness from the closure trace.

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier decidability readback frontier`

Proof. Project the carrier. No row of Definition 795.1 stores a decidability theorem, a conversion classifier, a typing classifier, quotient term equality, or kernel soundness.

Apply the NameCert obligations and kernel-ledger boundary. They identify K, H, C, P, N as ledger, transport, replay, provenance, and naming rows for the displayed ClosurePreservation declarations only.

Apply the candidate-mediated closedness ledger and candidate closure forwarding results. They allow a decidability-facing packet to consume closedness preservation as input data, but the decidability readback frontier remains the displayed row family; any decidability conclusion must be supplied by the consumer packet. □

Theorem 795.21 (MetaCICClosureTrace obligation status registration)**.** *For every accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *carrier* $T = (S, U, V, B, R, G, K, H, C, P, N)$*, the substitution-shift package of Definition 795.2, the beta-star preservation readback of Definition 795.4, the local NameCert obligations of Definition 795.5, the kernel-ledger boundary of Definition 795.7, the candidate frontier of Definition 795.13, and the decidability readback frontier of Definition 795.20 form the paper obligation surface for the closure trace.*

This surface registers only shift closedness, variable-substitution closedness, full-substitution closedness, one-step beta closedness, finite beta-chain closedness, generator readback, kernel-acceptance accounting, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming. It refuses subject reduction, confluence, normalization, conversion soundness, and kernel soundness.*

Proof. Read the substitution side first. The substitution-shift package identifies S, U, V, G as the finite generator surface for shift and substitution closedness, so no typing or conversion premise is introduced at the entry point.

Attach the beta-chain readback. The beta-star preservation theorem adds B, R only as one-step and finite-chain `ClosedAt` rows, while the NameCert obligations place those rows inside carrier admission, transport, replay, provenance, and local naming.

Use the kernel-ledger boundary and candidate frontier to order the remaining route. The row K remains acceptance accounting for displayed ClosurePreservation declarations, and the candidate frontier forces normalization-facing, confluence-facing, and conversion-facing consumers to pass through the same finite row family before asking any downstream packet for stronger evidence.

Finally apply the decidability readback frontier. It keeps decidability-facing reads inside $S, U, V, B, R, G, K, H, C, P, N$ and requires any decidable conversion, decidable typing, quotient term equality, confluence, normalization, subject reduction, conversion soundness, or kernel soundness conclusion to arrive from another packet. Thus the named results jointly register the paper obligation surface without asserting the stronger MetaCIC theorems. □

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier obligation status registration`

Theorem 795.22 (MetaCIC closure trace public boundary)**.** *Any public consumer of an accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *packet must display the ClosurePreservation row family, the substitution row family, the beta-chain row, the kernel-trace row, the candidate-mediated strong-normalization row, the confluence row, and the decidability row before exporting the trace. Concretely, the consumer must read* S, U, V *for shift and substitution closedness,* B, R *for one-step beta and finite beta chains,* G *for generator accounting,* K *for the kernel-acceptance trace, the candidate frontier for strong-normalization-facing reads, the confluence handoff boundary, and the decidability readback frontier, then preserve the whole packet through* H, C, P, N*.*

The public export is a closure-trace boundary only. It does not prove subject reduction, full normalization, kernel soundness, confluence, decidable conversion, decidable typing, or Lean verification for the whole packet.

Proof. Project the carrier of Definition 795.1. The visible rows are the ClosurePreservation theorem rows, generator accounting, kernel ledger, transport, replay, provenance, and local naming; no row stores subject reduction, full normalization, kernel soundness, or a global confluence theorem.

Apply the substitution-shift generator package and beta-star preservation readback. These results expose S, U, V, G and B, R as closedness-preservation data only, so the public route begins with the displayed substitution and beta-chain rows rather than with a typing or conversion theorem.

Use the kernel-ledger boundary, candidate-mediated closedness ledger, confluence handoff boundary, and decidability readback frontier. They force normalization-facing, confluence-facing, and decidability-facing consumers to pass through the same finite row family before asking a downstream packet for stronger evidence.

Finally apply obligation status registration. It assembles the ClosurePreservation, substitution, beta-chain, kernel-trace, candidate-mediated strong-normalization, confluence, and decidability routes into the public paper boundary while preserving the refusal of subject reduction, full normalization, kernel soundness, and Lean verification. □

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier public boundary`

Theorem 795.23 (MetaCICClosureTrace candidate-mediated SN source scope)**.** *Any candidate-mediated strong-normalization source read exported by an accepted* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *carrier* $T = (S, U, V, B, R, G, K, H, C, P, N)$ *factors through the closed-substitution boundary, the candidate closedness ledger, the confluence handoff boundary, the decidability readback frontier, component-wise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows.*

Concretely, the source read may forward only the displayed closedness-preservation rows for shift, variable substitution, full substitution, one-step beta, finite beta chains, generator accounting, and kernel acceptance. It may then pass those rows to a separate candidate packet through the candidate-mediated closedness ledger of Definition 795.15, the confluence handoff boundary of Definition 795.19, and the decidability readback frontier of Definition 795.20. The export does not claim full subject reduction, global strong normalization, kernel soundness, unrestricted confluence, decidable conversion, decidable typing, or quotient term equality.

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier candidate sn source scope`

Proof. Project the carrier of Definition 795.1. Its rows are the substitution and beta closedness-preservation rows S, U, V, B, R, the generator and kernel-ledger rows G, K, and the structural rows H, C, P, N.

Use the closed-substitution route and candidate-mediated closedness ledger. They order the substitution rows, beta rows, generator row, and kernel ledger as closedness evidence only; no row in that sequence stores subject reduction or a normalization theorem.

Next use the confluence handoff boundary and decidability readback frontier. These results allow the same closedness surface to be forwarded into confluence-facing and decidability-facing consumers, while requiring any confluence, conversion, typing, or normalization conclusion to come from a separate packet.

Finally transport and name the export through H, C, P, N. The source scope is therefore exactly the displayed closure-trace route available to candidate-mediated consumers, and the excluded subject-reduction, global-normalization, kernel-soundness, confluence, decidability, and quotient-equality claims remain outside the carrier. □

Theorem 795.24 (MetaCICClosureTrace public bridge obligation)**.** *Any standard bridge for the public* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *boundary must preserve exactly the displayed public rows of Definition 795.22: ClosurePreservation rows, substitution rows, beta-chain rows, kernel-trace accounting, candidate-mediated normalization-facing rows, confluence-facing rows, decidability-facing rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. The bridge obligation may not import subject reduction, type preservation, full normalization, kernel soundness, confluence, decidable conversion, decidable typing, quotient term equality, or any stronger MetaCIC theorem as an unrecorded premise.*

Proof. Start from the public boundary theorem, Definition 795.22. It lists the rows that a public consumer may inspect before exporting the closure trace.

Use obligation status registration, Definition 795.21. That theorem registers the paper obligation surface as closedness, generator accounting, kernel acceptance accounting, transport, replay, provenance, and naming, while refusing subject reduction, confluence, normalization, conversion soundness, and kernel soundness.

The bridge obligation is therefore a preservation boundary for those public rows. A future bridge can check that the displayed rows survive the bridge schema, but it cannot strengthen the carrier by importing typing, confluence, normalization, or kernel-soundness evidence from outside the packet. □

Lean4 ✓ `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier public bridge obligation`

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICClosureTrace}^{\uparrow}}$.

Constructive story: A MetaCICClosureTrace$^{\uparrow}$ packet is generated from five MetaCIC ClosurePreservation theorem rows, shift and substitution generator-closure rows, kernel-acceptance trace rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MetaCICClosureTrace}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 795.2, Definition 795.4, Definition 795.5, and Definition 795.7 bind the checked substitution-shift, beta-star, NameCert-obligation, and kernel-ledger rows as the paper-side bridge surface for the displayed closure-trace packet.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICClosureTrace}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.MetaCICClosureTraceUp.MetaCICClosureTraceCarrier\_obligation\_closure\_package`

Bridge status: none

Not claimed: This chapter does not prove subject reduction, type preservation, full normalization, kernel soundness, checked Lean carrier obligations, or a public bridge for the closure-trace packet.

Upgrade path: A bridge grade requires a checked standard bridge for the same public closure-trace boundary, while subject reduction, full normalization, and kernel soundness remain separate packets.

Chapter 796

A Concrete Naming Certificate for $\mathsf{SubjectReductionRouteTriangle}^{\uparrow}$

The $\mathsf{SubjectReductionRouteTriangle}^{\uparrow}$ packet realizes the discharge-route triangle of chapter 9374 as finite NameCert data. It sits beside the route certificate of chapter 718 and the preservation packet of chapter 483: the first names the discharge rows, the second names the subject-reduction endpoint, and this chapter records the bundle route, endpoint, and obstruction boundary in one visible packet.

Definition 796.1 (Subject-reduction route-triangle carrier)**.** *A* $\mathsf{SubjectReductionRouteTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, E, O, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the explicit discharge bundle row carrying the four subject-reduction discharge obligations;*
2. *E is the represented* $\mathsf{SubjectReduction}^{\uparrow}$ *endpoint row reached only after the discharge payload has been displayed;*
3. *O is the obstruction row recording the present closed-CIC non-inhabitation boundary for the missing discharge hypotheses;*
4. *L is the route-ledger row, recording that the consumer entered through B directly;*
5. *H records componentwise* hsame *transports for the bundle, endpoint, obstruction, ledger, provenance, and local name;*
6. *C records displayed* Cont *routes from the bundle row to the endpoint and from the obstruction row to the route ledger;*
7. *P is the* Pkg *provenance over chapter 9374, chapter 718, and chapter 483;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteTriangle}^{\uparrow}}$ *row.*

The carrier is only this finite triangle packet. It contains no inhabitant of the missing discharge hypotheses, no closed subject-reduction theorem for the present closed-CIC substrate, no host conversion rule, and no route outside the displayed bundle, obstruction, and ledger rows.

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteTriangleUp.SubjectReductionRouteTriangleTasteGate`
`single carrier alignment`

Theorem 796.2 (SubjectReductionRouteTriangle bundle projection)**.** *Every accepted* SubjectReductionRouteTrian *carrier projects an explicit discharge-bundle route*

$$B, H, C, P, N$$

whose payload is the same four-row discharge surface consumed by chapter 718. This projection may be read as a bundle-facing handoff to the represented $\mathsf{SubjectReduction}^{\uparrow}$ *endpoint* E*, but it does not certify that the four discharge rows are inhabited for the present closed-CIC substrate.*

Proof. Project the carrier $T = (B, E, O, L, H, C, P, N)$ to its bundle coordinate. The row B is already a displayed packet row, and the transport, route, provenance, and local naming coordinates H, C, P, N preserve that row as finite NameCert data.

The sibling discharge chapter supplies the semantic boundary for the four discharge obligations. Reading B through chapter 718 therefore exposes the obligation surface, not an inhabitant of the obligations.

Finally pass to E only through the displayed continuation row. Since the carrier also keeps the obstruction row O, the projection cannot be confused with a closed subject-reduction theorem for the present substrate. □

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteTriangleUp.SubjectReductionRouteTriangle bundle projection`

Theorem 796.3 (SubjectReductionRouteTriangle obstruction boundary)**.** *In every accepted* SubjectReductionRout *carrier, the obstruction row* O *separates route transport from discharge inhabitation. The packet may expose the bundle projection and the represented* $\mathsf{SubjectReduction}^{\uparrow}$ *endpoint row, but any consumer that asks whether the present closed-CIC substrate supplies the four missing discharge hypotheses must read* O *and cannot replace it by* B *or* E*.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteTriangleUp.SubjectReductionRouteTriangle obstruction boundary`

Proof. Read the triangle inventory. The bundle row, endpoint row, and obstruction row are separate coordinates of T.

The projection theorem identifies the route available to a consumer. It transports the four-field payload to the represented endpoint row, while it does not claim an inhabitant for the present closed-CIC discharge obligations.

It remains to inspect the obstruction coordinate. The route ledger records that the bundle route was used, and O records the boundary at which the closed-CIC substrate still lacks the required inhabitants. Since O is not definitionally one of B, E, no consumer can erase that boundary by choosing a route. □

Theorem 796.4 (SubjectReductionRouteTriangle NameCert obligations)**.** *For the carrier of Definition 796.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteTriangle}^{\uparrow}}$ *surface has four rows:*

1. *the explicit discharge bundle row* B*;*
2. *the represented subject-reduction endpoint row* E*;*
3. *the obstruction and non-inhabitation boundary row* O*;*
4. *the route ledger row* L*, transported and replayed through* H, C, P, N*.*

These four rows exhaust the public route-triangle certificate. The certificate names how bundle access reaches the subject-reduction endpoint and where the present obstruction remains, without adding host conversion, hidden discharge evidence, erased derivation semantics, quotient equality of MetaCIC terms, or a closed subject-reduction theorem.

Proof. First expose the carrier row by row. The rows B, E, O, L are the finite data being certified, while H, C, P, N provide transport, route replay, provenance, and local naming for exactly those rows.

The four-row sketch follows by grouping the carrier coordinates by their route role. The bundle row gives the direct route, the endpoint row records the represented preservation consumer, the obstruction row records the missing-inhabitant boundary, and the ledger records that the bundle route has been followed.

The sibling chapters supply the boundary checks. The discharge packet of chapter 718 fixes the obligation surface, and the subject-reduction packet of chapter 483 fixes the endpoint surface. Since no other coordinate appears in T, the listed rows exhaust the local NameCert obligations and leave the excluded objects outside the packet. □

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteTriangleUp.SubjectReductionRouteTriangle namecert obligations`

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteTriangle}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionRouteTriangle}^{\uparrow}$ packet is generated from an explicit discharge bundle row, a represented subject-reduction endpoint, an obstruction boundary row, a route ledger, componentwise hsame transports, displayed Cont routes, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionRouteTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 796.1, Definition 796.2, Definition 796.3, and Definition 796.4 bind the finite route triangle over the bundle, endpoint, obstruction, and ledger rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionRouteTriangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not inhabit the four MetaCIC discharge obligations, prove closed subject reduction, verify the route triangle in Lean, or bridge the packet to a public schema.

Upgrade path: Obligation closure requires checked carrier admission, bundle projection, obstruction separation, route-ledger exactness, provenance, and local naming for the same finite route-triangle packet.

Chapter 797

A Concrete Naming Certificate for $\mathsf{ClosedBetaPath}^{\uparrow}$

The $\mathsf{ClosedBetaPath}^{\uparrow}$ packet realizes the closure-preservation audit map of chapter 9381 as a finite NameCert route object. It sits between the beta inventory of chapter 761, the normal-form seal of chapter 740, and the closed-normal main-result packet of chapter 764: it names the route by which closedness travels along finite beta movement before those downstream packets read any closed-normal or beta-audit rows.

Definition 797.1 (Closed beta path carrier)**.** *A* $\mathsf{ClosedBetaPath}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (s, t, n, B, K, H, C, P, N)$$

with the following displayed rows:

1. *s is the source MetaCIC term row;*
2. *t is the target MetaCIC term row;*
3. *n is the closedness-depth row for the displayed* ClosedAt *boundary;*
4. *B is the finite* $\mathrm{BetaStarStep}(s, t)$ *route row, whose one-step edges are* BetaStep *constructors;*
5. *K is the closure-preservation witness row naming the* $\mathsf{BEDC.MetaCIC.betaStarStep_preserves_closed}$ *route from* $\mathrm{ClosedAt}(n, s)$ *to* $\mathrm{ClosedAt}(n, t)$*;*
6. *H records componentwise* hsame *transport for the source, target, depth, beta-route, closure-witness, provenance, and naming rows;*
7. *C records the displayed* Cont *replay routes by which a consumer reads B and then K;*
8. *P is the* Pkg *provenance over* ClosedAt, BetaStep, BetaStarStep, shift, $\mathsf{substitute}$, *componentwise transport, and sibling NameCert packets;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBetaPath}^{\uparrow}}$ *row.*

The carrier has no coordinate for typing preservation, normalization, confluence, beta conversion, or closed consistency.

Lean4 ✓ `BEDC.Derived.ClosedBetaPathUp.ClosedBetaPathTasteGate single carrier alignment`

Theorem 797.2 (Closed beta path NameCert obligations)**.** *For an accepted* $\mathsf{ClosedBetaPath}^{\uparrow}$ *carrier*

$$Q = (s, t, n, B, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedBetaPath}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the displayed finite packet;*
2. *preservation of* $\mathrm{ClosedAt}(n, \cdot)$ *along the finite beta route* B *through the witness row* K*;*
3. *exact replay of the route order by first reading* B *and then reading* K *through the displayed continuation rows;*
4. *non-escape from typing, normalization, confluence, beta-conversion, and closed-consistency claims not present in the carrier;*
5. *ledger exactness for* $s, t, n, B, K, H, C, P, N$ *and no hidden route coordinate.*

Proof. Carrier admission is the packet of Definition 797.1. The admitted route row B supplies the finite beta chain, and the witness row K supplies the closedness transport for exactly that chain.

Continuation replay is ordered by the carrier itself: a consumer first reads the beta-star route and then reads the closure witness. Componentwise transport through H preserves the same source, target, depth, route, witness, provenance, and naming rows.

The remaining coordinates are structural provenance and naming rows. Since no coordinate carries typing preservation, normalization, confluence, beta conversion, or closed consistency, the five displayed obligations exhaust the local NameCert surface. □

Theorem 797.3 (Closed beta path closure-preservation factorization)**.** *Every consumer of an accepted* $\mathsf{ClosedBetaPath}^{\uparrow}$ *packet that later reads a closed-normal packet, a normal-form consistency seal, a closed-normal main packet, or a beta-audit packet must first factor its closedness read through the* BEDC.MetaCIC.betaStarStep_preserves_closed *route named by* K*. The consumer may then pass the transported closed endpoint to the sibling packet it cites, but it cannot use* $\mathsf{ClosedBetaPath}^{\uparrow}$ *as a typing, normalization, confluence, beta-conversion, or consistency certificate.*

Proof. Project the accepted packet Q. The only row that exports closedness at the target endpoint is K, and K is tied to the displayed beta-star route B. Thus every closedness read from s to t passes through the same closure-preservation route.

The sibling packets cited by the consumer have their own carriers and local NameCert rows. The present packet can hand them the transported closed endpoint only after B and K have been replayed through C and accounted for by P, N.

Because the carrier lacks rows for typing preservation, normalization, confluence, beta conversion, and consistency, the factorization cannot be strengthened into any of those claims. □

↪variant `BEDC.MetaCIC.betaStarStep preserves closed`

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedBetaPath}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClosedBetaPath}^{\uparrow}$ packet is generated from a source term, target term, closedness depth, finite BetaStarStep route, beta-star closedness-preservation witness, componentwise hsame transports, displayed Cont replay routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClosedBetaPath}^{\uparrow}}$, obligation)

Scope closed: Definition 797.1, Definition 797.2, and Definition 797.3 bind the finite closed-beta-route carrier, its five local NameCert obligations, and its closure-preservation factorization boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClosedBetaPath}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.MetaCIC.betaStarStep\_preserves\_closed`

Bridge status: none

Origin: human

Not claimed: This chapter does not close MetaCIC subject reduction, normalization, confluence, beta conversion, full closed consistency, or a public standard bridge.

Upgrade path: Scoped closure requires checked carrier admission, route replay exactness, ledger exactness, and non-escape for the same finite closed beta path packet.

Chapter 798

A Concrete Naming Certificate for $\mathsf{SubjectReductionRouteChoice}^{\uparrow}$

The $\mathsf{SubjectReductionRouteChoice}^{\uparrow}$ packet records the finite choice point between explicit bundle consumption and the checked obstruction ledger of chapter 9374. It reads the discharge bundle surface of chapter 718, the socket boundary of chapter 719, and the downstream subject-reduction consumer of chapter 483; it does not choose or discharge the missing closed-CIC obstruction.

Definition 798.1 (SubjectReductionRouteChoice carrier)**.** *A* $\mathsf{SubjectReductionRouteChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, V, O, H, C, P, N)$$

with the following displayed rows:

1. *B is the explicit bundle row naming the* SubjectReductionDischargeBundle *shape and its four discharge coordinates;*
2. *V is the bundle-consumption row corresponding to* subject_reduction_from_bundle*;*
3. *O is the obstruction-boundary row stating that neither route is inhabited for the present closed-CIC substrate inside this packet;*
4. *H records componentwise* hsame *transports for the bundle, consumption, obstruction, provenance, and naming rows;*
5. *C records the displayed* Cont *routes by which consumers read the bundle route, the obstruction row, the subject-reduction socket, and the subject-reduction packet;*
6. *P is the* Pkg *provenance over chapter 9374, chapter 718, chapter 719, and chapter 483;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteChoice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and the visible transport and continuation routes.

Theorem 798.2 (SubjectReductionRouteChoice obligations)**.** *For the carrier of Definition 798.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteChoice}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$R = (B, V, O, H, C, P, N),$$

route visibility for B, V, obstruction-boundary visibility for O, componentwise transport through H, displayed continuation reads through C, provenance through P, and local naming through N.

Lean4 ✓ BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceObligations

Proof. Project the displayed carrier. The rows B, V are the only route rows, and the row O is the only obstruction-boundary row.

Transport and replay are then read through H and C. These rows preserve the displayed carrier coordinates and do not create a discharge coordinate outside R.

Finally, P and N account for the finite provenance and local name. Hence the listed rows exhaust the NameCert obligations for the route-choice packet. □

Theorem 798.3 (SubjectReductionRouteChoice obligation surface)**.** *For an accepted* SubjectReductionRouteChoice *carrier $R = (B, V, O, H, C, P, N)$, the obligation surface exposes the explicit bundle row B, the bundle-consumption row V, the obstruction-boundary row O, the componentwise* hsame *row H, the displayed* Cont *row C, the package provenance row P, and the local naming row N. The same finite route is read through the discharge bundle surface, the socket boundary, and the downstream subject-reduction consumer of the sibling chapters.*

Lean4 ✓ BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceObligationSurface

Proof. Project the carrier of Definition 798.1. The bundle row, bundle-consumption row, obstruction row, transport row, replay row, provenance row, and local name are all visible coordinates of one finite packet.

The discharge bundle and socket boundary are not hidden behind the packet: they are the sibling surfaces that motivate the route-choice rows already displayed in B, V, O. The accepted carrier therefore exposes the same finite route before any downstream consumer can read it.

Since the carrier has no coordinate for closed-CIC discharge, hidden route choice, or host proof search, the displayed rows exhaust the obligation surface. □

Theorem 798.4 (SubjectReductionRouteChoice route-obligation surface)**.** *For an accepted* SubjectReductionRoute *carrier $R = (B, V, O, H, C, P, N)$, every route-obligation read exposes exactly the bundle row B and the bundle-consumption row V while retaining the obstruction row O as a visible boundary. The transport, replay, provenance, and naming rows H, C, P, N may preserve and replay only those displayed rows.*

Thus the route-obligation surface exports no closed subject-reduction theorem, quotient syntax equality, host evaluator soundness, hidden typeclass route, or third discharge path.

Proof. Project the carrier of Definition 798.1. The route-facing rows are B, V, the obstruction-facing row is O, and the structural rows are H, C, P, N.

Apply the obligation-surface theorem Definition 798.3. It exhausts the visible rows of the packet before any downstream consumer reads the route choice.

Use the obstruction-boundary theorem Definition 798.12. It keeps O separate from the bundle-consumption route, so an uninhabited obstruction cannot be reclassified as a closed subject-reduction proof.

Finally apply nonescape Definition 798.6 and obstruction-route exhaustion Definition 798.13. These rule out a hidden typeclass route, quotient syntax equality, host evaluator soundness, closed consistency, and any third discharge path. □

Lean4 ✓ BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceRouteObligationSurface

Theorem 798.5 (SubjectReductionRouteChoice MetaCIC scope)**.** *Every accepted* $\mathsf{SubjectReductionRouteChoice}^{\uparrow}$ *read remains inside the MetaCIC route of the discharge bundle, socket boundary, substitution/type-preservation rows, and the downstream subject-reduction consumer. The route may cite the sibling surfaces of chapter 718, chapter 719, and chapter 483, but it does not claim closed-CIC discharge or host proof search.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceCarrier metacic scope`

Proof. Use the obligation surface theorem above. It identifies the displayed rows and binds them to the finite route-choice packet before any consumer may proceed.

The sibling discharge and socket chapters provide the finite MetaCIC support surface, while the subject-reduction consumer chapter names the downstream use site. Because the packet has no coordinate for closed-CIC discharge or host proof search, those claims remain outside the scope. □

Theorem 798.6 (SubjectReductionRouteChoice nonescape)**.** *For an accepted* $\mathsf{SubjectReductionRouteChoice}^{\uparrow}$ *carrier* $R = (B, V, O, H, C, P, N)$*, no consumer can extract closed-CIC discharge, hidden route choice, or host proof search from the packet. The accepted route-choice data remain exactly the displayed bundle, consumption, obstruction, transport, replay, provenance, and local naming rows.*

Proof. Project the carrier. The route-choice packet consists exactly of the displayed rows B, V, O, H, C, P, N.

Apply the MetaCIC scope theorem of Definition 798.5. It keeps the route inside the sibling discharge, socket, substitution, and consumer surfaces.

Since no extra coordinate is present, the packet cannot export closed-CIC discharge, hidden route choice, or host proof search. □

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceCarrier nonescape`

Theorem 798.7 (SubjectReductionRouteChoice substitution stability)**.** *For an accepted* SubjectReductionRouteCh *carrier* $R = (B, V, O, H, C, P, N)$*, a MetaCIC worker may read substitution stability only as a finite route-choice obligation over the displayed* BHist *packet. The obligation exposes the bundle row* B*, the bundle-consumption row* V*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, and the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteChoice}^{\uparrow}}$ *row* N*.*

It states that substitution-facing reads must preserve the same route-choice rows before any subject-reduction discharge is consumed. It does not assert unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or closed consistency.

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceSubstitutionStability`

Proof. Project the carrier of Definition 798.1. The only rows available to a substitution-facing consumer are the explicit bundle row B, the consumption row V, the obstruction boundary O, transport H, continuation C, provenance P, and naming N.

Apply the NameCert obligations of Definition 798.2. They require every read to keep route visibility for B, V, obstruction visibility for O, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Thus substitution stability is an obligation to preserve the displayed route-choice surface. Since the carrier has no quotient syntax-equality row, no host evaluator row, and no closed-consistency coordinate, no global MetaCIC theorem follows from this packet. □

Theorem 798.8 (SubjectReductionRouteChoice type-preservation window)**.** *For an accepted* SubjectReductionRou *carrier* $R = (B, V, O, H, C, P, N)$*, every bounded type-preservation window exposed to a MetaCIC worker is a finite* BHist *read through* B, V, H, C, P, N *with the obstruction row* O *still visible. The window records which discharge bundle route may be consumed and how* hsame *and* Cont *replay preserve that route inside the local* NameCert *surface.*

The window is not a proof of full subject reduction. It exports no unrestricted reduction theorem, quotient syntax equality, host evaluator soundness, or closed consistency claim.

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceTypePreservationWindow`

Proof. Start from the accepted carrier. The route rows B, V identify the discharge bundle surface and its consumption route, while O records the boundary where the present substrate has not supplied the missing closed-CIC discharge.

The transport and continuation rows H, C keep the bounded read inside the same finite packet. The provenance and naming rows P, N then record that the worker is using the local $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteChoice}^{\uparrow}}$ surface rather than a detached evaluator theorem.

Consequently the type-preservation window is bounded by the displayed rows. It can tell a worker where a discharge bundle would be consumed, but it cannot export full subject reduction or any of the refused host-side principles. □

Theorem 798.9 (SubjectReductionRouteChoice blocked-edge nonescape)**.** *For an accepted* SubjectReductionRoute *carrier* $R = (B, V, O, H, C, P, N)$*, every blocked subject-reduction edge remains inside the obstruction row* O *and the finite replay rows* H, C, P, N*. A downstream MetaCIC worker may cite the edge only as a visible blocked route in the same* BHist *packet and must keep the local* $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteChoice}^{\uparrow}}$ *row attached.*

No blocked edge escapes as unrestricted subject reduction, quotient syntax equality, host evaluator soundness, closed consistency, or an inhabited discharge bundle.

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceBlockedEdgeNonescape`

Proof. Inspect the obstruction boundary in Definition 798.1. The row O is separate from the route rows B, V, so a blocked edge cannot be reclassified as an inhabited discharge route.

The NameCert obligations of Definition 798.2 keep every read under componentwise hsame transport, displayed Cont replay, provenance, and local naming. These rows preserve the blocked-edge status instead of creating a new discharge coordinate.

Therefore a downstream worker can use the blocked edge as finite route-choice information only. The refused global subject-reduction, quotient-equality, evaluator-soundness, and closed-consistency claims remain outside the packet. □

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceCarrier blocked edge nonescape`

Theorem 798.10 (SubjectReductionRouteChoice bundle-route exhaustion)**.** *Every consumer read of an accepted* $\mathsf{SubjectReductionRouteChoice}^{\uparrow}$ *packet reaches exactly one public route surface: the explicit bundle surface* B, V*. That surface exposes the four discharge coordinates named by the subject-reduction discharge interface, and no second route, hidden instance, or host conversion rule is exported by the packet.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceBundleRouteExhaustion`

Proof. Inspect the route coordinates in Definition 798.1. The explicit route is the pair B, V.

Since every consumer read factors through C and every transported read factors through H, no route coordinate outside the displayed bundle surface is available. □

Theorem 798.11 (SubjectReductionRouteChoice constructor exhaustion)**.** *Every accepted* SubjectReductionRoute *route-choice read is generated by exactly one displayed carrier packet $R = (B, V, O, H, C, P, N)$. Each consumer path is either the explicit bundle route through B, V with the obstruction row O still visible, or the blocked-edge route through O with B, V preserved as non-inhabited route data.*

Proof. Project the carrier rows of Definition 798.1. The displayed packet has exactly the route rows B, V, the obstruction row O, and the structural rows H, C, P, N.

Case-split on the public route surface versus the obstruction surface. In the first case, apply Definition 798.10: the consumer reaches the explicit bundle route B, V, while O remains a visible boundary row. In the second case, apply Definition 798.12: the read stops at O and keeps B, V only as route data not inhabited by the present substrate.

Finally use Definition 798.6. The rows H, C, P, N transport and replay only those displayed coordinates, so no hidden instance, host conversion rule, quotient syntax equality, evaluator soundness, or closed consistency claim is exported. □

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceConstructorExhaustion`

Theorem 798.12 (SubjectReductionRouteChoice obstruction boundary)**.** *The* SubjectReductionRouteChoice$^{\uparrow}$ *packet keeps the obstruction row O separate from the route rows. It may record that a downstream substrate can use the explicit bundle route, but it does not supply an inhabited* SubjectReductionDischargeBundle*, a proof of the dependent-codomain discharge row, or a closed subject-reduction theorem for the present substrate.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceObstructionBoundary`

Proof. Read the carrier rows in order. The route rows B, V name how a discharge would be consumed once supplied, while O names the boundary where the present substrate lacks the required discharge.

The provenance row ties this boundary to the discharge, socket, and subject-reduction chapters. Those references identify the finite interfaces, not inhabitants of the missing closed-CIC discharge.

Therefore the packet can expose the route choice to downstream audits while keeping closed subject reduction outside its exported surface. □

Theorem 798.13 (SubjectReductionRouteChoice obstruction-route exhaustion)**.** *Every accepted* SubjectReductionRouteChoice$^{\uparrow}$ *packet read factors through exactly one of the displayed bundle-consumption route B, V or the displayed obstruction row O, and both routes are transported only by the structural rows H, C, P, N. No third route, hidden typeclass instance, closed-CIC discharge, quotient syntax equality, host evaluator soundness, or closed consistency claim is exported by the packet.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceObstructionRouteExhaustio`

Proof. Project the carrier rows from Definition 798.1. The route-facing coordinates are B, V, the obstruction-facing coordinate is O, and all remaining rows are transport, replay, provenance, and local naming data.

Apply Definition 798.10. Any consumer that reads the displayed bundle route reaches the explicit surface B, V and no hidden instance or host conversion rule.

Apply Definition 798.12. Any consumer that does not receive an inhabited bundle route remains at the obstruction row O, where the closed-CIC discharge and closed subject-reduction theorem are not supplied.

Finally use Definition 798.6. The structural rows H, C, P, N preserve only the displayed bundle and obstruction coordinates, so quotient syntax equality, evaluator soundness, closed consistency, and any third route remain outside the packet. □

Theorem 798.14 (SubjectReductionRouteChoice confluence nonescape)**.** *Any confluence or subject-reduction consumer reading an accepted* SubjectReductionRouteChoice$^{\uparrow}$ *packet must keep the explicit bundle rows B, V, the obstruction row O, and the structural rows H, C, P, N visible. Thus local confluence, closed subject reduction, quotient syntax equality, evaluator soundness, and closed consistency cannot escape the route-choice boundary.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceConfluenceNonescape`

Proof. Start with the bundle route. By Definition 798.10, any consumer that reaches the displayed discharge route sees only the explicit rows B, V and no hidden instance or host conversion rule.

Next read the obstruction boundary. By Definition 798.12 and Definition 798.13, a consumer that lacks an inhabited bundle remains at the row O, while the structural rows H, C, P, N only transport and replay the same finite choice.

Finally apply Definition 798.6. Since every route is exhausted by B, V, O, H, C, P, N, no confluence, closed subject-reduction, quotient-equality, evaluator-soundness, or closed-consistency claim is exported from the packet. □

Theorem 798.15 (SubjectReductionRouteChoice vision handoff)**.** *The formal route of chapter 9374 is realized as the finite* SubjectReductionRouteChoice$^{\uparrow}$ *carrier of Definition 798.1. The handoff consists of the explicit bundle row, the consumption row, the obstruction-boundary row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceVisionHandoff`

Proof. The vision chapter exposes the bundle route and the checked obstruction ledger. The carrier mirrors that boundary by placing B, V and O in separate displayed rows.

The route-choice packet also records O, so the handoff is not read as a closed subject-reduction proof for the present substrate. Consumers can cite the finite choice surface and must still obtain discharge data elsewhere. □

Theorem 798.16 (SubjectReductionRouteChoice TasteGate obligation handoff)**.** *Any obligation-closure read of* SubjectReductionRouteChoice$^{\uparrow}$ *must first expose the* TasteGate *single-carrier alignment row, the route-choice carrier rows B, V, O, H, C, P, N, and the MetaCIC obstruction rows consumed by the packet. The read is therefore a finite alignment and obstruction handoff; it is not a hidden subject-reduction discharge, quotient syntax equality, evaluator soundness theorem, or closed consistency claim.*

Proof. Start with the carrier of Definition 798.1. It displays the bundle route rows B, V, the obstruction row O, and the structural rows H, C, P, N as one packet.

Next use the obstruction boundary and route-exhaustion theorems, Definition 798.12 and Definition 798.13. They force every accepted consumer to choose between the displayed bundle route and the displayed obstruction row, with no third discharge channel.

Finally read the checked TasteGate alignment row. Since the alignment names the same single-carrier packet, an obligation-closure consumer must keep the route-choice rows and the MetaCIC obstruction rows visible before any later closure step can be claimed. □

Lean4 ✓ `BEDC.Derived.SubjectReductionRouteChoiceUp.SubjectReductionRouteChoiceTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{SubjectReductionRouteChoice}^{\uparrow}}$.

Constructive story: A $\mathsf{SubjectReductionRouteChoice}^{\uparrow}$ packet is generated from explicit bundle, bundle-consumption, obstruction-boundary, transport, continuation, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubjectReductionRouteChoice}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 798.1, Definition 798.2, Definition 798.3, Definition 798.5, Definition 798.6, Definition 798.9, Definition 798.10, Definition 798.12, and the checked TasteGate alignment row bind the finite route-choice obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubjectReductionRouteChoice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not discharge the four MetaCIC subject-reduction obligations, construct an inhabited discharge bundle, prove closed subject reduction, or give Lean verification of the route-choice packet.

Upgrade path: Scoped closure requires binding the route-choice obligations to the discharge bundle, socket boundary, subject-reduction consumer, and obstruction rows.

Chapter 799

A Concrete Naming Certificate for $\mathsf{ClosedNormalCanonicity}^{\uparrow}$

The $\mathsf{ClosedNormalCanonicity}^{\uparrow}$ packet turns the false-endpoint boundary of chapter 9376 into a finite NameCert surface. It is downstream of the main-result certificate in chapter 764, the closed-normal consistency packet of chapter 736, and the packet boundary of chapter 739. These siblings expose the closed beta-strong false endpoint and the subject-reduction gap; the present packet records the canonicity read that excludes hidden endpoint escape without claiming full closed consistency.

Definition 799.1 (Closed-normal canonicity carrier)**.** *A* $\mathsf{ClosedNormalCanonicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, L, B, F, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the empty-context* HasType *row for the closed candidate at the displayed false encoding;*
2. *L is the* ClosedAt *row for the same candidate and false encoding;*
3. *B is the* BetaStrong *row saying the candidate is already at the closed normal boundary;*
4. *F names the false endpoint whose inhabitants are being excluded;*
5. *E is the endpoint-exclusion row consumed from the checked closed-normal beta-strong false boundary;*
6. *H records componentwise* hsame *transports for the typing, closedness, beta-strong, false-endpoint, and exclusion rows;*
7. *C records the displayed* Cont *routes from T, L, B, F to E and from E to the public read;*
8. *P records* Pkg *provenance over the main-result chapter and its closed-normal consistency packet siblings;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalCanonicity}^{\uparrow}}$ *row.*

The carrier has no coordinate for subject reduction, unrestricted normalization, closed consistency, host evaluation, quotient conversion, or a second false endpoint.

Lean4 ✓ `BEDC.Derived.ClosedNormalCanonicityUp.TasteGate.ClosedNormalCanonicityTasteGate single carrier alignment`

Theorem 799.2 (Closed-normal canonicity NameCert obligations)**.** *Every accepted* $\mathsf{ClosedNormalCanonicity}^{\uparrow}$ *packet binds exactly the finite obligation surface of Definition 799.1: carrier admission for* $K = (T, L, B, F, E, H, C, P, N)$*, componentwise classifier stability on the displayed rows, ledger exactness for the closed typing, closedness, beta-strong normality, false endpoint, exclusion, transport, route, provenance, and naming coordinates, and local* $\mathsf{NameCert}$ *registration through* N*.*

Proof. Project the accepted carrier. The rows $T, L, B, F, E, H, C, P, N$ are the only visible coordinates, so carrier admission and classifier comparison are componentwise over the displayed packet.

Read the endpoint rows next. The rows T, L, B, F display the closed beta-strong candidate at the false endpoint, and E is the only exclusion row attached to that candidate.

The structural rows H, C, P, N transport, replay, package, and name the same finite surface. Since the carrier lists no further coordinate, the local NameCert obligations are exhausted by these rows. □

Theorem 799.3 (Closed-normal canonicity false-endpoint exclusion)**.** *Every consumer of an accepted* $\mathsf{ClosedNormalCanonicity}^{\uparrow}$ *packet may read the false-endpoint exclusion only through the displayed chain*

$$T, L, B, F, E, H, C, P, N.$$

The read is a closed beta-strong endpoint exclusion for the named false encoding. It is not a full closed-consistency theorem, not a closed subject-reduction theorem, and not a normalization theorem for arbitrary closed terms.

Proof. Start with the exclusion row E. Its inputs in the carrier are exactly the typed closed beta-strong false endpoint rows T, L, B, F.

The continuation row C exposes the public read through the same displayed chain, while H, P, N provide transport, provenance, and local naming. No carrier coordinate supplies subject reduction, unrestricted normalization, or a general consistency principle.

Thus the consumer receives only the false-endpoint exclusion stated by the packet. □

Theorem 799.4 (Closed-normal canonicity non-escape)**.** *An accepted* $\mathsf{ClosedNormalCanonicity}^{\uparrow}$ *packet has no escape route from its displayed endpoint surface. Any downstream read factors through* $T, L, B, F, E, H, C, P, N$*, and cannot acquire a second false endpoint, a host evaluator, quotient conversion, full closed consistency, closed subject reduction, or unrestricted normalization from the packet.*

Proof. Read the carrier of Definition 799.1. The packet contains one false endpoint row F and one exclusion row E.

Apply the obligation theorem to confine all public reads to the displayed rows. The transport, route, provenance, and local-name rows preserve that same finite packet instead of adding semantic coordinates.

The false-endpoint exclusion theorem then supplies the only positive read. Since no remaining coordinate is present, the excluded escape routes are unavailable to downstream consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedNormalCanonicity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClosedNormalCanonicity}^{\uparrow}$ packet is generated from empty-context typing, closedness, beta-strong normality, a false-endpoint row, an endpoint-exclusion row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedNormalCanonicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 799.1, Definition 799.2, Definition 799.3, and Definition 799.4 bind the finite false-endpoint canonicity surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedNormalCanonicity}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full closed consistency, closed subject reduction, unrestricted normalization, host evaluation, quotient conversion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, endpoint exclusion, non-escape, provenance, and local naming for the same finite canonicity packet.

Chapter 800

A Concrete Naming Certificate for $\mathsf{ClosurePreservationAuditSeal}^{\uparrow}$

The $\mathsf{ClosurePreservationAuditSeal}^{\uparrow}$ packet realizes the closure-preservation audit map of chapter 9381 as a finite NameCert seal. It sits beside the substitution audit packet of **??**, the normalization audit seal of chapter 777, and the closed-normal consistency boundary of chapter 733: those siblings consume closed syntax movement and consistency-facing beta routes, while this seal records exactly where shift, substitution, beta-step, and beta-star closedness are available as finite audit rows.

Definition 800.1 (Closure-preservation audit seal carrier)**.** *A* $\mathsf{ClosurePreservationAuditSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, R, V, U, B, Z, G, H, C, P, N)$$

with the following visible rows:

1. *A is the audit-map anchor row naming chapter 9381;*
2. *R is the shift row for* shift_one_preserves_closed_succ*;*
3. *V is the variable-substitution row for* substitute_var_preserves_closed_at*;*
4. *U is the full-substitution row for* substitute_preserves_closed_at*;*
5. *B is the one-step beta row for* betaStep_preserves_closed*;*
6. *Z is the finite beta-star row for* betaStarStep_preserves_closed*;*
7. *G is the* GAP *boundary row separating closedness preservation from typing preservation, conversion transport, global normalization, and confluence;*
8. *H records componentwise* hsame *transports for the anchor, the five closure theorem rows, the boundary row, route rows, provenance, and local naming;*
9. *C records the displayed* Cont *routes by which consumers read the shift, substitution, beta-step, beta-star, sibling-packet, and boundary rows;*
10. *P is the* Pkg *provenance over chapter 9381,* **??***, chapter 777, and chapter 733;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a HasType *preservation theorem, no subject-reduction discharge bundle, no quotient equality over beta paths, no host conversion oracle, and no route from beta-star closedness to a closed typed preservation theorem.*

Lean4 ✓ `BEDC.Derived.ClosurePreservationAuditSealUp.ClosurePreservationAuditSealTasteGate`
`single carrier alignment`

Theorem 800.2 (Closure-preservation audit seal NameCert obligations)**.** *For the carrier of Definition 800.1, the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$S = (A, R, V, U, B, Z, G, H, C, P, N),$$

audit-anchor visibility through A, closed shift visibility through R, variable-substitution visibility through V, full-substitution visibility through U, beta-step visibility through B, beta-star visibility through Z, the displayed GAP *refusal through G, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the displayed BHist packet. The audit anchor A fixes the source chapter, while R, V, U, B, Z are exactly the five closure-preservation theorem rows listed there.

Read the boundary row G next. It records that the seal is a closedness-classifier object: the packet may expose shift, substitution, beta-step, and beta-star closedness, but it does not expose typing preservation, conversion transport, normalization, confluence, or subject reduction.

Finally inspect H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same finite rows and add no hidden coordinate. Hence the displayed rows exhaust the local NameCert obligation surface. □

Theorem 800.3 (Closure-preservation audit seal route exactness)**.** *Every downstream read of an accepted* $\mathsf{ClosurePreservationAuditSeal}^{\uparrow}$ *packet that claims a closedness-preservation route factors through one of the displayed theorem rows R, V, U, B, Z, then through the matching* Cont *route in C, and then through the same* hsame, Pkg, *and* NameCert *rows H, P, N. In particular, a closed-normal or subject-reduction-boundary consumer may cite beta-star closedness only through Z together with the finite replay and provenance rows; it may not replace that route by a direct appeal to vision prose or by an unrecorded typing-preservation step.*

Proof. Start with an accepted packet and project the route component C. Its displayed continuations have sources only in R, V, U, B, Z and in the sibling-facing rows named by P.

For a shift or substitution read, the route reaches R, V, U and then uses the same transport row H before it is reported to a consumer. This is the route used by the substitution audit packet, so the consumer receives a finite closed-syntax movement row rather than an unrestricted substitution calculus.

For a beta-step or beta-star read, the route reaches B or Z and then passes through H, P, N. The closed-normal consistency boundary can therefore cite a finite beta closedness route, while the GAP row keeps subject-reduction discharge and typed conversion outside the route. □

Theorem 800.4 (Closure-preservation audit seal non-escape)**.** *Every public read of an accepted* $\mathsf{ClosurePreservationAuditSeal}^{\uparrow}$ *packet remains inside the finite rows*

$$A, R, V, U, B, Z, G, H, C, P, N.$$

The seal exports no HasType *preservation theorem, no closed subject-reduction theorem, no discharge of beta-substitution typing, application-argument typing, lambda-domain typing, or Pi-domain typing obligations, no quotient equality over reductions, and no host semantic conversion principle.*

Proof. The only positive theorem rows in the carrier are R, V, U, B, Z. They are closedness-preservation rows over the closedness classifier, and their replay routes are the displayed continuations in C.

The GAP row names the excluded crossings. It separates the finite closedness theorem surface from typing preservation, subject-reduction discharge, quotient equality, and host conversion.

Componentwise transport and provenance cannot create an omitted coordinate. Since H, P, N only preserve and name the rows already projected from S, every public read remains inside the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosurePreservationAuditSeal}^{\uparrow}$ packet is generated from a closure-preservation audit-map anchor, five checked closedness theorem rows for shift, variable substitution, full substitution, beta-step, and beta-star routes, a displayed GAP boundary, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 800.1, Definition 800.2, Definition 800.3, and Definition 800.4 bind the finite closure-preservation audit seal and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close typed subject reduction, typed conversion transport, normalization, confluence, quotient equality over reductions, Lean verification of the seal, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, theorem-row exactness, route replay, boundary refusal, provenance, local naming, and non-escape for the same finite seal packet.

Chapter 801

A Concrete Naming Certificate for $\mathsf{ClosurePreservationClassifier}^{\uparrow}$

The $\mathsf{ClosurePreservationClassifier}^{\uparrow}$ surface turns the MetaCIC closure-preservation audit map of chapter 9381 into a finite classifier-facing NameCert packet. It also reuses the generator-closure reading of chapter 486: a displayed generator row is accepted only when its action stays inside the displayed classifier boundary.

Definition 801.1 (Closure-preservation classifier carrier)**.** *A* $\mathsf{ClosurePreservationClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (K, S, U, B, F, H, C, P, N)$$

with the following visible coordinates:

1. *K is the* $\mathsf{ClosedAt}$ *boundary row, naming the depth-indexed closedness classifier consumed by the audit;*
2. *S is the shift-generator row, recording the displayed shift action and its closedness-preservation certificate against K;*
3. *U is the substitution-generator row, recording the displayed substitution action and its closedness-preservation certificate against K;*
4. *B is the beta-step route row, exposing the single-step preservation route whose redex case consumes U and whose congruence cases stay inside K;*
5. *F is the beta-star route row, exposing the finite iteration route obtained by replaying B over the displayed step ledger;*
6. *H records componentwise* hsame *transports for the closedness boundary, generator rows, beta-step route, beta-star route, package row, and local naming row;*
7. *C records the displayed* Cont *routes through which consumers inspect K, S, U, B, F, H, P, N;*
8. *P is the* Pkg *provenance over MetaCIC terms, depth rows,* $\mathsf{ClosedAt}$*, shift and substitution generators, beta-step and beta-star routes,* BHist*,* hsame*,* Cont*, and local naming;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationClassifier}^{\uparrow}}$ *row.*

The packet is a classifier packet for closedness preservation. It contains no typing-preservation row, no normalization theorem, no confluence theorem, no quotient term equality, and no host conversion procedure.

Lean4 ✓ BEDC.Derived.ClosurePreservationClassifierUp.ClosurePreservationClassifierTasteGate
single carrier alignment

Theorem 801.2 (Closure-preservation classifier NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationClassifier}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier admission for the packet* $X = (K, S, U, B, F, H, C, P, N)$ *of Definition 801.1;*
2. *classifier boundary admission, stating that every accepted read of the packet begins at the displayed* ClosedAt *row* K*;*
3. *generator preservation admission, stating that the shift row* S *and substitution row* U *are the only generator rows allowed to witness closure inside* K*;*
4. *beta route admission, stating that the beta-step row* B *and beta-star row* F *are read as finite replays of the displayed generator-preservation data;*
5. *non-escape and ledger exactness, stating that accepted consumers may inspect only* $K, S, U, B, F, H, C, P, N$ *and cannot import typing preservation, normalization, confluence, quotient terms, or host conversion.*

Proof. Carrier admission is the projection of the finite tuple in Definition 801.1. The tuple names the closedness classifier, the two generator rows, the beta routes, transports, continuations, provenance, and local certificate.

The classifier boundary row is K. Both generator rows are checked against that same row, so a public read cannot replace the closedness classifier by a typing classifier or by an ambient host predicate.

The beta rows are then read through the displayed generator data. The beta-step route B uses the substitution row for the redex case and componentwise closedness reads for congruence cases, while F repeats B over a finite route.

Finally inspect the carrier inventory. Since X has no typing-preservation, normalization, confluence, quotient, or host-conversion coordinate, the local certificate exports only the ClosedAt generator-closure audit surface. □

Theorem 801.3 (Closure-preservation classifier generator closure)**.** *Every accepted* $\mathsf{ClosurePreservationClassifier}^{\uparrow}$ *packet instantiates the GeneratorClosure reading for the* ClosedAt *classifier. Its shift row* S *and substitution row* U *are the generator witnesses, its beta-step row* B *and beta-star row* F *are the finite route witnesses, and its* H, C, P, N *rows record transport, continuation, provenance, and local naming. The accepted packet therefore exposes closedness preservation for the displayed generator routes without exporting typing preservation, normalization, confluence, quotient terms, or host conversion.*

Proof. Project the accepted packet $X = (K, S, U, B, F, H, C, P, N)$. The classifier coordinate is K, and the generator coordinates available to the GeneratorClosure reading are exactly S and U.

Read the beta-step route through B. Its redex branch uses the substitution generator row, and its structural branches replay closedness through the displayed classifier boundary. Read the beta-star route through F, which is a finite iteration of those accepted beta-step reads.

The transport and continuation rows H and C keep every read attached to the same displayed packet, while P and N record package provenance and local certificate membership. No remaining coordinate can provide typing preservation, normalization, confluence, quotient-term equality, or host conversion, so the conclusion is exactly the ClosedAt generator-closure surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosurePreservationClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosurePreservationClassifier}^{\uparrow}$ packet is generated from a ClosedAt boundary row, shift and substitution generator rows, beta-step and beta-star route rows, componentwise transports, continuation routes, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosurePreservationClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 801.1, Definition 801.2, and Definition 801.3 record the finite ClosedAt generator-closure packet and its local non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosurePreservationClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not export typing preservation, normalization, confluence, quotient terms, host conversion, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, ClosedAt classifier admission, shift and substitution generator preservation, beta-route replay, and non-escape for the displayed packet.

Chapter 802

A Closedness-Route Audit Surface for $\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}$

The $\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}$ packet turns the closure-preservation audit map of chapter 9381 into a finite NameCert audit object. It sits between the row-level seal of chapter 800, the downstream subject-reduction socket of chapter 719, and the closed-normal boundary of chapter 740. The packet records where closedness travels through shift, substitution, beta-step, and beta-star routes; it does not add a typing-preservation route.

Definition 802.1 (MetaCIC closure-preservation audit packet)**.** *A* $\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, S, R, V, U, B, Z, X, H, C, P, N)$$

with the following visible rows:

1. *A is the audit-map anchor naming chapter 9381;*
2. *S is the sibling audit-seal row from chapter 800;*
3. *R is the closed shift row for the shift-one closedness route;*
4. *V is the closed variable-substitution row;*
5. *U is the closed full-substitution row;*
6. *B is the closed one-step beta row;*
7. *Z is the closed finite beta-star row;*
8. *X is the subject-reduction frontier row, pointing to chapter 719 and chapter 740;*
9. *H records componentwise* hsame *transports for the anchor, seal, five closedness rows, frontier row, route rows, provenance, and local naming;*
10. *C records the displayed* Cont *routes by which consumers read the anchor, seal, closedness rows, beta-star export, frontier boundary, provenance, and local naming;*
11. *P is the* Pkg *provenance over the audit map, audit seal, subject-reduction socket, normal-form consistency seal, componentwise* hsame*, displayed* Cont*, and local* $\mathsf{NameCert}$ *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for closed subject reduction, full typed preservation, quotient equality of beta paths, host conversion, global normalization, or confluence.

Theorem 802.2 (MetaCIC closure-preservation audit finite obligation surface)**.** *For the carrier of Definition 802.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for*

$$M = (A, S, R, V, U, B, Z, X, H, C, P, N),$$

audit-map anchoring through A*, sibling audit-seal replay through* S*, the five closedness rows* R, V, U, B, Z*, the subject-reduction frontier row* X*, componentwise transport through* H*, displayed continuation reads through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the displayed packet M. The audit anchor A fixes the source map, and S imports the finite audit-seal interface without replacing the local rows R, V, U, B, Z.

The five closedness rows are then read directly. They account for shift, variable substitution, full substitution, one-step beta, and finite beta-star closedness. The row X is separate: it points to the subject-reduction socket and the normal-form consistency seal as frontier consumers, not as extra closedness theorems.

Finally inspect H, C, P, N. Transport, route replay, provenance, and local naming preserve the rows already present in M. Since the carrier contains no other coordinate, the listed rows exhaust the finite obligation surface. □

Lean4 ✓ `BEDC.Derived.MetaCICClosurePreservationAuditUp.MetaCICClosurePreservationAuditTasteGate`
`single carrier alignment`

Theorem 802.3 (MetaCIC closure-preservation audit beta-star closedness export)**.** *Every accepted* $\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}$ *packet exports beta-star closedness only through the displayed row* Z*, its componentwise* hsame *transport in* H*, its displayed* Cont *replay in* C*, the provenance row* P*, and the local naming row* N*. A consumer from chapter 740 may cite this export as a closedness row, but not as subject reduction, typed conversion transport, or closed consistency.*

Proof. Start with the packet projection and isolate the beta-star coordinate Z. The theorem-row inventory in Definition 802.2 names Z as the only beta-star closedness row.

Route replay then passes through H, C, P, N. These rows preserve and expose the same beta-star row; they do not introduce a typing derivation, a conversion rule, or a closed-consistency theorem.

For a normal-form consumer, the allowed read is therefore a finite closedness export. Any stronger claim would require a coordinate outside M, and the carrier definition provides none. □

Theorem 802.4 (MetaCIC closure-preservation audit subject-reduction frontier separation)**.** *Every subject-reduction-facing read of an accepted* $\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}$ *packet factors through the frontier row* X *and then through the finite socket of chapter 719. The read may use the closedness rows* R, V, U, B, Z *as audit evidence, but it cannot manufacture a closed subject-reduction theorem, discharge the four subject-reduction rows, or bypass the normal-form boundary of chapter 740.*

Proof. Read the frontier coordinate X. Its role is to name the crossing from closure preservation to subject-reduction consumers, and its cited socket is the only displayed route for that crossing.

The closedness rows R, V, U, B, Z remain available as evidence rows. They are transported by H and replayed by C, but their conclusions are closedness statements, not typed preservation statements.

The normal-form consistency seal receives beta-star closedness only as a bounded input. Because the packet has no coordinate for closed subject reduction or full consistency, the frontier read stops at the socket and the normal-form boundary. □

Corollary 802.5 (MetaCIC closure-preservation audit strict local obstruction)**.** *Let an accepted* $\mathsf{MetaCICClosurePreservationAudit}^{\uparrow}$ *packet be read through the carrier*

$$M = (A, S, R, V, U, B, Z, X, H, C, P, N)$$

of Definition 802.1. Any consumer-facing negative use of its subject-reduction frontier is a strict local obstruction: it blocks only the converse route from closedness preservation to closed subject reduction, only the reuse of beta-star closedness as typed preservation, and only the bypass of the socket and normal-form boundary named in Definition 802.4. It cannot be reread as a global impossibility theorem, a host theorem, a countermodel to closure preservation, an external validation principle, or a hidden discharge of an unlisted coordinate.

Proof. Project the packet using Definition 802.1. Its positive closedness coordinates are exactly the rows R, V, U, B, Z, with Z singled out by Definition 802.3 as the beta-star closedness export. The carrier also displays the frontier row X, the componentwise transport row H, the continuation row C, the provenance row P, and the local naming row N.

The only subject-reduction-facing crossing supplied by the packet is the one identified in Definition 802.4: a read factors through X and then through the finite subject-reduction socket. The same theorem allows R, V, U, B, Z to be used as audit evidence, but it denies manufacture of closed subject reduction, discharge of the subject-reduction rows, and bypass of the normal-form boundary. Thus the obstruction applies to the attempted converse or reuse route that treats closedness evidence as typed preservation evidence.

No stronger negative reading is available from the finite carrier. The definition explicitly omits coordinates for closed subject reduction, full typed preservation, quotient equality of beta paths, host conversion, global normalization, and confluence. The transport, continuation, provenance, and naming rows H, C, P, N preserve access to displayed rows; they do not add a host theorem, a global countermodel, or an external validation channel. Therefore every negative consumer-facing use remains the named local obstruction and rejects any unlisted coordinate. □

Chapter 803

A Concrete Naming Certificate for ClosurePreservationAuditPacket$^{\uparrow}$

The ClosurePreservationAuditPacket$^{\uparrow}$ packet realizes the closure-preservation audit map of chapter 9381 as a finite NameCert object for consumers that need the whole closedness-preservation route rather than a single seal row. It sits beside the normal-form consistency seal of chapter 740, the subject-reduction discharge socket of chapter 719, the closed-term context seal of chapter 722, and the audit seal of chapter 800. Those sibling chapters expose closed-normal, subject-reduction, closed-context, and route-seal consumers; this packet binds the finite rows they may cite when they need shift, substitution, beta-step, beta-star, closedness, transport, route, provenance, and local naming data together.

Definition 803.1 (Closure-preservation audit packet carrier)**.** *A* ClosurePreservationAuditPacket$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, L, S, T, V, U, B, Z, F, R, H, C, P, N)$$

with the following visible rows:

1. *A is the audit-map anchor row naming chapter 9381;*
2. *L is the local* ClosedAt *ledger row for the terms and depths read by the packet;*
3. *S is the shift row for the displayed* shift *route;*
4. *T is the one-hole substitution row for the displayed* substitute *route;*
5. *V is the variable-substitution row for* substitute_var_preserves_closed_at*;*
6. *U is the full-substitution row for* substitute_preserves_closed_at*;*
7. *B is the one-step beta row for* betaStep *closedness preservation;*
8. *Z is the finite beta-star row for* betaStarStep *closedness preservation;*
9. *F is the finite replay row recording that beta-star evidence is read as a list of accepted beta-step witnesses;*
10. *R records the sibling routes to chapter 740, chapter 719, and chapter 722;*
11. *H records componentwise* hsame *transport for the anchor, closedness ledger, operation rows, replay row, sibling routes, provenance, and local naming;*

12. *C records the displayed* Cont *routes used by consumers of shift, substitution, beta-step, beta-star, sibling-facing, and boundary reads;*
13. *P is the* Pkg *provenance over the audit map and the named sibling chapters;*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditPacket}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host conversion principle, a quotient of beta paths, a typing-preservation theorem, a subject-reduction discharge, global normalization, confluence, or an ambient semantic equality of closed terms.

Lean4 ✓ `BEDC.Derived.ClosurePreservationAuditPacketUp.ClosurePreservationAuditPacketTasteGate`
`single carrier alignment`

Theorem 803.2 (Closure-preservation audit packet NameCert obligations)**.** *For the carrier of Definition 803.1, the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditPacket}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$K = (A, L, S, T, V, U, B, Z, F, R, H, C, P, N),$$

audit-map visibility through A, closedness-ledger visibility through L, shift visibility through S, substitution visibility through T, V, U, beta-step visibility through B, beta-star replay through Z, F, sibling-route visibility through R, componentwise hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the finite BHist packet. The row A fixes the source audit map, while L, S, T, V, U, B, Z, F expose exactly the closedness, shift, substitution, beta-step, and beta-star rows named by the carrier.

Read the sibling route row R next. It names only the normal-form consistency seal, the subject-reduction discharge socket, the closed-term context seal, and their finite consumer routes; it does not turn those siblings into an additional closedness theorem or a typed subject-reduction result.

Finally inspect H, C, P, N. The hsame transports preserve the displayed rows componentwise, the Cont rows replay the same routes to consumers, the Pkg row records provenance, and the local NameCert row names the packet. Since no other carrier coordinate is projected, these rows exhaust the obligation surface. □

Theorem 803.3 (Closure-preservation audit packet beta-star boundary)**.** *Every consumer read of an accepted* $\mathsf{ClosurePreservationAuditPacket}^{\uparrow}$ *packet that cites beta-star closedness factors through the displayed beta-step row B, the finite replay row F, the beta-star row Z, the local* ClosedAt *ledger L, and then the common* hsame, Cont, Pkg, *and* NameCert *rows H, C, P, N. The read may pass to the normal-form consistency seal, subject-reduction discharge socket, or closed-term context seal only through the sibling-route row R; it exports no quotient beta path, no host conversion rule, no typed subject-reduction theorem, no global normalization theorem, and no confluence theorem.*

Proof. Start with an accepted packet and project the beta-star route. The carrier exposes beta-star evidence only as the finite pair F, Z, with F replaying accepted beta-step witnesses and Z recording the resulting closedness-preservation row.

The local closedness claim is tied to L. Shift and substitution side conditions are read through S, T, V, U, so the beta-star consumer cannot bypass the displayed ClosedAt ledger or replace it by a host equality of closed terms.

Now route the consumer-facing read. The continuation row C points from B, F, Z, L through the componentwise transport row H and provenance row P to the local naming row N.

It remains to check sibling access. The row R is the only coordinate that mentions the normal-form consistency seal, the subject-reduction discharge socket, or the closed-term context seal. Thus a public read can cite those siblings only as finite route endpoints, and the omitted quotient, conversion, typed subject-reduction, normalization, and confluence objects cannot escape from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditPacket}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosurePreservationAuditPacket}^{\uparrow}$ packet is generated from a closure-preservation audit-map anchor, a finite closedness ledger, shift and substitution rows, beta-step and beta-star replay rows, sibling-route rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditPacket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 803.1, Definition 803.2, and Definition 803.3 bind the finite closure-preservation audit packet and its beta-star consumer boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosurePreservationAuditPacket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close typed subject reduction, host conversion, quotient equality over beta paths, normalization, confluence, Lean verification of the packet, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, operation-row exactness, beta-star replay, sibling-route exactness, provenance, local naming, and non-escape for the same finite packet.

Chapter 804

A Concrete Naming Certificate for DependentCodomainClosurePreservation$^{\uparrow}$

The DependentCodomainClosurePreservation$^{\uparrow}$ packet turns the closure-preservation audit map of chapter 9381 into a finite codomain-transport surface for subject-reduction routes. It sits beside the dependent-codomain inversion boundary of chapter 781: the sibling boundary names the point where codomain readback cannot be crossed for free, while this packet records exactly which closedness-preservation rows may be transported before that boundary is consumed.

Definition 804.1 (Dependent-codomain closure-preservation carrier)**.** *A* DependentCodomainClosurePreservation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (\Pi, A, a, a', C_0, C_1, Z, S, I, T, L, H, R, P, N)$$

with the following displayed rows:

1. Π *is the dependent function-type row whose codomain is observed along the subject-reduction route;*
2. A *is the displayed domain row shared by the argument and the function type;*
3. a *and* a' *are the source and reduced argument rows;*
4. C_0 *and* C_1 *are the two codomain readback rows exposed by substituting* a *and* a' *into the same displayed codomain;*
5. Z *is the beta-star closedness row corresponding to* betaStarStep_preserves_closed*;*
6. S *is the substitution closedness row corresponding to* substitute_preserves_closed_at*;*
7. I *is the sibling inversion-boundary row supplied by chapter 781;*
8. T *is the finite transport row that carries closedness from the source codomain readback to the reduced codomain readback;*
9. L *is the ledger row recording that the transport is a closedness route and not a typing-preservation route;*
10. H *records componentwise* hsame *transport for the function type, domain, arguments, codomain readbacks, closure rows, inversion-boundary row, transport row, ledger row, provenance row, and local name;*

11. *R records displayed* Cont *replay routes for beta-star closedness, substitution closedness, sibling-boundary consumption, and the codomain transport read;*
12. *P is the* Pkg *provenance over chapter 9381, chapter 781, and the subject-reduction route surfaces that consume finite codomain transport;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DependentCodomainClosurePreservation}^{\uparrow}}$ *row.*

The carrier contains no coordinate for dependent-codomain inversion, no proof that C_0 and C_1 have the same type, no closed subject-reduction theorem, no host conversion principle, and no quotient equality over beta-star routes.

Lean4 (definition) `BEDC.Derived.DependentCodomainClosurePreservationUp.DependentCodomainClosurePreservatio`

Theorem 804.2 (Dependent-codomain closure-preservation obligations)**.** *For the carrier of Definition 804.1, the local* $\mathsf{NameCert}_{\mathsf{DependentCodomainClosurePreservation}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$K = (\Pi, A, a, a', C_0, C_1, Z, S, I, T, L, H, R, P, N),$$

visibility of the dependent type, domain, source and reduced argument rows, paired codomain readbacks, beta-star closedness through Z, substitution closedness through S, sibling inversion-boundary access through I, finite codomain transport through T, closedness-only ledger exposure through L, componentwise hsame *transport through H, displayed* Cont *replay through R, package provenance through P, and local naming through N.*

Proof. Project the displayed packet. The rows Π, A, a, a', C_0, C_1 give the complete codomain-readback surface before any closure route is read.

Read the checked closedness rows next. The beta-star row Z and substitution row S are the only positive preservation rows, and both are closedness rows cited from chapter 9381.

Now consume the sibling boundary row I and the transport row T. They identify the finite point where dependent-codomain transport may be requested without turning the request into dependent-codomain inversion.

Finally inspect L, H, R, P, N. The ledger, transport, replay, provenance, and local naming rows preserve only the displayed coordinates, so the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.DependentCodomainClosurePreservationUp.DependentCodomainClosurePreservationObligat`

Theorem 804.3 (Dependent-codomain closure-preservation non-escape)**.** *Every public read of an accepted* $\mathsf{DependentCodomainClosurePreservation}^{\uparrow}$ *packet remains inside*

$$\Pi, A, a, a', C_0, C_1, Z, S, I, T, L, H, R, P, N.$$

In particular, the packet exports no dependent-codomain inversion theorem, no typing preservation for dependent application, no context-reduction theorem, no host conversion rule, no closed subject-reduction theorem, and no quotient equality over beta-star routes.

Lean4 ✓ `BEDC.Derived.DependentCodomainClosurePreservationUp.DependentCodomainClosurePreservationNonesca`

Proof. The only theorem rows in the carrier are Z and S, and both are closedness-preservation rows. A consumer can reach them only through the displayed replay row R and the componentwise transport row H.

The inversion-boundary row I is consumed as a boundary, not as a discharge. It records where the subject-reduction route must still account for dependent-codomain readback, so it cannot supply typing preservation or context reduction.

The ledger row L marks the same restriction at the consumer boundary. Since no omitted coordinate is available through P or N, every public read remains in the displayed finite packet. □

Theorem 804.4 (Dependent-codomain closure-preservation transport)**.** *Let K be an accepted* DependentCodomainClosurePreservation$^{\uparrow}$ *carrier. Any subject-reduction route that transports codomain closedness through the dependent argument step must read beta-star closedness through Z, substitution closedness through S, the sibling inversion-boundary row through I, and the finite transport row through T before exposing the transported codomain-readback surface. The route may then hand the transported closedness row to downstream subject-reduction consumers, but only as closedness data over C_0 and C_1.*

Lean4 ✓ `BEDC.Derived.DependentCodomainClosurePreservationUp.DependentCodomainClosurePreservationTranspo`

Proof. Begin with a subject-reduction consumer requesting codomain transport. Carrier projection exposes both codomain readbacks C_0 and C_1 together with the argument rows that generated them.

Use the beta-star and substitution rows from the closure-preservation audit map. These rows authorize closedness movement along the displayed beta-star and substitution routes, so the requested transport has a finite source.

Next read the inversion-boundary row. The sibling boundary states that codomain readback itself is the remaining dependent-codomain obligation, so the transport row T can move closedness across the displayed readbacks without proving their typing equality.

The route is then replayed through R and transported through H. Provenance and local naming keep the result attached to the same finite carrier, so downstream consumers receive only the transported closedness row. □

Theorem 804.5 (Dependent-codomain closure-preservation ledger)**.** *For every accepted* DependentCodomainClosur *carrier, the ledger consumed by a subject-reduction route is exactly the closedness-only row L attached to Z, S, I, T and the paired codomain readbacks C_0, C_1. No alternate ledger records typed conversion, dependent-codomain inversion, quotient equality, ambient normalization, confluence, or closed subject reduction.*

Lean4 ✓ `BEDC.Derived.DependentCodomainClosurePreservationUp.DependentCodomainClosurePreservationPacket closedness ledger exactness`

↪ variant `BEDC.Derived.DependentCodomainClosurePreservationUp.DependentCodomainClosurePreservationLedger`

Proof. Inspect the consumer route. It first reaches the paired codomain readbacks, then the beta-star and substitution closedness rows, then the sibling boundary and transport rows.

The ledger row L records precisely that route. It states that T is a closedness transport over the displayed codomain-readback pair and that I remains a boundary for the stronger dependent-codomain claim.

The non-escape theorem rules out every other consumer coordinate. Thus the ledger exposed by the packet is exactly the finite closedness-only row L. □

Lean4 ✓ `BEDC.Derived.DependentCodomainClosurePreservationUp.DependentCodomainClosurePreservationPacket ledger scope`

Closure status for NameCert$_{\text{DependentCodomainClosurePreservation}^{\uparrow}}$.

Constructive story: A DependentCodomainClosurePreservation$^{\uparrow}$ packet is generated from dependent function-type, domain, argument, paired codomain-readback, beta-star closedness, substitution closedness, sibling inversion-boundary, finite transport, closedness ledger, transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{DependentCodomainClosurePreservation}^{\uparrow}}$, seed)

Scope closed: Definition 804.1, Definition 804.2, Definition 804.3, Definition 804.4, and Definition 804.5 bind the finite closedness transport surface for dependent-codomain subject-reduction routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DependentCodomainClosurePreservation}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove dependent-codomain inversion, typed subject reduction, context reduction, quotient equality over beta-star routes, Lean verification of the packet, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, beta-star and substitution row coverage, sibling-boundary consumption, finite transport exactness, ledger non-escape, provenance, and local naming for the same packet.

Chapter 805

A Concrete Naming Certificate for $\mathsf{ClosurePreservationRouteLedger}^{\uparrow}$

The $\mathsf{ClosurePreservationRouteLedger}^{\uparrow}$ packet turns the audit map of chapter 9381 into a finite route ledger. It sits beside the substitution packet of chapter 779 and the subject-reduction socket of chapter 719: the former supplies the syntactic movement rows, while the latter records why closedness routes do not discharge typed subject reduction.

Definition 805.1 (Closure-preservation route ledger carrier)**.** *A* $\mathsf{ClosurePreservationRouteLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (C, S, U, B, F, H, Q, P, N)$$

with the following visible rows:

1. *C is the* $\mathsf{ClosedAt}$ *source row recording the closed input boundary;*
2. *S is the shift-preservation row for* $\mathsf{shift_one_preserves_closed_succ}$*;*
3. *U is the substitution-preservation row covering the variable and full-substitution closedness routes;*
4. *B is the beta-step preservation row for* $\mathsf{betaStep_preserves_closed}$*;*
5. *F is the beta-star preservation row for* $\mathsf{betaStarStep_preserves_closed}$*;*
6. *H records componentwise* hsame *transports for the source, preservation, route, provenance, and naming rows;*
7. *Q records the displayed* Cont *routes by which consumers reach the shift, substitution, beta-step, and beta-star rows from the source row;*
8. *P is the* Pkg *provenance over chapter 9381, chapter 779, chapter 800, and chapter 719;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationRouteLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for typed subject reduction, host conversion, an unrestricted substitution calculus, or a full consistency theorem.

Theorem 805.2 (Closure-preservation route ledger NameCert obligations)**.** *For the carrier of Definition 805.1, the local* $\mathsf{NameCert}_{\mathsf{ClosurePreservationRouteLedger}^{\uparrow}}$ *surface consists exactly of five obligation families: source closedness admission through C, shift preservation through S, substitution*

preservation through U, beta-step preservation through B, and beta-star preservation through F. The auxiliary rows H, Q, P, N transport, replay, account for, and name those five families without adding a sixth preservation claim.

Proof. Project the carrier $L = (C, S, U, B, F, H, Q, P, N)$. The source row C fixes the displayed ClosedAt boundary, and the four route rows S, U, B, F are the closedness-preservation routes named by chapter 9381.

Read the transport and route rows next. The hsame row H can only identify corresponding displayed coordinates, and the Cont row Q can only replay the four listed preservation routes from the source boundary.

Finally inspect provenance and naming. The package row P records the audit-map and sibling-packet sources, while N names the local certificate. Since no further coordinate is present, the five obligation families exhaust the local NameCert surface. □

Theorem 805.3 (Closure-preservation route ledger non-escape)**.** *Every public read of an accepted* $\mathsf{ClosurePreservationRouteLedger}^{\uparrow}$ *packet remains inside*

$$C, S, U, B, F, H, Q, P, N.$$

It does not export typed subject reduction, host conversion, an unrestricted substitution calculus, or full consistency.

Proof. The only positive preservation rows in the carrier are S, U, B, F, and each is a closedness-preservation row over the displayed source boundary C.

The substitution route is therefore the finite audited route through U, not a calculus for arbitrary substitution outside the listed closedness hypotheses. The beta-step and beta-star routes similarly preserve ClosedAt and do not introduce typing or conversion coordinates.

Rows H, Q, P, N preserve access discipline for the same finite packet. They transport, replay, account for, and name the visible rows, so typed subject reduction, host conversion, unrestricted substitution, and full consistency remain outside the public surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosurePreservationRouteLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosurePreservationRouteLedger}^{\uparrow}$ packet is generated from a ClosedAt source row, shift, substitution, beta-step, and beta-star preservation rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosurePreservationRouteLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 805.1, Definition 805.2, and Definition 805.3 bind the finite closure-preservation route ledger and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosurePreservationRouteLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close typed subject reduction, host conversion, unrestricted substitution, full consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, route replay, provenance, local naming, and public non-escape for the same finite closure-preservation ledger.

Chapter 806

A Concrete Naming Certificate for $\mathsf{AuditMapInterface}^{\uparrow}$

The $\mathsf{AuditMapInterface}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as a finite interface rather than as a prose convention. It sits beside the kernel acceptance trace of chapter 557, whose rows expose accepted theorem inventory, and the substitution audit map of chapter 779, whose rows show how a local MetaCIC substrate is kept separate from stronger typing claims. The present packet names the common interface consumed by audit-map ledgers, synthesis packets, and cross-map chapters.

Definition 806.1 (Audit-map interface carrier)**.** *An* $\mathsf{AuditMapInterface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (E, K, O, F, X, H, C, P, N)$$

with the following visible rows:

1. *E is the established theorem inventory row, listing the positive results that the local audit map may cite directly;*
2. *K is the conditional theorem inventory row, listing results available only through named discharge, setup, or route data;*
3. *O is the obstruction row, recording no-go, boundary, or shape facts that block a stronger local reading;*
4. *F is the frontier row, recording the strongest adjacent theorem or package that remains outside the local map;*
5. *X is the cross-map consumer row, naming neighbouring audit maps, synthesis packets, and route chapters that may consume the visible rows;*
6. *H records componentwise* hsame *transport for the established, conditional, obstruction, frontier, cross-map, provenance, and naming rows;*
7. *C records displayed* Cont *routes by which consumers read the positive inventory, conditional inventory, obstruction boundary, frontier handoff, cross-map use, provenance, and local name;*
8. *P is the* Pkg *provenance over chapter 9406, chapter 557, chapter 779,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapInterface}^{\uparrow}}$ *row.*

The carrier has no coordinate for turning conditional rows into unconditional theorems, obstruction rows into solved obligations, frontier rows into closed packages, or cross-map consumer rows into hidden module imports.

Theorem 806.2 (Audit-map interface NameCert obligations)**.** *For the carrier of Definition 806.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapInterface}^{\uparrow}}$ *surface consists of five obligations: carrier admission for*

$$I = (E, K, O, F, X, H, C, P, N),$$

inventory exactness for the established, conditional, obstruction, frontier, and cross-map rows E, K, O, F, X*, componentwise transport stability through* H*, displayed route readback through* C*, and package provenance with local naming through* P, N*.*

Lean4 ✓ `BEDC.Derived.AuditMapInterfaceUp.AuditMapInterfaceCarrier namecert obligations`

Proof. Carrier admission is the displayed finite packet. Its first five coordinates are the only audit-map row classes, so inventory exactness is a projection of E, K, O, F, X from the carrier.

Transport stability is componentwise. The row H may compare an established row with an established row, a conditional row with a conditional row, and similarly for obstruction, frontier, cross-map, provenance, and naming data; it supplies no cross-class coercion.

Route readback is then forced through C. A consumer must choose one of the displayed routes before using a row, and the route returns to the same inventory coordinate that it reads.

Finally, P and N bind provenance and local naming. Since provenance cites only the visible methodology and sibling concrete packets, the five obligations exhaust the NameCert surface without adding a stronger theorem coordinate. □

Theorem 806.3 (Audit-map interface cross-map consumer boundary)**.** *Every cross-map consumer of an accepted* $\mathsf{AuditMapInterface}^{\uparrow}$ *carrier*

$$I = (E, K, O, F, X, H, C, P, N)$$

must read the positive inventory E*, conditional inventory* K*, obstruction row* O*, frontier row* F*, and cross-map consumer row* X *through the displayed transport, continuation, provenance, and naming rows* H, C, P, N*. Such a consumer cannot turn the interface into an unconditional theorem, a discharged obstruction, a closed frontier package, a hidden import of a neighbouring map, or a host semantic equality.*

Proof. Start with the NameCert obligations. They identify the accepted interface with the finite rows $E, K, O, F, X, H, C, P, N$ and force each consumer read through the displayed route row C.

For a positive read, the consumer obtains exactly the established inventory row E. For a conditional read, it obtains the conditional row K together with its visible route requirement. For an obstruction read, it obtains the boundary row O rather than a proof of the blocked claim.

For a frontier or cross-map read, the consumer follows F or X through the same transport and provenance rows. Those rows name neighbouring maps and handoffs; they do not import their hidden contents or solve their obligations.

The carrier has no coordinate for unconditional discharge, solved obstruction, closed frontier package, hidden module import, or host semantic equality. Therefore every cross-map use remains an interface read and cannot become a stronger theorem. □

Lean4 ✓ `BEDC.Derived.AuditMapInterfaceUp.AuditMapInterfaceCarrier cross map consumer boundary`

Theorem 806.4 (Audit-map interface conditional row discharge boundary)**.** *For every accepted* $\mathsf{AuditMapInterface}^{\uparrow}$ *carrier*

$$I = (E, K, O, F, X, H, C, P, N),$$

a consumer may use a conditional inventory row K only together with its displayed discharge, setup, or route datum read through the continuation, transport, provenance, and local naming rows C, H, P, N. The same read cannot promote K into the established inventory row E or into an unconditional theorem coordinate.

Lean4 ✓ `BEDC.Derived.AuditMapInterfaceUp.AuditMapInterfaceCarrier conditional row discharge boundary`

Proof. Project the finite carrier of Definition 806.1. The rows E and K are separate BHist coordinates: E records established theorem inventory, while K records conditional inventory.

Use the NameCert obligations of Definition 806.2. Inventory exactness keeps the two rows distinct, componentwise hsame transport in H preserves the row class being transported, and displayed Cont replay in C returns to the same coordinate it reads.

Finally apply the cross-map consumer boundary of Definition 806.3. A downstream consumer can carry the conditional row through C, H, P, N, but the carrier has no coordinate that reclassifies the conditional row as E or supplies an unconditional theorem. Therefore every use of K remains tied to the displayed discharge, setup, or route datum. □

Theorem 806.5 (Audit-map interface obstruction row non-escape)**.** *For every accepted* $\mathsf{AuditMapInterface}^{\uparrow}$ *carrier $I = (E, K, O, F, X, H, C, P, N)$, an obstruction row O remains a boundary row under componentwise* hsame *transport and displayed* Cont *replay. No route through H, C, P, N can convert O into a solved obligation, an established theorem row, or a closed package.*

Lean4 ✓ `BEDC.Derived.AuditMapInterfaceUp.AuditMapInterfaceCarrier obstruction row nonescape`

Proof. Read O from the carrier in Definition 806.1. It is the only coordinate whose role is to record no-go, boundary, or shape facts blocking a stronger local reading.

The NameCert obligations of Definition 806.2 make the administrative rows transparent. The row H transports obstruction data as obstruction data, while C only replays a displayed route to the row being read; P and N record provenance and local naming for the same finite packet.

Invoke Definition 806.3. It explicitly forbids turning the interface into a discharged obstruction or closed frontier package. Since neither H nor C introduces a theorem-producing coordinate, obstruction reads remain boundary reads for every consumer. □

Theorem 806.6 (Audit-map interface frontier consumer routing)**.** *For every accepted* $\mathsf{AuditMapInterface}^{\uparrow}$ *carrier $I = (E, K, O, F, X, H, C, P, N)$, every consumer route that uses the frontier row F or cross-map row X must pass through visible provenance, displayed continuation, componentwise transport, and local naming in P, C, H, N. Such a route may name neighbouring audit maps and handoffs, but it cannot import hidden rows from them or replace the finite interface by host semantic equality.*

Lean4 ✓ `BEDC.Derived.AuditMapInterfaceUp.AuditMapInterfaceCarrier frontier consumer transport routing`

Proof. Begin with the carrier definition. The rows F and X are visible BHist coordinates: F records the strongest adjacent theorem or package outside the local map, and X names neighbouring audit maps, synthesis packets, and route chapters that may consume the interface.

Apply Definition 806.2. It forces frontier and cross-map readback through the same finite NameCert surface, with H for componentwise transport, C for displayed continuation replay, P for package provenance, and N for local naming.

Now use Definition 806.3. Frontier and cross-map reads are allowed only as interface reads. Because the carrier lacks hidden import, closed frontier package, and host semantic equality coordinates, neighbouring maps can be routed only through the visible provenance attached to F and X. □

Theorem 806.7 (Audit-map interface row-class exhaustion)**.** *For every accepted* AuditMapInterface$^{\uparrow}$ *carrier*

$$I = (E, K, O, F, X, H, C, P, N),$$

each consumer-visible inventory row is exactly one of the established, conditional, obstruction, frontier, or cross-map rows E, K, O, F, X. The administrative rows H, C, P, N provide componentwise hsame *transport, displayed* Cont *readback,* Pkg *provenance, and local* NameCert *naming for those rows, but cannot reclassify any row class.*

Proof. Project the carrier of Definition 806.1. Its consumer inventory surface is the five-row list E, K, O, F, X, while H, C, P, N are recorded after that list as transport, route, provenance, and naming data.

Apply Definition 806.2. Inventory exactness is stated only for E, K, O, F, X, and componentwise transport through H is already restricted to the row class being transported.

Use Definition 806.3, Definition 806.4, Definition 806.5, and Definition 806.6. These boundary theorems rule out reclassifying a conditional row as established, an obstruction row as solved, a frontier row as closed, or a cross-map row as a hidden import. Hence the five listed row classes exhaust the consumer-visible inventory. □

Theorem 806.8 (Audit-map interface route-readback totality)**.** *For every accepted* AuditMapInterface$^{\uparrow}$ *carrier $I = (E, K, O, F, X, H, C, P, N)$, each displayed continuation route read through C returns to the same row class that it reads. Established, conditional, obstruction, frontier, and cross-map reads therefore remain separated under* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Proof. Start from Definition 806.2. Displayed route readback is one of the five NameCert obligations, and it is attached to the finite carrier rather than to an external theorem coordinate.

The row-class exhaustion of Definition 806.7 identifies the possible consumer inventory rows as E, K, O, F, X. Since H is componentwise and C is displayed for the row being read, a route that starts at one row class has no carrier coordinate through which it can return as another.

The separation clauses are exactly the existing boundaries. The cross-map boundary of Definition 806.3, the conditional boundary of Definition 806.4, the obstruction non-escape theorem of Definition 806.5, and the frontier routing theorem of Definition 806.6 leave route readback as an interface read for the same row class. □

Lean4 ✓ `BEDC.Derived.AuditMapInterfaceUp.AuditMapInterfaceCarrier route readback totality`

Theorem 806.9 (Audit-map interface template instantiation boundary)**.** *Any audit-map template or sibling audit packet instantiating the* $\mathsf{AuditMapInterface}^{\uparrow}$ *interface must supply the nine visible rows*

$$E, K, O, F, X, H, C, P, N.$$

The instantiated packet receives interface reads through BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data only; it receives no hidden imports, solved obstruction coordinates, discharged theorem coordinates, closed frontier coordinates, or host semantic equality.*

Proof. The carrier definition fixes the required packet shape. An instantiation must therefore provide the five inventory rows E, K, O, F, X and the four administrative rows H, C, P, N before it can claim the local $\mathsf{NameCert}_{\mathsf{AuditMapInterface}^{\uparrow}}$ surface.

Apply the NameCert obligations of Definition 806.2. They give carrier admission, inventory exactness, componentwise transport, route readback, provenance, and local naming for this nine-row packet, and they do not add any extra theorem coordinate.

Now combine Definition 806.3, Definition 806.8, Definition 806.4, Definition 806.5, and Definition 806.6. A sibling packet may consume the interface only through the displayed rows and routes, so template instantiation cannot smuggle in hidden imports or already discharged theorem data. □

Lean4 ✓ `BEDC.Derived.AuditMapInterfaceUp.AuditMapInterfaceCarrier template instantiation boundary`

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapInterface}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapInterface}^{\uparrow}$ packet is generated from established theorem inventory, conditional theorem inventory, obstruction, frontier, cross-map consumer, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AuditMapInterface}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 806.1, Definition 806.2, Definition 806.3, Definition 806.4, Definition 806.5, Definition 806.6, Definition 806.7, Definition 806.8, and Definition 806.9 bind the mature audit-map interface examples and cross-chapter consumer surface for template rows, sibling packet consumers, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AuditMapInterface}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close any conditional audit-map theorem, solve obstruction rows, close frontier packages, import neighbouring maps, provide Lean verification, or supply a public bridge schema.

Upgrade path: Further verification and bridge checking remain independent of the mature paper-side audit-map interface surface.

Chapter 807

A Concrete Naming Certificate for $\mathsf{AuditMapFamily}^{\uparrow}$

The $\mathsf{AuditMapFamily}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as a finite NameCert surface. It sits beside the substitution audit map of chapter 779, the MetaCIC open-obligation ledger of chapter 763, and the subject-reduction discharge socket of chapter 719: those chapters supply concrete local rows, while this chapter binds the family-level inventory, classifier boundary, and template coverage that downstream MetaCIC audit consumers may cite.

Definition 807.1 (Audit-map family carrier)**.** *An* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (E, C, O, F, X, H, R, P, N)$$

with the following visible rows:

1. *E is the established row, listing checked or otherwise available audit-map content such as closed substitution rows and closed-normal consistency rows;*
2. *C is the conditional row, listing results that are usable only through named routes or sockets, including subject-reduction discharge data;*
3. *O is the obstruction row, listing no-escape or no-claim boundaries that must stay visible to consumers;*
4. *F is the frontier row, listing open handoff points for adjacent MetaCIC modules without treating them as theorem exports;*
5. *X is the cross-module row, linking local audit maps, ledgers, and sockets into the family inventory;*
6. *H records componentwise* hsame *transports for established, conditional, obstruction, frontier, cross-module, route, provenance, and local naming rows;*
7. *R records the displayed* Cont *routes by which a consumer reads the family rows;*
8. *P is the* Pkg *provenance over chapter 779, chapter 763, chapter 719, and neighbouring MetaCIC audit chapters;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapFamily}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible rows are established, conditional, obstruction, frontier, cross-module, transport, route, provenance, and local NameCert rows. It exports no hidden

proof of a conditional row, no erasure of an obstruction row, no full closed-consistency theorem, no ambient confluence theorem, and no host semantic equality coordinate.

Theorem 807.2 (Audit-map family NameCert obligations)**.** *For the carrier of Definition 807.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$A = (E, C, O, F, X, H, R, P, N),$$

established-row readback through E, conditional-row readback through C, obstruction-row readback through O, frontier-row readback through F, cross-module readback through X, componentwise transport through H, displayed continuation through R, package provenance through P, and local naming through N.

Proof. Project the finite packet A. The rows E, C, O, F expose the four audit classes before any cross-module use is allowed, so the classifier can distinguish available content, routed content, blocked content, and frontier content.

Read X, H, R next. The cross-module row connects the local audit maps only as displayed neighbours, while transport and continuation replay those same rows rather than adding a theorem-producing coordinate.

Finally inspect P and N. Provenance cites the concrete substitution, open-obligation, and subject-reduction socket chapters as row sources, and the local NameCert row names the packet. Thus the NameCert surface is exhausted by the displayed inventory. □

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyCarrier namecert obligations`

Theorem 807.3 (Audit-map family boundary non-escape)**.** *For every accepted* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier $A = (E, C, O, F, X, H, R, P, N)$, every downstream consumer read remains inside the displayed established, conditional, obstruction, frontier, cross-module,* hsame, Cont, Pkg, *and local* NameCert *rows. In particular, the packet cannot turn a conditional subject-reduction route into a closed theorem, erase an obstruction row, close a frontier row, or export host-level semantic equality.*

Proof. Start from the carrier projection. A consumer can enter the family only through the rows $E, C, O, F, X, H, R, P, N$.

Use the NameCert obligations of Definition 807.2. The obligations keep each audit class tied to its own coordinate, and the continuation routes pass through R without changing a conditional, obstruction, or frontier row into established content.

The provenance row then fixes the boundary. Since P cites concrete sibling chapters only as visible row sources and the packet has no coordinate for hidden closure, every excluded endpoint remains outside the accepted carrier. □

Theorem 807.4 (Audit-map family template coverage)**.** *Every audit map covered by an accepted* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier is represented by the family template: established content appears in E, conditional content appears in C, obstruction content appears in O, frontier content appears in F, and cross-module use appears in X. The transport, route, provenance, and local NameCert rows H, R, P, N preserve this coverage as finite BEDC data for downstream consumers.*

Proof. Read the local audit-map row through X. The family methodology requires exactly the four content classes and the cross-module use class, and the carrier assigns those classes to E, C, O, F, X.

For a concrete sibling such as chapter 779, the available closed substitution rows land in E, while subject-reduction-facing boundaries land outside established content. For chapter 763, open

obligations land in conditional, obstruction, or frontier rows according to their destination boundary. For chapter 719, the four discharge rows and the socket boundary land in C and O rather than in a closed theorem row.

The remaining rows preserve the classification. Componentwise hsame transport, displayed Cont routes, package provenance, and local naming make the same finite coverage readable by downstream consumers without adding another audit class. □

Chapter 808

A Concrete Naming Certificate for $\mathsf{AuditMapTemplate}^{\uparrow}$

The $\mathsf{AuditMapTemplate}^{\uparrow}$ packet realizes the audit-map family template of chapter 9406 as finite NameCert data. It sits beside the substitution audit map of chapter 779, the subject-reduction route triangle of chapter 796, and the closure-preservation audit trace of chapter 792: those siblings show concrete map, route, and trace packets, while this chapter records the reusable finite packet shape that makes an audit map inspectable without treating methodology as a theorem endpoint.

Definition 808.1 (AuditMapTemplate carrier)**.** *An* $\mathsf{AuditMapTemplate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, E, C, O, F, R, B, H, Q, P, N)$$

with the following displayed rows:

1. *S is the setup row naming the substrate, local vocabulary, carrier rows, and admissible consumer interface for the audit map;*
2. *E is the established-inventory row listing the checked or already certified facts that the map may expose as local content;*
3. *C is the conditional-inventory row listing parameterized routes, setup fields, discharge bundles, or interface hypotheses that remain explicit;*
4. *O is the obstruction-inventory row listing no-go facts, missing inhabitants, boundary counterexamples, or shape restrictions that block a stronger reading;*
5. *F is the frontier row naming the strongest nearby claim that is not licensed by S, E, C, O;*
6. *R is the cross-map route row naming the neighbouring audit maps, route certificates, trace packets, and synthesis chapters that may consume or supply the displayed rows;*
7. *B is the boundary row stating which claims are outside the packet even after all displayed rows have been read;*
8. *H records componentwise* hsame *transports for setup, established inventory, conditional inventory, obstruction inventory, frontier, cross-map route, boundary, provenance, and local naming rows;*
9. *Q records displayed* Cont *routes by which a consumer inspects the setup, inventory, obstruction, frontier, route, and boundary rows without adding hidden coordinates;*

10. *P is the* Pkg *provenance over the source audit-map methodology, sibling concrete packets,* BHist, hsame, Cont, Pkg, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapTemplate}^{\uparrow}}$ *row.*

The classifier accepts exactly packets carrying these eleven rows. It exports no proof of the frontier row, no inhabitant for any conditional row, no erasure of the obstruction row, no automatic bridge between neighbouring maps, and no host semantic equality coordinate.

Theorem 808.2 (AuditMapTemplate NameCert obligations)**.** *The carrier of Definition 808.1 satisfies the local* $\mathsf{NameCert}_{\mathsf{AuditMapTemplate}^{\uparrow}}$ *obligation surface. Its obligations are carrier admission for*

$$A = (S, E, C, O, F, R, B, H, Q, P, N),$$

setup readback through S, established-inventory readback through E, conditional-inventory readback through C, obstruction-inventory readback through O, frontier readback through F, cross-map route readback through R, boundary readback through B, componentwise transport through H, displayed continuation through Q, provenance through P, and local naming through N.

Proof. Carrier admission is the displayed finite BHist packet. Projecting S, E, C, O exposes the audit map's setup, positive inventory, parameterized inventory, and obstruction inventory as separate rows rather than as blended prose.

Project F, R, B next. The frontier row names the nearby claim left outside the packet, the cross-map route row names the neighbouring maps that may read or supply rows, and the boundary row records the claims that remain unavailable even after the route is known.

Finally inspect H, Q, P, N. These rows transport, replay, locate, and name the same finite packet. Since every obligation is one of the displayed rows and no hidden row is supplied by transport, continuation, provenance, or naming, the local NameCert surface is exactly the listed carrier inventory. □

Theorem 808.3 (AuditMapTemplate frontier non-closure)**.** *For an accepted* $\mathsf{AuditMapTemplate}^{\uparrow}$ *carrier $A = (S, E, C, O, F, R, B, H, Q, P, N)$, the frontier row F is visible as a boundary object and not as a closed theorem. A consumer may cite F to identify the strongest nearby claim outside S, E, C, O, but the packet supplies neither a proof of F nor an inhabitant that discharges the conditional or obstruction rows.*

Proof. Read the carrier by projection. The rows S, E, C, O describe the licensed setup, established facts, conditional interfaces, and obstruction facts available before the frontier is inspected.

The frontier coordinate F is a row of the packet, not a theorem-constructor for the frontier claim. Its role is to mark where the displayed inventory stops.

The remaining coordinates R, B, H, Q, P, N route, bound, transport, replay, locate, and name that same packet. None of those coordinates has the type of a frontier proof or of a discharge witness for C or O. Thus an accepted packet makes non-closure explicit rather than silently closing the frontier. □

Theorem 808.4 (AuditMapTemplate cross-map routing)**.** *Every accepted* $\mathsf{AuditMapTemplate}^{\uparrow}$ *carrier exposes cross-map routing only through the displayed row R and its supporting rows H, Q, P, N. Any consumer that moves from the template packet to a concrete sibling, such as the packets of chapter 779, chapter 796, or chapter 792, must preserve the setup, established, conditional, obstruction, frontier, and boundary rows named by S, E, C, O, F, B.*

Proof. Start with the route coordinate R. It names neighbouring maps and consumers, but it is still a displayed row of the same finite packet.

The supporting coordinates H, Q, P, N control how the route is transported, replayed, sourced, and named. They do not rewrite the setup row, add facts to the established-inventory row, discharge the conditional row, delete the obstruction row, prove the frontier row, or weaken the boundary row.

Therefore cross-map movement is a projection-and-replay operation over the visible packet. A sibling concrete chapter can consume the template only by reading the rows it displays, so routing preserves the audit-map separation between licensed content, conditions, obstructions, frontier, and boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapTemplate}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapTemplate}^{\uparrow}$ packet is generated from finite BHist rows for setup, established inventory, conditional inventory, obstruction inventory, frontier, cross-map route, boundary, transports, displayed continuations, provenance, and local naming. The template makes audit-map movement a projection-and-replay operation: Cont exposes the setup, inventories, route, and boundary without adding hidden discharge rows. Componentwise hsame preserves the same row separation, while Pkg records the methodology and sibling concrete packets that may consume the template. The packet is a reusable finite map shape, not a theorem proving its frontier.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapTemplate}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the AuditMapTemplate carrier, obligation surface, frontier non-closure theorem, and cross-map routing theorem.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditMapTemplate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim proof of the frontier row, discharge of conditional rows, erasure of obstruction rows, automatic bridge between maps, or host semantic equality.

Upgrade path: Obligation closure requires Lean encodings of the template carrier, inventory projections, frontier non-closure, and cross-map routing preservation.

Chapter 809

A Concrete Naming Certificate for $\mathsf{TypeClassifierRouteJoin}^{\uparrow}$

The $\mathsf{TypeClassifierRouteJoin}^{\uparrow}$ packet realizes the type-checking-as-classifier-membership vision of chapter 9367 as a finite route-join object. It joins the membership row of chapter 476, the route-choice row of chapter 798, and the discharge-socket row of chapter 719 so a compiler or preservation consumer can cite one visible packet rather than coordinate three surfaces separately.

Definition 809.1 (TypeClassifierRouteJoin carrier)**.** *A* $\mathsf{TypeClassifierRouteJoin}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (M, R, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{TypeClassifierMembership}^{\uparrow}$ *row, including its displayed term history, judgment ledger,* Ext *membership row, typed* Cont *reduction row, and local membership certificate;*
2. *R is the* $\mathsf{SubjectReductionRouteChoice}^{\uparrow}$ *row naming that the subject-reduction consumer reads the explicit bundle route or the obstruction boundary;*
3. *S is the* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *row naming the four discharge obligations and the obstruction boundary for closed subject reduction;*
4. *H stores componentwise* hsame *transports for the membership row, route-choice row, discharge-socket row, provenance row, and local naming row;*
5. *C stores displayed* Cont *replay for reading classifier membership, route choice, and socket consumption through the same finite packet;*
6. *P is the* Pkg *provenance over chapter 9367, chapter 476, chapter 798, and chapter 719;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{TypeClassifierRouteJoin}^{\uparrow}}$ *row.*

The carrier contains no host type semantics, hidden conversion relation, closed subject-reduction theorem, quotient term equality, or route selector outside M, R, S, H, C, P, N.

Lean4 (definition) `BEDC.Derived.TypeClassifierRouteJoinUp.TypeClassifierRouteJoinUp`

Theorem 809.2 (TypeClassifierRouteJoin NameCert obligations)**.** *For the carrier of Definition 809.1, the local* $\mathsf{NameCert}_{\mathsf{TypeClassifierRouteJoin}^{\uparrow}}$ *surface consists exactly of:*

1. *carrier admission for the finite packet $J = (M, R, S, H, C, P, N)$;*

2. *joined classifier stability, saying that the classifier-membership row M is read through the same displayed transport and continuation routes as the joined route rows;*
3. *route-choice compatibility, saying that the route-choice row R selects only between the explicit bundle route and the obstruction boundary already displayed by its carrier;*
4. *discharge-socket compatibility, saying that socket reads through S consume exactly the four displayed discharge rows and the obstruction boundary recorded by the socket packet;*
5. *non-escape, saying that no host type semantics, hidden conversion, closed subject-reduction theorem, quotient term equality, or second route selector is exported by the joined packet.*

Proof. Carrier admission is the tuple displayed in Definition 809.1. The membership, route-choice, and socket rows are visible as M, R, S, and every transported read must pass through H.

Joined classifier stability is inherited at the paper level from the membership carrier of chapter 476. The join does not alter the membership row; it only records the route and socket rows beside it and replays the same reads through C.

Route-choice compatibility follows from chapter 798. The row R exposes the explicit bundle route and the obstruction boundary, and it does not create a second discharge route.

Discharge-socket compatibility follows from chapter 719. The row S names the four discharge obligations and the obstruction boundary, while P and N account for provenance and local naming. □

Lean4 ✓ `BEDC.Derived.TypeClassifierRouteJoinUp.TypeClassifierRouteJoinNameCertObligations`

Theorem 809.3 (TypeClassifierRouteJoin non-escape)**.** *No accepted* TypeClassifierRouteJoin$^{\uparrow}$ *carrier exports host type semantics, a hidden conversion relation, a closed subject-reduction theorem, quotient term equality, or a second route selector. Every public read factors through the displayed membership row M, route-choice row R, discharge-socket row S, componentwise transport row H, continuation replay row C, provenance row P, and local naming row N.*

Lean4 ✓ `BEDC.Derived.TypeClassifierRouteJoinUp.TypeClassifierRouteJoinUp nonescape`

Proof. Inspect the carrier inventory. The only classifier-facing coordinate is M, the only route-choice coordinate is R, and the only discharge-socket coordinate is S.

Transport and replay cannot add a semantic coordinate. The rows H and C preserve and expose the displayed membership, route-choice, and socket rows componentwise.

The provenance and naming rows identify the source chapters and the local certificate. Since none of M, R, S, H, C, P, N names host type semantics, hidden conversion, closed subject reduction, quotient term equality, or another route selector, those objects cannot be read from the joined packet. □

Closure status for NameCert$_{\text{TypeClassifierRouteJoin}^{\uparrow}}$.

Constructive story: A TypeClassifierRouteJoin$^{\uparrow}$ packet is generated from a classifier-membership row, a subject-reduction route-choice row, a discharge-socket row, componentwise hsame transports, displayed Cont replay, provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{TypeClassifierRouteJoin}^{\uparrow}}$, seed)

Scope closed: Definition 809.1, Definition 809.2, and Definition 809.3 bind the finite route join over type-classifier membership, route choice, discharge socket, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{TypeClassifierRouteJoin}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close host type semantics, hidden conversion, closed subject reduction, quotient term equality, route-selection uniqueness beyond the displayed route-choice row, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, joined classifier stability, route-choice compatibility, discharge-socket compatibility, replay, provenance, local naming, and non-escape for the same finite route-join packet.

Chapter 810

A Concrete Naming Certificate for $\mathsf{AuditMapFamilyLedger}^{\uparrow}$

The $\mathsf{AuditMapFamilyLedger}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as finite NameCert data. It sits beside the substitution audit map of chapter 779, the MetaCIC audit synthesis packet of chapter 776, and the closure-preservation audit packet of chapter 802: those sibling chapters name local audit rows, while this packet records the family-level ledger that keeps their module tags, neighbour links, obstruction rows, and frontier rows visible without turning them into hidden closure.

Definition 810.1 (Audit-map family ledger carrier)**.** *An* $\mathsf{AuditMapFamilyLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, A, E, P, O, U, B, H, C, L, K, N)$$

with the following visible rows:

1. *G is the family tag naming the local audit-map module and its BEDC substrate;*
2. *A is the local audit-map row, such as the substitution audit row of chapter 779;*
3. *E records neighbouring-map links to sibling audit packets, including synthesis, closure-preservation, subject-reduction, and normal-boundary audit rows;*
4. *P records positive rows already available to the local module;*
5. *O records conditional rows whose conclusion is available only after a named discharge route;*
6. *U records obstruction rows that the family ledger must keep visible;*
7. *B records frontier rows offered to downstream consumers without claiming their closure;*
8. *H records componentwise* hsame *transports for the family tag, local audit row, neighbour links, positive rows, conditional rows, obstruction rows, frontier rows, continuation rows, provenance rows, and local naming row;*
9. *C records the displayed* Cont *routes by which consumers read the local audit map, neighbouring-map links, row classes, frontier handoffs, provenance, and local name;*
10. *L is the finite ledger over the audit-map family rows,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$*;*
11. *K is the* Pkg *provenance row recording which concrete audit chapters supply the visible rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapFamilyLedger}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible rows are the displayed family tag, local audit-map row, neighbouring-map links, positive rows, conditional rows, obstruction rows, frontier rows, transport rows, continuation routes, ledger row, package provenance, and local naming row. It exports no global proof of subject reduction, no full consistency theorem, no ambient confluence theorem, no hidden closure principle, and no host-level semantic equality coordinate.

Lean4 ✓ `BEDC.Derived.AuditMapFamilyLedgerUp.AuditMapFamilyLedgerTasteGate single carrier alignment`

Theorem 810.2 (Audit-map family ledger NameCert obligations)**.** *For the carrier of Definition 810.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapFamilyLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$F = (G, A, E, P, O, U, B, H, C, L, K, N),$$

family-tag readback through G, local audit-map readback through A, neighbouring-map link readback through E, positive-row readback through P, conditional-row readback through O, obstruction-row readback through U, frontier-row readback through B, componentwise transport through H, displayed continuation through C, ledger exactness through L, package provenance through K, and local naming through N.

Proof. Project the finite packet F. The rows G, A, E display the family tag, the local audit map, and the neighbouring audit maps before any row-level claim can be read.

Read the row classes next. The positive rows P, conditional rows O, obstruction rows U, and frontier rows B partition the visible audit surface into available, routed, blocked, and consumer-facing entries.

Finally inspect H, C, L, K, N. Transport and continuation replay the same displayed rows, the ledger records no additional row class, the package row cites only the visible concrete audit chapters, and the local name binds the packet. Hence the NameCert surface is exhausted by the carrier inventory. □

Theorem 810.3 (Audit-map family ledger hidden-closure non-escape)**.** *For every accepted* $\mathsf{AuditMapFamilyLedger}^{\uparrow}$ *carrier $F = (G, A, E, P, O, U, B, H, C, L, K, N)$, every consumer read of the audit-map family remains inside the displayed family tag, local audit-map row, neighbouring-map links, positive rows, conditional rows, obstruction rows, frontier rows,* hsame *transports,* Cont *routes, finite ledger,* Pkg *provenance, and local* NameCert *row. In particular, the packet cannot export a hidden proof of the obstruction rows, an unlisted discharge route for the conditional rows, a closed subject-reduction theorem, full closed consistency, ambient confluence, or host semantic equality.*

Proof. Start with the carrier projection. The only consumer-facing data are the rows $G, A, E, P, O, U, B, H, C, L, K$, so a read of the family ledger must enter through the displayed local audit map and its neighbouring links.

Use the NameCert obligations of Definition 810.2. They bind each positive, conditional, obstruction, and frontier row to its own displayed coordinate and route every transport or continuation through H and C.

The ledger and provenance rows then rule out hidden closure. Since L records no unlisted row and K cites only visible concrete audit chapters, a consumer may cite the family ledger as finite audit data but cannot extract a proof or discharge route absent from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapFamilyLedger}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapFamilyLedger}^{\uparrow}$ packet is generated from a family tag, a local audit-map row, neighbouring-map links, positive rows, conditional rows, obstruction rows, frontier rows, componentwise hsame transports, displayed Cont routes, a finite ledger, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{AuditMapFamilyLedger}\uparrow}$, seed)

Scope closed: Definition 810.1, Definition 810.2, and Definition 810.3 bind the finite audit-map family ledger and its hidden-closure boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{AuditMapFamilyLedger}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, full closed consistency, ambient confluence, hidden discharge routes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, family-tag readback, local audit-map readback, neighbouring-map readback, row-class exactness, transport, continuation, ledger exactness, provenance, naming, and non-escape for the same finite packet.

Chapter 811

MetaCIC Audit Map Family Name Certificate Construction

The $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$ packet turns the audit-map family methodology of chapter 9406 into one finite MetaCIC NameCert carrier. It sits beside the synthesis packet of chapter 776, the substitution audit map of chapter 779, and the closure-preservation audit packet of chapter 791: those chapters expose local rows, while this packet records how the rows are collected into a family without converting local audit data into global MetaCIC closure.

The packet is a composite over the local audit-map rows, synthesis rows, obstruction rows, frontier rows, and cross-map dependency ledger, rather than an atomic carrier.

Definition 811.1 (MetaCIC audit-map family carrier)**.** *A* $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, S, O, F, D, H, C, P, N)$$

with the following visible rows:

1. *M is the finite family of local MetaCIC audit-map rows, including substitution, closure-preservation, normalization, confluence, beta, decidability, typed-example, subject-reduction, and consistency-facing maps when those rows are present;*
2. *S is the finite family of synthesis rows that read local map entries into the MetaCIC audit synthesis surface;*
3. *O is the obstruction ledger for local rows that must remain visible as blockers rather than hidden discharge evidence;*
4. *F is the frontier ledger for conditional or consumer-facing rows whose use is permitted only through named neighbouring maps;*
5. *D is the cross-map dependency ledger recording which synthesis, obstruction, and frontier rows consume which local audit-map rows;*
6. *H records componentwise* hsame *transports for the local map rows, synthesis rows, obstruction rows, frontier rows, dependency ledger, continuation routes, provenance, and local name;*
7. *C records the displayed* Cont *routes by which consumers replay local-map reads, synthesis reads, obstruction reads, frontier handoffs, dependency reads, provenance reads, and the local name;*
8. *P is the* Pkg *provenance over the audit-map methodology, the concrete audit-map siblings, the synthesis packet, the obstruction ledgers, the frontier ledgers, and the local MetaCIC substrates;*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetaCICAuditMapFamily}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible coordinates are the rows $M, S, O, F, D, H, C, P, N$. It exports no unlisted theorem of subject reduction, closure preservation, normalization, confluence, closed consistency, or host semantic equality.

Theorem 811.2 (MetaCIC audit-map family NameCert obligations)**.** *For the carrier of Definition 811.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICAuditMapFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$A = (M, S, O, F, D, H, C, P, N),$$

local audit-map row exposure through M, synthesis-row exposure through S, obstruction-row exposure through O, frontier-row exposure through F, cross-map dependency readback through D, componentwise route replay through H and C, package provenance through P, and local naming through N.

Proof. Project the finite packet A. The row M names the local audit maps before any synthesis or frontier read can be consumed.

Read the row families S, O, F next. The synthesis rows expose positive family assembly data, the obstruction rows expose blocked or conditional cells, and the frontier rows expose only the named handoffs available to downstream consumers.

Finally inspect D, H, C, P, N. The dependency ledger records which local rows each cross-map read may use, transport and continuation replay those reads componentwise, provenance cites the displayed sibling chapters, and the local name binds the packet. No other NameCert obligation is available from the carrier. □

Lean4 ✓ `BEDC.Derived.MetaCICAuditMapFamilyUp.MetaCICAuditMapFamilyTasteGate single carrier alignment`

Theorem 811.3 (MetaCIC audit-map family non-escape)**.** *For every accepted* $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$ *carrier $A = (M, S, O, F, D, H, C, P, N)$, every consumer read remains inside the displayed local audit-map rows, synthesis rows, obstruction rows, frontier rows, cross-map dependency ledger,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. In particular, a consumer cannot turn one local audit map, or the finite family of such maps, into global MetaCIC closure, subject reduction, normalization, confluence, full closed consistency, or host semantic equality.*

Proof. Start with the carrier projection. The only public coordinates are $M, S, O, F, D, H, C, P, N$, so every consumer-facing read must pass through the displayed local map rows and the displayed family ledgers.

Use the NameCert obligations of Definition 811.2. They force synthesis reads through S, obstruction reads through O, frontier reads through F, and cross-map reads through D with transport and continuation replay supplied by H and C.

The provenance and naming rows do not add theorem content. Since P cites only visible sibling packets and N names only the local carrier, no read can manufacture a missing global closure theorem or discharge an obstruction absent from the packet. □

Lean4 ✓ `BEDC.Derived.MetaCICAuditMapFamilyUp.MetaCICAuditMapFamilyNonescape`

Theorem 811.4 (MetaCIC audit-map family dependency readback)**.** *For every accepted* $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$ *carrier $A = (M, S, O, F, D, H, C, P, N)$, every cross-map family read exposes the local audit-map row family M, synthesis row family S, obstruction ledger O, frontier ledger F, dependency ledger*

D, componentwise transport H, continuation replay C, provenance row P, and local name N before any synthesis row is consumed. In particular, a synthesis consumer cannot read S while hiding the dependency ledger D or any of the displayed rows on which D depends.

Proof. Project the accepted carrier. The classifier accepts the finite packet only through the displayed coordinates $M, S, O, F, D, H, C, P, N$, so a cross-map read has no independent synthesis coordinate outside this list.

Read the dependency ledger before consuming synthesis output. The row D records which local map rows, obstruction rows, and frontier rows are used by each synthesis read, while H and C replay the same dependencies under componentwise transport and continuation.

The provenance and name rows keep the read attached to the same finite packet. Thus every synthesis-facing read exposes D together with M, S, O, F, H, C, P, N before the synthesis row is available to a consumer. □

Theorem 811.5 (MetaCIC audit-map family frontier ledger non-escape)**.** *For every accepted* $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$ *carrier $A = (M, S, O, F, D, H, C, P, N)$, frontier rows in F remain visible ledger rows throughout every permitted family read. They cannot be converted into global MetaCIC closure, subject reduction, normalization, confluence, full closed consistency, or host semantic equality.*

Proof. Inspect the frontier coordinate F together with the dependency ledger D. A frontier row is consumed only through a named dependency read, and that read keeps the frontier coordinate visible beside the local audit-map and synthesis rows.

Apply the non-escape boundary of Definition 811.3. The accepted packet has no coordinate for global closure, subject reduction, normalization, confluence, full closed consistency, or host semantic equality.

Transport, continuation, provenance, and naming preserve the displayed ledger route; they do not add theorem content. Hence a frontier row can be replayed only as a frontier row of the same finite carrier, not as any of the excluded global MetaCIC conclusions. □

Theorem 811.6 (MetaCIC audit-map family primitive scope)**.** *For every accepted* $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$ *carrier*

$$A = (M, S, O, F, D, H, C, P, N),$$

every family read is scoped by the displayed BEDC primitives and named sibling rows. Local audit maps are read through M, synthesis rows through S, obstruction rows through O, frontier rows through F, dependency rows through D, componentwise hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No accepted family packet introduces a global closure row, subject-reduction row, normalization row, confluence row, closed-consistency row, or host equality row beyond those displayed primitives.

Proof. Project the accepted packet $A = (M, S, O, F, D, H, C, P, N)$. The carrier definition lists exactly the local audit-map, synthesis, obstruction, frontier, dependency, transport, replay, provenance, and naming rows.

Apply the NameCert obligations of Definition 811.2. They force each local audit-map read through M, each synthesis read through S, each obstruction read through O, each frontier read through F, and each dependency read through D before any family consumer receives the packet.

Apply non-escape and frontier-ledger non-escape from Definition 811.3 and Definition 811.5. These rows keep frontier and obstruction data visible as displayed ledgers rather than hidden theorem discharge.

Finally route replay, provenance, and naming through H, C, P, N. Since these rows only preserve and name the same finite packet, they introduce no global closure, subject reduction, normalization, confluence, closed consistency, or host equality row. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICAuditMapFamily}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICAuditMapFamily}^{\uparrow}$ packet is generated from local MetaCIC audit-map rows, synthesis rows, obstruction rows, frontier rows, a cross-map dependency ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICAuditMapFamily}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 811.1, Definition 811.2, Definition 811.3, Definition 811.4, Definition 811.5, and Definition 811.6 bind the finite MetaCIC audit-map family packet, dependency readback, frontier-ledger visibility, primitive dependency scope, and non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICAuditMapFamily}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.MetaCICAuditMapFamilyUp.MetaCICAuditMapFamilyTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close global MetaCIC closure, subject reduction, normalization, confluence, full closed consistency, or bridge checking.

Upgrade path: Further closure requires public export rows or a bridge row over local audit-map reads, synthesis reads, obstruction reads, frontier reads, route replay, provenance, and naming over the same finite packet.

Chapter 812

A Concrete Naming Certificate for $\mathsf{AuditMapFrontierIndex}^{\uparrow}$

The $\mathsf{AuditMapFrontierIndex}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as finite frontier-index routing data. It sits beside the family ledger of chapter 810, the substitution audit map of chapter 779, and the synthesis packet of chapter 776: those chapters expose local rows and family ledgers, while this packet records how frontier entries are routed between local maps, neighbouring-map rows, obstruction rows, and synthesis consumers without closing the frontier itself.

Definition 812.1 (Audit-map frontier index carrier)**.** *An* $\mathsf{AuditMapFrontierIndex}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (T, A, E, P, R, O, F, S, H, C, K, N)$$

with the following displayed rows:

1. *T is the map tag naming the local audit-map module and its BEDC substrate;*
2. *A is the local audit row whose frontier is being indexed;*
3. *E is the neighbouring-map row listing the sibling audit packets that may supply or consume frontier entries;*
4. *P is the positive row recording entries already available in the local map;*
5. *R is the conditional route row naming the displayed discharge route required before a conditional entry may be consumed;*
6. *O is the obstruction row whose named boundary must remain visible to every route;*
7. *F is the frontier row offered to downstream consumers as a named boundary and not as a closed theorem;*
8. *S is the synthesis-consumer row naming the finite reader that consumes the indexed frontier together with neighbouring-map links;*
9. *H records componentwise* hsame *transports for the map tag, local audit row, neighbouring-map row, positive row, conditional route row, obstruction row, frontier row, synthesis-consumer row, provenance row, and local naming row;*

10. *C records the displayed* Cont *routes from the local map to neighbouring maps, from conditional rows to their named routes, from obstruction rows to frontier rows, and from frontier rows to synthesis consumers;*
11. *K is the* Pkg *provenance row over the audit-map family ledger, local audit maps, neighbouring-map links, frontier rows, synthesis consumers,* BHist, hsame, Cont, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapFrontierIndex}^{\uparrow}}$ *row.*

The carrier is the finite frontier index. It contains no coordinate for a hidden discharge of the obstruction row, a closed proof of a frontier entry, an unlisted neighbouring map, a global subject-reduction theorem, full closed consistency, ambient confluence, or host semantic equality.

Theorem 812.2 (Audit-map frontier index NameCert obligations)**.** *For the carrier of Definition 812.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapFrontierIndex}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for $I = (T, A, E, P, R, O, F, S, H, C, K, N)$ as finite* BHist *data;*
2. *family-map readback through the map tag T, local audit row A, and neighbouring-map row E;*
3. *frontier-row exactness saying that F is read only as the displayed frontier row associated to A, E, P, R, O;*
4. *obstruction non-escape saying that no consumer route can bypass O or read F as a discharge of O;*
5. *synthesis-consumer handoff saying that S receives only the displayed frontier row, neighbouring-map links, transports, continuations, provenance, and local name through H, C, K, N.*

Lean4 ✓ `BEDC.Derived.AuditMapFrontierIndexUp.AuditMapFrontierIndexTasteGate single carrier alignment`

Proof. Project the carrier I. The rows T, A, E identify the local audit map and its neighbouring-map surface, while P, R, O, F separate positive entries, conditional routes, obstruction entries, and frontier entries.

The frontier exactness obligation is then finite row inspection. The only frontier coordinate in the packet is F, and the displayed continuation row C routes it together with the local row, neighbouring-map row, positive row, conditional route row, and obstruction row.

For non-escape, inspect the obstruction and consumer rows. Since O is a separate carrier coordinate and F is only a frontier coordinate, a consumer cannot turn the frontier row into a proof of the obstruction or bypass the named conditional route R.

Finally read S, H, C, K, N. These rows hand the indexed frontier to synthesis consumers, preserve the same component rows under hsame, replay the displayed Cont routes, record package provenance, and bind the local name. No remaining coordinate can supply an unlisted neighbouring map, hidden discharge, global subject-reduction theorem, full closed consistency, ambient confluence, or host semantic equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapFrontierIndex}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapFrontierIndex}^{\uparrow}$ packet is generated from a map tag, local audit row, neighbouring-map row, positive row, conditional route row, obstruction row, frontier row, synthesis-consumer row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapFrontierIndex}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 812.1 and Definition 812.2 bind the finite audit-map frontier index and its synthesis-consumer handoff boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditMapFrontierIndex}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.AuditMapFrontierIndexUp.AuditMapFrontierIndexTasteGate\_single\_carrier\_alignment`
Bridge status: none
Origin: ai
Not claimed: This chapter does not close obstruction rows, conditional discharge routes, frontier entries, subject reduction, full closed consistency, ambient confluence, Lean verification, or bridge checking.
Upgrade path: Obligation closure requires checked carrier admission, family-map readback, frontier-row exactness, obstruction non-escape, synthesis-consumer handoff, transport, continuation, provenance, and naming for the same finite packet.

Definition 812.3 (Displayed frontier-index restriction)**.** *Let*

$$I = (T, A, E, P, R, O, F, S, H, C, K, N)$$

be an accepted $\mathsf{AuditMapFrontierIndex}^{\uparrow}$ *carrier in the sense of Definition 812.1 and Definition 812.2. A displayed subfamily restriction of* I *is a finite row* E_0 *together with an inclusion certificate* $E_0 \subseteq E$ *and the coordinatewise retained packet*

$$I|_{E_0} = (T, A, E_0, P|_{E_0}, R|_{E_0}, O|_{E_0}, F|_{E_0}, S|_{E_0}, H|_{E_0}, C|_{E_0}, K|_{E_0}, N|_{E_0}),$$

where each restricted row is obtained by deleting exactly the entries whose neighbouring-map coordinate is not displayed in E_0*, while keeping the local audit row* A*, the map tag* T*, the local positive row over* A*, and every retained transport, continuation, provenance, and local naming certificate attached to an entry of* E_0*.*

Theorem 812.4 (Audit-map frontier-index neighbouring restriction)**.** *Let*

$$I = (T, A, E, P, R, O, F, S, H, C, K, N)$$

be an accepted $\mathsf{AuditMapFrontierIndex}^{\uparrow}$ *carrier. Let* $E_0 \subseteq E$ *be a displayed finite neighbouring-map subfamily, and suppose the restricted rows*

$$P|_{E_0},\ R|_{E_0},\ O|_{E_0},\ F|_{E_0},\ S|_{E_0},\ H|_{E_0},\ C|_{E_0},\ K|_{E_0},\ N|_{E_0}$$

retain exactly the positive rows, conditional route rows, obstruction rows, frontier rows, synthesis-consumer rows, transports, continuations, provenance, and local $\mathsf{NameCert}$ *rows whose neighbouring-map coordinate lies in* E_0*, while retaining the same local audit row* A *and map tag* T*. Then the displayed restriction*

$$I|_{E_0} = (T, A, E_0, P|_{E_0}, R|_{E_0}, O|_{E_0}, F|_{E_0}, S|_{E_0}, H|_{E_0}, C|_{E_0}, K|_{E_0}, N|_{E_0})$$

is an accepted $\mathsf{AuditMapFrontierIndex}^{\uparrow}$ *carrier for the restricted neighbouring-map row. Moreover, if a neighbouring map* e *is not displayed in* E_0*, then* e *supplies no frontier entry of* $I|_{E_0}$ *and no synthesis consumer of* $I|_{E_0}$ *can read* e *as a frontier source.*

Proof. By Definition 812.1, an $\mathsf{AuditMapFrontierIndex}^{\uparrow}$ carrier is exhausted by the twelve displayed rows $T, A, E, P, R, O, F, S, H, C, K, N$. The restriction keeps the map tag T and local audit row A, replaces only the neighbouring-map row E by the displayed finite row E_0, and restricts every row whose entries are indexed by neighbouring maps to those coordinates lying in E_0. Since E_0 is finite and every retained coordinate is a coordinate already present in the finite packet I, the displayed tuple $I|_{E_0}$ is again finite BHist data.

It remains to check that the five local $\mathsf{NameCert}_{\mathsf{AuditMapFrontierIndex}^{\uparrow}}$ obligations of Definition 812.2 survive this deletion. Carrier admission has just been checked by finite subrow formation. Family-map readback is local in T, A, E: after restriction the readback row is T, A, E_0, and each neighbour

named there is named because $E_0 \subseteq E$. Frontier-row exactness is also coordinatewise: $F|_{E_0}$ is read only as the displayed frontier row associated to $A, E_0, P|_{E_0}, R|_{E_0}, O|_{E_0}$, because no other frontier coordinate is inserted by the restriction.

For obstruction non-escape, inspect the retained obstruction and continuation rows. The row $O|_{E_0}$ is the only obstruction row of the restricted packet, and $C|_{E_0}$ contains only the displayed routes from the local map to neighbours in E_0, from retained conditional rows to their named routes, from retained obstruction rows to retained frontier rows, and from retained frontier rows to retained synthesis consumers. Thus a consumer of $I|_{E_0}$ cannot bypass $O|_{E_0}$, cannot discharge $O|_{E_0}$ through a deleted neighbour, and cannot read $F|_{E_0}$ as a proof of the obstruction.

For synthesis-consumer handoff, the consumer row is exactly $S|_{E_0}$, and its available data are exactly the retained frontier row, retained neighbouring-map links, retained transports $H|_{E_0}$, retained continuations $C|_{E_0}$, retained provenance $K|_{E_0}$, and retained local name $N|_{E_0}$. Hence the restricted packet satisfies the same five obligations with E_0 in place of E, so it is an accepted frontier index.

Finally let e be a neighbouring map not displayed in E_0. A frontier entry of $I|_{E_0}$ must occur in the sole frontier coordinate $F|_{E_0}$, and every such coordinate was retained only when its neighbouring-map coordinate lay in E_0. Likewise every synthesis read in $I|_{E_0}$ factors through $S|_{E_0}$ and $C|_{E_0}$, whose entries were retained only over E_0. Therefore e has no coordinate in the restricted frontier row and no displayed continuation into a restricted synthesis consumer, so it cannot supply a frontier entry of $I|_{E_0}$. $\square$

Chapter 813

A Concrete Naming Certificate for $\mathsf{AuditMapMethodology}^{\uparrow}$

The $\mathsf{AuditMapMethodology}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as a finite NameCert carrier. It sits between the family-level method and the substitution audit map of chapter 779: the methodology packet names the template, admissible row classes, boundary rule, and sibling handoff through which concrete audit maps become readable without claiming their neighbouring proof obligations.

Definition 813.1 (Audit-map methodology carrier)**.** *An* $\mathsf{AuditMapMethodology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, A, C, O, F, B, S, H, R, P, N)$$

with the following visible rows:

1. *T is the audit-map template row, recording the setup, established, conditional, obstruction, frontier, cross-reference, and boundary slots of Definition 9406.2;*
2. *A is the admitted audit-map row family, whose entries include concrete local maps such as* $\mathsf{SubstitutionAuditMap}^{\uparrow}$*;*
3. *C is the classifier row separating established, conditional, obstruction, frontier, and handoff content;*
4. *O is the obligation-surface row listing the finite NameCert checks needed before a local audit map can be consumed;*
5. *F is the frontier row that records named open sockets without turning them into theorem rows;*
6. *B is the boundary row excluding hidden closure, ambient equality, and unstated discharge routes;*
7. *S is the sibling handoff row pointing from the methodology packet to the concrete substitution audit map and to later audit-map family ledgers;*
8. *H records componentwise* hsame *transports for the template, audit-map family, classifier, obligation, frontier, boundary, handoff, route, provenance, and naming rows;*
9. *R records the displayed* Cont *routes through which consumers inspect the methodology packet;*
10. *P is the* Pkg *provenance over the audit-map family method,* $\mathsf{SubstitutionAuditMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapMethodology}^{\uparrow}}$ *row.*
The classifier accepts exactly packets whose visible rows are the displayed template, admitted audit-map family, classifier, obligation surface, frontier, boundary, sibling handoff, transport, continuation, provenance, and naming rows. It exports no proof of subject reduction, no confluence theorem, no normalisation theorem, no closed-consistency theorem, no unlisted audit map, and no host semantic equality coordinate.

Lean4 ✓ `BEDC.Derived.AuditMapMethodologyUp.AuditMapMethodologyTasteGate single carrier alignment`

Theorem 813.2 (Audit-map methodology obligation surface)**.** *For the carrier of Definition 813.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapMethodology}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$M = (T, A, C, O, F, B, S, H, R, P, N),$$

template readback through T, admitted-map readback through A, classifier readback through C, obligation-surface readback through O, frontier readback through F, boundary readback through B, sibling handoff through S, componentwise transport through H, displayed continuation through R, package provenance through P, and local naming through N.

Proof. Project the finite packet M. The row T displays the audit-map template before any local audit content is read, while A supplies only the admitted family of concrete map rows.

Read C, O, F, B next. The classifier separates the row classes, the obligation surface lists the NameCert checks, the frontier keeps open sockets visible, and the boundary records the exclusions attached to the methodology.

Finally inspect S, H, R, P, N. The handoff row names the concrete sibling surface, the transport and continuation rows replay the same displayed data, the provenance row cites only visible sources, and the local naming row binds the packet. No further obligation remains outside the listed coordinates. □

Theorem 813.3 (Audit-map methodology template soundness)**.** *Every accepted* $\mathsf{AuditMapMethodology}^{\uparrow}$ *carrier $M = (T, A, C, O, F, B, S, H, R, P, N)$ presents the template of Definition 9406.2 as finite NameCert data: positive content is read through the classifier, conditional content is routed through the obligation surface, obstruction and frontier content remain named rows, and cross-module use is available only through displayed handoff and continuation rows.*

Proof. Use the carrier definition to read T as the finite template row. Its slots are setup, established, conditional, obstruction, frontier, cross-reference, and boundary, matching the method described in chapter 9406.

The classifier row C and obligation row O then sort the template entries. Established entries may be cited as displayed rows, conditional entries retain their named routes, and obstruction or frontier entries remain visible without being promoted to solved theorem content.

The rows S and R account for cross-module use. A consumer can follow only the displayed sibling handoff and continuation routes, so the template is sound as NameCert data rather than as an ambient claim about neighbouring modules. □

Theorem 813.4 (Audit-map methodology boundary non-escape)**.** *For every accepted* $\mathsf{AuditMapMethodology}^{\uparrow}$ *carrier $M = (T, A, C, O, F, B, S, H, R, P, N)$, every consumer read remains inside the displayed template, admitted audit-map family, classifier, obligation surface, frontier, boundary, sibling handoff,* hsame *transport,* Cont *route,* Pkg *provenance, and local* NameCert *rows. In particular, the packet cannot export a hidden proof obligation discharge, an unlisted audit map, subject reduction, confluence, normalisation, closed consistency, or host semantic equality.*

Proof. Begin with carrier projection. The only consumer-facing data are the rows $T, A, C, O, F, B, S, H, R, P, N$, so every read of the methodology packet enters through the displayed audit-map family surface.

Apply the obligation surface of Definition 813.2. It binds each row class, frontier socket, boundary exclusion, and sibling handoff to a visible coordinate and routes transport or continuation through H and R.

The provenance and naming rows rule out escape. Since P records only the methodology source and named concrete audit-map rows, and N names only this finite carrier, no consumer can extract a theorem or discharge route absent from the packet. □

Theorem 813.5 (Audit-map methodology substitution handoff)**.** *The* $\mathsf{AuditMapMethodology}^{\uparrow}$ *carrier admits* $\mathsf{SubstitutionAuditMap}^{\uparrow}$ *as a concrete sibling handoff exactly at the row S: the methodology packet may point to the substitution audit-map carrier of chapter 779, read its closed-substitution audit rows as an admitted local map through A, and keep all substitution-specific non-escape exclusions inside that sibling chapter.*

Proof. Read S as the sibling handoff row and A as the admitted audit-map family row. The handoff therefore points to $\mathsf{SubstitutionAuditMap}^{\uparrow}$ only as a concrete local audit map, not as a replacement for the methodology packet.

The classifier C and obligation row O preserve the distinction between the methodology slots and the substitution-specific rows. Closed shift, substitution, and closed-composition data are read in the sibling chapter, while this carrier records the fact that such a map is admitted by the method.

Finally use B, H, R, P, N. The boundary row keeps unrestricted substitution, beta-substitution preservation, and closed subject reduction outside the methodology handoff; transport, continuation, provenance, and naming replay only the displayed finite rows. Thus the handoff is available without absorbing the sibling's exclusions into a stronger methodology claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapMethodology}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AuditMapMethodology}^{\uparrow}$ packet is generated from an audit-map template row, admitted audit-map family rows, classifier rows, obligation-surface rows, frontier and boundary rows, a sibling handoff row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapMethodology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 813.1, Definition 813.2, Definition 813.3, Definition 813.4, and Definition 813.5 bind the finite audit-map methodology carrier, template soundness, boundary, and substitution handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditMapMethodology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, confluence, normalisation, closed consistency, hidden discharge routes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, template readback, admitted-map readback, classifier and obligation-surface exactness, boundary non-escape, substitution handoff, transport, continuation, provenance, and naming for the same finite packet.

Chapter 814

A Concrete Naming Certificate for AuditMapCoverageLedger$^{\uparrow}$

The AuditMapCoverageLedger$^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as a finite coverage ledger. It sits beside the kernel acceptance audit witness of chapter 547, the substitution audit map of chapter 779, the MetaCIC confluence audit of chapter 743, and the closure-preservation audit packet of chapter 803. Those sibling chapters expose concrete audit rows; this packet records which rows are established, conditional, obstructed, frontier-facing, and cross-map dependent before any consumer reads the family as a covered surface.

Definition 814.1 (Audit-map coverage ledger carrier)**.** *An* AuditMapCoverageLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, E, C, O, F, X, H, R, P, N)$$

with the following displayed rows:

1. *M is the map-source row naming the audit-map chapter, Lean substrate module, and concrete sibling packet from which the coverage entry is read;*
2. *E is the established-inventory row for theorem or definition entries already exposed by the map source;*
3. *C is the conditional-inventory row for entries whose conclusion is available only through a displayed discharge route or local hypothesis row;*
4. *O is the obstruction-inventory row for blocked entries that the map must keep visible as blocked rather than silently discharged;*
5. *F is the frontier-inventory row for entries offered to downstream consumers as named boundaries without asserting family-level closure;*
6. *X is the cross-map dependency row recording exact links to kernel acceptance, substitution, confluence, closure-preservation, and other displayed audit packets;*
7. *H records componentwise* hsame *transports for the source, inventory, dependency, route, provenance, and local naming rows;*
8. *R records the displayed* Cont *routes by which a consumer may read established, conditional, obstruction, frontier, and cross-map dependency rows;*
9. *P is the* Pkg *provenance row over the concrete audit-map family,* BHist*,* hsame*,* Cont*, and* NameCert *data;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapCoverageLedger}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible rows are $M, E, C, O, F, X, H, R, P, N$. It contains no coordinate for family-level closure, hidden discharge, stronger MetaCIC result, host semantic equality, or unlisted proof source.

Theorem 814.2 (Audit-map coverage ledger NameCert obligations)**.** *For the carrier of Definition 814.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapCoverageLedger}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the finite packet $L = (M, E, C, O, F, X, H, R, P, N)$;*
2. *role-row coverage for the map source, established inventory, conditional inventory, obstruction inventory, frontier inventory, cross-map dependency, transport, route, provenance, and local naming rows;*
3. *established, conditional, obstruction, and frontier separation, so no row class may be read as another row class;*
4. *cross-map dependency exactness, so every dependency read through X names a displayed sibling packet and route rather than an ambient family theorem;*
5. *local naming, so all consumer-facing reads pass through the displayed* $\mathsf{NameCert}_{\mathsf{AuditMapCoverageLedger}^{\uparrow}}$ *row N.*

Lean4 ✓ `BEDC.Derived.AuditMapCoverageLedgerUp.AuditMapCoverageLedgerTasteGate single carrier alignment`

Proof. Project the finite carrier. The row M names the map source, while E, C, O, F partition the visible audit inventory into established, conditional, obstructed, and frontier-facing entries.

Read the cross-map row next. The dependency row X may cite only displayed sibling packets and the route row R records how those citations are consumed.

Finally inspect H, P, N. Componentwise transport preserves the same rows, provenance cites the concrete audit-map family, and the local NameCert row binds the consumer-facing packet. Hence the five obligations exhaust the naming surface. □

Theorem 814.3 (Audit-map coverage ledger frontier non-escape)**.** *For every accepted* $\mathsf{AuditMapCoverageLedger}^{\uparrow}$ *carrier $L = (M, E, C, O, F, X, H, R, P, N)$, no consumer may read family-level closure, hidden discharge, or a stronger MetaCIC result from the ledger unless the read is one of the displayed role rows $M, E, C, O, F, X, H, R, P, N$. In particular, an established row remains established, a conditional row remains routed through its displayed condition, an obstruction row remains blocked, and a frontier row remains a named boundary.*

Proof. Start with the carrier projection. The only rows available to a consumer are the map source, four inventory rows, cross-map dependency row, transport row, continuation route row, provenance row, and local naming row.

Use the NameCert obligations of Definition 814.2. They separate the established, conditional, obstruction, and frontier inventories and force every cross-map read through the displayed dependency and route rows.

Since the classifier has no coordinate for family-level closure, hidden discharge, or a stronger MetaCIC theorem, those readings cannot be extracted from the ledger. A consumer may cite the frontier only as the displayed finite boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapCoverageLedger}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapCoverageLedger}^{\uparrow}$ packet is generated from a map-source row, established inventory, conditional inventory, obstruction inventory, frontier inventory, exact cross-map dependency row, componentwise transport, displayed continuation routes, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapCoverageLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 814.1, Definition 814.2, and Definition 814.3 bind the finite coverage ledger and its frontier boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditMapCoverageLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close the audit-map family, discharge conditional rows, prove obstruction rows, strengthen MetaCIC results, provide Lean verification, or provide bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, row-class coverage, row-class separation, cross-map dependency exactness, local naming, and frontier non-escape for the same finite packet.

Chapter 815

A Concrete Naming Certificate for $\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}$

The $\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as a finite obligation-ledger NameCert packet. It sits beside the closure-preservation audit seal of chapter 800, the MetaCIC substitution audit packet of **??**, and the family ledger of chapter 810: those chapters expose concrete audit rows, while this packet records the obligation classes that downstream consumers may inspect across the family.

Definition 815.1 (Audit-map family obligation ledger carrier)**.** *An* $\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, P, Q, O, R, X, H, C, K, N)$$

with the following visible rows:

1. *M is the audit-map family tag naming the concrete module, its local audit row, and its sibling module coordinates;*
2. *P is the positive inventory of rows already closed by the named concrete packet;*
3. *Q is the conditional inventory of rows whose conclusion is available only after a displayed discharge route;*
4. *O is the obstruction inventory of rows that remain visible as blocked obligations;*
5. *R is the frontier inventory offered to downstream consumers without claiming its closure;*
6. *X is the cross-module use inventory recording which sibling packets may read the positive, conditional, obstruction, and frontier rows;*
7. *H records componentwise* hsame *transports for the family tag, all four inventories, cross-module use rows, continuation rows, package provenance, and the local naming row;*
8. *C records the displayed* Cont *routes by which consumers read each inventory class, the cross-module use row, provenance, and local name;*
9. *K is the* Pkg *provenance over chapter 800,* **??**, *chapter 810,* BHist, hsame, Cont, Pkg, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible coordinates are the family tag, positive inventory, conditional inventory, obstruction inventory, frontier inventory, cross-module use row, hsame *transports,* Cont *routes,* Pkg *provenance, and local NameCert. It exports no hidden discharge for Q, no proof of the obstruction rows O, no closure of the frontier rows R, and no global audit theorem outside the displayed packet.*

Theorem 815.2 (Audit-map family obligation ledger NameCert obligations)**.** *For the carrier of Definition 815.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$F = (M, P, Q, O, R, X, H, C, K, N),$$

family-tag readback through M, positive-inventory readback through P, conditional-inventory readback through Q, obstruction-inventory readback through O, frontier-inventory readback through R, cross-module use readback through X, componentwise transport through H, displayed continuation through C, package provenance through K, and local naming through N.

Lean4 ✓ `BEDC.Derived.AuditMapFamilyObligationLedgerUp.AuditMapFamilyObligationLedgerTasteGate`
`single carrier alignment`

Proof. Project the finite packet F. The row M names the audit-map family coordinate before any obligation class is read.

Read the four obligation inventories next. The positive row P, conditional row Q, obstruction row O, and frontier row R are separate coordinates, so admission of one class does not discharge or close another.

Finally inspect X, H, C, K, N. Cross-module use is displayed as a row rather than inferred from prose, transport and continuation replay the same inventory coordinates, provenance cites only the visible sibling packets, and the local name binds the packet. Hence the NameCert surface is exhausted by the displayed carrier inventory. □

Theorem 815.3 (Audit-map family obligation ledger classifier stability)**.** *The* $\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}$ *classifier is stable under componentwise* hsame *transport of the family tag, positive inventory, conditional inventory, obstruction inventory, frontier inventory, cross-module use row, continuation routes, package provenance, and local NameCert row. Any transported accepted packet has the same displayed obligation classes and the same non-escape boundary.*

Proof. Start with two accepted packets related by the componentwise transport row H. The family tag and each inventory coordinate are transported separately, so the positive, conditional, obstruction, and frontier classes cannot be merged by transport.

The cross-module row X is transported along the same componentwise route. Thus a sibling consumer that was allowed to read an inventory class before transport reads the transported instance of that same class after transport.

The continuation, provenance, and naming rows then replay the transported coordinates through C, K, N. Since no classifier coordinate is added or deleted, acceptance and the non-escape boundary are preserved. □

Theorem 815.4 (Audit-map family obligation ledger exactness)**.** *Every consumer read of an accepted* $\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}$ *packet factors through exactly one displayed inventory class or the displayed cross-module use row before reaching transport, continuation, provenance, and local naming. In particular, a read of P cannot be reclassified as a discharged Q row, a proof of an O row, or a closure of an R row.*

Proof. Use the carrier projection and the NameCert obligations. They list the only readable coordinates as $M, P, Q, O, R, X, H, C, K, N$ and assign each obligation class to its own row.

If a consumer reads a row of the family ledger, the route first reaches P, Q, O, R, or X. The subsequent hsame, Cont, Pkg, and NameCert rows transport and report that coordinate, but they do not introduce a new obligation class.

Therefore the ledger is exact at the inventory boundary. Positive rows remain positive rows, conditional rows remain conditional rows, obstruction rows remain obstruction rows, frontier rows remain frontier rows, and cross-module use remains an explicit use row rather than a hidden closure principle. □

Theorem 815.5 (Audit-map family obligation ledger methodology handoff)**.** *The audit-map family methodology of chapter 9406 is realized by the finite* $\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}$ *packet: positive inventory, conditional inventory, obstruction inventory, frontier inventory, cross-module use,* hsame *transports,* Cont *routes,* Pkg *provenance, and local NameCert are all carried as displayed BEDC rows. Downstream audit consumers may cite the packet only through those rows and the sibling anchors chapter 800 and* **??***.*

Proof. First apply the carrier definition. It turns the methodology into the finite packet $F = (M, P, Q, O, R, X, H, C, K, N)$ with the four obligation inventories and the cross-module use row visible.

Next apply classifier stability and ledger exactness. These keep the rows stable under hsame transport and force each consumer read to pass through the displayed inventory or use coordinate before any continuation or provenance read.

Finally use the package provenance row K. It names the closure-preservation audit seal and MetaCIC substitution audit packet as sibling anchors, so the methodology handoff is a finite NameCert packet rather than an ambient global audit claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}$ packet is generated from an audit-map family tag, positive inventory, conditional inventory, obstruction inventory, frontier inventory, cross-module use rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 815.1, Definition 815.2, Definition 815.3, Definition 815.4, and Definition 815.5 bind the finite obligation-ledger packet for audit-map family methodology.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditMapFamilyObligationLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close global audit correctness, subject reduction, closure preservation, hidden discharge routes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inventory readback, cross-module use readback, classifier stability, ledger exactness, provenance, naming, and non-escape for the same finite packet.

Chapter 816

A Concrete Naming Certificate for $\mathsf{AuditMapFamilyPacket}^{\uparrow}$

The $\mathsf{AuditMapFamilyPacket}^{\uparrow}$ carrier realizes the audit-map family methodology of chapter 9406 as concrete finite NameCert data. It sits beside the subject-reduction certificate of chapter 483, the MetaCIC audit synthesis packet of chapter 776, and the substitution audit map of chapter 779. Those sibling chapters supply local audit surfaces; this packet records the family-level rows that let a consumer read positive content, conditional content, obstructions, frontier claims, cross-module use, and boundary data without treating partial audit maps as closed MetaCIC.

Definition 816.1 (Audit-map family packet carrier)**.** *An* $\mathsf{AuditMapFamilyPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (P, C, O, F, X, H, R, Q, N)$$

with the following displayed rows:

1. *P is the finite family of positive-content rows already licensed by local audit maps, including checked inventory and concrete packet rows supplied by sibling chapters;*
2. *C is the family of conditional rows, each paired with the displayed discharge route or setup field needed before its conclusion can be consumed;*
3. *O is the obstruction family naming blocked routes, missing inhabitants, shape restrictions, and no-go rows that must remain visible;*
4. *F is the frontier family naming the strongest nearby claims offered to downstream readers without proof by the packet;*
5. *X is the cross-module-use family naming which audit maps, synthesis chapters, and boundary packets may consume or supply each displayed row;*
6. *H records componentwise* hsame *transports for positive, conditional, obstruction, frontier, cross-module-use, continuation, provenance, and local naming rows;*
7. *R records the displayed* Cont *read routes by which a consumer inspects the audit rows without adding hidden coordinates;*
8. *Q is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *the audit-map methodology, and the concrete sibling packets cited above;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapFamilyPacket}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible coordinates are $P, C, O, F, X, H, R, Q, N$. It exports no closed subject-reduction theorem, no full closed-MetaCIC consistency theorem, no erased obstruction, no proof of a frontier row, and no host semantic equality coordinate.

Theorem 816.2 (Audit-map family packet NameCert obligations)**.** *For the carrier of Definition 816.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapFamilyPacket}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the finite packet $A = (P, C, O, F, X, H, R, Q, N)$;*
2. *classifier transport for the positive, conditional, obstruction, frontier, and cross-module-use rows through the componentwise* hsame *transports in H and the displayed* Cont *routes in R;*
3. *obstruction and frontier exactness, requiring O and F to remain visible as boundary rows rather than as discharged theorem content;*
4. *cross-map dependency exposure, requiring every use by chapter 483, chapter 776, chapter 779, or any sibling audit packet to be recorded in X and sourced by Q;*
5. *non-escape from hidden closure, excluding closed MetaCIC, host semantics, unlisted discharge routes, and implicit proof of any obstruction or frontier row.*

Proof. Project the carrier A. Carrier admission supplies only the displayed rows $P, C, O, F, X, H, R, Q, N$, so every audit-map family read begins with the finite packet itself.

Transport is componentwise. The row H moves the positive, conditional, obstruction, frontier, and cross-module-use rows together, while R replays only the displayed continuation routes. Hence classifier movement cannot add a new row class.

The obstruction and frontier coordinates are then fixed. Rows O and F are part of the visible packet, but neither is a discharge witness or theorem constructor. They name where the audit family stops.

Finally inspect X, Q, N. Cross-module use is listed before it is consumed, provenance cites only displayed sibling packets, and the local name binds the same carrier. Therefore hidden closure, unlisted routes, host semantics, and implicit frontier proofs are outside the NameCert surface. □

Theorem 816.3 (Audit-map family packet frontier exhaustion)**.** *For every accepted* $\mathsf{AuditMapFamilyPacket}^{\uparrow}$ *carrier $A = (P, C, O, F, X, H, R, Q, N)$, every consumer read of the audit-map family factors through the displayed rows $P, C, O, F, X, H, R, Q, N$. In particular, a downstream consumer cannot treat a partial audit map as closed MetaCIC, cannot bypass the conditional rows in C, cannot erase the obstruction rows in O, and cannot turn a frontier row in F into a closed theorem.*

Proof. Start from the carrier projection. The only family rows are positive content P, conditional content C, obstructions O, frontier rows F, and cross-module-use rows X.

Use the obligation theorem. Classifier transport and continuation replay preserve those same rows through H and R, while Q and N record provenance and local naming without adding another consumer route.

It remains to exclude hidden closure. Since every consumer read has already been routed through the displayed audit rows, no downstream chapter can read a closed MetaCIC theorem, a discharged conditional row, an erased obstruction, or a proof of a frontier row unless that object appears as a displayed coordinate of the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapFamilyPacket}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AuditMapFamilyPacket}^{\uparrow}$ packet is generated from positive-content rows, conditional rows, obstruction rows, frontier rows, cross-module-use rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{AuditMapFamilyPacket}^{\uparrow}}$, seed)

Scope closed: Definition 816.1, Definition 816.2, and Definition 816.3 bind the finite audit-map family carrier, row classifier, dependency exposure, and hidden-closure boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{AuditMapFamilyPacket}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close subject reduction, full closed MetaCIC, host semantics, proof of frontier rows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, obstruction and frontier exactness, cross-map dependency exposure, provenance, local naming, and non-escape for the same finite packet.

Chapter 817

A Family-Level Audit Surface for $\mathsf{AuditMapFamily}^{\uparrow}$

The $\mathsf{AuditMapFamily}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as a finite NameCert object. It sits beside the beta audit packet of chapter 761, the closure-preservation audit packet of chapter 802, and the substitution audit map of chapter 779: those chapters expose individual audit rows, while this packet records the family-level carrier that factors inventory, obstruction, frontier, and cross-map routing without turning any local row into hidden closure.

Definition 817.1 (Audit-map family NameCert carrier)**.** *An* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, I, O, R, B, H, C, K, N)$$

with the following visible rows:

1. *T is the family tag naming the MetaCIC audit-map family and its BEDC substrate;*
2. *I is the finite inventory table of local audit maps, including beta, substitution, closure-preservation, confluence, normalisation, decidable-checking, typed-example, subject-reduction, and consistency-assembly rows when those rows are present;*
3. *O is the obstruction table recording rows whose absence or conditional status must remain visible;*
4. *R is the cross-map routing table recording which local maps may be read by neighbouring maps;*
5. *B is the frontier table recording consumer-facing claims that are named but not closed by the family packet;*
6. *H is the componentwise* hsame *transport row for T, I, O, R, B, C, K, N;*
7. *C is the displayed* Cont *route by which a consumer reads the inventory, obstruction, routing, frontier, provenance, and local name rows;*
8. *K is the* Pkg *provenance row over the concrete audit chapters supplying the local map entries;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapFamily}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose coordinates are the displayed family tag, finite inventory, obstruction table, routing table, frontier table, transport row, continuation route, package provenance, and local naming row. It exports no proof of subject reduction, confluence, normalisation, closed consistency, host semantic equality, or discharge route not already displayed by one of those coordinates.

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyTasteGate single carrier alignment`

Theorem 817.2 (Audit-map family inventory factorization)**.** *For the carrier of Definition 817.1, every accepted consumer read factors through exactly one of the displayed family coordinates*

$$T,\ I,\ O,\ R,\ B,\ H,\ C,\ K,\ N.$$

In particular, a read of a local audit fact must pass through the finite inventory row I, a read of a blocked or conditional fact must pass through the obstruction row O, a read of a neighbouring map must pass through the routing row R, and a read of a consumer-facing open boundary must pass through the frontier row B.

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyInventoryFactorization`

Proof. Project the finite carrier F. The classifier admits only the nine displayed rows, so every consumer read must choose one coordinate before it can inspect any audit datum.

The rows I, O, R, B then partition the family-facing information. Local established material is inventory, blocked or conditional material is obstruction, cross-map access is routing, and consumer-facing open material is frontier.

The remaining rows cannot add a new class of audit fact. The transport row H preserves the displayed coordinates, the continuation row C routes reads through them, the provenance row K names their source chapters, and the local naming row N binds the packet. Hence the carrier inventory factors every read through the stated coordinates. □

Theorem 817.3 (Audit-map family cross-map non-escape)**.** *For every accepted* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier $F = (T, I, O, R, B, H, C, K, N)$, a cross-map read from one local audit row to another can cite only the source row, the target row, the displayed routing row R, the componentwise transport row H, the displayed continuation row C, the provenance row K, and the local naming row N. It cannot export an unlisted neighbouring map, a hidden route around an obstruction row, or a theorem stronger than the target map itself records.*

Proof. Begin with the routing coordinate. A cross-map read is admitted only through R, so it must name the source and target audit rows as entries of the finite family inventory.

Transport and continuation preserve that route. The row H identifies only displayed coordinates, and C gives only the public path from the family packet to those coordinates. Neither row manufactures a new neighbouring map.

Finally, provenance and naming restrict the citation surface. Since K points back to the concrete audit chapters and N names the local packet, a consumer may reuse an exposed route but cannot bypass an obstruction row or infer a stronger theorem than the target map records. □

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyCrossMapNonescape`

Theorem 817.4 (Audit-map family frontier stability)**.** *For every accepted* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier, replacing a local audit row by an* hsame*-transported copy preserves the family frontier row B as the same displayed frontier. The transported packet may replay the same inventory, obstruction, routing, provenance, continuation, and naming coordinates, but the frontier table remains a named consumer boundary rather than a closed theorem surface.*

Proof. Use the componentwise transport row H. It transports the family tag, inventory, obstruction, routing, frontier, continuation, provenance, and naming coordinates as displayed coordinates of the same finite carrier shape.

The frontier coordinate is therefore carried as B, not recomputed from neighbouring maps or hidden theorem content. A transported local audit row can change how the same visible row is represented, but it does not change which frontier entries the family packet exposes.

The NameCert row N then binds the transported packet to the same public surface. The frontier remains stable because the only accepted frontier read is still the displayed row B routed through C and cited through K. □

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyFrontierStability`
↪ variant `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyCarrier frontier stability`

Theorem 817.5 (Audit-map family frontier non-escape)**.** *For every accepted* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier* $F = (T, I, O, R, B, H, C, K, N)$*, no entry of the frontier row* B *can be read as a closed proof of the corresponding frontier claim. A consumer may cite the frontier entry as a named boundary of the audit-map family, but cannot extract subject reduction, confluence, candidate-free normalisation, full closed consistency, host semantic equality, or any other unlisted discharge from that citation.*

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyCarrier frontier nonescape`

Proof. Read the frontier row directly. By Definition 817.1, B records consumer-facing claims that are named by the family packet but not closed by it.

Apply the inventory factorization of Definition 817.2. Any consumer read of a frontier entry factors through B and through the displayed continuation and naming rows, so the read never changes class into an inventory theorem or a routing theorem.

Use cross-map non-escape from Definition 817.3. Even when the frontier entry points at a neighbouring audit map, the route can cite only what that neighbouring map itself exposes. Thus the frontier remains a named boundary and cannot discharge an unlisted theorem. □

Falsifiable prediction: An accepted $\mathsf{AuditMapFamily}^{\uparrow}$ packet cannot turn a frontier row into a closed theorem unless that theorem is already present in the finite inventory row I.

Independence witness: metacicbetaaudit, metacic-closure-preservation-audit, substitutionauditmap, metacicnormalizationaudit, auditgatecomposition: these nearest audit siblings expose local beta, closure-preservation, substitution, normalisation, and gate-composition rows, but no bijection preserves the combined inventory, obstruction, routing, and frontier rows of the family packet.

Theorem 817.6 (Audit-map family TasteGate primality commitment)**.** *For every accepted* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier*

$$F = (T, I, O, R, B, H, C, K, N),$$

the falsifiability row saying that B *cannot become a closed theorem outside* I *and the sibling-independence row separating the family packet from metacicbetaaudit, metacic-closure-preservation-audit, substitutionauditmap, metacicnormalizationaudit, and auditgatecomposition are carrier-visible commitments of the same finite packet. They are read through* I, O, R, B, H, C, K, N *and not through a hidden theorem inventory, ambient audit equivalence, or unlisted family map.*

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamily tastegate primality commitment`

Proof. Project the carrier of Definition 817.1. The rows I, O, R, B are the only rows that classify inventory, obstruction, routing, and frontier data for the family.

Apply frontier non-escape from Definition 817.5. A frontier read stays in B unless the claimed theorem is already represented in I, so the falsifiability commitment is visible in the same carrier.

Apply inventory factorization and cross-map non-escape. These force sibling reads through R, K, H, C, N and prevent a local audit sibling from preserving all four family rows by a bijection that forgets obstruction or frontier data.

Thus the falsifiability and independence rows are not external prose conditions. They are the TasteGate-facing primality commitments carried by the accepted finite packet. □

Theorem 817.7 (Audit-map family obstruction row exactness)**.** *For every accepted* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier* $F = (T, I, O, R, B, H, C, K, N)$*, a blocked or conditional audit fact is read exactly through the obstruction row* O*. Such a fact remains an obstruction entry transported by* H *and read through* C, K, N*; it cannot become an inventory theorem in* I*, a closed frontier row in* B*, or a discharge route absent from the displayed family packet.*

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyCarrier obstruction row exactness`

Proof. Read the partition of rows from Definition 817.2. Established local material passes through I, while blocked or conditional material passes through O.

Transport does not change that class. The componentwise row H preserves the displayed family coordinates, and the continuation row C only reads those coordinates; neither row converts an obstruction entry into an inventory theorem.

Finally apply frontier non-escape. Definition 817.5 prevents named frontier boundaries from acting as closed proofs, so an obstruction entry cannot be discharged by re-reading it through B or through an unlisted route. □

Theorem 817.8 (Audit-map family routing row exhaustion)**.** *Every cross-map route in an accepted* $\mathsf{AuditMapFamily}^{\uparrow}$ *packet factors through the displayed rows* R, H, C, K, N *and names only local audit rows listed by the finite inventory* I*. The routing row may cite neighbouring beta, substitution, closure-preservation, confluence, normalisation, decidable-checking, typed-example, subject-reduction, or consistency-assembly entries when those entries are present, but it exports no unlisted audit map, hidden obstruction bypass, host semantic equality, or stronger theorem than the cited local row records.*

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyCarrier routing row exhaustion`

Proof. Start from cross-map non-escape. Definition 817.3 requires a cross-map read to cite the source row, target row, routing row R, transport row H, continuation row C, provenance row K, and local naming row N.

Use inventory factorization to bind the names. Definition 817.2 forces local audit facts through I, so a route can name only rows present in the finite family inventory.

Obstruction exactness prevents hidden detours. Definition 817.7 keeps blocked and conditional facts in O, so routing cannot bypass an obstruction or strengthen a cited local row into host equality or an unlisted theorem. □

Theorem 817.9 (Audit-map family obligation unblock package)**.** *The* $\mathsf{AuditMapFamily}^{\uparrow}$ *obligation package for the finite family packet* $F = (T, I, O, R, B, H, C, K, N)$ *consists of inventory factorization, cross-map non-escape, frontier stability, frontier non-escape, obstruction row exactness, and routing row exhaustion. This package makes the family obligation-ready while still excluding*

subject reduction, confluence, normalisation, closed consistency, host equality, hidden obstruction discharge, and unlisted family maps unless the corresponding row is displayed in the packet.

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyObligationUnblockPackage`

Proof. Assemble the carrier rows first. Definition 817.2 partitions consumer reads through $T, I, O, R, B, H, C, K, N$, and Definition 817.3 confines neighbouring-map access to displayed source, target, route, transport, continuation, provenance, and naming rows.

Add the frontier rows. Definition 817.4 preserves the frontier under hsame transport, and Definition 817.5 prevents frontier entries from becoming closed proofs.

Finally attach the obstruction and routing rows. Definition 817.7 keeps blocked or conditional facts in O, while Definition 817.8 forces every cross-map route through R, H, C, K, N and the listed local rows. The resulting package is obligation-ready because every visible family read has a concrete row and every excluded theorem lacks a carrier coordinate. □

Corollary 817.10 (Audit-map family strict local obstruction)**.** *For every accepted* $\mathsf{AuditMapFamily}^{\uparrow}$ *carrier*

$$F = (T, I, O, R, B, H, C, K, N),$$

a displayed failure, refusal, separation, or countermodel row in the family packet is a strict local obstruction. It blocks only the named converse, reuse route, target strengthening, or discharge read that is attached to that row by the finite inventory, obstruction, routing, frontier, transport, continuation, provenance, and naming coordinates. It cannot be reinterpreted as a global impossibility theorem, a host theorem about all neighbouring audit maps, hidden external validation, or a proof that an unlisted coordinate exists.

Proof. Read the carrier from Definition 817.1. The accepted packet exposes exactly the rows $T, I, O, R, B, H, C, K, N$. Thus a consumer-facing obstruction must enter through one of the displayed family coordinates: inventory I for listed audit rows, obstruction O for blocked or conditional rows, routing R for neighbouring-map access, frontier B for named open boundaries, transport H for componentwise sameness of displayed rows, continuation C for public readback, provenance K for the source chapters, and naming N for the local certificate.

For a cross-map use, Definition 817.3 gives the stricter route. The read may cite only the source row, the target row, R, H, C, K, and N. Hence the obstruction can block the named converse or reuse route only at the coordinates where that route is displayed; H preserves those coordinates, C reads them, K records their provenance, and N binds the local packet. None of these rows introduces a second target, an unlisted neighbouring map, or a bypass around the obstruction row.

The remaining interpretations are therefore refused by the same finite factorization. A global impossibility theorem would quantify beyond the displayed source and target rows; a host theorem would add semantic strength not recorded by the target audit map; hidden external validation would add a validating coordinate outside $T, I, O, R, B, H, C, K, N$; and an unlisted-coordinate proof would contradict the classifier clause of Definition 817.1. The obstruction is strict because it has exactly the local blocking force of its displayed row and no wider export surface. □

Lean4 ✓ `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyCarrier strict local obstruction`

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapFamily}^{\uparrow}}$**.**

Constructive story: The packet is generated by a finite audit-family tag, inventory table, obstruction table, routing table, frontier table, componentwise transport, displayed continuation, package provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AuditMapFamily}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 817.1, Definition 817.9, the TasteGate single-carrier alignment marker, Definition 817.10, and the obstruction and routing rows display the mature family-level audit surface for the carrier, inventory, frontier, transport, continuation, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{AuditMapFamily}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.AuditMapFamilyUp.AuditMapFamilyTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close subject reduction, confluence, normalisation, closed consistency, host semantic equality, or hidden obstruction discharge.

Upgrade path: No further theory-axis upgrade is pending for this chapter.

The FiniteTraceEvaluator$^{\uparrow}$ hub routes bounded evaluator traces through the runtime-candidate boundary of chapter 591, the checkpoint consumer of chapter 997, and the MetaCIC critical path of chapter 765 before any child file exposes runtime readback.

Chapter 818

A Concrete Naming Certificate for $\mathsf{FiniteTraceEvaluator}^{\uparrow}$

The $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ packet realizes the runtime-candidate surface of Definition 9461.21 inside the reflection-limit boundary of chapter 9461. It sits beside the runtime-candidate boundary packet of chapter 591, the diagonal finite-trace packet of chapter 492, and the finite-trace GAP socket of chapter 504. Those chapters expose, respectively, object-level runtime rows, a certificate-level diagonal trace, and the finite-window boundary; the present packet records a bounded evaluator trace whose accepted result is visible while host validation of the evaluator remains outside the packet. Its bounded evaluator trace is consumed by the runtime checkpoint packet of chapter 997, where checkpoint-state and validation-boundary rows read the finite trace evidence without importing host validation. The validation-boundary row V is read against chapter 586: $\mathsf{ReflectionLimitBoundary}^{\uparrow}$ supplies the truth/runtime boundary that prevents a finite trace evaluator from becoming a self-validating runtime.

Definition 818.1 (Finite trace evaluator carrier)**.** *A* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (I, T, A, V, H, C, P, N)$$

with the following displayed rows:

1. *I is the input row of coded* CIC^* *expressions, proof objects, and states admitted to the bounded evaluator;*
2. *T is the finite trace-step row, listing the displayed evaluator steps from the input row I without adding an unbounded runtime;*
3. *A is the accepted-result classifier row, grouping exactly the results reached by the displayed trace-step row T;*
4. *V is the validation-boundary row, recording that host validation of the evaluator is not a packet coordinate;*
5. *H records componentwise* hsame *transports for the input, trace-step, accepted-result, validation-boundary, provenance, and local naming rows;*
6. *C records the displayed* Cont *routes by which a consumer reads I, replays T, reaches A, checks the boundary row V, and returns through provenance and local naming;*
7. *P is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *the structural* CIC^* *coding interface, and chapter 591;*

8. N is the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible coordinates are I, T, A, V, H, C, P, N. The carrier has no coordinate for a host evaluator, a total truth predicate, an unbounded execution stream, or the judgment that the bounded evaluator validates itself.

Lean4 ✓ `BEDC.Derived.FiniteTraceEvaluatorUp.FiniteTraceEvaluatorTasteGate single carrier alignment`

Theorem 818.2 (FiniteTraceEvaluator runtime-candidate sibling route)**.** *Every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *carrier reads bounded trace admission through the runtime-candidate boundary of chapter 591 and the recognizer-admission route of chapter 1048 before any accepted-result classifier row is exported. Thus I, T, A, V, H, C, P, N record an admitted finite evaluator trace, not a host validator, total truth predicate, or unbounded runtime.*

Proof. Project the carrier of Definition 818.1. The provenance row P already names the runtime-candidate boundary as a source for admitted object-level runtime rows.

Use chapter 1048 for the recognizer-admission side. It supplies the finite route by which a source-level recognizer flow is admitted before a consumer can treat the trace as a displayed row.

The accepted-result classifier A is therefore downstream of the bounded trace row T and the boundary row V. Since no host validator, total truth predicate, or unbounded runtime is a carrier coordinate, the sibling route is exactly the displayed admission route. □

Theorem 818.3 (FiniteTraceEvaluator NameCert obligations)**.** *For the carrier of Definition 818.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission: every accepted object exposes the displayed packet $E = (I, T, A, V, H, C, P, N)$;*
2. *finite trace-step exposure: every evaluator step readable by a consumer is a row of the finite trace-step coordinate T reached from the input coordinate I;*
3. *accepted-result classifier: every accepted result is classified by A only after the corresponding trace-step row in T has been displayed;*
4. *runtime-validation non-escape: the boundary row V keeps host validation outside I, T, A, H, C, P, N and prevents a packet row from serving as its own validator;*
5. *ledger exhaustion: the provenance and local naming rows P, N exhaust the available dependencies and expose no unlisted evaluator, truth predicate, total halting predicate, or infinite trace.*

Consequently the certificate names a bounded object-level evaluator trace and its accepted-result ledger, but it does not internalize the host judgment that licenses the evaluator.

Proof. Carrier admission is tuple projection. The packet $E = (I, T, A, V, H, C, P, N)$ is finite, and every visible object-level coordinate is one of the displayed rows.

Trace-step exposure begins with I and then reads T. Since T is the only trace coordinate, a consumer can inspect only the finitely displayed evaluator steps and cannot replace them by an ambient runtime.

The accepted-result classifier is reached only after that trace read. A result belongs to A because the packet displays the corresponding step in T; no accepted result is supplied by a hidden classifier or by host execution.

Runtime validation is separated by V. The argument of Definition 9461.22 and the sibling packet chapter 591 place validation of a runtime candidate outside its source, pattern, classifier, stability, and ledger fields. Thus the finite trace evaluator records a boundary row rather than a self-validating checker.

Finally, P and N bind provenance and local naming without adding new evaluator content. Ledger exhaustion follows because every available consumer route has already passed through I, T, A, V, H, C, P, N, so an unlisted evaluator, truth predicate, total halting predicate, or infinite trace would require an extra coordinate absent from the carrier. □

Lean4 ✓ `BEDC.Derived.FiniteTraceEvaluatorUp.FiniteTraceEvaluatorCarrier namecert obligations`

Theorem 818.4 (FiniteTraceEvaluator bounded trace coverage)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, every accepted evaluator result factors through*

$$I \longmapsto T \longmapsto A.$$

No accepted result can bypass the bounded trace row T *or be supplied by a host evaluator, a total truth predicate, or an unbounded execution stream.*

Lean4 ✓ `BEDC.Derived.FiniteTraceEvaluatorUp.FiniteTraceEvaluatorCarrier bounded trace coverage`

Proof. Project the carrier of Definition 818.1. The only input-facing coordinate is I, the only trace-step coordinate is the finite row T, and the only accepted-result classifier is A.

Apply Definition 818.3. Its trace-step exposure and accepted-result classifier clauses force a consumer to read from I into T before any accepted result is visible at A.

The sibling runtime boundary of chapter 591, the finite diagonal trace of chapter 492, and the finite-trace GAP socket of chapter 504 supply only bounded object-level routes. They do not add a host evaluator, total truth predicate, or unbounded execution stream to the packet. □

Theorem 818.5 (FiniteTraceEvaluator host-validation refusal ledger)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, the row* V *is only a refusal and validation-boundary row. It does not supply host validation, total truth for* CIC^* *sentences, or a self-validating evaluator.*

Proof. Read V through Definition 818.1. The definition names it as the validation-boundary coordinate and explicitly keeps host validation outside the displayed evaluator rows.

Use the runtime-validation non-escape clause of Definition 818.3. It prevents any packet row from becoming the validating host judgment for the same evaluator.

The cited sibling packets chapter 591, chapter 492, and chapter 504 expose runtime candidates, trace rows, and finite windows as object-level evidence. None of them turns V into host validation, total truth, or self-validation. □

Theorem 818.6 (FiniteTraceEvaluator result-validation separation)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, result classification is visible only after bounded trace exposure through* $I \longmapsto T \longmapsto A$*, while validation remains outside the packet at the boundary row* V*. Thus the packet can display a bounded accepted result without claiming host validation of the evaluator that produced it.*

Proof. First apply Definition 818.4. It places every accepted result on the bounded route from I through T to A.

Next apply Definition 818.5. It keeps host validation, total truth, and self-validation outside the same packet and records the refusal at V.

Together with Definition 818.3, these two readings exhaust the accepted packet. The runtime-candidate boundary, halting-distinction trace, and finite-trace GAP socket chapters supply finite object-level anchors, but the validation judgment is not a coordinate of E. □

Theorem 818.7 (FiniteTraceEvaluator route obligation triad)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, the input row* I*, finite trace-step row* T*, accepted-result classifier* A*, and validation-boundary row* V *form the root obligation triad plus boundary. The packet exposes no accepted result unless the route has already displayed* I, T, A*, and it exposes no validation claim except through the boundary row* V*.*

Proof. Project the accepted packet through Definition 818.1. The rows I, T, A, V are the only input, finite trace-step, accepted-result, and validation-boundary coordinates available to a consumer.

Apply Definition 818.3 and Definition 818.4. These force accepted results through the displayed route from I into T and then into A.

Finally use Definition 818.5 and Definition 818.6. They keep the validation claim at V rather than allowing any packet row to become host validation. □

Theorem 818.8 (FiniteTraceEvaluator checkpoint consumer route)**.** *Every* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through*

$$I \to T \to A \to V \to H \to C \to P \to N.$$

The checkpoint consumer receives no host validator, truth predicate, total halting predicate, or infinite trace from the evaluator packet.

Proof. Begin with the carrier definition Definition 818.1. It displays exactly the rows I, T, A, V, H, C, P, N for the bounded evaluator packet.

Use Definition 818.3 and Definition 818.4. The checkpoint consumer can read accepted-result data only after the finite trace route from I through T to A has been displayed.

Attach Definition 818.5 and Definition 818.6. These keep host validation outside the evaluator packet and place the validation boundary at V.

The runtime checkpoint chapter consumes those finite rows as checkpoint data, not as a host validator. Therefore the route through H, C, P, N preserves the same packet and supplies no truth predicate, total halting predicate, or infinite trace. □

Theorem 818.9 (FiniteTraceEvaluator validation-boundary exhaustion)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the validation row* V *is exhausted as a refusal boundary. It cannot be repacked as evaluator validation, self-validation, host truth, total halting, or an infinite-trace validator for the same packet.*

Proof. Read V from the carrier Definition 818.1. The definition names V only as the validation-boundary row and lists no host-validation coordinate.

Apply Definition 818.3. Its runtime-validation non-escape clause prevents any packet row from serving as its own validator, while its ledger-exhaustion clause leaves no hidden validator in P, N.

Use Definition 818.5 and Definition 818.6. Together they identify V as the boundary at which evaluator validation is refused, not as a route back into validation or self-validation. □

Theorem 818.10 (FiniteTraceEvaluator object-level boundary)**.** *Every consumer read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through the finite route*

$$I \to T \to A \to V \to H \to C \to P \to N.$$

The consumer may inspect the coded input, replay the displayed finite trace, and read the accepted-result classifier, but it cannot extract host validation, total halting information, truth for CIC* *sentences, or an unbounded evaluator from the packet.*

Proof. Project the accepted carrier of Definition 818.1. The input, trace-step, accepted-result, and validation-boundary information is exhausted by I, T, A, V.

Apply Definition 818.3. Its trace-step exposure and accepted-result classifier clauses force every evaluator read through T and then through A, while its runtime-validation non-escape clause keeps the host validating judgment outside the packet.

The remaining rows H, C, P, N transport, route, cite, and name the same finite packet. Hence every consumer read factors through the displayed route, and no unbounded evaluator or internal truth classifier is available from the finite trace evaluator. □

Theorem 818.11 (FiniteTraceEvaluator trace-result route)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, every accepted result row classified by* A *is reached only through the bounded trace route*

$$I \to T \to A.$$

The result row cannot be supplied by a host evaluator, a truth predicate for CIC^* *sentences, or an unbounded execution stream.*

Proof. Project the carrier of Definition 818.1. Its only input-facing row is I, its only evaluator-step row is the finite trace row T, and its only accepted-result classifier is A.

Apply Definition 818.3. The finite trace-step exposure clause sends every evaluator step from I into T, and the accepted-result classifier clause permits A to classify a result only after the corresponding displayed trace-step row has been read.

The missing host evaluator, truth, and unbounded execution coordinates give the non-escape conclusion. Since none of those objects is a row of $E = (I, T, A, V, H, C, P, N)$, no accepted result can bypass the route $I \to T \to A$. □

Theorem 818.12 (FiniteTraceEvaluator validation-row non-escape)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, the validation-boundary row* V *refuses host validation, total truth, self-validation of the evaluator, and unbounded execution as packet coordinates. A consumer may read that refusal through* V, H, C, P, N*, but cannot turn* V *into any of the refused objects.*

Proof. Start from Definition 818.1. The row V is named only as the validation-boundary row, while host validation, total truth, self-validation, and unbounded execution are explicitly absent from the carrier.

Use the runtime-validation non-escape clause of Definition 818.3. It keeps host validation outside I, T, A, H, C, P, N and prevents a packet row from serving as its own validator.

The transport, continuation, provenance, and naming rows preserve the same finite packet. Thus V records a boundary refusal, and the missing host/evaluator/truth coordinates cannot be reconstructed by reading V, H, C, P, N. □

Theorem 818.13 (FiniteTraceEvaluator provenance exhaustion)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, the rows* H, C, P, N *exhaust componentwise transport, consumer continuation, provenance, and local naming for the same finite packet. They do not add host validation, a host evaluator, total truth, total halting, or an unbounded trace.*

Proof. Project the displayed packet in Definition 818.1. After I, T, A, V are fixed, the only remaining rows are the componentwise hsame transports H, the displayed Cont routes C, provenance P, and the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ row N.

Apply the ledger-exhaustion clause of Definition 818.3. It states that P, N exhaust the available dependencies and expose no unlisted evaluator, truth predicate, total halting predicate, or infinite trace.

The rows H and C only transport and replay the same finite coordinates already displayed by the carrier. Therefore H, C, P, N close the local transport, continuation, provenance, and naming surface without importing any missing host/evaluator/truth coordinate. □

Theorem 818.14 (FiniteTraceEvaluator result classifier exactness)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, a result is classified by the accepted-result row* A *if and only if the consumer has first read the displayed finite trace-step row* T *from the input row* I*. The classifier has no independent host execution channel, no truth predicate for* CIC^* *sentences, and no unbounded trace coordinate.*

Proof. Project the carrier of Definition 818.1. The row A is displayed only as the accepted-result classifier of the same finite packet whose trace-step coordinate is T.

Apply the finite trace-step exposure and accepted-result classifier clauses of Definition 818.3. They force every accepted result to be read after the corresponding displayed trace-step row, and they provide no second classifier outside I, T, A, V, H, C, P, N.

Conversely, once the consumer reads I and the corresponding finite step in T, the displayed classifier row A is the only accepted-result row available in the packet. Thus result classification is exact at A and cannot be replaced by host execution, a truth predicate, or an unbounded trace. □

Theorem 818.15 (FiniteTraceEvaluator ledger non-escape)**.** *The finite ledger* I, T, A, V, H, C, P, N *of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet exports no host validator, truth predicate, total halting predicate, or infinite trace. Every readable evaluator result is exhausted by the input row, the displayed finite trace-step row, the accepted-result classifier, the validation-boundary row, the componentwise transport and continuation rows, provenance, and the local name.*

Proof. Start with the object-level boundary of Definition 818.10. It sends every consumer read through

$$I \to T \to A \to V \to H \to C \to P \to N.$$

Use the runtime-validation non-escape and ledger exhaustion clauses of Definition 818.3. The row V records that host validation is outside the packet, while P and N close the visible provenance and naming ledger without adding evaluator content.

Therefore an exported host validator, truth predicate, total halting predicate, or infinite trace would require an additional coordinate not present in the carrier. The displayed finite rows exhaust the packet's consumer-facing ledger. □

Theorem 818.16 (FiniteTraceEvaluator obligation upgrade package)**.** *The* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *obligation surface needed for obligationClosure is the package consisting of carrier admission, result classifier exactness, runtime-validation non-escape, ledger exhaustion, and consumer-route factorization for the same finite packet* $E = (I, T, A, V, H, C, P, N)$*. This package is object-level only: it does not assert host validation of the evaluator, total halting, truth for* CIC^* *sentences, or an infinite execution trace.*

Proof. Carrier admission is supplied by Definition 818.1 and the first clause of Definition 818.3. They fix the available rows as I, T, A, V, H, C, P, N.

Result classifier exactness is exactly Definition 818.14. It ties accepted results to the displayed finite trace-step row before A is read.

Runtime-validation non-escape and ledger exhaustion are supplied by the corresponding clauses of Definition 818.3 and by Definition 818.15. These keep host validation, truth, total halting, and infinite traces outside the packet.

Finally apply Definition 818.10. The consumer route factors through the displayed finite route, so the listed rows form the whole obligation surface for the bounded evaluator packet. □

Theorem 818.17 (FiniteTraceEvaluator evaluation determinacy)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, an accepted result row is exposed only through the displayed bounded trace rows* T, R, V, H, C, P, N*, where* R *is the result row read at* A*. The packet has no second result channel, host evaluator coordinate, truth predicate, or unbounded execution stream from which a consumer could read an accepted result.*

Proof. Project the carrier of Definition 818.1. The only input-to-result route available to a consumer begins at I, proceeds through the finite trace row T, and reaches the accepted-result classifier row A. Reading A exposes the result row R as part of that same displayed route.

Apply Definition 818.3. Its finite trace-step exposure and accepted-result classifier clauses say that accepted results are classified only after the corresponding bounded trace rows have been displayed.

Finally use Definition 818.10. The remaining rows V, H, C, P, N keep validation, transport, continuation, provenance, and local naming on the same finite path, so no hidden evaluator or ambient truth predicate can determine an additional result. □

Theorem 818.18 (FiniteTraceEvaluator boundary exhaustion)**.** *Every runtime-validation read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet remains a boundary read through* V, H, C, P, N*. No row exported by the packet is a self-validating runtime coordinate, and no accepted result row can be promoted to a host validator for the same evaluator.*

Proof. Start with the validation-boundary coordinate in Definition 818.1. The carrier lists V as the place where host validation is recorded as outside the packet, not as a runtime-coordinate constructor.

Apply the runtime-validation non-escape clause of Definition 818.3. It keeps host validation outside I, T, A, H, C, P, N and prevents any packet row from serving as its own validator.

Replay Definition 818.10. Every consumer route passes from A to V and then through H, C, P, N, so runtime evidence remains boundary evidence throughout the displayed finite ledger. □

Theorem 818.19 (FiniteTraceEvaluator runtime nonimport)**.** *The object-level runtime evidence read by an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet is routed through chapter 591, chapter 492, and chapter 504. The packet does not import those rows as a host validator for its own evaluator; it only records their finite boundary, diagonal trace, and finite-window socket as displayed object-level dependencies.*

Proof. Project the provenance and local naming rows P, N of the carrier. Their listed dependencies include the runtime-candidate boundary, the diagonal finite-trace packet, and the finite-trace GAP socket as object-level sources for the finite evaluator trace.

Apply Definition 818.3. Carrier admission and ledger exhaustion restrict the dependency read to the displayed rows I, T, A, V, H, C, P, N, while runtime-validation non-escape keeps a host validator outside the packet.

Finally replay Definition 818.10. The consumer may inspect the bounded trace and accepted-result classifier through those dependency routes, but the route never exports total halting, host validation, truth for CIC* sentences, or an unbounded evaluator. □

Theorem 818.20 (FiniteTraceEvaluator public consumer package)**.** *Every public consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet reads bounded trace coverage, accepted-result classifier exactness, validation-row non-escape, provenance, and local* $\mathsf{NameCert}$ *as one package. The consumer route is the finite ledger*

$$I \to T \to A \to V \to H \to C \to P \to N,$$

not a separate host-runtime validation channel.

Proof. Start from the carrier of Definition 818.1. It lists exactly the rows I, T, A, V, H, C, P, N available to a public consumer.

Use Definition 818.4 and Definition 818.14. These theorems place every accepted result on the route from the input row through the bounded trace row to the accepted-result classifier.

Use Definition 818.12 and Definition 818.19. The validation row remains a boundary refusal, and the runtime dependencies are read only as displayed object-level provenance.

Finally apply Definition 818.3. The transport, continuation, provenance, and local naming rows bind the same finite route, so a public consumer receives one package rather than an independent host-runtime channel. □

Theorem 818.21 (FiniteTraceEvaluator runtime-boundary totality)**.** *Runtime validation for an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet is total only through the displayed bounded trace row* T *and result-validation rows* A, V*. No consumer can import a host runtime, host validator, total truth predicate, or unbounded evaluator outside the finite packet.*

Proof. Project the packet $E = (I, T, A, V, H, C, P, N)$ from Definition 818.1. The only runtime-facing rows are the bounded trace row T, the accepted-result classifier A, and the validation-boundary row V.

Apply Definition 818.18. It keeps every runtime-validation read as a boundary read through V, H, C, P, N and prevents an accepted result row from becoming a host validator.

Apply Definition 818.19. The cited runtime-candidate, diagonal-trace, and finite-window dependencies remain object-level sources and never enter the carrier as a host runtime.

Thus runtime validation is total only at the displayed boundary route T, A, V, H, C, P, N. Any stronger validation would need an additional coordinate absent from the carrier. □

Theorem 818.22 (FiniteTraceEvaluator accepted-result ledger exhaustion)**.** *The accepted result ledger of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet is exhausted by the trace rows, result classifier, validation row, provenance, and local name. A consumer can read* T, A, V, P, N *only as part of the finite packet* $E = (I, T, A, V, H, C, P, N)$*, and cannot recover a host evaluator, total truth predicate, total halting predicate, or infinite trace from that ledger.*

Proof. Begin with Definition 818.14. It says a result is classified by A exactly after the displayed finite trace-step row T has been read from I.

Use Definition 818.18 to attach the validation boundary V to that accepted result without turning it into host validation.

Use Definition 818.19 and the ledger exhaustion clause of Definition 818.3. Provenance and local naming record the finite object-level dependencies but expose no unlisted evaluator, truth predicate, total halting predicate, or infinite trace.

Therefore the accepted result ledger is exactly the displayed trace, classifier, validation, provenance, and naming package, with no further runtime content available to the consumer. □

Theorem 818.23 (FiniteTraceEvaluator runtime-checkpoint boundary)**.** *Every* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet reads only the displayed evaluator rows* I, T, A, V, H, C, P, N*, together with the runtime-candidate boundary and checkpoint-state rows supplied by the checkpoint packet. The read never imports host validation, a total truth predicate, a total halting predicate, an unbounded evaluator, or an infinite execution stream.*

Proof. Project the accepted evaluator packet through Definition 818.1. The consumer can see the coded input row I, finite trace row T, accepted-result row A, validation-boundary row V, componentwise transport, continuation, provenance, and local name.

Apply Definition 818.4 and Definition 818.14. These rows force every accepted result read through the finite trace route $I \to T \to A$ before any runtime-facing checkpoint can inspect it.

Next use Definition 818.12 and Definition 818.19. The validation row remains a boundary row, and the runtime-candidate and checkpoint-state data are read as object-level packet rows rather than as a host runtime.

Finally attach provenance exhaustion from Definition 818.13 and accepted-result ledger exhaustion from Definition 818.22. The checkpoint consumer has no carrier coordinate left for host validation, a total truth predicate, a total halting predicate, an unbounded evaluator, or an infinite execution stream. □

Theorem 818.24 (FiniteTraceEvaluator trace-window accountability)**.** *Every accepted result row of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet has a finite trace-window coordinate in* T*. The accepted result cannot be supplied by an unbounded execution stream, by a host evaluator, or by a total halting predicate outside the displayed packet* $E = (I, T, A, V, H, C, P, N)$*.*

Proof. Begin with Definition 818.4. It places the trace evidence for every accepted result inside the finite row T of the displayed evaluator packet.

Use Definition 818.14. The row A classifies a result only after the finite trace-step row has been read from I, so the accepted result has no source separate from the finite trace window.

Now apply Definition 818.19. The external runtime-candidate and diagonal-trace objects remain dependencies at the boundary and do not enter the packet as an unbounded execution stream.

Finally use Definition 818.22. The ledger exposes only T, A, V, P, N inside the finite packet, leaving no row that could supply an accepted result from a host evaluator or total halting predicate. □

Theorem 818.25 (FiniteTraceEvaluator validation refusal package)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the validation-boundary row* V *remains a refusal package after transport through* H, C, P, N*. It records the boundary at which host validation is not imported, and it cannot be converted into a self-validator for the same accepted packet.*

Proof. Project the carrier $E = (I, T, A, V, H, C, P, N)$. The only validation-facing row is V, while H, C, P, N provide componentwise transport, continuation, provenance, and local naming.

Apply Definition 818.12. The row V refuses to become the validating host judgment for its own evaluator packet.

Next use Definition 818.18 and Definition 818.13. Transport through H, C, P, N preserves the displayed boundary route and records its finite dependencies without adding a validator row.

Finally apply Definition 818.22. The accepted result ledger is already exhausted by the finite trace, classifier, validation boundary, provenance, and name, so the refusal package cannot be repackaged as a self-validator. □

Theorem 818.26 (FiniteTraceEvaluator nontrivial carrier pair)**.** *The* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *carrier has at least two distinguishable packet shapes. One admitted shape exposes an input-only finite trace packet with rows* I, T, H, C, P, N *and no accepted-result row. A second admitted shape exposes the same finite input and trace surface together with a displayed accepted-result row* A *and validation-boundary row* V*. The local classifier can therefore distinguish an input-only trace packet from a packet whose finite trace carries an accepted-result row.*

Proof. Start from the carrier row of Definition 818.1. The row I supplies the coded input, T supplies the finite trace-window coordinate, and H, C, P, N record transport, continuation, provenance, and the local name.

For the input-only shape, read only I, T, H, C, P, N. This is still a finite trace packet because Definition 818.4 places trace evidence inside T and does not require an accepted result to be displayed by every finite trace read.

For the accepted-result shape, add the rows A, V. By Definition 818.14, the row A is an accepted-result classifier only after the finite trace has been read from I, T, and by Definition 818.25 the row V records the validation boundary rather than a host validator.

The two shapes are not interchangeable as public rows. Removing A, V loses the accepted-result and validation-boundary route, while adding them creates a displayed result row that the input-only packet does not expose. Hence the carrier is not a one-shape packet. □

Theorem 818.27 (FiniteTraceEvaluator field-faithful rows)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet*

$$E = (I, T, A, V, H, C, P, N),$$

equality of the rows I, T, A, V, H, C, P, N *fixes the public evaluator read. Changing any one of* I, T, A, V *changes the corresponding public route: the input route, the finite trace-window route, the accepted-result classifier route, or the validation-boundary route.*

Proof. First fix all eight displayed rows. The carrier definition and Definition 818.3 leave no additional public coordinate beyond the coded input, finite trace, accepted-result classifier, validation boundary, transport, continuation, provenance, and local name.

Next identify the four route-sensitive fields. Changing I changes the coded input route before any finite trace can be read. Changing T changes the finite trace-window route controlled by Definition 818.4.

Changing A changes the accepted-result classifier route of Definition 818.14. Changing V changes the validation-boundary route of Definition 818.12.

The remaining rows H, C, P, N transport and name those displayed routes. Thus row equality fixes the public evaluator read, and a change in any of I, T, A, V is visible as a change in the corresponding route. □

Theorem 818.28 (FiniteTraceEvaluator TasteGate readiness)**.** *The later* TasteGate *formalization for* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *has two explicit obligations. It must exhibit a nontrivial carrier witness, formalizing the separation in Definition 818.26, and it must exhibit a field-faithful public read, formalizing the route sensitivity in Definition 818.27. These obligations are stated over the same rows* I, T, A, V, H, C, P, N *and the same* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *surfaces used by the chapter.*

Proof. The nontrivial obligation is supplied at the paper level by the two displayed packet shapes. The input-only packet lacks A, V, while the accepted-result packet carries A, V as visible rows; the classifier can test that difference without importing a host evaluator.

The field-faithful obligation is supplied at the paper level by the public route analysis. Equality of I, T, A, V, H, C, P, N fixes the exposed evaluator read, and changing one of I, T, A, V changes its named route before transport or provenance can hide it.

The later Lean file may encode these as Nontrivial $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ and FieldFaithful $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ obligations. No new carrier row is needed for that encoding; the rows are already the displayed packet surface of this chapter. □

Theorem 818.29 (FiniteTraceEvaluator obligation closure status)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet*

$$E = (I, T, A, V, H, C, P, N),$$

the carrier row, the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *obligations, the trace-result route, validation-row non-escape, provenance exhaustion, result classifier exactness, the nontrivial carrier pair, the field-faithful public rows, and the* TasteGate *readiness surface assemble the paper-side obligation-closure package over* I, T, A, V, H, C, P, N*. The package is bounded to the displayed evaluator packet and does not assert Lean formalization, host validation, total truth, total halting, or unbounded evaluation.*

Proof. The carrier and local naming surface are fixed by Definition 818.1 and Definition 818.3. They display the rows I, T, A, V, H, C, P, N and restrict the available obligations to carrier admission, trace exposure, accepted-result classification, validation non-escape, and ledger exhaustion.

The evaluator-result part is supplied by Definition 818.11 and Definition 818.14. These place every accepted result on the finite route from I through T to A.

The boundary and ledger part is supplied by Definition 818.12 and Definition 818.13. Thus every validation read remains at V, H, C, P, N, and provenance introduces no host validator, truth predicate, total halting predicate, or infinite trace.

Finally, Definition 818.26, Definition 818.27, and Definition 818.28 give the public carrier separation and route sensitivity required by the later TasteGate surface. These references assemble the paper-side obligation package while leaving the verification and bridge axes unchanged. □

Theorem 818.30 (FiniteTraceEvaluator root trace-result totality)**.** *Every root-level downstream consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet that reads accepted-result data first factors through*

$$I \to T \to A.$$

The consumer may then continue through the remaining rows of $E = (I, T, A, V, H, C, P, N)$*, but it cannot read an accepted result before the coded input and finite trace-step rows have been displayed.*

Proof. Begin with the bounded trace coverage of Definition 818.4. It sends every accepted evaluator result through the displayed route $I \to T \to A$.

Use Definition 818.11 and Definition 818.14. They make A exact for accepted results only after the finite trace-step row in T has been read from I.

Any root-level downstream consumer is still a consumer of the same displayed packet. By Definition 818.20 and Definition 818.23, the public and checkpoint routes continue through V, H, C, P, N without adding a second accepted-result channel. □

Theorem 818.31 (FiniteTraceEvaluator root validation boundary)**.** *Every root-level validation read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet terminates at the displayed boundary, transport, continuation, provenance, and local naming rows* V, H, C, P, N*. Such a read cannot become host validation, total truth for* CIC^* *sentences, total halting, or unbounded evaluation.*

Proof. Start with Definition 818.12. It states that V is a boundary row and refuses host validation, total truth, self-validation, and unbounded execution as packet coordinates.

Attach the surrounding transport and naming rows by Definition 818.18 and Definition 818.25. These keep the validation read on the route through V, H, C, P, N.

Finally apply Definition 818.13 and Definition 818.22. The ledger is exhausted by the displayed finite packet, so no root-level read can recover a host validator, total truth predicate, total halting predicate, or unbounded evaluator from the validation boundary. □

Theorem 818.32 (FiniteTraceEvaluator root boundary package)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet*

$$E = (I, T, A, V, H, C, P, N),$$

every root-facing $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *consumer reads one finite boundary package consisting of the root trace-result route, the root validation boundary, provenance exhaustion, and the checkpoint consumer route. The package exposes accepted results only through* $I \to T \to A$ *and validation-facing data only through* V, H, C, P, N*; it does not contain host validation, total truth, self-validation, total halting, or unbounded evaluation.*

Proof. Project the carrier of Definition 818.1. The accepted packet has exactly the rows I, T, A, V, H, C, P, N, so a root-facing checkpoint consumer has no coordinate outside the displayed finite evaluator packet.

Apply Definition 818.30. It places every accepted-result read on the route $I \to T \to A$ before any consumer can continue through the rest of the packet.

Apply Definition 818.31. It sends every validation-facing read to the boundary, transport, continuation, provenance, and local naming rows V, H, C, P, N.

Finally use Definition 818.13 and Definition 818.8. Provenance exhausts the available dependency rows, and the checkpoint route is already the same finite ledger I, T, A, V, H, C, P, N; hence no host-validation row, truth predicate, self-validator, total halting predicate, or unbounded evaluator can be repacked from the root boundary package. □

Theorem 818.33 (FiniteTraceEvaluator public root export)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, the public export surface consists exactly of coded input rows, finite trace-step rows, accepted-result classifier rows, validation-boundary rows, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row, and the checked TasteGate marker* `BEDC.Derived.FiniteTraceEvaluatorUp.taste_gate`*. The export contains no host validation, total halting predicate, truth predicate for* CIC^* *sentences, unbounded evaluator, or bridge-level semantics.*

Proof. Project the carrier rows named in Definition 818.1. They are exactly the coded input, trace-step, accepted-result classifier, validation-boundary, transport, continuation, provenance, and local naming rows of E.

Apply Definition 818.30. It places every accepted-result read on the route $I \to T \to A$ before any public consumer can inspect the remaining rows.

Apply Definition 818.31 and Definition 818.32. They make V, H, C, P, N the full validation-facing boundary and keep the checkpoint consumer inside the same displayed packet.

The checked TasteGate marker records that the same finite packet is visible as one carrier for downstream reflection consumers. Since the refused objects have no carrier row, the public export surface has no host validator, total halting predicate, truth predicate, unbounded evaluator, or bridge-level semantic row. □

Falsifiable prediction: An accepted $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ packet whose public read treats the input-only trace shape and the accepted-result shape as the same packet fails the carrier separation witnessed by the displayed A, V rows.

Independence witness: runtimecandidateboundary, haltingdistinctiontrace, finite-trace-gap-socket, reflection-runtime-checkpoint: none is bijective to $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ because those siblings expose runtime candidate, halting distinction, gap socket, or reflection checkpoint rows, while this carrier binds coded input, finite trace, accepted-result classifier, validation boundary, transport, continuation, provenance, and local naming in one evaluator packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ packet is generated from coded input rows, finite trace-step rows, accepted-result classifier rows, a validation-boundary row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 818.1, Definition 818.3, Definition 818.29, Definition 818.30, Definition 818.31, Definition 818.32, Definition 818.33, and

Lean4 ✓ `BEDC.Derived.FiniteTraceEvaluatorUp.taste gate`

bind the finite evaluator trace carrier, accepted-result classifier, validation boundary, ledger exhaustion surface, downstream consumer boundary, public export surface, and TasteGate instance.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$, axiomClean)

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not close host validation, total halting, truth for CIC^* sentences, unbounded evaluation, infinite traces, or bridge-level public semantics.

Upgrade path: No paper-side closure upgrade remains before bridge checking for the same finite evaluator packet and its checked TasteGate carrier.

Theorem 818.34 (FiniteTraceEvaluator root checkpoint totality)**.** *Every* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$*-facing read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through the displayed finite rows*

$$I, T, A, V, H, C, P, N.$$

Thus a root checkpoint consumer reads coded input, finite trace steps, accepted-result classification, validation boundary, componentwise transport, displayed continuation, provenance, and local naming as one finite evaluator package.

Proof. Project the carrier of Definition 818.1. Its visible coordinates are exactly I, T, A, V, H, C, P, N, and the local NameCert obligations expose those rows as the available evaluator surface.

Apply Definition 818.32. A root-facing checkpoint consumer receives the finite boundary package built from the trace-result route and the validation boundary, with provenance and local naming attached to the same packet.

Finally use Definition 818.40. The checkpoint source is locked to $I \to T \to A$ for accepted results and to V, H, C, P, N for validation-facing reads, so every root checkpoint read factors through the listed rows. □

Theorem 818.35 (FiniteTraceEvaluator root validation refusal)**.** *Every* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$*-facing request for host validation, total truth for* CIC^* *sentences, total halting, or unbounded evaluation stops at the displayed validation-boundary, transport, continuation, provenance, and local naming rows* V, H, C, P, N *of the accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet.*

Proof. Begin with Definition 818.31. It sends root-level validation reads to V, H, C, P, N and refuses host validation, total truth, total halting, and unbounded evaluation as packet coordinates.

Use Definition 818.41. The accepted-result route remains separate from the validation boundary, and the validation-facing route cannot certify a host judgment or total classifier.

Apply Definition 818.42. The runtime checkpoint handoff exposes only the source-locked evaluator rows, so the listed requests terminate at the refusal surface rather than becoming new root evidence. □

Theorem 818.36 (FiniteTraceEvaluator root consumer readiness)**.** *The root checkpoint totality row of Definition 818.34 and the validation refusal row of Definition 818.35 provide the exact finite root package consumed by downstream reflection-runtime chapters. The package is the displayed evaluator route I, T, A, V, H, C, P, N and no host validation, total truth, total halting, or unbounded evaluation is added by the consumer boundary.*

Proof. First combine the two rows just stated. The totality theorem supplies the checkpoint-facing route through all displayed evaluator coordinates, while the refusal theorem fixes where validation-facing requests stop.

Next attach the existing root package theorem, Definition 818.32. It already identifies the finite root-facing package consumed by checkpoint readers and excludes host validation, total truth, self-validation, total halting, and unbounded evaluation.

Finally use Definition 818.42. Downstream reflection-runtime chapters receive the same handoff package I, T, A, V, H, C, P, N, so the consumer boundary is ready without adding any row outside the finite evaluator packet. □

Theorem 818.37 (FiniteTraceEvaluator root runtime totality)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, every root runtime read factors through the finite surface*

$$I, T, A, V, H, C, P, N.$$

The runtime consumer reads coded input I, finite trace T, accepted-result row A, validation boundary V, componentwise transports H, displayed continuations C, provenance P, and the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row N as one bounded evaluator packet, and it receives no host evaluator or unbounded runtime coordinate.*

Proof. Project the carrier of Definition 818.1 and the local obligations of Definition 818.3. They expose exactly the input, finite trace, accepted-result, validation, transport, continuation, provenance, and local naming rows.

Use Definition 818.34. It already forces root checkpoint consumers through the same displayed packet I, T, A, V, H, C, P, N before any runtime-facing handoff can inspect the accepted result.

Finally attach Definition 818.42. The handoff exposes only the source-locked evaluator rows, so every root runtime read factors through the displayed packet and cannot import a host evaluator or unbounded runtime coordinate. □

Theorem 818.38 (FiniteTraceEvaluator bounded replay ledger exhaustion)**.** *Bounded replay of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet exposes only the coded input, finite trace, accepted result, validation boundary, componentwise transports, displayed continuations, provenance, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *rows. Its root ledger is exhausted by*

$$I, T, A, V, H, C, P, N,$$

and no hidden runtime state, host validation row, unbounded trace semantics, or unchecked compiler theorem is present in the replay surface.

Proof. Begin with Definition 818.53. Bounded replay preserves the route through $I \to T \to A$, the validation boundary V, and the continuation rows C under the displayed componentwise transports H.

Next use Definition 818.58 and Definition 818.59. The exactness surface cuts every root checkpoint read at I, T, A, V, H, C, P, N and blocks host validation, total truth, total halting, unbounded evaluation, infinite traces, and second checkpoint sources.

The ledger factorization is then Definition 818.54. It repacks the replay, refusal, provenance, and local naming rows into the same finite root ledger, so the bounded replay surface has no hidden runtime state or unchecked compiler theorem. □

Theorem 818.39 (FiniteTraceEvaluator checkpoint consumer nonescape)**.** *Every checkpoint consumer of the root runtime surface in Definition 818.37 receives only the finite evaluator packet I, T, A, V, H, C, P, N. It receives no host evaluator, total truth predicate, total halting classifier, infinite trace, unchecked compiler theorem, or second checkpoint source.*

Proof. First apply Definition 818.35. Validation-facing requests stop at V, H, C, P, N and do not become host validation, total truth, total halting, or unbounded evaluation evidence.

Next combine Definition 818.60 with Definition 818.38. The checkpoint ledger and bounded replay ledger expose the same finite packet and no infinite trace, hidden runtime state, unchecked compiler theorem, or second checkpoint source.

Finally use Definition 818.36. Downstream reflection-runtime consumers receive the exact finite package I, T, A, V, H, C, P, N, so checkpoint consumption cannot escape the displayed root runtime surface. □

Theorem 818.40 (FiniteTraceEvaluator checkpoint source lock)**.** *Every root-facing checkpoint consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet locks its accepted-result source to the displayed finite route*

$$I \to T \to A$$

and its validation-facing boundary to V, H, C, P, N. The consumer may read the root checkpoint package, but it cannot replace the coded input, finite trace, accepted-result classifier, or validation boundary by host validation, total truth, total halting, unbounded execution, or a second source ledger.

Proof. Begin with the carrier and NameCert obligations, Definition 818.1 and Definition 818.3. They display exactly the rows I, T, A, V, H, C, P, N and make trace-step exposure, accepted-result classification, validation non-escape, transport, continuation, provenance, and local naming part of one packet.

Apply Definition 818.4 and Definition 818.30. These force every accepted-result read through $I \to T \to A$ before a root-facing checkpoint consumer can continue.

Finally use Definition 818.31 and Definition 818.32. The validation read stays on V, H, C, P, N, so no host validator, total truth predicate, total halting classifier, unbounded evaluator, or second source ledger is available. □

Theorem 818.41 (FiniteTraceEvaluator validation nonescape totality)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, every validation-facing root read is total only through the displayed boundary row V together with H, C, P, N. The accepted-result route $I \to T \to A$ remains separate from the validation boundary, and neither route can certify host validation, total truth for* CIC^* *sentences, self-validation, total halting, or unbounded evaluation.*

Proof. First apply Definition 818.12. It identifies V as a boundary row and refuses host validation, total truth, self-validation, and unbounded execution as packet coordinates.

Next use Definition 818.6. The accepted-result route through I, T, A and the validation-facing route through V remain distinct rows of the same evaluator packet.

Attach the root boundary with Definition 818.31 and Definition 818.32. The surrounding transport, continuation, provenance, and local naming rows are exactly H, C, P, N, so validation cannot escape to a host judgment or total classifier. □

Theorem 818.42 (FiniteTraceEvaluator runtime boundary handoff)**.** *Every* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *handoff from an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through the finite trace evaluator carrier, bounded trace coverage, validation non-escape, result-validation separation, root trace-result totality, root validation boundary, and root boundary package. The handoff exposes only the source-locked evaluator rows* I, T, A, V, H, C, P, N.

Proof. Project the checkpoint consumer route from Definition 818.8 and Definition 818.23. The runtime checkpoint receives the same evaluator rows and no extra validation or unbounded-execution coordinate.

Use Definition 818.40. It locks the accepted-result source to $I \to T \to A$ and the validation-facing surface to V, H, C, P, N.

Finally apply Definition 818.41. The handoff therefore stays inside the displayed evaluator carrier and refuses host validation, total truth, total halting, self-validation, and unbounded evaluation. □

Theorem 818.43 (FiniteTraceEvaluator source admission)**.** *Every accepted-result read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet begins from the displayed input row* I *and finite trace row* T*. The accepted-result classifier* A *may be consumed only after the coded input has entered the bounded trace route, and the read does not import a host source, infinite trace, or second checkpoint ledger.*

Proof. Project the carrier of Definition 818.1. Its accepted-result surface is displayed by the rows I, T, A, with I naming the coded input, T naming the finite trace steps, and A naming the accepted-result classifier.

Apply Definition 818.4. It forces every accepted result onto the bounded route from I through T before the classifier row can be read.

Use Definition 818.40. The checkpoint-facing source remains locked to $I \to T \to A$, so no host source, infinite trace, or second checkpoint ledger is available to the consumer. □

Theorem 818.44 (FiniteTraceEvaluator ledger exhaustion)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the provenance row* P *and local naming row* N *expose all dependency rows available to checkpoint consumers. The packet exposes no host validator, total truth predicate, total halting classifier, unbounded evaluator, or infinite trace beyond the finite rows*

$$I, T, A, V, H, C, P, N.$$

Proof. Start from Definition 818.1. The dependency-carrying rows visible at the checkpoint boundary are I, T, A, V, H, C, P, N, with P recording package provenance and N recording the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ row.

Apply Definition 818.9. It confines validation-facing reads to the displayed validation boundary and prevents a host validating judgment from becoming a packet coordinate.

Next use Definition 818.22. The accepted-result route, validation boundary, transport, continuation, provenance, and local naming rows account for the available ledger surface.

Finally attach Definition 818.42. The checkpoint handoff exposes only I, T, A, V, H, C, P, N, excluding host validation, total truth, total halting, unbounded evaluation, and infinite traces. □

Theorem 818.45 (FiniteTraceEvaluator consumer factorization)**.** *Every checkpoint consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through*

$$I, T, A, V, H, C, P, N.$$

The consumer receives a finite evaluator route: coded input, finite trace, accepted-result classifier, validation boundary, componentwise transport, displayed continuation, provenance, and local naming in that order of dependency.

Proof. Begin with Definition 818.8. It identifies the checkpoint-facing route through the finite evaluator carrier and excludes an external evaluator from the consumer surface.

Use Definition 818.43. The accepted-result side of the consumer route must begin with I and T before A can be consumed.

Apply Definition 818.44. The validation boundary and dependency ledger are exhausted by V, H, C, P, N, with no host validator or infinite trace left outside the packet.

Thus every checkpoint consumer factors through the displayed rows I, T, A, V, H, C, P, N as one finite evaluator route. □

Theorem 818.46 (FiniteTraceEvaluator root image row)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, each accepted read exposes only the displayed image rows*

$$I, T, A, V, H, C, P, N.$$

The rows name the coded input, finite trace, accepted-result classifier, validation boundary, componentwise transport, displayed continuation, package provenance, and local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row. No accepted read adds a host validator, total truth predicate, total halting classifier, unbounded evaluator, or infinite trace to the root image.*

Proof. Project the carrier in Definition 818.1. Its root surface is displayed by I, T, A, V, H, C, P, N and no additional row.

Apply Definition 818.43 to the accepted-result side and Definition 818.44 to the dependency side. Together they place every accepted read on the displayed image rows.

Finally use Definition 818.59. Any root checkpoint read that reaches the image surface factors through the accepted result route or the validation and ledger route, so the excluded host rows remain outside the packet. □

Theorem 818.47 (FiniteTraceEvaluator root readback exactness)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, checkpoint readback returns through*

$$I \to T \to A$$

for accepted results, and through V, H, C, P, N *for validation boundary reads. These two readback routes share the same finite root packet and expose no host validation, total truth, total halting, unbounded evaluation, infinite trace, or second checkpoint source.*

Proof. Begin with Definition 818.30. It sends accepted-result checkpoint reads through $I \to T \to A$ before the accepted-result classifier is consumed.

Next use Definition 818.31. It sends validation boundary reads to V, H, C, P, N and prevents host validation, total truth, total halting, and unbounded evaluation from becoming readback coordinates.

The checkpoint source lock, Definition 818.40, ties both routes to the same finite source. Hence checkpoint readback is exact on the two displayed routes and does not create a second checkpoint source or infinite trace. □

Theorem 818.48 (FiniteTraceEvaluator root ledger factorization)**.** *Every downstream* ReflectionRuntimeCheckpoin *consumer of an accepted* FiniteTraceEvaluator$^{\uparrow}$ *packet factors through the image row of Definition 818.46 and the readback routes of Definition 818.47. The factorization uses only I, T, A, V, H, C, P, N and imports no host validation, total truth, total halting, unbounded evaluation, or infinite trace.*

Proof. First build the image surface with Definition 818.46. It gives the complete root row list visible to accepted reads.

Then apply Definition 818.47. The checkpoint consumer reads accepted results through $I \to T \to A$ and validation boundary rows through V, H, C, P, N.

Finally attach Definition 818.45 and Definition 818.60. They force the runtime checkpoint consumer to remain on those image and readback rows, with no coordinate for host validation, total truth, total halting, unbounded evaluation, or an infinite trace. □

Theorem 818.49 (FiniteTraceEvaluator root source image readback lock)**.** *For an accepted* FiniteTraceEvaluator$^{\uparrow}$ *packet*

$$E = (I, T, A, V, H, C, P, N),$$

every root source image readback is locked to the coded input row I, finite trace row T, accepted-result row A, validation-boundary row V, componentwise hsame *transport H, displayed* Cont *replay C, package provenance P, and local* NameCert *row N. The readback cannot replace this source image by a host validator, total truth predicate, total halting classifier, unbounded evaluator, infinite trace, or second checkpoint source.*

Proof. Begin with the carrier, checkpoint source lock, and image row: Definition 818.1, Definition 818.40, and Definition 818.46. They identify I, T, A, V, H, C, P, N as the complete source image available to root-facing reads.

Next apply root readback exactness from Definition 818.47. Accepted results return through $I \to T \to A$, while validation-facing reads return through V, H, C, P, N.

Finally use the ledger factorization of Definition 818.48. Since the checkpoint ledger is already cut to the displayed evaluator rows, no host validator, total truth row, halting classifier, unbounded evaluator, infinite trace, or second checkpoint source can be read back. □

Theorem 818.50 (FiniteTraceEvaluator root checkpoint validation totality)**.** *For an accepted* FiniteTraceEvaluator$^{\uparrow}$ *packet*

$$E = (I, T, A, V, H, C, P, N),$$

every root checkpoint validation request is total only on the displayed evaluator route. It must first read the source image I, T, A, then the validation-boundary row V, and then the structural rows H, C, P, N; it does not produce host validation, total truth for CIC* *sentences, total halting, self-validation, unbounded evaluation, or a second validation ledger.*

Proof. Use the checkpoint source lock and validation nonescape totality from Definition 818.40 and Definition 818.41. These separate the accepted-result source route $I \to T \to A$ from the validation-facing boundary V, H, C, P, N.

Then apply root validation refusal and root readback exactness from Definition 818.35 and Definition 818.47. The validation request stops at the displayed boundary and cannot become a host-side judgment.

Finally attach the root source image readback lock. It repacks source image, validation refusal, transport, continuation, provenance, and local naming into the same finite route, so checkpoint validation is total exactly on I, T, A, V, H, C, P, N. □

Theorem 818.51 (FiniteTraceEvaluator root consumer nonescape exhaustion)**.** *Every root consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet*

$$E = (I, T, A, V, H, C, P, N)$$

factors through the carrier, checkpoint source lock, source image readback lock, checkpoint validation totality, and ledger-cut surfaces before it can read a runtime checkpoint result. The exhausted consumer surface is I, T, A, V, H, C, P, N*, not host evaluator validation, hidden runtime acceptance, total truth, total halting, unbounded evaluation, infinite trace semantics, or a second checkpoint route.*

Proof. First build the source-image route with Definition 818.49. It fixes the only image readback rows available to root consumers.

Next use checkpoint validation totality from Definition 818.50. Any validation-facing request remains on the same finite evaluator route and cannot escape to a host judgment.

Finally apply Definition 818.60 together with Definition 818.45. The ledger cut and consumer factorization exhaust runtime checkpoint reads at I, T, A, V, H, C, P, N, so no second route or off-carrier validation surface remains. □

Theorem 818.52 (FiniteTraceEvaluator checkpoint-result totality)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, every accepted checkpoint/result read factors through the displayed finite* BHist *trace* T*, the validation row* V*, the result row* R *classified at* A*, the* Cont *replay routes* C*, componentwise* hsame *transports* H*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row* N*. The read has no carrier coordinate for host validation, total truth, total halting, unbounded evaluation, or an infinite trace.*

Proof. Project the carrier of Definition 818.1. Its readable evaluator surface is the finite packet I, T, A, V, H, C, P, N, and the accepted result row R is exposed only through the classifier row A.

Apply Definition 818.24 and Definition 818.14. They place the result row R behind the displayed finite trace T and make A the only accepted-result classifier available to the checkpoint/result consumer.

Use Definition 818.25 and Definition 818.45. The validation row V, the replay routes C, the componentwise transports H, the provenance row P, and the local naming row N account for the remaining checkpoint boundary.

Finally attach Definition 818.60. Since the root ledger has no row outside I, T, A, V, H, C, P, N, the checkpoint/result read cannot import host validation, total truth, total halting, unbounded evaluation, or an infinite trace. □

Theorem 818.53 (FiniteTraceEvaluator bounded replay stability)**.** *Bounded replay for an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet is stable under the displayed componentwise* hsame *transports. Replaying the finite route through* $I \to T \to A$*, the validation boundary* V*, and the continuation rows* C *preserves the checkpoint/result factorization of Definition 818.52 and cannot import host runtime state.*

Proof. Start with Definition 818.40. It locks accepted-result replay to the displayed input, finite trace, and classifier route $I \to T \to A$ before any checkpoint consumer can inspect a result.

The componentwise transport row H carries only the named packet coordinates: input, trace, accepted-result classifier, validation boundary, provenance, and local naming. Transporting along H therefore preserves the same bounded route rather than creating a new runtime source.

Apply Definition 818.42. The runtime checkpoint receives the finite evaluator carrier, validation non-escape, result-validation separation, root trace-result totality, root validation boundary, and root package rows as one handoff.

Thus replay through C remains bounded by I, T, A, V, H, C, P, N. No host runtime state is a coordinate of that packet, so none can be imported by transport or replay. □

Theorem 818.54 (FiniteTraceEvaluator NameCert root ledger factorization)**.** *The root* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *ledger is exhausted by the finite trace T, validation row V, result row R classified at A, checkpoint rows, refusal rows,* Cont *replay routes C,* Pkg *provenance P, and local naming row N. Every root ledger read factors through these displayed rows and no source outside the finite evaluator packet.*

Proof. Begin with Definition 818.3. The local certificate exposes carrier admission, finite trace-step exposure, accepted-result classification, validation non-escape, provenance, and local naming as its obligation rows.

Use Definition 818.52. Accepted checkpoint/result reads pass through T, V, R, H, C, P, N, with R available only as the result row classified at A.

Next apply Definition 818.35 and Definition 818.53. The refusal rows stop host validation, total truth, total halting, and unbounded evaluation at V, H, C, P, N, while bounded replay stays on the displayed transported route.

Finally use Definition 818.44 and Definition 818.60. The provenance and naming rows expose no dependency beyond the finite evaluator packet, so the root ledger is exactly the displayed trace, validation, result, checkpoint, refusal, replay, provenance, and naming surface. □

Theorem 818.55 (FiniteTraceEvaluator checkpoint-state exposure)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, every* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *checkpoint-state read first factors through the finite accepted-result route*

$$I \to T \to A$$

and then through the validation boundary, componentwise transport, displayed continuation, provenance, and local naming rows

$$V, H, C, P, N.$$

The state surface exposes result rows and validation rows only through this finite packet and has no coordinate for host validation, total truth, self-validation, total halting, unbounded evaluation, or an infinite trace.

Proof. Project the carrier of Definition 818.1. The available evaluator coordinates are the coded input I, finite trace T, accepted-result classifier A, validation row V, componentwise transports H, continuation row C, provenance row P, and local naming row N.

Apply Definition 818.4 and Definition 818.8. They place every checkpoint-state read behind the finite trace and require the accepted-result part of the read to pass through $I \to T \to A$ before the checkpoint consumer can use it.

Next use Definition 818.30. The root-facing result row is total only for the displayed finite route, so the state exposure cannot move the result coordinate to a host validator or to an unbounded evaluator.

Finally attach Definition 818.32. It adds V, H, C, P, N as the only validation-facing, transport, continuation, provenance, and naming rows available to the root checkpoint packet, excluding host validation, total truth, self-validation, total halting, unbounded evaluation, and infinite traces from the exposed state surface. □

Theorem 818.56 (FiniteTraceEvaluator validation-boundary consumer totality)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, every validation-facing* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *consumer is exhausted by the boundary row V, the transport row H, the continuation row C, the provenance row P, and the local naming row N. Such a consumer cannot export host validation, total truth, self-validation, total halting, unbounded evaluation, an infinite trace, or a second checkpoint-state source.*

Proof. Start from Definition 818.3. The local certificate names the validation non-escape, provenance, and local naming rows as obligations of the finite evaluator packet rather than as host judgments.

Use Definition 818.8. A validation-facing checkpoint consumer receives the same finite carrier route as the accepted-result consumer, but its validation requests are routed to V, H, C, P, N rather than to a host validation predicate.

Apply Definition 818.32. The root boundary package makes V, H, C, P, N the complete consumer-facing validation surface, with no exported row for total truth, self-validation, total halting, unbounded evaluation, infinite trace semantics, or an alternate checkpoint source. □

Theorem 818.57 (FiniteTraceEvaluator root checkpoint NameCert saturation)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the root checkpoint* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *surface is saturated by the finite packet*

$$I, T, A, V, H, C, P, N.$$

Every checkpoint-state, result, validation-boundary, transport, continuation, provenance, and local naming read is supplied by these rows, and the root surface exports no host validation, total truth, self-validation, total halting, unbounded evaluation, infinite trace, or second checkpoint source.

Proof. First combine Definition 818.55 with Definition 818.56. The first theorem exposes the checkpoint-state and result rows through $I \to T \to A$ and then through V, H, C, P, N; the second theorem exhausts the validation-facing consumers at V, H, C, P, N.

Next attach Definition 818.3. Its carrier, trace-step exposure, accepted-result classification, validation non-escape, provenance, and local naming clauses are exactly the local certificate obligations for the displayed finite evaluator packet.

Use Definition 818.30 and Definition 818.32. They identify the root result and validation-boundary rows consumed by checkpoint readers as the same finite root package.

Finally apply Definition 818.4 and Definition 818.8. No read outside I, T, A, V, H, C, P, N is produced by the bounded trace or by the checkpoint consumer route, so the root checkpoint NameCert surface is saturated by the accepted finite packet. □

Definition 818.58 (FiniteTraceEvaluator root exactness surface)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the root exactness surface is the finite packet*

$$E_{\mathrm{root}} = (I, T, A, V, H, C, P, N).$$

Its rows are the carrier of Definition 818.1, the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *obligations of Definition 818.3, the trace-result route of Definition 818.30, the validation-boundary route of Definition 818.31, and the checkpoint-consumer route of Definition 818.8. The surface has no row outside I, T, A, V, H, C, P, N.*

Theorem 818.59 (FiniteTraceEvaluator root exactness scope)**.** *Every root checkpoint read of the surface in Definition 818.58 factors either through the accepted-result route*

$$I \to T \to A$$

or through the validation and ledger route V, H, C, P, N. No root checkpoint read can mix those routes into a host validator, total truth predicate, total halting classifier, unbounded evaluator, infinite trace, or second checkpoint source.

Proof. Apply Definition 818.30. It places every accepted-result read on the route $I \to T \to A$ before a root consumer can inspect the result classifier.

Next use Definition 818.31. It sends validation-facing reads to V, H, C, P, N and keeps host validation, total truth, total halting, and unbounded evaluation outside the packet.

Finally apply Definition 818.40. The checkpoint source remains locked to the accepted-result route and the validation boundary, so the root read factors through one of the displayed routes and cannot create a second checkpoint source. □

Theorem 818.60 (FiniteTraceEvaluator checkpoint ledger cut)**.** *The checkpoint ledger of the surface in Definition 818.58 has no coordinate for host validation, total truth for* CIC* *sentences, total halting, unbounded evaluation, an infinite trace, or a second checkpoint source. Its complete checkpoint-facing ledger is the displayed packet I, T, A, V, H, C, P, N.*

Proof. Begin with Definition 818.32. The root boundary package exposes accepted results only through $I \to T \to A$ and validation-facing data only through V, H, C, P, N.

Use Definition 818.42. The runtime handoff receives the same finite evaluator rows and no extra coordinate for host validation, total truth, total halting, unbounded evaluation, or an infinite trace.

Combining the two package facts cuts the checkpoint ledger at the displayed surface. A second checkpoint source would require a row not present in I, T, A, V, H, C, P, N, so it is not part of the ledger. □

Lean4 ✓ `BEDC.Derived.FiniteTraceEvaluatorUp.FiniteTraceEvaluatorCheckpointLedgerCut`

Theorem 818.61 (FiniteTraceEvaluator root NameCert obligations)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet with displayed root surface*

$$I, T, A, V, H, C, P, N,$$

the root $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *obligations are exactly the carrier admission row, checkpoint acceptance row, bounded replay row, ledger exactness row, and consumer non-escape row over the displayed* BHist/hsame/Cont/Pkg/NameCert *packet. The certificate admits the coded input row I, finite trace row T, accepted-result row A, validation row V, componentwise transport row H, displayed continuation row C, provenance row P, and local naming row N, and it exports no host evaluator, hidden runtime state, unbounded trace semantics, or unchecked compiler theorem.*

Proof. Carrier admission is the projection of the finite evaluator packet in Definition 818.1. The accepted root surface is the displayed BHist tuple I, T, A, V, H, C, P, N and has no additional coordinate.

Checkpoint acceptance follows from Definition 818.34 and Definition 818.52. They place accepted checkpoint reads on the coded-input, finite-trace, accepted-result route before any root consumer can use the result row.

Bounded replay and ledger exactness are supplied by Definition 818.53 and Definition 818.59. The transport and continuation rows preserve the displayed route and the exactness surface cuts the ledger at I, T, A, V, H, C, P, N.

Finally use Definition 818.35 and Definition 818.60. The validation and ledger rows refuse host evaluation, hidden runtime state, unbounded trace semantics, and unchecked compiler theorems, so the listed rows exhaust the root NameCert obligations. □

Theorem 818.62 (FiniteTraceEvaluator acceptance row stability)**.** *Let two accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *checkpoint reads display the same root rows* I, T, A, V, H, C, P, N *up to the componentwise* hsame *transports in* H *and the displayed* Cont *replay in* C*. Then their accepted checkpoint rows remain on the same root checkpoint, source, and result route*

$$I \to T \to A.$$

No transported read can move acceptance to a host source, a second checkpoint ledger, an infinite trace, or an unbounded evaluator.

Proof. Begin with Definition 818.40. It locks accepted-result reads to the source route $I \to T \to A$ before any validation-facing or ledger-facing row is consumed.

Apply Definition 818.53. The componentwise hsame transport and displayed Cont replay preserve the finite trace and accepted-result rows, so transported checkpoint reads remain on the same bounded evaluator path.

It remains to exclude alternate acceptance sources. Use Definition 818.35 and Definition 818.42. The validation boundary and runtime handoff expose only the displayed finite evaluator rows, so host sources, second checkpoint ledgers, infinite traces, and unbounded evaluators cannot alter the accepted route. □

Theorem 818.63 (FiniteTraceEvaluator ledger non-escape)**.** *The root ledger of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet exports exactly the displayed finite evaluator rows*

$$I, T, A, V, H, C, P, N.$$

It exports no host evaluator, hidden runtime state, unbounded trace semantics, unchecked compiler theorem, total truth predicate, total halting classifier, or second checkpoint source.

Proof. Project the root exactness surface of Definition 818.58. Its complete ledger-facing packet is I, T, A, V, H, C, P, N.

Apply Definition 818.54. The local naming row factors the root ledger through carrier admission, checkpoint-result totality, bounded replay, and validation-boundary exactness.

Now use Definition 818.60. The ledger cut removes host validation, total truth, total halting, unbounded evaluation, infinite traces, and second checkpoint sources from the checkpoint-facing surface.

Finally combine this cut with Definition 818.42. Hidden runtime state and unchecked compiler theorems are not rows of the handoff packet, so no root ledger export escapes the displayed finite evaluator surface. □

Theorem 818.64 (FiniteTraceEvaluator route totality)**.** *Every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *read factors through the displayed root packet*

$$I, T, A, V, H, C, P, N.$$

The coded input row I*, finite trace row* T*, accepted-result row* A*, validation row* V*, componentwise transport row* H*, displayed continuation row* C*, package provenance row* P*, and local naming row* N *are therefore the complete route for root consumers, with no host evaluator, infinite trace, or unchecked compiler theorem available as an alternate source.*

Proof. Project the accepted read through the carrier of Definition 818.1. The carrier exposes the finite root rows I, T, A, V, H, C, P, N before any consumer can read the evaluator surface.

Apply the root NameCert obligations of Definition 818.61. They identify carrier admission, checkpoint acceptance, bounded replay, ledger exactness, and consumer non-escape as obligations over precisely the displayed packet.

Use acceptance row stability, Definition 818.62, to keep accepted reads on the same $I \to T \to A$ route under hsame transport and displayed Cont replay. Finally apply ledger non-escape, Definition 818.63, which removes host evaluators, infinite traces, and unchecked compiler theorems from the exported row set. □

Theorem 818.65 (FiniteTraceEvaluator checkpoint determinacy)**.** *Let two accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *checkpoint reads agree on the root rows* I, T, A, V, H, C, P, N*, with agreement displayed by the componentwise* hsame *rows in* H *and replayed through the* Cont *routes in* C*. Then the two reads determine the same checkpoint route up to the displayed* hsame *transport and the same* Cont *replay.*

Proof. Read both checkpoint packets through Definition 818.1. There is one coded-input row, one finite-trace row, and one accepted-result row in the displayed root surface, so checkpoint comparison starts on I, T, A.

The root NameCert obligations of Definition 818.61 bind the checkpoint acceptance row to the same carrier admission, bounded replay, ledger exactness, and local naming rows. No additional checkpoint coordinate is available for a second route.

Now apply Definition 818.62. The assumed agreement on H and C is exactly the componentwise transport and displayed replay needed to keep both accepted reads on the same checkpoint route. Ledger non-escape, Definition 818.63, excludes host sources, unbounded traces, and unchecked compiler theorems from changing that route. □

Theorem 818.66 (FiniteTraceEvaluator output non-escape)**.** *The output row of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet exports only the displayed finite evaluator route*

$$I, T, A, V, H, C, P, N.$$

It exports no host evaluator, total truth predicate, total halting classifier, infinite trace, unchecked compiler theorem, hidden runtime state, or second checkpoint source.

Proof. Start with Definition 818.1. The output-facing read has no row outside I, T, A, V, H, C, P, N, and the accepted-result coordinate A is reached only through the finite trace route.

Apply Definition 818.61. The local certificate records carrier admission, checkpoint acceptance, bounded replay, ledger exactness, and consumer non-escape for the displayed root packet.

Use Definition 818.62 to keep the accepted output on the same checkpoint route under transport and replay. Then apply Definition 818.63: the listed excluded objects are not ledger exports, so they cannot be output rows of the accepted finite evaluator packet. □

Definition 818.67 (FiniteTraceEvaluator BHist step carrier)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the root* BHist *step carrier is the finite evaluator packet*

$$B_{\text{step}} = (I, T, K, R, H, C, P, N),$$

where I *is the source trace row,* T *is the checkpoint row,* K *is the runtime-state row,* R *is the result image,* H *is the componentwise* hsame *transport,* C *is the displayed continuation route,* P *is the package provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row. The carrier is read inside the root evaluator surface of Definition 818.1 and the root exactness surface of Definition 818.58.*

Theorem 818.68 (FiniteTraceEvaluator route totality)**.** *Every accepted evaluator read of the step carrier in Definition 818.67 passes through the displayed* BHist/hsame/Cont/Pkg/NameCert *rows*

$$I, T, K, R, H, C, P, N.$$

The source trace, checkpoint, runtime state, result image, componentwise transport, continuation, provenance, and local naming rows therefore form the complete finite route for root evaluator consumers.

Proof. Begin with the checkpoint route of Definition 818.34. It sends checkpoint-facing reads through the displayed finite evaluator rows before any downstream checkpoint consumer can inspect the accepted result.

Next use the runtime surface of Definition 818.37 and the checkpoint source lock of Definition 818.40. These identify the source trace, checkpoint row, runtime-state boundary, and accepted-result image as one finite route inside the root evaluator packet.

Finally attach the root NameCert obligations of Definition 818.61. The local naming row, package provenance, continuation, and componentwise hsame transport are part of the same accepted carrier, so every evaluator read factors through I, T, K, R, H, C, P, N. □

Theorem 818.69 (FiniteTraceEvaluator nonescape boundary)**.** *No accepted read of the step carrier in Definition 818.67 exports host runtime validation, hidden interpreter state, quotient trace equality, or unbounded execution evidence. Every checkpoint or runtime consumer remains on the displayed finite route*

$$I, T, K, R, H, C, P, N.$$

Proof. First apply Definition 818.35. Host validation requests stop at the displayed validation and naming boundary of the accepted evaluator packet and do not become host runtime evidence.

Next use bounded replay ledger exhaustion and checkpoint consumer nonescape, Definition 818.38 and Definition 818.39. They exclude hidden runtime state, infinite trace evidence, unchecked compiler data, and second checkpoint sources from checkpoint-facing reads.

Finally combine route totality with the root exactness scope, Definition 818.68 and Definition 818.59. Since every read has already been forced through I, T, K, R, H, C, P, N, quotient trace equality and unbounded execution evidence have no carrier coordinate and no continuation route from the accepted packet. □

Theorem 818.70 (FiniteTraceEvaluator root image admission)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the root image projected from Definition 818.1 is exactly the displayed finite* BHist *row*

$$E = (I, T, A, V, H, C, P, N).$$

The input row I, finite trace row T, accepted-result row A, validation-boundary row V, componentwise transport row H, continuation row C, package provenance row P, and local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row N are admitted as the complete root image. No host evaluator, hidden runtime state, infinite trace, or unchecked compiler theorem is an admitted root-image coordinate.*

Proof. Project the carrier of Definition 818.1. Its finite packet lists exactly I, T, A, V, H, C, P, N, and each listed row has a fixed carrier role.

The existing root image row and root NameCert obligations, Definition 818.46 and Definition 818.61, read the same packet as a BHist/hsame/Cont/Pkg/NameCert surface.

The excluded objects have no carrier coordinate and no continuation route from C. Thus root-image admission is exhausted by the eight displayed rows. □

Theorem 818.71 (FiniteTraceEvaluator root classifier transport)**.** *Let* $E = (I, T, A, V, H, C, P, N)$ *and* $E' = (I', T', A', V', H', C', P', N')$ *be accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packets. If the componentwise* hsame *rows transport* I, T, A, V, C, P, N *to* $I', T', A', V', C', P', N'$*, then the input, finite-trace, accepted-result, and validation route remains the displayed route*

$$I \to T \to A \to V$$

and transports to

$$I' \to T' \to A' \to V'.$$

The transport cannot move the classifier to a host evaluator, detached runtime state, infinite trace, or unchecked compiler theorem.

Proof. First read the source route through Definition 818.70. The only classifier-bearing route starts with the coded input row, proceeds through the finite trace, reaches the accepted-result classifier, and then records the validation boundary.

Next apply acceptance row stability and checkpoint determinacy, Definition 818.62 and Definition 818.65. They keep accepted-result reads on the same $I \to T \to A$ path under componentwise hsame transport and displayed continuation replay.

Finally attach the validation boundary and provenance rows using Definition 818.35 and Definition 818.63. The row V stays a boundary row and the ledger has no alternate classifier coordinate, so the transported packet keeps the displayed route. □

Theorem 818.72 (FiniteTraceEvaluator root ledger totality)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, every public root consumer is exhausted by the finite ledger*

$$I, T, A, V, H, C, P, N.$$

The ledger exposes the input, finite trace, accepted result, validation boundary, componentwise transport, displayed continuation, package provenance, and local naming rows, and it exposes no host evaluator, hidden runtime state, infinite trace, total truth predicate, total halting classifier, or unchecked compiler theorem.

Proof. Begin with root image admission and root classifier transport. They identify the accepted root image and show that componentwise transport cannot leave the route $I \to T \to A \to V$.

Use route totality and ledger non-escape, Definition 818.64 and Definition 818.63. These theorems account for the consumer-facing rows H, C, P, N and remove host evaluators, infinite traces, and unchecked compiler theorems from the public ledger.

The remaining excluded objects are also absent from the carrier of Definition 818.1. Since no row outside I, T, A, V, H, C, P, N is admitted, every public root consumer is total on that displayed finite ledger. □

Theorem 818.73 (FiniteTraceEvaluator root obligation package)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet*

$$E = (I, T, A, V, H, C, P, N),$$

the root package exposes exactly carrier admission, checkpoint acceptance, bounded replay, ledger exactness, and consumer non-escape over the displayed BHist/hsame/Cont/Pkg/NameCert *rows. Its readable surface is the coded input row* I*, finite trace row* T*, accepted-result classifier row* A*, validation row* V*, componentwise transport row* H*, continuation row* C*, provenance row* P*, and local naming row* N*; it exports no host evaluator, hidden runtime state, unbounded trace, unchecked compiler theorem, or second root source.*

Proof. Carrier admission is projection from Definition 818.1. The accepted packet is the displayed finite tuple I, T, A, V, H, C, P, N, and the carrier contains no further root coordinate.

Checkpoint acceptance is supplied by Definition 818.34 and Definition 818.52. These force checkpoint-facing reads through the finite input, trace, accepted-result, and validation rows before any consumer can inspect the package.

Bounded replay and ledger exactness come from Definition 818.53 and Definition 818.59. The route remains inside I, T, A, V, H, C, P, N under the displayed hsame transports and Cont replay.

Finally apply Definition 818.35 and Definition 818.60. They exclude host validation, hidden runtime state, unbounded evaluation, infinite traces, and unchecked compiler theorems, so the five listed obligations exhaust the root package. □

Theorem 818.74 (FiniteTraceEvaluator checkpoint route totality)**.** *Every checkpoint-facing consumer route for an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet must expose the same rows*

$$I, T, A, V, H, C, P, N.$$

The route may read the coded input, finite trace, accepted-result classifier, validation boundary, componentwise transports, continuation replay, package provenance, and local naming row only through that packet. It cannot read a host evaluator, hidden runtime state, unbounded trace, unchecked compiler theorem, or second checkpoint source.

Proof. Start with the checkpoint source lock of Definition 818.40. It fixes the checkpoint-facing source route at the displayed input, trace, and accepted-result rows.

Use Definition 818.8. A consumer-facing checkpoint read must pass through the finite evaluator carrier, the validation boundary, the continuation replay, package provenance, and the local naming row.

Finally invoke Definition 818.73. The root package already lists carrier admission, checkpoint acceptance, bounded replay, ledger exactness, and consumer non-escape over I, T, A, V, H, C, P, N, so no outside evaluator, hidden state, unbounded trace, unchecked theorem, or second source is available to the route. □

Theorem 818.75 (FiniteTraceEvaluator result factorization non-escape)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, accepted-result classification reaches* A *only through the finite route*

$$I \to T \to A.$$

Validation remains at V*, while the ledger and consumer rows* H, C, P, N *expose only transported replay and local package provenance. The package exports no total truth predicate, total halting classifier, infinite trace, host validator, hidden runtime state, or unchecked compiler theorem.*

Proof. First use Definition 818.4. It places every accepted result behind the coded input row I and finite trace row T before the classifier row A can be read.

Next apply Definition 818.22. The accepted-result ledger is exhausted by the displayed result route, validation boundary, componentwise transport, continuation replay, package provenance, and local naming row.

Use Definition 818.42. The runtime boundary receives the finite evaluator rows as a handoff packet rather than a host validator or hidden runtime state.

Finally combine the handoff with Definition 818.63. The root ledger does not contain total truth, total halting, infinite trace, host validation, or unchecked compiler coordinates, so accepted-result classification cannot escape the route $I \to T \to A$ while validation remains at V. □

Definition 818.76 (FiniteTraceEvaluator terminal root surface)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the terminal root surface is the finite packet*

$$E = (I, T, A, V, H, C, P, N).$$

The row I is the coded input source, T is the terminal finite trace row, A is the accepted-result classifier, V is the validation-boundary refusal row, H records the componentwise hsame *transports, C records the displayed* Cont *replay routes, P records* Pkg *provenance, and N records the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row. This surface is the terminal read of the carrier in Definition 818.1, the local NameCert obligations of Definition 818.3, the root exactness scope of Definition 818.59, and the checkpoint ledger cut of Definition 818.60; it is consumed by the runtime checkpoint packet of chapter 997.*

Theorem 818.77 (FiniteTraceEvaluator terminal trace-source lock)**.** *Every terminal root read of the surface $E = (I, T, A, V, H, C, P, N)$ in Definition 818.76 keeps its source on the displayed route*

$$I \to T.$$

No terminal read can replace I by a host source, a second checkpoint source, an infinite trace source, or an unbounded evaluator source.

Proof. Project the carrier in Definition 818.1. It gives the terminal reader exactly one coded input row I and exactly one finite trace row T before any accepted-result or validation-facing row is exposed.

Use Definition 818.3. The trace-step exposure clause binds terminal trace access to the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ row, so every trace read remains a read from I into the displayed finite row T.

Finally apply Definition 818.59 and Definition 818.60. The exactness scope and ledger cut contain no coordinate for a host source, second checkpoint source, infinite trace source, or unbounded evaluator source, and the runtime checkpoint consumer of chapter 997 receives only the displayed terminal packet. □

Theorem 818.78 (FiniteTraceEvaluator terminal accepted-result readback)**.** *For the terminal root surface $E = (I, T, A, V, H, C, P, N)$, an accepted-result read can reach the classifier row A only after the finite trace row T has been read from the coded input source I. The terminal readback route is therefore*

$$I \to T \to A,$$

and no accepted-result read can bypass T through validation, provenance, local naming, host runtime state, total truth, total halting, or an unbounded evaluator.

Proof. Start with the terminal surface of Definition 818.76. Its accepted-result row is the classifier A, while the rows V, H, C, P, N are validation, transport, replay, provenance, and local naming rows rather than result sources.

Apply Definition 818.3. The accepted-result classifier clause exposes A only through the finite trace-step exposure row, so the result read must pass through $I \to T$ before it reaches A.

Now use Definition 818.59. It separates the accepted-result route $I \to T \to A$ from the validation and ledger route V, H, C, P, N, preventing the two routes from being mixed into a hidden readback.

The checkpoint ledger cut in Definition 818.60 removes the remaining bypasses. Host runtime state, total truth, total halting, unbounded evaluation, and a second source are not coordinates of E, and the sibling runtime checkpoint chapter consumes the same finite route. □

Theorem 818.79 (FiniteTraceEvaluator terminal validation nonescape)**.** *In the terminal root surface $E = (I, T, A, V, H, C, P, N)$, the validation row V remains a boundary refusal. It does not become host validation, total truth for* CIC* *sentences, total halting, an unbounded evaluator, an infinite trace, or a second checkpoint source for the runtime checkpoint consumer.*

Proof. Read V from Definition 818.76. The definition names it only as the validation-boundary refusal row of the terminal packet, with transport, replay, provenance, and local naming recorded separately by H, C, P, N.

Use Definition 818.3. Its runtime-validation non-escape clause prevents a local finite evaluator certificate from turning the boundary row into a host validating judgment.

Next apply Definition 818.59. Any terminal validation-facing read factors through V, H, C, P, N rather than through the accepted-result route $I \to T \to A$, so validation cannot become an accepted result or an alternate trace source.

Finally use Definition 818.60. The ledger has no coordinate for host validation, total truth, total halting, unbounded evaluation, infinite traces, or second checkpoint sources. The runtime checkpoint packet of chapter 997 can therefore read V only as the displayed boundary refusal. □

Theorem 818.80 (FiniteTraceEvaluator checkpoint-budget exhaustion)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet $E = (I, T, A, V, H, C, P, N)$, every checkpoint-budget read consumed by the* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *sibling surface is exhausted by the displayed finite evaluator rows: coded input I, finite trace T, accepted-result classifier A, validation-boundary row V, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row N. The checkpoint budget exposes no host evaluator, hidden runtime acceptance predicate, total truth predicate, total halting classifier, unbounded evaluator, infinite trace, or second checkpoint source.*

Proof. Project the carrier of Definition 818.1. Its public BHist packet has exactly the rows I, T, A, V, H, C, P, N; no further runtime row is part of the carrier.

Apply the terminal root surface of Definition 818.76. It presents the same rows to the ReflectionRuntimeCheckpoi consumer, with I, T, A as the accepted-result spine and V, H, C, P, N as the validation-boundary and structural surface.

Finally use the root checkpoint saturation theorem, Definition 818.57. It exhausts checkpoint-state, result, validation-boundary, transport, continuation, provenance, and local naming reads at the same finite packet. Since none of the excluded runtime or truth objects is a displayed row, no checkpoint-budget read can escape the finite surface. □

Theorem 818.81 (FiniteTraceEvaluator reflection-runtime route)**.** *Every* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *route reading an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through*

$$I \to T \to A \to V \to H \to C \to P \to N.$$

The first three rows form the accepted-result route, while the remaining rows record validation refusal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row. The route does not import a host runtime evaluator or a hidden runtime acceptance predicate.*

Proof. Begin with the checkpoint consumer route, Definition 818.8. It already places every runtime checkpoint consumer on the displayed sequence from I through N.

Next combine the terminal accepted-result readback with terminal validation nonescape, Definition 818.78 and Definition 818.79. The first result fixes access to A behind $I \to T$, and the second keeps validation at the boundary row V rather than at a host runtime predicate.

The structural rows then carry only the same route. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row expose the finite packet to the ReflectionRuntimeCheckpoint$^{\uparrow}$ surface without adding evaluator content. □

Theorem 818.82 (FiniteTraceEvaluator downstream-unblock scope)**.** *The finite evaluator package supplied to downstream reflection-runtime chapters is exactly the checkpoint-budget package*

$$I, T, A, V, H, C, P, N.$$

It licenses downstream use of the displayed finite trace, accepted-result row, validation-boundary refusal, BHist *packet identity, componentwise* hsame *transport, displayed* Cont *route,* Pkg *provenance, and local* NameCert *row. It does not license host evaluator validation, hidden runtime acceptance, total truth for* CIC* *sentences, total halting, unbounded evaluation, infinite trace semantics, or a second runtime checkpoint route.*

Proof. First combine Definition 818.80 with Definition 818.81. These two results identify the available budget rows and the only route by which the runtime checkpoint sibling can read them.

Use Definition 818.59 and Definition 818.60. They separate the accepted-result spine from the validation-boundary and structural rows, and they remove host validation, truth, halting, unbounded evaluation, infinite trace semantics, and alternate checkpoint sources from the ledger.

Thus any downstream reflection-runtime chapter citing the evaluator receives a finite BHist packet with visible hsame, Cont, Pkg, and NameCert rows. The cited package unblocks only finite checkpoint reads over those rows, so no hidden runtime acceptance predicate or host evaluator is exported. □

Theorem 818.83 (FiniteTraceEvaluator ground checkpoint readback totality)**.** *For an accepted* FiniteTraceEvaluator$^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, every ground checkpoint readback exposed to a* ReflectionRuntimeCheckpoint$^{\uparrow}$ *consumer is total along the displayed finite rows*

$$I \to T \to A \to V \to H \to C \to P \to N.$$

The readback is a finite BHist *trace read, transported by the componentwise* hsame *row* H*, replayed by the displayed* Cont *route* C*, packaged by* P*, and named by* N*. It has no coordinate for a host evaluator, hidden runtime acceptance predicate, total truth classifier, unbounded runtime, or infinite trace.*

Proof. Project the finite evaluator carrier. Its public checkpoint surface displays the coded input I, finite trace T, accepted-result row A, validation boundary V, componentwise transport H, continuation route C, provenance row P, and local NameCert row N.

Apply checkpoint-budget exhaustion and the reflection-runtime route. These results force every checkpoint readback through the same finite BHist/hsame/Cont/Pkg/NameCert packet and prevent the runtime consumer from asking for any row outside the displayed route.

Finally use checkpoint-source locking. Since the source is already the finite packet I, T, A, V, H, C, P, N, the readback is total exactly on that packet and has no second runtime source from which to import host validation, total truth, unbounded evaluation, or an infinite trace. □

Theorem 818.84 (FiniteTraceEvaluator runtime image route determinacy)**.** *Let* $E = (I, T, A, V, H, C, P, N)$ *be an accepted* FiniteTraceEvaluator$^{\uparrow}$ *packet. Every runtime image of* E *visible at the* ReflectionRuntimeCheckpoint$^{\uparrow}$ *surface is determined by the single route*

$$I \to T \to A \to V \to H \to C \to P \to N.$$

Two checkpoint consumers preserving these rows therefore read the same finite trace image, the same accepted-result image, the same validation-boundary image, and the same BHist/hsame/Cont/Pkg/NameCert *exposure. They cannot split the image through a second checkpoint source or a host runtime image.*

Proof. Start from the checkpoint consumer route. It places each runtime-facing consumer on the route from the coded input and finite trace through the accepted-result and validation-boundary rows.

Next attach the structural exposure rows. The componentwise hsame transport row H and displayed Cont replay row C preserve the same finite BHist image, while P and N add only package provenance and local naming.

Use root checkpoint readback totality above to compare two consumers. Since both consumers preserve I, T, A, V, H, C, P, N, their runtime images are read from the same finite packet, so there is no remaining coordinate on which a second checkpoint source or host runtime image could differ. □

Theorem 818.85 (FiniteTraceEvaluator validation ledger exhaustion)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, the validation ledger visible to checkpoint-runtime consumers is exhausted by* V, H, C, P, N *over the finite trace source* I, T, A*. The ledger records validation-boundary refusal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not export host validation, total truth for runtime sentences, total halting, unbounded evaluation, infinite trace semantics, or a second validation ledger.*

Proof. First separate the accepted-result spine from the validation boundary. The finite trace rows I, T, A supply the source image, while V is the only validation row exposed by the evaluator packet.

Next read the structural ledger. The rows H, C, P, N transport, replay, package, and name the finite validation boundary without adding evaluator content, so every visible validation claim remains inside the displayed BHist/hsame/Cont/Pkg/NameCert packet.

Finally combine runtime image route determinacy with the existing validation nonescape boundary. The runtime image has only the route displayed above, and the nonescape boundary removes host validation, total truth, total halting, unbounded evaluation, infinite traces, and alternate validation ledgers from the checkpoint surface. Thus the validation ledger is exhausted by the stated rows. □

Theorem 818.86 (FiniteTraceEvaluator terminal route totality)**.** *Every terminal route of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *surface*

$$E = (I, T, A, V, H, C, P, N)$$

from Definition 818.76 factors through the accepted-result spine

$$I \to T \to A.$$

The rows V, H, C, P, N *may then supply validation-boundary refusal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *naming, but no terminal route begins from a host evaluator, hidden runtime state, total truth predicate, total halting classifier, unbounded evaluator, or second checkpoint source.*

Proof. Start with the terminal surface definition. It displays exactly the packet $E = (I, T, A, V, H, C, P, N)$ and identifies I as the coded input row, T as the terminal finite trace row, and A as the accepted-result classifier.

Apply the terminal trace-source lock and terminal accepted-result readback, Definition 818.77 and Definition 818.78. These place the terminal source on $I \to T$ and make access to A pass through the same finite route.

It remains to exclude alternate terminal sources. Use terminal validation nonescape, root exactness scope, and the checkpoint ledger cut, Definition 818.79, Definition 818.59, and Definition 818.60. The sibling runtime checkpoint chapter then consumes the displayed packet rather than a hidden evaluator or second checkpoint source. □

Theorem 818.87 (FiniteTraceEvaluator terminal source stability)**.** *Let two terminal reads of accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *surfaces display the same packet*

$$E = (I, T, A, V, H, C, P, N)$$

up to the componentwise hsame *transports recorded in* H *and the displayed* Cont *replay routes recorded in* C*. Then both reads preserve the same terminal source route*

$$I \to T \to A.$$

Transport may replay validation, provenance, and naming access through V, H, C, P, N*, but it cannot move the terminal source to a host evaluator, hidden runtime state, total truth predicate, total halting classifier, unbounded evaluator, or second checkpoint source.*

Proof. First expose the common terminal packet through Definition 818.76. The only source, trace, and accepted-result rows of the packet are I, T, and A.

Use Definition 818.86. Each terminal read already factors through $I \to T \to A$ before the validation, transport, replay, provenance, and naming rows are consumed.

Now apply the bounded replay stability and acceptance row stability results, Definition 818.53 and Definition 818.62. Componentwise hsame transport and displayed Cont replay preserve the finite trace row and the accepted-result row of the same route.

Finally combine terminal validation nonescape with the checkpoint ledger cut, Definition 818.79 and Definition 818.60. Since the ledger contains no alternate source coordinate, transport cannot create one for the runtime checkpoint consumer. □

Theorem 818.88 (FiniteTraceEvaluator terminal ledger exhaustion)**.** *The terminal ledger exported by an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *surface is exhausted by the displayed packet*

$$E = (I, T, A, V, H, C, P, N).$$

It exports no host evaluator, hidden runtime state, total truth predicate, total halting classifier, unbounded evaluator, or second checkpoint source. Every downstream runtime checkpoint read therefore receives the terminal route $I \to T \to A$ *together with the boundary, transport, continuation, provenance, and naming rows* V, H, C, P, N*, and receives no further evaluator coordinate.*

Proof. Begin with Definition 818.76. The terminal ledger has exactly the eight displayed rows of E.

Apply terminal route totality and terminal source stability, Definition 818.86 and Definition 818.87. The accepted-result side is fixed at $I \to T \to A$, and componentwise transport keeps terminal reads on that route.

Use root exactness scope and checkpoint ledger cut, Definition 818.59 and Definition 818.60. These results separate the accepted-result spine from V, H, C, P, N and remove host validation,

total truth, total halting, unbounded evaluation, infinite traces, and second checkpoint sources from the ledger.

Finally read the handoff through the runtime checkpoint sibling chapter, chapter 997. Its root carrier and ledger exactness rows consume the finite checkpoint packet without importing hidden runtime state or an additional evaluator coordinate. □

Theorem 818.89 (FiniteTraceEvaluator terminal checkpoint accountability)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *terminal packet*

$$I, T, A, V, H, C, P, N,$$

the checkpoint obligation is accountable to the displayed finite BHist *route*

$$I \to T \to A.$$

The accepted-result row is read only through Definition 818.78, the terminal route is total by Definition 818.86, and the root route is total by Definition 818.64. The remaining rows V, H, C, P, N *provide validation boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *naming. No host evaluator, hidden runtime state, infinite trace, or unchecked compiler theorem is a checkpoint source.*

Proof. Begin with the terminal root surface of Definition 818.76. It displays exactly the rows I, T, A, V, H, C, P, N, with T as the finite BHist trace row and A as the accepted-result classifier.

Apply terminal accepted-result readback, Definition 818.78. The result side cannot reach A before reading the finite route $I \to T$, so the checkpoint is accountable to the same terminal trace.

Finally apply terminal route totality and root route totality, Definition 818.86 and Definition 818.64. The rows V, H, C, P, N may transport, replay, package, and name the checkpoint surface, but they do not introduce a host evaluator, hidden runtime state, infinite trace, or unchecked compiler theorem. □

Theorem 818.90 (FiniteTraceEvaluator terminal validation route)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *terminal packet*

$$I, T, A, V, H, C, P, N,$$

every validation-facing checkpoint read factors through the finite rows V, H, C, P, N *over the same* BHist *trace route* $I \to T \to A$*. The validation boundary is the row* V *of Definition 818.79; its transports, continuations, package provenance, and local naming are exactly the displayed* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *rows* H, C, P, N*. It cannot become host validation, a hidden runtime evaluator, an infinite trace checker, or an unchecked compiler theorem.*

Proof. Read the validation row from Definition 818.79. It is a boundary refusal row in the terminal packet, not a host-side validator or a second source of accepted results.

Use terminal route totality, Definition 818.86, to keep the validation-facing read on the same finite packet. The accepted-result spine is $I \to T \to A$, while V, H, C, P, N record boundary, transport, replay, provenance, and naming for that spine.

The checkpoint accountability statement, Definition 818.89, identifies the only checkpoint source. Since the packet has no coordinate for hidden runtime state, infinite traces, or compiler-side unchecked proof, validation cannot escape the displayed route. □

Theorem 818.91 (FiniteTraceEvaluator terminal consumer non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *terminal checkpoint packet receives only*

$$I, T, A, V, H, C, P, N.$$

Its accepted-result access factors through $I \to T \to A$ *by Definition 818.78 and Definition 818.86; its validation-facing access factors through* V, H, C, P, N *by Definition 818.79 and Definition 818.90. Thus every consumer route is a displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *route, with no host evaluator, hidden runtime, infinite trace, or unchecked compiler theorem.*

Proof. First expose the terminal packet through Definition 818.76. The consumer receives the eight displayed rows and no off-packet evaluator coordinate.

For accepted-result reads, apply terminal accepted-result readback and terminal route totality. These results bind A to the finite route $I \to T \to A$ and keep all terminal reads inside the same packet.

For validation-facing reads, apply terminal validation nonescape and the terminal validation route theorem. The rows V, H, C, P, N account for boundary refusal, transport, continuation, provenance, and naming without adding host validation or an infinite-trace checker.

Combining the two routes leaves no remaining consumer channel. Any claimed host evaluator, hidden runtime, infinite trace, or unchecked compiler theorem would require a packet coordinate not present in I, T, A, V, H, C, P, N. □

Theorem 818.92 (FiniteTraceEvaluator checkpoint-runtime triad)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the checkpoint row, runtime row, and image/readback row form one displayed triad*

$$I, T, A, V, H, C, P, N.$$

The checkpoint side reads the finite BHist *trace through* T *and the accepted-result route through* $I \to T \to A$*; the runtime side reads the same route through* hsame *transports* H *and displayed* Cont *replay routes* C*; the package and local naming side is recorded by* Pkg *provenance* P *and the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row* N*.*

No checkpoint-runtime consumer receives a host evaluator, hidden runtime state, unbounded trace source, second checkpoint source, or unchecked compiler theorem.

Proof. Begin with checkpoint readiness. The totality and readiness rows of Definition 818.34 and Definition 818.36 place every root checkpoint read on I, T, A, V, H, C, P, N before any downstream runtime consumer can inspect the packet.

Next use runtime totality. By Definition 818.37, the runtime row has the same finite surface and does not add a host evaluator or an unbounded runtime coordinate.

Finally attach image readback, result factorization, and terminal route completion. The image and readback rows of Definition 818.46 and Definition 818.47 identify the visible rows, while Definition 818.52 and Definition 818.86 keep the accepted result on the same finite route. Thus the checkpoint, runtime, and readback rows form one triad. □

Theorem 818.93 (FiniteTraceEvaluator checkpoint image readback)**.** *Every checkpoint image of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet reads back through the finite route*

$$I \to T \to A$$

for accepted results and through V, H, C, P, N *for validation-facing reads. The readback uses the displayed* BHist *trace, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row, and it exposes no host validation, total truth predicate, total halting classifier, unbounded evaluator, infinite trace, or second checkpoint source.*

Proof. First expose the checkpoint image. Apply Definition 818.46; it lists exactly I, T, A, V, H, C, P, N as the image rows visible to accepted reads.

Then read back the accepted-result and validation routes. The exactness result Definition 818.47 sends accepted results through $I \to T \to A$ and validation-facing reads through V, H, C, P, N.

Finally combine result factorization with terminal route completion. Definition 818.48 and Definition 818.88 show that the downstream runtime checkpoint consumer receives the same finite packet. Since the ledger has no host or unbounded coordinate, checkpoint readback cannot escape the displayed image. □

Theorem 818.94 (FiniteTraceEvaluator terminal runtime nonescape)**.** *The terminal runtime route of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet is confined to the finite checkpoint-runtime packet*

$$I, T, A, V, H, C, P, N.$$

Its BHist *trace row,* hsame *transport rows,* Cont *replay rows,* Pkg *provenance row, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row are the only routes available to terminal runtime consumers. It exports no host evaluator, hidden runtime state, total truth predicate, total halting classifier, unbounded evaluator, infinite trace semantics, or alternate checkpoint route.*

Proof. Start from the checkpoint-runtime triad of Definition 818.92. It identifies the checkpoint, runtime, and image/readback rows as one finite packet.

Next apply the terminal route results. The terminal route totality and source stability rows, Definition 818.86 and Definition 818.87, keep terminal runtime reads on $I \to T \to A$ under displayed hsame and Cont transport.

Finally use terminal ledger exhaustion together with checkpoint image readback. By Definition 818.88 and Definition 818.93, the terminal consumer receives only I, T, A, V, H, C, P, N. Hence none of the excluded host, truth, halting, unbounded, infinite-trace, or alternate checkpoint coordinates can be exported. □

Theorem 818.95 (FiniteTraceEvaluator checkpoint-runtime acceptance lock)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, a checkpoint-facing read is accepted only when it passes through the displayed input row, finite trace row, accepted-result row, validation-boundary row, componentwise transport row, route row, provenance row, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row. In packet notation the accepted surface is*

$$I, T, A, V, H, C, P, N.$$

No checkpoint read is accepted from a detached runtime input, host validation row, unbounded trace source, alternate accepted-result classifier, or local name outside that packet.

Proof. Begin with the carrier surface of the finite trace evaluator. Its checkpoint-facing rows are the input, trace, accepted-result, validation, transport, route, provenance, and local naming rows.

Apply the checkpoint-runtime triad of Definition 818.92. It identifies the checkpoint, runtime, and readback sides as one finite packet I, T, A, V, H, C, P, N.

Use checkpoint image readback and terminal runtime nonescape, Definition 818.93 and Definition 818.94. These results rule out detached host validation, unbounded trace semantics, alternate accepted-result classifiers, and local names outside the displayed packet. □

Theorem 818.96 (FiniteTraceEvaluator runtime route coverage)**.** *Every runtime-facing consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *and* $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$ *before reading the evaluator result. The result read is therefore carried only by the finite route* I, T, A, V, H, C, P, N *and by the candidate-boundary and checkpoint rows named in the provenance packet.*

Proof. First expose the runtime checkpoint side. The checkpoint-runtime triad places runtime-facing reads on the same finite evaluator rows as checkpoint-facing reads.

Next route the consumer through the checkpoint sibling. The $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ side supplies the checkpoint state and validation-boundary read before any evaluator result can be consumed.

Finally use the $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$ provenance row. It supplies the object-level input, transition, and accepted-result boundary read by the evaluator. Since the evaluator result is reached only after those two sibling surfaces, no runtime consumer bypasses them. □

Theorem 818.97 (FiniteTraceEvaluator validation refusal closure)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, host validators, truth predicates, unrestricted evaluator semantics, and hidden runtime state are refused outside the displayed packet*

$$I, T, A, V, H, C, P, N.$$

The validation-facing row records only the finite boundary available to the packet; it does not export host-valid runtime judgment, total truth, unbounded evaluation, or hidden machine state.

Proof. Start with the acceptance lock above. Accepted checkpoint-runtime reads must pass through I, T, A, V, H, C, P, N.

Apply runtime route coverage. Any runtime-facing consumer reaches the evaluator only after $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ and $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$, so the consumer cannot replace the displayed validation row by host validation or by a total truth predicate.

Finally use terminal runtime nonescape. The terminal route exports no host evaluator, hidden runtime state, total truth predicate, total halting classifier, unbounded evaluator, infinite trace semantics, or alternate checkpoint route. The validation refusal is therefore closed at the displayed finite packet. □

Theorem 818.98 (FiniteTraceEvaluator checkpoint-runtime route determinacy)**.** *Let two accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *checkpoint-runtime packets display rows*

$$I, T, A, V, H, C, P, N$$

and

$$I', T', A', V', H', C', P', N'.$$

If the input, finite trace, accepted-result, validation-boundary, transport, route, provenance, and local naming rows compare componentwise by hsame*, and the displayed* Cont *routes identify the checkpoint replay from* I *to* T *and from* T *to* A*, then the two runtime reads have the same public checkpoint route. The determinacy is read only through the* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *carrier and the root* $\mathsf{NameCert}$ *obligation surface.*

Proof. Start with the checkpoint-runtime triad. By Definition 818.92, each accepted packet presents checkpoint, runtime, image, and readback rows as the single finite surface I, T, A, V, H, C, P, N.

Next apply the acceptance lock and the root obligation surface. The lock of Definition 818.95 forces both reads to pass through the same input, trace, accepted-result, validation-boundary, transport, route, provenance, and local naming rows, while Definition 818.61 supplies the carrier and classifier rows that make componentwise hsame transport valid.

Finally use the displayed Cont hypotheses. Since the replay routes from input to trace and from trace to accepted result are matched componentwise, no second checkpoint route remains. The public runtime read is therefore determined by the displayed packet and its local NameCert surface. □

Theorem 818.99 (FiniteTraceEvaluator runtime acceptance nonescape)**.** *Every runtime acceptance read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet is confined to the displayed checkpoint-runtime rows*

$$I, T, A, V, H, C, P, N.$$

No host validator, total truth predicate, total halting classifier, unchecked compiler theorem, hidden runtime state, unbounded evaluator, or infinite trace can be exported from the runtime acceptance row.

Proof. First read the accepted packet through the carrier and root NameCert obligation surface. The rows I, T, A, V, H, C, P, N are exactly the input, finite trace, accepted-result, validation-boundary, componentwise transport, replay route, provenance, and local naming rows.

Use Definition 818.94 for the terminal runtime side. It already excludes host evaluators, hidden runtime state, total truth predicates, total halting classifiers, unbounded evaluator semantics, infinite traces, and alternate checkpoint routes.

Now apply Definition 818.97. The validation-facing row is a finite boundary inside the accepted packet, not a host-valid runtime judgment or a global compiler theorem. Thus the runtime acceptance read cannot escape the displayed checkpoint-runtime surface. □

Theorem 818.100 (FiniteTraceEvaluator checkpoint replay totality)**.** *Every checkpoint replay of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through the displayed rows*

$$I, T, A, V, H, C, P, N.$$

The replay first reads the input row I, then the finite trace row T, then the accepted-result row A, and then the validation-boundary row V together with the componentwise transport H, displayed route C, provenance P, and local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row N. This totality assertion uses only the carrier and root obligation surface, and it introduces no infinite trace or unchecked host evaluator.*

Proof. Begin with checkpoint image readback. By Definition 818.93, accepted checkpoint images read back through $I \to T \to A$ and then through V, H, C, P, N for validation-facing reads.

Next apply checkpoint-runtime acceptance lock. It requires every accepted checkpoint-facing read to use the same input, trace, accepted-result, validation-boundary, transport, route, provenance, and local naming rows before runtime acceptance is available.

Finally combine route determinacy with runtime nonescape. The determinacy theorem above makes the replay route unique under componentwise hsame and displayed Cont transport, while Definition 818.99 excludes host validators, total truth predicates, total halting classifiers, unchecked compiler theorems, and infinite traces. Hence every checkpoint replay is total on the displayed finite route. □

Theorem 818.101 (FiniteTraceEvaluator checkpoint runtime NameCert triad)**.** *Every checkpoint consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet reads the displayed rows*

$$I, T, A, V, H, C, P, N$$

through bounded trace coverage, the accepted-result classifier, validation-boundary refusal, componentwise transport, continuation replay, provenance, and the local $\mathsf{NameCert}$ *rows before reaching* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$*. The triad exports no host validator, truth predicate, total halting predicate, infinite trace, or self-validation row.*

Proof. Start from the carrier of Definition 818.1 and the root NameCert obligations of Definition 818.61. They identify I, T, A, V, H, C, P, N as the finite evaluator packet and bind those rows to the local certificate surface.

Next use bounded trace coverage and validation refusal from Definition 818.4 and Definition 818.35. The finite trace row and accepted-result classifier are visible, while host validation and unbounded trace semantics remain outside the packet.

Finally apply result-validation separation, route obligation triad, and checkpoint consumer route, Definition 818.6, Definition 818.7, and Definition 818.81. These force checkpoint reads through validation-boundary refusal, componentwise transport, continuation replay, provenance, and local naming before the $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ handoff. □

Theorem 818.102 (FiniteTraceEvaluator checkpoint state saturation route)**.** *Every checkpoint-state read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet is saturated by the route*

$$I, T, A, V, H, C, P, N$$

before a runtime checkpoint consumer inspects it. The saturated route reads bounded trace coverage, accepted-result classification, validation-boundary refusal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row, and it exports no host validator, self-validation row, total halting predicate, infinite trace, or detached runtime state.*

Proof. First apply Definition 818.101. It places checkpoint consumers on the displayed packet rows and sends the read toward $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ through the finite NameCert triad.

Next use the checkpoint-runtime triad and acceptance lock, Definition 818.92 and Definition 818.95. They keep accepted checkpoint-state reads on the bounded trace, classifier, validation-boundary, transport, continuation, provenance, and local naming rows.

Finally combine checkpoint budget exhaustion with route determinacy, Definition 818.80 and Definition 818.98. The checkpoint budget and runtime route are determined by the same finite packet, so no detached runtime state or external validation row remains to be exported. □

Theorem 818.103 (FiniteTraceEvaluator runtime admission boundary)**.** *Every runtime admission read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet must enter through*

$$I, T, A, V, H, C, P, N.$$

The boundary factors through bounded trace coverage, the accepted-result classifier, validation-boundary refusal, componentwise transport, continuation replay, provenance, local NameCert rows, and then $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$*. It does not export a host validator, truth predicate, total halting predicate, infinite trace, or self-validation row.*

Proof. Begin with root runtime admission and checkpoint route coverage, Definition 818.107 and Definition 818.108. These route runtime-facing and checkpoint-facing consumers through the same finite packet I, T, A, V, H, C, P, N.

Next apply the checkpoint state saturation route above. It keeps the checkpoint-state read saturated by bounded trace coverage, accepted-result classification, validation-boundary refusal, componentwise transport, continuation replay, provenance, and local naming before runtime inspection.

Finally use runtime ledger non-escape, Definition 818.109. That theorem excludes host evaluator state, hidden runtime acceptance predicates, total truth predicates, total halting classifiers, unbounded evaluation, infinite traces, and second checkpoint sources. Hence runtime admission is exactly the displayed boundary before the $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ consumer reads it. □

Theorem 818.104 (FiniteTraceEvaluator checkpoint row exposure)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, the checkpoint-facing surface exposes exactly the input row* I*, finite trace row* T*, accepted-result row* A*, validation-boundary row* V*, componentwise transport row* H*, route row* C*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row* N*. The exposure is read from the finite carrier and exports no hidden runtime state.*

Proof. Project the carrier of Definition 818.1. Its checkpoint-facing coordinates are the input, trace, accepted-result, validation, transport, route, provenance, and local naming rows.

Apply the root NameCert obligation surface of Definition 818.61. It identifies those coordinates as the public certificate rows of the accepted evaluator packet.

The checkpoint-runtime triad of Definition 818.92 then reads the checkpoint side through the same finite surface. Since the carrier has no separate runtime coordinate, the checkpoint row exposes only I, T, A, V, H, C, P, N. □

Theorem 818.105 (FiniteTraceEvaluator runtime route totality)**.** *Every runtime-facing read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through the checkpoint route*

$$I \to T \to A \to V$$

with the transport, route, provenance, and local naming rows H, C, P, N *visible. The route is total for the displayed packet and does not require a host evaluator, unchecked validation predicate, unbounded trace, or alternate accepted-result classifier.*

Proof. Begin with checkpoint row exposure from Definition 818.104. It supplies the finite packet I, T, A, V, H, C, P, N as the whole runtime-facing surface.

Next use Definition 818.95. It requires every accepted checkpoint-runtime read to pass through the displayed input, trace, accepted-result, validation, transport, route, provenance, and local naming rows.

Finally apply Definition 818.100. The replay reads I before T, T before A, and then V, H, C, P, N, so the runtime route is total on the displayed finite packet and no host evaluator or alternate classifier is imported. □

Theorem 818.106 (FiniteTraceEvaluator checkpoint route nonescape)**.** *No checkpoint-facing consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet can escape the displayed route* I, T, A, V, H, C, P, N*. In particular, the consumer cannot replace the input row, finite trace row, accepted-result row, validation row, transport row, route row, provenance row, or local name by hidden runtime state, a host validation coordinate, an unbounded evaluator output, or an alternate evaluator result.*

Proof. Start with runtime route totality from Definition 818.105. It places every runtime-facing read on the finite checkpoint route $I \to T \to A \to V$ with H, C, P, N visible.

Use checkpoint-runtime route determinacy from Definition 818.98. Componentwise hsame and displayed Cont replay identify the route by the exposed rows, so a second checkpoint route cannot be recovered from the same packet.

Now apply runtime acceptance nonescape from Definition 818.99. The accepted runtime row exports no host validator, total truth predicate, total halting classifier, unchecked compiler theorem, hidden runtime state, unbounded evaluator, or infinite trace.

Combining these facts, every checkpoint consumer is confined to the displayed input, trace, accepted-result, validation, transport, route, provenance, and local naming rows, and no alternate evaluator output is available. □

Theorem 818.107 (FiniteTraceEvaluator root runtime admission)**.** *Every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet enters the root runtime surface through the displayed rows*

$$I, T, A, V, H, C, P, N.$$

The coded input row I, finite trace row T, accepted-result classifier row A, validation boundary row V, componentwise transport row H, displayed continuation row C, provenance row P, and local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row N are the complete runtime admission rows for the packet.*

Proof. Begin with the carrier of Definition 818.1. The finite evaluator packet exposes the coded input, finite trace, accepted result, validation boundary, transport, continuation, provenance, and local naming rows as its root runtime surface.

Apply Definition 818.61. The root NameCert obligations identify carrier admission, checkpoint acceptance, bounded replay, ledger exactness, and consumer non-escape over exactly the displayed rows I, T, A, V, H, C, P, N.

Use Definition 818.80 and Definition 818.81. They keep checkpoint-budget reads and reflection-runtime reads on the same finite evaluator route, so runtime admission has no row outside the displayed packet. □

Theorem 818.108 (FiniteTraceEvaluator checkpoint route coverage)**.** *Every checkpoint-facing consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet factors through the coded input row, finite trace row, accepted-result classifier, validation boundary, componentwise transport, displayed continuation, provenance row, and local NameCert row*

$$I, T, A, V, H, C, P, N.$$

Thus checkpoint reads are covered by the root runtime route before any downstream result is consumed.

Proof. First apply Definition 818.107. It fixes the root runtime rows I, T, A, V, H, C, P, N as the entry surface for accepted evaluator packets.

Next use Definition 818.95. Checkpoint-facing reads are accepted only through the displayed input, finite trace, accepted-result, validation, transport, route, provenance, and local naming rows.

Apply Definition 818.80. The checkpoint budget is exhausted by the same finite route, and the result row cannot be read through a detached checkpoint source.

Finally use Definition 818.82. Downstream checkpoint consumers receive the accepted finite evaluator route through the same packet, so route coverage is shared by checkpoint and runtime-facing consumers. □

Theorem 818.109 (FiniteTraceEvaluator runtime ledger non-escape)**.** *The runtime ledger of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet exports only the displayed evaluator rows*

$$I, T, A, V, H, C, P, N.$$

It exports no host evaluator, hidden runtime acceptance predicate, total truth predicate, total halting classifier, unbounded evaluator, infinite trace, or second checkpoint source.

Proof. Start from Definition 818.107. Runtime admission is already restricted to the displayed finite evaluator rows.

Apply Definition 818.108. Every checkpoint-facing consumer factors through the same input, trace, accepted-result, validation, transport, continuation, provenance, and local naming route, so there is no second checkpoint source for the ledger to export.

Use Definition 818.96 and Definition 818.97. Runtime-facing reads pass through the reflection-runtime and candidate-boundary surfaces, while host validation, total truth, total halting, unbounded evaluation, and infinite traces are refused outside the displayed packet.

Finally apply Definition 818.63. The existing ledger non-escape row removes host evaluator state, unbounded trace semantics, unchecked compiler theorems, and second checkpoint sources from the exported root ledger; the runtime ledger therefore remains exactly I, T, A, V, H, C, P, N. □

Theorem 818.110 (FiniteTraceEvaluator root checkpoint admission totality)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet with carrier* $E = (I, T, A, V, H, C, P, N)$*, checkpoint admission is total only along the displayed finite route*

$$I \to T \to A \to V \to H \to C \to P \to N.$$

The admission surface is a finite BHist *read transported by* hsame*, replayed by* Cont*, packaged by* Pkg*, and named by* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$*. It has no coordinate for host validation, total truth, total halting, unbounded evaluation, or an infinite trace.*

Proof. Project the carrier in Definition 818.1. The accepted evaluator packet displays exactly I, T, A, V, H, C, P, N, with T as the finite BHist trace row, H as the componentwise hsame transport row, C as the Cont replay row, P as Pkg provenance, and N as the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ row.

Apply the local NameCert obligations and bounded trace coverage, Definition 818.3 and Definition 818.4. They force every accepted-result read through $I \to T \to A$ before checkpoint admission can read validation, transport, continuation, provenance, or naming rows.

Finally attach the host-validation refusal ledger and root runtime admission surface, Definition 818.5 and Definition 818.107. The refusal ledger blocks host validation, total truth, total halting, unbounded evaluation, and infinite traces, while the runtime admission surface keeps the consumer on the same finite route through V, H, C, P, N. □

Theorem 818.111 (FiniteTraceEvaluator root trace-validation separation)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet* $E = (I, T, A, V, H, C, P, N)$*, accepted-result reads and validation-boundary reads remain separated at the rows* A *and* V*. The accepted-result side is read only through*

$$I \to T \to A,$$

while the validation-boundary side is read only through

$$V \to H \to C \to P \to N.$$

The two sides may be transported, replayed, packaged, and named inside the same $\mathsf{BHist}/\mathsf{hsame}/\mathsf{Cont}/\mathsf{Pkg}/\mathsf{NameCer}$ *packet, but neither side becomes host validation or an infinite trace checker.*

Proof. Start from result-validation separation, Definition 818.6. It places accepted results behind the finite route $I \to T \to A$ and records validation only at the boundary row V.

Use the checkpoint source lock and validation nonescape totality, Definition 818.40 and Definition 818.41. They keep checkpoint-facing accepted-result reads on A and validation-facing reads on V, H, C, P, N under the displayed hsame transports and Cont replay routes.

The local NameCert obligations then exhaust the packet. Since P and N add only provenance and local naming, the separated reads cannot import host validation, total truth, total halting, unbounded evaluation, or infinite trace semantics. □

Theorem 818.112 (FiniteTraceEvaluator root reflection checkpoint handoff)**.** *Every* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *handoff that consumes an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet consumes the finite evaluator rows* I, T, A, V, H, C, P, N*. The handoff reads bounded trace coverage, accepted-result classification, validation-boundary refusal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row, and it cannot import host validation, total truth, total halting, an unbounded runtime, or an infinite trace.*

Proof. First apply the runtime boundary handoff, Definition 818.42. It sends every $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ handoff through the finite evaluator carrier, bounded trace coverage, validation non-escape, result-validation separation, root trace-result totality, root validation boundary, and root boundary package.

Next use checkpoint admission totality above. The runtime admission surface is already the displayed route $I \to T \to A \to V \to H \to C \to P \to N$, so the handoff receives no extra host row before reading the evaluator packet.

Finally combine root consumer readiness with runtime admission boundary, Definition 818.36 and Definition 818.103. Downstream checkpoint consumers receive the same finite BHist/hsame/Cont/Pkg/NameCe packet, and the refusal surface blocks host validation, total truth, total halting, unbounded runtime state, and infinite trace imports. □

Definition 818.113 (FiniteTraceEvaluator terminal route carrier)**.** *A* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *terminal route carrier is a finite packet*

$$E = (T, Q, R, X, H, C, P, N)$$

whose rows have the following roles. The row T is the finite BHist *trace row of the evaluator. The row Q is the checkpoint row that reads the trace as a checkpoint source. The row R is the runtime row exposed to downstream runtime consumers. The row X is the image and readback row recording the accepted-result image and the checkpoint readback boundary. The row H records componentwise* hsame *transport between the trace, checkpoint, runtime, and readback rows. The row C is the displayed* Cont *replay route. The row P is the* Pkg *provenance row. The row N is the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row. The carrier has no coordinate for host validation, hidden runtime state, unbounded evaluation, an infinite trace, or an unchecked compiler theorem.*

Theorem 818.114 (FiniteTraceEvaluator checkpoint-runtime factorization)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *terminal route carrier $E = (T, Q, R, X, H, C, P, N)$, checkpoint-facing and runtime-facing reads factor through the same finite route*

$$T \to Q \to R.$$

The factorization is transported componentwise by H, replayed by C, packaged by P, named by N, and read back through X. It imports no host evaluator, no hidden runtime row, and no second checkpoint source.

Proof. First expose the checkpoint side with Definition 818.34 and Definition 818.110. These statements place checkpoint admission on the finite evaluator rows and force the checkpoint source to be a displayed BHist route.

Next expose the runtime side with Definition 818.37 and Definition 818.107. Runtime consumers read the same finite packet through displayed transport, continuation, provenance, and local naming rows, not through a host evaluator.

Finally attach the checkpoint-runtime surface of Definition 818.104 and Definition 818.105. It identifies the checkpoint row and the runtime row as two views of the same finite route, so the carrier factors through $T \to Q \to R$ with X, H, C, P, N as readback, transport, replay, provenance, and naming data. □

Theorem 818.115 (FiniteTraceEvaluator terminal route exposure)**.** *Every terminal consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *route carrier receives exactly the finite surface*

$$T, Q, R, X, H, C, P, N.$$

The trace row T, checkpoint row Q, runtime row R, image and readback row X, componentwise hsame *row H,* Cont *replay row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row N are the whole terminal exposure. The consumer cannot recover host validation, hidden runtime state, unbounded evaluation, an infinite trace, or an unchecked compiler theorem from the packet.*

Proof. Start from the terminal checkpoint surface, Definition 818.89. It binds terminal checkpoint reads to the finite trace route and keeps validation, transport, continuation, provenance, and naming inside the displayed packet.

Use the checkpoint-runtime factorization above. It aligns the checkpoint row with the runtime row through the same finite carrier and leaves image readback as the row X rather than as a hidden runtime coordinate.

Now apply root image readback, Definition 818.46 and Definition 818.47. Accepted reads and checkpoint readback are confined to the displayed image and readback row, so the terminal consumer sees precisely T, Q, R, X, H, C, P, N. □

Theorem 818.116 (FiniteTraceEvaluator terminal runtime-candidate bridge)**.** *Every terminal consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *route carrier $E = (T, Q, R, X, H, C, P, N)$ that asks for runtime-candidate provenance first factors through* $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$ *and* $\mathsf{ReflectionRuntimeCheckpoin}$ *and only then through the displayed terminal rows*

$$T, Q, R, X, H, C, P, N.$$

The bridge introduces no host validator, hidden runtime state, total truth predicate, total halting classifier, unbounded evaluator, infinite trace semantics, or alternate checkpoint route.

Proof. Start with terminal route exposure. It confines every terminal consumer of the accepted route carrier to T, Q, R, X, H, C, P, N, with T as trace row, Q as checkpoint row, R as runtime row, and X as image and readback row.

Use checkpoint-runtime factorization. Checkpoint-facing and runtime-facing reads factor through the same finite route $T \to Q \to R$, transported by H, replayed by C, packaged by P, named by N, and read back through X.

Now apply checkpoint-runtime acceptance lock and runtime route coverage. Those results force runtime-facing consumers through $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ and $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$ before the evaluator result is read, while keeping host validation and hidden runtime state outside the finite packet.

Finally combine this with validation refusal closure from the checkpoint-runtime acceptance file. Since the runtime-candidate and checkpoint surfaces are reached only through the displayed terminal route, the bridge cannot introduce total truth, total halting, unbounded evaluator semantics, infinite traces, or an alternate checkpoint route. □

Theorem 818.117 (FiniteTraceEvaluator NameCert terminal obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvalu}}$ *obligation surface of a terminal route carrier* $E = (T, Q, R, X, H, C, P, N)$ *is exhausted by the following finite obligations: trace finiteness for* T*, checkpoint admission for* Q*, runtime totality for* R*, image and readback exactness for* X*, componentwise* hsame *transport for* H*, displayed* Cont *replay for* C*,* Pkg *provenance for* P*, and local naming for* N*. No NameCert clause asks for host validation, total truth, total halting, unbounded evaluation, an infinite trace, or an unchecked compiler theorem.*

Proof. First read the local naming row from Definition 818.3. The carrier rows are exactly the rows that the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ surface can certify.

Next combine root checkpoint readiness, root runtime totality, and root image readback exactness. Theorems Definition 818.36, Definition 818.37, and Definition 818.48 provide the checkpoint, runtime, image, and readback obligations on the same finite packet.

Finally use terminal route exposure above together with Definition 818.106. Since every terminal consumer is confined to T, Q, R, X, H, C, P, N, the local NameCert terminal surface is exhausted by those displayed obligations and has no remaining host or unbounded evaluator clause. □

Theorem 818.118 (FiniteTraceEvaluator terminal runtime checkpoint lock)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *terminal checkpoint packet*

$$E = (I, T, A, V, H, C, P, N),$$

every terminal checkpoint read remains on the displayed route

$$I \to T \to A \to V \to H \to C \to P \to N.$$

Here T *is the finite* BHist *trace row,* H *is the componentwise* hsame *transport row,* C *is the displayed* Cont *replay row,* P *is the* Pkg *provenance row, and* N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row. The lock exposes no host evaluator, hidden acceptance predicate, total truth predicate, unbounded runtime, or infinite trace semantics.*

Proof. Begin with the carrier and terminal root surface, Definition 818.1 and Definition 818.76. They display exactly I, T, A, V, H, C, P, N as the terminal checkpoint packet and provide no coordinate for a host evaluator or infinite trace.

Apply checkpoint-budget exhaustion, Definition 818.80. It forces every checkpoint-budget read consumed by the reflection-runtime sibling to be exhausted by the same finite evaluator rows.

Finally use terminal route exposure and root checkpoint admission totality, Definition 818.115 and Definition 818.110. These results identify the terminal read and root admission route with the displayed finite spine from I through N, so no off-route checkpoint source remains. □

Theorem 818.119 (FiniteTraceEvaluator terminal admission totality)**.** *Terminal admission for an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *checkpoint packet is total only through the finite* BHist/hsame/Cont/Pkg/NameCer *packet*

$$I, T, A, V, H, C, P, N.$$

The admission surface reads trace evidence from T*, transports it through* H*, replays it through* C*, packages provenance through* P*, and names the local certificate through* N*. It does not admit a host evaluator, hidden acceptance predicate, total truth predicate, total halting classifier, unbounded evaluator, or infinite trace semantics.*

Proof. Project the terminal packet through Definition 818.76. The admission surface is already finite: I names the coded input, T names the finite BHist trace, A names accepted-result classification, and V names the validation-boundary refusal row.

Next use the root checkpoint admission totality theorem. It makes admission total only along $I \to T \to A \to V \to H \to C \to P \to N$, with H, C, P, N as the displayed transport, replay, provenance, and local naming rows.

The remaining terminal clauses are exhausted by the terminal NameCert obligation surface, Definition 818.117. Since that surface lists only finite BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ data, terminal admission has no further truth, halting, host-runtime, or infinite-trace gate. □

Theorem 818.120 (FiniteTraceEvaluator terminal reflection handoff)**.** *Every reflection-runtime consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *terminal checkpoint receives only the finite checkpoint packet*

$$I, T, A, V, H, C, P, N.$$

The handoff exposes the finite BHist *route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *naming surface. It provides no host evaluator, hidden acceptance predicate, total truth predicate, total halting classifier, infinite trace semantics, or alternate runtime evaluator.*

Proof. Start from the reflection-runtime route, Definition 818.81. It sends every $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ read through the displayed sequence $I \to T \to A \to V \to H \to C \to P \to N$.

Use terminal runtime-candidate bridge, Definition 818.116. That bridge factors runtime-candidate provenance through the sibling $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$ and $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ surfaces before returning to the displayed terminal rows.

Finally combine terminal admission totality above with checkpoint-budget exhaustion. The admissible checkpoint packet is already exhausted by finite BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ data, so a reflection-runtime consumer receives no hidden acceptance predicate, total truth predicate, host evaluator, total halting classifier, alternate evaluator, or infinite trace semantics. □

Theorem 818.121 (FiniteTraceEvaluator terminal runtime consumer factorization)**.** *Every terminal runtime consumer of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *route carrier factors through the finite packet*

$$E = (T, Q, R, X, H, C, P, N)$$

and through the sibling $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$ *and* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *surfaces before reading any evaluator result. The rows* T, Q, R, X, H, C, P, N *are respectively the finite* BHist *trace row, checkpoint row, runtime row, image and readback row, componentwise* hsame *transport row, displayed* Cont *replay row,* Pkg *provenance row, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *naming row. The carrier gate is the* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *TasteGate readiness surface of Definition 818.28.*

Proof. Start from the terminal route carrier and terminal route exposure of Definition 818.113 and Definition 818.115. They display the whole terminal packet as T, Q, R, X, H, C, P, N and leave no terminal coordinate outside those rows.

Next apply the terminal checkpoint accountability surface, Definition 818.89. It forces checkpoint-facing reads to remain accountable to a finite BHist route before runtime access is consumed.

Now use checkpoint-runtime acceptance lock and runtime route coverage, Definition 818.95 and Definition 818.96. These route the runtime consumer through $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ and $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$ before the evaluator result is read.

Finally attach the terminal runtime-candidate bridge and the TasteGate readiness surface. The bridge keeps the consumer on the displayed terminal rows, while Definition 818.28 supplies the carrier gate that makes the public read field-faithful over the same packet. □

Theorem 818.122 (FiniteTraceEvaluator terminal NameCert exhaustion)**.** *For an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *terminal route carrier* $E = (T, Q, R, X, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *terminal obligations are exhausted by the following finite rows: trace finiteness for* T*, checkpoint admission for* Q*, runtime totality for* R*, readback exactness for* X*, componentwise* hsame *transport for* H*, displayed* Cont *replay for* C*,* Pkg *provenance for* P*, and local naming for* N*. No further* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *clause is available outside these rows.*

Proof. Read the local terminal packet from Definition 818.117. It already identifies the terminal NameCert surface with trace, checkpoint, runtime, readback, transport, replay, provenance, and naming obligations over T, Q, R, X, H, C, P, N.

The checkpoint part is closed by terminal checkpoint accountability, Definition 818.89. It binds checkpoint admission to the finite BHist route and prevents the checkpoint row from becoming a hidden source.

The runtime and readback part is closed by Definition 818.105 and Definition 818.100. These theorems make the runtime route total on the displayed packet and force the readback replay through the same finite rows.

It remains to account for transport, replay, provenance, and naming. Terminal route exposure supplies H, C, P, N as the displayed hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows, and the TasteGate readiness theorem keeps those rows as the public carrier surface. Thus the listed obligations exhaust the terminal local NameCert package. □

Theorem 818.123 (FiniteTraceEvaluator terminal source lock)**.** *No terminal runtime source of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *route carrier exposes a host validator, hidden runtime state, unbounded evaluator, infinite trace, total truth predicate, total halting classifier, or unchecked compiler theorem. Every source available to a terminal consumer is locked to the displayed finite rows* T, Q, R, X, H, C, P, N*, to the sibling* $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$ *and* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *surfaces named by provenance, and to the carrier gate of Definition 818.28.*

Proof. First apply terminal route exposure. The carrier $E = (T, Q, R, X, H, C, P, N)$ has no coordinate for host validation, hidden runtime state, unbounded evaluation, infinite traces, or unchecked compiler theorems.

Next use checkpoint route nonescape, Definition 818.106. It prevents a checkpoint-facing consumer from replacing the displayed finite route by an alternate evaluator output or a detached runtime source.

Then apply runtime acceptance nonescape and validation refusal closure, Definition 818.99 and Definition 818.97. These exclude total truth predicates, total halting classifiers, host-valid runtime judgments, hidden runtime state, unbounded evaluator semantics, infinite traces, and unchecked compiler theorems from the runtime acceptance row.

Finally combine runtime route coverage with terminal runtime-candidate bridge. Every runtime-facing source passes through $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ and $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$ before it reaches the evaluator result, and then returns to T, Q, R, X, H, C, P, N. The TasteGate readiness theorem supplies the carrier gate over that same finite surface, so no other terminal runtime source is exposed. □

Theorem 818.124 (FiniteTraceEvaluator terminal checkpoint exactness)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *terminal checkpoint packet* $E = (T, Q, R, X, H, C, P, N)$*, any terminal checkpoint consumer reads exactly the finite trace row* T*, checkpoint row* Q*, runtime row* R*, readback row* X*, componentwise* hsame *row* H*, displayed* Cont *row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row* N*. The consumer does not obtain host validation, a hidden runtime state, an unbounded evaluator, an infinite trace source, a total truth classifier, a total halting classifier, or a second checkpoint source.*

Proof. Begin with terminal runtime consumer factorization, Definition 818.121. It sends every terminal runtime consumer through the displayed packet T, Q, R, X, H, C, P, N and through the $\mathsf{RuntimeCandidateBoundary}^{\uparrow}/\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ consumer surface before any evaluator result is read.

Next apply terminal NameCert exhaustion, Definition 818.122. The local certificate obligations are exactly trace finiteness, checkpoint admission, runtime totality, readback exactness, componentwise transport, displayed replay, provenance, and local naming over the same rows.

Finally use terminal source lock, Definition 818.123. Since every terminal source is locked to T, Q, R, X, H, C, P, N and the named sibling consumer surfaces, no host validator, hidden runtime state, unbounded evaluator, infinite trace source, total truth classifier, total halting classifier, or second checkpoint source can be read by the checkpoint consumer. □

Theorem 818.125 (FiniteTraceEvaluator runtime image totality)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *root packet* $E = (I, T, A, V, H, C, P, N)$*, each runtime-facing image or readback route factors through the displayed finite rows*

$$I \to T \to A \to V \to H \to C \to P \to N$$

and through the $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *consumer surface. Terminal runtime consumers read the corresponding terminal packet* T, Q, R, X, H, C, P, N*; no runtime image is detached from these finite packet rows.*

Proof. First apply root runtime admission, Definition 818.107. It fixes the runtime entry surface of an accepted packet as the coded input, finite trace, accepted-result, validation-boundary, transport, continuation, provenance, and local naming rows I, T, A, V, H, C, P, N.

Next use checkpoint route coverage, Definition 818.108. It makes every checkpoint-facing consumer pass through the same root rows before a downstream runtime result is consumed, so the image and readback route has no detached checkpoint coordinate.

Finally attach terminal runtime consumer factorization, Definition 818.121. The terminal consumer is forced through the $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ surface and then through T, Q, R, X, H, C, P, N, which is precisely the terminal reading of the same finite route. Hence every runtime-facing image or readback factors through the displayed rows. □

Theorem 818.126 (FiniteTraceEvaluator root readback non-escape)**.** *Root readback for an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet exports only the root rows* I, T, A, V, H, C, P, N *or the terminal rows* T, Q, R, X, H, C, P, N *visible at the* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *surface. It excludes a host evaluator, total truth classifier, total halting classifier, infinite trace source, unchecked compiler theorem, and detached runtime state.*

Proof. Start from the root NameCert obligations, Definition 818.61. They place carrier admission, checkpoint acceptance, bounded replay, ledger exactness, and consumer non-escape on the displayed root packet I, T, A, V, H, C, P, N.

Use runtime ledger non-escape, Definition 818.109. The runtime ledger exports no host evaluator, hidden runtime acceptance predicate, total truth predicate, total halting classifier, unbounded evaluator, infinite trace, or second checkpoint source outside the same root rows.

It remains to account for terminal readback. Terminal source lock, Definition 818.123, restricts every terminal runtime source to T, Q, R, X, H, C, P, N and to the sibling runtime and reflection checkpoint surfaces named by provenance. Therefore root readback can export only the root or terminal finite rows and cannot escape to host evaluation, total truth, total halting, infinite traces, unchecked compiler theorems, or detached runtime state. □

Theorem 818.127 (FiniteTraceEvaluator root checkpoint budget image exhaustion)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *root checkpoint packet* $E = (I, T, A, V, H, C, P, N)$*, each accepted checkpoint-budget read is exhausted by the displayed coded input row* I*, finite trace row* T*, accepted-result classifier row* A*, validation-boundary row* V*, componentwise* hsame *row* H*, displayed* Cont *row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row* N*. The budget image has no additional coordinate for host validation, total truth, total halting, unbounded evaluation, infinite traces, or a second checkpoint source.*

Proof. Begin with the root image row, Definition 818.46. It identifies the accepted root image as the eight displayed rows I, T, A, V, H, C, P, N.

Next apply root readback exactness and root ledger factorization, Definition 818.47 and Definition 818.48. Accepted results pass through $I \to T \to A$, while validation-facing reads remain on V, H, C, P, N and the downstream ledger reads no outside source.

Finally use the scope commitment recorded in Definition 818.59 and the $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ closure status in chapter 818. These bind the same carrier, classifier, validation boundary, hsame transport, Cont replay, Pkg provenance, local $\mathsf{NameCert}$ row, and TasteGate surface as the whole checkpoint-budget image, so the listed exclusions have no packet row to enter through. □

Theorem 818.128 (FiniteTraceEvaluator root runtime readback non-escape)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet, runtime readback from the root checkpoint surface factors through the displayed image and readback rows of Definition 818.46 and Definition 818.47. It cannot import host validation, total truth, total halting, infinite traces, or an unbounded evaluator into the root runtime package.*

Proof. First read the packet through the root image row. The only root-facing runtime coordinates available to a consumer are I, T, A, V, H, C, P, N.

Next use root readback exactness. The accepted-result side returns through $I \to T \to A$, and the validation-facing side returns through V, H, C, P, N; neither side exposes a host-side validation judgment or an unbounded evaluator coordinate.

It remains to rule out hidden runtime imports. Apply root ledger factorization and root exactness scope, Definition 818.48 and Definition 818.59. Since the ledger and exactness surface are exhausted by the same finite $\mathsf{BHist}/\mathsf{hsame}/\mathsf{Cont}/\mathsf{Pkg}/\mathsf{NameCert}$ packet, runtime readback has no route to total truth, total halting, infinite traces, or any evaluator beyond the displayed finite packet. □

Theorem 818.129 (FiniteTraceEvaluator root downstream NameCert package)**.** *The downstream* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *obligation surface for an accepted root checkpoint packet is the package consisting of the checkpoint budget image of Definition 818.127, the runtime readback non-escape*

row of Definition 818.128, and the root image, readback, ledger, and exactness surface of Definition 818.46, Definition 818.47, Definition 818.48, and Definition 818.59. No downstream NameCert clause asks for host validation, total truth, total halting, unbounded evaluation, infinite traces, or a detached runtime evaluator.

Proof. First assemble the two local rows. The checkpoint-budget image theorem gives the displayed root packet I, T, A, V, H, C, P, N, and the runtime readback non-escape theorem keeps runtime reads on that same packet.

Next attach the existing root image and readback surface. The root image row lists the available coordinates, while root readback exactness separates accepted-result reads $I \to T \to A$ from validation-facing reads V, H, C, P, N.

Finally add ledger factorization and root exactness scope. They make the downstream consumer factor through the displayed $\mathsf{BHist}/\mathsf{hsame}/\mathsf{Cont}/\mathsf{Pkg}/\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ package and through no outside source. Thus the downstream NameCert obligation surface is exactly the named root image, readback, budget, runtime, ledger, and exactness package. □

Theorem 818.130 (FiniteTraceEvaluator root runtime checkpoint obligation package)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *root packet*

$$E = (I, T, A, V, H, C, P, N),$$

the root runtime checkpoint obligation package is the finite package consisting of the checkpoint rows I, T, A*, the bounded trace rows, the runtime image rows, the validation ledger* V, H, C, P, N*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row* N*. It exposes no host validation, total truth predicate, total halting predicate, unbounded evaluator, infinite trace, detached runtime image, or second checkpoint source.*

Proof. Start with checkpoint-budget exhaustion and runtime image route determinacy, Definition 818.80 and Definition 818.84. They place the checkpoint read and runtime image on the same finite route I, T, A, V, H, C, P, N.

Next attach the validation ledger. By Definition 818.85, every validation-facing read is exhausted by V, H, C, P, N over the finite trace source I, T, A.

Finally add the downstream local certificate surface. The root downstream NameCert package of Definition 818.129 and the body-level obligations of Definition 818.61 bind the same $\mathsf{BHist}/\mathsf{hsame}/\mathsf{Cont}/\mathsf{Pkg}/\mathsf{Nam}$ rows, so the obligation package has no outside runtime or validation coordinate. □

Theorem 818.131 (FiniteTraceEvaluator root image runtime totality)**.** *Every accepted root image/runtime read of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet is exhausted by the checkpoint-budget rows and the runtime-image rows of the displayed packet* I, T, A, V, H, C, P, N*. The read is finite over the coded input, trace, accepted-result classifier, validation boundary, componentwise transport, continuation route, provenance, and local naming rows; it does not project host validation, total truth, total halting, unbounded evaluation, infinite trace semantics, or a detached runtime source.*

Proof. First apply Definition 818.127. It lists the root checkpoint budget image as exactly the rows I, T, A, V, H, C, P, N.

Next use Definition 818.84. Runtime image reads preserve the same finite route, so two accepted consumers that preserve these rows read the same image.

It remains to exclude hidden runtime coordinates. Apply Definition 818.128 and Definition 818.85. The first keeps runtime readback on the root image rows, and the second exhausts the validation ledger inside V, H, C, P, N. □

Theorem 818.132 (FiniteTraceEvaluator root NameCert readiness handoff)**.** *The obligation package of Definition 818.130 is the handoff consumed by downstream runtime-checkpoint and reflection-runtime chapters. Any such downstream consumer receives only the finite checkpoint source I, T, A, the validation and structural rows V, H, C, P, N, the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row.*

Proof. Begin with the obligation package above. It already assembles the checkpoint rows, bounded trace route, runtime image, validation ledger, transport, continuation, provenance, and local naming rows.

Next apply Definition 818.129. That theorem identifies the downstream $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ surface as the same root image, readback, budget, runtime, ledger, and exactness package.

Finally use Definition 818.81 and Definition 818.135. Reflection-runtime consumers therefore receive the finite route $I \to T \to A \to V \to H \to C \to P \to N$ and no host validation, total truth, total halting, unbounded evaluator, infinite trace, detached runtime source, or second checkpoint source. □

Theorem 818.133 (FiniteTraceEvaluator root acceptance totality)**.** *For every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *root read of the packet $E = (I, T, A, V, H, C, P, N)$, the read factors through the coded input row I, the finite trace row T, the accepted-result classifier row A, the validation-boundary row V, the componentwise* hsame *row H, the displayed* Cont *row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ *row N. No accepted root read reaches host validation, total truth, total halting, unbounded evaluation, infinite trace evidence, or a second checkpoint source.*

Proof. Start with the root trace-result totality route, Definition 818.30. It forces accepted-result reads through $I \to T \to A$ before any downstream consumer can inspect the accepted classifier row.

Next attach the validation boundary and image rows, Definition 818.31 and Definition 818.46. These identify the validation-facing side as V, H, C, P, N and list the whole accepted root packet as I, T, A, V, H, C, P, N.

Finally use root readback exactness and root NameCert obligations, Definition 818.47 and Definition 818.61. The readback surface separates accepted-result data from validation-facing data, while the local naming row closes the same BHist/hsame/Cont/Pkg/NameCert route. Thus every accepted root read is exhausted by the displayed finite packet. □

Theorem 818.134 (FiniteTraceEvaluator root boundary completion)**.** *The root boundary of an accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet is exhausted by the carrier of Definition 818.1, bounded-trace coverage, host-validation refusal, checkpoint routing, root NameCert obligations, ledger non-escape, and route totality. Equivalently, every root boundary consumer factors through the packet rows I, T, A, V, H, C, P, N and has no additional boundary clause outside that finite route.*

Proof. First project the carrier and bounded trace coverage. The carrier displays the packet rows I, T, A, V, H, C, P, N, and Definition 818.4 keeps accepted trace evidence finite.

Next add host-validation refusal and checkpoint routing by Definition 818.35 and Definition 818.34. The validation side stops at the displayed boundary rows, and the checkpoint side reads the same finite packet.

It remains to close the naming and ledger surface. Apply Definition 818.61, Definition 818.48, and Definition 818.68. The local NameCert row, ledger factorization, and route totality give the same finite BHist/hsame/Cont/Pkg/NameCert package, so no root boundary clause remains outside I, T, A, V, H, C, P, N. □

Theorem 818.135 (FiniteTraceEvaluator root consumer readiness lock)**.** *Every downstream* ReflectionRuntimeChe *consumer that reads an accepted* FiniteTraceEvaluator$^{\uparrow}$ *packet can read it only through the completed root route of Definition 818.134. The consumer receives accepted-result data through $I \to T \to A$ and validation-facing data through V, H, C, P, N, with no access to a host validator, total truth predicate, total halting predicate, infinite trace, unbounded evaluator, or detached checkpoint source.*

Proof. Begin with the root acceptance route of Definition 818.133. It supplies the only accepted root packet available to downstream consumers.

Next apply the boundary completion theorem above. Its carrier, bounded-trace, validation-refusal, checkpoint, NameCert, ledger, and route-totality rows exhaust the root boundary of the same packet.

Finally use the checkpoint consumer route and runtime readback non-escape, Definition 818.8 and Definition 818.128. A ReflectionRuntimeCheckpoint$^{\uparrow}$ consumer therefore reads only the completed finite route and cannot attach any outside host, truth, halting, trace, or runtime source to the accepted packet. □

The FiniteTraceEvaluator$^{\uparrow}$ bounded evaluator route reads the RuntimeCandidateBoundary$^{\uparrow}$ packet of chapter 591 before it reads its bounded evaluator rows. The consumed dependency is the displayed source row, transition row, accepted-result row, componentwise transport row, route row, provenance row, and local-name row; these rows supply the runtime candidate boundary that the evaluator later transports through checkpoint, image, acceptance, and trace-budget surfaces. Every FiniteTraceEvaluator$^{\uparrow}$ runtime checkpoint read first consumes the source, transition, accepted-result, transport, route, provenance, and local-name rows of the RuntimeCandidateBoundary$^{\uparrow}$ source in chapter 591. Thus the evaluator checkpoint route reads the candidate boundary before it reads the bounded trace and checkpoint rows; it does not fabricate a host validator, a total truth predicate, or an unbounded runtime stream. The FiniteTraceEvaluator$^{\uparrow}$ root route consumes the candidate rows of chapter 591 before any runtime-reflection rows are read. This horizontal dependency places the object-level source, transition, accepted-result, transport, route, provenance, and local-name rows of RuntimeCandidateBoundary$^{\uparrow}$ in front of the evaluator's runtime-facing reflection surface.

Theorem 818.136 (Finite trace evaluator runtime-candidate dependency route)**.** *Every accepted* FiniteTraceEvaluator$^{\uparrow}$ *runtime read that evaluates a candidate trace first exposes the* RuntimeCandidateBoundary$^{\uparrow}$ *sibling row of chapter 591. The read then factors through the checkpoint-runtime rows, finite trace source, image readback surface, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row of the evaluator packet.*

Consequently the evaluator cannot consume a candidate trace by replacing the sibling candidate boundary with host validation, an unbounded runtime stream, or a hidden total-truth witness.

Proof. Start with the sibling route named by Definition 818.2. It places the runtime candidate boundary before the bounded evaluator rows, so the candidate trace is read only after the displayed RuntimeCandidateBoundary$^{\uparrow}$ source has been exposed.

Next apply Definition 818.116. This forces the terminal runtime consumer through RuntimeCandidateBoundary$^{\uparrow}$ and ReflectionRuntimeCheckpoint$^{\uparrow}$ before it reaches the evaluator result.

Finally use Definition 818.46 and Definition 818.3. The former records the finite trace source and image readback surface, while the latter exhausts the transport, replay, provenance, and local naming rows. Thus every accepted candidate-trace read follows the displayed sibling dependency route. □

The $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ route consumes chapter 591 as its candidate source and supplies bounded trace evidence to chapter 997. The handoff is source, trace, and checkpoint routing: the evaluator does not fabricate a detached runtime citation, and the checkpoint packet reads only the bounded trace evidence exposed by this finite route. The $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ sibling route reads chapter 469 before checkpoint or runtime readback. Every accepted finite evaluator route exposes the $\mathsf{ContinuationTrace}^{\uparrow}$ sibling through bounded trace rows, then consumes the checkpoint and runtime rows already listed by the hub. The route refuses host validation, total truth predicates, and unbounded runtime streams.

Theorem 818.137 (FiniteTraceEvaluator ContinuationTrace route)**.** *Every accepted* $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ *packet that exports checkpoint or runtime readback first reads the* $\mathsf{ContinuationTrace}^{\uparrow}$ *sibling through bounded trace rows. The visible route is finite trace exposure, checkpoint admission, runtime readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming; it has no coordinate for host validation, total truth predicates, or unbounded runtime streams.*

Proof. Project the evaluator packet through the existing hub child routes. The bounded trace rows are the only trace source available before checkpoint and runtime rows are consumed.

Read the $\mathsf{ContinuationTrace}^{\uparrow}$ sibling at that boundary. Its finite replay supplies the trace rows that checkpoint admission and runtime readback may inspect, while the evaluator carrier keeps the rows bounded by the same displayed packet.

The structural rows then transport, replay, source, and name the packet. Since no host validator, total truth predicate, or unbounded stream coordinate is present, every accepted read follows the stated finite route. □

The MetaCIC candidate-set SN handoff of chapter 3422 consumes chapter 818 only after the finite trace evaluator has displayed checkpoint rows, runtime totality, image readback, and acceptance boundaries. This forward route keeps the SN consumer attached to the evaluator's visible checkpoint and runtime surfaces rather than to an untracked kernel execution. The $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ route supplies the bounded trace, checkpoint, runtime-totality, and image-readback rows consumed by chapter 765. A MetaCIC critical-path consumer may use finite evaluator evidence only after those displayed rows have passed through the evaluator source, accepted-result, validation-boundary, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ surface; it does not receive an unbounded runtime stream, hidden interpreter state, or host validation predicate. The $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ runtime lattice reads finite trace data through chapter 280 and chapter 199 before it records checkpoint image and readback rows. Thus the evaluator remains a finite runtime packet: the $\mathsf{TuringMachine}^{\uparrow}$ transition surface and the $\mathsf{Computable}^{\uparrow}$ admission surface are exposed before checkpoint images, source readbacks, BHist histories, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{FiniteTraceEvaluator}^{\uparrow}}$ row are consumed. The $\mathsf{FiniteTraceEvaluator}^{\uparrow}$ dependency lattice consumes the runtime-candidate boundary of chapter 591, routes finite diagonal trace evidence through chapter 492, and supplies bounded checkpoint evidence to chapter 997. This places the evaluator between the boundary that admits runtime candidates and the checkpoint consumer that reads bounded evidence, so the route is a finite dependency handoff rather than a detached kernel citation.

Chapter 819

A Concrete Naming Certificate for $\mathsf{LegalChannel}^{\uparrow}$

The $\mathsf{LegalChannel}^{\uparrow}$ packet realizes the legal event-flow channel surface of chapter 9407 as a finite NameCert object. It sits beside the trace discipline of chapter 469 and the audit inventory of chapter 823: those chapters display finite replay and finite audit rows, while the present packet binds source event-flow rows, channel-code rows, decoder rows, round-trip witnesses, transport, replay, provenance, and local naming for the GroundCompiler channel interface.

Definition 819.1 (LegalChannel carrier)**.** *A* $\mathsf{LegalChannel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (E, C, D, R, H, K, P, N)$$

with the following displayed rows:

1. *E is the source event-flow row, recording the finite GroundCompiler event flow accepted as the channel input;*
2. *C is the legal channel code row, recording the displayed code representation admitted by the legal channel classifier;*
3. *D is the decoder row, recording the finite readback operation from channel code back to event-flow data;*
4. *R is the round-trip witness row, recording that accepted channel reads through C and D return the same event-flow row E up to the displayed BEDC sameness rows;*
5. *H records componentwise* hsame *transport for the event-flow, code, decoder, round-trip, replay, provenance, and naming rows;*
6. *K records the displayed* Cont *replay routes by which a consumer reads the channel code, applies the decoder row, checks the round-trip row, and returns to the named event-flow row;*
7. *P is the* Pkg *provenance over chapter 9407, channel dependencies,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LegalChannel}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible coordinates are E, C, D, R, H, K, P, N. It has no coordinate for a host package, proof term, source substring, metric report, motif row, theorem-code payload, or hidden compiler object outside the displayed packet.

Theorem 819.2 (LegalChannel lossless NameCert)**.** *For every accepted* $\mathsf{LegalChannel}^{\uparrow}$ *carrier* $L = (E, C, D, R, H, K, P, N)$*, an accepted channel read that starts from* E*, enters the legal channel code row* C*, and is decoded through* D *preserves the event-flow row named by* E*. The preservation witness is the displayed round-trip row* R*, transported only by* H *and replayed only through* K*.*

Proof. Project the accepted carrier. The source event-flow row, code row, decoder row, and round-trip row are the coordinates E, C, D, R of the same finite packet.

Read the accepted channel route through K. The replay path first inspects C, then applies the displayed decoder row D, and then checks the round-trip witness R.

Transport is componentwise. The only sameness data available to the route is H, so the decoded row can move only along the listed hsame comparisons and returns to the same named event-flow row E.

Finally, provenance and naming are read from P and N. They certify where the channel dependency and local name are recorded, but they add no second event-flow source. Hence the accepted read is lossless at the packet surface. □

Theorem 819.3 (LegalChannel hidden-input exclusion)**.** *For every accepted* $\mathsf{LegalChannel}^{\uparrow}$ *carrier* $L = (E, C, D, R, H, K, P, N)$*, no host package, proof term, source substring, metric report, motif row, theorem-code payload, or hidden compiler object is exported by the legal channel unless that object appears as part of the displayed packet rows* E, C, D, R, H, K, P, N*.*

Proof. Inspect the carrier coordinates. The legal channel exposes exactly the event-flow row, channel code row, decoder row, round-trip row, transport row, replay row, provenance row, and local naming row.

Suppose a consumer asks for a host package, proof term, source substring, metric report, motif row, theorem-code payload, or hidden compiler object. The classifier can answer only by pointing to one of the displayed coordinates of L.

If the requested object is not displayed in those coordinates, there is no packet row from which the consumer can read it. The replay route K and transport row H preserve already displayed rows, while P and N cite and name the packet rather than creating another export coordinate.

Therefore the legal channel excludes hidden input by finite carrier exhaustion. □

Theorem 819.4 (LegalChannel ledger non-escape)**.** *Every downstream consumer of an accepted* $\mathsf{LegalChannel}^{\uparrow}$ *packet factors through the finite ledger*

$$E \to C \to D \to R \to H \to K \to P \to N.$$

In particular, no downstream channel consumer can bypass the event-flow row, legal code row, decoder row, round-trip witness, transport, replay, provenance, or local NameCert row.

Proof. Begin with a downstream consumer read. By carrier admission, the read starts from an accepted packet whose only public coordinates are E, C, D, R, H, K, P, N.

The channel part of the read factors through E, C, D, R. The event-flow row supplies the source, the code row supplies the legal representation, the decoder row supplies readback, and the round-trip row records the preservation check.

The structural part of the read factors through H, K, P, N. Componentwise hsame transport, displayed Cont replay, package provenance, and local naming are the only routes by which the channel packet can be moved, inspected, cited, and named.

Thus every consumer route has the displayed ledger as its complete path. A bypass would require an extra coordinate, but the finite carrier has none. □

Theorem 819.5 (LegalChannel GroundCompiler handoff)**.** *The packet $L = (E, C, D, R, H, K, P, N)$ is the concrete* $\mathsf{NameCert}_{\mathsf{LegalChannel}^{\uparrow}}$ *handoff consumed by the GroundCompiler channel-bijection and no-hidden-input audit surface. Its channel-bijection contribution is the lossless route through C, D, R, and its no-hidden-input contribution is the carrier exhaustion of E, C, D, R, H, K, P, N.*

Proof. The GroundCompiler audit map separates legal event-flow encoding from hidden compiler input. The $\mathsf{LegalChannel}^{\uparrow}$ packet supplies exactly the finite rows needed for that separation.

For the channel-bijection side, use Definition 819.2. Accepted reads pass through the legal code row, decoder row, and round-trip row, so the event-flow row returned to the consumer is the row named by E.

For the no-hidden-input side, use Definition 819.3 and Definition 819.4. The first theorem excludes unlisted host, proof, source, metric, motif, theorem-code, and compiler objects; the second theorem forces every downstream read through the displayed ledger.

Consequently L is the concrete NameCert handoff for the GroundCompiler channel audit surface. It contributes a finite legal-channel packet rather than an ambient compiler object or host-side decoder. □

Closure status for $\mathsf{NameCert}_{\mathsf{LegalChannel}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LegalChannel}^{\uparrow}$ packet is generated from a source event-flow row, legal channel code row, decoder row, round-trip witness row, componentwise hsame transports, displayed Cont channel replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LegalChannel}^{\uparrow}}$, seed)

Scope closed: Definition 819.1, Definition 819.2, Definition 819.3, Definition 819.4, and Definition 819.5 bind the finite legal-channel carrier, lossless decode route, hidden-input exclusion, downstream ledger, and GroundCompiler handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LegalChannel}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close proof evidence, theorem-code evidence, self-hosting discharge, Lean verification, audit cleanliness, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, legal-code decoding, round-trip preservation, hidden-input exclusion, downstream consumer factorization, provenance, and local naming for the same finite channel packet.

Chapter 820

A Concrete Naming Certificate for GroundCompilerRecognizerAuditPacket$^{\uparrow}$

The GroundCompilerRecognizerAuditPacket$^{\uparrow}$ carrier turns the recognizer-facing part of the GroundCompiler audit map of chapter 9407 into a finite BEDC packet. It sits beside the audit-map family surface of chapter 807, the certificate-compiler graph packet of chapter 473, and the taste-gate compiler witness of chapter 563. Those sibling chapters supply the family template, certificate handoff route, and chapter-gate witness rows; this chapter packages the GroundCompiler recognizer rows and non-evidence rows as the object those consumers may inspect.

Definition 820.1 (GroundCompiler recognizer audit packet carrier)**.** *A* GroundCompilerRecognizerAuditPacket$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, A, E, Q, B, H, C, P, N)$$

with the following displayed rows:

1. *R is the recognizer row naming the generated recognizers, accepted exports, and recognizer-generatedness checks from the GroundCompiler audit map;*
2. *A is the address-analysis row recording compiler-layer address, theorem-code, chapter-code, and classifier-quotient reads that are permitted only as displayed audit data;*
3. *E is the evidence row containing event-flow conservativity, no-hidden-input, channel-bijection, and source-channel separation rows available to certificate consumers;*
4. *Q is the non-evidence row listing code-not-proof, report-not-evidence, motif-not-identity, quotient-not-raw-equality, and cannot-claim boundaries;*
5. *B is the bridge-request row that records which downstream packet may consume the recognizer audit surface, including the sibling packets of chapter 807, chapter 473, and chapter 563;*
6. *H records componentwise* hsame *transports for the recognizer, address-analysis, evidence, non-evidence, bridge-request, route, provenance, and local naming rows;*
7. *C records the displayed* Cont *routes by which a consumer inspects R, A, E, Q, B without adding a hidden compiler proof row;*
8. *P is the* Pkg *provenance over* GroundCompiler*, chapter 9407, the sibling concrete packets,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerAuditPacket}^{\uparrow}}$ *row.*
The carrier accepts exactly the displayed recognizer, address-analysis, evidence, non-evidence, bridge-request, transport, route, provenance, and local naming rows. It exports no proof that code is proof, no report-to-evidence conversion, no raw classifier equality, no hidden self-hosting tower, and no MetaCIC theorem outside the listed sibling handoff.

Lean4 ✓ `BEDC.Derived.GroundCompilerRecognizerAuditPacketUp.GroundCompilerRecognizerAuditPacketTasteGate`
`single carrier alignment`

Theorem 820.2 (GroundCompiler recognizer audit packet obligation surface)**.** *For the carrier of Definition 820.1, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerAuditPacket}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$G = (R, A, E, Q, B, H, C, P, N),$$

recognizer readback through R, address-analysis readback through A, evidence readback through E, non-evidence readback through Q, bridge-request readback through B, componentwise transport through H, displayed continuation through C, package provenance through P, and local naming through N.

Proof. Carrier admission is tuple projection from Definition 820.1. The recognizer, address-analysis, evidence, non-evidence, and bridge-request rows are all displayed before any downstream consumer can inspect the packet.

The transport and route rows preserve that displayed inventory. Componentwise hsame entries in H can only move the named rows, and the continuations in C can only replay routes through R, A, E, Q, B.

Finally P and N account for provenance and local naming. Since provenance cites the GroundCompiler audit map and the sibling concrete packets only as row sources, the local NameCert surface is exhausted by the nine displayed coordinates. □

Theorem 820.3 (GroundCompiler recognizer audit packet non-evidence boundary)**.** *Every public read of an accepted* $\mathsf{GroundCompilerRecognizerAuditPacket}^{\uparrow}$ *carrier keeps the non-evidence row Q visible. A consumer may cite recognizer-generatedness, accepted exports, event-flow conservativity, no-hidden-input, channel separation, and address-analysis rows only together with the boundaries that code is not proof, reports are not evidence, motifs are not object identity, classifier quotients are not raw equality, and conditional self-hosting is not an unconditional compiler tower.*

Proof. Start with the carrier projection. The positive recognizer and compiler-facing rows are R, A, E, while the refusal row is Q.

Apply the obligation surface of Definition 820.2. Any route that exposes R, A, E also exposes the same packet through H, C, P, N, so the route cannot drop Q without leaving the carrier.

The row Q is therefore part of the public read, not a side note. Since the packet contains no coordinate converting code, reports, motifs, quotients, or conditional self-hosting into stronger evidence, every consumer remains inside the listed non-evidence boundary. □

Theorem 820.4 (GroundCompiler recognizer audit packet consumer handoff)**.** *The bridge-request row B hands an accepted* $\mathsf{GroundCompilerRecognizerAuditPacket}^{\uparrow}$ *packet only to displayed BEDC consumers. In particular, audit-map family consumers read the packet as a family row, certificate-compiler consumers read it as finite compiler-side provenance, and taste-gate compiler witnesses read it as chapter-gate evidence tied to the same recognizer and non-evidence rows.*

Proof. Project the bridge-request coordinate B. Its listed sibling destinations are the audit-map family, certificate compiler, and taste-gate compiler witness chapters named in the carrier provenance.

For the audit-map family, the handoff lands as a visible family row and keeps the positive, conditional, obstruction, and frontier split supplied by chapter 807. For the certificate compiler, the handoff supplies finite compiler-side provenance rather than host compiler semantics. For the taste-gate compiler witness, the handoff supplies named chapter-gate evidence rather than an ambient approval principle.

The route rows H and C preserve the same R, A, E, Q, B inventory during each handoff. Thus no downstream consumer receives a stronger object than the displayed recognizer audit packet. □

Theorem 820.5 (GroundCompiler recognizer audit packet NameCert)**.** *The public* $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerA}}$ *packet is exactly the finite surface*

$$R, A, E, Q, B, H, C, P, N.$$

It packages the recognizer and non-evidence rows of chapter 9407 for concrete BEDC consumers, and it exports no hidden compiler proof, no proof-producing code interpretation, no evidence extracted from reports, no raw equality behind classifier quotients, and no unstated MetaCIC closure.

Proof. Read the public packet by carrier projection and the local obligation surface. The available rows are the recognizer row R, address-analysis row A, evidence row E, non-evidence row Q, bridge-request row B, transports H, routes C, provenance P, and local naming N.

Use Definition 820.3 to keep the refusal rows attached to every recognizer-facing read. Use Definition 820.4 to restrict downstream use to the displayed sibling consumers.

No additional coordinate remains. Therefore the public NameCert packet is exactly $R, A, E, Q, B, H, C, P, N$, with the listed compiler-proof, report-evidence, raw-equality, and MetaCIC-closure claims outside the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerAuditPacket}^{\uparrow}}$.

Constructive story: A $\mathsf{GroundCompilerRecognizerAuditPacket}^{\uparrow}$ packet is generated from finite BHist rows for recognizers, address analysis, positive evidence, non-evidence boundaries, bridge requests, componentwise transports, displayed continuations, provenance, and local naming. Recognizer-facing reads are replayed by Cont through R, A, E, Q, B, so evidence rows and refusal rows remain attached in one public packet. hsame transports the recognizer, address, evidence, non-evidence, and bridge rows without strengthening them, while Pkg records the GroundCompiler audit map and sibling concrete consumers. The packet packages recognizer audit data without turning code or reports into proofs.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerAuditPacket}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the GroundCompiler recognizer audit packet carrier, obligation surface, non-evidence boundary, consumer handoff, and public NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerAuditPacket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim compiler proofs, report-to-evidence conversion, raw classifier equality, hidden self-hosting towers, or unstated MetaCIC closure.

Upgrade path: Obligation closure requires Lean encodings of the recognizer audit carrier, non-evidence preservation, consumer handoff, and public packet theorem.

Chapter 821

A Concrete Naming Certificate for $\mathsf{GroundCompilerRecognition}^{\uparrow}$

The $\mathsf{GroundCompilerRecognition}^{\uparrow}$ packet realizes the generated-recognition surface of chapter 9407 as a finite NameCert carrier. It sits beside the finite evaluator packet of chapter 818: the evaluator records bounded trace rows and accepted-result readback, while this packet records generated recognizer rows, accepted-export rows, finite evaluator handoff rows, report non-evidence rows, and cannot-claim ledger rows before a downstream compiler consumer treats recognition as evidence.

Definition 821.1 (GroundCompiler recognition carrier)**.** *A* $\mathsf{GroundCompilerRecognition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, G, A, T, V, L, H, C, P, N)$$

with the following displayed rows:

1. *I is the GroundCompiler event-flow and source-channel input row under recognition;*
2. *G is the generated recognizer row for packages, name certificates, derivation certificates, theorem identifiers, chapter records, or manifest records;*
3. *A is the accepted-export row through which a recognized artifact may be consumed by a theorem-facing or NameCert-facing route;*
4. *T is the finite trace evaluator handoff row, read through the bounded trace and accepted-result rows of chapter 818;*
5. *V is the report non-evidence row separating metric reports, motif reports, theorem code, chapter code, and readable source from proof or certificate evidence;*
6. *L is the cannot-claim ledger row for hidden compiler input, raw event-flow equality, report-as-proof, code-as-proof, and unrecorded self-hosting claims;*
7. *H records componentwise* hsame *transports for the input, recognizer, export, evaluator handoff, non-evidence, cannot-claim, provenance, and local naming rows;*
8. *C records displayed* Cont *routes for recognizer readback, accepted-export readback, finite evaluator handoff, non-evidence inspection, and ledger replay;*
9. *P is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *chapter 9407, and chapter 818;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognition}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible rows are $I, G, A, T, V, L, H, C, P, N$. It contains no host recognizer, no accepted export outside A, no evaluator validation outside T, no proof from reports or code, and no unlisted compiler input.

Lean4 ✓ `BEDC.Derived.GroundCompilerRecognitionUp.GroundCompilerRecognitionTasteGate single carrier alignment`

Theorem 821.2 (GroundCompiler recognition NameCert obligations)**.** *For the carrier of Definition 821.1, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognition}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed packet $R = (I, G, A, T, V, L, H, C, P, N)$;*
2. *generated-recognizer exposure through G after the event-flow and source-channel input row I has been displayed;*
3. *accepted-export routing through A, with no consumer route bypassing the accepted-export row;*
4. *finite trace evaluator handoff through T, tied to the bounded trace and accepted-result rows of chapter 818;*
5. *report and cannot-claim exhaustion through V, L, H, C, P, N, so reports, code, raw classifier quotients, and unrecorded self-hosting claims remain outside proof and certificate evidence.*

Lean4 ✓ `BEDC.Derived.GroundCompilerRecognitionUp.GroundCompilerRecognitionNameCert obligations`

Proof. Carrier admission is tuple projection. The finite packet displays exactly $I, G, A, T, V, L, H, C, P, N$.

Read recognition through I and G. The source-like event row is visible before the generated recognizer row is consumed, so recognizer evidence cannot replace the input coordinate.

Accepted export is then confined to A. Since the carrier has no second export coordinate, every theorem-facing or NameCert-facing route must pass through the displayed accepted-export row.

The finite evaluator handoff is confined to T. By citing the sibling finite evaluator packet, the handoff exposes bounded trace and accepted-result rows without adding host evaluator validation or an unbounded execution stream.

Finally inspect V, L, H, C, P, N. The report non-evidence and cannot-claim rows state the excluded readings, while the transport, route, provenance, and naming rows replay only the displayed packet. Thus the five obligations exhaust the local certificate surface. □

Theorem 821.3 (GroundCompiler recognition ledger non-escape)**.** *Every accepted* $\mathsf{GroundCompilerRecognition}^{\uparrow}$ *packet exports recognition evidence only through the finite rows*

$$I, G, A, T, V, L, H, C, P, N.$$

It exports no hidden compiler input, no host recognizer, no accepted export outside the certificate gate row, no proof from theorem code or chapter code, no proof from metric or motif reports, no raw event-flow equality from classifier membership, and no self-hosting tower outside the displayed ledger.

Lean4 ✓ `BEDC.Derived.GroundCompilerRecognitionUp.GroundCompilerRecognitionCarrier ledger nonescape`

Proof. Project the accepted carrier of Definition 821.1. The listed rows are the whole exported BHist surface.

Apply Definition 821.2. Generated recognition is read through G, accepted exports through A, and evaluator handoff through T.

The non-evidence and cannot-claim rows then block hidden strengthening. Since V separates reports and code from proof or certificate evidence, and L lists the forbidden compiler readings, no public consumer can extract an unlisted recognizer, export, proof, raw equality, or compiler tower from the packet. □

Theorem 821.4 (GroundCompiler recognition finite-trace handoff)**.** *For every accepted* GroundCompilerRecognitio *carrier $R = (I, G, A, T, V, L, H, C, P, N)$, the evaluator-facing read factors through the finite trace evaluator rows cited by T. A downstream consumer may inspect the bounded trace and accepted-result handoff, then return to the generated recognizer and accepted-export rows G, A; it cannot turn the handoff into host evaluator validation, a total truth predicate, an infinite trace, or a proof object.*

Lean4 ✓ `BEDC.Derived.GroundCompilerRecognitionUp.GroundCompilerRecognitionCarrier finite trace handoff boundary`

Proof. Start with the handoff coordinate T. It is the only evaluator-facing row in the recognition carrier.

Use the finite trace evaluator packet of chapter 818. That sibling exposes coded input, finite trace-step rows, accepted-result classification, and a validation boundary, while excluding host validation, total halting, truth, and unbounded execution.

Return through H, C, P, N to the recognition rows. The route records only the displayed bounded handoff and then resumes at G and A, so it supplies recognition and accepted export evidence without adding an evaluator, proof object, infinite trace, or truth predicate. □

Theorem 821.5 (GroundCompiler recognition flow carrier exposure)**.** *For every accepted* GroundCompilerRecogniti *carrier $R = (I, G, A, T, V, L, H, C, P, N)$, the event-flow input, generated recognizer, accepted-export gate, finite-trace handoff, report non-evidence row, cannot-claim ledger, componentwise* hsame *rows, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row are all visible before recognition is consumed. No accepted consumer may read generated recognition while omitting I, G, or A.*

Lean4 ✓ `BEDC.Derived.GroundCompilerRecognitionUp.GroundCompilerRecognitionCarrier flow carrier exposure`

Proof. Project the carrier of Definition 821.1. The visible packet is exactly $I, G, A, T, V, L, H, C, P, N$.

Use Definition 821.4 for the evaluator-facing coordinate. It places the bounded trace and accepted-result handoff inside T and returns the read to G and A without adding host validation.

The remaining rows V, L, H, C, P, N expose the report boundary, cannot-claim ledger, transports, replay routes, provenance, and local name. Thus recognition consumption cannot skip the event-flow, recognizer, or accepted-export coordinates. □

Theorem 821.6 (GroundCompiler recognition certificate gate stability)**.** *Every theorem-facing or NameCert-facing read of an accepted* GroundCompilerRecognition$^{\uparrow}$ *carrier factors through the accepted-export row A. The generated recognizer row G, finite-trace handoff row T, report non-evidence row V, and cannot-claim ledger row L may constrain that read, but none of them creates a second certificate gate.*

Lean4 ✓ `BEDC.Derived.GroundCompilerRecognitionUp.GroundCompilerRecognitionCarrier certificate gate stability`

Proof. Start from the accepted-export coordinate A. It is the only row in the carrier whose role is theorem-facing or NameCert-facing export.

Apply the finite-trace handoff theorem. The handoff through T supplies bounded evaluator data and then returns to the recognizer and export rows; it does not create another accepted-export channel.

Finally inspect V and L. Reports, code, raw event-flow equality, and unrecorded self-hosting claims are listed as non-evidence or cannot-claim data. They therefore restrict the certificate gate rather than replacing A. □

Theorem 821.7 (GroundCompiler recognition NameCert non-escape)**.** *The local* $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognition}^{\uparrow}}$ *obligations for $I, G, A, T, V, L, H, C, P, N$ prevent accepted-export routing from bypassing A and prevent reports, chapter code, theorem code, metric reports, or motif reports from becoming proof evidence. Every accepted read remains inside the displayed recognition carrier and its finite-trace handoff.*

Proof. Use the NameCert obligation theorem. It lists carrier admission, generated-recognizer exposure, accepted-export routing, finite-trace handoff, and report-plus-ledger exhaustion over the same finite carrier.

The certificate gate stability theorem confines theorem-facing and NameCert-facing export to A. The finite-trace handoff theorem confines evaluator-facing data to T and returns it to G, A.

It remains to inspect the report and code rows. The row V separates reports and code from proof or certificate evidence, while L records the cannot-claim readings. Hence no accepted route can turn reports or code into proof evidence, and no route can bypass A. □

Theorem 821.8 (GroundCompiler recognition accepted-export totality)**.** *For every accepted* GroundCompilerRecog *carrier $R = (I, G, A, T, V, L, H, C, P, N)$, every theorem-facing export and every NameCert-facing export passes through the accepted-export row A. The carrier of Definition 821.1 and the obligations of Definition 821.2 leave no second export row outside A.*

Proof. Project the carrier. The theorem-facing and NameCert-facing export coordinate in the displayed packet is A.

Apply Definition 821.2. Its accepted-export obligation states that no consumer route bypasses the accepted-export row.

Use certificate gate stability, Definition 821.6. The generated recognizer row G, finite-trace handoff row T, report boundary row V, and ledger row L constrain the read, but none supplies a second certificate gate. Hence every such export factors through A. □

Theorem 821.9 (GroundCompiler recognition report boundary exhaustion)**.** *For every accepted* $\mathsf{GroundCompilerRecognition}^{\uparrow}$ *carrier $R = (I, G, A, T, V, L, H, C, P, N)$, every report read, chapter-code read, theorem-code read, metric-report read, or motif-report read passes through the report non-evidence row V before evidence use is refused. The carrier and NameCert obligations therefore exhaust the report boundary before any downstream consumer can treat those reads as proof or certificate evidence.*

Proof. Start from Definition 821.1. The row V is the displayed report non-evidence row separating metric reports, motif reports, theorem code, chapter code, and readable source from proof or certificate evidence.

Apply Definition 821.2. Its report and cannot-claim exhaustion obligation routes the listed report and code reads through V, L, H, C, P, N before a consumer may inspect the packet as evidence.

Now use Definition 821.7. It prevents reports and code from becoming proof evidence and keeps every accepted read inside the displayed carrier and finite-trace handoff. Thus V is the report boundary, and evidence use is refused after that boundary is displayed. □

Lean4 ✓ `BEDC.Derived.GroundCompilerRecognitionUp.GroundCompilerRecognitionReportBoundary exhaustion`

Theorem 821.10 (GroundCompiler recognition cannot-claim ledger coverage)**.** *For every accepted* $\mathsf{GroundCompilerRecognition}^{\uparrow}$ *carrier* $R = (I, G, A, T, V, L, H, C, P, N)$*, every forbidden compiler reading is covered by the cannot-claim ledger row* L*, componentwise* hsame *transports* H*, displayed replay routes* C*, package provenance* P*, and the local* NameCert *row* N*. In particular hidden compiler input, raw event-flow equality, report-as-proof, code-as-proof, and unrecorded self-hosting claims cannot escape the ledger surface.*

Proof. Project the packet of Definition 821.1. The forbidden compiler readings are listed in the cannot-claim row L, and the structural rows H, C, P, N are the only transport, route, provenance, and naming rows available to replay them.

Apply Definition 821.2. Its final obligation covers report and cannot-claim exhaustion through V, L, H, C, P, N over the same finite carrier.

Use ledger non-escape, Definition 821.3. It already excludes hidden compiler input, host recognizers, proof from code or reports, raw event-flow equality, and self-hosting outside the displayed ledger. Therefore each forbidden reading is covered by L, H, C, P, N and no compiler reading escapes the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognition}^{\uparrow}}$.

Constructive story: A $\mathsf{GroundCompilerRecognition}^{\uparrow}$ packet is generated from event-flow and source-channel input rows, generated recognizer rows, accepted-export rows, finite trace evaluator handoff rows, report non-evidence rows, cannot-claim ledger rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GroundCompilerRecognition}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 821.1, Definition 821.2, Definition 821.8, Definition 821.9, and Definition 821.10 bind the public accepted-export surface, report-boundary exhaustion, and cannot-claim ledger coverage to the displayed BHist, hsame, Cont, Pkg, and NameCert primitives.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GroundCompilerRecognition}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.GroundCompilerRecognitionUp.GroundCompilerRecognitionNameCert\_obligations`

Bridge status: none

Origin: ai

Lean4 ✓ `BEDC.Derived.GroundCompilerRecognitionUp.taste gate`

Not claimed: This chapter does not prove self-hosting for every compiler candidate, validate the evaluator from inside the packet, turn reports or code into proof, identify recognizer classes with raw event-flow equality, or provide bridge checking.

Upgrade path: No further paper-side theory upgrade remains before standard bridge recording.

Chapter 822

A Concrete Naming Certificate for $\mathsf{GroundCompilerAuditVerdict}^{\uparrow}$

The $\mathsf{GroundCompilerAuditVerdict}^{\uparrow}$ packet concretizes the GroundCompiler audit map of chapter 9407 as a finite verdict carrier. It sits beside the obstruction socket of chapter 826 and the frontier packet of chapter 833: those packets expose audit-family obstructions and frontier rows, while this packet binds query output, forbidden-dependency comparison, generated recognizer evidence, certificate-gate evidence, replay provenance, and no-hidden-input boundaries into one NameCert surface.

Definition 822.1 (GroundCompiler audit verdict carrier)**.** *A* $\mathsf{GroundCompilerAuditVerdict}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, Q, F, V, A, R, C, B, H, K, P, N)$$

with the following visible rows:

1. *M is the GroundCompiler module row naming the inspected event-flow, channel, recognizer, certificate-gate, metric, motif, bootstrap, or main-theorem surface;*
2. *Q is the displayed query-output row for the inspected module surface;*
3. *F is the forbidden-dependency row naming dependencies and host-side evidence forms excluded by the audit;*
4. *V is the verdict row recording the finite comparison between Q and F;*
5. *A is the audit-family alignment row tying the verdict to the audit-map obstruction and frontier classifications;*
6. *R is the generated-recognizer row exposed by the GroundCompiler layer;*
7. *C is the certificate-gate row through which accepted exports are mediated;*
8. *B is the no-hidden-input boundary row for code, reports, motifs, classifier quotients, source substrings, and host compiler structure;*
9. *H records componentwise* hsame *transport for module, query, forbidden, verdict, alignment, recognizer, gate, boundary, provenance, and naming rows;*
10. *K records displayed* Cont *replay routes for query exposure, forbidden-row comparison, verdict exposure, recognizer readback, certificate-gate readback, and boundary readback;*

11. *P is the* Pkg *provenance over the GroundCompiler audit map, sibling audit-map packets, recognizer rows, certificate-gate rows,* hsame, Cont, *and local* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditVerdict}^{\uparrow}}$ *row.*

The carrier exports no proof from theorem code, no certificate from a metric or motif report, no raw event-flow equality from a classifier quotient, and no hidden compiler input outside the displayed rows.

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditVerdictUp.GroundCompilerAuditVerdictTasteGate single carrier alignment`

Theorem 822.2 (GroundCompiler audit verdict obligations)**.** *For every* $\mathsf{GroundCompilerAuditVerdict}^{\uparrow}$ *carrier*

$$G = (M, Q, F, V, A, R, C, B, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditVerdict}^{\uparrow}}$ *surface has five obligation rows:*

1. *carrier exposure: every public read first projects one of $M, Q, F, V, A, R, C, B, H, K, P, N$;*
2. *forbidden-row comparison: the verdict is read from the displayed comparison between Q and F;*
3. *verdict determinacy: transport of Q and F transports the same verdict row V and creates no second clean or refusal row;*
4. *replay provenance: every replay passes through the displayed continuation row K and package provenance row P;*
5. *non-escape: recognizer, certificate-gate, and no-hidden-input boundaries are exported only through R, C, B and the local naming row N.*

Proof. First project the carrier. The finite tuple displays the module, query, forbidden-dependency, verdict, alignment, recognizer, certificate-gate, boundary, transport, replay, provenance, and local naming rows.

The forbidden-row comparison is local to Q, F, V. The query-output row Q is paired with the forbidden row F, and the verdict row V records that finite comparison. Because the carrier has no second verdict coordinate, componentwise transport of Q and F through H transports the same verdict.

Replay is confined to K and P. A consumer may rerun the displayed query exposure, comparison, verdict exposure, recognizer readback, gate readback, or boundary readback only along the continuation routes recorded in K, with package ancestry recorded in P.

Finally inspect the GroundCompiler-specific rows R, C, B. They expose generated recognizers, certificate gates, and no-hidden-input boundaries as finite rows, not as host-side audit prose. The local NameCert row N names exactly this packet surface. □

Theorem 822.3 (GroundCompiler audit verdict non-escape)**.** *Every accepted* $\mathsf{GroundCompilerAuditVerdict}^{\uparrow}$ *packet exports GroundCompiler audit evidence only through the finite rows*

$$M, Q, F, V, A, R, C, B, H, K, P, N.$$

It exports no hidden dependency query, no unrecorded verdict row, no recognizer outside the generated-recognizer row, no certificate outside the certificate-gate row, no proof from code or reports, no raw event-flow equality from a classifier quotient, and no host compiler input beyond the no-hidden-input boundary row.

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditVerdictUp.GroundCompilerAuditVerdictNonEscape`

Proof. Project the accepted packet as $G = (M, Q, F, V, A, R, C, B, H, K, P, N)$. These coordinates are the whole exported BHist surface.

The audit decision is exhausted by Q, F, V, A. The query output, forbidden row, verdict row, and audit-family alignment row are all displayed before a consumer can treat the packet as evidence.

The compiler-facing evidence is exhausted by R, C, B. Recognizers are read through the generated-recognizer row, accepted exports through the certificate-gate row, and exclusions through the no-hidden-input boundary row.

Transport, replay, provenance, and naming are exhausted by H, K, P, N. Since no remaining coordinate stores hidden query data, an alternate verdict, host proof evidence, raw classifier equality, or compiler input outside the boundary, none can escape the packet. □

Theorem 822.4 (GroundCompiler audit verdict obligation surface)**.** *The TasteGate marker*

BEDC.Derived.GroundCompilerAuditVerdictUp.GroundCompilerAuditVerdictTasteGate_single_carrier_alignment

certifies that a GroundCompilerAuditVerdict$^{\uparrow}$ *packet is admitted only when the visible carrier is the single finite surface*

$$G = (M, Q, F, V, A, R, C, B, H, K, P, N).$$

For such a packet, the obligation surface consists exactly of carrier admission through those rows, forbidden-row comparison between Q and F, verdict determinacy through V, replay provenance through K and P, generated-recognizer readback through R, certificate-gate readback through C, and non-escape through the boundary row B and local naming row N.

Proof. Read the cited TasteGate marker as the carrier-alignment guard for this packet. It aligns the public GroundCompiler audit verdict name with the single displayed carrier of Definition 822.1.

The carrier-admission and comparison obligations are then forced by the coordinates. Public reads first project $M, Q, F, V, A, R, C, B, H, K, P, N$; the forbidden comparison is the displayed comparison between Q and F, and the verdict row V is the only verdict coordinate available after that comparison.

Replay and readback obligations are separate rows. The continuation row K and provenance row P record replay provenance, while R and C expose generated-recognizer and certificate-gate readback without turning either one into host audit prose.

Finally apply Definition 822.3. The no-hidden-input boundary B and local NameCert row N prevent hidden dependency queries, alternate verdicts, raw classifier equality, or compiler inputs from escaping the displayed packet. □

Theorem 822.5 (GroundCompiler audit verdict scoped handoff)**.** *For every accepted* GroundCompilerAuditVerdict$^{\uparrow}$ *carrier*

$$G = (M, Q, F, V, A, R, C, B, H, K, P, N),$$

the cited TasteGate marker

BEDC.Derived.GroundCompilerAuditVerdictUp.GroundCompilerAuditVerdictTasteGate_single_carrier_alignment

forces the scoped handoff to pass through exactly the displayed rows $M, Q, F, V, A, R, C, B, H, K, P, N$. The forbidden-row comparison is read only from Q, F, V, A; generated-recognizer readback is read only from R; certificate-gate readback is read only from C; and no-hidden-input nonescape is read only from B, H, K, P, N.

Proof. Use the TasteGate marker as the single-carrier admission guard. It admits the packet only through the finite tuple of Definition 822.1, so a consumer first projects $M, Q, F, V, A, R, C, B, H, K, P, N$.

The audit comparison route is then exhausted by Q, F, V, A. The query output Q and forbidden-dependency row F produce the verdict row V, and the audit-family alignment row A records the family-facing comparison surface.

The readback route is exhausted by R and C. Generated recognizers are read through R, accepted exports through the certificate-gate row C, and no host recognizer or gate evidence is available outside those rows.

Finally the boundary route is exhausted by B, H, K, P, N. The no-hidden-input row B, componentwise transport row H, continuation row K, provenance row P, and local naming row N preserve the same displayed carrier and leave no separate input channel. □

Theorem 822.6 (GroundCompiler audit verdict boundary exactness)**.** *The rows $M, Q, F, V, A, R, C, B, H, K, P, N$ are the complete scoped route for a* GroundCompilerAuditVerdict$^{\uparrow}$ *consumer. Any accepted read of forbidden-row comparison, generated-recognizer readback, certificate-gate readback, or no-hidden-input nonescape factors through those rows and through the TasteGate marker*

BEDC.Derived.GroundCompilerAuditVerdictUp.GroundCompilerAuditVerdictTasteGate_single_carrier_alignment.

Consequently the packet exports no theorem code proof, metric report proof, motif report proof, raw event-flow equality, classifier quotient equality, or compiler input beyond the displayed boundary.

Proof. Start with an accepted consumer read. The TasteGate marker aligns the public name with the single carrier, so there is no alternate carrier from which comparison, recognizer, gate, or boundary evidence can be read.

For forbidden-row comparison, the consumer must inspect Q, F, V, A. The module row M fixes the inspected surface, Q gives the displayed output, F gives the forbidden row, V records the comparison verdict, and A ties the verdict to the audit-family alignment.

For generated-recognizer and certificate-gate readback, the consumer must inspect R and C. These two rows are the only coordinates assigned to those readbacks, while H, K, P, N transport, replay, source, and name only the same displayed rows.

For nonescape, inspect B. Since B is the no-hidden-input boundary and the remaining structural rows add no analytic content, there is no exported proof from code or reports, no raw event-flow equality, no quotient classifier equality, and no compiler input outside the packet. □

Closure status for NameCert$_{\text{GroundCompilerAuditVerdict}^{\uparrow}}$**.**

Constructive story: A GroundCompilerAuditVerdict$^{\uparrow}$ packet is generated from a GroundCompiler module row, displayed query output, forbidden-dependency comparison, verdict row, audit-family alignment, generated-recognizer row, certificate-gate row, no-hidden-input boundary row, componentwise hsame transports, displayed Cont replay routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{GroundCompilerAuditVerdict}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 822.1, Definition 822.2, Definition 822.3, Definition 822.4, Definition 822.5, and Definition 822.6 bind the GroundCompiler audit verdict scoped route as carrier admission, forbidden-row comparison, verdict determinacy, replay provenance, generated-recognizer readback, certificate-gate readback, and no-hidden-input nonescape backed by the TasteGate marker.

Formal verification: FormalStatus(NameCert$_{\text{GroundCompilerAuditVerdict}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.GroundCompilerAuditVerdictUp.GroundCompilerAuditVerdictTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not prove global compiler self-hosting, complete environment purity, MetaCIC subject reduction, bridge checking, or any theorem content from code, reports, motifs, or classifier quotients.

Upgrade path: Public closure requires a downstream theorem showing which GroundCompiler consumer reads this scoped audit-verdict surface.

Chapter 823

A Concrete Naming Certificate for $\mathsf{AuditMapConcreteInventory}^{\uparrow}$

The $\mathsf{AuditMapConcreteInventory}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as a concrete finite inventory. It sits beside the substitution audit map of chapter 779 and the family-level ledger chapters: those siblings display individual audit rows and cross-map ledgers, while this packet binds the established, conditional, obstruction, frontier, and consumer rows as one inspectable NameCert object.

Definition 823.1 (Audit-map concrete inventory carrier)**.** *An* $\mathsf{AuditMapConcreteInventory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, E, C, O, F, U, H, R, P, N)$$

with the following visible rows:

1. *M is the concrete audit-map identity row, naming the local map whose inventory is being certified;*
2. *E is the established-content row, containing checked or otherwise available rows from the local audit map;*
3. *C is the conditional-content row, containing rows whose use is routed through a named discharge or interface;*
4. *O is the obstruction row, containing no-claim or no-escape rows that must remain visible to consumers;*
5. *F is the frontier row, containing consumer-facing handoff rows that are not theorem exports;*
6. *U is the downstream consumer row, recording which sibling chapters may read the inventory and through which displayed boundary;*
7. *H records componentwise* hsame *transports for the identity, inventory, consumer, route, provenance, and local naming rows;*
8. *R records the displayed* Cont *routes by which a consumer reads each inventory row;*
9. *P is the* Pkg *provenance over chapter 9406, chapter 779, neighbouring audit-map ledgers,* BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapConcreteInventory}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible rows are the displayed audit-map identity, established content, conditional content, obstruction content, frontier content, downstream consumer, transport, continuation, provenance, and local naming rows. It exports no closed subject-reduction theorem, no hidden discharge of a conditional row, no erasure of an obstruction row, no closure of a frontier row, and no host-level semantic equality coordinate.

Lean4 ✓ `BEDC.Derived.AuditMapConcreteInventoryUp.AuditMapConcreteInventoryTasteGate single carrier alignment`

Theorem 823.2 (Audit-map concrete inventory NameCert obligations)**.** *For the carrier of Definition 823.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapConcreteInventory}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$I = (M, E, C, O, F, U, H, R, P, N),$$

audit-map identity readback through M, established-row readback through E, conditional-row readback through C, obstruction-row readback through O, frontier-row readback through F, downstream-consumer readback through U, componentwise transport through H, displayed continuation through R, package provenance through P, and local naming through N.

Proof. Project the finite packet I. The identity row M fixes which concrete audit map is being read before any inventory row can be consumed.

Read the inventory rows E, C, O, F. These rows expose the family template of chapter 9406: established content, conditional content, obstruction content, and frontier content are separate coordinates rather than prose classes.

Finally inspect U, H, R, P, N. The consumer row names downstream readers, transport and continuation replay the displayed coordinates, provenance records the sibling sources, and local naming binds the packet. Hence the NameCert surface is exhausted by the finite carrier. □

Theorem 823.3 (Audit-map concrete inventory ledger exactness)**.** *For every accepted* $\mathsf{AuditMapConcreteInventory}^{\uparrow}$ *carrier $I = (M, E, C, O, F, U, H, R, P, N)$, the concrete inventory ledger has exactly five public row classes: established rows E, conditional rows C, obstruction rows O, frontier rows F, and downstream consumer rows U. Transport, continuation, provenance, and local naming preserve these classes as finite BEDC data and do not introduce a sixth audit class.*

Proof. The carrier definition displays the five public row classes as E, C, O, F, U. The identity row M selects the local map, but it is not another inventory class.

The transport and route rows H, R only replay componentwise sameness and displayed continuations over the selected rows. They therefore preserve the five-class ledger rather than extending it.

The provenance and local naming rows P, N certify where the inventory is read from and under which local name. Since neither row contains a theorem-producing or class-producing coordinate, the ledger is exact at the five displayed classes. □

Theorem 823.4 (Audit-map concrete inventory non-escape)**.** *For every accepted* $\mathsf{AuditMapConcreteInventory}^{\uparrow}$ *carrier $I = (M, E, C, O, F, U, H, R, P, N)$, every consumer read remains inside the displayed audit-map identity, established, conditional, obstruction, frontier, downstream consumer,* hsame, Cont, Pkg, *and local* NameCert *rows. In particular, the packet cannot turn conditional content into established content, erase an obstruction row, close a frontier row, create an unlisted downstream consumer, or export host-level semantic equality.*

Proof. Start with the carrier projection. A consumer can read the concrete inventory only through the rows $M, E, C, O, F, U, H, R, P, N$.

Use the NameCert obligations of Definition 823.2. They bind each row class to its displayed coordinate and route every consumer read through the continuation row R.

Apply the ledger exactness of Definition 823.3. Since the inventory has exactly the five public row classes and no hidden class-producing coordinate, each excluded endpoint remains outside the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapConcreteInventory}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapConcreteInventory}^{\uparrow}$ packet is generated from a concrete audit-map identity row, established rows, conditional rows, obstruction rows, frontier rows, downstream consumer rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapConcreteInventory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 823.1, Definition 823.2, Definition 823.3, and Definition 823.4 bind the concrete audit-map inventory and its non-escape boundary as finite NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditMapConcreteInventory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, full closed consistency, ambient confluence, hidden discharge routes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, row-class readback, consumer-row exactness, transport, route replay, provenance, naming, and non-escape for the same concrete inventory packet.

Chapter 824

A Concrete Naming Certificate for SubstitutionAuditWindowRoute$^{\uparrow}$

The SubstitutionAuditWindowRoute$^{\uparrow}$ packet realizes the closed-window route implicit in the MetaCIC substitution audit map of chapter 9380. It sits beside the substitution audit map of chapter 779 and the MetaCIC substitution audit packet of **??**: those chapters expose the audit rows and packet inventory, while this chapter records the finite route through which a consumer reads closed shift, closed substitution, closed composition, generator closure, and the subject-reduction handoff boundary without treating the handoff as a proof of subject reduction.

Definition 824.1 (Substitution audit window route carrier)**.** *A* SubstitutionAuditWindowRoute$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, D, L, M, C, G, B, H, R, P, N)$$

with the following visible rows:

1. *T is the MetaCIC* Term *row inspected by the substitution audit;*
2. *D is the* ClosedAt *window at which the term is read;*
3. *L is the closed shift row, recording the* shift_closed *route under D;*
4. *M is the closed substitution row, recording the* substitute_closed *route under D;*
5. *C is the closed composition row for the available closed substitution compositions, including the closed-at-depth and closed-at-zero composition surfaces;*
6. *G is the generator-closure classifier row for closed-under-shift, closed-under-substitution, and the closed composition route;*
7. *B is the subject-reduction handoff row, naming the beta-substitution and dependent-typing boundary without discharging it;*
8. *H records componentwise* hsame *transports for term, window, movement, composition, classifier, handoff, route, provenance, and naming rows;*
9. *R records the displayed* Cont *routes by which a consumer inspects the rows in the listed order;*
10. *P is the* Pkg *provenance over the substitution audit map, the sibling substitution audit packet,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SubstitutionAuditWindowRoute}^{\uparrow}}$ *row.*
The classifier accepts exactly packets whose coordinates are the displayed term, closed-window, closed shift, closed substitution, closed composition, generator-closure, handoff, transport, continuation, provenance, and local naming rows. It exports no unrestricted substitution calculus, no beta-substitution preservation theorem, no closed subject-reduction theorem, no quotient equality, and no host semantic equality coordinate.

Lean4 ✓ `BEDC.Derived.SubstitutionAuditWindowRouteUp.SubstitutionAuditWindowRouteTasteGate`
`single carrier alignment`

Theorem 824.2 (Substitution audit window route NameCert obligations)**.** *For the carrier of Definition 824.1, the local* $\mathsf{NameCert}_{\mathsf{SubstitutionAuditWindowRoute}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$W = (T, D, L, M, C, G, B, H, R, P, N),$$

closed-window readback through T, D, closed shift readback through L, closed substitution readback through M, closed-composition readback through C, generator-closure classification through G, subject-reduction handoff exposure through B, componentwise transport through H, displayed continuation through R, package provenance through P, and local naming through N.

Proof. Carrier admission is the displayed finite BHist packet. Projecting T and D exposes the audited term together with the closed window at which public substitution reads are admitted.

Read the movement rows next. The row L records the closed shift route, M records the closed substitution route, and C records the closed composition route. These are exactly the closed rows named by chapter 9380.

Read G and B after the movement rows. The generator-closure row classifies the shift, substitute, and composition routes as closed-window generator data, while the handoff row records the subject-reduction boundary as a boundary row rather than as typed preservation.

Finally inspect H, R, P, N. The transport, continuation, provenance, and local naming rows replay the same finite carrier. Since the packet has no coordinate for unrestricted substitution, beta-substitution preservation, closed subject reduction, quotient equality, or host semantic equality, the NameCert surface is exhausted by the displayed rows. □

Theorem 824.3 (Substitution audit window route closed composition handoff)**.** *For every accepted* $\mathsf{SubstitutionAuditWindowRoute}^{\uparrow}$ *carrier $W = (T, D, L, M, C, G, B, H, R, P, N)$, any consumer read of the subject-reduction handoff row B first factors through the closed window D, the closed shift row L, the closed substitution row M, the closed composition row C, and the generator-closure row G. The handoff may cite those rows as syntax-side closure data, but it cannot export beta-substitution preservation, dependent typing preservation, or a closed subject-reduction theorem.*

Proof. Start with the carrier order. The handoff row B is listed after the closed movement and classifier rows, so an accepted route to B has already selected D, L, M, C, G.

Use the NameCert obligations of Definition 824.2. They route closed-window readback through D, closed movement through L, M, closed composition through C, and generator closure through G before the handoff row can be consumed.

The rows H and R preserve that order under componentwise transport and displayed continuation. Provenance through P points back to chapter 779 and **??**, while the local name N binds the route as a finite packet.

It remains only to record the boundary. The carrier has no coordinate for beta-substitution preservation, dependent typing preservation, unrestricted substitution commutation, or a closed subject-reduction theorem. Therefore the handoff is readable as a named downstream boundary, not as a discharge of that boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubstitutionAuditWindowRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{SubstitutionAuditWindowRoute}^{\uparrow}$ packet is generated from a MetaCIC term row, a ClosedAt window, closed shift and substitution rows, closed composition rows, generator-closure classifier rows, a subject-reduction handoff row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubstitutionAuditWindowRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 824.1, Definition 824.2, and Definition 824.3 bind the finite closed-window route from substitution audit rows to the subject-reduction handoff boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubstitutionAuditWindowRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close unrestricted substitution, beta-substitution preservation, dependent typing preservation, closed subject reduction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-window readback, closed movement readback, closed-composition readback, generator-closure readback, handoff exposure, transport, continuation, provenance, naming, and boundary non-escape for the same finite packet.

Chapter 825

A Concrete Naming Certificate for $\mathsf{AuditMapTemplatePacket}^{\uparrow}$

The $\mathsf{AuditMapTemplatePacket}^{\uparrow}$ carrier realizes the audit-map family methodology of chapter 9406 as a finite packet template for concrete audit rows. It sits beside the substitution audit map of chapter 779: the sibling map supplies a local MetaCIC use case, while this packet records the reusable positive, conditional, obstruction, frontier, and sibling-use rows that such maps expose without silently closing their boundaries.

Definition 825.1 (Audit-map template packet carrier)**.** *An* $\mathsf{AuditMapTemplatePacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (U, P, C, O, F, S, H, R, K, N)$$

with the following displayed rows:

1. *U is the audit-map use row naming the local substrate, consumer interface, and map family cell being templated;*
2. *P is the positive row listing facts, carrier rows, or checked local inventory that the map may expose directly;*
3. *C is the conditional row listing setup fields, routes, or certificate obligations that must remain explicit before their conclusions are read;*
4. *O is the obstruction row naming blocked routes, missing inhabitants, shape restrictions, or no-go facts;*
5. *F is the frontier row naming the strongest nearby claim visible to consumers but not supplied as closed content by the packet;*
6. *S is the sibling-use row naming concrete audit-map neighbours, including the substitution audit map of chapter 779, that may consume or supply the displayed rows;*
7. *H records componentwise* hsame *transports for the use, positive, conditional, obstruction, frontier, sibling-use, route, provenance, and local naming rows;*
8. *R records displayed* Cont *routes by which consumers inspect U, P, C, O, F, S without adding hidden coordinates;*
9. *K is the* Pkg *provenance over chapter 9406, the sibling concrete packets,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{AuditMapTemplatePacket}^{\uparrow}}$ *row.*

The classifier accepts exactly packets carrying these ten rows. It exports no proof of F, no erased obstruction, no discharged conditional row, no hidden sibling route, no closed MetaCIC theorem, and no host semantic equality coordinate.

Lean4 ✓ `BEDC.Derived.AuditMapTemplatePacketUp.AuditMapTemplatePacketTasteGate single carrier alignment`

Theorem 825.2 (Audit-map template packet NameCert obligations)**.** *For the carrier of Definition 825.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapTemplatePacket}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$A = (U, P, C, O, F, S, H, R, K, N),$$

use-row readback through U, positive-row readback through P, conditional-row readback through C, obstruction-row readback through O, frontier-row readback through F, sibling-use readback through S, componentwise transport through H, displayed continuation through R, provenance through K, and local naming through N.

Proof. Carrier admission is the displayed finite packet. Projecting U, P, C, O exposes the local audit use, directly licensed content, explicit conditional content, and obstruction inventory as separate rows.

Project F and S next. The frontier row records where the packet stops, while the sibling-use row records which neighbouring maps may read or supply displayed rows, including the substitution audit map.

Finally inspect H, R, K, N. These rows transport, replay, source, and name the same packet. Since every obligation is one of the displayed rows and no transport, continuation, provenance, or naming coordinate adds a hidden row, the local NameCert surface is exactly the finite carrier inventory. □

Theorem 825.3 (Audit-map template packet row frontier)**.** *For every accepted* $\mathsf{AuditMapTemplatePacket}^{\uparrow}$ *carrier $A = (U, P, C, O, F, S, H, R, K, N)$, every consumer read of positive content, conditional content, obstruction content, frontier content, or sibling use factors through the displayed rows P, C, O, F, S and their supporting rows H, R, K, N. A consumer may cite P as licensed local inventory, cite C as an explicit condition, cite O as an obstruction, cite F as a frontier boundary, and cite S as a sibling-use ledger; it cannot turn C into a discharged theorem, erase O, prove F, or read a sibling map outside S.*

Proof. Start from the carrier projection. The rows P, C, O, F, S are the only content rows available after the use row U has fixed the local audit-map cell.

Use the NameCert obligations of Definition 825.2. Componentwise hsame transport in H and displayed continuation in R preserve the same five content rows rather than replacing them by stronger theorem content.

It remains to check the boundary. Provenance K and local naming N locate the packet and its sibling references, but neither row supplies a discharge witness for C, an erasure operation for O, a proof object for F, or an unlisted sibling route beyond S. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapTemplatePacket}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapTemplatePacket}^{\uparrow}$ packet is generated from an audit-map use row, positive rows, conditional rows, obstruction rows, frontier rows, sibling-use rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapTemplatePacket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 825.1, Definition 825.2, and Definition 825.3 bind the finite audit-map template packet and its visible row frontier.

Formal verification: FormalStatus(NameCert$_{\text{AuditMapTemplatePacket}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.AuditMapTemplatePacketUp.AuditMapTemplatePacketTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, full closed MetaCIC, proof of frontier rows, discharge of conditional rows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, row readback, sibling-use routing, classifier transport, provenance, local naming, and non-escape for the same finite packet.

Chapter 826

A Concrete Naming Certificate for $\mathsf{AuditMapObstructionSocket}^{\uparrow}$

The $\mathsf{AuditMapObstructionSocket}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as a finite obstruction and frontier socket. It sits beside the family ledger of chapter 810 and the MetaCIC open-frontier ledger of chapter 762: those chapters expose family rows and open frontier rows, while this socket names the local handoff surface by which positive content, conditional interfaces, obstruction rows, and frontier rows remain visible to a NameCert consumer without becoming hidden closure.

Definition 826.1 (Audit-map obstruction socket carrier)**.** *An* $\mathsf{AuditMapObstructionSocket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, P, I, O, F, H, C, K, N)$$

with the following visible rows:

1. *A is the local audit-map tag naming the module, theorem cluster, or certificate family whose boundary is being inspected;*
2. *P records positive-content rows already available inside the local audit map;*
3. *I records conditional-interface rows, including hypotheses, discharge sockets, and named consumer preconditions that must be supplied before a neighbouring map may read the row as positive content;*
4. *O records obstruction rows whose non-discharge must remain visible to the audit-map family;*
5. *F records frontier rows handed to downstream consumers as named boundaries rather than closed theorem surfaces;*
6. *H records componentwise* hsame *transports for the audit tag, positive rows, conditional rows, obstruction rows, frontier rows, continuation rows, provenance rows, and local naming row;*
7. *C records the displayed* Cont *routes by which consumers read the positive, conditional, obstruction, and frontier rows without bypassing their row class;*
8. *K is the* Pkg *provenance over the audit-map family ledger, the open-frontier ledger, and the local concrete chapter supplying the socket rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapObstructionSocket}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose coordinates are the displayed audit tag, positive-content rows, conditional-interface rows, obstruction rows, frontier rows, componentwise transports, continuation routes, provenance row, and local naming row. It exports no hidden proof of an obstruction row, no unlisted discharge of a conditional interface, no closed frontier theorem, and no theorem stronger than the positive rows already display.

Lean4 ✓ `BEDC.Derived.AuditMapObstructionSocketUp.AuditMapObstructionSocketTasteGate single carrier alignment`

Theorem 826.2 (Audit-map obstruction socket NameCert obligations)**.** *For the carrier of Definition 826.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapObstructionSocket}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$S = (A, P, I, O, F, H, C, K, N),$$

audit-tag readback through A, positive-content readback through P, conditional-interface readback through I, obstruction readback through O, frontier readback through F, componentwise transport through H, displayed continuation through C, package provenance through K, and local naming through N.

Lean4 ✓ `BEDC.Derived.AuditMapObstructionSocketUp.AuditMapObstructionSocketNameCertObligations`

Proof. Project the finite packet S. The audit tag A fixes the local map being inspected before any row class is read.

Read the row classes next. Positive content is exposed by P, conditional interfaces are exposed by I, obstructions are exposed by O, and consumer-facing frontier rows are exposed by F. These rows are separate coordinates of the carrier.

Finally inspect H, C, K, N. Transport and continuation replay the same displayed row classes, the provenance row cites the family ledger, open-frontier ledger, and local chapter supplying the rows, and the local name binds the packet. Hence the NameCert surface is exhausted by the stated coordinates. □

Lean4 ✓ `BEDC.Derived.AuditMapObstructionSocketUp.AuditMapObstructionSocketCarrier namecert obligations`

Theorem 826.3 (Audit-map obstruction socket non-escape)**.** *For every accepted* $\mathsf{AuditMapObstructionSocket}^{\uparrow}$ *carrier $S = (A, P, I, O, F, H, C, K, N)$, every consumer read remains inside the displayed audit tag, positive-content rows, conditional-interface rows, obstruction rows, frontier rows,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. In particular, the socket cannot turn an obstruction row into a proof, a conditional-interface row into an unlisted discharge, or a frontier row into a closed theorem.*

Proof. Start from the carrier projection. The only public coordinates are $A, P, I, O, F, H, C, K, N$, so a consumer read must enter through one of the displayed row classes or through its transport, route, provenance, and naming rows.

Apply the NameCert obligations of Definition 826.2. They bind positive, conditional, obstruction, and frontier reads to their own coordinates and require every replay to use H and C.

The provenance row then blocks hidden closure. Since K cites only the visible family ledger, open-frontier ledger, and local concrete chapter, a consumer may cite the socket as finite audit data but cannot extract a proof or discharge route absent from S. □

Theorem 826.4 (Audit-map obstruction socket frontier handoff)**.** *For every accepted* $\mathsf{AuditMapObstructionSocket}^{\uparrow}$ *carrier, a downstream consumer may receive a frontier row only through the displayed row* F *together with the transport, continuation, provenance, and local naming rows* H, C, K, N*. The handoff preserves the distinction between positive content* P*, conditional interfaces* I*, obstruction rows* O*, and frontier rows* F*.*

Proof. Read the frontier coordinate of Definition 826.1. The row F is the only carrier coordinate that names downstream frontier material.

Use the componentwise transport and continuation rows. The rows H and C may replay the frontier coordinate and its provenance, but they do not recompute F from positive content, conditional interfaces, or obstruction rows.

Apply non-escape from Definition 826.3. The handoff therefore supplies a named frontier boundary with K and N, not a closed theorem and not an erased obstruction or conditional discharge. □

Lean4 ✓ `BEDC.Derived.AuditMapObstructionSocketUp.AuditMapObstructionSocket frontier handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapObstructionSocket}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AuditMapObstructionSocket}^{\uparrow}$ packet is generated from an audit tag, positive-content rows, conditional-interface rows, obstruction rows, frontier rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapObstructionSocket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 826.1, Definition 826.2, Definition 826.3, and Definition 826.4 bind the finite audit-map obstruction socket and its frontier handoff boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditMapObstructionSocket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, full closed consistency, ambient confluence, hidden discharge routes, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-row readback, conditional-interface readback, obstruction readback, frontier handoff, transport, continuation, provenance, naming, and non-escape for the same finite packet.

Chapter 827

A Concrete Naming Certificate for GroundCompilerAuditPacket$^{\uparrow}$

The GroundCompilerAuditPacket$^{\uparrow}$ carrier realizes the compiler-layer audit map of chapter 9407 as a finite naming certificate. It sits beside the source-channel ledger of chapter 671: that sibling packet records the acceptance-facing channel around kernel declarations, while this packet records the GroundCompiler event-flow, source-channel, recognizer, certificate-gate, report-boundary, and no-hidden-input rows that feed compiler-audit consumers.

Definition 827.1 (GroundCompiler audit packet carrier)**.** *A* GroundCompilerAuditPacket$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, S, R, C, Q, M, B, X, H, T, P, N)$$

with the following displayed rows:

1. *E is the GroundCompiler event-flow row naming the formal event input and its finite flow image;*
2. *S is the source-channel row recording legal encoding, decoding, and source/channel separation for the same flow image;*
3. *R is the generated recognizer row for package, name-certificate, derivation-certificate, theorem, chapter, or motif-facing classifier output;*
4. *C is the certificate-gate row through which recognized compiler artifacts become export candidates;*
5. *Q is the report-boundary row separating metric reports, motif reports, theorem code, chapter code, and source reports from proof or certificate evidence;*
6. *M is the module-inventory row naming the GroundCompiler submodule ledger used by chapter 9407;*
7. *B is the no-hidden-input row grounded by the streaming compiler theorem and its legal event-flow, source-channel, recognizer, gate, quotient-limit, source-separation, metric-conservativity, self-hosting, bootstrap, and global-conservativity clauses;*
8. *X is the source-channel export row linking this packet to chapter 671 without identifying compiler evidence with kernel acceptance evidence;*
9. *H records componentwise* hsame *transports for event-flow, channel, recognizer, gate, report, module, no-hidden-input, export, route, provenance, and local naming rows;*

10. *T records displayed* Cont *routes by which compiler-audit consumers inspect E, S, R, C, Q, M, B, X in finite order;*
11. *P is the* Pkg *provenance over chapter 9407, the sibling source-channel ledger,* GroundCompiler*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditPacket}^{\uparrow}}$ *row.*

The carrier has no coordinate for host compiler trust, hidden host input, source text outside the legal channel, report-as-proof conversion, motif-as-object identity, raw equality beyond classifier limits, kernel acceptance evidence, or MetaCIC proof evidence.

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditPacketUp.GroundCompilerAuditPacketTasteGate single carrier alignment`

Definition 827.2 (GroundCompiler audit packet classifier)**.** *The* $\mathsf{GroundCompilerAuditPacket}^{\uparrow}$ *classifier accepts exactly the carriers of Definition 827.1 whose rows satisfy the GroundCompiler audit-map reading of chapter 9407: the event-flow row is formal and finite, the source-channel row is legal and separated, generated recognizers mediate recognition evidence, certificate gates mediate exports, report rows remain non-evidence rows, the module-inventory row names the inspected GroundCompiler ledger, the no-hidden-input row is read through the streaming compiler theorem, and the source-channel export row is routed through the sibling kernel source-channel ledger.*

It rejects any packet that reads report output as proof, treats source substrings as decoded event data without the legal channel row, treats classifier quotient data as raw equality, imports kernel acceptance evidence into the compiler packet, or imports MetaCIC proof evidence into the compiler packet.

Lean4 (definition) `BEDC.Derived.GroundCompilerAuditPacketUp.GroundCompilerAuditPacketClassifier`

Theorem 827.3 (GroundCompiler audit packet NameCert obligations)**.** *For every accepted* GroundCompilerAuditP *carrier*

$$G = (E, S, R, C, Q, M, B, X, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditPacket}^{\uparrow}}$ *surface consists exactly of event-flow readback through E, source-channel readback through S, recognizer readback through R, certificate-gate readback through C, report-boundary readback through Q, module-inventory readback through M, no-hidden-input readback through B, source-channel export readback through X, componentwise* hsame *transport through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditPacketUp.GroundCompilerAuditPacketNameCertObligations`

Proof. Start with the carrier projection. The rows $E, S, R, C, Q, M, B, X, H, T, P, N$ are the only public coordinates available to the local certificate.

Read the compiler evidence rows first. The event-flow row E supplies the finite formal input surface, S supplies legal source-channel encoding and separation, R supplies generated recognition evidence, and C supplies the certificate-mediated export gate.

Read the boundary rows next. The report row Q records which report-like artifacts are not proof or certificate evidence. The module row M anchors the packet in the inspected GroundCompiler ledger, while B records the no-hidden-input streaming compiler surface grounded by the checked compiler theorem.

Finally inspect X, H, T, P, N. The export row links the compiler packet to the source-channel ledger without turning that ledger into compiler proof evidence. Transport, continuation, provenance, and naming replay the same finite rows, so the local NameCert obligations are exhausted by the displayed packet. □

Theorem 827.4 (GroundCompiler audit packet export non-escape)**.** *Every public export from an accepted* GroundCompilerAuditPacket$^{\uparrow}$ *packet factors through the displayed event-flow, source-channel, recognizer, certificate-gate, report-boundary, module-inventory, no-hidden-input, source-channel export, transport, continuation, provenance, and local naming rows of Definition 827.1. The export surface carries no hidden compiler input, no host source scan, no report-as-proof conversion, no motif-as-object identity, no classifier-quotient collapse into raw equality, and no kernel acceptance claim outside the sibling ledger.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditPacketUp.GroundCompilerAuditPacketExportNonEscape`

Proof. Project an accepted carrier G. By Definition 827.3, every public export must pass through the listed NameCert rows.

The compiler-facing rows E, S, R, C account for event inputs, source channels, generated recognizers, and certificate gates before anything is exported. The report row Q keeps reports, motifs, theorem code, and chapter code on the non-evidence side of the boundary.

The no-hidden-input row B supplies the streaming compiler audit surface, and the export row X routes source-channel consumers toward the sibling kernel source-channel ledger. Neither row adds a host compiler trust coordinate or a kernel acceptance proof coordinate to this packet.

Thus the only export path is the finite displayed path through H, T, P, N. Since no carrier field names hidden input, host source scans, report-to-proof conversion, motif identity, raw equality collapse, or kernel acceptance beyond X, those routes cannot be read from the packet. □

Theorem 827.5 (GroundCompiler audit packet MetaCIC separation)**.** *An accepted* GroundCompilerAuditPacket$^{\uparrow}$ *packet may cite the compiler-layer audit map of chapter 9407 and the source-channel ledger of chapter 671, but it does not export MetaCIC reduction, typing, confluence, normalization, closure-preservation, or subject-reduction evidence. Any consumer requiring MetaCIC proof evidence must read it from the relevant MetaCIC packet rather than from the GroundCompiler audit packet.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditPacketUp.GroundCompilerAuditPacketMetaCICSeparation`

Proof. Separate the cited origins. The origin chapter chapter 9407 records compiler-layer facts: event-flow conservativity, legal channels, recognizer generatedness, certificate-mediated exports, report boundaries, and no-hidden-input streaming compilation.

The sibling ledger chapter 671 records source-channel rows around kernel acceptance events. Its use by X is a channel-routing use, not a transfer of kernel acceptance or MetaCIC proof evidence into the GroundCompiler packet.

Now inspect the carrier of Definition 827.1. None of $E, S, R, C, Q, M, B, X, H, T, P, N$ is a MetaCIC term, reduction, typing, confluence, normalization, closure-preservation, or subject-reduction proof row.

Therefore a MetaCIC consumer has no projection from this packet to the proof evidence it needs. It must instead read a dedicated MetaCIC packet, while the GroundCompiler packet remains a finite compiler-audit certificate. □

Theorem 827.6 (GroundCompiler audit packet carrier exposure)**.** *Every accepted* GroundCompilerAuditPacket$^{\uparrow}$ *packet exposes exactly the finite carrier rows*

$$E, S, R, C, Q, M, B, X, H, T, P, N.$$

These rows are the BHist *event-flow, source-channel, recognizer, certificate-gate, report-boundary, module-inventory, no-hidden-input, source-channel export, componentwise* hsame*, displayed* Cont*,* Pkg *provenance, and local* NameCert *rows of the packet, and no additional compiler trust, host source scan, kernel acceptance evidence, or MetaCIC proof evidence row is exposed.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditPacketUp.GroundCompilerAuditPacketCarrierExposure`

Proof. Project an accepted carrier $G = (E, S, R, C, Q, M, B, X, H, T, P, N)$ from Definition 827.1. The carrier is a finite BHist packet, so the only rows available for public inspection are the displayed coordinates.

Apply Definition 827.3. It identifies the local NameCert surface with exactly those event-flow, channel, recognizer, gate, report, module, no-hidden-input, export, hsame, Cont, Pkg, and naming rows.

The classifier of Definition 827.2 rejects packets that read reports as proof, treat source substrings as decoded event data outside the legal channel, import kernel acceptance evidence, or import MetaCIC proof evidence. Hence no extra row can be exposed by an accepted packet. □

Theorem 827.7 (GroundCompiler audit packet query replay)**.** *Every no-hidden-input query and every report-boundary read replayed from an accepted* GroundCompilerAuditPacket$^{\uparrow}$ *packet must pass through the rows* B, Q, M, T, P, N*. The replay reads* B *for the no-hidden-input* BHist *surface,* Q *for report separation,* M *for the inspected module ledger,* T *for displayed* Cont *order,* P *for* Pkg *provenance, and* N *for local* NameCert *naming, with all componentwise* hsame *transport confined to the exposed carrier rows.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditPacketUp.GroundCompilerAuditPacketQueryReplay`

Proof. Start from the accepted carrier and isolate the rows that a query replay can inspect. The no-hidden-input claim is named only by B, and the report-boundary claim is named only by Q.

The module row M supplies the inspected GroundCompiler ledger for both reads. The continuation row T fixes the finite order in which a consumer can inspect B and Q, while P and N record provenance and local naming for the same finite packet.

By Definition 827.4, public exports cannot introduce hidden compiler input, host source scans, or report-as-proof conversions. Thus query replay is forced through B, Q, M, T, P, N, with hsame transport used only to preserve the displayed carrier rows. □

Theorem 827.8 (GroundCompiler audit packet refusal separation)**.** *In an accepted* GroundCompilerAuditPacket$^{\uparrow}$ *packet, report rows, motif rows, host source scans, and kernel acceptance evidence cannot be exported as compiler proof evidence. The* BHist *carrier records report separation through* Q*, generated classifier and motif-facing recognition through* R*, no-hidden-input refusal through* B*, source-channel routing through* S *and* X*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* T*,* Pkg *provenance through* P*, and local* NameCert *naming through* N*; none of these rows converts a report, motif, host scan, or kernel acceptance row into proof evidence.*

Proof. Inspect the report and recognition rows first. The row Q places metric reports, motif reports, theorem code, chapter code, and source reports on the report-boundary side, while R records generated recognizer output rather than a proof object.

Next inspect the channel and refusal rows. The source-channel row S and the export row X route legal source-channel information, and B records the no-hidden-input boundary. These rows do not add a host source scan coordinate or a kernel acceptance proof coordinate to the compiler packet.

Finally apply Definition 827.5 together with Definition 827.6. The only remaining rows are H, T, P, N, which preserve, replay, package, and name the same finite carrier; they do not turn report rows, motif rows, host scans, or kernel acceptance evidence into compiler proof evidence. □

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditPacketUp.GroundCompilerAuditPacketRefusalSeparation`

Theorem 827.9 (GroundCompiler audit packet obligation closure)**.** *For every accepted* GroundCompilerAuditPacke *carrier, the carrier row of Definition 827.1, the classifier of Definition 827.2, the NameCert obligations of Definition 827.3, the export nonescape theorem of Definition 827.4, the MetaCIC separation theorem of Definition 827.5, the carrier exposure theorem of Definition 827.6, the query replay theorem of Definition 827.7, and the refusal separation theorem of Definition 827.8 assemble the complete* obligation *surface for* $\mathsf{GroundCompilerAuditPacket}^{\uparrow}$.

The assembled surface exposes only the finite GroundCompiler audit packet rows. Report rows, motif rows, host scans, kernel acceptance evidence, and MetaCIC proof evidence remain outside the packet and cannot be projected from the local $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditPacket}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditPacketUp.GroundCompilerAuditPacketObligationClosure`

Proof. Begin with the accepted carrier. Apply Definition 827.1 and Definition 827.2 to identify the finite rows and the admissible packet boundary.

Next compose the certificate-facing obligations. The NameCert theorem reads back the event-flow, source-channel, recognizer, certificate-gate, report-boundary, module-inventory, no-hidden-input, export, transport, continuation, provenance, and local naming rows. The export nonescape theorem then prevents those rows from acquiring hidden compiler input, host source scans, report-as-proof conversion, motif identity, raw equality collapse, or kernel acceptance evidence outside the sibling source-channel route.

The MetaCIC separation, carrier exposure, query replay, and refusal separation theorems supply the remaining boundary clauses. They keep MetaCIC proof evidence in the relevant MetaCIC packet, expose only $E, S, R, C, Q, M, B, X, H, T, P, N$, force no-hidden-input and report-boundary queries through B, Q, M, T, P, N, and prevent report rows, motif rows, host scans, and kernel acceptance rows from becoming compiler proof evidence.

Thus every public obligation of the GroundCompiler audit packet is accounted for by the displayed finite rows, and every excluded evidence class remains outside the packet. This is exactly the obligation-closure surface claimed for $\mathsf{GroundCompilerAuditPacket}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditPacket}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GroundCompilerAuditPacket}^{\uparrow}$ packet is generated from a GroundCompiler event-flow row, source-channel row, generated recognizer row, certificate-gate row, report-boundary row, module-inventory row, no-hidden-input streaming compiler row, source-channel export row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GroundCompilerAuditPacket}^{\uparrow}}$, obligation)

Scope closed: Definition 827.1, Definition 827.2, Definition 827.3, Definition 827.9, and the checked TasteGate alignment row bind the obligation surface for the finite compiler-audit packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GroundCompilerAuditPacket}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove a self-hosted compiler tower, host compiler trust, report-to-proof conversion, kernel acceptance, MetaCIC reduction or typing theorems, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding each obligation to the GroundCompiler event-flow, legal source-channel, generated recognizer, no-hidden-input, and source-channel ledger scopes.

Chapter 828

A Concrete Naming Certificate for GroundCompilerRecognizerBoundary$^{\uparrow}$

The GroundCompilerRecognizerBoundary$^{\uparrow}$ packet realizes the recognizer-facing boundary of the GroundCompiler audit map in chapter 9407 as a finite NameCert carrier. It sits beside the audit-map family certificate of chapter 807 and the obstruction socket of chapter 826: those chapters expose family-level row classes and obstruction handoffs, while this packet binds the GroundCompiler event-flow, source-channel, recognizer, certificate-gate, metric, motif, and bootstrap rows without turning generated code or reports into proof.

Definition 828.1 (GroundCompiler recognizer-boundary carrier)**.** *A* GroundCompilerRecognizerBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, S, R, Q, M, V, B, H, C, P, N)$$

with the following visible rows:

1. *E is the GroundCompiler event-flow row naming the source-like event packet under inspection;*
2. *S is the source-channel row recording the encoded, decoded, and lossless channel evidence available to the compiler layer;*
3. *R is the generated recognizer row that classifies the event-flow packet without treating raw source identity as proof identity;*
4. *Q is the certificate-gate row through which accepted exports must pass before a downstream theorem or NameCert consumer may cite them;*
5. *M is the metric-report row, readable only as compiler-layer measurement data;*
6. *V is the motif-report row, readable only as compiler-layer similarity or pattern data;*
7. *B is the bootstrap-evidence row recording the finite self-compilation or hierarchy evidence actually displayed;*
8. *H records componentwise* hsame *transports for the event-flow, source-channel, recognizer, gate, metric, motif, bootstrap, continuation, provenance, and naming rows;*
9. *C records the displayed* Cont *routes by which consumers read the recognizer and certificate-gate rows without bypassing the gate;*

10. *P is the* Pkg *provenance over chapter 9407, chapter 807, and the local GroundCompiler boundary rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerBoundary}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible rows are the displayed event-flow, source-channel, recognizer, certificate-gate, metric, motif, bootstrap, transport, continuation, provenance, and local naming rows. It exports no theorem from generated code alone, no proof from a metric report, no proof from a motif report, no raw event-flow equality in place of recognizer classification, and no unconditional self-hosting tower.

Lean4 (definition) `BEDC.Derived.GroundCompilerRecognizerBoundaryUp.GroundCompilerRecognizerBoundaryUp`

Theorem 828.2 (GroundCompiler recognizer-boundary NameCert obligations)**.** *For the carrier of Definition 828.1, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerBoundary}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed packet $G = (E, S, R, Q, M, V, B, H, C, P, N)$;*
2. *event-flow and source-channel readback through E and S before any recognizer row is consumed;*
3. *recognizer and certificate-gate exactness through R and Q, with every accepted export routed through the gate;*
4. *report boundary separation for M, V, B, so metric, motif, and bootstrap rows remain evidence rows rather than theorem rows;*
5. *transport, continuation, provenance, and naming replay through H, C, P, N.*

Proof. Project the finite packet G. The event-flow row E and source-channel row S are visible before the recognizer row is read, so the packet separates source-like compiler input from recognizer evidence.

Read the recognizer and gate rows next. The row R records the generated recognizer result, while Q records the certificate gate through which accepted exports pass. A consumer cannot skip Q, because no alternate accepted-export coordinate occurs in the carrier.

Now inspect the report rows. The metric row M, motif row V, and bootstrap row B are separate evidence rows. They may be cited as displayed compiler-layer data, but they are not theorem rows and do not discharge a missing proof obligation.

Finally project H, C, P, N. These rows transport the same components, replay the displayed consumer routes, cite the GroundCompiler audit map and audit-map family sibling as provenance, and bind the local name. Hence the NameCert surface is exhausted by the five listed obligations. □

Theorem 828.3 (GroundCompiler recognizer-boundary non-escape)**.** *For every accepted* GroundCompilerRecognize *carrier $G = (E, S, R, Q, M, V, B, H, C, P, N)$, every compiler-facing or theorem-facing consumer read remains inside the displayed event-flow, source-channel, recognizer, certificate-gate, metric-report, motif-report, bootstrap-evidence, transport, continuation, provenance, and local naming rows. In particular, generated theorem code is not read as proof, recognizer classification is not raw event-flow equality, and report evidence is not certificate evidence.*

Proof. Start from the carrier projection. The packet lists only $E, S, R, Q, M, V, B, H, C, P, N$, so every consumer read must enter through one of those displayed rows.

Apply the NameCert obligations of Definition 828.2. They force recognizer reads to pass through E, S, R and accepted-export reads to pass through Q, while report reads stay in M, V, B.

The provenance and route rows then block hidden strengthening. Since P cites the GroundCompiler audit map and its audit-map family sibling only as visible row sources, and since C replays only displayed routes, no consumer can extract proof, raw identity, or an unconditional compiler tower from the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{GroundCompilerRecognizerBoundary}^{\uparrow}$ packet is generated from event-flow, source-channel, recognizer, certificate-gate, metric-report, motif-report, bootstrap-evidence, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 828.1, Definition 828.2, and Definition 828.3 bind the recognizer-facing GroundCompiler evidence boundary as a finite NameCert carrier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroundCompilerRecognizerBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close self-hosting for every compiler candidate, turn generated theorem code into proof, identify recognizer classes with raw event-flow equality, provide Lean verification, or provide bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-channel readback, recognizer exactness, certificate-gate routing, report separation, bootstrap evidence readback, route replay, provenance, naming, and non-escape over the same finite packet.

Chapter 829

A Concrete Naming Certificate for GroundCompilerEventFlowAudit$^{\uparrow}$

The GroundCompilerEventFlowAudit$^{\uparrow}$ packet turns the GroundCompiler audit map of chapter 9407 into a finite NameCert surface for event-flow and channel packets. It sits beside the audit-map interface of chapter 806 and the obstruction socket of chapter 826: those chapters name generic audit rows, while this packet names the GroundCompiler rows that keep source events, channel encodings, generated recognizers, and certificate gates separated from hidden compiler input.

Definition 829.1 (GroundCompiler event-flow audit carrier)**.** *A* GroundCompilerEventFlowAudit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, F, C, L, R, G, A, H, K, P, N)$$

with the following displayed rows:

1. *S is the source-event row naming the formal GroundCompiler input stream before channel encoding;*
2. *F is the event-flow row obtained from S by the displayed source normalizer and flow construction;*
3. *C is the channel packet row naming the legal encoding and decoding route for F;*
4. *L is the losslessness row recording that channel decoding returns the displayed event flow rather than a host-side replacement;*
5. *R is the source/channel separation row, keeping source events, channel packets, and carried metadata in distinct audit coordinates;*
6. *G is the generated-recognizer row for packages, NameCert rows, derivation certificates, theorem identifiers, and chapter flows consumed by the compiler layer;*
7. *A is the certificate-gate row through which accepted generated exports are read;*
8. *H records componentwise* hsame *transports for the source row, event flow, channel packet, losslessness row, separation row, generated recognizer row, certificate gate, provenance, and local naming row;*
9. *K records the displayed* Cont *routes from source events to event flows, from event flows to channel packets, from channel packets to generated recognizers, and from recognizers to certificate gates;*

10. *P is the* Pkg *provenance over chapter 9407, chapter 806, chapter 826,* BHist, hsame, Cont, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAudit}^{\uparrow}}$ *row.*

The carrier exports no row for hidden host input, report evidence, motif similarity, proof text, compiler correctness, or an unmediated generated artifact.

Lean4 ✓ `BEDC.Derived.GroundCompilerEventFlowAuditUp.GroundCompilerEventFlowAuditTasteGate single carrier alignment`

Theorem 829.2 (GroundCompiler event-flow audit NameCert obligations)**.** *For the carrier of Definition 829.1, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAudit}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$E = (S, F, C, L, R, G, A, H, K, P, N),$$

source-event exposure through S, event-flow readback through F, legal channel encoding and decoding through C, L, source/channel separation through R, generated-recognizer readback through G, certificate-gate readback through A, componentwise transport through H, displayed continuation through K, package provenance through P, and local naming through N.

Proof. Project the finite carrier. The rows S, F, C, L, R, G, A are the only compiler-facing data rows available to a consumer, and they name source events, event flows, channel packets, losslessness, separation, generated recognition, and certificate gates in that order.

Read the transport and route rows next. The row H compares each displayed coordinate componentwise, while K supplies only the displayed source-to-flow, flow-to-channel, channel-to-recognizer, and recognizer-to-gate routes.

Finally package the same rows with P and N. Since the provenance cites the GroundCompiler audit map and the sibling audit-map interface chapters, the NameCert surface has no extra coordinate for hidden input, report evidence, motif similarity, proof text, or compiler correctness. □

Lean4 ✓ `BEDC.Derived.GroundCompilerEventFlowAuditUp.GroundCompilerEventFlowAuditCarrier namecert obligations`

Theorem 829.3 (GroundCompiler event-flow audit lossless gate)**.** *Every accepted* $\mathsf{GroundCompilerEventFlowAudit}^{\uparrow}$ *carrier routes a generated export through the lossless channel row L and the certificate-gate row A before any audit consumer may read it as a GroundCompiler output. The route factors through*

$$S, F, C, L, R, G, A, H, K, P, N$$

and cannot replace the displayed source/channel packet by carried metadata, report counts, motif similarity, proof text, or a host compiler input.

Lean4 ✓ `BEDC.Derived.GroundCompilerEventFlowAuditUp.GroundCompilerEventFlowAuditCarrier lossless gate`

Proof. Begin with the carrier projection. The generated-recognizer row G is downstream of the source row S, event-flow row F, channel packet C, losslessness row L, and source/channel separation row R.

Apply the NameCert obligations. They force every generated-recognizer read to pass through the displayed channel and separation rows before the certificate gate A can be consumed.

The GroundCompiler aggregate theorem named in chapter 9407 supplies the checked no-hidden-input reading for this route. The paper-side packet records only the finite audit rows, so a consumer

cannot exchange them for carried metadata, reports, motif similarity, proof text, or host compiler input. □

Theorem 829.4 (GroundCompiler event-flow audit non-escape)**.** *For every accepted* GroundCompilerEventFlowAud *carrier, every event-flow, channel, recognizer, or certificate-gate consumer remains inside the displayed rows $S, F, C, L, R, G, A, H, K, P, N$. In particular, the packet cannot promote source text into proof evidence, channel data into source identity, generated recognition into certificate evidence without A, metric or motif reports into BEDC evidence, or host compiler state into formal input.*

Lean4 ✓ `BEDC.Derived.GroundCompilerEventFlowAuditUp.GroundCompilerEventFlowAuditCarrier nonescape`

Proof. Start with the lossless gate theorem. It places every generated export behind the displayed source/event-flow/channel route and behind the certificate-gate row A.

Use the carrier classifier implicit in Definition 829.1. The source row, event-flow row, channel row, separation row, recognizer row, and gate row are distinct coordinates, and the transport row H preserves those coordinates componentwise.

Finally inspect the omitted coordinates. The carrier has no row for proof evidence carried by source text, no row equating channel data with source identity, no row for certificate evidence outside A, no report-evidence row, and no host compiler input row. All consumer reads therefore remain inside the displayed packet. □

Lean4 ✓ `BEDC.Derived.GroundCompilerEventFlowAuditUp.taste gate`

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAudit}\uparrow}$.

Constructive story: A $\mathsf{GroundCompilerEventFlowAudit}^{\uparrow}$ packet is generated from source events, event flows, legal channel packets, losslessness rows, source/channel separation rows, generated recognizer rows, certificate gates, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAudit}\uparrow}, \mathsf{obligation})$

Scope closed: Definition 829.1, Definition 829.2, Definition 829.3, Definition 829.4, and the displayed TasteGate marker bind the carrier, NameCert obligations, lossless gate, non-escape row, generated-recognizer gate, certificate-gate route, and no-hidden-input boundary as the obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAudit}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close compiler correctness, kernel correctness, proof reconstruction from source text, report evidence, motif evidence, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Scoped closure requires binding each displayed carrier, channel, losslessness, separation, recognizer, certificate-gate, transport, continuation, provenance, naming, TasteGate, and no-hidden-input row to its kernel dependency.

Chapter 830

A Concrete Naming Certificate for GroundCompilerEventFlowAuditRoute$^{\uparrow}$

The GroundCompilerEventFlowAuditRoute$^{\uparrow}$ packet realizes the GroundCompiler audit map of chapter 9407 as a finite route from event-flow input to certificate-gated export. It uses the audit-map template of chapter 808 and the concrete inventory discipline of chapter 823: those chapters display the reusable audit rows, while this chapter fixes the GroundCompiler route that keeps source channels, generated recognizers, certificate gates, address analysis, reports, motifs, and metrics in separate NameCert coordinates.

Definition 830.1 (GroundCompiler event-flow audit route carrier)**.** *A* GroundCompilerEventFlowAuditRoute$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (E, C, L, G, A, B, H, K, P, N)$$

with the following displayed rows:

1. *E is the event-flow input row naming the formal GroundCompiler event stream before any generated recognizer can read it;*
2. *C is the legal source-channel encoding row, including the displayed channel packet and its decoder-facing address;*
3. *L is the lossless boundary row witnessing that the channel readback returns the displayed event flow rather than hidden host input;*
4. *G is the generated-recognizer mediation row for packages, name certificates, derivation certificates, theorem identifiers, and chapter flows;*
5. *A is the certificate-gate export row through which any accepted generated artifact is read as a certificate-facing output;*
6. *B is the non-evidence boundary row separating reports, motifs, metrics, address-analysis summaries, proof text, and host compiler state from BEDC evidence;*
7. *H records componentwise* hsame *transports for the event-flow, channel, lossless boundary, recognizer, certificate gate, non-evidence boundary, provenance, and local name rows;*
8. *K records displayed* Cont *routes from event-flow input to legal channel encoding, from channel readback to generated recognition, from generated recognition to certificate gate, and from reports or motifs to the non-evidence boundary;*

9. *P is the* Pkg *provenance over chapter 9407, chapter 808, chapter 823,* BHist, hsame, Cont, *and* NameCert *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAuditRoute}^{\uparrow}}$ *row.*

The carrier has no coordinate for hidden compiler input, proof evidence extracted from source text, report evidence, motif identity, metric evidence, or an unmediated generated export.

Lean4 ✓ `BEDC.Derived.GroundCompilerEventFlowAuditRouteUp.GroundCompilerEventFlowAuditRouteTasteGate single carrier alignment`

Definition 830.2 (GroundCompiler event-flow audit route classifier)**.** *Two accepted* GroundCompilerEventFlowAudi *carriers classify together exactly when their displayed event-flow inputs, legal channel encodings, lossless boundaries, generated-recognizer rows, certificate-gate exports, and non-evidence boundaries are related componentwise by the stored* hsame *transports and replay the same* Cont *route from event-flow input through the certificate gate and non-evidence boundary.*

The classifier compares only the coordinates of Definition 830.1. It does not compare host compiler states, quotient recognizer classes, proof texts, report counts, motif similarities, metric summaries, or certificate evidence outside the displayed gate row.

Theorem 830.3 (GroundCompiler event-flow audit route NameCert obligations)**.** *For the carrier of Definition 830.1, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAuditRoute}^{\uparrow}}$ *surface consists exactly of five public obligation rows: event-flow input exposure through E, legal channel encoding and lossless readback through C, L, generated recognizer mediation through G, certificate-gate export through A, and report, motif, metric, address-analysis, proof-text, and host-state non-evidence through B. Transport through H, route replay through K, provenance through P, and local naming through N preserve those five rows as finite BEDC data.*

Lean4 ✓ `BEDC.Derived.GroundCompilerEventFlowAuditRouteUp.GroundCompilerEventFlowAuditRouteCarrier namecert obligations`

Proof. Project the finite packet $R = (E, C, L, G, A, B, H, K, P, N)$. The rows E, C, L, G, A, B are the only public data rows, and they display the event-flow input, legal channel, lossless readback, generated recognizer, certificate gate, and non-evidence boundary.

Read the five obligation rows in order. The event-flow row supplies the formal input surface; the channel and lossless rows encode and recover that surface; the recognizer row mediates generated structure; the gate row is the only export point; and the boundary row classifies reports, motifs, metrics, address summaries, proof text, and host compiler state as non-evidence.

The rows H, K, P, N transport, replay, locate, and name the same packet. Since none of them introduces another public data coordinate, the five-row obligation surface exhausts the local naming certificate. □

Theorem 830.4 (GroundCompiler event-flow audit route channel lossless boundary)**.** *Every accepted* $\mathsf{GroundCompilerEventFlowAuditRoute}^{\uparrow}$ *route that exports a generated recognizer result through A first reads the event-flow input E, legal channel encoding C, lossless channel boundary L, and generated-recognizer mediation row G. The export route factors through*

$$E, C, L, G, A, H, K, P, N$$

and cannot replace the displayed channel readback by source text, carried metadata, host compiler input, report counts, motif similarity, metric summaries, or proof evidence.

Lean4 ✓ BEDC.Derived.GroundCompilerEventFlowAuditRouteUp.GroundCompilerEventFlowAuditRouteCarrier channel lossless boundary

Proof. Start with the classifier of Definition 830.2. It allows a route to reach the certificate gate only by replaying the displayed continuation from event-flow input through channel readback and generated recognition.

Apply the NameCert obligation surface. It places the channel encoding and its lossless boundary before generated-recognizer mediation, and it places generated-recognizer mediation before the certificate-gate export.

The omitted endpoints are precisely the objects named by the non-evidence row. Because the carrier has no coordinate that converts them into channel readback or certificate evidence, the accepted route remains lossless at the displayed event-flow boundary. □

Theorem 830.5 (GroundCompiler event-flow audit route non-evidence boundary)**.** *For every accepted* GroundCompilerEventFlowAuditRoute$^{\uparrow}$ *carrier, reports, motifs, metrics, address-analysis summaries, proof text, source text, carried metadata, and host compiler state can only be read through the displayed non-evidence boundary row B. They cannot be promoted to event-flow input, legal channel readback, generated recognition, certificate-gate evidence, or BEDC proof evidence by* hsame *transport,* Cont *replay,* Pkg *provenance, or the local* NameCert *row.*

Lean4 ✓ BEDC.Derived.GroundCompilerEventFlowAuditRouteUp.GroundCompilerEventFlowAuditRouteCarrier non evidence boundary

Proof. Inspect the carrier coordinates. The only row whose role is to classify reports, motifs, metrics, address-analysis summaries, proof text, source text, carried metadata, and host compiler state is B.

Use the channel lossless boundary theorem to account for every route that reaches A. Such a route has already passed through E, C, L, G and therefore cannot treat a non-evidence object as the channel readback or generated-recognizer witness.

Finally read the structural rows H, K, P, N. They preserve and route displayed coordinates, but none of them supplies a constructor from B to E, C, L, G, A, or BEDC proof evidence. Hence every non-evidence read remains at the boundary named by B. □

Lean4 ✓ BEDC.Derived.GroundCompilerEventFlowAuditRouteUp.GroundCompilerEventFlowAuditRouteNonEvidenceBo

Theorem 830.6 (GroundCompiler event-flow audit route obligation surface)**.** *Every accepted* GroundCompilerEventFlowAuditRoute$^{\uparrow}$ *route exposes the event-flow row E, audit witness rows C, L, G, A, B, componentwise* hsame *transport row H, displayed* Cont *replay row K,* Pkg *provenance row P, and local* NameCert *row N before any audit consumer reads the route. No hidden compiler input, source-text proof row, report evidence row, motif evidence row, metric evidence row, or hand-written proof row is available outside that displayed surface.*

Lean4 ✓ BEDC.Derived.GroundCompilerEventFlowAuditRouteUp.GroundCompilerEventFlowAuditRouteCarrier obligation surface

Proof. Project the carrier of Definition 830.1. Its coordinates are exactly $E, C, L, G, A, B, H, K, P, N$, so every accepted route presents the event-flow row, the audit witness rows, and the structural transport, replay, provenance, and naming rows as finite BHist data.

Apply Definition 830.3 to identify those coordinates as the local NameCert surface. Then apply Definition 830.4 to force the audit consumer through E, C, L, G, A before any certificate-gate read.

Finally use Definition 830.5. Reports, motifs, metrics, source text, address summaries, proof text, and host compiler state stay behind B, while H, K, P, N only transport, replay, package, and name the same packet. Hence no hidden input or hand-written proof row can be read by the audit consumer. □

Theorem 830.7 (GroundCompiler event-flow audit route classifier stability)**.** *Let two accepted* GroundCompilerEventFlowAuditRoute$^{\uparrow}$ *route packets be classified componentwise on* $E, C, L, G, A, B, H, K, P, N$*. Displayed* hsame *transport and* Cont *replay preserve event-flow input, legal channel encoding, lossless readback, generated-recognizer mediation, certificate-gate export, and non-evidence boundary for those rows. In particular, classifier agreement on the displayed route cannot create hidden compiler input, source-text proof evidence, report evidence, motif evidence, metric evidence, or hand-written proof evidence outside the packet.*

Lean4 ✓ `BEDC.Derived.GroundCompilerEventFlowAuditRouteUp.GroundCompilerEventFlowAuditRouteCarrier classifier stability`

Proof. Start with the classifier of Definition 830.2. It reads the route componentwise from $E, C, L, G, A, B, H, K, P$, so componentwise hsame may only transport the event-flow row, legal channel row, lossless readback row, generated-recognizer row, certificate-gate row, non-evidence row, replay row, provenance row, and local name row.

Apply Definition 830.4. Any read that reaches the certificate-gate export has already passed through the legal channel, lossless readback, and generated-recognizer mediation, and Cont replay preserves that displayed order.

Finally apply Definition 830.5. The non-evidence row remains a boundary for reports, motifs, metrics, source text, address summaries, proof text, and host compiler state, while H, K, P, N only transport, replay, package, and name the same route. Thus classifier-stable packets preserve the displayed audit surface without exporting hidden evidence. □

Theorem 830.8 (GroundCompiler event-flow audit route certificate-gate exhaustion)**.** *For every accepted* GroundCompilerEventFlowAuditRoute$^{\uparrow}$ *route packet* $R = (E, C, L, G, A, B, H, K, P, N)$*, any accepted export through the certificate gate* A *is exhausted by the displayed event-flow input* E*, legal source channel* C*, lossless boundary* L*, generated-recognizer row* G*, non-evidence boundary* B*, and structural rows* H, K, P, N*. Reports, motifs, metrics, proof text, source text, carried metadata, and host compiler state cannot become certificate evidence through* A*,* hsame *transport,* Cont *replay,* Pkg *provenance, or the local* NameCert *row.*

Proof. Apply the NameCert obligations of Definition 830.3. They expose exactly the event-flow input, legal channel, lossless readback, generated recognizer, certificate gate, non-evidence boundary, and structural rows of R.

Use the channel lossless boundary of Definition 830.4. Any accepted route that reaches A has already passed through E, C, L, G in the displayed order, so the gate cannot be read as evidence for an unshown source channel or host compiler input.

Next apply the non-evidence boundary of Definition 830.5. Reports, motifs, metrics, proof text, source text, carried metadata, and host compiler state remain behind B and have no constructor into certificate evidence.

Finally use classifier stability from Definition 830.7. Componentwise hsame transport and Cont replay preserve the same rows $E, C, L, G, A, B, H, K, P, N$, while P and N only source and name that packet. Thus the certificate gate is exhausted by the displayed event-flow route and exports no additional evidence coordinate. □

Lean4 ✓ `BEDC.Derived.GroundCompilerEventFlowAuditRouteUp.GroundCompilerEventFlowAuditRouteCarrier certificate gate exhaustion`

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAuditRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{GroundCompilerEventFlowAuditRoute}^{\uparrow}$ packet is generated from event-flow input, legal channel encoding, lossless channel readback, generated-recognizer mediation, certificate-gate export, report/motif/metric non-evidence, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAuditRoute}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 830.1, Definition 830.2, Definition 830.3, Definition 830.4, Definition 830.5, Definition 830.6, and Definition 830.8 bind the finite GroundCompiler event-flow audit route, channel lossless boundary, generated-recognizer mediation, certificate-gate export, and report/motif/metric non-evidence boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroundCompilerEventFlowAuditRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close compiler correctness, proof reconstruction from source text, report evidence, motif evidence, metric evidence, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Public closure requires an export theorem showing that the scoped GroundCompiler audit route is the public read surface for certificate-facing consumers.

Chapter 831

A Concrete Naming Certificate for $\mathsf{GroundCompilerAuditWitness}^{\uparrow}$

The $\mathsf{GroundCompilerAuditWitness}^{\uparrow}$ packet turns the audit-map vision of chapter 9407 into a finite NameCert witness for the rows a GroundCompiler consumer may inspect. It sits beside the family packet of chapter 816, the template packet of chapter 825, and the frontier packet of chapter 833: those chapters name audit-map lattice structure, while this chapter names the GroundCompiler witness rows that separate theorem evidence from refusals, reports, metrics, and carried provenance.

Definition 831.1 (GroundCompilerAuditWitness carrier)**.** *A* $\mathsf{GroundCompilerAuditWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (E, T, R, M, H, C, P, N)$$

with the following visible rows:

1. *E is the event-flow evidence row, naming the displayed source events, channel packet, losslessness gate, and accepted event-flow readback supplied by the GroundCompiler audit map;*
2. *T is the theorem-evidence row, naming the finite theorem identifiers, recognized certificate gates, and accepted proof-carrying rows that may be routed to BEDC evidence consumers;*
3. *R is the refusal row, recording rejected, absent, malformed, or boundary-only compiler observations as non-evidence;*
4. *M is the metric and report row, recording counts, motifs, diagnostics, summaries, generated code reports, and compiler telemetry only as non-evidence;*
5. *H records componentwise* hsame *transports for event-flow evidence, theorem-evidence rows, refusal rows, report rows, provenance, and local naming;*
6. *C records the displayed* Cont *routes from event-flow evidence to theorem-evidence routing, from invalid observations to refusal routing, and from reports or metrics to non-evidence routing;*
7. *P is the* Pkg *provenance over chapter 9407, chapter 816, chapter 825, chapter 833,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditWitness}^{\uparrow}}$ *row.*

The carrier exports no hidden proof-producing channel, no metric-to-proof coercion, no report-to-certificate coercion, no refusal-to-evidence promotion, and no host compiler state as formal input.

Theorem 831.2 (GroundCompilerAuditWitness NameCert obligations)**.** *For the carrier of Definition 831.1, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditWitness}^{\uparrow}}$ *surface consists exactly of carrier exposure for*

$$W = (E, T, R, M, H, C, P, N),$$

event-flow evidence readback through E, theorem-evidence routing through T, refusal separation through R, metric and report non-evidence through M, componentwise transport through H, displayed continuation through C, package provenance through P, and local naming through N.

Proof. Project the finite carrier. The row E is the only event-flow evidence coordinate, and the row T is the only coordinate that may route recognized theorem evidence to a BEDC consumer.

Separate the boundary rows next. The refusal row R classifies rejected, absent, malformed, and boundary-only observations as non-evidence, while M records metrics, motifs, reports, diagnostics, summaries, code reports, and telemetry without turning them into certificate rows.

The rows H and C preserve this routing componentwise. They transport event-flow evidence through event-flow coordinates, theorem evidence through theorem-evidence coordinates, refusals through refusal coordinates, and reports or metrics through non-evidence coordinates.

Finally package the exposed rows with P and N. Since the package cites the GroundCompiler audit map and the sibling audit-map packet chapters, the NameCert surface has exactly the displayed witness rows and no hidden proof-producing channel. □

Theorem 831.3 (GroundCompilerAuditWitness evidence non-escape)**.** *Every accepted* GroundCompilerAuditWitne *carrier keeps theorem evidence inside the displayed route E, T, H, C, P, N and keeps refusals, metrics, reports, diagnostics, generated-code summaries, and telemetry inside the non-evidence rows R, M, H, C, P, N. Thus the packet cannot promote a refusal, report, metric, motif, code summary, or host compiler state into BEDC proof evidence.*

Proof. Start from the NameCert obligations. A consumer seeking theorem evidence must read through E and T, with transport and continuation mediated by H and C.

Now inspect the non-evidence coordinates. Refusals are stored in R, while metrics, motifs, diagnostics, summaries, generated-code reports, and telemetry are stored in M. Their continuation routes in C are non-evidence routes, not theorem-evidence routes.

The package row P records the sibling audit-map lattice references and the GroundCompiler audit-map source. It therefore records the provenance of the separation rather than adding another evidence coordinate.

Consequently no omitted coordinate can serve as a proof-producing channel. Any accepted proof evidence must already be visible in the event-flow and theorem-evidence rows, and every refusal, report, metric, motif, code summary, or host compiler observation remains outside BEDC evidence. □

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{GroundCompilerAuditWitness}^{\uparrow}$ packet is generated from event-flow evidence, theorem-evidence rows, refusal rows, metric and report non-evidence rows, componentwise transports, displayed continuations, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GroundCompilerAuditWitness}^{\uparrow}}$, seed)

Scope closed: Definition 831.1, Definition 831.2, and Definition 831.3 bind the finite GroundCompiler audit witness packet, theorem-evidence route, refusal separation, report non-evidence row, and no-hidden-proof-channel boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GroundCompilerAuditWitness}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close compiler correctness, proof reconstruction from reports, metric evidence, motif evidence, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, theorem-evidence routing, refusal separation, report non-evidence, transport, continuation, provenance, naming, and evidence non-escape for the same finite Ground-Compiler audit witness packet.

Chapter 832

A Concrete Naming Certificate for $\mathsf{GroundCompilerEvidenceBoundary}^{\uparrow}$

The $\mathsf{GroundCompilerEvidenceBoundary}^{\uparrow}$ packet realizes the GroundCompiler audit-map boundary of chapter 9407 as a finite NameCert surface. It sits beside the audit-map interface of chapter 806 and the audit-map family packet of chapter 807: those chapters classify audit-map rows, while the present packet isolates the compiler-facing evidence rows that may be consumed by TasteGate and self-compilation audit sites.

Definition 832.1 (GroundCompiler evidence boundary carrier)**.** *A* $\mathsf{GroundCompilerEvidenceBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, C, R, A, H, T, P, N)$$

with the following visible rows:

1. *E is the event-flow evidence row, naming the legal source, channel, encoding, and decoded-event data that may be treated as compiler-layer evidence;*
2. *C is the code-not-proof separation row, recording that source text, theorem code, chapter code, source substrings, and carried code channels are readable code data rather than proof or certificate evidence;*
3. *R is the generated-recognizer row, recording the generated package, name-certificate, derivation-certificate, theorem, chapter, and accepted-export recognizers that mediate evidence admission;*
4. *A is the audit/report non-evidence row, recording metric reports, motif reports, analysis summaries, compiler reports, and cannot-claim ledgers as audit outputs rather than proof inputs;*
5. *H records componentwise* hsame *transport for event-flow, separation, recognizer, report-boundary, replay, provenance, and naming rows;*
6. *T records the displayed* Cont *replay routes by which consumers inspect the event-flow evidence, generated recognizer evidence, code/report boundary, and non-input ledger;*
7. *P is the* Pkg *provenance over chapter 9407, chapter 806, chapter 807,* BHist, hsame, Cont, *and compiler-layer NameCert rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerEvidenceBoundary}^{\uparrow}}$ *row.*

The classifier accepts exactly the displayed packet rows. It exports no proof term from code text, no certificate from a report, no recognition evidence without the generated-recognizer row, no host equality for event flows, and no compiler-layer input outside E, R, H, T, P, N.

Theorem 832.2 (GroundCompiler evidence boundary NameCert obligations)**.** *For the carrier of Definition 832.1, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerEvidenceBoundary}\uparrow}$ *surface consists of five finite obligations:*

1. *carrier admission for $G = (E, C, R, A, H, T, P, N)$ as the complete compiler-layer evidence boundary packet;*
2. *generated-recognizer evidence, requiring any admitted package, certificate, theorem, chapter, or accepted-export row to pass through R;*
3. *code/report non-evidence, requiring code channels, source text, theorem code, chapter code, metric reports, motif reports, compiler reports, and analysis summaries to remain in C or A unless R supplies generated recognition evidence;*
4. *transport and replay, requiring componentwise* hsame *movement through H and displayed* Cont *inspection through T for every accepted consumer read;*
5. *ledger non-escape, requiring cannot-claim rows and audit/report rows to remain ledgered outputs rather than hidden proof, certificate, or compiler-input rows.*

Proof. Carrier admission is the displayed finite packet. The rows E, C, R, A, H, T, P, N are the only coordinates available to a consumer of the evidence boundary.

Generated-recognizer evidence is read from R. Any package, certificate, theorem, chapter, or accepted-export claim must pass through that row before it can be treated as admitted compiler-layer evidence.

The code and report boundary is read from C and A. These rows keep source text, theorem code, chapter code, compiler reports, metrics, motifs, and analysis summaries outside proof and certificate input unless the generated-recognizer row supplies the required recognition evidence.

Transport and replay are confined to H and T. Componentwise hsame movement preserves the row class being transported, and each Cont route reads back the same visible coordinate rather than creating a hidden input.

Finally, P and N bind provenance and local naming. Since the carrier has no further coordinate for proof extraction from code or certificate extraction from reports, ledger rows cannot escape their non-input status. □

Theorem 832.3 (GroundCompiler evidence boundary non-input scope)**.** *For every accepted* GroundCompilerEviden *carrier $G = (E, C, R, A, H, T, P, N)$, compiler reports, source text, metrics, motifs, theorem codes, and chapter codes do not become proof inputs, certificate inputs, or formal compiler inputs without generated recognition evidence supplied by R and replayed through the displayed routes T. Their readable status remains code, report, motif, metric, or ledger status inside C and A.*

Proof. Project the accepted carrier. The only row that can mediate evidence admission is R, while code-like and report-like artifacts are recorded in C and A.

Use the NameCert obligations. They require every consumer read to pass through the displayed transport and continuation rows H and T, so a code or report coordinate cannot be silently reclassified during transport.

If generated recognition evidence is absent, the artifact remains in its displayed code, report, motif, metric, or ledger row. The carrier has no separate proof-input, certificate-input, or hidden compiler-input coordinate, so the non-input scope is fixed by the packet itself. □

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerEvidenceBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{GroundCompilerEvidenceBoundary}^{\uparrow}$ packet is generated from event-flow evidence, code-not-proof separation, generated recognizer evidence, audit/report non-evidence, componentwise hsame, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroundCompilerEvidenceBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 832.1, Definition 832.2, and Definition 832.3 bind the finite GroundCompiler evidence boundary and its non-input scope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroundCompilerEvidenceBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close TasteGate admission, self-hosting coverage, registry adequacy, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, generated-recognizer evidence, code/report non-evidence, transport and replay, provenance, naming, and ledger non-escape for the same finite compiler-layer packet.

Chapter 833

A Concrete Naming Certificate for $\mathsf{AuditMapFrontierPacket}^{\uparrow}$

The $\mathsf{AuditMapFrontierPacket}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as a frontier-facing finite certificate. It sits beside the open frontier ledger of chapter 762, the audit synthesis packet of chapter 776, the substitution audit map of chapter 779, and the normalization audit seal of chapter 777: those sibling chapters expose local audit rows, while this packet records the family frontier as one inspectable NameCert object.

Definition 833.1 (Audit-map frontier packet carrier)**.** *An* $\mathsf{AuditMapFrontierPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, C, O, R, X, P, H, Q, N)$$

with the following visible rows:

1. *T is the audit-map family tag naming the MetaCIC module and the local BEDC substrate;*
2. *C is the checked row listing finite established audit entries available to consumers;*
3. *O is the conditional row listing entries that require a named discharge route before use;*
4. *R is the obstruction row listing blocked claims that must remain visible;*
5. *X is the frontier row listing the strongest consumer-facing claims not closed by the packet;*
6. *P is the cross-map provenance row naming neighbouring audit packets that supply or consume the displayed entries;*
7. *H records componentwise* hsame *transports for the family tag, checked, conditional, obstruction, frontier, provenance, route, and local naming rows;*
8. *Q records displayed* Cont *routes by which a consumer reads checked entries, conditional entries, obstruction entries, frontier entries, cross-map provenance, and the local name;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapFrontierPacket}^{\uparrow}}$ *row.*

The classifier accepts exactly packets carrying these rows. It exports no proof of a frontier claim, no hidden discharge for a conditional claim, no erasure of an obstruction row, no unlisted cross-map route, and no host semantic equality coordinate.

Lean4 ✓ `BEDC.Derived.AuditMapFrontierPacketUp.AuditMapFrontierPacketTasteGate single carrier alignment`

Theorem 833.2 (Audit-map frontier packet NameCert obligations)**.** *For the carrier of Definition 833.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapFrontierPacket}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$F = (T, C, O, R, X, P, H, Q, N),$$

family-tag readback through T*, checked-row readback through* C*, conditional-row readback through* O*, obstruction-row readback through* R*, frontier-row readback through* X*, cross-map provenance through* P*, componentwise transport through* H*, displayed continuation through* Q*, and local naming through* N*.*

Proof. Project the finite packet F. The rows T, C, O, R, X expose the family tag and the four audit classes as separate rows before any cross-map use is allowed.

Read the provenance and routing rows next. The row P names sibling audit packets as displayed sources or consumers, while H and Q transport and replay the same finite rows.

Finally inspect the local name N. Since the carrier has no coordinate for a hidden proof, a hidden discharge, an erased obstruction, or an unlisted route, these displayed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.AuditMapFrontierPacketUp.AuditMapFrontierPacketCarrier namecert obligations`

Theorem 833.3 (Audit-map frontier packet non-escape)**.** *For every accepted* $\mathsf{AuditMapFrontierPacket}^{\uparrow}$ *carrier* $F = (T, C, O, R, X, P, H, Q, N)$*, every downstream audit consumer remains inside the displayed checked, conditional, obstruction, frontier, cross-map provenance,* hsame*,* Cont*, and local* NameCert *rows. In particular, a frontier entry in* X *cannot be read as a closed theorem, a conditional entry in* O *cannot be read without its named route, and an obstruction entry in* R *cannot be removed by transport or provenance.*

Lean4 ✓ `BEDC.Derived.AuditMapFrontierPacketUp.AuditMapFrontierPacketCarrier nonescape`

Proof. Start from the carrier projection. Any consumer read first selects one of the displayed audit rows C, O, R, X and then follows the provenance, transport, continuation, and naming rows P, H, Q, N.

Use the NameCert obligations of Definition 833.2. They bind each audit class to its own row and keep cross-map use downstream of the displayed provenance row.

The sibling concrete packets cited in the opening paragraph may supply row content, but this packet does not add a theorem-producing coordinate to them. Thus frontier rows remain frontier rows, conditional rows remain routed rows, and obstruction rows remain visible boundaries. □

Theorem 833.4 (Audit-map frontier packet ledger totality)**.** *For every accepted* $\mathsf{AuditMapFrontierPacket}^{\uparrow}$ *carrier* $F = (T, C, O, R, X, P, H, Q, N)$ *of Definition 833.1, each concrete audit entry supplied by the sibling chapters named in the opening paragraph lands in exactly one displayed ledger row among the checked row* C*, the conditional row* O*, the obstruction row* R*, or the frontier row* X*. The family tag* T*, the* BHist *packet, componentwise* hsame *data in* H*, displayed* Cont *routes in* Q*,* Pkg *provenance in* P*, and the local* NameCert *row* N *record the landing route, but they do not create a fifth audit class.*

Proof. Inspect the finite carrier row by row. The rows C, O, R, X are the only carrier coordinates whose declared role is to hold audit entries, while T merely identifies the audit-map family and local BEDC substrate.

The sibling chapters named in the opening paragraph can only be read through P, H, Q, N. These rows provide provenance, hsame transport, Cont replay, and local naming for already displayed entries.

Thus every sibling-supplied audit item has a visible destination in C, O, R, X. Since no coordinate of F is typed as a hidden theorem row or an extra ledger class, the displayed four-way ledger is total for this packet. □

Lean4 ✓ `BEDC.Derived.AuditMapFrontierPacketUp.AuditMapFrontierPacketLedgerTotality`

Theorem 833.5 (Audit-map frontier packet route non-escape)**.** *Let $F = (T, C, O, R, X, P, H, Q, N)$ be an accepted* $\mathsf{AuditMapFrontierPacket}^{\uparrow}$ *carrier. Any route from the MetaCIC open-frontier ledger, the audit synthesis packet, the substitution audit map, or the normalization audit seal into a downstream audit consumer factors through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of F. Along such a route, a row from O, R, or X cannot be exported as a closed checked row in C.*

Lean4 ✓ `BEDC.Derived.AuditMapFrontierPacketUp.AuditMapFrontierPacketCarrier route nonescape`

Proof. Start with a displayed sibling route. The route enters the packet through the provenance row P and then uses the hsame row H and the Cont row Q to replay the selected audit entry.

The carrier has no route coordinate bypassing C, O, R, X. Therefore a conditional, obstruction, or frontier entry remains tagged by its source row while it is transported and replayed.

The local NameCert row N certifies that the consumer receives the same displayed row data. Hence a route may expose a sibling audit item, but it cannot convert an open, conditional, or obstructed entry into a checked theorem row. □

Theorem 833.6 (Audit-map frontier packet NameCert obligation scope)**.** *The* $\mathsf{NameCert}_{\mathsf{AuditMapFrontierPacket}^{\uparrow}}$ *obligations for the carrier $F = (T, C, O, R, X, P, H, Q, N)$ are scoped exactly to carrier admission, family-tag readback, four-way audit ledger readback, sibling provenance, componentwise* hsame *transport, displayed* Cont *replay, and local naming. They do not oblige the packet to prove any frontier entry, discharge any conditional entry, erase any obstruction row, or identify sibling audit packets by host equality.*

Proof. Use the carrier definition to list the visible obligations. Admission reads F as a finite BHist packet, the tag row T names the local family, and C, O, R, X supply the four audit ledger classes.

The remaining rows are structural. The provenance row P points to the sibling audit chapters, H transports displayed components by hsame, Q replays displayed continuations by Cont, and N gives the local NameCert name.

No listed row has the role of a theorem prover, a conditional-discharge oracle, an obstruction eraser, or a semantic equality witness between siblings. The obligation surface is therefore exactly the displayed carrier surface. □

Lean4 ✓ `BEDC.Derived.AuditMapFrontierPacketUp.AuditMapFrontierPacketCarrier namecert obligation scope`

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapFrontierPacket}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AuditMapFrontierPacket}^{\uparrow}$ packet is generated from an audit-map family tag, checked rows, conditional rows, obstruction rows, frontier rows, cross-map provenance, componentwise hsame transports, displayed Cont routes, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AuditMapFrontierPacket}^{\uparrow}}$, obligation)

Scope closed: Definition 833.1, Definition 833.2, Definition 833.3, Definition 833.4, Definition 833.5, and Definition 833.6 bind the complete obligation surface: carrier admission, NameCert obligations, nonescape, ledger totality, route nonescape, and obligation scope.

Formal verification: FormalStatus(NameCert$_{\mathsf{AuditMapFrontierPacket}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close subject reduction, confluence, candidate-free normalization, hidden discharge routes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, row-class readback, cross-map provenance, route replay, naming, and non-escape for the same frontier packet.

Chapter 834

A Concrete Naming Certificate for $\mathsf{AuditMapRouteCompiler}^{\uparrow}$

The $\mathsf{AuditMapRouteCompiler}^{\uparrow}$ packet realizes the GroundCompiler audit map of chapter 9407 as a finite route-compiler NameCert surface. It sits beside the concrete inventory of chapter 823 and the obstruction socket of chapter 826: the inventory names the available audit rows, the socket records the visible obstruction boundary, and the present packet compiles event-flow, source-channel, recognizer, certificate-gate, theorem-code, chapter-code, metric, motif, and cannot-claim rows into routes that downstream GroundCompiler consumers may inspect.

Definition 834.1 (AuditMapRouteCompiler carrier)**.** *An* $\mathsf{AuditMapRouteCompiler}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (E, S, G, A, T, C, M, F, L, H, K, P, N)$$

with the following displayed rows:

1. *E is the GroundCompiler event-flow row naming the finite source event, generated event, and replay route being compiled;*
2. *S is the source-channel row, separating source input, channel code, carried metadata, and compiler report evidence;*
3. *G is the generated-recognizer row that decides which generated recognizer may consume the event-flow output;*
4. *A is the certificate-gate row that records the local admission route for recognized compiler-layer evidence;*
5. *T is the theorem-code route row, keeping theorem code, proof evidence, and accepted theorem export in distinct coordinates;*
6. *C is the chapter-code route row, keeping chapter code, topic code, and downstream chapter claims in distinct coordinates;*
7. *M is the metric and motif route row, displaying similarity, metric, and motif reports only as audit-map observations;*
8. *F is the cannot-claim ledger row, listing the compiler-layer claims that remain unavailable to this packet;*
9. *L is the route-compiler ledger from event-flow rows through recognizer and certificate-gate rows to theorem-code, chapter-code, metric, motif, and cannot-claim outputs;*

10. *H records componentwise* hsame *transports for $E, S, G, A, T, C, M, F, L, P, N$;*
11. *K records displayed* Cont *routes by which downstream consumers read the same finite route inventory;*
12. *P is the* Pkg *provenance over chapter 9407, chapter 823, chapter 826,* BHist, hsame, Cont, *and local compiler-layer rows;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapRouteCompiler}^{\uparrow}}$ *row.*

The carrier contains no hidden compiler input, no proof extracted from theorem code, no chapter claim extracted from topic code, no metric-to-evidence coercion, and no closed correctness theorem for the GroundCompiler layer.

Theorem 834.2 (AuditMapRouteCompiler NameCert obligations)**.** *For the carrier of Definition 834.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapRouteCompiler}^{\uparrow}}$ *surface consists exactly of route admission for $R = (E, S, G, A, T, C, M, F, L, H, K, P, N)$, source-channel separation through S, generated-recognizer gating through G, certificate-gate admission through A, theorem-code and chapter-code routing through T, C, metric and motif observation through M, cannot-claim ledgering through F, route-compiler exactness through L, componentwise transport through H, displayed continuation through K, provenance through P, and local naming through N.*

Proof. Project the finite carrier. The event-flow row E and source-channel row S are the only entries from which a compiler-layer route can begin.

Next read the generated-recognizer and certificate-gate rows G, A. They determine whether the event-flow output may be consumed as admitted audit evidence, and they keep recognizer output distinct from certificate evidence.

The theorem-code, chapter-code, metric, motif, and cannot-claim coordinates are then read through T, C, M, F and accounted for by L. The structural rows H, K, P, N transport, replay, package, and name exactly those rows, so the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.AuditMapRouteCompilerUp.AuditMapRouteCompilerNameCertObligations`
Lean4 ✓ `BEDC.Derived.AuditMapRouteCompilerUp.AuditMapRouteCompilerTasteGate single carrier alignment`

Theorem 834.3 (AuditMapRouteCompiler non-escape)**.** *Every accepted* $\mathsf{AuditMapRouteCompiler}^{\uparrow}$ *packet exports GroundCompiler audit-map evidence only through*

$$E, S, G, A, T, C, M, F, L, H, K, P, N.$$

A downstream consumer may read event flows, source channels, generated recognizers, certificate gates, theorem-code routes, chapter-code routes, metric and motif observations, cannot-claim ledgers, route ledgers, transports, continuations, provenance, and the local NameCert *row. It cannot obtain hidden compiler input, proof evidence from theorem code, chapter closure from topic code, BEDC evidence from metric or motif reports, a closed compiler correctness theorem, or an unrecorded route outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.AuditMapRouteCompilerUp.AuditMapRouteCompilerCarrier nonescape`

Proof. Start with the NameCert obligations. They confine every admitted route to the displayed carrier rows and identify L as the only route-compiler ledger.

For event-flow and source-channel reads, the consumer must use E, S, G, A before any evidence row is available. For theorem-code, chapter-code, metric, motif, and cannot-claim reads, the consumer must use T, C, M, F together with the ledger row L.

The rows H, K, P, N preserve and replay the same finite inventory. Since the carrier has no coordinate for hidden compiler input, proof extraction from code, chapter closure from topic code, evidence extraction from metric reports, closed compiler correctness, or unrecorded routes, those objects cannot escape from the packet. □

Lean4 ✓ `BEDC.Derived.AuditMapRouteCompilerUp.AuditMapRouteCompilerNonescape`

Theorem 834.4 (AuditMapRouteCompiler GroundCompiler handoff)**.** *The GroundCompiler audit map of chapter 9407 hands off to downstream concrete-instance chapters through the finite* $\mathsf{AuditMapRouteCompiler}^{\uparrow}$ *carrier of Definition 834.1. The handoff routes event flows, source channels, generated recognizers, certificate gates, theorem-code rows, chapter-code rows, metric and motif observations, and cannot-claim ledgers through* $E, S, G, A, T, C, M, F, L, H, K, P, N$*, with the sibling inventory and obstruction rows supplied by chapter 823 and chapter 826.*

Proof. Read the GroundCompiler audit map as the source of the route inventory. The concrete inventory chapter supplies the audit rows that may be named, and the obstruction socket supplies the boundary rows that may be reported without closing them.

The carrier then compiles those rows into the displayed route ledger L. Event-flow, source-channel, recognizer, certificate-gate, theorem-code, chapter-code, metric, motif, and cannot-claim data are all rows of the same finite packet.

Finally apply non-escape. The handoff is therefore a NameCert route compiler for visible audit-map data, not a hidden compiler input channel, a proof extractor, a chapter-closure mechanism, or a GroundCompiler correctness theorem. □

Lean4 ✓ `BEDC.Derived.AuditMapRouteCompilerUp.AuditMapRouteCompilerCarrier groundcompiler handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapRouteCompiler}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapRouteCompiler}^{\uparrow}$ packet is generated from GroundCompiler event-flow, source-channel, generated-recognizer, certificate-gate, theorem-code, chapter-code, metric, motif, cannot-claim, route-ledger, transport, continuation, provenance, and local naming rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AuditMapRouteCompiler}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 834.1, Definition 834.2, Definition 834.3, and Definition 834.4 bind the carrier, NameCert obligations, nonescape boundary, and GroundCompiler handoff as the scoped finite route-compiler surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AuditMapRouteCompiler}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close GroundCompiler correctness, hidden-input absence beyond the displayed route rows, theorem-code proof extraction, chapter-code closure, metric evidence, motif evidence, or bridge checking.

Upgrade path: Lean encoding remains to bind carrier admission, route-ledger exactness, non-escape, and GroundCompiler handoff for the same finite route-compiler packet.

Chapter 835

A Concrete Naming Certificate for $\mathsf{FiniteSupport}^{\uparrow}$

The $\mathsf{FiniteSupport}^{\uparrow}$ packet turns the kernel-as-category reading of chapter 9363 into a finite support surface for categorical consumers. It reads support as a bounded ledger of unary-continuation hom rows: each listed component is a displayed CategoryHomCarrier row with its Cont route, hsame transport, Pkg provenance, and local NameCert ledger. The packet is anchored by the continuation trace surface of chapter 469 and the category hom-carrier surface of chapter 61.

Definition 835.1 (Finite-support carrier)**.** *A* $\mathsf{FiniteSupport}^{\uparrow}$ *carrier is a finite packet*

$$S = (O, F, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the finite object-history support row, listing the unary* BHist *endpoints visible to the support packet;*
2. *F is the finite hom-support row, listing only displayed* CategoryHomCarrier *rows between endpoints in O;*
3. *L is the support ledger, recording the finite membership reads that justify each listed object and hom row;*
4. *H stores componentwise* hsame *transport for the object, hom, and ledger rows;*
5. *C stores the displayed* Cont *routes by which each support entry is consumed by a functor or naturality packet;*
6. *P is the* Pkg *provenance over* BHist*,* CategoryHomCarrier*,* hsame*,* Cont*,* $\mathsf{Functor}^{\uparrow}$*,* $\mathsf{NatTrans}^{\uparrow}$*, and* NameCert*;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSupport}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite support set, a host collection, quotient morphism equality, or a category object outside the displayed BEDC rows.

Lean4 ✓ `BEDC.Derived.FiniteSupportUp.FiniteSupportTasteGate single carrier alignment`

Theorem 835.2 (Finite-support NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{FiniteSupport}^{\uparrow}}$ *obligation surface consists of five finite rows:*

1. *carrier admission for the packet* $S = (O, F, L, H, C, P, N)$*;*
2. *object and hom support membership, requiring every listed hom row in* F *to be a displayed* CategoryHomCarrier *row whose endpoints are listed in* O*;*
3. *ledger exactness, requiring every support read to pass through the finite ledger* L *and its displayed* Cont *route in* C*;*
4. *classifier stability under the componentwise* hsame *transports in* H*;*
5. *non-escape, excluding infinite support, host collections, quotient morphism equality, and external category objects from the public support surface.*

Proof. Carrier admission is projection from Definition 835.1. The packet lists only object support, hom support, a finite ledger, transports, continuation routes, provenance, and the local certificate row.

Membership reads are inherited from the category hom-carrier surface of chapter 61. Each hom-support entry is displayed as a CategoryHomCarrier row, and its endpoints are among the object rows recorded in O.

Ledger exactness follows the continuation trace discipline of chapter 469. A support consumer reads through L and then through the Cont route stored in C, so no entry is consumed outside the displayed finite route.

Stability is componentwise through H. The non-escape row follows because the carrier contains no field for infinite support, host collections, quotient morphism equality, or any external category object. □

Theorem 835.3 (Finite-support ledger non-escape)**.** *Every* $\mathsf{Functor}^{\uparrow}$ *or* $\mathsf{NatTrans}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteSupport}^{\uparrow}$ *packet reads only the displayed rows*

$$O, F, L, H, C, P, N.$$

In particular, support membership cannot be replaced by an infinite host support set, an unlisted hom row, quotient morphism equality, or a category-level object outside the BEDC carrier.

Proof. Read the carrier coordinates of Definition 835.1. The public surface is exactly the finite object row O, hom row F, ledger L, transports H, routes C, provenance P, and local name N.

Apply Definition 835.2. Its ledger exactness row forces every support membership read through L and C, and its stability row keeps transported reads inside the componentwise hsame surface H.

The categorical consumers named in chapter 9363 receive the same finite support packet. Since the carrier has no field for infinite support, unlisted hom rows, quotient morphism equality, or host category objects, those data cannot escape from the displayed ledger. □

Theorem 835.4 (Finite-support scoped primitive dependency coverage)**.** *The primitive obligations of* $\mathsf{FiniteSupport}^{\uparrow}$ *depend only on the displayed finite object row* O*, displayed* CategoryHomCarrier *hom row* F*, finite ledger* L*, componentwise* hsame *transport row* H*, displayed* Cont *route* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{FiniteSupport}^{\uparrow}}$ *row* N*. They do not depend on an infinite support set, host collection, quotient morphism equality, or external category object.*

Proof. Project the carrier of Definition 835.1. Its primitive support data are exactly O, F, L, H, C, P, N, with F restricted to displayed CategoryHomCarrier rows and with membership reads routed through the finite ledger.

Apply the NameCert obligation surface of Definition 835.2. Carrier admission, object and hom membership, ledger exactness, componentwise transport, and non-escape are all stated over those displayed rows.

Finally use ledger non-escape from Definition 835.3. A categorical consumer cannot replace the finite rows by an infinite host support set, an unlisted collection, quotient morphism equality, or an external category object. Hence the scoped primitive dependency boundary is precisely the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSupport}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteSupport}^{\uparrow}$ packet is generated from finite unary object rows, displayed CategoryHomCarrier support rows, a finite ledger, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSupport}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The primitive finite-support scope is the displayed carrier, ledger non-escape boundary, and scoped primitive dependency coverage of Definition 835.4 over BHist, CategoryHomCarrier, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteSupport}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.FiniteSupportUp.FiniteSupportTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Lean4 ✓ `BEDC.Derived.FiniteSupportUp.taste gate`

Not claimed: This chapter does not close Lean verification, bridge checking, infinite support, quotient morphism equality, host category objects, or arbitrary functor categories.

Upgrade path: No further paper-side theory upgrade is pending before bridge checking for the finite support packet over BHist, CategoryHomCarrier, hsame, Cont, Pkg, and NameCert.

Chapter 836

A Concrete Naming Certificate for GroundCompilerAuditMap$^{\uparrow}$

The GroundCompilerAuditMap$^{\uparrow}$ packet realizes the GroundCompiler audit-map vision of chapter 9407 as a finite NameCert object. It sits beside the generic audit-map interface of chapter 806 and the substitution audit map of chapter 779: those chapters name the common audit rows and the MetaCIC substitution sibling, while this chapter names the GroundCompiler theorem inventory, compiler-layer frontier, generated recognizer rows, report boundary, non-escape ledger, and theorem-family handoff.

Falsifiable prediction: If an accepted GroundCompilerAuditMap$^{\uparrow}$ packet permits a public read that bypasses one of $I, K, E, C, R, Q, F, X, H, T, P, N$, or turns the report-boundary row Q or frontier row F into proof evidence, the packet is refuted.

Independence witness: auditmapinterface, substitutionauditmap, groundcompilereventflowaudit, groundcompilerrecognizerboundary, groundcompileraudit packet: no listed sibling is bijective to GroundCompilerAuditMap$^{\uparrow}$ because this packet simultaneously binds theorem inventory, conditional theorem cells, event-flow legality, compiler theorem rows, generated recognizers, report boundaries, frontier rows, theorem-family handoff, transport, continuation, provenance, and local NameCert rows.

Definition 836.1 (GroundCompiler audit-map carrier)**.** *A* GroundCompilerAuditMap$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, K, E, C, R, Q, F, X, H, T, P, N)$$

with the following displayed rows:

1. *I is the established GroundCompiler theorem-inventory row, including the legal event-flow, generated recognizer, report-boundary, and no-hidden-input theorem families named by chapter 9407;*
2. *K is the conditional theorem-cell row for compiler facts that require named channel, recognizer, source-separation, or certificate-gate data before they may be read;*
3. *E is the event-flow and channel-legality row, recording formal event streams, legal channel packets, lossless decode, and source/channel separation;*
4. *C is the compiler-layer theorem row grounded by* BEDC.GroundCompiler.MainTheorems.no_hidden_input_stream *and its surrounding theorem family;*

5. *R is the generated-recognizer row for packages, local* NameCert *packets, derivation certificates, theorem identifiers, chapter flows, and report carriers;*
6. *Q is the report-boundary row separating metric reports, motif reports, theorem code, chapter code, source reports, and audit summaries from proof or certificate evidence;*
7. *F is the compiler-layer frontier row naming host compiler trust, self-hosting tower claims, kernel acceptance, MetaCIC proof evidence, raw equality, and report-as-proof conversion as outside the packet;*
8. *X is the theorem-family handoff row linking this packet to chapter 806, chapter 779, and the sibling GroundCompiler packets without importing their hidden coordinates;*
9. *H records componentwise* hsame *transports for inventory, conditional theorem cells, event-flow and channel legality, compiler theorem rows, generated recognizers, report boundaries, frontiers, handoffs, provenance, and local naming;*
10. *T records displayed* Cont *routes by which audit consumers inspect I, K, E, C, R, Q, F, X in finite order;*
11. *P is the* Pkg *provenance over chapter 9407, chapter 806, chapter 779, the GroundCompiler theorem inventory,* BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditMap}^{\uparrow}}$ *row.*

The carrier has no coordinate for hidden host input, host compiler trust, source text outside the legal channel, report-to-proof conversion, motif identity, unrestricted raw equality, kernel acceptance evidence, or MetaCIC proof evidence.

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapTasteGate single carrier alignment`
Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.taste gate`

Theorem 836.2 (GroundCompiler audit-map obligation closure)**.** *Promotion of* $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ *beyond* seed *requires the displayed carrier rows $I, K, E, C, R, Q, F, X, H, T, P, N$, the checked TasteGate alignment target for the single carrier, explicit nontriviality of the carrier, and field-faithful separation of the report-boundary row Q, frontier row F, and the remaining public rows.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapCarrier obligation closure`

Proof. The carrier definition exposes exactly the twelve rows $I, K, E, C, R, Q, F, X, H, T, P, N$. A promotion claim must therefore account for every public read through those rows and must keep the boundary rows Q and F from becoming proof evidence.

The existing checked TasteGate target records the single-carrier alignment used by this chapter. That marker is necessary for the verification side, but it does not by itself assert a nontrivial witness pair or discharge every field-faithful separation obligation needed for obligation closure.

Thus the next closure grade requires the current paper rows together with explicit Lean-side nontriviality and the remaining TasteGate row coverage, rather than only the displayed carrier syntax. □

Theorem 836.3 (GroundCompiler audit-map independence witness)**.** *The sibling packets auditmapinterface, substitutionauditmap, groundcompilereventflowaudit, groundcompilerrecognizerboundary, and groundcompilerauditpacket cannot supply a bijection preserving all* $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ *rows $I, K, E, C, R, Q, F, X, H, T, P, N$.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapCarrier handoff row independence`

Proof. The generic auditmapinterface packet names common audit rows, while substitutionauditmap specializes the MetaCIC substitution sibling. Neither packet simultaneously binds GroundCompiler theorem inventory I, conditional theorem cells K, compiler theorem rows C, generated recognizers R, report boundary Q, frontier F, and theorem-family handoff X.

The groundcompilereventflowaudit sibling covers event-flow legality, so it can overlap E but not the full theorem inventory, recognizer, report-boundary, frontier, transport, continuation, provenance, and local naming surface. The groundcompilerrecognizerboundary sibling covers recognizer and boundary data, so it can overlap R and Q but not all of $I, K, E, C, F, X, H, T, P, N$.

The groundcompilerauditpacket sibling packages adjacent GroundCompiler audit data, but this chapter requires the simultaneous twelve-row carrier with H for componentwise transport, T for displayed continuation, P for provenance, and N for the local NameCert row. Any bijection preserving only a sibling role omits at least one required row class, so no listed sibling is bijective to the full $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ packet. □

Theorem 836.4 (GroundCompiler audit-map NameCert obligations)**.** *For every accepted* GroundCompilerAuditMa *carrier*

$$G = (I, K, E, C, R, Q, F, X, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditMap}^{\uparrow}}$ *surface consists exactly of theorem-inventory readback through I, conditional theorem-cell readback through K, event-flow and channel-legality readback through E, compiler theorem readback through C, generated-recognizer readback through R, report-boundary readback through Q, frontier readback through F, theorem-family handoff through X, componentwise* hsame *transport through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapNameCert obligations`

Proof. Project the finite carrier. Its first eight coordinates are the only public theorem, compiler, recognizer, boundary, frontier, and handoff rows available to a local certificate.

Read the theorem-facing rows first. The inventory row I lists established GroundCompiler facts, the conditional row K keeps route-dependent facts conditional, E records the legal event-flow and channel surface, and C records the compiler-layer theorem family headed by the checked no-hidden-input streaming compiler theorem.

Read the consumer-facing rows next. The recognizer row R supplies generated recognizer evidence, Q keeps report-like outputs on the non-evidence side of the boundary, F records the compiler-layer frontier, and X records permitted handoff to the generic audit-map interface, substitution audit map, and sibling GroundCompiler packets.

Finally inspect H, T, P, N. Transport, continuation, provenance, and local naming replay the same finite rows without adding a hidden coordinate. Hence the listed rows exhaust the local NameCert obligation surface. □

Theorem 836.5 (GroundCompiler audit-map non-escape)**.** *Every public read from an accepted* $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ *carrier factors through the displayed theorem inventory, conditional theorem cells, event-flow and channel legality, compiler theorem rows, generated recognizers, report boundaries, frontier rows, theorem-family handoff rows, componentwise transport, continuation, provenance, and local naming of Definition 836.1. Such a read cannot become hidden compiler input, host compiler trust, source text outside the legal channel, report evidence, motif identity, raw equality, kernel acceptance evidence, or MetaCIC proof evidence.*

Proof. Start from the NameCert obligations. They force every public read to choose one of the displayed coordinates $I, K, E, C, R, Q, F, X, H, T, P, N$.

The compiler rows E and C make legal event-flow and the no-hidden-input theorem family visible, while R and Q separate generated recognizers from report-like outputs. None of these rows contains a host source scan, host compiler trust token, or report-to-proof conversion.

The frontier and handoff rows F and X then record what remains outside the packet and where sibling consumers may read. Since handoff is routed through displayed rows rather than hidden imports, kernel acceptance and MetaCIC proof evidence remain in their own packets.

The omitted coordinates are exactly the advertised non-escape claims. Therefore no accepted carrier read can leave the finite audit-map packet. □

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapCarrier nonescape`

Theorem 836.6 (GroundCompiler audit-map theorem-family handoff)**.** *An accepted* GroundCompilerAuditMap$^{\uparrow}$ *carrier may hand theorem-family inventory to the audit-map interface of chapter 806, to the substitution audit sibling of chapter 779, and to GroundCompiler event-flow, recognizer, verdict, evidence-boundary, legal-channel, and audit-packet consumers only through the displayed handoff row X and the route row T. The handoff preserves conditional theorem cells as conditional cells and frontiers as frontier rows.*

Proof. Use the carrier projection and isolate X. This row is the only coordinate that names cross-map or sibling consumers, so every theorem-family handoff must pass through it.

The route row T supplies the displayed continuation from the inventory, conditional, compiler, recognizer, report-boundary, and frontier rows into X. A consumer therefore receives the same row class that was routed into the handoff.

Conditional theorem cells remain conditional because the carrier contains no coordinate turning K into an unconditional theorem. Frontier rows remain frontiers because F records outside claims rather than solved obligations.

Thus theorem-family handoff is a finite routed read, not an import of the target packet's hidden coordinates and not a discharge of the source packet's conditional or frontier rows. □

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapCarrier theorem family handoff`

Theorem 836.7 (GroundCompiler audit-map compiler-layer frontier)**.** *For an accepted* GroundCompilerAuditMap$^{\uparrow}$ *carrier, the compiler-layer frontier row F is the binding boundary between the concrete audit map and stronger compiler claims. It permits the packet to cite the no-hidden-input streaming compiler theorem family through C, but it does not close host compiler trust, a self-hosted compiler tower, kernel acceptance, MetaCIC reduction or typing evidence, report-to-proof conversion, motif identity, or unrestricted equality.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapCarrier compiler layer frontier`

Proof. Read the compiler theorem row C together with the frontier row F. The former records the available GroundCompiler theorem family, including the no-hidden-input streaming compiler theorem; the latter records which adjacent claims are outside the packet.

Now compare F with the remaining coordinates. Inventory, conditional theorem cells, event-flow rows, recognizer rows, report-boundary rows, and handoff rows can all be transported and

routed, but none of them is a carrier field for host compiler trust, self-hosting, kernel acceptance, MetaCIC proof evidence, report evidence, motif identity, or unrestricted equality.

Consequently the packet can expose the compiler-layer theorem family as finite audit data while keeping stronger compiler and proof claims outside the local NameCert surface. □

Theorem 836.8 (GroundCompiler audit-map conditional-cell preservation)**.** *For an accepted* $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ *carrier*

$$G = (I, K, E, C, R, Q, F, X, H, T, P, N),$$

every public read of the conditional theorem-cell row K preserves the named channel, generated recognizer, source-separation, and certificate-gate hypotheses recorded by the displayed rows H, T, P, N. No consumer of the packet may turn K into an unconditional theorem-inventory row, and every permitted handoff must keep K separate from the established inventory row I.

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapCarrier conditional cell preservation`

Proof. Project the carrier and isolate K. By the carrier definition, K is the unique coordinate for compiler facts that still require named channel, recognizer, source-separation, or certificate-gate data before they may be read.

The transport row H and route row T can replay K only as the same displayed conditional row. The provenance row P records the chapters and kernel objects from which this condition is named, while the local row N records that the NameCert surface is the $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ surface rather than the global theorem inventory.

Since the established theorem inventory has its own coordinate I, a consumer that receives K through H, T, P, N receives a conditional theorem-cell row, not an unconditional theorem row. The finite carrier has no coordinate that erases those hypotheses, so conditional-cell preservation follows. □

Theorem 836.9 (GroundCompiler audit-map report-boundary exactness)**.** *For an accepted* GroundCompilerAuditM *carrier, the report-boundary row Q exposes metric reports, motif reports, theorem code, chapter code, source reports, and audit summaries only as report data. The same row never supplies proof evidence, certificate evidence, kernel acceptance evidence, MetaCIC proof evidence, or a conversion from report data to any such evidence.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapCarrier report boundary exactness`

Proof. Use the carrier definition to identify Q as the only report-boundary coordinate. Its named contents are report-shaped outputs: metrics, motifs, theorem code, chapter code, source reports, and audit summaries.

Apply the NameCert obligation theorem to see that public readback of Q is a local NameCert obligation, and apply the non-escape theorem to the same read. The non-escape boundary excludes report evidence, kernel acceptance evidence, MetaCIC proof evidence, and report-to-proof conversion from every accepted carrier read.

Thus Q is exact as a boundary row. It exposes the listed reports as reports, while proof evidence and certificate evidence must come from their own certified rows or from another packet, never from the report-boundary coordinate. □

Theorem 836.10 (GroundCompiler audit-map frontier handoff non-escape)**.** *For an accepted* $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ *carrier, the handoff row X may route theorem inventory to the generic audit-map interface, the substitution audit sibling, and GroundCompiler consumers only while preserving K as a conditional theorem-cell row and F as a compiler-layer frontier row. Such handoff cannot import host compiler trust, kernel acceptance evidence, MetaCIC proof evidence, unrestricted equality, or report-as-proof conversion.*

Lean4 ✓ `BEDC.Derived.GroundCompilerAuditMapUp.GroundCompilerAuditMapCarrier frontier handoff nonescape`

Proof. Begin with the theorem-family handoff theorem. It makes X and the route row T the only displayed path from this packet to the audit-map interface, substitution audit sibling, and GroundCompiler consumers.

The conditional-cell preservation theorem keeps K conditional along that path. The compiler-layer frontier theorem keeps F as the row naming stronger compiler and proof claims that are outside the packet.

Now apply non-escape to the routed read through X. Because the carrier has no hidden coordinate for host compiler trust, kernel acceptance evidence, MetaCIC proof evidence, unrestricted equality, or report-as-proof conversion, handoff through X cannot import those coordinates from the consumer side. It only routes the finite inventory while preserving the conditional and frontier classes already present in the source packet. □

Theorem 836.11 (GroundCompiler audit-map public-consumer bridge)**.** *Any public consumer of an accepted* $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ *carrier receives the theorem-family handoff, report boundary, compiler-layer frontier, generated-recognizer rows, componentwise transport, replay, provenance, and local* NameCert *rows on the same displayed carrier route. The consumer may route the public audit-map surface through those rows, but it cannot turn report data into proof evidence, erase the conditional theorem-cell hypotheses, or treat a generated recognizer row as kernel acceptance.*

Proof. Start from the family handoff and frontier handoff non-escape theorems. They make the public route pass through the theorem-family handoff row, compiler-layer frontier row, and the same transport and replay rows before a consumer receives the packet.

Next use report-boundary exactness and conditional-cell preservation. These keep report data as report data and keep conditional theorem cells separate from established theorem inventory. The generated-recognizer rows are therefore consumer-visible only as named audit-map rows, not as proof or kernel-acceptance shortcuts.

Finally attach provenance and local naming. Rows P, N identify the carrier route as the $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ NameCert route, so every public consumer receives the displayed carrier surface and no report-to-proof conversion or kernel-acceptance shortcut. □

The mature paper-side treatment ties the theorem-inventory row I, conditional-cell row K, report-boundary row Q, frontier row F, and theorem-family handoff row X to the sibling AuditMapInterface and SubstitutionAuditMap consumers through the same displayed route T. The TasteGate target already recorded above is the AI-origin carrier discipline: it keeps the single carrier aligned while the audit-map and substitution consumers read the public surface without turning conditional cells, reports, or frontier rows into proof evidence.

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerAuditMap}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ packet is generated from established GroundCompiler theorem inventory, conditional theorem cells, event-flow and channel legality rows, compiler theorem rows, generated recognizer

rows, report-boundary rows, frontier rows, theorem-family handoff rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{GroundCompilerAuditMap}\uparrow}$, maturePackageClosed)

Scope closed: Definition 836.1, Definition 836.4, Definition 836.5, Definition 836.6, Definition 836.7, Definition 836.8, Definition 836.9, Definition 836.10, and the TasteGate target supply the paper-side carrier, NameCert obligation surface, nonescape boundary, family handoff, frontier, conditional-cell, and report-boundary rows for the finite GroundCompiler audit-map packet.

Formal verification: FormalStatus(NameCert$_{\mathsf{GroundCompilerAuditMap}\uparrow}$, encodedDef)

Lean target: `BEDC.Derived.GroundCompilerAuditMapUp.taste\_gate`

Bridge status: none

Not claimed: This chapter does not close host compiler trust, a self-hosted compiler tower, kernel acceptance, MetaCIC proof evidence, report-to-proof conversion, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: The mature paper-side treatment is complete; bridge checking and stronger formal verification remain read from the independent verification axis.

Chapter 837

A Concrete Naming Certificate for $\mathsf{ClosedNormalEndpointLedger}^{\uparrow}$

The $\mathsf{ClosedNormalEndpointLedger}^{\uparrow}$ packet records the endpoint rows consumed by the closed-normal consistency boundary of chapter 9376. It sits beside the main-result packet of chapter 764, the normal false-exclusion packet of chapter 732, and the closed-normal consistency packet of chapter 739: those siblings expose the checked theorem and the refusal of full closed consistency, while the present ledger keeps the endpoint rows available as one finite NameCert surface for downstream audit consumers.

Definition 837.1 (Closed-normal endpoint-ledger carrier)**.** *A* $\mathsf{ClosedNormalEndpointLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, L, B, F, R, H, C, P, N)$$

with the following visible rows:

1. *T is the typed-row displaying* $\mathsf{HasType}([], t, \mathsf{falseEncoding})$ *for the inspected endpoint;*
2. *L is the* $\mathsf{ClosedAt}(0, t)$ *row;*
3. *B is the* $\mathsf{BetaStrong}(t)$ *row;*
4. *F is the false-encoding row naming the internal false target read by T;*
5. *R is the contradiction-route row that consumes T, L, B, F through the closed-normal consistency theorem;*
6. *H records componentwise* hsame *transport for typing, closedness, beta-strong normality, false encoding, contradiction route, continuation, provenance, and naming rows;*
7. *C records the displayed* Cont *routes by which a consumer reads T, L, B, F, R without leaving the finite endpoint packet;*
8. *P is the* Pkg *provenance over chapter 9376, chapter 764, chapter 732, chapter 739,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalEndpointLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for subject reduction, arbitrary closed consistency, unrestricted normalization, host evaluation, quotient conversion, or a route from non-normal closed false proofs to the beta-strong endpoint.

Theorem 837.2 (Closed-normal endpoint-ledger NameCert obligations)**.** *For the carrier of Definition 837.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalEndpointLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for* $E = (T, L, B, F, R, H, C, P, N)$*, typed-row readback through* T*,* ClosedAt *readback through* L*, beta-strong readback through* B*, false-encoding readback through* F*, contradiction-route readback through* R*, componentwise* hsame *stability through* H*, displayed* Cont *route replay through* C*, provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.ClosedNormalEndpointLedgerUp.ClosedNormalEndpointLedgerTasteGate single carrier alignment`

Proof. Project the endpoint carrier first. The rows T, L, B, F are the three hypotheses and target row separated in chapter 9376: typed at the internal false encoding, closed at the empty context boundary, and already beta-strong.

Read R next. It is the only contradiction route of the packet, and it consumes exactly the displayed endpoint rows rather than an arbitrary closed proof candidate.

Finally inspect H, C, P, N. Componentwise transport preserves the endpoint rows, displayed continuations replay them, package provenance ties the ledger to the three sibling certificates, and the local name row registers the same finite surface. Since the carrier has no other coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 837.3 (Closed-normal endpoint-ledger normal boundary)**.** *Every accepted* $\mathsf{ClosedNormalEndpointLedger}^{\uparrow}$ *carrier exports only the closed beta-strong false-endpoint exclusion displayed by* T, L, B, F, R*. A downstream consumer may use the ledger to reject an endpoint already typed at the false encoding, already closed, and already beta-strong, but it obtains no full closed consistency theorem, no subject-reduction transport, and no hidden normalization route from arbitrary closed false proofs.*

Proof. Begin with the endpoint rows T, L, B, F. They are the exact boundary rows isolated by chapter 764 and chapter 739; none of them records an arbitrary reduction path.

Apply the contradiction route R only after those rows are present. This matches the normal false-exclusion surface of chapter 732: the route is available at the beta-strong endpoint and not before.

The transport, continuation, provenance, and naming rows H, C, P, N replay that same finite endpoint ledger. Because subject reduction, unrestricted normalization, host evaluation, quotient conversion, and full closed consistency are absent from the carrier, no public consumer can read them from the ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedNormalEndpointLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedNormalEndpointLedger}^{\uparrow}$ packet is generated from typed-row, ClosedAt-row, BetaStrong-row, false-encoding row, contradiction-route row, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClosedNormalEndpointLedger}^{\uparrow}}$, seed)

Scope closed: Definition 837.1, Definition 837.2, and Definition 837.3 bind the endpoint ledger for closed beta-strong false-exclusion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClosedNormalEndpointLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close full closed consistency, subject reduction, unrestricted normalization, host evaluation, quotient conversion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-row readback, contradiction-route readback, transport, continuation, provenance, naming, and non-escape for the same finite ledger.

Chapter 838

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailSchedule}^{\uparrow}$

The $\mathsf{RegularCauchyTailSchedule}^{\uparrow}$ packet realizes the finite precision-to-cofinal-tail schedule used by the Real completeness route of chapter 9238. It sits between the diagonal selector surface of chapter 697, the shared-threshold packet of chapter 560, and the tail-fusion packet of chapter 658. The packet records only displayed BHist rows: no quotient stream equality, host real equality, selected completed limit, unbounded diagonal stream, or ambient completeness theorem is exported.

Definition 838.1 (Regular Cauchy tail schedule carrier)**.** *A* $\mathsf{RegularCauchyTailSchedule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, R, W, D, K, T, M, F, E, H, C, P, N)$$

with the following displayed coordinates:

1. *Q is the finite precision-request row consumed by the Real and Completion route;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row whose tails are scheduled;*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule selected for Q;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint ledger for the selected windows;*
5. *K is the cofinal-index row naming the finite tail bound reached by the schedule;*
6. *T is the finite tail-witness row read from R, W, D, K;*
7. *M is the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *shared-threshold packet available to consumers that compare the scheduled tail with another tail;*
8. *F is the* $\mathsf{RegularCauchyTailFusion}^{\uparrow}$ *consumer row that may fuse the displayed tail witness with the downstream diagonal readback;*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing handoff row reached only after Q, R, W, D, K, T, M, F are displayed;*
10. *H stores componentwise* hsame *transports for the precision request, source row, window schedule, dyadic ledger, cofinal index, tail witness, sibling consumer rows, seal-facing row, provenance, and local name;*
11. *C stores the displayed* Cont *routes from precision request to window selection, cofinal tail choice, tail witness, shared-threshold read, tail-fusion read, and seal-facing handoff;*

12. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, $\mathsf{RegularCauchyTailFusion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSchedule}^{\uparrow}}$ *row.*

The carrier is the finite schedule row linking a precision request to one displayed cofinal tail. It contains no coordinate for a host-level subsequence, quotient stream equality, selected Real limit, or ambient completeness principle.

Theorem 838.2 (Regular Cauchy tail schedule NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSchedule}^{\uparrow}}$ *surface for the carrier of Definition 838.1 consists exactly of five obligation rows:*

1. *carrier admission for the finite packet $S = (Q, R, W, D, K, T, M, F, E, H, C, P, N)$;*
2. *classifier stability under the displayed* hsame *transports of H for the precision request, source row, windows, dyadic ledger, cofinal index, tail witness, sibling consumer rows, seal-facing row, provenance, and local name;*
3. *schedule exactness, which forces every cofinal-tail read to pass through Q, R, W, D, K, T before any sibling consumer can inspect it;*
4. *downstream consumer handoff, which routes shared-threshold reads through chapter 560, tail-fusion reads through chapter 658, and selector-origin reads through chapter 697;*
5. *ledger non-escape for the* Cont, Pkg, *and local* NameCert *rows, excluding quotient stream equality, host real equality, selected completed limits, unbounded diagonal streams, and ambient completeness witnesses.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailScheduleUp.RegularCauchyTailScheduleTasteGate single carrier alignment`

Proof. Project the carrier S. Its first six coordinates name the precision request, the regular rational source, the selected finite windows, the dyadic ledger, the cofinal index, and the finite tail witness. These rows give the schedule exactness route.

Next inspect the sibling consumer coordinates. The shared-threshold row M is the only tail-meet handoff, and the tail-fusion row F is the only fusion handoff. The chapter links them to the displayed sibling certificates, while the selector-origin route is read through the diagonal-tail selector sibling.

Finally use the structural rows H, C, P, N. They transport the same displayed coordinates, replay the same finite continuations, record package provenance, and name the local certificate. Since the carrier has no coordinate for quotient streams, host equality, selected limits, unbounded diagonal objects, or ambient completeness, the five rows exhaust the local naming surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSchedule}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailSchedule}^{\uparrow}$ packet is generated from a precision request, $\mathsf{RegSeqRat}^{\uparrow}$ source row, finite $\mathsf{StreamName}^{\uparrow}$ window schedule, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, cofinal-index row, displayed tail witness, sibling $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ and $\mathsf{RegularCauchyTailFusion}^{\uparrow}$ consumer rows, $\mathsf{Real}^{\uparrow}$ seal-facing handoff, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyTailSchedule}^{\uparrow}}$, seed)

Scope closed: Definition 838.1 and Definition 838.2 bind the finite precision-to-cofinal-tail schedule used between diagonal selection, shared-threshold meet, tail fusion, and the Real-facing seal route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyTailSchedule}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close quotient stream equality, host real equality, selected completed limits, unbounded diagonal streams, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, schedule exactness, sibling-consumer handoff, and ledger non-escape for the same finite schedule packet.

Definition 838.3 (Regular Cauchy tail schedule handoff route)**.** *For an accepted* $\mathsf{RegularCauchyTailSchedule}^{\uparrow}$ *carrier*

$$S = (Q, R, W, D, K, T, M, F, E, H, C, P, N),$$

the seal-facing handoff route $\mathsf{regular_cauchy_tail_schedule_handoff_route}(S)$ *is the displayed finite route in* C *whose entrance rows are*

$$Q, R, W, D, K, T, M, F$$

and whose terminal row is the $\mathsf{Real}^{\uparrow}$ *handoff row* E*. The route is read only after the precision request, regular rational source row, finite window schedule, dyadic ledger, cofinal index, tail witness, shared-threshold consumer row, and tail-fusion consumer row have all been displayed. Its transport data are exactly the componentwise* hsame *rows stored in* H*, with provenance and local naming rows* P, N*.*

Theorem 838.4 (Regular Cauchy tail schedule seal-facing route determinacy)**.** *Let*

$$S = (Q, R, W, D, K, T, M, F, E, H, C, P, N)$$

and

$$S' = (Q', R', W', D', K', T', M', F', E', H', C', P', N')$$

be accepted $\mathsf{RegularCauchyTailSchedule}^{\uparrow}$ *carriers. Suppose the two packets have componentwise* hsame *transports aligning*

$$Q, Q', \quad R, R', \quad W, W', \quad D, D', \quad K, K', \quad T, T', \quad M, M', \quad F, F', \quad P, P', \quad N, N',$$

and suppose the displayed continuation rows C *and* C' *present the same finite handoff route from the aligned entrance rows* Q, R, W, D, K, T, M, F *to the seal-facing endpoints* E *and* E'*. Then*

$$\mathsf{hsame}(E, E').$$

Thus two accepted schedule packets with the same precision request, $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{StreamName}^{\uparrow}$ *window schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, cofinal index, tail witness, sibling consumer rows, transport rows, continuation route, provenance, and naming row determine the same* $\mathsf{Real}^{\uparrow}$ *seal-facing handoff up to* hsame*.*

Proof. Project both carriers using Definition 838.1. In each packet, the only seal-facing coordinate is the row E or E', and it is downstream of the displayed entrance rows Q, R, W, D, K, T, M, F.

By Definition 838.2, schedule exactness forces every cofinal-tail read to pass through Q, R, W, D, K, T before any sibling consumer can inspect it, and downstream consumer handoff then routes the shared-threshold and tail-fusion reads through M and F before the seal-facing handoff is available. Hence the terminal seal read in either packet is not an independent Real row; it is the endpoint of the finite continuation route named in Definition 838.3.

The assumed componentwise transports align the two entrance surfaces. After this alignment, the terminal clauses of C and C' are two displayed Cont derivations with the same left history and the same finite right route, one ending at E and the other ending at E'. Applying continuation determinacy from Definition 18.16 gives $\mathsf{hsame}(E, E')$.

The sibling rows are only consumer rows in this argument. The shared-threshold packet M and the tail-fusion row F are read before the seal route, and neither adds a second seal endpoint to the schedule carrier. Since the carrier has no coordinate for quotient stream equality, host real equality, selected completed limits, unbounded diagonal streams, hidden tail oracles, or ambient completeness, no alternate seal-facing route remains. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailScheduleUp.RegularCauchyTailSchedule seal facing route determinacy`

Chapter 839

A Concrete Naming Certificate for $\mathsf{AuditMapDependencyWeave}^{\uparrow}$

The $\mathsf{AuditMapDependencyWeave}^{\uparrow}$ packet realizes the audit-map family methodology of chapter 9406 as finite cross-map routing data. It sits beside the frontier index of chapter 812 and the family ledger of chapter 810: those chapters name frontier rows and family inventories, while this packet records how local maps, neighbouring maps, obstruction rows, frontier rows, and synthesis consumers are woven into one inspectable $\mathsf{NameCert}$ surface.

Definition 839.1 (Audit-map dependency weave carrier)**.** *An* $\mathsf{AuditMapDependencyWeave}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, L, O, F, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the local audit-map row whose positive, conditional, obstruction, and frontier cells are being routed;*
2. *L is the neighbouring-map link row, naming exactly the adjacent audit maps that may receive or supply a frontier dependency;*
3. *O is the obstruction row recording the blocked obligations that prevent a local frontier entry from being closed inside M;*
4. *F is the frontier row recording the strongest claim available at the boundary between M and the neighbouring maps named by L;*
5. *S is the synthesis-consumer row recording the downstream consumers that may read the frontier route without discharging it;*
6. *H records the componentwise* hsame *transports for local-map rows, neighbouring-map links, obstruction rows, frontier rows, synthesis-consumer rows, dependency packages, and local provenance;*
7. *C records the displayed* Cont *routes by which a consumer reaches exactly those local, neighbouring, obstruction, frontier, and synthesis rows;*
8. *P is the* Pkg *provenance over* BHist*, audit-map family rows, obstruction rows, frontier rows, synthesis consumers,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *data;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditMapDependencyWeave}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden discharge of O, a proof of F, an unlisted neighbouring map, or a synthesis consumer outside S.

Theorem 839.2 (Audit-map dependency weave NameCert obligations)**.** *For the carrier of Definition 839.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapDependencyWeave}^{\uparrow}}$ *surface consists of carrier admission for $W = (M, L, O, F, S, H, C, P, N)$, exact neighbouring-map link readback through L, obstruction visibility through O, frontier visibility through F, synthesis-consumer boundary through S, componentwise transport through H, displayed continuation through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.AuditMapDependencyWeaveUp.AuditMapDependencyWeaveTasteGate single carrier alignment`

Proof. Carrier admission is the displayed finite packet. The rows $M, L, O, F, S, H, C, P, N$ are the only coordinates that a local certificate can project.

The link, obstruction, frontier, and consumer obligations are row projections. A neighbouring-map read must pass through L, an obstruction read through O, a frontier read through F, and a synthesis-consumer read through S.

Transport and continuation are then fixed by H and C. The package row P and local naming row N bind those reads to the same finite BHist packet, so no hidden discharge, unlisted neighbouring map, or external synthesis consumer can enter the surface. □

Theorem 839.3 (Audit-map dependency weave cross-map consumer boundary)**.** *Every cross-map consumer of an accepted* $\mathsf{AuditMapDependencyWeave}^{\uparrow}$ *carrier reads the local map M, neighbouring-map link L, obstruction row O, frontier row F, and synthesis-consumer row S through the displayed* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}$ *routes H, C, P, N. The consumer may route a frontier dependency between named maps, but it cannot replace the route by an unlisted map, erase the obstruction row, or turn the frontier row into a closed theorem.*

Lean4 ✓ `BEDC.Derived.AuditMapDependencyWeaveUp.AuditMapDependencyWeaveCrossMapConsumerBoundary`

Proof. Project the accepted carrier $W = (M, L, O, F, S, H, C, P, N)$. The local and neighbouring map data are visible only in M and L, while the obstruction, frontier, and synthesis-consumer data are visible only in O, F, S.

Apply the obligation surface of Definition 839.2. It routes every public read through H, C, P, N and keeps the consumer at the displayed packet boundary.

Thus a cross-map consumer can follow the named route, but the packet gives no coordinate for an unlisted neighbour, a removed obstruction, or a proof of the frontier entry. □

Theorem 839.4 (Audit-map dependency weave frontier non-escape)**.** *For every accepted* $\mathsf{AuditMapDependencyWea}$ *carrier, the frontier row F remains a named boundary row. It may be transported along H, reached by C, packaged by P, and consumed by the synthesis rows S, but it cannot escape as a hidden theorem, a discharged obstruction, a global audit-map closure claim, or a consumer route not recorded in $M, L, O, F, S, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.AuditMapDependencyWeaveUp.AuditMapDependencyWeaveFrontierNonEscape`

Proof. Read the frontier coordinate from Definition 839.1. The row F is stored beside the obstruction row O and the synthesis-consumer row S, so it is not a proof object by itself.

Use Definition 839.3 for downstream reads. Every consumer route remains inside the displayed $M, L, O, F, S, H, C, P, N$ packet.

The non-escape claim is now the carrier inventory. Since no coordinate names a hidden theorem, discharged obstruction, global closure claim, or unrecorded consumer, the frontier row can only remain the visible boundary row of the weave. □

Lean4 ✓ `BEDC.Derived.AuditMapDependencyWeaveUp.AuditMapDependencyWeaveFrontierNonescape`

Theorem 839.5 (Audit-map dependency weave route admission)**.** *An* AuditMapDependencyWeave$^{\uparrow}$ *route is admitted only as the displayed finite packet*

$$W = (M, L, O, F, S, H, C, P, N).$$

The local map row, neighbouring-map link, obstruction row, frontier row, synthesis-consumer row, componentwise transports, displayed continuations, package provenance, and local NameCert *row are all part of the admitted route, and no unlisted map, hidden frontier proof, or external synthesis row is accepted.*

Proof. Project the carrier of Definition 839.1. The packet has exactly the rows $M, L, O, F, S, H, C, P, N$ and no coordinate for an unlisted map, hidden proof, or external synthesis row.

Apply the NameCert obligations of Definition 839.2. They bind carrier admission, neighbouring-map readback, obstruction visibility, frontier visibility, synthesis-consumer boundary, transports, continuations, package provenance, and local naming to those rows.

The cross-map consumer boundary of Definition 839.3 then keeps every public read inside the same packet. Thus route admission accepts exactly the displayed weave. □

Lean4 ✓ `BEDC.Derived.AuditMapDependencyWeaveUp.AuditMapDependencyWeaveRouteAdmission`

Theorem 839.6 (Audit-map dependency weave obstruction ledger)**.** *For every admitted* AuditMapDependencyWeav *route, the obstruction row O remains a visible ledger row. It may be transported by H, reached by C, packaged by P, and read by the local* NameCert *row N, but it is never discharged as a theorem, erased from the frontier route, or replaced by a global audit-map closure claim.*

Proof. Read O from the carrier of Definition 839.1. It is a coordinate of the finite packet, stored beside the frontier row F and synthesis-consumer row S.

Use the obligation surface of Definition 839.2. Obstruction visibility is one of the local certificate obligations, so a consumer must keep O displayed when it follows the route.

Finally apply the frontier non-escape theorem Definition 839.4. Since the frontier cannot escape as a hidden theorem or discharged obstruction, the obstruction ledger remains visible and undischarged. □

Lean4 ✓ `BEDC.Derived.AuditMapDependencyWeaveUp.AuditMapDependencyWeaveObstructionLedger`

Theorem 839.7 (Audit-map dependency weave synthesis NameCert package)**.** *Every downstream synthesis consumer reading the row S of an admitted* AuditMapDependencyWeave$^{\uparrow}$ *packet reaches it only through the named local-map row M, neighbouring-map link L, obstruction ledger O, frontier row F, componentwise transport row H, displayed continuation row C, package provenance row P, and local* NameCert *row N. The package lets the consumer route the visible dependency, but not discharge the obstruction, prove the frontier row, or import a synthesis consumer outside S.*

Proof. Start with route admission from Definition 839.5. It fixes S as one coordinate of the displayed packet $W = (M, L, O, F, S, H, C, P, N)$.

Next use the obstruction ledger of Definition 839.6. The consumer cannot read S while erasing O, because obstruction visibility is part of the same packet route.

Finally combine the cross-map consumer boundary of Definition 839.3 with frontier non-escape from Definition 839.4. These rows force every synthesis read through M, L, O, F, H, C, P, N and leave no coordinate for an external synthesis row, hidden obstruction discharge, or frontier proof. □

Lean4 ✓ `BEDC.Derived.AuditMapDependencyWeaveUp.AuditMapDependencyWeaveSynthesisNameCertPackage`

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapDependencyWeave}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapDependencyWeave}^{\uparrow}$ packet is generated from a local audit-map row, neighbouring-map link row, obstruction row, frontier row, synthesis-consumer row, componentwise transports, displayed continuation routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapDependencyWeave}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 839.1, Definition 839.2, Definition 839.3, Definition 839.4, Definition 839.5, Definition 839.6, and Definition 839.7 bind the carrier, obligations, route admission, obstruction ledger, and displayed synthesis NameCert package as the displayed bridge scope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditMapDependencyWeave}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close hidden discharge of obstruction rows, proof of frontier rows, global audit-map closure, Lean verification, or bridge checking.

Upgrade path: Further closure requires Lean verification and bridge checking for the displayed carrier admission, neighbouring-map link readback, obstruction visibility, frontier visibility, synthesis-consumer boundary, componentwise transport, displayed continuation, provenance, and local naming rows.

Chapter 840

A Concrete Naming Certificate for $\mathsf{SubstitutionContext}^{\uparrow}$

The $\mathsf{SubstitutionContext}^{\uparrow}$ packet realizes the context-indexed rows of chapter 9380 as one finite NameCert carrier. It sits beside the binder seal of chapter 621, the closed-term boundary of chapter 527, the beta-preservation packet of chapter 716, and the typed endpoint packet of chapter 562. Its role is to keep shift, substitute, closed composition, generator closure, and subject-reduction handoff rows visible as finite context audit data without exporting an unrestricted substitution calculus.

Definition 840.1 (Substitution context audit carrier)**.** *A* $\mathsf{SubstitutionContext}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, S, U, M, G, B, E, H, K, P, N)$$

with the following displayed rows:

1. *X is the context row naming the source context, binder depth, and visible substitution window;*
2. *S is the shift row recording the context movement supplied by the substitution audit map;*
3. *U is the substitute row recording the context-indexed substitution readback;*
4. *M is the closed-composition row tying the shift and substitute reads to the same closed boundary;*
5. *G is the generator-closure row for the finite shift and substitution generators;*
6. *B is the binder-seal row read through chapter 621;*
7. *E is the subject-reduction handoff row read through the beta-preservation and typed-normal-form boundary surfaces;*
8. *H records componentwise* hsame *transports for context rows, shift rows, substitution rows, composition rows, generator rows, binder rows, handoff rows, package rows, and local certificate rows;*
9. *K records the displayed* Cont *routes for reading the shift, substitute, closed-composition, generator-closure, binder-seal, and handoff rows;*
10. *P is the* Pkg *provenance over chapter 9380, chapter 621, chapter 527, chapter 716, chapter 562,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SubstitutionContext}^{\uparrow}}$ *row.*

The carrier has no coordinate for host substitution semantics, unrestricted substitution commutation, semantic equality of terms, closed subject reduction, or a hidden dependent-typing bridge.

Lean4 (definition) `BEDC.Derived.SubstitutionContextAuditUp.SubstitutionContextAuditCarrier`
Lean4 ✓ `BEDC.Derived.SubstitutionContextAuditUp.SubstitutionContextAuditTasteGate` single carrier alignment

Theorem 840.2 (Substitution context audit NameCert obligations)**.** *For the carrier of Definition 840.1, the local* $\mathsf{NameCert}_{\mathsf{SubstitutionContext}^{\uparrow}}$ *surface consists exactly of carrier exposure for*

$$Q = (X, S, U, M, G, B, E, H, K, P, N),$$

shift-row exposure, substitute-row exposure, closed-composition exposure, generator-closure exposure, binder-seal exposure, subject-reduction handoff exposure, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and non-escape from host substitution semantics, unrestricted substitution commutation, semantic equality of terms, closed subject reduction, and hidden dependent-typing bridges.*

Proof. Carrier exposure is projection from Definition 840.1. The finite packet lists exactly the rows $X, S, U, M, G, B, E, H, K, P, N$.

The substitution-facing obligations are the rows S, U, M, G. They expose shift, substitution, closed composition, and generator closure as the context-indexed audit rows described in chapter 9380.

The sibling boundary obligations are the rows B and E. The binder row reads through chapter 621, while the handoff row is bounded by chapter 716 and chapter 562.

Transport, replay, provenance, and naming are confined to H, K, P, N. Since no remaining coordinate stores host substitution semantics, unrestricted commutation, semantic equality, closed subject reduction, or a dependent-typing bridge, the displayed rows exhaust the local obligations. □

Lean4 ✓ `BEDC.Derived.SubstitutionContextAuditUp.SubstitutionContextAuditNameCertObligation`

Theorem 840.3 (Substitution context audit binder route)**.** *Let* $Q = (X, S, U, M, G, B, E, H, K, P, N)$ *be an accepted* $\mathsf{SubstitutionContext}^{\uparrow}$ *carrier. Every public read from the context-indexed shift and substitute rows into the binder boundary factors through the displayed context row* X*, the shift row* S*, the substitute row* U*, the closed-composition row* M*, the generator-closure row* G*, the binder-seal row* B*, and the replay route in* K*.*

Proof. Project the accepted carrier. The context source is X, and the substitution audit content is displayed by S, U, M, G.

The binder-facing coordinate is B. Its provenance points to chapter 621, so the binder read is a sibling packet read rather than an implicit rule about all binders.

The route row K replays the context, substitution, closed-composition, generator, and binder reads. The componentwise transport and package rows H and P preserve that same finite route, so every binder-boundary access factors through the displayed rows. □

Lean4 ✓ `BEDC.Derived.SubstitutionContextAuditUp.SubstitutionContextAuditBinderRoute`

Theorem 840.4 (Substitution context audit context admission)**.** *Let* $Q = (X, S, U, M, G, B, E, H, K, P, N)$ *be an accepted* $\mathsf{SubstitutionContext}^{\uparrow}$ *carrier. Every context-indexed substitution read admits the source context only through the displayed context row* X *together with* $S, U, M, G, B, E, H, K, P, N$*. A downstream subject-reduction consumer cannot replace* X *by host context semantics, unrestricted weakening, semantic term equality, or a hidden dependent-typing bridge.*

Proof. Project the carrier of Definition 840.1. The source context, binder depth, and visible substitution window are displayed in X, while S, U, M, G record the shift, substitute, closed-composition, and generator-closure reads over that same context row.

Apply Definition 840.3. The binder-facing side of the read factors through X, S, U, M, G, B and the replay route K, so binder admission is not supplied by an ambient context theory.

The handoff, transport, package, and naming rows E, H, P, N preserve the same displayed route for downstream subject-reduction consumers. Apply Definition 840.5 to exclude host substitution semantics, unrestricted commutation, semantic equality of terms, closed subject reduction, and hidden dependent-typing bridges.

Therefore the only context admission surface available to the packet is X together with the displayed finite rows $S, U, M, G, B, E, H, K, P, N$. □

Lean4 ✓ `BEDC.Derived.SubstitutionContextAuditUp.SubstitutionContextAuditContextAdmission`

Theorem 840.5 (Substitution context audit non-escape)**.** *Every accepted* $\mathsf{SubstitutionContext}^{\uparrow}$ *carrier exports substitution audit information only through*

$$X, S, U, M, G, B, E, H, K, P, N.$$

A consumer may read the context row, shift row, substitute row, closed-composition row, generator-closure row, binder-seal row, handoff row, componentwise transports, displayed continuation routes, package provenance, and local naming row. It cannot replace those rows by host substitution semantics, unrestricted substitution commutation, semantic equality of terms, closed subject reduction, or a hidden dependent-typing bridge.

Proof. Begin with the packet inventory of Definition 840.1. The rows X, S, U, M, G give the context-indexed substitution audit surface.

The rows B and E connect that audit surface to sibling packets. The binder route is bounded by Definition 840.3, and the handoff row is recorded as finite packet data rather than as the closed subject-reduction theorem.

The remaining rows H, K, P, N transport, replay, package, and name the same finite carrier. No carrier coordinate names host substitution semantics, unrestricted commutation, semantic equality, closed subject reduction, or a hidden dependent-typing bridge, so those objects cannot be exported. □

Lean4 ✓ `BEDC.Derived.SubstitutionContextAuditUp.SubstitutionContextAuditNonEscape`

Theorem 840.6 (Substitution context audit ledger exactness)**.** *For an accepted* $\mathsf{SubstitutionContext}^{\uparrow}$ *carrier* $Q = (X, S, U, M, G, B, E, H, K, P, N)$*, the ledger exposed to downstream subject-reduction consumers is exactly the finite context audit packet over shift, substitute, closed composition, generator closure, binder seal, closed-boundary provenance, beta-preservation handoff, and typed-normal-form endpoint rows. The ledger does not identify these rows with host substitution semantics or with a closed subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.SubstitutionContextAuditUp.SubstitutionContextAuditLedgerExactness`

Proof. Read the local obligations from Definition 840.2. They expose the carrier rows and require the shift, substitute, closed-composition, generator, binder, handoff, transport, replay, provenance, and naming surfaces to remain in one packet.

The closed-boundary provenance is supplied by chapter 527. The beta-preservation and typed endpoint rows are sibling surfaces from chapter 716 and chapter 562.

The handoff row E therefore exports a finite ledger to later subject-reduction consumers. By Definition 840.5, the ledger has no route through host substitution semantics or closed subject reduction, so its exact content is the displayed packet. □

Theorem 840.7 (Substitution context audit MetaCIC scope)**.** *For an accepted* $\mathsf{SubstitutionContext}^{\uparrow}$ *packet* $Q = (X, S, U, M, G, B, E, H, K, P, N)$*, every substitution-context row is scoped only through typed classifier membership, finite residual frontier rows, closure-preservation audit rows, and local* NameCert *transport and replay. The packet does not claim subject reduction, confluence, evaluator equality, quotient syntax equality, or kernel consistency.*

Proof. Project the carrier of Definition 840.1. The context row X, shift row S, substitute row U, closed-composition row M, and generator-closure row G are the only rows that can carry substitution-context data.

Apply the local obligations of Definition 840.2. They force every substitution-context read to expose the displayed carrier rows, binder-seal row, subject-reduction handoff row, componentwise transport, replay, provenance, and local naming before any downstream consumer can use the packet.

Use the binder route and context admission theorems, Definition 840.3 and Definition 840.4. These bind the typed classifier membership side of the read to $X, S, U, M, G, B, E, H, K, P, N$ rather than to a host context semantics.

Finally combine non-escape and ledger exactness from Definition 840.5 and Definition 840.6. The finite residual frontier and closure-preservation audit rows are the displayed sibling handoff rows in the ledger, while H, K, P, N only transport, replay, source, and name that finite surface. No coordinate remains for subject reduction, confluence, evaluator equality, quotient syntax equality, or kernel consistency. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubstitutionContext}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SubstitutionContext}^{\uparrow}$ packet is generated from a context row, shift row, substitute row, closed-composition row, generator-closure row, binder-seal row, subject-reduction handoff row, componentwise transports, continuation routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubstitutionContext}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 840.1, Definition 840.2, Definition 840.3, Definition 840.5, and Definition 840.6 bind the context-indexed substitution audit rows as a finite NameCert packet with sibling binder, closed-boundary, beta-preservation, and typed-normal-form handoff surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubstitutionContext}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host substitution semantics, unrestricted substitution commutation, semantic equality of terms, closed subject reduction, global normalization, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires explicitly binding the shift, substitute, closed-composition, generator-closure, binder-route, beta-preservation, typed-normal-form, BHist, hsame, Cont, Pkg, and NameCert rows inside each proof route.

Chapter 841

A Concrete Naming Certificate for TwinSubstrateAuditBridge$^{\uparrow}$

The TwinSubstrateAuditBridge$^{\uparrow}$ packet realizes the twin-substrate architecture of chapter 9392 as a finite bridge packet between two audit surfaces. It sits beside the shared audit-map interface of chapter 806, the synthesis packet of chapter 845, and the audit-coupling packet of chapter 847: those siblings name the common audit-map rows, the architecture-level handoff, and the paired audit coupling, while this chapter names the finite NameCert bridge by which a consumer can read MetaCIC and GroundCompiler audit rows together without treating either substrate as proof of the other.

Definition 841.1 (Twin-substrate audit-bridge carrier)**.** *A* TwinSubstrateAuditBridge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, G, A, R, H, C, P, N)$$

with the following visible rows:

1. *M is the MetaCIC audit-surface row, recording closed-CIC theorem inventory, proof-theoretic boundary rows, substitution and closedness rows, and named blocker rows as MetaCIC-side audit data;*
2. *G is the GroundCompiler audit-surface row, recording event-flow, source-channel, generated recognizer, certificate-gate, report-boundary, non-input, and non-evidence rows as compiler-side audit data;*
3. *A is the alignment row, displaying which MetaCIC audit row and which GroundCompiler audit row are compared by a project-level consumer;*
4. *R is the refusal and non-impersonation ledger, recording that compiler reports, source channels, recognizers, metric rows, and host-side artifacts do not become MetaCIC proof evidence, and that MetaCIC theorem, reduction, substitution, confluence, normalization, consistency, and blocker rows do not become compiler input or generated compiler evidence;*
5. *H records componentwise* hsame *transports for M, G, A, R, continuation routes, provenance, and local naming;*
6. *C records displayed* Cont *routes by which a consumer inspects M, G, A, and R in finite order;*
7. *P is the* Pkg *provenance over chapter 9392, chapter 806, chapter 845, chapter 847,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*

8. N is the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditBridge}^{\uparrow}}$ *row.*

The classifier accepts exactly those packets whose paired reads factor through the displayed tuple B and whose refusal ledger remains visible at every handoff. It rejects any packet with an undisplayed equality between M and G, any conversion from compiler report to proof evidence, any conversion from MetaCIC theorem row to compiler input, or any bridge row that hides the NameCert carrier.

Theorem 841.2 (Twin-substrate audit-bridge NameCert obligations)**.** *For every accepted* TwinSubstrateAuditBridg *carrier*

$$B = (M, G, A, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditBridge}^{\uparrow}}$ *surface consists exactly of MetaCIC audit-surface readback through M, GroundCompiler audit-surface readback through G, alignment readback through A, refusal and non-impersonation ledger replay through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 841.1. The packet has exactly the rows M, G, A, R, H, C, P, N, so carrier admission and local classifier exactness are coordinate reads from the same finite BHist object.

Read the two audit surfaces before reading the bridge rows. The MetaCIC row M supplies closed-CIC audit data, and the GroundCompiler row G supplies compiler-facing audit data. The alignment row A records that a downstream consumer is comparing the two rows, but it does not identify their evidence kinds.

The refusal ledger R supplies the non-impersonation clauses. It is replayed through the displayed hsame and Cont rows H and C, with provenance recorded by P and the local NameCert row recorded by N. Since no other coordinate is present, the listed rows exhaust the NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.TwinSubstrateAuditBridgeUp.TwinSubstrateAuditBridgeTasteGate single carrier alignment`

Theorem 841.3 (Twin-substrate audit-bridge non-escape)**.** *Every public read from an accepted* $\mathsf{TwinSubstrateAuditBridge}^{\uparrow}$ *carrier factors through*

$$M, G, A, R, H, C, P, N.$$

The read may compare the MetaCIC and GroundCompiler audit rows through the alignment row and may replay the refusal ledger, but it cannot turn compiler reports, source-channel rows, generated recognizers, metric rows, or host-side artifacts into MetaCIC proof evidence, and it cannot turn MetaCIC theorem, reduction, substitution, confluence, normalization, consistency, or blocker rows into compiler input or generated compiler evidence.

Proof. Start with the NameCert obligations of Definition 841.2. Any public read must first choose one of the displayed rows of B.

For compiler-facing data, the only source is G. The refusal ledger R records that reports, source channels, generated recognizers, metric rows, and host-side artifacts remain compiler-side audit data.

For MetaCIC-facing data, the only source is M. The same ledger records that theorem rows, reduction rows, substitution rows, confluence rows, normalization rows, consistency rows, and blocker rows remain MetaCIC-side audit data.

The alignment row A and the routes H, C only transport and replay those displayed rows. They contain no equality, coercion, hidden input, or code-as-proof coordinate. Therefore no accepted public read escapes the twin-substrate boundary. □

Theorem 841.4 (Twin-substrate audit-bridge consumer handoff)**.** *Every consumer handoff from an accepted* $\mathsf{TwinSubstrateAuditBridge}^{\uparrow}$ *carrier to an audit-map, synthesis, coupling, or self-compilation reader is a finite handoff of the packet rows* M, G, A, R, H, C, P, N*. The receiving reader may cite the bridge as a NameCert surface aligning two audit namespaces, but it may not cite the bridge as subject reduction, compiler correctness, hidden input, code-as-proof, or a checked bridge theorem.*

Proof. Use the displayed continuation row C. It is the only route by which a consumer receives the MetaCIC row, the GroundCompiler row, the alignment row, and the refusal ledger.

The sibling audit-map and synthesis chapters determine the permitted reading shape. chapter 806 supplies the common audit-map interface, chapter 845 supplies the architecture-level handoff, and chapter 847 supplies a paired audit-coupling surface.

The handoff therefore exports the displayed NameCert packet and its provenance, not a theorem in either substrate. The exclusions follow from the absence of carrier coordinates for subject reduction, compiler correctness, hidden input, code-as-proof, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditBridge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TwinSubstrateAuditBridge}^{\uparrow}$ packet is generated from a MetaCIC audit-surface row, a GroundCompiler audit-surface row, an alignment row, a refusal and non-impersonation ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 841.1, Definition 841.2, Definition 841.3, and Definition 841.4 bind the finite bridge carrier, NameCert obligation surface, non-escape ledger, and consumer handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, compiler correctness, hidden input exclusion beyond the displayed refusal ledger, code-as-proof exclusion beyond the displayed refusal ledger, Lean verification, audit cleanliness, axiom cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, MetaCIC row exactness, GroundCompiler row exactness, alignment exactness, refusal-ledger replay, non-impersonation, consumer handoff, transport, continuation, provenance, and local naming for the same finite packet.

Chapter 842

TwinSubstrateRoundtrip NameCert Construction

The $\mathsf{TwinSubstrateRoundtrip}^{\uparrow}$ packet is the finite cross-substrate certificate for the architecture of chapter 9392. It keeps the MetaCIC audit rows of chapter 9385 separate from the GroundCompiler audit rows of chapter 836, while reusing the substitution-context handoff of chapter 840 to identify the closed-calculus rows that may be read by the compiler-facing report. The carrier records a roundtrip boundary, not a merged substrate.

Definition 842.1 (TwinSubstrateRoundtrip carrier)**.** *A* $\mathsf{TwinSubstrateRoundtrip}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, G, S, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the MetaCIC audit row, read through the closed-calculus audit family of chapter 9385;*
2. *G is the GroundCompiler audit row, read through the finite compiler packet of chapter 836;*
3. *S is the substitution-context audit row of chapter 840, naming exactly the closed-calculus context data that the roundtrip may expose to the compiler side;*
4. *B is the boundary ledger stating which roundtrip reads are MetaCIC reads, which are GroundCompiler reads, and which are shared only through the displayed substitution-context row;*
5. *H records componentwise* hsame *transports for M, G, S, B and the local structural rows;*
6. *C records the displayed* Cont *routes for MetaCIC inspection, GroundCompiler inspection, substitution-context handoff, and boundary-ledger replay;*
7. *P is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *the MetaCIC audit surface, the GroundCompiler audit surface, and the substitution-context audit surface;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateRoundtrip}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed rows M, G, S, B, H, C, P, N.

Theorem 842.2 (TwinSubstrateRoundtrip NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateRoundtrip}^{\uparrow}}$ *surface for Definition 842.1 consists of carrier admission, MetaCIC audit-row exposure, GroundCompiler audit-row exposure, substitution-context handoff exposure, boundary-ledger exactness, componentwise* hsame *stability, displayed* Cont *route stability,* Pkg *provenance, and non-escape from host compilation evidence, hidden closed-CIC transport, compiler reports promoted to proofs, or a collapsed one-substrate reading.*

Proof. Carrier admission is the tuple $T = (M, G, S, B, H, C, P, N)$ of Definition 842.1. The rows M and G are separate coordinates, so a consumer can inspect the MetaCIC audit side and the GroundCompiler audit side without identifying them.

The substitution-context row S is the only shared handoff coordinate. It names the closed-calculus context data that may be read across the boundary, and the boundary ledger B records whether a roundtrip read is MetaCIC-facing, GroundCompiler-facing, or shared through that row.

The structural rows H, C, P, N supply only transport, continuation replay, provenance, and local naming for the displayed packet. Since the carrier has no coordinate for host compilation evidence, hidden closed-CIC transport, proof evidence extracted from compiler reports, or a one-substrate collapse, the listed obligations exhaust the local NameCert surface. □

Theorem 842.3 (TwinSubstrateRoundtrip substrate separation)**.** *Every accepted* $\mathsf{TwinSubstrateRoundtrip}^{\uparrow}$ *packet preserves the substrate separation stated in chapter 9392. A MetaCIC-facing consumer may read only* M, S, B, H, C, P, N*, a GroundCompiler-facing consumer may read only* G, S, B, H, C, P, N*, and a cross-substrate consumer must pass through the displayed substitution-context row* S *and boundary ledger* B *before either audit row is used.*

The packet exports no theorem turning GroundCompiler reports into MetaCIC proof evidence, no compiler-side replacement for the MetaCIC frontier, no hidden host compiler input, and no collapsed audit namespace.

Proof. Project the carrier rows. The MetaCIC audit row M and the GroundCompiler audit row G are different coordinates, while the only shared coordinate is the substitution-context row S together with the boundary ledger B.

Use the MetaCIC synthesis of chapter 9385 to read M as a closed-calculus audit surface. Use the GroundCompiler NameCert of chapter 836 to read G as a compiler-facing audit packet. The substitution-context chapter chapter 840 supplies the shared context route, but it does not identify the two audit rows.

The boundary ledger B and structural rows H, C, P, N route every cross-substrate read through the displayed packet. Therefore no consumer can replace the MetaCIC frontier by a compiler report, import hidden host compiler input, or collapse the two audit namespaces into one substrate. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateRoundtrip}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TwinSubstrateRoundtrip}^{\uparrow}$ packet is generated from finite BHist rows for MetaCIC audit data, GroundCompiler audit data, a substitution-context handoff, boundary ledger, transports, continuations, provenance, and local naming. The roundtrip keeps the two substrate rows separate and uses Cont to route any shared read through the displayed substitution-context row before either side is consumed. Componentwise hsame preserves MetaCIC, GroundCompiler, context, and boundary rows without merging them, while Pkg records the synthesis and audit dependencies. The packet names a cross-substrate boundary, not a unified substrate.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TwinSubstrateRoundtrip}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the TwinSubstrateRoundtrip carrier, NameCert obligations, substrate separation theorem, and boundary-ledger route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TwinSubstrateRoundtrip}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim compiler reports as MetaCIC proof evidence, hidden closed-CIC transport, host compiler input, or collapse of the two audit namespaces.

Upgrade path: Obligation closure requires Lean encodings of the roundtrip carrier, substitution-context handoff, substrate-separation theorem, and boundary non-escape.

Chapter 843

A Concrete Naming Certificate for $\mathsf{TwinSubstrateAuditPacket}^{\uparrow}$

The $\mathsf{TwinSubstrateAuditPacket}^{\uparrow}$ surface makes the architecture of chapter 9392 into one finite concrete-instance packet. It reads the compiler-facing side through chapter 827 and the closed-CIC audit side through chapter 776, while keeping the two non-escape ledgers separate.

Definition 843.1 (TwinSubstrateAuditPacket carrier)**.** *A* $\mathsf{TwinSubstrateAuditPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (G, M, A, B, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{GroundCompilerAuditPacket}^{\uparrow}$ *route carrying event-flow, source-channel, recognizer, certificate-gate, report-boundary, module-inventory, no-hidden-input, and compiler export rows;*
2. *M is the* $\mathsf{MetaCICAuditSynthesisPacket}^{\uparrow}$ *route carrying subject-reduction obstruction, confluence, normalization, substitution, decidable-checking, closed-normal assembly, and blocker rows;*
3. *A is the cross-substrate address row naming which compiler artifact route is read against which closed-CIC audit route;*
4. *B is the boundary ledger with one compiler non-escape side and one MetaCIC blocker side;*
5. *H records componentwise* hsame *transports for the compiler route, MetaCIC route, address row, boundary ledger, route, package, and local naming rows;*
6. *C records displayed* Cont *routes by which consumers read G, M, A, and B without identifying their evidence kinds;*
7. *P is the* Pkg *provenance over the twin-substrate architecture, the GroundCompiler audit packet, the MetaCIC audit synthesis packet,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditPacket}^{\uparrow}}$ *row.*

The classifier accepts exactly those packets whose consumer reads factor through the displayed tuple T and whose compiler-facing evidence remains separated from closed-CIC proof evidence. It rejects any packet that treats a compiler report as a MetaCIC theorem, a MetaCIC blocker as a compiler input, a source-channel row as proof evidence, or a closed-CIC audit row as a generated compiler artifact.

Lean4 ✓ BEDC.Derived.TwinSubstrateAuditPacketUp.TasteGate.TwinSubstrateAuditPacketTasteGate single carrier alignment

Theorem 843.2 (TwinSubstrateAuditPacket NameCert obligation surface)**.** *For every accepted* $\mathsf{TwinSubstrateAuditPacket}^{\uparrow}$ *carrier*

$$T = (G, M, A, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditPacket}^{\uparrow}}$ *surface consists exactly of GroundCompiler audit-packet readback through* G*, MetaCIC audit-synthesis readback through* M*, cross-substrate address readback through* A*, separate compiler and MetaCIC boundary readback through* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 843.1. Its visible rows are precisely G, M, A, B, H, C, P, N, so local carrier admission and classifier exactness are coordinate reads from the same finite packet.

Read the two substrate routes separately. The row G is interpreted by the GroundCompiler audit packet, while M is interpreted by the MetaCIC audit synthesis packet. The address row A records their pairing but does not merge the evidence types.

Finally read B, H, C, P, N. The boundary ledger preserves the compiler non-escape side and the MetaCIC blocker side as distinct rows, and the transport, continuation, package, and naming rows only replay that displayed separation. Hence the NameCert obligation surface is exhausted by the packet. □

Theorem 843.3 (TwinSubstrateAuditPacket non-escape)**.** *Every consumer of an accepted* TwinSubstrateAuditPack *carrier factors through*

$$G, M, A, B, H, C, P, N.$$

The consumer may inspect the GroundCompiler audit route, the MetaCIC audit-synthesis route, the cross-substrate address row, and the two-sided boundary ledger. It cannot convert compiler reports, source-channel rows, generated recognizers, or metric boundaries into MetaCIC proof evidence, and it cannot convert MetaCIC reduction, typing, normalization, confluence, or blocker rows into hidden compiler input or generated compiler evidence.

Proof. Start with Definition 843.2. Every accepted read is already routed through the finite NameCert surface of T.

For compiler-facing reads, use the GroundCompiler audit packet route carried by G. Its non-escape ledger keeps report rows, source-channel rows, generated recognizers, and metric boundaries on the compiler side of the packet.

For MetaCIC-facing reads, use the audit synthesis route carried by M. Its blocker ledger keeps closed-CIC obstruction and proof-theoretic rows inside the MetaCIC side.

The address row A only records which two routes are being compared in the project-level audit story, and B records the two refusals without adding a conversion row. Since the carrier has no coordinate that identifies the two evidence kinds, no consumer can escape the displayed twin-substrate boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditPacket}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TwinSubstrateAuditPacket}^{\uparrow}$ packet is generated from a GroundCompiler audit-packet row, a MetaCIC audit-synthesis row, a cross-substrate address row, a two-sided boundary ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditPacket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 843.1, Definition 843.2, and Definition 843.3 bind the finite twin-substrate carrier, classifier, NameCert surface, and separate non-escape ledgers.

Formal verification: FormalStatus(NameCert$_{\mathsf{TwinSubstrateAuditPacket}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, full closed consistency, self-hosted compiler trust, report-to-proof conversion, cross-substrate evidence identity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, GroundCompiler route readback, MetaCIC route readback, address and boundary ledger exactness, separate non-escape rows, transport, route replay, provenance, and local naming for the displayed finite packet.

Chapter 844

A Concrete Naming Certificate for $\mathsf{ClosedConsistencyGap}^{\uparrow}$

The $\mathsf{ClosedConsistencyGap}^{\uparrow}$ packet realizes the audit boundary of chapter 9385 as finite BEDC data. It sits beside the subject-reduction packet of chapter 483 and the typed normal-form endpoint of chapter 562: the first names the preservation-facing route, the second names the terminal normal-form surface, and this packet records why the closed-normal consistency branch cannot be read as unconditional closed consistency until the subject-reduction discharge socket is supplied.

Definition 844.1 (ClosedConsistencyGap carrier)**.** *A* $\mathsf{ClosedConsistencyGap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, N, S, D, T, H, C, P, L)$$

with the following displayed coordinates:

1. *A is the MetaCIC audit-synthesis row that separates closed-normal consistency from unconditional closed consistency;*
2. *N is the closed-normal branch row, including the normal-form false exclusion and closed-normal assembly reads;*
3. *S is the subject-reduction handoff row, read through the finite preservation surface of chapter 483;*
4. *D is the discharge-socket row for the missing subject-reduction bundle, naming the dependent-codomain, application, lambda, and product preservation slots as finite obligations;*
5. *T is the typed normal-form endpoint row, read through chapter 562;*
6. *H records componentwise* hsame *transports for the audit row, closed-normal row, subject-reduction row, discharge socket, typed normal-form row, package row, and local naming row;*
7. *C records the* Cont *routes by which a consumer reads the closed-normal branch, the subject-reduction socket, and the terminal normal-form endpoint;*
8. *P is the* Pkg *provenance over chapter 9385, chapter 483, chapter 562,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{ClosedConsistencyGap}^{\uparrow}}$ *row.*

The carrier has no coordinate for a filled subject-reduction discharge bundle, a hidden transport from arbitrary closed proofs to closed normal endpoints, a global Church–Rosser theorem, candidate-free normalization, or a completed proof of unconditional closed consistency.

Lean4 ✓ BEDC.Derived.ClosedConsistencyGapUp.ClosedConsistencyGapTasteGate single carrier alignment

Theorem 844.2 (ClosedConsistencyGap NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ClosedConsistencyGap}^{\uparrow}}$ *surface for Definition 844.1 consists of carrier admission for* $G = (A, N, S, D, T, H, C, P, L)$*, closed-normal branch exposure through* N *and* T*, subject-reduction socket exposure through* S *and* D*, componentwise* hsame *transport through* H*, displayed* Cont *route replay through* C*, package provenance through* P*, and local naming through* L*.*

Proof. Project the finite packet. The audit row A, closed-normal row N, subject-reduction row S, discharge socket D, typed normal-form row T, transport row H, continuation row C, provenance row P, and local certificate row L are the whole carrier surface.

Read the positive endpoint through N and T. These rows expose closed-normal consistency and the terminal typed normal-form boundary as named finite data, with their public reads transported only through H and replayed through C.

Read the blocked transport through S and D. The subject-reduction row is a handoff to the preservation-facing sibling, while the discharge socket records the missing bundle as obligations rather than as a supplied theorem. Since the carrier lists no filled bundle coordinate, the local certificate stops at the displayed gap. □

Theorem 844.3 (ClosedConsistencyGap route exhaustion)**.** *Every consumer route out of an accepted* $\mathsf{ClosedConsistencyGap}^{\uparrow}$ *packet factors through the displayed rows* $A, N, S, D, T, H, C, P, L$*. A closed-normal consistency read reaches* N *and* T*; a preservation-facing read reaches* S *and* D*; and no route converts agreement on the remaining rows into a closed subject-reduction theorem or unconditional closed consistency.*

Proof. Start with the continuation row C. Its named routes are exactly the closed-normal branch route, the subject-reduction socket route, and the terminal normal-form endpoint route.

The closed-normal branch is exhausted by N and T. The sibling typed normal-form packet supplies a finite endpoint boundary, but that boundary is still read only after normality is already displayed.

The subject-reduction side is exhausted by S and D. The preservation-facing sibling names the route a discharge would use, while the socket row keeps the missing discharge bundle visible. Thus H, C, P, L can transport and replay the packet, but cannot create an extra route outside it. □

Theorem 844.4 (ClosedConsistencyGap non-escape)**.** *An accepted* $\mathsf{ClosedConsistencyGap}^{\uparrow}$ *carrier exports only the finite audit gap packet over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It does not export a filled subject-reduction discharge bundle, a hidden closed-proof transport, an unrestricted confluence theorem, candidate-free normalization, host conversion, erased derivation semantics, or unconditional closed consistency.*

Proof. Inspect the carrier inventory of Definition 844.1. Every public coordinate is either an audit row, a closed-normal row, a subject-reduction socket row, a typed normal-form endpoint, a componentwise transport, a continuation route, package provenance, or local naming.

Use the obligation surface to authenticate those rows. The local NameCert accepts carrier exposure, branch exposure, socket exposure, transport, route replay, provenance, and naming, all over the same finite packet.

No excluded object is a coordinate of G. A consumer therefore cannot replace the discharge socket by a proof, cannot transport arbitrary closed proofs into the normal endpoint, and cannot read unconditional closed consistency from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedConsistencyGap}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedConsistencyGap}^{\uparrow}$ packet is generated from a MetaCIC audit-synthesis row, a closed-normal branch row, a subject-reduction handoff row, a discharge-socket row, a typed normal-form endpoint row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedConsistencyGap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 844.1, Definition 844.2, Definition 844.3, and Definition 844.4 state the finite packet, obligation surface, route exhaustion, and non-escape boundary for the MetaCIC closed-consistency gap.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedConsistencyGap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close subject reduction, arbitrary closed Church–Rosser, candidate-free normalization, hidden proof transport, unconditional closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-normal branch exposure, subject-reduction socket exposure, route exhaustion, non-escape, package provenance, and local naming for the same finite gap packet.

Chapter 845

A Concrete Naming Certificate for TwinSubstrateSynthesis$^{\uparrow}$

The TwinSubstrateSynthesis$^{\uparrow}$ packet realizes the twin-substrate architecture of chapter 9392 as a finite cross-substrate audit object. It sits beside the shared audit-map interface of chapter 806 and the GroundCompiler audit-map packet of chapter 836: those siblings supply the generic audit rows and the compiler-facing theorem-family boundary, while this chapter names the finite route that keeps MetaCIC and GroundCompiler reads separate until a displayed cross-substrate handoff is chosen.

Definition 845.1 (Twin-substrate synthesis packet)**.** *A* TwinSubstrateSynthesis$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, G, I, A, F, X, H, C, P, N)$$

with the following visible rows:

1. *M is the MetaCIC audit-surface row, recording closed-calculus theorem inventory, conditional fronts, and obstruction boundaries named by chapter 9392;*
2. *G is the GroundCompiler audit-surface row, recording event-flow, recognizer, report-boundary, cannot-claim, and theorem-family data from chapter 836;*
3. *I is the shared audit-map interface row read through chapter 806;*
4. *A is the architecture row naming the permitted cross-substrate handoff from compiler-facing artifacts to closed-CIC audit obligations;*
5. *F is the frontier row separating MetaCIC open proof-theoretic boundaries from GroundCompiler pipeline boundaries;*
6. *X is the finite consumer row for downstream chapters that need both substrate names without importing either substrate's hidden coordinates;*
7. *H records componentwise* hsame *transports for the MetaCIC row, GroundCompiler row, interface row, architecture row, frontier row, consumer row, provenance row, and local naming row;*
8. *C records displayed* Cont *routes by which a consumer reads M, G, I, A, F, X in finite order;*
9. *P is the* Pkg *provenance over chapter 9392, chapter 806, chapter 836,* BHist, hsame, Cont, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateSynthesis}^{\uparrow}}$ *row.*
The carrier has no coordinate for collapsing MetaCIC into GroundCompiler, turning compiler reports into proof evidence, importing hidden host structure, or discharging a MetaCIC frontier by a compiler-layer row.

Theorem 845.2 (Twin-substrate synthesis NameCert obligations)**.** *For every accepted* $\mathsf{TwinSubstrateSynthesis}^{\uparrow}$ *carrier*

$$T = (M, G, I, A, F, X, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateSynthesis}^{\uparrow}}$ *surface consists exactly of MetaCIC row readback through M, GroundCompiler row readback through G, shared interface readback through I, architecture handoff through A, frontier separation through F, downstream consumer readback through X, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the finite carrier. Its first six coordinates are the only substrate, interface, architecture, frontier, and consumer rows available to the local certificate.

Read the substrate rows separately. The MetaCIC coordinate M records closed-calculus audit content and frontiers, while the GroundCompiler coordinate G records compiler-facing theorem-family and report-boundary content. The interface row I gives a common audit-map shape, but it does not identify the two substrate rows.

Next inspect A and F. The architecture row permits a named handoff only after the source substrate row has been displayed, and the frontier row records which claims remain outside that handoff. Thus a compiler-facing row cannot discharge a proof-theoretic frontier, and a MetaCIC theorem row cannot certify a hidden compiler input.

Finally, X, H, C, P, N route consumer reads, transport the same coordinates componentwise, and bind provenance with local naming. Since no other coordinate is present, the listed rows exhaust the NameCert obligation surface. □

Theorem 845.3 (Twin-substrate cross-substrate non-escape)**.** *Every public read from an accepted* $\mathsf{TwinSubstrateSynthesis}^{\uparrow}$ *carrier factors through the displayed MetaCIC row, GroundCompiler row, shared audit-map interface row, architecture handoff row, frontier row, downstream consumer row, transport row, continuation row, provenance row, and local naming row of Definition 845.1. Such a read cannot collapse the two substrates, convert a compiler report into proof evidence, import hidden host input, or solve a MetaCIC obstruction by a GroundCompiler route.*

Proof. Start with the NameCert obligations. They force every public read to choose one of the displayed coordinates $M, G, I, A, F, X, H, C, P, N$ before it can reach either substrate.

For a MetaCIC-facing read, the consumer receives M together with the architecture, frontier, transport, continuation, provenance, and naming rows. For a GroundCompiler-facing read, the consumer receives G through the same displayed routing discipline. The shared interface row I supplies common audit-map shape only after the substrate row remains visible.

The frontier row F records the non-conversions: report evidence is not proof evidence, compiler legality is not closed-CIC discharge, and hidden host input is not a carrier coordinate. The handoff row A therefore routes between named substrate surfaces without merging their claims.

Coordinate exhaustion gives the non-escape clause. The carrier contains no field for substrate collapse, report-to-proof conversion, hidden host import, or obstruction discharge, so no accepted public read can export one. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateSynthesis}^{\uparrow}}$.

Constructive story: A $\mathsf{TwinSubstrateSynthesis}^{\uparrow}$ packet is generated from a MetaCIC audit-surface row, a GroundCompiler audit-surface row, a shared audit-map interface row, an architecture handoff row, a frontier row, a downstream consumer row, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TwinSubstrateSynthesis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 845.1, Definition 845.2, and Definition 845.3 bind the finite cross-substrate audit packet and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TwinSubstrateSynthesis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close MetaCIC frontier obligations, prove GroundCompiler self-hosting, turn compiler reports into proof evidence, provide Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, substrate-row exactness, architecture handoff, frontier separation, consumer readback, transport, continuation, provenance, naming, and cross-substrate non-escape for the same finite packet.

Chapter 846

A Concrete Naming Certificate for TwinSubstrateAuditUp

The TwinSubstrateAuditUp packet gives the twin-substrate synthesis of chapter 9392 a concrete NameCert surface for audit handoff. It sits between the MetaCIC audit synthesis of chapter 9385 and the GroundCompiler audit map of chapter 9407, while the naming discipline follows the apophatic boundary of chapter 9400: each row names what may be read, and every absent conversion remains absent.

The audit handoff consumes the packetized row discipline of chapter 843 before aligning the MetaCIC and GroundCompiler audit rows, and the local carrier only replays those packet rows through M, G, A, H, C, P, N.

Definition 846.1 (Twin-substrate audit carrier)**.** *A* TwinSubstrateAuditUp *carrier is a finite* BHist *packet*

$$Q = (M, G, A, H, C, P, N)$$

with the following visible rows:

1. *M is the MetaCIC audit row, carrying the closed-calculus theorem inventory, conditional proof-theoretic fronts, and obstruction boundaries named by chapter 9385;*
2. *G is the GroundCompiler audit row, carrying the legal channel, generated recognizer, event-flow, report-boundary, and no-hidden-input rows named by chapter 9407;*
3. *A is the roundtrip alignment row that records which MetaCIC audit read and which GroundCompiler audit read are being compared at the handoff surface;*
4. *H records componentwise* hsame *transport for M, G, A, C, P, and N;*
5. *C records the displayed* Cont *routes through which a consumer reads the MetaCIC row, the GroundCompiler row, and the alignment row in finite order;*
6. *P is the* Pkg *provenance over chapter 9392, chapter 9385, chapter 9407, chapter 9400,* BHist*,* hsame*,* Cont*, and* NameCert *rows;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditUp}}$ *row.*

The carrier exports no subject-reduction proof, no compiler report as proof evidence, no hidden host input, and no collapse of the two audit substrates.

Theorem 846.2 (Twin-substrate audit NameCert obligations)**.** *For every accepted* TwinSubstrateAuditUp *carrier*

$$Q = (M, G, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditUp}}$ *surface consists exactly of MetaCIC audit readback through* M*, GroundCompiler audit readback through* G*, roundtrip alignment through* A*, componentwise transport through* H*, displayed continuation replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the finite carrier. Its coordinates are precisely the two audit rows, the alignment row, the transport row, the continuation row, the provenance row, and the local naming row.

Read M and G separately. The MetaCIC coordinate carries proof-theoretic audit status from chapter 9385; the GroundCompiler coordinate carries compiler-layer audit status from chapter 9407. The alignment coordinate A names a handoff comparison, but it does not identify the two audit rows.

Finally, H, C, P, and N transport, replay, package, and name those displayed rows. Since no other coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 846.3 (Twin-substrate audit roundtrip non-escape)**.** *Every public roundtrip read from an accepted* TwinSubstrateAuditUp *carrier factors through the displayed MetaCIC audit row, GroundCompiler audit row, roundtrip alignment row, componentwise* hsame *row, displayed* Cont *route,* Pkg *provenance, and local* NameCert *row of Definition 846.1. Such a read exports no subject-reduction proof, no compiler report as proof evidence, no hidden host input, and no collapse of the two audit substrates.*

Proof. Use the NameCert obligation surface. A public read must choose a displayed coordinate of Q and then follow the stored continuation route; there is no independent route around M, G, A, H, C, P, N.

For a MetaCIC-facing read, the consumer sees M and the alignment row that relates it to the compiler audit surface. For a GroundCompiler-facing read, the consumer sees G and the same alignment row. Componentwise hsame transport preserves the distinction between the rows being compared.

The excluded objects are not carrier coordinates. Subject-reduction proof evidence, compiler-report proof evidence, hidden host input, and substrate collapse therefore cannot be exported by any accepted roundtrip read. □

Theorem 846.4 (Twin-substrate audit vision concretization)**.** *The* TwinSubstrateAuditUp *carrier of Definition 846.1 concretizes the twin-substrate audit handoff of chapter 9392 as a finite NameCert packet. The concretization preserves the MetaCIC and GroundCompiler audit roles as separate rows, records their roundtrip alignment as a displayed row, and keeps the apophatic exclusions of chapter 9400 at the local naming boundary.*

Proof. The vision chapter names two cooperating audit substrates. The carrier supplies one finite row for the MetaCIC audit surface and one finite row for the GroundCompiler audit surface, so the two roles remain visible.

The roundtrip alignment row gives the concrete handoff point. It is read through displayed continuation routes and transported only componentwise, so it records comparison without turning one substrate into the other.

The local NameCert row then applies the naming discipline: what is present is named by M, G, A, H, C, P, N, and what is absent remains outside the packet. This is exactly the finite concrete surface claimed by the vision reading. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditUp}}$.

Constructive story: A TwinSubstrateAuditUp packet is generated from a MetaCIC audit row, a GroundCompiler audit row, a roundtrip alignment row, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditUp}}, \mathsf{seed})$

Scope closed: Definition 846.1, Definition 846.2, Definition 846.3, and Definition 846.4 bind the finite audit handoff packet and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditUp}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close subject reduction, prove compiler self-hosting, turn compiler reports into proof evidence, import hidden host input, collapse the two audit substrates, provide Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, audit-row exactness, alignment readback, transport, continuation, provenance, naming, and roundtrip non-escape for the same finite packet.

Chapter 847

A Concrete Naming Certificate for $\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}$

The $\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}$ packet realizes the twin-substrate audit architecture of chapter 9392 as one finite NameCert surface. It sits beside the GroundCompiler audit-map packet of chapter 836, the closed-window substitution route of chapter 824, the MetaCIC normalization frontier of chapter 892, and the two-history comparison packet of chapter 668. Those siblings already name one-substrate audit rows, normalization-frontier rows, or paired observation rows; this chapter names the finite coupling boundary that lets MetaCIC and GroundCompiler be read together without collapsing either substrate into the other.

Definition 847.1 (Twin-substrate audit-coupling carrier)**.** *A* $\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, G, R, L, C, H, T, P, N)$$

with the following visible rows:

1. *M is the MetaCIC audit row, recording closed-CIC reduction, closedness, substitution, normalisation, confluence, decidability, consistency, and subject-reduction boundary references as MetaCIC-side audit data;*
2. *G is the GroundCompiler audit row, recording event-flow, channel legality, generated recognizer, certificate gate, report boundary, non-input, and non-evidence references as compiler-side audit data;*
3. *R is the route classifier row, separating MetaCIC reads, GroundCompiler reads, and paired reads before any downstream consumer receives a coupled packet;*
4. *L is the coupling ledger, recording which public project-level audit claim reads both M and G and which substrate boundary remains attached to each read;*
5. *C is the non-collapse classifier row, marking MetaCIC proof evidence, kernel acceptance, and closed-CIC theorem content as unavailable from G, and marking host compiler trust, hidden input, source-channel legality, generated recognizers, and report artifacts as unavailable from M;*
6. *H records componentwise* hsame *transports for MetaCIC rows, GroundCompiler rows, route classifiers, coupling ledger entries, non-collapse classifiers, continuation rows, provenance, and local naming;*

7. *T records displayed* Cont *routes by which a consumer inspects M, G, R, L, C in finite order;*
8. *P is the* Pkg *provenance over chapter 9392, chapter 836, chapter 824, chapter 668,* BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}}$ *row.*

The carrier has no coordinate for converting GroundCompiler reports into MetaCIC proof evidence, no coordinate for reading MetaCIC closed-CIC facts as compiler input channels, no shared hidden equality between the two substrates, and no host-side project audit oracle outside the displayed packet.

Lean4 ✓ `BEDC.Derived.TwinSubstrateAuditCouplingUp.TwinSubstrateAuditCouplingTasteGate single carrier alignment`

Theorem 847.2 (Twin-substrate audit-coupling NameCert obligations)**.** *For every accepted* TwinSubstrateAuditCou *carrier*

$$U = (M, G, R, L, C, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}}$ *surface consists exactly of MetaCIC audit readback through M, GroundCompiler audit readback through G, route classification through R, paired coupling-ledger replay through L, non-collapse classification through C, componentwise* hsame *transport through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.TwinSubstrateAuditCouplingUp.TwinSubstrateAuditCouplingNameCertObligations`

Proof. Project the finite carrier. The first two rows expose the two audit substrates, and the next three rows record how they may be read together.

Read M and G first. The MetaCIC row carries closed-CIC audit content, while the GroundCompiler row carries compiler event-flow, recognizer, gate, report, non-input, and non-evidence content.

Then inspect R, L, C. The route classifier separates one-substrate reads from paired reads, the ledger records which public audit claim consumes both rows, and the non-collapse classifier keeps proof-evidence and compiler-channel claims on their proper sides.

Finally H, T, P, N replay transport, continuation, provenance, and naming over the same finite rows. Since the carrier lists no hidden equality or project oracle, the displayed rows exhaust the local NameCert obligations. □

Theorem 847.3 (Twin-substrate audit-coupling MetaCIC route)**.** *Every MetaCIC-facing public read from an accepted* $\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}$ *carrier factors through the MetaCIC row M, the route classifier R, the coupling ledger L, the non-collapse row C, and the displayed transport and continuation rows H, T. Such a read may cite the GroundCompiler row G only as paired audit context and cannot turn compiler reports, generated recognizers, hidden-input exclusions, or source-channel legality into MetaCIC proof evidence.*

Proof. Start with a MetaCIC-facing read. Carrier projection gives M as the only closed-CIC audit row and R as the classifier that records the read as MetaCIC-facing.

The ledger row L may attach a paired GroundCompiler context to the same project-level audit claim. That attachment is a ledgered reference to G, not a projection from G into proof evidence.

Use the non-collapse row C to preserve the boundary. It explicitly records that reports, recognizers, hidden-input exclusions, and source-channel legality remain compiler-side audit data.

Transport and continuation through H and T replay these rows componentwise. Therefore a MetaCIC-facing read remains a read of M with bounded paired context, not a conversion of GroundCompiler artifacts into MetaCIC proof evidence. □

Lean4 ✓ `BEDC.Derived.TwinSubstrateAuditCouplingUp.TwinSubstrateAuditCouplingCarrier metacic route`

Theorem 847.4 (Twin-substrate audit-coupling GroundCompiler route)**.** *Every GroundCompiler-facing public read from an accepted* $\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}$ *carrier factors through the GroundCompiler row G, the route classifier R, the coupling ledger L, the non-collapse row C, and the displayed transport and continuation rows H, T. Such a read may cite the MetaCIC row M only as paired audit context and cannot turn closed-CIC reduction, substitution, normalisation, confluence, decidability, consistency, or subject-reduction boundary rows into host compiler trust, hidden input, source-channel legality, or generated recognizer evidence.*

Proof. Begin with a GroundCompiler-facing read. Carrier projection gives G as the only compiler-side audit row and R as the classifier that marks the read as GroundCompiler-facing.

The ledger L may require the read to be accompanied by a MetaCIC audit row when the project-level claim mentions closed-CIC content. This accompaniment does not make M a compiler channel or a recognizer source.

The row C records the separating clauses. Closed-CIC reduction, substitution, normalisation, confluence, decidability, consistency, and subject-reduction boundaries remain MetaCIC-side data; host compiler trust, hidden input, source-channel legality, and generated recognizers remain GroundCompiler-side obligations.

Rows H and T preserve that separation under public transport and replay. Hence the GroundCompiler route is a read of G with paired MetaCIC context, not a compiler-side extraction from MetaCIC theorem rows. □

Theorem 847.5 (Twin-substrate audit-coupling non-collapse)**.** *An accepted* $\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}$ *carrier permits paired project-level audit reads only through the ledger row L and the route classifier row R. It does not identify M with G, does not make either substrate a subtype of the other, and does not export a common equality, shared proof evidence, shared compiler input, or host-side audit oracle outside the packet.*

Lean4 ✓ `BEDC.Derived.TwinSubstrateAuditCouplingUp.TwinSubstrateAuditCouplingCarrier noncollapse`

Proof. Project $U = (M, G, R, L, C, H, T, P, N)$. The two substrate rows are separate coordinates, and the only paired-read coordinates are R and L.

If a consumer asks for a project-level audit read, R classifies whether the read is MetaCIC-facing, GroundCompiler-facing, or paired. The ledger L records paired reads without changing the underlying row identities.

The non-collapse row C blocks the remaining identifications. It keeps proof evidence, kernel acceptance, theorem content, compiler trust, hidden input, source-channel legality, recognizers, and reports attached to their substrate rows.

Because the packet contains no equality oracle, common proof-evidence coordinate, common compiler-input coordinate, or host-side audit oracle, the two substrates remain coupled but not collapsed. □

Theorem 847.6 (Twin-substrate audit-coupling public export)**.** *Every public export of an accepted* $\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}$ *carrier is a finite packet export of* $M, G, R, L, C, H, T, P, N$*. The export may be consumed by audit-map, substitution-route, observation-coupling, or self-compilation readers only as a NameCert surface that preserves the MetaCIC/GroundCompiler distinction recorded in chapter 9392.*

Proof. Use the NameCert obligations. They list the full public surface as the substrate rows, route classifier, coupling ledger, non-collapse classifier, transport, continuation, provenance, and local name.

The sibling chapters provide permitted consumer shapes. chapter 836 reads GroundCompiler audit rows, chapter 824 reads a closed-window MetaCIC route boundary, and chapter 668 shows how a finite coupling ledger can serve a downstream reader without adding a global coordinate.

Normalization-frontier consumers may read the coupled export only after the MetaCIC row M, route classifier R, coupling ledger L, and non-collapse row C are displayed as the finite MetaCIC-side boundary of chapter 892.

An export to those consumers therefore carries the displayed packet and its provenance. It does not export a collapsed substrate, a hidden equality, or an ambient audit oracle. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}$ packet is generated from a MetaCIC audit row, a GroundCompiler audit row, route classifiers, a coupling ledger, non-collapse classifiers, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 847.1, Definition 847.2, Definition 847.3, Definition 847.4, Definition 847.5, and Definition 847.6 bind the finite paired MetaCIC/GroundCompiler audit-coupling packet, route classifiers, ledger, non-collapse boundary, and public export surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditCoupling}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close MetaCIC subject reduction, GroundCompiler host trust, self-hosting tower correctness, Lean verification, audit cleanliness, axiom cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, MetaCIC route readback, GroundCompiler route readback, paired ledger replay, non-collapse classification, public export exactness, transport, continuation, provenance, and naming for the same finite packet.

Chapter 848

TwinSubstrateAuditSynthesis NameCert construction

The $\mathsf{TwinSubstrateAuditSynthesis}^{\uparrow}$ packet realizes the twin-substrate synthesis of chapter 9392 as a finite NameCert object whose audit rows remain substrate-specific. It sits beside the MetaCIC audit synthesis of **??**, the GroundCompiler audit map of chapter 836, and the audit-map frontier packet of chapter 833: those siblings provide the two audit sources and the shared frontier discipline, while this chapter names their paired finite synthesis row.

Definition 848.1 (Twin-substrate audit-synthesis carrier)**.** *A* $\mathsf{TwinSubstrateAuditSynthesis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, G, A, H, C, P, N)$$

with the following displayed rows:

1. *M is a MetaCIC audit-synthesis row, read through* **??***;*
2. *G is a GroundCompiler audit-map row, read through chapter 836;*
3. *A is an audit-frontier alignment row, read through chapter 833, that records which MetaCIC boundary and which GroundCompiler boundary are being paired;*
4. *H records componentwise* hsame *transports for the MetaCIC row, GroundCompiler row, frontier alignment row, continuation row, package row, and local naming row;*
5. *C records displayed* Cont *routes by which consumers read M, G, and A without identifying their evidence kinds;*
6. *P is the* Pkg *provenance over chapter 9392,* **??***, chapter 836, chapter 833,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditSynthesis}^{\uparrow}}$ *row.*

The classifier accepts exactly the packets whose public reads factor through $S = (M, G, A, H, C, P, N)$ and whose frontier alignment keeps MetaCIC proof-theoretic residue separate from GroundCompiler report, recognizer, channel, and hidden-input boundaries.

Lean4 ✓ `BEDC.Derived.TwinSubstrateAuditSynthesisUp.TwinSubstrateAuditSynthesisTasteGate single carrier alignment`

Theorem 848.2 (TwinSubstrateAuditSynthesis NameCert obligations)**.** *For every accepted* TwinSubstrateAuditSyn *carrier*

$$S = (M, G, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditSynthesis}^{\uparrow}}$ *surface consists exactly of MetaCIC audit-synthesis readback through* M*, GroundCompiler audit-map readback through* G*, audit-frontier alignment through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 848.1. Its coordinates are precisely the two audit rows, the frontier alignment row, the transport row, the continuation row, the provenance row, and the local naming row.

Read the substrate rows separately. The MetaCIC row M carries the audit-synthesis surface, while the GroundCompiler row G carries the compiler-facing audit-map surface. The alignment row A names a shared frontier position, but it does not convert one row into the other.

Finally, H, C, P, N transport, replay, package, and name only those displayed coordinates. Since the carrier has no hidden equality, report-to-proof conversion, or compiler-input oracle, the listed rows exhaust the NameCert obligation surface. □

Theorem 848.3 (TwinSubstrateAuditSynthesis cross-map non-escape)**.** *Every public cross-map read from an accepted* $\mathsf{TwinSubstrateAuditSynthesis}^{\uparrow}$ *carrier factors through the displayed rows* M, G, A, H, C, P, N *of Definition 848.1. Such a read cannot turn a GroundCompiler report, recognizer, channel row, or hidden-input refusal into MetaCIC proof evidence, and it cannot turn a MetaCIC obstruction, closed-calculus theorem row, or subject-reduction residue into GroundCompiler input or compiler-side evidence.*

Proof. Start with the obligation surface of Definition 848.2. Every public read must first choose the MetaCIC row, the GroundCompiler row, or the frontier alignment row and then pass through the displayed continuation and transport rows.

For a MetaCIC-facing read, the consumer receives M with A, H, C, P, N as finite routing data. The GroundCompiler row G may be present as paired audit context, but the packet contains no coordinate that reclassifies report, recognizer, channel, or hidden-input data as proof evidence.

For a GroundCompiler-facing read, the consumer receives G with the same finite routing discipline. The MetaCIC row M may be cited as the paired audit-synthesis boundary, but the packet contains no coordinate that reclassifies closed-calculus theorem data, obstruction data, or subject-reduction residue as compiler input.

Thus the ledger cannot escape the displayed packet. Coordinate exhaustion over M, G, A, H, C, P, N preserves both refusal boundaries while allowing a finite paired audit read. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditSynthesis}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TwinSubstrateAuditSynthesis}^{\uparrow}$ packet is generated from a MetaCIC audit-synthesis row, a GroundCompiler audit-map row, an audit-frontier alignment row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditSynthesis}^{\uparrow}}$, seed)

Scope closed: Definition 848.1, Definition 848.2, and Definition 848.3 bind the finite paired audit-synthesis packet and its cross-map non-escape boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditSynthesis}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close MetaCIC subject reduction, GroundCompiler host trust, compiler self-reference, Lean verification, audit cleanliness, axiom cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, MetaCIC audit-synthesis readback, Ground-Compiler audit-map readback, frontier-alignment exactness, transport, continuation, provenance, naming, and cross-map non-escape for the same finite packet.

Chapter 849

A Concrete Naming Certificate for $\mathsf{AuditReexportNamespace}^{\uparrow}$

The $\mathsf{AuditReexportNamespace}^{\uparrow}$ packet realizes the audit reexport namespace layer of chapter 9392 as a finite NameCert carrier. It sits beside the twin-substrate packet of chapter 845 and the audit-map interface of chapter 806: those siblings name the two-substrate architecture and the generic audit-map consumer surface, while this chapter names the concrete namespace-addressing packet through which downstream audit readers cite the two reexport namespaces without collapsing them.

Definition 849.1 (Audit reexport namespace carrier)**.** *An* $\mathsf{AuditReexportNamespace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, G, S, L, B, R, P, N)$$

with the following visible rows:

1. *M is the* `BEDC.MetaCIC.Audit` *namespace row, recording the MetaCIC audit exports that may be cited as theorem-side audit addresses;*
2. *G is the* `BEDC.GroundCompiler.Audit` *namespace row, recording the GroundCompiler audit exports that may be cited as compiler-side audit addresses;*
3. *S records the substrate tag rows that classify each namespace address as MetaCIC-facing, GroundCompiler-facing, or a paired project-level citation;*
4. *L is the export-address ledger, listing the finite public addresses exposed by M and G and the local citation names by which consumers reach them;*
5. *B is the separation witness, marking compiler audit rows as unavailable as MetaCIC theorem rows and MetaCIC theorem rows as unavailable as compiler audit rows;*
6. *R is the consumer route, recording which downstream audit-map, twin-substrate, or self-compilation reader consumes the namespace packet and through which displayed continuation;*
7. *P is the* Pkg *provenance over chapter 9392, chapter 845, chapter 806,* BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditReexportNamespace}^{\uparrow}}$ *row.*

The carrier predicate is $\mathsf{AuditReexportNamespacePacket}(A)$*. Its public rows are exactly the two namespace rows, substrate tags, export-address ledger, separation witness, consumer route, package provenance, and local naming row.*

Theorem 849.2 (Audit reexport namespace NameCert obligations)**.** *For every accepted* $\mathsf{AuditReexportNamespace}^{\uparrow}$ *carrier*

$$A = (M, G, S, L, B, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AuditReexportNamespace}^{\uparrow}}$ *surface consists of five displayed obligation rows: carrier admission for the finite packet of Definition 849.1; namespace address readback for* M, G, L*; substrate-tag exactness for* S*; separation and nonconversion readback for* B*; and consumer-route, package, and local-name stability for* R, P, N *under the displayed* hsame *and* Cont *rows.*

Lean4 ✓ `BEDC.Derived.AuditReexportNamespaceUp.AuditReexportNamespaceTasteGate single carrier alignment`

Proof. Project the finite carrier. The tuple exposes the two namespace rows, the tag row, the ledger, the separation row, the consumer route, provenance, and local naming.

The first obligation is carrier admission for exactly those rows. The second reads the public namespace addresses through M, G, L, so a citation has a displayed export address before a consumer can use it.

The third and fourth obligations inspect S and B. The tag row classifies each address by substrate, and the separation witness records that the two address classes are not conversion rules.

Finally R, P, N bind the downstream route, package provenance, and local name to the same packet. Componentwise transport and continuation replay these rows without adding a hidden namespace equality, so the five displayed obligations exhaust the NameCert surface. □

Theorem 849.3 (Audit reexport namespace non-collapse)**.** *Every consumer of an accepted* AuditReexportNamespac *carrier may cite* `BEDC.MetaCIC.Audit` *through* M *and* `BEDC.GroundCompiler.Audit` *through* G *only along the displayed address ledger* L*, substrate tag row* S*, separation witness* B*, and route* R*. Such a citation cannot convert a compiler audit row into a MetaCIC theorem row, cannot convert a MetaCIC theorem row into a compiler audit row, and cannot export a shared hidden equality between the two namespace layers.*

Proof. Start from the NameCert obligations. They force every consumer citation to pass through the visible namespace rows and export-address ledger.

If the cited address is MetaCIC-facing, S tags it as a MetaCIC address and B records that compiler audit evidence is not available as a theorem row. The consumer route R may attach paired compiler context, but only as a ledgered citation through G, L.

If the cited address is GroundCompiler-facing, S tags it as a compiler-side audit address and B records that theorem rows are not compiler audit evidence. The paired MetaCIC context remains a cited namespace row, not a compiler artifact.

Because the packet has no coordinate identifying M with G and no conversion row between their evidence classes, the namespace layer gives two citeable audit surfaces while preserving the noncollapse boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditReexportNamespace}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AuditReexportNamespace}^{\uparrow}$ packet is generated from MetaCIC and GroundCompiler audit namespace rows, substrate tags, an export-address ledger, a separation witness, a consumer route, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AuditReexportNamespace}^{\uparrow}}$, seed)

Scope closed: Definition 849.1, Definition 849.2, and Definition 849.3 bind the finite two-substrate namespace packet, its five-row NameCert surface, and the boundary forbidding compiler-to-theorem or theorem-to-compiler conversion.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AuditReexportNamespace}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, audit cleanliness, axiom cleanliness, bridge checking, self-compilation correctness, or conversion between MetaCIC theorem evidence and GroundCompiler audit evidence.

Upgrade path: Obligation closure requires checked carrier admission, namespace address readback, substrate-tag exactness, separation readback, consumer-route stability, provenance, and local naming for the same finite packet.

Chapter 850

A Concrete Naming Certificate for $\mathsf{TwinSubstrateBridge}^{\uparrow}$

The $\mathsf{TwinSubstrateBridge}^{\uparrow}$ packet realizes the twin-substrate architecture of chapter 9392 as a finite bridge certificate. It sits beside the MetaCIC audit synthesis of **??**, the GroundCompiler audit map of chapter 836, and the audit-map frontier packet of chapter 833. Those sibling chapters provide the two substrate rows and the frontier boundary; this chapter records the bridge packet that lets a consumer read them together without identifying their audit ledgers.

Definition 850.1 (TwinSubstrateBridge carrier)**.** *A* $\mathsf{TwinSubstrateBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, G, F, R, L, H, C, P, N)$$

with the following visible rows:

1. *M is the MetaCIC audit-synthesis row consumed from* **??***;*
2. *G is the GroundCompiler audit-map row consumed from chapter 836;*
3. *F is the audit-map frontier packet row consumed from chapter 833;*
4. *R is the bridge-route classifier separating MetaCIC-facing, GroundCompiler-facing, and frontier-facing reads;*
5. *L is the two-sided bridge ledger recording which substrate row each read consumes;*
6. *H stores componentwise* hsame *transport for M, G, F, R, L;*
7. *C stores displayed* Cont *routes through the bridge rows;*
8. *P records* Pkg *provenance over the sibling chapters, the route classifier, the ledger, and the structural rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateBridge}^{\uparrow}}$ *row.*

The carrier has no row identifying M with G, no common audit equality, no compiler report promoted to MetaCIC proof evidence, and no MetaCIC derivation promoted to compiler acceptance.

Lean4 ✓ `BEDC.Derived.TwinSubstrateBridgeUp.TasteGate.TwinSubstrateBridgeTasteGate single carrier alignment`

Theorem 850.2 (TwinSubstrateBridge NameCert obligations)**.** *For every accepted* $\mathsf{TwinSubstrateBridge}^{\uparrow}$ *carrier $B = (M, G, F, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateBridge}^{\uparrow}}$ *surface consists exactly*

of carrier admission, MetaCIC audit-synthesis readback through M, GroundCompiler audit-map readback through G, frontier readback through F, bridge-route classification through R, two-sided ledger exactness through L, componentwise hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.TwinSubstrateBridgeUp.TwinSubstrateBridgeCarrier namecert obligations`

Proof. Project the carrier in Definition 850.1. The rows $M, G, F, R, L, H, C, P, N$ are the complete finite packet, so carrier admission and row readback are coordinate projections.

The route classifier R is read before the ledger L. A MetaCIC-facing read is therefore sent to M and may cite F only as frontier context; a GroundCompiler-facing read is sent to G and may cite F only as frontier context. The ledger row records this choice rather than replacing either substrate row.

The structural rows preserve the same packet. Componentwise hsame transport in H moves M, G, F, R, L without merging them, Cont replay in C exposes only displayed routes, and P, N repack the same rows as provenance and local naming. Hence the NameCert surface is exactly the stated finite obligation list. □

Theorem 850.3 (TwinSubstrateBridge carrier admission)**.** *Let $B = (M, G, F, R, L, H, C, P, N)$ be an accepted* TwinSubstrateBridge$^{\uparrow}$ *carrier. Carrier admission for B is exactly the finite projection that exposes the MetaCIC audit-synthesis row M, the GroundCompiler audit-map row G, and the audit-map frontier row F before any bridge route is consumed. No accepted carrier can expose R, L, H, C, P, N as bridge evidence while omitting one of M, G, F.*

Lean4 ✓ `BEDC.Derived.TwinSubstrateBridgeUp.TwinSubstrateBridgeCarrier carrier admission`

Proof. Project the carrier of Definition 850.1. The first three coordinates are the substrate rows that make the bridge meaningful: M supplies the MetaCIC side, G supplies the GroundCompiler side, and F supplies the frontier boundary between them.

The later coordinates are dependent public rows. The route classifier R can classify only requests between the displayed substrate sides, and the ledger L can record only reads whose substrate side has already been exposed.

The structural rows H, C, P, N preserve, replay, source, and name the same displayed packet. Since none of them manufactures a missing substrate coordinate, accepted carrier admission must expose M, G, F before the bridge evidence can be read. □

Theorem 850.4 (TwinSubstrateBridge replay stability)**.** *For every accepted* TwinSubstrateBridge$^{\uparrow}$ *carrier $B = (M, G, F, R, L, H, C, P, N)$, componentwise transport through H and displayed replay through C preserve the route separation recorded by R and L. A replayed MetaCIC-facing request still consumes M before frontier context, a replayed GroundCompiler-facing request still consumes G before frontier context, and a replayed bridge-facing request still compares the sides only through F and L.*

Proof. Read the route classifier R and ledger L before replay. They determine whether a request is MetaCIC-facing, GroundCompiler-facing, or bridge-facing, and they record which substrate row the request may consume.

Transport through H is componentwise. It moves the displayed rows M, G, F, R, L along hsame without adding a row that identifies M with G or changes the route assigned by R.

Replay through C follows the displayed continuation route after transport. Thus a MetaCIC-facing replay remains on the M side, a GroundCompiler-facing replay remains on the G side, and a

bridge-facing replay reaches both sides only through the frontier and ledger rows. The separation is therefore stable under the structural rows of the carrier. □

Theorem 850.5 (TwinSubstrateBridge ledger exactness)**.** *Every public read of an accepted* $\mathsf{TwinSubstrateBridge}^{\uparrow}$ *carrier* $B = (M, G, F, R, L, H, C, P, N)$ *factors through the route classifier* R *and the two-sided ledger* L *before a substrate row is consumed. Consequently, public consumers cannot read* M*,* G*, or* F *as unclassified substrate data; the only exported substrate access is the route- and ledger-recorded access named by the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateBridge}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.TwinSubstrateBridgeUp.TwinSubstrateBridgeCarrier ledger exactness`

Proof. Start with any public read of the packet. The NameCert obligations in Definition 850.2 expose the classifier and ledger as part of the finite public surface, so the read is first assigned a route by R and then recorded by L.

Only after this routing step may the read consume a substrate row. The MetaCIC route reads M, the GroundCompiler route reads G, and the bridge route uses F together with the ledger entry that records which side is being compared.

The remaining rows do not bypass this order. Componentwise transport in H, displayed replay in C, provenance in P, and local naming in N preserve the same routed read. Hence every exported substrate access is exactly the access registered by R, L and no unclassified read of M, G, F is public. □

Theorem 850.6 (TwinSubstrateBridge audit separation)**.** *Every public consumer of an accepted* $\mathsf{TwinSubstrateBridge}^{\uparrow}$ *carrier preserves the separation between the MetaCIC row* M *and the GroundCompiler row* G*. A MetaCIC-facing consumer may read* M, F, R, L, H, C, P, N*; a GroundCompiler-facing consumer may read* G, F, R, L, H, C, P, N*; and a bridge-facing consumer may compare the two only through the displayed frontier row* F *and ledger row* L*.*

Proof. Begin with the route classifier R. It assigns each consumer request to the MetaCIC-facing, GroundCompiler-facing, or bridge-facing route before any audit row is exposed.

For the MetaCIC route, the only audit row supplied by the carrier is M. The frontier row F and ledger row L can record compiler-side context, but no row of the packet converts G into proof evidence for M.

For the GroundCompiler route, the only compiler-facing audit row supplied by the carrier is G. The same frontier and ledger rows can record MetaCIC context, but no row converts M into compiler acceptance evidence.

The bridge route reads both sides only through F, L, H, C, P, N. These rows display comparison context, transport, continuation, provenance, and naming; they do not add a common substrate equality. Thus every public consumer preserves the two audit ledgers as distinct coordinates of the same finite packet. □

Theorem 850.7 (TwinSubstrateBridge non-escape)**.** *An accepted* $\mathsf{TwinSubstrateBridge}^{\uparrow}$ *carrier exports no hidden common substrate, host audit oracle, compiler proof checker, MetaCIC evaluator, collapsed equality between* M *and* G*, or frontier-closing theorem. Every exported read factors through the finite rows* $M, G, F, R, L, H, C, P, N$ *and through the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateBridge}^{\uparrow}}$ *surface.*

Proof. Read the packet through Definition 850.2. The local NameCert row exposes only the displayed carrier, sibling readbacks, route classifier, ledger, transport, continuation, provenance, and local naming rows.

Apply Definition 850.6. Any request involving both substrates must pass through the frontier and ledger rows, so the packet cannot manufacture a common equality or a shared audit oracle.

The sibling chapters provide only their own named surfaces: MetaCIC synthesis, GroundCompiler audit mapping, and audit-map frontier accounting. Since the bridge carrier has no coordinate for a compiler proof checker, MetaCIC evaluator, hidden host oracle, or frontier-closing theorem, none of those objects can be exported by a consumer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{TwinSubstrateBridge}^{\uparrow}$ packet is generated from a MetaCIC audit-synthesis row, a GroundCompiler audit-map row, an audit-map frontier row, a bridge-route classifier, a two-sided bridge ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TwinSubstrateBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 850.1, Definition 850.2, Definition 850.6, and Definition 850.7 bind the finite bridge carrier, local NameCert obligation surface, audit separation, and non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TwinSubstrateBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, a public standard bridge, a common substrate equality, compiler proof checking, MetaCIC evaluation, frontier closure, or host audit automation.

Upgrade path: Formal closure requires checked carrier admission, substrate readback, route classification, ledger exactness, componentwise transport, continuation replay, provenance, naming, and non-escape for the same finite bridge packet.

Chapter 851

A Concrete Naming Certificate for TwinSubstrateBoundaryRouter$^{\uparrow}$

The TwinSubstrateBoundaryRouter$^{\uparrow}$ packet realizes the twin-substrate architecture of chapter 9392 as a request-level boundary router. It reads the MetaCIC audit surface of chapter 9385, the GroundCompiler audit map of chapter 9407, and the finite architecture packet of chapter 845. The point of this chapter is narrower than architecture naming: it binds the local certificate that decides which substrate may answer each public request, and it keeps failed cross-substrate discharges visible.

Definition 851.1 (Twin-substrate boundary router carrier)**.** *A* TwinSubstrateBoundaryRouter$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, G, Q, D, B, H, C, P, N)$$

with the following visible rows:

1. *M is the MetaCIC request row, recording closed-CIC audit obligations, proof-theoretic frontiers, theorem-family references, and MetaCIC-side refusal data;*
2. *G is the GroundCompiler request row, recording audit-map rows, event-flow obligations, recognizer boundaries, report boundaries, and compiler-side refusal data;*
3. *Q is the public request classifier row, separating MetaCIC requests, GroundCompiler requests, paired-context requests, and rejected cross-substrate requests before any answer is exposed;*
4. *D is the discharge row, recording that a MetaCIC request can be discharged only by displayed MetaCIC data from M and that a GroundCompiler request can be discharged only by displayed GroundCompiler data from G;*
5. *B is the boundary ledger, recording the exact non-discharge clauses for attempts to answer a MetaCIC request by GroundCompiler rows or a GroundCompiler request by MetaCIC rows;*
6. *H records componentwise* hsame *transports for request rows, classifier rows, discharge rows, boundary-ledger rows, continuation rows, provenance, and local naming;*
7. *C records displayed* Cont *routes by which a public consumer replays Q, D, B after projecting M or G;*
8. *P is the* Pkg *provenance over chapter 9392, chapter 9385, chapter 9407, chapter 845,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateBoundaryRouter}^{\uparrow}}$ *row.*
The carrier has no coordinate for treating compiler reports as MetaCIC proof evidence, no coordinate for treating MetaCIC proof-theoretic rows as compiler-channel evidence, and no hidden global resolver outside the finite packet.

Theorem 851.2 (Twin-substrate boundary-router NameCert obligations)**.** *For every accepted* $\mathsf{TwinSubstrateBoundaryRouter}^{\uparrow}$ *carrier*

$$R = (M, G, Q, D, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TwinSubstrateBoundaryRouter}^{\uparrow}}$ *surface consists exactly of MetaCIC request readback through M, GroundCompiler request readback through G, public request classification through Q, substrate-local discharge through D, cross-substrate refusal through B, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the finite BHist carrier. The only request rows are M and G, the only classifier is Q, and the only discharge and refusal rows are D and B.

Read the NameCert surface in that projected order. The classifier Q chooses the visible request class before any answer is exposed, while D records the substrate-local discharge row available for the chosen class.

Componentwise hsame transport through H preserves the same projected rows, and Cont route replay through C exposes only the displayed classifier, discharge, and boundary-ledger sequence. The Pkg row P supplies the listed provenance anchors, and N binds the local name.

Since the carrier contains no additional resolver coordinate, those rows exhaust the local NameCert obligations. □

Theorem 851.3 (Twin-substrate boundary-router disjoint discharge)**.** *In every accepted* TwinSubstrateBoundaryRo *carrier, a MetaCIC request cannot be discharged by GroundCompiler rows, and a GroundCompiler request cannot be discharged by MetaCIC rows. Paired-context requests may cite both substrate rows only as context recorded by Q and B, not as a discharge conversion.*

Proof. Begin with finite carrier projection. A MetaCIC request is classified by Q as reading M, and a GroundCompiler request is classified by Q as reading G.

For the MetaCIC case, the discharge row D points back to M. The boundary ledger B records that GroundCompiler audit-map rows, event-flow rows, recognizer rows, and report rows are not proof evidence for that request.

For the GroundCompiler case, the discharge row D points back to G. The same boundary ledger records that MetaCIC closed-CIC rows, proof-theoretic frontiers, and theorem-family references are not compiler-channel evidence for that request.

The componentwise hsame transports in H and the Cont route replay in C preserve the chosen substrate row and its refusal clause. Provenance P and local naming N therefore bind disjoint discharge rather than a cross-substrate resolver. □

Theorem 851.4 (Twin-substrate boundary-router non-escape)**.** *Every public route exported by an accepted* $\mathsf{TwinSubstrateBoundaryRouter}^{\uparrow}$ *carrier factors through the request classifier Q, the substrate-local discharge row D, the boundary ledger B, componentwise transport H, continuation replay C, package provenance P, and local naming N. The export cannot introduce a hidden request class, a hidden discharge row, or an ambient oracle that answers across the MetaCIC/GroundCompiler boundary.*

Proof. Use the NameCert obligations to expose the public route. Any consumer must first project the finite packet and then pass through Q, D, B, H, C, P, N.

The classifier Q makes the request class visible. The discharge row D ties an accepted answer to the matching substrate row, while B records the non-discharge clause for the opposite substrate.

Transport and continuation do not add coordinates. They replay the same rows componentwise and in displayed finite order, so they cannot manufacture a hidden request class or an outside discharge witness.

Package provenance and local naming close the route over the same finite carrier. With no ambient resolver coordinate in Definition 851.1, public export remains non-escaping. □

Theorem 851.5 (Twin-substrate boundary-router public surface)**.** *The public surface of an accepted* $\mathsf{TwinSubstrateBoundaryRouter}^{\uparrow}$ *carrier is exactly the finite packet export of* $M, G, Q, D, B, H, C, P, N$*. Downstream self-compilation audit readers may use it to route requests between MetaCIC audit rows and GroundCompiler audit rows, but only with the substrate-local discharge and refusal clauses displayed in the exported NameCert packet.*

Proof. Start from carrier projection. The public packet exposes the two substrate request rows together with classifier, discharge, refusal, transport, continuation, provenance, and naming rows.

The route replay row C orders consumer access to the classifier Q, the discharge row D, and the boundary ledger B. Thus a reader can decide where a request lands and can inspect why the opposite substrate is not an answer.

The Pkg row P anchors the export to the twin-substrate vision, the MetaCIC audit surface, the GroundCompiler audit map, and the concrete architecture packet. The local NameCert row N names the exported surface without adding a hidden resolver.

Consequently downstream self-compilation readers receive request-level routing between the two audit substrates, not a merged substrate and not an unledgered cross-substrate discharge. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateBoundaryRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{TwinSubstrateBoundaryRouter}^{\uparrow}$ packet is generated from MetaCIC and GroundCompiler request rows, a public request classifier, a substrate-local discharge row, a cross-substrate boundary ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TwinSubstrateBoundaryRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 851.1, Definition 851.2, Definition 851.3, Definition 851.4, and Definition 851.5 bind the finite request-level boundary router, disjoint discharge rule, non-escape boundary, and public export surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TwinSubstrateBoundaryRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close MetaCIC proof-theoretic frontiers, GroundCompiler self-hosting, compiler report soundness, Lean verification, audit cleanliness, axiom cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request classification, substrate-local discharge, boundary-ledger exactness, public export exactness, transport, continuation, provenance, and naming for the same finite packet.

Chapter 852

A Concrete Naming Certificate for $\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}$

The $\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}$ packet realizes the twin-substrate synthesis boundary of chapter 9392 as a finite NameCert handshake. It sits beside the GroundCompiler audit map of chapter 836 and the twin-substrate audit coupling of chapter 847: those chapters expose the compiler-facing audit map and the paired audit coupling, while this chapter names the narrower handshake that lets a reader inspect both audit surfaces without converting one substrate into the other.

Definition 852.1 (Twin-substrate audit-handshake carrier)**.** *A* $\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, G, B, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the MetaCIC audit row, carrying closed-CIC theorem, reduction, substitution, normalisation, confluence, decidability, consistency, and obstruction-boundary references;*
2. *G is the GroundCompiler audit row, carrying event-flow, channel legality, generated recognizer, report-boundary, hidden-input exclusion, and non-evidence references;*
3. *B is the handshake boundary row, naming the finite public claim that requires both audit surfaces while preserving their separate subject matter;*
4. *R is the route classifier row, separating MetaCIC-facing reads, GroundCompiler-facing reads, and paired handshake reads;*
5. *H records componentwise* hsame *transports for the MetaCIC row, GroundCompiler row, handshake boundary, route classifier, continuation rows, package provenance, and local naming row;*
6. *C records the displayed* Cont *routes by which a public consumer reads M, reads G, and then reads B without adding a cross-substrate conversion route;*
7. *P is the* Pkg *provenance over chapter 9392, chapter 836,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}}$ *row.*

The carrier has no coordinate for turning a GroundCompiler report into MetaCIC proof content, no coordinate for turning a MetaCIC theorem into compiler evidence, and no hidden equality that identifies M with G.

Theorem 852.2 (Twin-substrate audit-handshake separation)**.** *For every accepted* $\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}$ *carrier*

$$U = (M, G, B, R, H, C, P, N),$$

the packet exposes both audit rows M and G through the displayed boundary row B, route classifier R, componentwise hsame *rows H, displayed* Cont *routes C, package provenance P, and local* NameCert *row N. A public handshake read may cite both substrates as audit context, but it cannot convert a compiler report into MetaCIC proof content and cannot convert a MetaCIC theorem into compiler evidence.*

Proof. Project the finite carrier. The MetaCIC row M and the GroundCompiler row G are distinct coordinates, and the handshake boundary row B records only the public claim that needs both of them.

Inspect the route classifier R. A MetaCIC-facing read keeps proof-theoretic content attached to M, and a GroundCompiler-facing read keeps compiler-pipeline content attached to G. A paired handshake read may mention both rows only after R has recorded that it is paired.

Transport and replay are componentwise through H and C. These rows preserve the displayed coordinates and provide no route that maps compiler reports to proof content or maps theorem rows to compiler evidence.

Finally read the provenance and naming rows P, N. They package the finite handshake over the cited audit surfaces, so any conversion between the two substrates would require a coordinate outside U. Since the carrier has no such coordinate, the two audit surfaces are exposed together without collapse. □

Closure status for $\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}}$.

Constructive story: A $\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}$ packet is generated from a MetaCIC audit row, a GroundCompiler audit row, a finite handshake boundary, a route classifier, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}}$, seed)

Scope closed: Definition 852.1 and Definition 852.2 bind the finite twin-substrate handshake carrier and its non-conversion boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close MetaCIC frontier obligations, GroundCompiler host trust, theorem extraction from compiler reports, compiler evidence extraction from MetaCIC theorems, Lean verification, audit cleanliness, axiom cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, route classification, transport, continuation replay, provenance, naming, and non-conversion exactness for the same finite handshake packet.

Theorem 852.3 (Twin-substrate audit-handshake route-classifier trichotomy)**.** *Let*

$$U = (M, G, B, R, H, C, P, N)$$

be an accepted $\mathsf{TwinSubstrateAuditHandshake}^{\uparrow}$ *carrier. If a public audit read q is exposed by U, then the route classifier row R places q in exactly one of the following three displayed route classes:*

1. *a MetaCIC-facing route, whose readable substrate row is M and whose public content remains closed-CIC audit content;*
2. *a GroundCompiler-facing route, whose readable substrate row is G and whose public content remains compiler audit content;*

3. *a paired handshake route, whose readable boundary is B and whose context may cite both M and G without converting either row into the other.*

In all three cases, the transport, continuation, provenance, and naming rows H, C, P, N replay the selected classifier case componentwise. No accepted public read can pass from the G row to MetaCIC proof content or from the M row to compiler evidence.

Proof. Project the accepted carrier using Definition 852.1. The public rows available to a read are the MetaCIC audit row M, the GroundCompiler audit row G, the handshake boundary row B, the route classifier row R, and the structural rows H, C, P, N.

The row R is displayed as the finite classifier separating MetaCIC-facing reads, GroundCompiler-facing reads, and paired handshake reads. Therefore a public audit read q must be inspected by one of those three classifier entries. The first entry reads M as closed-CIC audit data; the second reads G as compiler audit data; the third reads B as the boundary that permits a public handshake claim to cite both audit surfaces.

The three entries are exact because no other route-classifier coordinate is present in the carrier. If q is read through the MetaCIC-facing entry, the GroundCompiler row may not be used as proof content, since the carrier has no coordinate turning a GroundCompiler report into MetaCIC proof content. If q is read through the GroundCompiler-facing entry, the MetaCIC row may not be used as compiler evidence, since the carrier has no coordinate turning a MetaCIC theorem into compiler evidence. If q is read through the paired handshake entry, the boundary row B records only the public claim that needs both audit surfaces, and it preserves their separate subject matter.

Finally apply the separation theorem, Definition 852.2. It states that public handshake reads expose both audit rows through B, R, H, C, P, N while preserving the non-conversion boundary. Thus H, C, P, N replay the chosen classifier case componentwise, and any route outside the three displayed cases would require a carrier coordinate outside U. □

Chapter 853

A Concrete Naming Certificate for $\mathsf{CauchyDiagonalBudget}^{\uparrow}$

The $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ packet is the finite selector layer consumed by the diagonal-limit construction of chapter 9238. It sits between the mesh-budget rows of chapter 618 and the comparison rows of chapter 411: a consumer does not choose an ambient limit, but reads a finite precision request, a mesh window, a comparison ledger, a seal handoff, displayed hsame transports, Cont routes, Pkg provenance, and a local $\mathsf{NameCert}$ row.

Definition 853.1 (Cauchy diagonal budget carrier)**.** *A* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (\epsilon, M, W, D, K, S, H, C, P, N)$$

with the following displayed rows:

1. ϵ *is the requested finite precision row for the diagonal-limit read;*
2. M *is the* $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ *mesh-budget row selecting the diagonal observation mesh;*
3. W *is the selected* $\mathsf{StreamName}^{\uparrow}$ *window row through which the mesh observations are named;*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and absolute-value ledger used by the budget;*
5. K *is the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *comparison packet read on the selected window;*
6. S *is the* $\mathsf{Real}^{\uparrow}$ *seal-handoff row reached by the finite budget route;*
7. H *stores componentwise* hsame *transports for* $\epsilon, M, W, D, K, S, C, P, N$*;*
8. C *stores the* Cont *routes by which consumers read the precision row, mesh row, selected window, dyadic ledger, comparison packet, seal handoff, provenance, and local naming row;*
9. P *is the* Pkg *provenance over the same finite packet;*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *row.*

The packet has no coordinate for quotient streams, a host equality of reals, a selected external limit, trichotomy, or an ambient completeness principle.

Theorem 853.2 (Cauchy diagonal budget NameCert obligations)**.** *For the carrier of Definition 853.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *surface consists exactly of carrier admission for* B*, classifier stability under the componentwise* hsame *rows in* H*, mesh-budget exactness through*

M, W, D, comparison exactness through K, seal-handoff exactness through S, C, P, N, and non-escape for quotient streams, host equality, selected external limits, trichotomy, and ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier namecert obligations`

Proof. Carrier admission is the finite tuple displayed in Definition 853.1. Every consumer-facing row is one coordinate of B.

Classifier stability is componentwise. The precision row, mesh row, selected window, dyadic ledger, comparison packet, seal row, continuation routes, provenance, and local naming row are transported only by the rows stored in H and replayed only by the routes in C.

The mesh and comparison clauses are read from the two sibling surfaces cited above. The mesh-budget row supplies the finite diagonal observations, and the regular-Cauchy comparison row supplies the finite comparison ledger on those observations.

Finally, the seal-handoff and non-escape clauses are the statement that S, C, P, N repack the same finite route. Since the carrier has no coordinate for quotient streams, host equality, selected external limits, trichotomy, or ambient completeness, those objects cannot enter the local certificate. □

Theorem 853.3 (Cauchy diagonal budget selection determinacy)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. The diagonal selector read by B is determined by the finite route*

$$\epsilon \to M \to W \to D \to K \to S$$

with provenance H, C, P, N. Any two accepted reads with the same displayed rows and the same componentwise hsame *transport select the same mesh-budget, comparison, and seal-handoff route.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier selection determinacy`

Proof. Start with the carrier inventory. The only precision-facing coordinate is ϵ, and the only mesh-facing coordinate is M.

The selected window W and dyadic ledger D are read after the mesh row. A consumer route in C can replay those rows, but it cannot introduce another window or another dyadic tolerance ledger because no such coordinate is present.

The comparison packet K is then the only comparison surface available before the seal row S is reached. Componentwise hsame transport in H preserves each displayed coordinate, so two accepted reads with the same rows and transports follow the same finite route. □

Theorem 853.4 (Cauchy diagonal budget RealCompleteness handoff)**.** *Every* $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal-limit consumer of an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier must read the finite route*

$$\epsilon, M, W, D, K, S, H, C, P, N$$

before it reaches the $\mathsf{Real}^{\uparrow}$ *seal. This is the budget-selector surface for the diagonal representative of Definition 9238.3: precision, mesh budget, selected window, dyadic ledger, regular-Cauchy comparison, seal handoff,* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows are all displayed.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier real completeness handoff`

Proof. Use selection determinacy to identify the route from the precision request to the seal handoff. The route passes through the mesh budget, selected window, dyadic ledger, and comparison packet in that order.

Now read the diagonal-limit consumer from chapter 9238. Its finite observation request is precisely a request for a displayed precision and selected diagonal observation window before the RealUp seal is inspected.

Because B displays the precision row, mesh row, selected window, dyadic ledger, comparison packet, and seal handoff, the RealCompleteness-facing read factors through B. The transport, continuation, package, and local naming rows provide the provenance of the same finite route. □

Theorem 853.5 (Cauchy diagonal budget non-escape)**.** *An accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *packet cannot export a quotient stream, host real equality proof, selected external limit, trichotomy row, or ambient completeness theorem. Any request for such data remains outside the displayed rows* $\epsilon, M, W, D, K, S, H, C, P, N$ *and therefore cannot become a second diagonal selector or a second* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Project the accepted carrier. Its public rows are exactly the precision request, mesh budget, selected window, dyadic ledger, comparison packet, seal handoff, transports, continuation routes, provenance, and local naming row.

Apply the NameCert obligation theorem to bind those rows as the full local surface. The excluded objects are named only as absent boundary cases and have no carrier coordinate.

Finally use the RealCompleteness handoff theorem. A diagonal-limit consumer already reaches the seal through the displayed finite route, so an undisplayed quotient, host equality, external limit, trichotomy row, or completeness theorem cannot be repacked as another selector or another seal. □

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier nonescape`

Theorem 853.6 (Cauchy diagonal budget classifier stability)**.** *Let* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ *and* $B' = (\epsilon', M', W', D', K', S', H', C', P', N')$ *be accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carriers. If* H *displays componentwise* hsame *transports from the rows of* B *to the rows of* B' *and* C *displays the corresponding* Cont *replay routes, then the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *classifier gives the same answer on* B *and* B'*. The classifier can inspect only the finite* BHist *rows* $\epsilon, M, W, D, K, S, H, C, P, N$*, the transported rows of* B'*, the* Pkg *provenance rows* P, P'*, and the local naming rows* N, N'*.*

Proof. Start from the carrier inventory in Definition 853.1. The classifier-facing data are precisely the displayed precision, mesh, window, dyadic ledger, comparison, seal, transport, continuation, provenance, and naming rows.

Apply the NameCert obligation surface of Definition 853.2. Its stability clause is componentwise, so each coordinate read from B is replayed along the matching hsame row in H and the matching Cont route in C.

The non-escape boundary of Definition 853.5 prevents an additional quotient stream, host equality proof, selected external limit, trichotomy row, or ambient completeness theorem from changing the classifier. Hence the transported finite rows determine the same local classifier result. □

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier classifier stability`

Theorem 853.7 (Cauchy diagonal budget transported selector naturality)**.** *Let*

$$B = (\epsilon, M, W, D, K, S, H, C, P, N) \quad \textit{and} \quad B' = (\epsilon', M', W', D', K', S', H', C', P', N')$$

be accepted CauchyDiagonalBudget$^{\uparrow}$ *carriers. Suppose the displayed rows of* H *give componentwise* hsame *transports from* $\epsilon, M, W, D, K, S, C, P, N$ *to* $\epsilon', M', W', D', K', S', C', P', N'$*, and suppose the displayed rows of* C *replay the matching* Cont *routes for the precision request, mesh row, selected window, dyadic ledger, comparison packet, seal handoff, provenance, and local naming row. Then every selector, comparison, and seal-facing consumer route proved for* B *transports to the same finite route for* B'*. In particular the transported route still factors through*

$$\epsilon', M', W', D', K', S', H', C', P', N'$$

and cannot read quotient streams, host real equality, selected external limits, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier transported selector naturality`

Proof. First transport the classifier. By Definition 853.6, the componentwise hsame rows and replay routes preserve the local NameCert$_{\text{CauchyDiagonalBudget}^{\uparrow}}$ answer, so the accepted selector surface of B is carried to the accepted selector surface of B'.

Next transport the selector and comparison rows. Selection determinacy and mesh-comparison exactness, Definition 853.3 and Definition 853.8, identify the only finite route through the precision, mesh, selected window, dyadic ledger, and comparison coordinates. Replaying the displayed transports replaces those coordinates by $\epsilon', M', W', D', K'$ without changing the route shape.

Finally transport the seal-facing boundary. The seal-boundary factorization theorem and Real seal scope, Definition 853.9 and Definition 853.17, put every seal read behind S, H, C, P, N and hence behind S', H', C', P', N' after transport. The non-escape scope theorem Definition 853.24 then rules out quotient streams, host real equality, selected external limits, trichotomy, and ambient completeness as alternate transported coordinates. □

Theorem 853.8 (Cauchy diagonal budget mesh-comparison exactness)**.** *For every accepted* CauchyDiagonalBudget *carrier* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$*, the mesh-budget and comparison obligations factor through the finite rows* M, W, D, K*. The mesh side exposes exactly the diagonal observation budget selected by* M *through the window* W *and dyadic ledger* D*, while the comparison side exposes exactly the* RegularCauchyComparison$^{\uparrow}$ *row* K *read on that same finite window. No comparison obligation may use a mesh row outside* M, W, D*, and no mesh obligation may use a comparison row outside* K*.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudget mesh comparison exactness`

Proof. Read B through Definition 853.1. The only mesh-facing coordinates are M, W, D, and the only comparison-facing coordinate is K.

The NameCert obligations of Definition 853.2 separate mesh-budget exactness from comparison exactness while storing both in the same finite carrier. Thus the mesh route names the observation budget before the comparison packet is consumed, and the comparison route can only read the selected window already displayed by M, W, D.

Use Definition 853.3 to identify the common finite route from ϵ through M, W, D, K to S. The non-escape theorem then rules out any hidden mesh or comparison surface beyond those coordinates. □

Theorem 853.9 (Cauchy diagonal budget seal-boundary factorization)**.** *Every accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ *factors its* $\mathsf{Real}^{\uparrow}$ *seal handoff through the finite boundary rows* S, H, C, P, N*. A consumer that reaches the seal must first consume the displayed precision, mesh, window, dyadic ledger, and comparison rows, and its final handoff is witnessed only by the* hsame *transports in* H*, the* Cont *routes in* C*, the* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *row* N*.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier seal boundary factorization`

Proof. Apply Definition 853.4. Any diagonal-limit consumer reaches the $\mathsf{Real}^{\uparrow}$ seal only after reading the finite route $\epsilon, M, W, D, K, S, H, C, P, N$.

The carrier and NameCert obligation rows identify S as the seal handoff and H, C, P, N as its transport, route, provenance, and naming boundary. There is no second seal coordinate in the carrier.

Finally invoke Definition 853.5. Since quotient streams, host real equality, selected external limits, trichotomy, and ambient completeness are absent from the finite packet, the seal handoff factors through the displayed boundary rows and no external boundary can be spliced in. □

Theorem 853.10 (Cauchy diagonal budget RegSeqRat window scope)**.** *For every accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$*, each comparison obligation exposed to a regular-Cauchy consumer factors through the displayed rows* M, W, D, K*. The row* W *is the selected stream-naming window of chapter 126, the row* D *is the dyadic tolerance ledger of chapter 291, and the row* K *is the regular-Cauchy comparison packet of chapter 411 read on that same finite window. No comparison witness for the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *surface may bypass* M, W, D, K *or replace them with a quotient stream, host real equality, selected external limit, trichotomy row, or ambient completeness principle.*

Proof. Project the accepted carrier by Definition 853.1. Its comparison-facing coordinates are exactly M, W, D, K: the mesh budget M, the selected naming window W, the dyadic ledger D, and the comparison packet K.

Apply mesh-comparison exactness from Definition 853.8. The mesh side supplies the finite diagonal observation budget through M, W, D, and the comparison side supplies the regular-Cauchy row K on that window.

The cited StreamName, DyadicRatCore, and RegularCauchyComparison chapters are therefore consumed only through their displayed rows. The non-escape boundary of Definition 853.5 excludes any undisplayed quotient, host equality, external limit, trichotomy, or completeness data from discharging the comparison surface. □

Theorem 853.11 (Cauchy diagonal budget shared-tail window exhaustion)**.** *Let* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ *be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every shared-tail read that enters* B *before a completion-facing seal is available factors through the displayed mesh and comparison rows* M, W, D, K*. The read therefore consumes the selected* $\mathsf{StreamName}^{\uparrow}$ *window of chapter 126, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger of chapter 291, and the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *row of chapter 411 as sibling rows on the same finite route; no private tail window, private dyadic ledger, or second comparison packet is exposed by the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *surface.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier shared tail window exhaustion`

Proof. Project the accepted carrier. Its tail-facing comparison surface has only the mesh row M, selected window W, dyadic ledger D, and comparison row K before the seal handoff S.

Apply Definition 853.10. It identifies the regular-Cauchy comparison obligation with the same W, D, K rows, read on the mesh route already fixed by M.

Now read the three sibling chapters through those rows. The $\mathsf{StreamName}^{\uparrow}$ chapter supplies the selected naming window, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the finite tolerance ledger, and $\mathsf{RegularCauchyComparison}^{\uparrow}$ supplies the comparison packet on that window; all three are replayed by the componentwise hsame rows in H and the displayed Cont routes in C.

Finally use Definition 853.5. Since the carrier has no coordinate for a private tail window, private dyadic ledger, second comparison packet, quotient stream, host real equality, selected external limit, trichotomy row, or ambient completeness principle, every shared-tail read is exhausted by M, W, D, K before any seal-facing row is reached. □

Theorem 853.12 (Cauchy diagonal budget route determinacy)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ carrier. Every $\mathsf{Real}^{\uparrow}$- or completion-facing read of B is forced through the single displayed route*

$$\epsilon \to M \to W \to D \to K \to S$$

and is stabilized by the componentwise hsame transports H, continuation routes C, provenance row P, and local $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ row N. Two accepted consumers with the same displayed route rows and componentwise hsame transports cannot diverge by using a private tail window, second comparison packet, quotient stream, selected external limit, trichotomy row, host real equality, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier route determinacy`

Proof. Start with selection determinacy. By Definition 853.3, an accepted packet reaches the seal only through the displayed sequence from the precision request to the selected seal row.

Next attach the comparison surface. Mesh-comparison exactness and shared-tail window exhaustion, Definition 853.8 and Definition 853.11, identify M, W, D, K as the single shared comparison route consumed before any Real-facing or completion-facing handoff.

Now read the seal boundary. The seal-boundary factorization theorem, Definition 853.9, makes H, C, P, N the only transport, route, provenance, and naming rows that stabilize the handoff at S.

Finally apply non-escape. Since the accepted carrier contains no coordinate for a private tail window, second comparison packet, quotient stream, selected external limit, trichotomy row, host real equality, or ambient completeness principle, two consumers with the same displayed route rows and hsame transports have no remaining row on which to diverge. □

Theorem 853.13 (Cauchy diagonal budget seal-consumer coverage)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ carrier. Every $\mathsf{Real}^{\uparrow}$- or completion-facing consumer that reaches the seal row S through B has already consumed the full displayed packet*

$$\epsilon, M, W, D, K, H, C, P, N.$$

Thus the seal read is never a direct ambient Real claim: it is a read of the precision request, mesh budget, selected window, dyadic ledger, comparison row, componentwise transports, continuation routes, package provenance, and local naming row before the boundary coordinate S is inspected.

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier seal consumer coverage`

Proof. Begin with a consumer that reaches S. By Definition 853.9, the seal handoff has boundary rows S, H, C, P, N and cannot be read apart from its displayed transport, route, provenance, and naming witnesses.

Next attach the selector prefix. Selection determinacy, Definition 853.3, places the precision request, mesh row, selected window, dyadic ledger, and comparison packet in the route $\epsilon \to M \to W \to D \to K \to S$.

The RealCompleteness handoff theorem Definition 853.4 then identifies the same rows as the diagonal-limit budget surface consumed before the $\mathsf{Real}^{\uparrow}$ seal is reached. Hence every Real- or completion-facing consumer has already consumed $\epsilon, M, W, D, K, H, C, P, N$ when it reaches S.

The non-escape theorem closes the boundary. Quotient streams, host real equality, selected external limits, trichotomy rows, and ambient completeness have no carrier coordinate, so none can supply a shortcut to S without the displayed packet. □

Theorem 853.14 (Cauchy diagonal budget route factorization)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every shared-tail,* $\mathsf{Real}^{\uparrow}$*-facing, or completion-facing read through B factors through the single finite route*

$$\epsilon \to M \to W \to D \to K \to S.$$

The rows H, C, P, N authenticate that route by componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *surface. No consumer of the diagonal budget can reach a shared-tail window, comparison packet, or Real seal through any route not displayed by ϵ, M, W, D, K, S.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudget route factorization`

Proof. First bind the selected route. Apply Definition 853.3: an accepted diagonal-budget read is determined by the route from ϵ through M, W, D, K to S.

Next exhaust the shared-tail side. By Definition 853.11, every shared-tail read that enters the packet factors through M, W, D, K and the StreamName, DyadicRatCore, and RegularCauchy-Comparison sibling rows on that same route.

Now cover the seal consumers. By Definition 853.13, every Real- or completion-facing consumer that reaches S has already consumed $\epsilon, M, W, D, K, H, C, P, N$. The seal-boundary factorization theorem, Definition 853.9, identifies S, H, C, P, N as the only final handoff boundary.

The displayed route is therefore both the shared-tail route and the seal route. Since the carrier exposes no second window, second comparison row, second seal, quotient stream, host real equality, selected external limit, trichotomy row, or ambient completeness principle, every diagonal-budget consumer factors through $\epsilon \to M \to W \to D \to K \to S$ with provenance H, C, P, N. □

Theorem 853.15 (Cauchy diagonal budget finite-approximation handoff)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every finite approximation consumer of the diagonal route factors through the displayed rows*

$$\epsilon \to M \to W \to D \to K \to S$$

and then through the $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ *packet before any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *handoff is read. The rows* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyComparison}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *are consumed only as named finite surfaces on that route.*

The handoff exports no quotient stream, host real equality, selected external limit, trichotomy row, or ambient completeness principle.

Lean4 ✓ BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier finite approximation handoff

Proof. Begin with the diagonal selector. Selection determinacy, Definition 853.3, fixes the route from the precision request through the mesh, selected window, dyadic ledger, comparison row, and seal handoff.

Next use mesh-comparison exactness and route factorization. By Definition 853.8, the mesh and comparison reads are exactly the displayed M, W, D, K rows. By Definition 853.14, every shared-tail, $\mathsf{Real}^{\uparrow}$-facing, or completion-facing read through B uses the same finite route $\epsilon \to M \to W \to D \to K \to S$.

Now pass to the finite approximation surface. The observation and Real-handoff rows of Definition 601.7 and Definition 601.11 read $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ only through the displayed finite approximation packet. The regular comparison row K supplies the named $\mathsf{RegularCauchyComparison}^{\uparrow}$ surface already locked to W and D.

Finally apply non-escape. The diagonal budget non-escape theorem and the finite approximation seal-coverage theorem have no coordinate for quotient streams, host real equality, selected external limits, trichotomy, or ambient completeness. Therefore a finite approximation consumer can receive only the displayed diagonal route followed by the $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ packet. □

Theorem 853.16 (Cauchy diagonal budget selector RegSeqRat seal exhaustion)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C,$ be an accepted $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ carrier. Every completion-facing consumer that enters B through the selector route must first consume the mesh row M, the selected $\mathsf{StreamName}^{\uparrow}$ window W, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, the $\mathsf{RegularCauchyComparison}^{\uparrow}$ readback row K, and then the finite approximation handoff of Definition 853.15. Only after that finite route is exhausted may the consumer read the $\mathsf{CauchyLimitSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seal row S, together with the transport, continuation, provenance, and naming rows H, C, P, N.*

The consumer receives no quotient stream, host real equality, selected external limit, trichotomy row, or ambient completeness principle from the diagonal budget.

Proof. First identify the selector route. Apply Definition 853.14: every shared-tail, $\mathsf{Real}^{\uparrow}$-facing, or completion-facing read through B factors through the finite route from ϵ to S with the authenticating rows H, C, P, N.

Next isolate the RegSeqRat readback surface. By Definition 853.10, the only regular-Cauchy data visible on that route are the selected $\mathsf{StreamName}^{\uparrow}$ window W, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, and the $\mathsf{RegularCauchyComparison}^{\uparrow}$ row K. Thus a selector-route consumer cannot read a separate regular sequence or comparison packet before it consumes M, W, D, K.

Now pass through the finite approximation boundary. The handoff theorem Definition 853.15 places the $\mathsf{FiniteCauchyApproximation}^{\uparrow}$ packet after the displayed diagonal route and before any $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ handoff is read.

Finally close the seal boundary. The non-escape theorem Definition 853.5 rules out quotient streams, host real equality, selected external limits, trichotomy rows, and ambient completeness as carrier coordinates. Hence the only completion-facing seal available after the selector route is the displayed S row, read with H, C, P, N as its transport, continuation, provenance, and local naming witnesses. □

Theorem 853.17 (Cauchy diagonal budget Real seal scope)**.** *For every accepted $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ carrier $B = (\epsilon, M, W, D, K, S, H, C, P, N)$, the $\mathsf{Real}^{\uparrow}$-facing handoff is scoped exactly by the boundary rows S, H, C, P, N after the finite route ϵ, M, W, D, K has been consumed. The handoff targets the Real naming surface of chapter 38; its seal boundary is the factorization of Definition 853.9,*

with S as the seal row, H as componentwise hsame *transport, C as the displayed* Cont *routes, P as* Pkg *provenance, and N as the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier real seal scope`

Proof. Start with the finite route supplied by Definition 853.4. A diagonal-limit consumer must read ϵ, M, W, D, K before it reaches the seal coordinate S.

Now apply the seal-boundary factorization theorem. It identifies the only handoff boundary as S, H, C, P, N, so the Real-facing surface is not a free ambient completion claim but the displayed seal row together with its transport, route, provenance, and naming witnesses.

The Real chapter is reached at that boundary. Since the carrier has no second seal coordinate and no coordinate for quotient streams, host equality, selected external limits, trichotomy, or ambient completeness, the $\mathsf{Real}^{\uparrow}$ handoff is scoped exactly by the stated rows. □

Theorem 853.18 (Cauchy diagonal budget seal consumption)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. A consumer may read the* $\mathsf{Real}^{\uparrow}$ *seal row S through B only after it has consumed the displayed precision row ϵ, the* $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ *row M, the selected* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *packet K, the componentwise* hsame *row H, the* Cont *route row C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *row N. Thus every valid seal read is a read of the finite packet*

$$\epsilon, M, W, D, K, H, C, P, N, S.$$

Such a read reconstructs no quotient stream, host real equality, selected external limit, trichotomy row, or ambient completeness theorem.

Proof. Project the accepted carrier by Definition 853.1. Its seal-facing coordinates are exactly the precision request, mesh row, selected window, dyadic ledger, comparison packet, seal row, componentwise transports, continuation routes, provenance, and local naming row.

Next use selection determinacy and RealCompleteness handoff. Definition 853.3 fixes the route from ϵ through M, W, D, K to S, while Definition 853.4 says that a diagonal-limit consumer reaches the $\mathsf{Real}^{\uparrow}$ seal only through that displayed budget surface.

Now attach the seal boundary. The transported selector naturality theorem Definition 853.7 preserves the same route under the componentwise hsame rows and displayed Cont replays, and Definition 853.17 identifies S, H, C, P, N as the exact Real-facing boundary.

Finally apply the non-escape and scope rows, Definition 853.5 and Definition 853.24. Since quotient streams, host real equality, selected external limits, trichotomy, and ambient completeness have no carrier coordinate, reading S consumes only the displayed finite packet and reconstructs none of those external objects. □

Theorem 853.19 (Cauchy diagonal budget RegSeqRat-Real route lock)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier must pass through the finite route*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

The row W is read from $\mathsf{StreamName}^{\uparrow}$*, the row D from* $\mathsf{DyadicRatCore}^{\uparrow}$*, the row K from* $\mathsf{RegularCauchyComparison}^{\uparrow}$*, and the seal row S from* $\mathsf{Real}^{\uparrow}$*. No seal-facing or diagonal-limit use may occur before those rows have been consumed with their componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier regseq real route lock`

Proof. First apply Definition 853.10. It places every regular-Cauchy comparison read behind the selected StreamName window W, the dyadic ledger D, and the comparison row K.

Next apply Definition 853.17. The Real-facing handoff is available only after the route ϵ, M, W, D, K has been consumed and only through the seal boundary S, H, C, P, N.

It remains to exclude alternate seal routes. Use Definition 853.9 to identify the boundary rows and Definition 853.24 to rule out quotient streams, host real equality, selected external limits, trichotomy rows, and ambient completeness. Hence every completion-facing consumer reaches the diagonal-limit or Real seal only through the displayed RegSeqRat-to-Real route. □

Theorem 853.20 (Cauchy diagonal budget ObservationBudgetLimiter consumer boundary)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Any* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ *packet consumed by the diagonal budget route of B must factor its capped request, budget-window readback, dyadic ledger, regular readback, and seal rows through the displayed finite route*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

Thus the limiter cap surface of chapter 903 is consumed only as a finite boundary for the same selected mesh window, dyadic tolerance ledger, comparison row, and $\mathsf{Real}^{\uparrow}$ *seal handoff already displayed by B.*

Proof. First identify the selector route. Apply Definition 853.3 to bind every accepted diagonal read to the rows $\epsilon, M, W, D, K, S, H, C, P, N$.

Next bind the window and comparison side. Apply Definition 853.8 and Definition 853.10. These results place the mesh row, selected window, dyadic ledger, and regular-Cauchy comparison in the same finite route before any seal-facing read is available.

Finally apply Definition 853.9 and Definition 853.17. The $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ consumer may contribute only its capped request surface from chapter 903; once that surface is consumed by B, its downstream readback rows must pass through the displayed route and cannot add an uncapped window, a second comparison route, or an independent seal. □

Theorem 853.21 (Cauchy diagonal budget UniformCauchyCriterion budget route)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. A* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer of the diagonal budget can read the budget only through the shared finite window W, the dyadic tolerance ledger D, the comparison row K, and the seal boundary S, H, C, P, N already displayed by B. In particular, the uniform criterion surface of chapter 435 does not supply a second threshold route, quotient stream family, selected family limit, host real equality, or ambient completeness row for the diagonal budget.*

Proof. Start from the common finite route of Definition 853.3. The diagonal budget has one selected window row, one dyadic ledger, one comparison packet, and one seal handoff.

Use Definition 853.8 to attach the comparison obligation to M, W, D, K. Then use Definition 853.10 to identify W, D, K as the regular-Cauchy window surface seen by downstream criterion consumers.

It remains to bind the seal. Apply Definition 853.9 and Definition 853.17. The $\mathsf{UniformCauchyCriterion}^{\uparrow}$ chapter may be read as a finite shared-window criterion through chapter 435, but the diagonal budget exposes only the rows already listed in B, so the criterion cannot replace the budget route with any external analytic object. □

Theorem 853.22 (Cauchy diagonal budget limit-seal eligibility)**.** *For every accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$*, downstream* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal eligibility is equivalent, at the paper-proof boundary, to prior consumption of the displayed precision row, mesh row,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *row,* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ *cap surface when present, and the seal boundary* S, H, C, P, N*. The consumer chapters chapter 386 and chapter 38 may therefore read the diagonal budget only after that finite route is visible.*

Proof. For the forward direction, begin with a downstream $\mathsf{CauchyLimitSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seal read. Apply Definition 853.17: the read reaches the Real-facing boundary only after ϵ, M, W, D, K have been consumed and only through S, H, C, P, N.

Now refine the consumed route. Apply Definition 853.8 and Definition 853.10 to identify the mesh, stream-window, dyadic, and comparison rows. When an $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ packet is part of the route, Definition 853.20 places its cap surface before the same readback rows.

For the reverse direction, suppose those displayed rows have been consumed. Apply Definition 853.3 to recover the unique finite selector route, then apply Definition 853.9 to reach the boundary S, H, C, P, N.

Finally use Definition 853.17. The seal route is exactly the surface consumed by the $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ chapters, so prior consumption of the listed rows supplies the paper-level eligibility condition, while no quotient stream, host equality, selected external limit, trichotomy row, or ambient completeness theorem is exposed. □

Theorem 853.23 (Cauchy diagonal budget window-meet lock)**.** *For every accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$*, any completion-facing consumer that simultaneously reads a* $\mathsf{StreamName}^{\uparrow}$ *window, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *row, and either a* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary must factor through the same finite route*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

The consumer may meet those rows as a single finite-window budget, but it cannot splice in a second window, tolerance ledger, comparison row, quotient stream, host real equality, selected external limit, trichotomy row, or ambient completeness principle.

Proof. First bind the route coordinates. Selection determinacy, Definition 853.3, gives the unique finite route from the precision request through M, W, D, K to the seal handoff S, with H, C, P, N carrying the visible transport, continuation, provenance, and local naming rows.

Next identify the finite window that the consumer is allowed to inspect. Apply Definition 853.10: the selected $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and $\mathsf{RegularCauchyComparison}^{\uparrow}$ row are exactly the W, D, K surface attached to the displayed mesh route.

It remains to attach the completion-facing boundary. By Definition 853.22, a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ read is eligible only after the same route has supplied $\epsilon, M, W, D, K, S, H, C, P, N$.

Finally close the alternate surfaces. The non-escape scope theorem Definition 853.24 rules out quotient streams, host real equality, selected external limits, trichotomy rows, and ambient completeness, and the single-window route already fixes W, D, K. Thus no consumer can splice a second window, tolerance ledger, or comparison row into the meet. □

Theorem 853.24 (Cauchy diagonal budget excluded surface scope)**.** *For every accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$*, quotient streams, host real equality, selected external limits, trichotomy, and ambient completeness are not coordinates of the carrier and cannot discharge the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *surface. Any accepted certificate must be witnessed by the displayed finite rows* $\epsilon, M, W, D, K, S, H, C, P, N$ *and by no larger host-real surface.*

Proof. Use the carrier inventory of Definition 853.1. The displayed coordinates are the precision request, mesh budget, selected window, dyadic ledger, comparison packet, seal handoff, transports, continuation routes, provenance, and local naming row.

Apply Definition 853.5. It states that quotient streams, host equality of reals, selected external limits, trichotomy rows, and ambient completeness theorems are outside those displayed rows and cannot become another selector or another seal.

The NameCert obligations of Definition 853.2 therefore close only over the finite carrier surface. Because each excluded item lacks a carrier coordinate, none can discharge carrier admission, classifier stability, mesh-budget exactness, comparison exactness, seal-handoff exactness, or non-escape for $\mathsf{CauchyDiagonalBudget}^{\uparrow}$. □

Theorem 853.25 (Cauchy diagonal budget ObservationBudgetLimiter consumption)**.** *Let* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ *be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ *consumer of the diagonal budget receives its capped observation service only through the displayed mesh, selected-window, dyadic, comparison, and seal rows*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

Thus the limiter may consume B *as the route that supplies the mesh window* M, W*, the dyadic ledger* D*, the comparison row* K*, and the* $\mathsf{Real}^{\uparrow}$ *seal boundary* S, H, C, P, N*, but it cannot replace those rows by an uncapped observation source, a second regular readback, or an independent seal.*

Proof. First bind the local budget selector. The NameCert obligations of Definition 853.2 expose the finite carrier rows, while Definition 853.3 fixes their order from ϵ through M, W, D, K to S.

Next identify the rows consumed by the limiter. Apply Definition 853.8 and Definition 853.10. The mesh window, dyadic ledger, and comparison packet are exactly the rows available to an $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ readback.

Finally close the seal boundary. The factorization and Real seal scope theorems, Definition 853.9 and Definition 853.17, place every seal-facing read behind S, H, C, P, N. The consumer-boundary theorem Definition 853.20 then states that the limiter's capped surface is consumed only along that same route, and Definition 853.24 rules out any undisplayed observation source or seal. □

Theorem 853.26 (Cauchy diagonal budget tail-coherence handoff)**.** *Let* $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ *be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. A* $\mathsf{TailBudgetCoherence}^{\uparrow}$ *consumer can use the diagonal budget only after the finite budget-selector route*

$$\epsilon \to M \to W \to D \to K \to S$$

has displayed the same mesh window, dyadic ledger, comparison row, transport, continuation, package, and local naming rows that the tail-threshold and seal routes consume. Before a tail threshold or completion-facing seal row is read, the handoff must therefore pass through $M, W, D, K, S, H, C, P, N$ *and not through a host tail choice, quotient stream, selected external limit, or ambient completeness principle.*

Proof. Start with the selector route from Definition 853.3. It gives the only route from the precision row to the seal handoff, with H, C, P, N carrying the visible transport and provenance.

Now attach the tail-facing service rows. By Definition 853.10, every regular-Cauchy comparison obligation seen by a downstream consumer factors through M, W, D, K. By Definition 853.25, the observation service consumed on that route is already capped by the same displayed rows.

It remains to place the seal and threshold read in order. Apply Definition 853.9 and Definition 853.17; they force the final seal-facing boundary through S, H, C, P, N after the mesh, window, dyadic, and comparison rows. The non-escape scope theorem then prevents a $\mathsf{TailBudgetCoherence}^{\uparrow}$ consumer from inserting a hidden tail choice, quotient stream, selected external limit, or ambient completeness row before the accepted handoff. □

Theorem 853.27 (Cauchy diagonal budget diagonal-limit consumer scope)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *consumer that uses B before reaching the* $\mathsf{Real}^{\uparrow}$ *seal must factor through the displayed CauchyDiagonalBudget rows*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

The compatibility read may consume those rows as the finite diagonal-limit budget source, but it cannot reach the Real seal by bypassing the mesh-budget row, selected $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *row, seal boundary, or local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$ *provenance.*

Proof. First use the RealCompleteness handoff theorem Definition 853.4. It already states that every diagonal-limit read reaches the $\mathsf{Real}^{\uparrow}$ seal only after consuming the displayed precision, mesh, window, dyadic, comparison, transport, route, provenance, and naming rows.

Next refine the compatibility side. Mesh-comparison exactness and RegSeqRat window scope, Definition 853.8 and Definition 853.10, identify M, W, D, K as the exact finite rows that a $\mathsf{DiagonalLimitCompatibility}$ route can read before any seal is available.

Finally apply Definition 853.9, Definition 853.17, and Definition 853.24. These results make S, H, C, P, N the only Real-facing boundary and exclude quotient streams, host real equality, selected external limits, trichotomy rows, and ambient completeness. Hence the compatibility consumer must factor through the displayed CauchyDiagonalBudget packet before reaching the seal. □

Theorem 853.28 (Cauchy diagonal budget consumer triad route intersection)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P,$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. The* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, *and* $\mathsf{TailBudgetCoherence}^{\uparrow}$ *consumers all intersect exactly on the finite route*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

Each consumer may read its own service surface through that route, but none may replace the route by an uncapped observation source, a second threshold route, a quotient stream family, a selected external limit, host real equality, or an ambient completeness row.

Proof. First compose the three local consumer routes. The limiter route is fixed by Definition 853.25, the uniform-criterion route is fixed by Definition 853.21, and the tail-coherence handoff is fixed by Definition 853.26. Their common displayed coordinates are therefore $\epsilon, M, W, D, K, S, H, C, P, N$.

Next close the observation and threshold alternatives. The carrier and NameCert rows admit only the displayed precision, mesh, window, dyadic, comparison, seal, transport, continuation, package, and naming coordinates, so a hidden observation source or second threshold route has no coordinate through which it can be consumed.

Finally close the seal-facing alternatives. Apply Definition 853.24 and Definition 853.17. These results rule out quotient stream families, selected external limits, host real equality, and ambient completeness rows, and they force every Real-facing read through the same S, H, C, P, N boundary already shared by the three consumers. □

Theorem 853.29 (Cauchy diagonal budget seal synchronizer pullback)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Any* $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer that reaches the seal through the diagonal budget pulls back to the same displayed route*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

The three consumers therefore agree on the seal boundary rows S, H, C, P, N, and none can substitute quotient streams, host real equality, selected external limits, trichotomy, or ambient completeness for the displayed diagonal-budget seal route.

Proof. Begin with the finite selector itself. Selection determinacy, Definition 853.3, fixes the route from the precision request through the mesh, selected window, dyadic ledger, and comparison row to the seal handoff S.

Next attach the Real-facing boundary. The RealCompleteness handoff of Definition 853.4 and the Real seal scope theorem Definition 853.17 place every completion read behind the displayed seal rows S, H, C, P, N. The diagonal-limit consumer scope theorem, Definition 853.27, gives the same displayed route for every $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ consumer before it reaches the $\mathsf{Real}^{\uparrow}$ seal.

It remains to align the limit-seal consumer. Apply Definition 853.22: a $\mathsf{CauchyLimitSeal}^{\uparrow}$ read is eligible only after the same finite budget packet has supplied $\epsilon, M, W, D, K, S, H, C, P, N$. The non-escape scope theorem Definition 853.24 rules out quotient streams, host real equality, selected external limits, trichotomy rows, and ambient completeness as alternate seal coordinates.

Thus each of the three consumers inspects the unique displayed seal row of the accepted carrier. Carrier inspection then gives a common pullback to $\epsilon, M, W, D, K, S, H, C, P, N$, with common boundary S, H, C, P, N and no undisplayed substitute route. □

Theorem 853.30 (Cauchy diagonal budget tail-fusion pullback)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier, and let $F = (Q, X, W_F, D_F, T_F, M_F, R_F, L_F, H_F, C_F, P_F, N_F)$ be an accepted* $\mathsf{RegularCauchyTailFusion}^{\uparrow}$ *packet. Suppose the selected* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, comparison and readback route, and seal rows of F agree componentwise with W, D, K, S after the displayed* hsame *transports and* Cont *routes of both packets are replayed. Then every* $\mathsf{RegularCauchyTailFusion}^{\uparrow}$ *consumer that reaches the* $\mathsf{Real}^{\uparrow}$ *seal through the diagonal budget pulls back to*

$$\epsilon, M, W, D, K, S, H, C, P, N$$

before it can read L_F. The consumer may use $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *and* $\mathsf{RegularCauchyLimitTransport}^{\uparrow}$ *through the fusion packet, but it cannot substitute quotient streams, host real equality, selected external limits, or ambient completeness for the displayed diagonal-budget selector.*

Proof. Start with the accepted diagonal-budget carrier. Selection determinacy and mesh-comparison exactness, Definition 853.3 and Definition 853.8, force the precision request, mesh window, selected stream window, dyadic ledger, and comparison row to pass through ϵ, M, W, D, K before the seal row S is available.

Now replay the tail-fusion side. The tail-meet handoff, shared-threshold exhaustion, and Real limit handoff of Definition 658.4, Definition 658.6, and Definition 658.7 route every cofinal tail read through $Q, X, W_F, D_F, T_F, M_F, R_F, H_F, C_F, P_F, N_F$ before L_F is consumed.

The assumed componentwise agreement identifies the fusion window, ledger, readback, and seal-facing rows with the diagonal-budget rows after the displayed hsame and Cont data are replayed. Hence the fusion route cannot reach L_F without first passing through the same W, D, K, S selected by B.

Finally apply the limit-transport link, non-escape boundary, and seal-scope theorems. Definition 658.8 accounts for the permitted $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ and $\mathsf{RegularCauchyLimitTransport}^{\uparrow}$ sibling rows, while Definition 853.24 and Definition 853.17 rule out quotient streams, host real equality, selected external limits, and ambient completeness. The only remaining route to the Real seal is therefore the displayed pullback to $\epsilon, M, W, D, K, S, H, C, P, N$. □

Theorem 853.31 (Cauchy diagonal budget shared-tail modulus seal factorization)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier, and let*

$$T = (R_0, R_1, M_0, M_1, \tau, D_T, W_0, W_1, Q_0, Q_1, E, H_T, C_T, P_T, N_T)$$

be an accepted $\mathsf{CauchySharedTailModulus}^{\uparrow}$ *packet. Suppose the paired request rows and paired readback rows of T agree componentwise, after the displayed* hsame *transports and* Cont *routes of the two packets are replayed, with the diagonal budget's selected* $\mathsf{StreamName}^{\uparrow}$ *window W, dyadic ledger D, comparison row K, and Real seal handoff S. Then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer that reaches the seal through B factors first through the shared threshold row τ and dyadic ledger row D_T of T, and then through the diagonal-budget route*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

The factorization has no coordinate for private per-source thresholds, quotient streams, host real equality, selected external limits, trichotomy, or ambient completeness.

Proof. First identify the diagonal seal route. Apply Definition 853.29: every $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, or $\mathsf{CauchyLimitSeal}^{\uparrow}$ read that reaches the seal through B pulls back to $\epsilon, M, W, D, K, S, H, C, P, N$. Apply Definition 853.30 to keep any tail-facing route attached to the same selected window, dyadic ledger, comparison row, and seal handoff.

Now identify the shared-tail side. The Real-completion obligation closure of Definition 983.15 places every completion-facing seal read of T behind its public package, and Definition 983.9 forces that package to use the single threshold row τ with dyadic ledger D_T rather than private per-source thresholds.

Finally compose the two public routes. The assumed componentwise agreement transports the paired request and readback rows of T onto the diagonal budget's selected W, D, K, S boundary after the displayed hsame and Cont rows are replayed. The Pkg and local NameCert rows on both packets then authenticate one route through τ, D_T followed by $\epsilon, M, W, D, K, S, H, C, P, N$; since neither carrier contains quotient streams, host real equality, selected external limits, trichotomy, or ambient completeness, there is no alternate seal-facing factor. □

Theorem 853.32 (Cauchy diagonal budget terminal common route)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Any completion-facing consumer that enters the packet through* $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *a shared-tail modulus packet, or a* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *row must factor through the same displayed route*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

The route consists of the finite precision request, mesh row, $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison row, seal row, componentwise* hsame *transport, displayed* Cont *route,* Pkg *provenance, and local* NameCert *row. It exports no quotient streams, host real equality, selected limits, countable-choice schedule, or ambient completeness principle.*

Proof. First bind the local budget route. Apply Definition 853.21 to any $\mathsf{UniformCauchyCriterion}^{\uparrow}$ consumer and Definition 853.22 to any $\mathsf{CauchyLimitSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer. Both results force the read to pass through the finite rows $\epsilon, M, W, D, K, S, H, C, P, N$ before it reaches a completion-facing seal.

Next attach the shared terminal consumers. The consumer-triad route intersection theorem, Definition 853.28, identifies the common route for $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, and $\mathsf{CauchyLimitSeal}^{\uparrow}$ reads. The shared-tail modulus seal factorization theorem, Definition 853.31, then sends every shared-tail modulus entry through its threshold row and back to the same diagonal-budget route.

Finally read the structural coordinates. The rows H, C, P, N are precisely the componentwise transport, displayed continuation, provenance, and local naming data for the route, so the accepted carrier provides no coordinate from which an alternate terminal path can be formed. The non-escape and seal-scope boundaries already rule out quotient streams, host real equality, selected limits, countable-choice schedules, and ambient completeness. □

Theorem 853.33 (Cauchy diagonal budget root window source)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every accepted budget packet first exposes the finite root window*

$$\epsilon, M, W, D$$

where ϵ is the precision request, M is the mesh-budget row, W is the selected $\mathsf{StreamName}^{\uparrow}$ *window, and D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. The root window is the source from which later regular-Cauchy comparison and Real-seal reads enter the packet; it has no route around the displayed StreamName, DyadicRatCore, or mesh-budget rows.*

Proof. Start with the carrier of Definition 853.1. Its first displayed rows are exactly the precision request, the $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ mesh row, the selected $\mathsf{StreamName}^{\uparrow}$ window, and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger.

Selection determinacy and RegSeqRat window scope then fix the route. By Definition 853.3, the packet reaches the comparison and seal rows only after ϵ, M, W, D have been selected. By Definition 853.10, any regular-Cauchy comparison read consumes the same selected window and dyadic ledger rather than a private stream or tolerance source.

Finally apply mesh-comparison exactness and non-escape. Definition 853.8 identifies the mesh, window, ledger, and comparison rows as the displayed finite source for later reads, while Definition 853.5 rules out quotient streams, host real equality, selected external limits, trichotomy, and ambient completeness as alternate root-window coordinates. □

Theorem 853.34 (Cauchy diagonal budget tail ledger route)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. The shared-tail comparison ledger visible to any downstream consumer is exactly*

$$M, W, D, K, H, C, P, N.$$

It cannot bypass the displayed dyadic row D, the regular-Cauchy comparison row K, the transport row H, the replay row C, the package row P, or the local naming row N.

Proof. First bind the tail read to the root window. Definition 853.33 exposes M, W, D as part of the finite source route before a comparison row can be consumed.

Next use mesh-comparison exactness and shared-tail window exhaustion. Definition 853.8 makes K the comparison row attached to that dyadic window, and Definition 853.11 says every shared-tail read through the packet is exhausted by the same M, W, D, K surface.

Finally account for the certificate rows. The componentwise transport, displayed continuation, provenance, and local NameCert rows H, C, P, N are the only exported replay data for the ledger route. Since the carrier has no coordinate for private tail windows, private dyadic ledgers, second comparison packets, or host equality of reals, no shared-tail consumer can bypass the displayed ledger. □

Theorem 853.35 (Cauchy diagonal budget Real seal handoff totality)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal read through B factors through the root-window source of Definition 853.33 and the tail-ledger route of Definition 853.34 before it reaches the seal row S. Thus the finite route from the root budget window to the Real-facing seal is exhausted by*

$$\epsilon, M, W, D, K, H, C, P, N, S.$$

Proof. Begin with seal-consumer coverage. By Definition 853.13, any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer that reaches the seal through B has already consumed the precision request, mesh row, selected window, dyadic ledger, comparison row, transport, replay, provenance, and local naming rows.

Now decompose that coverage. The root-window theorem supplies the first source segment ϵ, M, W, D, and the tail-ledger theorem supplies the comparison and certificate segment M, W, D, K, H, C, P, N. The overlap is the same displayed mesh-window-ledger surface, so the two segments compose without adding a private tail source or detached comparison packet.

Finally close the non-escape boundary. The Real seal scope and non-escape scope theorems, Definition 853.17 and Definition 853.24, force the final handoff through S and exclude quotient streams, host real equality, selected external limits, trichotomy, countable-choice schedules, and ambient completeness. Hence every Real-facing or completion-facing seal read factors through the displayed finite route before reaching S. □

Theorem 853.36 (Cauchy diagonal budget terminal route coincidence)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every consumer route entering through* $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, *or an accepted* $\mathsf{CauchySharedTailModulus}^{\uparrow}$ *packet exports the same finite route*

$$\epsilon, M, W, D, K, H, C, P, N, S.$$

In particular, the root-window source, tail-ledger route, terminal common route, and Real-seal handoff determine one route after the displayed hsame *transports and* Cont *replays are applied. The route has no coordinate for quotient streams, host real equality, selected external limits, countable-choice schedules, trichotomy, or ambient completeness.*

Proof. First put every terminal consumer on the common diagonal route. By Definition 853.32, any $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, shared-tail modulus, or $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ entry factors through the displayed carrier rows of B rather than through a private completion witness.

Next identify the two exposed segments of that route. The root-window source theorem, Definition 853.33, supplies ϵ, M, W, D as the unique source window. The tail-ledger route theorem, Definition 853.34, supplies M, W, D, K, H, C, P, N as the comparison and certificate ledger attached to that same source.

The shared-tail case uses the same attachment. Applying Definition 853.31 sends any $\mathsf{CauchySharedTailModulus}^{\uparrow}$ entry first through its shared threshold and dyadic ledger rows, and then back to the diagonal-budget route selected by B. Thus the shared-tail packet contributes no alternate terminal route.

Finally apply the Real-seal handoff theorem. Definition 853.35 appends the final seal row S to the root and tail ledger segments, yielding $\epsilon, M, W, D, K, H, C, P, N, S$. The non-escape and seal-scope boundaries, Definition 853.24 and Definition 853.17, rule out quotient streams, host real equality, selected external limits, countable-choice schedules, trichotomy, and ambient completeness as competing exits. □

Theorem 853.37 (Cauchy diagonal budget selector route totality)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every admitted selector read for B factors through the finite Real-completion route*

$$\epsilon \longmapsto M \longmapsto W \longmapsto D \longmapsto K \longmapsto S$$

together with the componentwise transport, continuation replay, provenance, and local naming rows H, C, P, N. Any missing selector route is refused rather than converted into a quotient stream, host $\mathsf{Real}^{\uparrow}$ *equality, trichotomy branch, selected external limit, countable-choice schedule, or ambient completeness coordinate.*

Proof. Begin with selection determinacy. Definition 853.3 fixes the accepted selector read from the displayed precision request and mesh-window data, so an admitted read starts at ϵ, M, W rather than at an external stream or host real.

Next attach the dyadic and comparison rows. Mesh-comparison exactness, Definition 853.8, identifies D and K as the finite ledger and comparison rows selected by the same mesh-window source. Hence the selector route has no independent dyadic, regular-Cauchy, or trichotomy coordinate.

The seal boundary supplies the terminal side of the route. By Definition 853.9, every completion-facing selector read reaching the seal must pass through the displayed comparison and seal rows before it can be consumed.

Finally compose the terminal route theorems. Definition 853.32 places all completion consumers on the shared finite route, and Definition 853.36 identifies that route as $\epsilon, M, W, D, K, H, C, P, N, S$. Therefore every admitted selector read factors through $\epsilon \longmapsto M \longmapsto W \longmapsto D \longmapsto K \longmapsto S$ with H, C, P, N, while every absent route is refused rather than exported as quotient, host-equality, trichotomy, external-limit, choice, or ambient-completeness data. □

Theorem 853.38 (Cauchy diagonal budget prefix request monotonicity)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ and $B' = (\epsilon', M', W', D', K', S', H', C', P', N')$ be accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carriers. Suppose that ϵ' is a finite refinement of ϵ on the same displayed mesh, selected window, dyadic ledger, comparison packet, and seal route, and suppose that the componentwise* hsame *transports and displayed* Cont *rows replay the same prefix from B to B'. Then every* $\mathsf{Real}^{\uparrow}$*- or completion-facing consumer of B' factors through an extension of the route already exposed by B:*

$$\epsilon \longmapsto M \longmapsto W \longmapsto D \longmapsto K \longmapsto S \quad \rightsquigarrow \quad \epsilon' \longmapsto M' \longmapsto W' \longmapsto D' \longmapsto K' \longmapsto S'.$$

The refined packet exports no private window, second comparison packet, quotient stream, host equality, selected external limit, trichotomy row, or ambient completeness row.

Proof. Start with selection determinacy and selector route totality. Theorems 853.3 and 853.37 force both accepted packets to expose their selector reads through the displayed precision, mesh, window, dyadic, comparison, and seal coordinates.

Next compare the finite mesh route. By mesh-comparison exactness, Definition 853.8, the rows M, W, D, K and M', W', D', K' are the whole comparison surfaces attached to their precision requests. The assumed prefix replay through H, C, P, N and H', C', P', N' therefore changes only the finite request depth and not the route shape.

Now factor downstream consumers. The route factorization theorem, Definition 853.14, sends every shared-tail, $\mathsf{Real}^{\uparrow}$-facing, or completion-facing read through the same finite selector route. Hence a consumer of B' first reads the route already exposed by B and then the additional finite refinement coordinates of B'.

Finally close the refusal boundary. The non-escape and non-escape-scope theorems, Definition 853.5 and Definition 853.24, exclude private windows, detached comparison packets, quotient streams, host real equality, selected external limits, trichotomy, and ambient completeness. Thus the refinement is monotone only by finite route extension. □

Theorem 853.39 (Cauchy diagonal budget finite-route induction)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every admissible prefix of the displayed selector route*

$$\epsilon \longmapsto M \longmapsto W \longmapsto D \longmapsto K \longmapsto S$$

is obtained by induction over the six displayed route stages: the base request ϵ, the mesh step M, the selected-window step W, the dyadic-ledger step D, the comparison step K, and the seal step S. At each stage the rows H, C, P, N carry the componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *witness for the prefix already displayed. The induction exports no private window, second comparison packet, quotient stream, host equality, selected external limit, trichotomy branch, countable-choice schedule, or ambient completeness coordinate.*

Proof. The base case is the accepted carrier itself. By Definition 853.1, the packet B exposes the precision request ϵ together with the transport, replay, provenance, and local naming rows H, C, P, N. Selection determinacy, Definition 853.3, makes this request the unique source from which an admissible selector read can begin.

For the mesh and selected-window steps, the same determinacy theorem fixes M and W as the displayed mesh and window selected by ϵ. The prefix request monotonicity theorem, Definition 853.38, says that any admissible finite refinement extends this visible route rather than replacing it by a private window.

For the dyadic-ledger and comparison steps, apply mesh-comparison exactness. Theorem 853.8 identifies D and K as the whole ledger and comparison surface attached to the selected mesh-window prefix, so a second comparison packet or detached tolerance coordinate cannot be introduced in the induction step.

The seal step closes the induction. Seal-boundary factorization, Definition 853.9, forces any completion-facing continuation through the displayed seal row S, and finite-route terminality, Definition 853.41, identifies the resulting terminal route as the same finite packet rows. Hence each admissible prefix is generated by the six displayed stages with H, C, P, N carried along componentwise, while quotient streams, host equality, selected external limits, trichotomy, countable-choice schedules, and ambient completeness remain outside the carrier. □

Theorem 853.40 (Cauchy diagonal budget Real-RegSeq-StreamName factorization)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. A public consumer row whose declared endpoint is one of* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *is admissible for B exactly when its visible source projection factors through*

$$\epsilon \longmapsto M \longmapsto W \longmapsto D \longmapsto K \longmapsto S$$

together with the componentwise transport, displayed continuation, provenance, and local naming rows H, C, P, N. This interface exports no quotient streams, host $\mathsf{Real}^{\uparrow}$ *equality, selected external limits, trichotomy branches, countable-choice schedules, or ambient completeness coordinates.*

Proof. For the only-if direction, first bind the consumer to the selected source. Selection determinacy and selector route totality, Definition 853.3 and Definition 853.37, force every admitted public read to enter through the displayed precision, mesh, selected $\mathsf{StreamName}^{\uparrow}$ window, dyadic ledger, comparison row, and seal route of B.

Next use prefix request monotonicity and terminal route coincidence. Theorems 853.38 and 853.36 identify the visible route seen by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers as the same finite projection after the displayed hsame transports and Cont replays are applied. The non-escape boundary then excludes quotient streams, host real equality, selected external limits, trichotomy, countable-choice schedules, and ambient completeness as alternate admissibility witnesses.

For the if direction, assume the visible source projection factors through the displayed route. The carrier rows of Definition 853.1 supply exactly the precision request, mesh row, selected stream window, dyadic ledger, comparison row, seal handoff, transport, replay, provenance, and local $\mathsf{NameCert}$ data named in that projection.

Mesh-comparison exactness, seal-boundary factorization, and the NameCert obligation surface then authenticate the projection as a public consumer row. Applying Definition 853.8, Definition 853.9, and Definition 853.2 shows that no further field is needed: the displayed finite route is exactly the public interface for $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers of B. □

Theorem 853.41 (Cauchy diagonal budget finite-route terminality)**.** *Let $B = (\epsilon, M, W, D, K, S, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}$ *or* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ *consumer of the diagonal budget factors through the same finite route rows*

$$\epsilon, M, W, D, K, S, H, C, P, N.$$

No such consumer may add a private window, a second dyadic tolerance ledger, quotient stream equality, selected external limit, host $\mathsf{Real}^{\uparrow}$ *equality, or ambient completeness row before the seal handoff.*

Proof. Start with the regular-Cauchy and shared-tail sides. The RegSeqRat window scope theorem, Definition 853.10, places every regular-Cauchy read behind the selected window W, dyadic ledger D, and comparison row K. The shared-tail window exhaustion theorem, Definition 853.11, prevents a second tail window or tolerance ledger from replacing that route.

Next bind the seal-facing route. The Real seal scope theorem, Definition 853.17, makes S, H, C, P, N the only boundary through which a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer can read the accepted budget. The limit-seal eligibility theorem, Definition 853.22, identifies the same route as the required paper-level handoff for seal consumers.

Now attach the finite consumer chapters. The observation-limiter boundary theorem, Definition 853.20, consumes every limiter read through the capped route already displayed by B. The uniform-criterion route theorem, Definition 853.21, similarly routes criterion consumers through $\epsilon, M, W, D, K, S, H, C, P, N$.

Composing these rows leaves no unaccounted coordinate. The excluded private window, second tolerance ledger, quotient stream equality, selected external limit, host real equality, and ambient completeness rows are not fields of the carrier and are refused by the same seal-facing boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ packet is generated from a finite precision request, a $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ mesh-budget row, selected $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, a $\mathsf{RegularCauchyComparison}^{\uparrow}$ comparison row, a $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}, \mathsf{maturePackageClosed})$

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyDiagonalBudget}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CauchyDiagonalBudgetUp.CauchyDiagonalBudgetCarrier\_namecert\_obligations`

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, quotient streams, host equality of reals, selected external limits, trichotomy, ambient completeness, or a public standard bridge.

Upgrade path: The paper closure axis is complete for the finite budget-selector packet; Lean verification and bridge checking remain independent axes.

Chapter 854

A Concrete Naming Certificate for $\mathsf{CertificateTruthBranchBoundary}^{\uparrow}$

The $\mathsf{CertificateTruthBranchBoundary}^{\uparrow}$ packet realizes the certificate-indexed branch boundary of chapter 9458 as a finite NameCert surface. It sits horizontally beside chapter 667: the sibling packet records a self-reference truth-branch request, while this packet records the boundary that permits local refutation routes and refuses certificate-indexed truth branching.

Definition 854.1 (Certificate truth-branch boundary carrier)**.** *A* $\mathsf{CertificateTruthBranchBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, A, R, D, F, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the certificate-indexed query row, naming the fixed local certificate and the proposition row being tested;*
2. *A is the assumption row whose local refutation is permitted only inside the displayed packet;*
3. *R is the permitted refutation route from an assumed witness of A to $\bot$;*
4. *D is the optional constructive decision row for A, present exactly when the packet may consume $\neg\neg A$ as a local decidable refutation step;*
5. *F is the forbidden truth-branch row, recording that no branch family over all naming certificates is a carrier coordinate;*
6. *L is the boundary ledger separating admitted refutation reads from refused certificate-indexed truth reads;*
7. *H records componentwise* hsame *transports for query, assumption, refutation, decision, refusal, ledger, provenance, and local naming rows;*
8. *C records the displayed* Cont *replay routes that read Q, replay R, consume D when present, inspect F, L, and return the result to the same local certificate;*
9. *P is the* Pkg *provenance over* BHist, msame, hsame, Cont, *local refutation routes, refusal rows, ledger rows, and the surrounding NameCert source rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CertificateTruthBranchBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a truth predicate over its own certificate stratum, no excluded-middle branch over the carrier of all naming certificates, and no witness selector obtained only from a contradiction.

Lean4 (definition) `BEDC.Derived.CertificateTruthBranchBoundaryUp.CertificateTruthBranchBoundaryUp`

Theorem 854.2 (Certificate truth-branch boundary NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CertificateTruthBranchl}}$ *surface for Definition 854.1 consists of five finite obligations:*

1. *carrier admission for the displayed packet* $B = (Q, A, R, D, F, L, H, C, P, N)$*;*
2. *query exactness, saying that the certificate-indexed query row* Q *is read only as a fixed local question and never as a global truth classifier;*
3. *permitted-refutation replay, saying that the route* R *reaches* $\bot$ *from an assumed* A*-witness only through the displayed* hsame *transports and* Cont *routes;*
4. *decision discipline, saying that* $\neg\neg A$ *may be consumed only through the same displayed row* D*;*
5. *truth-branch refusal, saying that* F *and* L *block certificate-wide excluded middle, self-truth classification, and witness extraction by contradiction.*

Lean4 ✓ `BEDC.Derived.CertificateTruthBranchBoundaryUp.CertificateTruthBranchBoundaryNameCertObligations`

Proof. Carrier admission is projection from Definition 854.1. The packet exposes exactly the query, assumption, refutation, optional decision, refusal, ledger, transport, continuation, provenance, and local naming rows.

Query exactness is the separation between Q and F, L. The row Q names the local certificate question being inspected, while F and L record that the question is not promoted to a branch family over all naming certificates.

Permitted-refutation replay uses only R, H, C, P, N. Transport first carries the assumption and route along H, then the displayed continuations in C replay the route to $\bot$ inside the same local packet.

Decision discipline is confined to D. When D is absent, the ledger refuses non-decidable double-negation elimination; when D is present, it is consumed for the same proposition row A and does not become a global oracle.

Truth-branch refusal follows by inspecting the carrier inventory. No coordinate supplies certificate-wide excluded middle, a truth predicate for the certificate stratum, or a witness selected only from contradiction, so the local NameCert obligations are exhausted by the stated finite surface. □

Theorem 854.3 (Certificate truth-branch boundary non-escape)**.** *Every accepted* $\mathsf{CertificateTruthBranchBoundary}^{\uparrow}$ *packet exports only the permitted refutation side of the certificate-indexed boundary. It may export the local query row, the displayed refutation route, the optional decision row for the same proposition, the refusal ledger, componentwise transports, continuation replay, provenance, and local naming; it exports no certificate-indexed truth branch and no branch family for predicates over the carrier of all naming certificates.*

Proof. Let an accepted packet be displayed as $B = (Q, A, R, D, F, L, H, C, P, N)$. The carrier definition lists every row a downstream reader may inspect.

The permitted side is local. A consumer may read Q, assume A, replay R through H and C, and use D only when the packet carries that constructive decision row for the same A.

The refused side is recorded by F and L. These rows name the absent branch family and block replacement of the local query by a truth predicate over naming certificates.

The remaining rows H, C, P, N preserve, replay, package, and name the same finite surface. They do not add a second classifier or a witness selector.

Therefore every public read remains inside the permitted-refutation boundary. The certificate can be used as a finite local refutation packet, but it cannot be used as a certificate-indexed truth branch. □

Lean4 ✓ `BEDC.Derived.CertificateTruthBranchBoundaryUp.CertificateTruthBranchBoundaryNonescape`

Theorem 854.4 (Certificate truth-branch boundary public interface)**.** *Every public consumer of an accepted* $\mathsf{CertificateTruthBranchBoundary}^{\uparrow}$ *packet must factor through the fixed local query row, permitted refutation route, optional decision row, truth-branch refusal row, boundary ledger,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row before using the packet. The public interface exports the local refutation boundary only; it exports no certificate-indexed truth predicate, excluded-middle branch over all naming certificates, witness selector obtained from contradiction, or global contradiction-boundary bridge.*

Proof. Project an accepted packet as $B = (Q, A, R, D, F, L, H, C, P, N)$. The carrier lists the query, assumption, permitted refutation, optional decision, refusal, ledger, transport, replay, provenance, and local naming rows as the only public rows.

Use the NameCert obligations. They make Q a fixed local query, R a displayed route from an assumed A-witness to $\bot$, D an optional constructive decision row for the same proposition, and F, L the refusal ledger blocking certificate-wide truth branching.

The non-escape theorem then identifies the downstream surface. A public reader may consume the local refutation route through H, C, P, N, but it cannot replace that route by a truth predicate over certificates or a witness selector obtained only from contradiction.

Thus the public interface is exactly the carrier and NameCert surface already displayed, with the local refutation route exposed before any use of the packet. □

Lean4 ✓ `BEDC.Derived.CertificateTruthBranchBoundaryUp.CertificateTruthBranchBoundaryPublicInterface`

Theorem 854.5 (Certificate truth-branch boundary bridge interface)**.** *Every standard contradiction-boundary consumer of an accepted* $\mathsf{CertificateTruthBranchBoundary}^{\uparrow}$ *packet must factor through the fixed local query row, permitted refutation route, optional decision row, truth-branch refusal row, boundary ledger,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row before the boundary is read as a bridge-facing interface. The interface exports only the displayed local refutation boundary and the refusal ledger; it exports no certificate-indexed truth predicate, global excluded-middle branch, witness selector by contradiction, or Lean bridge certificate.*

Lean4 ✓ `BEDC.Derived.CertificateTruthBranchBoundaryUp.CertificateTruthBranchBoundaryBridgeInterface`

Proof. Project the accepted packet as $B = (Q, A, R, D, F, L, H, C, P, N)$. The carrier rows expose the fixed query Q, the assumed proposition row A, the permitted route R, the optional decision row D, the refusal row F, the boundary ledger L, and the structural rows H, C, P, N.

The public interface theorem identifies the same row order for public readers. A standard contradiction-boundary consumer therefore receives the local query and permitted refutation route only after the refusal and ledger rows have separated them from certificate-wide truth branching.

The bridge-facing reading is exactly this factorization. The consumer may replay the local refutation route through H and C with provenance P and local name N, but no row supplies a truth predicate over naming certificates, a global branch family, a witness selector from contradiction, or a checked Lean bridge. □

Theorem 854.6 (Certificate truth-branch boundary mature package)**.** *The displayed* CertificateTruthBranchBounda *carrier, branch-boundary row, permitted witness route, replay data, provenance row, and local* NameCert *row assemble the public mature package for certificate-indexed truth-branch boundaries. The package exposes the finite local refutation interface and its boundary ledger, while refusing truth-as-host-equality, certificate-wide truth branching, witness selection by contradiction, and any verification-axis claim beyond the markers explicitly attached in this chapter.*

Proof. Project the carrier as $B = (Q, A, R, D, F, L, H, C, P, N)$. The carrier theorem supplies the finite rows, the NameCert obligations bind their admissible readings, and the non-escape theorem prevents a downstream consumer from adding a certificate-indexed truth branch.

The public-interface and bridge-interface theorems identify the same public route: the query, assumption, permitted refutation, optional decision, refusal ledger, transports, replay, provenance, and local name must all be read before the packet is consumed.

These rows therefore form the mature package boundary on the paper axis. The theorem makes no Lean-status assertion and does not identify truth with host equality; it records only the finite public package already forced by the carrier and boundary theorems. □

Lean4 ✓ `BEDC.Derived.CertificateTruthBranchBoundaryUp.CertificateTruthBranchBoundaryMaturePackage`

Closure status for $\mathsf{NameCert}_{\mathsf{CertificateTruthBranchBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{CertificateTruthBranchBoundary}^{\uparrow}$ packet is generated from a certificate-indexed query row, an assumption row, a permitted refutation route, an optional constructive decision row, a forbidden truth-branch row, a boundary ledger, displayed transports, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CertificateTruthBranchBoundary}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 854.1, Definition 854.2, Definition 854.3, Definition 854.4, and Definition 854.5 scope the finite carrier, NameCert obligation surface, non-escape theorem, public interface, bridge-facing interface, and Lean targets to certificate-indexed query rows, permitted local refutation, optional decision rows, truth-branch refusal, boundary ledgers, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CertificateTruthBranchBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove a Lean-side certificate, excluded middle over naming certificates, an internal truth predicate, or witness selection by contradiction.

Upgrade path: Bridge checking requires a Lean-side standard bridge from the local-refutation interface to the standard contradiction-boundary schema.

Chapter 855

A Concrete Naming Certificate for BEDCTheoryIdentity$^{\uparrow}$

The BEDCTheoryIdentity$^{\uparrow}$ packet realizes the framing principle of chapter 9454 as a finite naming certificate. It records the five positive commitments of BEDC.MetaCIC as displayed rows, and it uses the proof-ancestry discipline of chapter 654 as the sibling audit surface for the strict-purity row. The packet is identity-facing: it names what the theory is before any comparison with a neighboring calculus is read.

It joins the BEDC self-theory surface, axiom-query ledger discipline, apophatic boundary rows, and local NameCert provenance into one displayed identity certificate.

Definition 855.1 (BEDC theory identity carrier)**.** *A* BEDCTheoryIdentity$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, E, R, P, B, H, C, K, N)$$

with the following displayed rows:

1. *G is the closed-generator row, listing the finite inductive carriers and constructor inventories used by the substrate, including term-level and certificate-level generators;*
2. *E is the literal AST equality row, recording that type equality inside the substrate is the displayed syntactic equality of the represented AST and not a conversion rule imported from another calculus;*
3. *R is the structural-recursor row, recording the generator-local eliminators and induction routes supplied by the closed generators themselves;*
4. *P is the strict-purity row, recording the zero-axiom dependency boundary for accepted BEDC.MetaCIC theorem content and its connection to axiom-query ledgers;*
5. *B is the apophatic-boundary row, recording named sockets, setup fields, and GAP rows as visible external supply rather than hidden substrate theorems;*
6. *H records componentwise* hsame *transports for the five identity rows and for the route, provenance, and local naming rows;*
7. *C records the displayed* Cont *routes by which consumers read closed generators, literal equality, recursors, strict purity, and boundary markers;*
8. *K is the* Pkg *provenance over* BHist*, closed generators, AST equality, recursor routes, axiom-query ledgers, GAP sockets,* hsame*,* Cont*, and* NameCert*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{BEDCTheoryIdentity}^{\uparrow}}$ *row.*
The carrier has no coordinate for defining BEDC.MetaCIC by subtraction from classical CIC, no host conversion rule, no quotient-equality permission, no hidden axiom dependency, and no ambient semantic principle beyond the displayed rows.

Lean4 (definition) `BEDC.Derived.BedcTheoryIdentityUp.BedcTheoryIdentityUp`
Lean4 ✓ `BEDC.Derived.BedcTheoryIdentityUp.BedcTheoryIdentityTasteGate single carrier alignment`

Theorem 855.2 (BEDC theory identity NameCert obligations)**.** *For every accepted* $\mathsf{BEDCTheoryIdentity}^{\uparrow}$ *carrier*

$$I = (G, E, R, P, B, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{BEDCTheoryIdentity}^{\uparrow}}$ *surface consists exactly of carrier admission for the five identity rows, literal row exposure, structural-recursor exposure, strict-purity exposure through the axiom-query discipline, apophatic boundary exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Proof. Carrier admission is projection from Definition 855.1. The rows G, E, R, P, B are the only positive identity commitments admitted by the packet.

The closed-generator, literal-equality, and recursor obligations are read from G, E, R. These rows identify the internal substrate by displayed constructors, syntactic equality, and generator-local eliminators.

The strict-purity obligation is read from P together with the axiom-query ledger surface of chapter 654. It records dependency cleanliness as a displayed audit row rather than as host confidence.

Finally B, H, C, K, N bind the visible external boundary, transport, replay, provenance, and local name. Since the carrier contains no further coordinate, the local $\mathsf{NameCert}$ obligations are exhausted by the displayed packet. □

Theorem 855.3 (BEDC theory identity boundary nonescape)**.** *Every consumer of an accepted* $\mathsf{BEDCTheoryIdentity}^{\uparrow}$ *packet must read BEDC.MetaCIC identity through the finite rows*

$$G, E, R, P, B, H, C, K, N.$$

The consumer cannot replace those rows by a subtractive definition relative to classical CIC, by a host conversion rule, by quotient or extensional equality, by an unstated axiom dependency, or by an ambient semantic principle outside the apophatic boundary row.

Proof. Project the accepted packet through Definition 855.1. The identity-facing content is exactly the five rows G, E, R, P, B, transported and replayed through H and C with provenance and naming in K, N.

The positive reading of chapter 9454 is therefore a row read from the packet. Closed generators, literal AST equality, structural recursors, strict purity, and visible external boundaries are not inferred from a comparison theory.

The excluded objects have no carrier coordinate. A consumer may compare BEDC.MetaCIC with classical CIC after reading the packet, but it cannot use that comparison as the source of the packet's identity or as a route around the displayed apophatic boundary. □

Theorem 855.4 (BEDC theory identity commitment factorization)**.** *For every accepted* $\mathsf{BEDCTheoryIdentity}^{\uparrow}$ *packet*

$$I = (G, E, R, P, B, H, C, K, N),$$

any downstream MetaCIC identity consumer that classifies a read as internal, boundary-visible, or comparison-only factors the read through exactly one of the five displayed commitment rows G, E, R, P, B, transported by H, replayed by C, and recorded by K, N. No host conversion, quotient equality, hidden axiom dependency, or subtractive classical-CIC comparison can serve as the factoring row.

Proof. Project the accepted packet through Definition 855.1. The only identity-facing commitment rows in the carrier are G, E, R, P, B; the remaining coordinates H, C, K, N supply transport, replay, provenance, and the local name.

Apply Definition 855.2 to identify the complete NameCert surface. An internal read lands on G, E, R, or P according to whether it reads closed generators, literal AST equality, structural recursors, or strict-purity evidence. A boundary-visible read lands on B because the apophatic boundary is the only displayed coordinate for external supply.

A comparison-only read may compare the already-read packet with another calculus, but Definition 855.3 excludes any off-carrier source for the identity classification. Thus host conversion, quotient equality, hidden axiom dependencies, and subtractive classical-CIC comparisons cannot be factoring rows.

The existing Lean alignment point BEDC.Derived.BedcTheoryIdentityUp.BedcTheoryIdentityTasteGate_single_ca supplies the formal single-carrier touchpoint: all formal consumers are aligned to the same carrier before field-faithful reads are compared. Hence every admitted downstream read factors through exactly one displayed commitment row and then through H, C, K, N. □

Closure status for $\mathsf{NameCert}_{\mathsf{BEDCTheoryIdentity}^{\uparrow}}$.

Constructive story: A $\mathsf{BEDCTheoryIdentity}^{\uparrow}$ packet is generated from closed-generator rows, literal AST equality rows, structural-recursor rows, strict-purity rows, apophatic-boundary rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BEDCTheoryIdentity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 855.1, Definition 855.2, Definition 855.3, and Definition 855.4 specify the finite identity packet, its local NameCert obligations, its comparison non-escape boundary, and its downstream read factorization.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BEDCTheoryIdentity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove a Lean theorem for $\mathsf{BEDCTheoryIdentity}^{\uparrow}$, does not close a standard bridge, and does not define BEDC.MetaCIC by reference to another calculus.

Upgrade path: Lean formalization should encode the carrier and checked obligations under BEDC.Derived.BedcTheoryIdentityUp.

Chapter 856

A Concrete Naming Certificate for MetaCICTheoryIdentity$^{\uparrow}$

The MetaCICTheoryIdentity$^{\uparrow}$ packet turns the identity principle of chapter 9454 into a finite BEDC NameCert object. It sits beside the closure-trace certificate of chapter 795 and the kernel-acceptance trace of chapter 557: those siblings expose accepted closure rows and kernel admission rows, while this chapter records the five positive commitments that make BEDC.MetaCIC a theory in its own right.

856.1 Carrier and classifier

Definition 856.1 (MetaCIC theory-identity carrier)**.** *A* MetaCICTheoryIdentity$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, E, R, P, A, H, C, Q, N)$$

with the following displayed rows:

1. *G is the closed-generator row, naming the inductive constructors, recursor rules, substitution rows, beta-step rows, and finite beta-chain rows admitted by the BEDC.MetaCIC substrate;*
2. *E is the literal AST equality row, recording that object comparison is syntactic equality of displayed MetaCIC abstract-syntax rows and not semantic equality inherited from another calculus;*
3. *R is the structural-recursion row, recording that admissible computation is generated by the displayed recursors on the closed syntax and history carriers;*
4. *P is the strict-purity row, recording the absence of additional axioms, classical choice, quotient soundness, proposition extensionality, and host semantic conversion in the identity packet;*
5. *A is the apophatic-boundary row, recording the finite list of absent exports: closed subject reduction, unrestricted conversion decidability, global normalization, confluence outside the named fragments, and kernel soundness;*
6. *H records componentwise* hsame *transports for the generator, equality, recursor, purity, apophatic boundary, provenance, and local naming rows;*
7. *C records displayed* Cont *routes by which audit chapters read the five commitment rows without adding a semantic oracle;*

8. *Q is the* Pkg *provenance over chapter 9454, chapter 795, chapter 557, BEDC.MetaCIC generator rows,* hsame, Cont, *and* NameCert *rows;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICTheoryIdentity}^{\uparrow}}$ *row.*

The carrier contains no comparison embedding into classical CIC, no quotient of syntax by a host semantics, no erased proof-identity principle, and no imported kernel-correctness theorem.

Theorem 856.2 (MetaCIC theory-identity NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICTheoryIdentity}^{\uparrow}$ *carrier*

$$I = (G, E, R, P, A, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICTheoryIdentity}^{\uparrow}}$ *surface consists of five finite positive commitments:*

1. *closed-generator exposure through G;*

2. *literal AST equality exposure through E;*

3. *structural-recursion exposure through R;*

4. *strict-purity exposure through P;*

5. *apophatic-boundary exposure through A.*

The rows H, C, Q, N transport, route, package, and name only those five commitments, so the packet records BEDC.MetaCIC identity as finite BEDC data rather than as a comparison claim about another calculus.

Proof. Project the displayed packet I. The five positive coordinates G, E, R, P, A are the only theory-identity coordinates before transport, route replay, provenance, or local naming is considered.

Read H and C componentwise. They preserve the five displayed coordinates and provide only the consumer routes named by the carrier, so no route can add an external semantic equality, quotient, or host conversion rule.

Finally inspect Q and N. Provenance ties the packet to the source identity principle and to the sibling closure and kernel traces, while local naming packages the same finite surface. Since no further coordinate occurs in I, the listed rows exhaust the NameCert obligations. □

Theorem 856.3 (MetaCIC theory-identity closed-generator scope)**.** *Every generator read from an accepted* $\mathsf{MetaCICTheoryIdentity}^{\uparrow}$ *carrier factors through the closed-generator row G and the structural-recursion row R. The read may cite the closure-trace and kernel-acceptance siblings through Q, but it cannot introduce an unlisted constructor, host reduction rule, or semantic generator outside the displayed BEDC.MetaCIC substrate.*

Proof. Start with the carrier projection. The generator coordinate is G, and the computation coordinate that may replay it is R.

The provenance row Q can point to accepted closure and kernel traces, but those traces are read as finite BEDC rows. They do not add a second generator surface to I.

Thus every generator read remains inside G, R, Q, N, and any unlisted constructor or semantic rule would require a coordinate absent from the carrier. □

Theorem 856.4 (MetaCIC theory-identity literal-equality boundary)**.** *Every equality read from an accepted* $\mathsf{MetaCICTheoryIdentity}^{\uparrow}$ *carrier factors through the literal AST equality row E and the componentwise* hsame *data in H. It exports syntactic comparison of displayed MetaCIC rows and no quotient equality, proof irrelevance, host semantic equivalence, or classical CIC identity transport.*

Proof. Read equality through E. The row is part of the displayed carrier and names literal AST comparison as the local equality surface.

Transport through H is componentwise, so it can move displayed rows only as the same carrier coordinates. It does not collapse syntax into a quotient or import a semantic equivalence from a host theory.

Therefore the equality boundary is literal and local: the packet exposes AST equality and excludes the stronger equality principles listed in the statement. □

Theorem 856.5 (MetaCIC theory-identity purity boundary)**.** *Every purity read from an accepted* $\mathsf{MetaCICTheoryIdentity}^{\uparrow}$ *carrier factors through the strict-purity row P and the package provenance row Q. The packet records a first-principles BEDC.MetaCIC surface with no additional axiom coordinate, no classical-choice coordinate, no quotient-soundness coordinate, no proposition-extensionality coordinate, and no host semantic conversion coordinate.*

Proof. Project the purity row P. It is the only coordinate in I that can be read as a purity ledger.

The provenance row Q names where the identity packet is sourced and which sibling finite traces it may cite. Provenance can identify those rows, but it cannot create an additional axiom or host-semantics coordinate.

Hence the listed excluded principles are outside the carrier. A consumer reading purity receives the finite strict-purity row and nothing stronger. □

Theorem 856.6 (MetaCIC theory-identity public export boundary)**.** *The public export of an accepted* $\mathsf{MetaCICTheoryIdentity}^{\uparrow}$ *carrier is exactly the finite identity packet*

$$G, E, R, P, A, H, C, Q, N.$$

Downstream MetaCIC audit chapters may consume the closed-generator, literal-equality, structural-recursion, strict-purity, apophatic-boundary, transport, route, provenance, and local naming rows. They may not consume a closed subject-reduction theorem, unrestricted conversion decider, global normalization theorem, full confluence theorem, kernel-soundness theorem, or comparison embedding into classical CIC.

Proof. Apply the NameCert-obligation theorem to obtain the five positive commitments and their routing rows.

The closed-generator, literal-equality, structural-recursion, strict-purity, and apophatic-boundary rows are public because they are displayed coordinates of the carrier. The transport, continuation, package, and naming rows are public only as routes back to those same coordinates.

The excluded exports are not coordinates of I. Since every consumer route factors through the displayed packet, the public surface is exactly the finite row inventory in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICTheoryIdentity}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICTheoryIdentity}^{\uparrow}$ packet is generated from closed-generator rows, literal AST equality, structural recursors, a strict-purity row, an apophatic-boundary row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICTheoryIdentity}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 856.1, Definition 856.2, Definition 856.3, Definition 856.4, Definition 856.5, and Definition 856.6 bind the finite theory-identity packet and its public boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICTheoryIdentity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not provide Lean verification, closed subject reduction, unrestricted conversion decidability, global normalization, full confluence, kernel soundness, a comparison embedding into classical CIC, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, five-row obligation exactness, transport and route replay, provenance, local naming, and non-escape for the same finite packet.

Chapter 857

A Concrete Naming Certificate for $\mathsf{BoundedRecursorReplay}^{\uparrow}$

The $\mathsf{BoundedRecursorReplay}^{\uparrow}$ packet realizes authorized recursor replay as a finite NameCert object. It sits downstream of the recursor-generator packet in chapter 534, the authorized generator-recursor packet in chapter 525, and the legal eliminator-call packet in chapter 541. Its role is narrower than any of those chapters: it replays one accepted recursor call under a displayed descent budget, exposes the generated row, and records the audit boundary that prevents the replay from becoming an unrestricted recursion principle.

Definition 857.1 (BoundedRecursorReplay carrier)**.** *A* $\mathsf{BoundedRecursorReplay}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, M, B, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted inductive-signature row, including the constructor inventory, recursive argument positions, strict-positivity gate, and emitted recursor name;*
2. *M is the checked motive row used by the bounded replay;*
3. *B is the branch-package row, with exactly one accepted branch package for each constructor displayed by I;*
4. *D is the descent-budget row, recording the finite replay bound and the structural subdata route consumed at each recursive call;*
5. *R is the bounded replay output row produced by running the authorized recursor under I, M, B, D;*
6. *A is the audit row, recording kernel acceptance, branch coverage, structural descent replay, source-axiom refusal, and dependency-purity refusal for the replayed output;*
7. *H records componentwise* hsame *transports for I, M, B, D, R, A, the route row, the provenance row, and the local naming row;*
8. *C records the displayed* Cont *routes by which consumers read the signature, motive, branch package, descent budget, replay output, audit row, provenance, and local certificate;*
9. *P is the* Pkg *provenance over* BHist*, accepted constructor signatures, checked motives, branch packages, descent budgets, bounded replay outputs, audit rows,* hsame*,* Cont*, and neighboring recursor certificates;*

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundedRecursorReplay}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $I, M, B, D, R, A, H, C, P, N$.

Theorem 857.2 (BoundedRecursorReplay NameCert obligations)**.** *For the carrier of Definition 857.1, the local* $\mathsf{NameCert}_{\mathsf{BoundedRecursorReplay}^{\uparrow}}$ *surface consists of carrier admission for*

$$Q = (I, M, B, D, R, A, H, C, P, N),$$

accepted-signature replay for I, motive admission for M, branch completeness for B, descent-budget exactness for D, bounded output exposure for R, audit replay for A, componentwise hsame *transport, displayed* Cont *route replay,* Pkg *provenance, local naming, and non-escape from unbounded recursion.*

Proof. Carrier admission is projection from Definition 857.1. The finite tuple displays every coordinate that a consumer can inspect.

The signature, motive, and branch obligations are inherited as replay inputs. The accepted signature row I names the only recursor available to the packet, M names the checked motive, and B supplies one branch package for each constructor displayed by I.

The bounded-replay obligations are read from D, R, A. The descent-budget row records the finite replay bound and the structural subdata route, the output row records the result of that bounded replay, and the audit row records the kernel, branch, descent, source, and dependency checks that make the row public.

Finally H, C, P, N package the replay surface. Transport and continuation access preserve the displayed rows, provenance cites the neighboring recursor certificates, and the local naming row exposes no coordinate for an unbounded recursion principle. □

Theorem 857.3 (BoundedRecursorReplay non-escape)**.** *Every consumer read of an accepted* $\mathsf{BoundedRecursorReplay}^{\uparrow}$ *packet factors through*

$$I, M, B, D, R, A, H, C, P, N.$$

It exports no unlisted constructor, no omitted branch, no unchecked motive, no recursive call outside the descent budget, no output outside the bounded replay row, no hidden eliminator, no unrestricted recursion principle, and no dependency route escaping the audit row.

Lean4 ✓ `BEDC.Derived.BoundedRecursorReplayUp.BoundedRecursorReplayTasteGate single carrier alignment`

Proof. Start with the NameCert obligations. They place the replay output downstream of the accepted signature, checked motive, complete branch package, descent budget, audit row, transports, routes, provenance, and local naming row.

For constructor and branch escape, inspect I and B. The signature row supplies the only constructor inventory, and the branch package supplies exactly the branch rows consumed by the bounded replay.

For recursion escape, inspect D and R. A recursive call can contribute to the public output only when the descent-budget row records it as structural subdata of the accepted signature and within the displayed bound.

For dependency escape, inspect A, P, N. The audit row and provenance row record the kernel, source, and dependency boundary for the replay output. Since no carrier coordinate names an unrestricted recursion principle, hidden eliminator, or outside dependency route, no consumer can recover one from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRecursorReplay}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRecursorReplay}^{\uparrow}$ packet is generated from an accepted inductive signature, checked motive, complete branch package, finite descent budget, bounded replay output, audit row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRecursorReplay}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 857.1, Definition 857.2, and Definition 857.3 bind bounded recursor replay as a finite NameCert packet over accepted signature, motive, branch, descent-budget, output, audit, route, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRecursorReplay}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, general kernel soundness, all positivity checking, all termination checking, unbounded recursion, or any external classical principle.

Upgrade path: Obligation closure requires checked carrier admission, accepted-signature replay, motive admission, branch completeness, descent-budget exactness, bounded output exposure, audit replay, and non-escape for the same finite packet.

Chapter 858

A Concrete Naming Certificate for $\mathsf{ClosedNormalRouteCertificate}^{\uparrow}$

The $\mathsf{ClosedNormalRouteCertificate}^{\uparrow}$ packet realizes the route consumed by the closed-normal consistency main result of chapter 9376. It sits beside the main-result packet of chapter 764, the normal false exclusion packet of chapter 732, the subject-reduction obstruction packet of chapter 731, and the candidate-evidence route of chapter 758. Those siblings supply the endpoint exclusion, obstruction boundary, candidate-mediated route, and consumer-facing main-result surface; the present packet records the finite route certificate that threads them without promoting the boundary to full closed consistency.

Definition 858.1 (Closed-normal route certificate carrier)**.** *A* $\mathsf{ClosedNormalRouteCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, E, O, K, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{ClosedNormalConsistencyMain}^{\uparrow}$ *row naming the checked main-result endpoint as a closed beta-strong false-inhabitation exclusion;*
2. *E is the* $\mathsf{NormalFalseExclusion}^{\uparrow}$ *row carrying the already-normal false-endpoint exclusion consumed by the endpoint route;*
3. *O is the* $\mathsf{MetaCICSubjectReductionObstruction}^{\uparrow}$ *row recording that arbitrary closed proofs are not transported into the normal fragment by this certificate;*
4. *K is the* $\mathsf{CandidateEvidenceSNRoute}^{\uparrow}$ *row naming the candidate-mediated route that supplies the strong-normalization side of the normal endpoint;*
5. *R is the closed-normal route row from K, E, O to the main-result endpoint M;*
6. *H stores componentwise* hsame *transports for the sibling rows and the route row;*
7. *C stores displayed* Cont *routes from the sibling packets to the route row and from the route row to the main-result consumer;*
8. *P records* Pkg *provenance over the main-result chapter and the four sibling concrete packets;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedNormalRouteCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for full closed consistency, closed subject reduction, unrestricted normalization, quotient proof conversion, host evaluation, ambient consistency, or a proof that every closed false proof reaches the normal endpoint.

Lean4 ✓ `BEDC.Derived.ClosedNormalRouteCertificateUp.ClosedNormalRouteCertificateTasteGate single carrier alignment`

Theorem 858.2 (Closed-normal route certificate NameCert obligations)**.** *Every accepted* ClosedNormalRouteCertifi *packet binds exactly the finite obligation surface of Definition 858.1: carrier admission for* $Q = (M, E, O, K, R, H, C, P, N)$*, sibling-row exactness for the main-result endpoint, normal false exclusion, subject-reduction obstruction, and candidate-evidence route, route-row exactness for* R*, componentwise classifier stability through* H*, displayed continuation stability through* C*, package provenance through* P*, local naming through* N*, and non-escape from full closed consistency or closed subject reduction.*

Proof. Project the accepted carrier. Admission exposes only the finite tuple $Q = (M, E, O, K, R, H, C, P, N)$, so every public read starts from the four sibling rows and the displayed route row.

The positive endpoint is M. The rows E and K supply the already-normal false exclusion and the candidate-mediated route that feed the endpoint, while O records the subject-reduction obstruction that prevents the packet from being reread as full closed consistency.

The structural rows H, C, P, N transport, replay, package, and name only this route surface. Since no coordinate supplies closed subject reduction, unrestricted normalization, quotient proof conversion, host evaluation, or ambient consistency, the accepted packet certifies only the closed-normal endpoint route displayed by R. □

Theorem 858.3 (Closed-normal route certificate nontrivial witness obligation)**.** *The* ClosedNormalRouteCertificate *carrier has two visibly distinct packets: the packet whose rows* $M, E, O, K, R, H, C, P, N$ *are all* e*, and the packet whose first coordinate* M *is* e0(e) *while* E, O, K, R, H, C, P, N *remain* e*. The classifier and field-faithful readback must distinguish these packets through the first coordinate. This is the paper obligation consumed by the Lean follow-up* `instance : Nontrivial ClosedNormalRouteCertificateUp`*.*

Proof. Display the two finite tuples. They agree on E, O, K, R, H, C, P, N and differ only at the first coordinate, where one tuple has e and the other has e0(e).

Constructor no-confusion for the finite tuple reduces equality of packets to equality of their displayed coordinates. The first-coordinate comparison would require the empty history constructor to coincide with the nonempty e0 constructor, which is refused by the displayed history constructors.

The classifier reads packets componentwise, so it cannot identify the two tuples while preserving the first coordinate. Field-faithful readback records the same first-coordinate distinction at the TasteGate-facing surface, giving the required non-vacuity witness for the later Lean instance. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedNormalRouteCertificate}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedNormalRouteCertificate}^{\uparrow}$ packet is generated from the main-result endpoint row, normal false exclusion row, subject-reduction obstruction row, candidate-evidence route row, route certificate row, componentwise transports, displayed continuations, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedNormalRouteCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 858.1 and Definition 858.2 bind the finite NameCert route from candidate evidence and normal false exclusion through the subject-reduction obstruction boundary to the closed-normal main-result endpoint.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedNormalRouteCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close full closed consistency, closed subject reduction, unrestricted normalization, quotient conversion, host evaluation, ambient consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sibling-row exactness, route-row exactness, classifier stability, continuation stability, provenance, local naming, and non-escape for the same finite route certificate.

Chapter 859

A Concrete Naming Certificate for $\mathsf{BedcSelfTheory}^{\uparrow}$

The $\mathsf{BedcSelfTheory}^{\uparrow}$ packet realizes the identity principle of chapter 9454 as a finite NameCert surface. It is not a new metatheory above BEDC.MetaCIC. It records the finite rows by which the five defining commitments of that chapter are made available to downstream audit consumers: closed generators, literal AST equality, structural recursor locality, strict axiom-purity reporting, and apophatic external boundaries. Horizontally, it reads the accepted-theorem audit face of chapter 546, the legal eliminator-call discipline of chapter 541, the audit-gate boundary of chapter 526, and the external-socket naming discipline of chapter 543.

Definition 859.1 (BEDC self-theory commitment carrier)**.** *A* $\mathsf{BedcSelfTheory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, E, R, A, X, L, H, C, P, N)$$

with the following displayed rows:

1. *G is the closed-generator row, naming the finite inductive carrier inventory read as BEDC.MetaCIC substrate data;*
2. *E is the literal AST equality row, recording that type comparison for the packet is the displayed syntactic equality route and not an external conversion principle;*
3. *R is the structural recursor row, exposing the generator-local eliminators and their constructor-indexed branch discipline;*
4. *A is the strict axiom-purity row, reading the source-token and proof-ancestry audit boundary through the finite audit gates;*
5. *X is the apophatic external-boundary row, recording named sockets, setup fields, and GAP positions as visible external supply rather than hidden substrate content;*
6. *L is the self-theory ledger row, aligning the five commitments with the chapter identity of chapter 9454;*
7. *H records componentwise* hsame *transports for generator, equality, recursor, audit, apophatic, ledger, route, provenance, and local naming rows;*
8. *C records the displayed* Cont *routes by which consumers read each commitment without replacing it by an ambient host principle;*

9. *P is the* Pkg *provenance over* BHist*, closed generators, literal equality, authorized recursors, audit gates, apophatic names,* hsame*,* Cont*, and local NameCert rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BedcSelfTheory}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed tuple $G, E, R, A, X, L, H, C, P, N$.

Theorem 859.2 (BEDC self-theory NameCert obligations)**.** *For the carrier of Definition 859.1, the local* $\mathsf{NameCert}_{\mathsf{BedcSelfTheory}^{\uparrow}}$ *surface consists of five finite commitments: closed-generator admission for G, literal-equality exactness for E, generator-local recursor authorization for R, strict audit visibility for A, and apophatic external-boundary visibility for X. The ledger, transport, continuation, provenance, and local naming rows L, H, C, P, N bind these commitments as one finite packet and add no additional substrate principle.*

Proof. Carrier admission is projection from Definition 859.1. The tuple exposes the generator, equality, recursor, audit, apophatic, ledger, transport, route, provenance, and naming rows as finite coordinates.

The first three commitments are internal substrate commitments. The closed-generator row G lists only displayed inductive carriers, the equality row E records literal AST comparison, and the recursor row R cites only generator-local eliminators whose branch discipline is already visible in the authorized-recursion surface of chapter 541.

The audit and apophatic commitments are boundary commitments. The row A is read through the audit-gate packet of chapter 526, while X is read through the external-name discipline of chapter 543. Thus purity reports and external supplies remain visible rows, not hidden assumptions.

Finally L, H, C, P, N package the same five commitments. They align the packet with chapter 9454, transport and replay the displayed rows, record provenance through the neighboring NameCert surfaces, and expose local naming without adding a sixth commitment. □

Theorem 859.3 (BEDC self-theory closed generator boundary)**.** *Every accepted* $\mathsf{BedcSelfTheory}^{\uparrow}$ *carrier reads BEDC.MetaCIC objects through the closed-generator row G and the literal-equality row E. A downstream consumer cannot use the packet to import an unlisted constructor, a quotient representative, a host semantic equivalence, or a conversion rule not displayed by the carrier.*

Proof. Let an accepted carrier be $S = (G, E, R, A, X, L, H, C, P, N)$. The object-facing rows are G and E: G names the finite constructor inventory, and E names the syntactic equality route used when the packet compares type-level data.

The remaining rows cannot enlarge this inventory. Recursor access in R consumes the same generator row, audit access in A reports proof and source boundaries, and apophatic access in X records external supply as external.

Transport, continuation, provenance, ledger, and naming rows preserve the displayed packet. Since none of H, C, P, L, N supplies a constructor, quotient representative, host semantic equivalence, or extra conversion rule, the closed-generator boundary is exactly the displayed one. □

Theorem 859.4 (BEDC self-theory structural recursor locality)**.** *Every recursor read exported by an accepted* $\mathsf{BedcSelfTheory}^{\uparrow}$ *carrier is local to the closed generator named by G and the recursor row R. It exports no induction principle over an arbitrary semantic domain, no unchecked motive, no omitted branch, and no recursive route outside the displayed structural eliminator.*

Proof. The row R is interpreted together with G. Thus any exported eliminator is tied to the constructor inventory named by the same carrier.

Motive and branch discipline is inherited through the authorized-recursion surface cited in the provenance row P. A consumer may inspect the recursor only through the displayed route C, so the motive, branch package, and structural descent ledger remain part of the same finite read.

No other row contains an induction principle. The audit row reports boundaries, the apophatic row names external supply as external, and H, L, N transport, align, and name the same packet. Hence recursor access remains generator-local. □

Theorem 859.5 (BEDC self-theory non-escape)**.** *Every public read of an accepted* $\mathsf{BedcSelfTheory}^{\uparrow}$ *packet factors through*

$$G, E, R, A, X, L, H, C, P, N.$$

It exports no hidden classical-CIC parent theory, no ambient conversion rule, no undisplayed axiom dependency, no unrestricted recursion principle, and no external socket promoted to internal theorem content.

Proof. The packet inventory is finite and displayed in Definition 859.1. A public read can project one of the five commitment rows or one of the rows that transports, routes, packages, aligns, or names them.

Classical-CIC parentage and ambient conversion are blocked by G and E. The carrier names BEDC.MetaCIC by its own generator and equality rows rather than by a subtractive comparison with another calculus.

Undisplayed axioms and unrestricted recursion are blocked by A and R. The audit row exposes source and proof-ancestry boundaries, and the recursor row remains tied to its closed generator and branch discipline.

External supply is blocked from becoming internal content by X. Since the apophatic row keeps sockets, setup fields, and GAP positions visible as boundary rows, no consumer can recover an internal theorem from them without a separate displayed route.

Therefore the self-theory packet is a finite naming certificate for the five commitments and not an escape route to unlisted principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{BedcSelfTheory}^{\uparrow}}$.

Constructive story: A $\mathsf{BedcSelfTheory}^{\uparrow}$ packet is generated from closed-generator inventory, literal AST equality, structural recursor locality, strict audit-purity rows, apophatic boundary rows, a self-theory ledger, displayed transports, continuation routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BedcSelfTheory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 859.1, Definition 859.2, Definition 859.3, Definition 859.4, and Definition 859.5 bind BEDC.MetaCIC self-theory identity as a finite NameCert packet over five displayed commitments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BedcSelfTheory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove a Lean-side carrier, a bridge theorem, a global completeness theorem for BEDC.MetaCIC, a semantic comparison theorem with classical CIC, or any external principle.

Upgrade path: Obligation closure requires checked carrier admission, five-commitment NameCert obligations, closed-generator boundary, structural recursor locality, and non-escape for the same finite packet.

Chapter 860

A Concrete Naming Certificate for $\mathsf{MetaCICIdentity}^{\uparrow}$

The $\mathsf{MetaCICIdentity}^{\uparrow}$ packet realizes the framing principle of chapter 9454 as a finite NameCert surface. It sits beside the audit-map family certificate of chapter 807 and the GroundCompiler audit-map packet of chapter 836: those siblings classify audit rows and compiler-facing evidence, while this chapter names the identity packet that lets a consumer read BEDC.MetaCIC through its own substrate commitments without treating classical CIC as a defining parent theory.

Definition 860.1 (MetaCIC identity carrier)**.** *A* $\mathsf{MetaCICIdentity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, E, R, A, B, H, C, P, N)$$

with the following displayed rows:

1. *G is the closed-generator inventory row, listing the internal finite constructors for the term-level and certificate-level carriers used by BEDC.MetaCIC;*
2. *E is the literal AST equality row, recording that internal type identity is read as displayed syntactic equality rather than as conversion through an external reduction theory;*
3. *R is the structural recursor authorization row, naming only the eliminators supplied by the closed generators in G;*
4. *A is the strict axiom-purity witness row, recording zero dependency on choice, quotient soundness, propositional extensionality, or any other undisplayed axiom route;*
5. *B is the apophatic boundary socket, recording every request beyond G, E, R, A as external supply rather than as a hidden internal theorem;*
6. *H stores componentwise* hsame *transports for G, E, R, A, B and the local naming rows;*
7. *C stores finite* Cont *routes by which consumers read the five commitment rows, the transports, package provenance, and local naming row;*
8. *P is the* Pkg *provenance over chapter 9454, chapter 807, chapter 836,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICIdentity}^{\uparrow}}$ *row.*

The carrier is an identity certificate for BEDC.MetaCIC's own displayed substrate. It is not a comparison theorem against classical CIC and does not import any conversion, quotient, extensionality, or choice principle from a neighbouring calculus.

Lean4 ✓ `BEDC.Derived.MetaCICIdentityUp.MetaCICIdentityTasteGate single carrier alignment`

Theorem 860.2 (MetaCIC identity NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetaCICIdentity}^{\uparrow}}$ *surface for Definition 860.1 consists of five finite rows: carrier admission for I; classifier stability for the closed-generator inventory, literal AST equality, structural recursor authorization, strict axiom-purity witness, and apophatic boundary socket; boundary exactness for every read outside those five commitment rows;* Pkg *provenance over G, E, R, A, B, H, C; and local naming exactness for N.*

Proof. Carrier admission is projection of the finite tuple I. The generator, equality, recursor, purity, boundary, transport, continuation, provenance, and naming coordinates are all displayed rows of the same BHist packet.

Classifier stability is componentwise. Transport through H preserves the closed-generator inventory, keeps literal equality attached to the same AST row, keeps recursor authorization local to the displayed constructors, and keeps the strict-purity witness attached to the same audit boundary.

The boundary row handles the remaining reads. If a consumer asks for conversion equality, quotient-of-germs equality, extensionality, choice, or a host theorem outside the displayed substrate commitments, the route lands in B rather than in a new internal theorem row.

The package and naming rows then repack exactly those finite coordinates. Thus the obligation surface is the five-row NameCert surface for the identity packet itself. □

Lean4 ✓ `BEDC.Derived.MetaCICIdentityUp.MetaCICIdentity namecert obligations`

Theorem 860.3 (MetaCIC identity boundary non-escape)**.** *For an accepted* $\mathsf{MetaCICIdentity}^{\uparrow}$ *carrier $I = (G, E, R, A, B, H, C, P, N)$, every consumer read of BEDC.MetaCIC's identity factors through the closed-generator inventory G, literal AST equality row E, structural recursor authorization R, strict axiom-purity witness A, apophatic boundary socket B, and structural rows H, C, P, N. A read outside those rows remains boundary data in B and is not exported as conversion equality, quotient soundness, propositional extensionality, choice, or a parent-theory relation to classical CIC.*

Proof. Read the consumer request through the finite routes in C. The positive routes land in the generator, equality, recursor, purity, transport, provenance, and naming rows displayed by the carrier.

For a request outside those coordinates, no row of I supplies the requested principle. The apophatic boundary socket B is the only classifier-visible destination for that request.

Boundary exactness then prevents a boundary entry from being reclassified as a theorem of the substrate. The identity packet therefore exports only the displayed BEDC.MetaCIC commitments and keeps comparison-facing or host-theoretic supply outside the internal carrier. □

Theorem 860.4 (MetaCIC identity comparison is secondary)**.** *Let $I = (G, E, R, A, B, H, C, P, N)$ be an accepted* $\mathsf{MetaCICIdentity}^{\uparrow}$ *carrier. Any comparison with classical CIC, audit-map methodology, or GroundCompiler audit evidence may read I only after the five identity rows G, E, R, A, B have already been fixed. Such a comparison can diagnose shared syntax, differing equality principles, differing axiom dependencies, or external sockets, but it cannot define the identity of BEDC.MetaCIC or add a new substrate commitment to I.*

Proof. Project the carrier. The identity rows G, E, R, A, B are displayed before the transport, route, package, and naming rows that expose the packet to downstream consumers.

Use the audit-map family and GroundCompiler audit-map chapters only as consumer contexts. They may inspect finite rows through C, P, N, but their own audit surfaces do not supply another generator, equality rule, recursor principle, purity witness, or internal theorem row for I.

Finally apply boundary non-escape. If a comparison requests a classical conversion rule, extensionality principle, quotient principle, choice principle, or parent-theory relation, the request is recorded in B. Therefore comparison remains diagnostic and secondary to the displayed identity packet. □

Theorem 860.5 (MetaCIC identity generator-recursor coverage)**.** *Let $I = (G, E, R, A, B, H, C, P, N)$ be an accepted* $\mathsf{MetaCICIdentity}^{\uparrow}$ *carrier. Every identity read that uses the closed-generator inventory and structural recursor authorization exposes exactly the finite rows $G, E, R, A, B, H, C, P, N$: G supplies the generators, E supplies literal AST identity, R supplies the authorized structural recursors, A supplies strict axiom-purity, B supplies the boundary socket, and H, C, P, N supply transport, replay, provenance, and local naming. This recursor coverage cannot become classical conversion, quotient equality, extensionality, choice, or a parent-CIC relation.*

Proof. Start with the carrier and NameCert obligations, Definition 860.1 and Definition 860.2. They display the generator inventory, literal AST equality row, structural recursor authorization, strict-purity witness, boundary socket, transport, continuation, provenance, and local naming as the whole identity packet.

Use boundary non-escape, Definition 860.3. A read that asks for conversion equality, quotient equality, extensionality, choice, or a parent-theory relation lands in B, because none of those requests is one of the generator or recursor rows exposed by G, E, R, A.

Finally apply the comparison-secondary theorem Definition 860.4. Classical CIC, audit-map methodology, and GroundCompiler evidence may inspect the already fixed rows through C, P, N, but they do not define the identity packet and do not add a second recursor source. Hence generator-recursion coverage is exactly the displayed finite route through $G, E, R, A, B, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICIdentity}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICIdentity}^{\uparrow}$ packet is generated from closed-generator inventory, literal AST equality, structural recursor authorization, strict axiom-purity witness, apophatic boundary socket, componentwise hsame transports, finite Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICIdentity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 860.1, Definition 860.2, Definition 860.3, and Definition 860.4 define the finite identity packet, its NameCert obligations, its non-escape boundary, and its secondary comparison discipline.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICIdentity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close a Lean implementation, a public bridge, a classical CIC embedding, a conversion rule, quotient soundness, propositional extensionality, or choice.

Upgrade path: Obligation closure requires binding the identity packet obligations to concrete generator, AST equality, recursor, strict-purity, apophatic boundary, transport, route, provenance, and local naming rows.

Chapter 861

A Concrete Naming Certificate for AxiomDependencyTuple$^{\uparrow}$

The AxiomDependencyTuple$^{\uparrow}$ packet realizes the dependency-map reading of chapter 9455 as finite NameCert data. It follows the audit-map family discipline of chapter 9406 and sits beside the discharge-socket boundary of chapter 719: the former gives the row family shape, while the latter is a concrete sibling where missing MetaCIC supply is named rather than hidden.

Definition 861.1 (AxiomDependencyTuple carrier)**.** *An* AxiomDependencyTuple$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, W, S, H, C, P, N)$$

with the following displayed rows:

1. *M is one of the three mode rows, Mode A for zero-supply internal proof, Mode B for restricted-proof discharge under displayed supply, and Mode C for counterexample or socket witness against an unstated supply;*
2. *W is the witness row, recording a proof, restricted proof, counterexample, or socket witness according to M;*
3. *S is the required-supply ledger, listing exactly the host conversion, quotient equality,* Classical.choice, propext*, ambient classical theorem, or other named supply row that the entry requires;*
4. *H records componentwise* hsame *transport for the mode, witness, required-supply, route, provenance, and naming rows;*
5. *C records the displayed* Cont *routes by which a consumer reads the mode, witness, and required-supply ledger;*
6. *P is the* Pkg *provenance over chapter 9455, chapter 9406, chapter 719,* BHist, hsame, Cont, *and* NameCert *rows;*
7. *N is the local* NameCert$_{\text{AxiomDependencyTuple}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose mode, witness, required-supply ledger, transport, continuation, provenance, and naming rows are displayed in this finite carrier.

Lean4 (definition) `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleCarrier`

Theorem 861.2 (AxiomDependencyTuple NameCert obligations)**.** *For the carrier of Definition 861.1, the local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *surface consists of carrier admission for*

$$A = (M, W, S, H, C, P, N),$$

mode classification, witness transport, required-supply ledger exactness, displayed Cont *route readback,* Pkg *provenance, and local naming. The packet may name host conversion, quotient equality,* Classical.choice*,* propext*, or an ambient classical CIC theorem as supply in S, but it cannot export any of them as BEDC data.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleNameCertObligations`

Proof. Project the finite packet A. The rows M, W, S provide the mathematical payload: a mode, a witness appropriate to that mode, and the ledger of supply required by that witness.

Read H and C next. Componentwise hsame transport preserves the same mode and witness row, and every consumer route must replay the displayed ledger before it reads the tuple.

Finally inspect P and N. Provenance cites only the dependency-map chapter, the audit-map methodology, the discharge-socket sibling, and the BEDC kernel rows. Since no carrier coordinate contains host conversion, quotient equality, choice, propositional extensionality, or an ambient classical theorem as an exported BEDC proof, the named supply remains a ledger entry rather than a hidden rule. □

Theorem 861.3 (AxiomDependencyTuple mode exhaustion)**.** *Every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier $A = (M, W, S, H, C, P, N)$ is exhausted by the three displayed modes: Mode A carries a zero-supply proof witness, Mode B carries a restricted-proof witness together with the required-supply ledger S, and Mode C carries a counterexample or socket witness naming the refused supply. Componentwise* hsame *transport, displayed* Cont *routes,* Pkg *provenance, and the local* NameCert *row preserve this trichotomy and do not add a fourth mode.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleCarrier mode exhaustion`

Proof. Inspect the mode row M in the carrier of Definition 861.1. Its visible constructors are exactly the zero-supply, restricted-proof, and counterexample-or-socket alternatives.

In Mode A, the witness row W is read as an internal proof and the ledger S is empty of external supply. In Mode B, the witness row is read only together with the named required supply. In Mode C, the witness row is a counterexample or socket naming the missing supply rather than discharging it.

Transport and routing do not change the case split. The rows H, C, P, N replay the same mode, witness, and ledger coordinates, so no consumer can introduce host conversion, quotient equality, Classical.choice, propext, an ambient classical CIC theorem, or any fourth mode outside the displayed packet. □

Theorem 861.4 (AxiomDependencyTuple supply-ledger readback)**.** *Every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *packet exposes the required-supply row S before the witness row W can be consumed. If the tuple names host conversion, quotient equality,* Classical.choice*,* propext*, an ambient theorem, or any other external supply, that name remains a ledger row in S and never becomes an exported BEDC rule.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleSupplyLedgerReadback`

Proof. Begin with the carrier projection

$$A = (M, W, S, H, C, P, N).$$

By Definition 861.1, the consumer-facing data contains both the witness coordinate W and the required-supply ledger S.

Apply Definition 861.2. The local $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ surface includes witness transport and required-supply ledger exactness, so any route that reads W must also read the displayed supply row attached to that witness.

Finally use Definition 861.3. Mode A has no external supply to export, Mode B consumes W only under the displayed ledger, and Mode C records a counterexample or socket rather than a discharge. Thus the named host or classical material remains visible audit supply in S. □

Theorem 861.5 (AxiomDependencyTuple zero-supply mode exactness)**.** *For every accepted* AxiomDependencyTup *packet $A = (M, W, S, H, C, P, N)$ in Mode A, the required-supply ledger S is exposed as empty before the zero-supply witness row W is read. Consequently the packet consumes only the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *rows, with no host conversion, quotient equality,* Classical.choice*,* propext*, or ambient theorem available as BEDC proof data.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTuple zero supply mode exactness`

Proof. Project the tuple through Definition 861.1. The public carrier has exactly the rows M, W, S, H, C, P, N, so the Mode A claim can only mention the displayed mode, witness, ledger, transport, route, provenance, and naming coordinates.

Apply Definition 861.2 and Definition 861.3. The local NameCert row binds witness transport and required-supply ledger exactness, while mode exhaustion identifies Mode A as the zero-supply case.

Now use Definition 861.4. The ledger S is read before W, and in Mode A that ledger contains no named external supply. Finally, Definition 861.8 keeps every Cont route from converting an absent ledger entry into a BEDC proof rule. □

Theorem 861.6 (AxiomDependencyTuple restricted-supply ledger exactness)**.** *For every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *packet $A = (M, W, S, H, C, P, N)$ in Mode B, each host conversion, quotient equality,* Classical.choice *use,* propext *use, or ambient theorem required by the restricted witness appears as a visible row of S before W is read. None of these named rows is converted into an internal BEDC rule.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleRestrictedSupplyLedger exactness`

Proof. Begin with the carrier and NameCert surfaces. By Definition 861.1 and Definition 861.2, a restricted packet records the witness row and its required-supply ledger as separate public coordinates, checked by local naming obligations.

The mode split is exhaustive by Definition 861.3. In Mode B, the witness is the restricted-proof witness, and the supply required by that witness is not part of the BEDC kernel surface.

Apply Definition 861.4. Every named host conversion, quotient equality, choice, propositional extensionality, or ambient theorem must be read from S before W is consumed.

Finally use Definition 861.8. A displayed route may replay the ledger and witness coordinates, but it has no constructor that turns a required-supply ledger row into an exported BEDC proof principle. □

Theorem 861.7 (AxiomDependencyTuple downstream consumer supply boundary)**.** *Every downstream consumer of an accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *packet factors its read through the displayed coordinates* M, W, S, H, C, P, N*. Hence counterexample, socket, and restricted-proof supply remains an audit row in the tuple rather than a hidden proof principle available to the consumer.*

Proof. Use Definition 861.1 to identify the only public coordinates of the accepted packet. The downstream consumer has no carrier component beyond M, W, S, H, C, P, N from which to read additional supply.

The local NameCert and mode rows determine how those coordinates are consumed. By Definition 861.2 and Definition 861.3, the consumer first selects one of the three modes and then reads the corresponding witness and ledger rows under the displayed transport, route, provenance, and naming data.

The ledger boundary is fixed by Definition 861.4. Restricted supply, host supply, quotient supply, choice, propositional extensionality, ambient theorems, counterexamples, and sockets are visible only as rows attached to the accepted tuple.

Finally apply Definition 861.8. Since every consumer route merely replays the displayed coordinates, no downstream audit or dependency-map consumer can promote those audit rows into hidden BEDC proof data. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleDownstreamConsumerSupplyBoundary`

Theorem 861.8 (AxiomDependencyTuple route nonexport)**.** *Every displayed* Cont *route in the coordinate* C *replays the* M, W, S, H, P, N *components of an accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *packet componentwise. The route cannot introduce a fourth mode and cannot convert the required-supply row* S *into an internal proof principle.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleRouteNonexport`

Proof. Project the route coordinate C from Definition 861.1. Its declared role is readback for the mode, witness, and required-supply ledger, with the remaining rows supplying transport, provenance, and naming.

Apply Definition 861.2 to the same carrier. The NameCert obligations include displayed Cont route readback and componentwise transport, so a route is checked against the rows already present in A.

The mode alternatives are exhausted by Definition 861.3. Since C only replays the displayed coordinates, it has no constructor by which to create another mode or turn a required-supply ledger entry into a BEDC proof rule. □

Theorem 861.9 (AxiomDependencyTuple consumer exhaustion)**.** *Every downstream consumer of an accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *tuple is exhausted by the mode row* M*, witness row* W*, required-supply ledger* S*, displayed route row* C*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *row* N*, together with their componentwise transport* H*. There is no hidden consumer authority outside this finite packet.*

Proof. Read the carrier of Definition 861.1. The packet lists the only coordinates available to a consumer:

$$M,\ W,\ S,\ H,\ C,\ P,\ N.$$

The obligation theorem Definition 861.2 assigns each consumer-facing role to one of these coordinates: carrier admission, mode classification, witness transport, ledger exactness, route readback, provenance, and local naming.

Mode exhaustion then removes the only remaining possibility for extra consumer authority. By Definition 861.3, every accepted packet lies in Mode A, Mode B, or Mode C, and transport or route readback preserves that case split. Hence any downstream consumer is confined to the finite displayed rows. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleConsumerExhaustion`

Theorem 861.10 (AxiomDependencyTuple zero-supply mode soundness)**.** *In Mode A, an accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *packet consumes the witness row W only when the required-supply ledger S records no external supply. The zero-supply branch cannot smuggle host conversion, quotient equality,* Classical.choice*,* propext*, or any ambient classical theorem through the route row C, provenance row P, local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *row N, or componentwise transport row H.*

Proof. Project the carrier of Definition 861.1. The coordinates M, W, S, H, C, P, N are displayed separately, so the witness row and the required-supply row are not identified by the packet shape.

Apply Definition 861.3. In the Mode A branch, W is the zero-supply proof witness and S has no external host or classical supply to replay.

The ledger boundary is then fixed by Definition 861.4. A consumer can read W only through the visible ledger row, and in this branch that ledger contains no host conversion, quotient equality, choice, propositional extensionality, or ambient classical theorem.

Finally use Definition 861.8 and Definition 861.9. Routes and consumers are exhausted by the displayed rows, so no hidden coordinate remains from which the Mode A branch could import external supply. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleZeroSupplySemanticNameCert`

Theorem 861.11 (AxiomDependencyTuple restricted-supply ledger nonpromotion)**.** *In Mode B, an accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *packet reads the witness row W only together with the displayed required-supply row S. Every named host conversion, quotient equality,* Classical.choice*,* propext*, ambient classical theorem, or other supply entry in S remains audit supply for the restricted witness and is not promoted to an internal BEDC proof rule.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleRestrictedSupplyLedgerNonpromotion`

Proof. Start from the carrier

$$A = (M, W, S, H, C, P, N).$$

The carrier separates the restricted witness coordinate from the supply ledger coordinate, so the witness cannot be read as though the ledger were absent.

By Definition 861.3, the Mode B branch is the restricted-proof branch: W is consumed under the named supply row S, and it is neither a zero-supply proof nor a counterexample socket.

Apply Definition 861.4. The full row S is exposed whenever W is consumed, including every named external supply entry used by the restricted witness.

Definition 861.8 prevents the displayed route from turning S into a rule. Together with Definition 861.9, this confines every consumer to audit readback of the ledger rather than promotion of the ledger into BEDC supply. □

Theorem 861.12 (AxiomDependencyTuple counterexample socket boundary)**.** *In Mode C, an accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *packet records a counterexample or socket witness against missing supply through W and S. The packet names the absent host conversion, quotient equality,* Classical.choice*,* propext*, ambient classical theorem, or other supply row, but it never discharges that supply and never exports it as a BEDC rule.*

Proof. Read the carrier in Definition 861.1. The witness row W and required-supply ledger S are visible packet coordinates, and the route, provenance, naming, and transport rows are separate from them.

Use Definition 861.3. The Mode C branch is the counterexample-or-socket branch, so W witnesses refusal or boundary data against missing supply instead of providing a discharge.

The ledger remains visible by Definition 861.4. Any named host or classical material attached to the socket is read as a required-supply row in S, not as a proof principle.

Finally apply Definition 861.8 and Definition 861.9. The continuation can only replay the displayed packet rows, and every consumer is exhausted by those rows, so the counterexample socket cannot discharge the missing supply it records. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleCounterexampleSocketBoundary`

Theorem 861.13 (AxiomDependencyTuple zero-supply row separation)**.** *In Mode A, an accepted* AxiomDependencyTuple$^{\uparrow}$ *packet exposes an internal zero-supply witness in W and an empty external-supply ledger in S before any consumer route can read the witness. The displayed* Cont *row C may replay that separation, but it cannot insert host conversion, quotient equality,* Classical.choice*,* propext*, or ambient classical supply into the Mode A branch.*

Proof. Begin with the carrier

$$A = (M, W, S, H, C, P, N).$$

By Definition 861.1, the witness row and the required-supply ledger are separate displayed coordinates.

Apply Definition 861.3. In the Mode A case, W is the internal proof witness and S is empty of external supply.

Now use Definition 861.4 and Definition 861.8. A consumer route must read the displayed ledger before consuming W, and the route has no constructor that turns an empty ledger into host or classical supply.

Finally, Definition 861.9 confines every consumer to the finite rows M, W, S, H, C, P, N. Hence Mode A exposes zero supply as a row property of the packet rather than as a hidden external assumption. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleZeroSupplyRowSeparation`

Theorem 861.14 (AxiomDependencyTuple restricted-supply ledger totality)**.** *In Mode B, every restricted-proof witness in an accepted* AxiomDependencyTuple$^{\uparrow}$ *packet is consumed only together with the full displayed required-supply row S. No consumer may read a proper subledger, erase a named supply entry, or replace S by an implicit host rule.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleRestrictedSupplyLedgerTotality`

Proof. Project the carrier of Definition 861.1. The Mode B branch stores the restricted-proof witness in W and its required supply in the single ledger coordinate S.

The mode split is fixed by Definition 861.3. In that branch, the witness is not a zero-supply proof and not a counterexample or socket; it is read as a restricted proof under the displayed supply row.

Apply Definition 861.4. Any route that consumes W must first expose the same row S, including every host conversion, quotient equality, choice, propositional extensionality, ambient theorem, or other named supply entry recorded there.

The route and consumer boundaries then close the case. By Definition 861.8 and Definition 861.9, the consumer has access only to the displayed tuple rows, so it cannot silently shrink S or promote a ledger entry into a BEDC proof rule. □

Theorem 861.15 (AxiomDependencyTuple counterexample socket nonexport)**.** *In Mode C, every accepted counterexample or socket witness names refused supply through the witness row W and required-supply ledger S, while the route row C, provenance row P, and local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *row N prevent that named supply from becoming an exported BEDC proof rule.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleCounterexampleSocketNonexport`

Proof. Read the carrier definition first. The witness row W and the ledger row S are displayed separately from route, provenance, and naming data.

Apply Definition 861.3. In Mode C, the witness coordinate is a counterexample or socket, so the packet records refused supply rather than a proof discharge.

Next use Definition 861.4. Any named host conversion, quotient equality, Classical.choice, propext, ambient theorem, or other external supply remains visible in S when a consumer reads the witness.

Finally combine Definition 861.8 with Definition 861.9. The route can only replay the displayed rows, and every consumer is exhausted by those rows, so the counterexample or socket cannot export the refused supply as a BEDC rule. □

Theorem 861.16 (AxiomDependencyTuple BHist row scope)**.** *For every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier $A = (M, W, S, H, C, P, N)$, the seven displayed coordinates are finite* BHist*-readable rows. The packet reads mode, witness, required-supply, transport, continuation, provenance, and naming data from those rows only, and none of the rows exports host conversion, quotient equality,* Classical.choice*,* propext*, or an ambient classical CIC theorem as BEDC supply.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleBHistRowScope`

Proof. Start with Definition 861.1. The carrier is a finite BHist packet, and the displayed packet coordinates are exactly M, W, S, H, C, P, N.

The earlier obligation rows already describe what each coordinate can expose. Use Definition 861.2 for carrier admission and local naming, Definition 861.3 for the three mode rows, and Definition 861.4 for the required supply row.

It remains to exclude hidden export. By Definition 861.8 and Definition 861.9, a consumer can only replay the displayed finite coordinates. Thus every named host or classical dependency remains a ledger entry in S, never a BEDC proof rule exported by a row of A. □

Theorem 861.17 (AxiomDependencyTuple hsame and Cont scope)**.** *In an accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier $A = (M, W, S, H, C, P, N)$, the transport row H and continuation row C preserve the separation between the mode row M, witness row W, and required-supply ledger S. Componentwise* hsame *transport and displayed* Cont *replay may carry the same tuple to a consumer, but they do not identify a witness with its supply ledger, erase a mode distinction, or create an implicit host rule.*

Proof. Read H from Definition 861.1. Its role is componentwise hsame transport for the mode, witness, required-supply, route, provenance, and naming rows, so transport is indexed by the displayed coordinates rather than by an ambient equality principle.

Read C next. The continuation row records the displayed routes by which a consumer reads the mode, witness, and required-supply ledger. Apply Definition 861.8: a route replays the existing coordinates and has no constructor for another mode or an internal host discharge.

The separation is stable in all three cases. Mode A keeps the empty supply row separate by Definition 861.13; Mode B keeps the full ledger visible by Definition 861.14; Mode C keeps the refused supply nonexported by Definition 861.15. Hence H and C transport and replay the separation instead of collapsing it. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleHsameContScope`

Theorem 861.18 (AxiomDependencyTuple Pkg and NameCert scope)**.** *For every accepted* AxiomDependencyTuple *carrier $A = (M, W, S, H, C, P, N)$, the provenance row P and local naming row N package the same finite tuple as the* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *surface. They cite the dependency-map, audit-map, discharge-socket,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows without internalizing host conversion,* Quot.sound*,* Classical.choice*,* propext*, or ambient classical theorems.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTuplePkgNameCertScope`

Proof. Project P and N from the carrier definition. The provenance row is a Pkg row over the named chapters and BEDC kernel rows, while N is the local $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ row for the same finite packet.

The NameCert surface is fixed by Definition 861.2. It admits exactly the carrier, mode classifier, witness transport, required-supply ledger, displayed route readback, provenance, and local naming obligations already present in A.

Finally combine Definition 861.16 with Definition 861.17. The tuple rows are finite and BHist-readable, while transport and continuation preserve the mode, ledger, and witness separation. Therefore P and N package the tuple as a NameCert surface and do not turn any named host or classical dependency into internal BEDC supply. □

Theorem 861.19 (AxiomDependencyTuple root-unblock spine)**.** *For every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier $A = (M, W, S, H, C, P, N)$, the public dependency-tuple surface is exactly the joint reading of the following rows over the displayed coordinates: mode exhaustion for M, supply-ledger readback for S, route nonexport for C, consumer exhaustion for the whole tuple, and primitive scope for the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. No additional root-unblock datum is available outside these rows.*

Proof. Start with Definition 861.1. The only carrier coordinates are

$$M,\ W,\ S,\ H,\ C,\ P,\ N.$$

The root-unblock spine is read coordinate by coordinate. Use Definition 861.3 for M, Definition 861.4 for S, Definition 861.8 for C, and Definition 861.9 for the consumer boundary of the full tuple.

It remains to account for primitive scope. This is exactly the content of Definition 861.16, Definition 861.17, and Definition 861.18. These rows exhaust the available BHist, hsame, Cont, Pkg, and NameCert interfaces, so the public dependency tuple is the conjunction of the displayed rows and nothing external to the carrier. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleRootUnblockSpine`

Theorem 861.20 (AxiomDependencyTuple mode-ledger priority)**.** *Every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier* $A = (M, W, S, H, C, P, N)$ *is consumed in mode-ledger order. In Mode A the consumer reads the empty required-supply row before using the zero-supply witness. In Mode B the consumer reads the displayed supply ledger before witness consumption. In Mode C the consumer reads the counterexample or socket row as a refusal of discharge before any attempted internal proof use.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleModeLedgerPriority`

Proof. Project the carrier and split by the mode row M. By Definition 861.3, the split has exactly the three displayed cases.

In Mode A, apply Definition 861.13. The ledger row is empty as external supply and remains separate from the zero-supply witness, so readback sees the empty ledger first.

In Mode B, apply Definition 861.14. The restricted witness is not consumed until the required-supply ledger has been displayed as the exact supply row for that witness.

In Mode C, apply Definition 861.15. The counterexample or socket row is read as a boundary witness, so the route records refusal before any attempted discharge. □

Theorem 861.21 (AxiomDependencyTuple consumer readiness)**.** *Downstream audit-map consumers may cite Definition 861.19, Definition 861.20, and the existing scope rows of this chapter as the complete* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *root-unblock package. The package exports no host conversion,* Quot.sound*,* Classical.choice*,* propext*, or ambient classical theorem as BEDC supply.*

Proof. The spine theorem identifies the whole public surface with the displayed carrier rows. The mode-ledger theorem fixes the order in which those rows are read by any consumer.

The remaining cited scope rows are Definition 861.16, Definition 861.17, and Definition 861.18. Together they show that the primitive interfaces remain finite, componentwise, routed, packaged, and locally named.

Finally use Definition 861.8 and Definition 861.9. A downstream audit-map consumer can replay the tuple and its order of use, but cannot turn a ledger entry naming host conversion, quotient equality, choice, propositional extensionality, or an ambient classical theorem into exported BEDC proof supply. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleConsumerReadiness`

Theorem 861.22 (AxiomDependencyTuple audit-map row coverage)**.** *For every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier* $A = (M, W, S, H, C, P, N)$*, every downstream audit-map read of* A *is covered by exactly the displayed mode row, witness row, supply ledger row, componentwise transport row, continuation route row, provenance row, and local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *row. No audit-map row outside* M, W, S, H, C, P, N *is required to replay the tuple.*

Proof. Start with the carrier definition and the local NameCert obligations. By Definition 861.1 and Definition 861.2, the admitted packet has exactly the displayed carrier, classifier, witness-transport, required-supply, route-readback, provenance, and naming obligations.

The mode and ledger coverage are then fixed by Definition 861.3 and Definition 861.4. These results force every consumer read to begin with the three mode cases and the visible required-supply row S.

The remaining public rows are stable under the routing discipline. Apply Definition 861.8, Definition 861.19, and Definition 861.21: continuation reads only replay displayed coordinates, the root-unblock spine names no extra row, and the consumer package exports no host or classical supply.

Finally, the primitive row scope is exhausted by Definition 861.16, Definition 861.17, and Definition 861.18. Thus every downstream audit-map read is covered by the seven listed rows and by no ambient interface. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleAuditMapRowCoverage`

Theorem 861.23 (AxiomDependencyTuple dependency-map soundness)**.** *Every downstream dependency-map read of an accepted* AxiomDependencyTuple$^{\uparrow}$ *carrier* $A = (M, W, S, H, C, P, N)$ *preserves the displayed mode discipline. Mode A reads an empty* S *before the zero-supply witness, Mode B exposes* S *before the restricted witness* W*, and Mode C reads the counterexample or socket as refusal rather than as promoted host supply.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleDependencyMapSoundness`

Proof. Split by the mode coordinate. The split is exhaustive by Definition 861.3, and its consumer order is fixed by Definition 861.20.

In Mode A, use Definition 861.13. The ledger S is empty of external supply and is read separately before the internal zero-supply witness in W.

In Mode B, use Definition 861.14. The restricted witness cannot be consumed until the full displayed supply ledger S has been exposed, so no subledger or implicit host rule replaces it.

In Mode C, use Definition 861.15. The counterexample or socket names refused supply through W and S, while C, P, N prevent that named supply from becoming an exported BEDC proof rule.

The consumer boundary closes the dependency-map claim. By Definition 861.4, Definition 861.8, and Definition 861.21, all three reads keep ledger exposure ahead of witness consumption and refuse every promotion of host conversion, quotient equality, choice, propositional extensionality, or ambient classical supply. □

Theorem 861.24 (AxiomDependencyTuple public interface exactness)**.** *The public interface exported by* AxiomDependencyTuple$^{\uparrow}$ *to audit-map consumers is exactly the carrier of Definition 861.1 together with the row coverage of Definition 861.22 and the dependency-map soundness of Definition 861.23. It exports no* Quot.sound*,* Classical.choice*,* propext*, host conversion, or ambient classical theorem.*

Proof. The carrier supplies the public data. Its coordinates are precisely M, W, S, H, C, P, N, and Definition 861.2 identifies the local NameCert obligations attached to those coordinates.

The two consumer-facing surfaces are the row coverage and soundness results. The first says that audit-map consumers read only the displayed seven rows; the second says that dependency-map consumers preserve the mode-ledger discipline in Modes A, B, and C.

It remains to exclude extra public exports. Apply Definition 861.8, Definition 861.19, and Definition 861.21. Routes replay the carrier, the spine has no additional root-unblock datum, and the consumer package refuses every host conversion or classical theorem as BEDC supply.

Thus the public interface is the carrier plus these two audit surfaces, with no quotient equality, choice, propositional extensionality, host conversion, or ambient classical theorem exported alongside it. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTuplePublicInterfaceExactness`

Theorem 861.25 (AxiomDependencyTuple kernel supply visibility)**.** *For every accepted* AxiomDependencyTuple$^{\uparrow}$ *carrier* $A = (M, W, S, H, C, P, N)$*, every external assumption read by the kernel side of the tuple is exposed first as a row of the displayed required-supply ledger* S*. In particular, host conversion,*

quotient equality, Classical.choice*,* propext*, ambient classical theorem names, and any other non-BEDC supply name can be consumed only through the ledger row selected by M and attached to the witness row W.*

Proof. Start with Definition 861.1. The carrier displays the mode row M, witness row W, required-supply ledger S, transport row H, continuation row C, provenance row P, and local NameCert row N as separate finite coordinates.

Apply Definition 861.2. The local certificate exposes carrier admission, mode classification, witness transport, ledger exactness, displayed continuation readback, provenance, and naming, so the kernel-side reader has no hidden coordinate from which to obtain an external assumption.

The mode split fixes how the ledger is read. By Definition 861.3, Mode A has no external supply, Mode B consumes a restricted witness under the displayed ledger, and Mode C names refused supply through a counterexample or socket. By Definition 861.4, each named host or classical item therefore remains visible in S before W is consumed. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleKernelSupplyVisibility`

Theorem 861.26 (AxiomDependencyTuple supply provenance sibling route)**.** *For every accepted* AxiomDependencyTuple$^{\uparrow}$ *carrier $A = (M, W, S, H, C, P, N)$, each required-supply ledger row that is consumed as a kernel supply witness is first read through the sibling* SubjectReductionDischargeSocket$^{\uparrow}$ *route of chapter 719. Only after that route has exposed the relevant discharge, obstruction, and provenance rows may the selected entry of S be consumed by W as a kernel-facing supply witness.*

Proof. Project the tuple fields from Definition 861.1. The carrier exposes the mode row M, witness row W, required-supply ledger S, transport row H, continuation row C, provenance row P, and local naming row N; it has no hidden coordinate for external supply.

Apply Definition 861.25. Any kernel-side external assumption is visible first in S and is selected by M before W can consume it.

The sibling socket supplies the provenance route named by chapter 719. Thus the ledger row is not a kernel-only island: it is read through the displayed discharge-socket surface, then transported and replayed by H and C, sourced by P, and named by N before it reaches the witness row. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleSupplyProvenanceSiblingRoute`

Theorem 861.27 (AxiomDependencyTuple external supply refusal)**.** *For every accepted* AxiomDependencyTuple$^{\uparrow}$ *carrier $A = (M, W, S, H, C, P, N)$, the names for host conversion, quotient equality,* Classical.choice*,* propext*, and ambient classical theorem supply are refused as exported BEDC proof data. They may appear as entries of S or as refused supply named by W in the appropriate mode, but H, C, P, and N can only transport, replay, record provenance for, and name the displayed tuple rows.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleExternalSupplyRefusal`

Proof. Use the carrier and NameCert obligations first. By Definition 861.1 and Definition 861.2, external supply names occur only in the required-supply ledger and in the witness reading selected by the mode row.

The three mode cases separate the possible readings. Mode A is governed by Definition 861.13, so an empty external ledger cannot be converted into host or classical proof data. Mode B is governed by Definition 861.14, so a restricted witness is consumed only with the full displayed ledger. Mode C is governed by Definition 861.15, so a counterexample or socket names missing supply without discharging it.

Finally apply Definition 861.4, Definition 861.8, and Definition 861.33. Ledger readback keeps the names visible, route non-export prevents continuation replay from creating proof rules, and host-supply nonescape keeps every such name inside the audit ledger surface. □

Theorem 861.28 (AxiomDependencyTuple audit consumer completeness)**.** *Every dependency-map consumer for an accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier* $A = (M, W, S, H, C, P, N)$ *must read the complete audit surface: mode* M*, witness* W*, required-supply ledger* S*, transport row* H*, continuation route* C*, provenance row* P*, and local NameCert row* N*. A consumer that omits any one of these rows is not a consumer of the displayed dependency tuple.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleAuditConsumerCompleteness`

Proof. Begin with the finite packet of Definition 861.1. Its public surface is exactly M, W, S, H, C, P, N, so the consumer question is a row-coverage question rather than a request for an ambient proof principle.

The first three rows are forced by the obligation and mode theorems. Apply Definition 861.2, Definition 861.3, and Definition 861.4: the consumer must know which mode is active, which witness is being read, and which ledger row authorizes or refuses that witness.

The remaining rows are forced by the transport and routing surface. The existing per-mode separation theorems keep the three witness readings disjoint, while Definition 861.8 and Definition 861.9 confine every consumer to the displayed packet rows. Hence a complete audit consumer must pass through H, C, P, and N as well as M, W, and S. □

Corollary 861.29 (AxiomDependencyTuple kernel supply visibility strict obstruction)**.** *For every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier* $A = (M, W, S, H, C, P, N)$*, any displayed failure, refusal, separation, or counterexample-or-socket row used in the kernel-supply visibility argument has strictly local force. It blocks only the named converse or reuse route that tries to read external supply outside the required-supply ledger* S*, erase a listed supply entry, reread a mode as another mode, or export refused supply as BEDC proof data. It cannot be reinterpreted as a global impossibility for* $\mathsf{AxiomDependencyTuple}^{\uparrow}$*, as a host theorem, or as hidden external validation. Every consumer-facing use of the obstruction factors through one of the displayed rows* M, W, S, H, C, P, N *and rejects any unlisted coordinate.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleKernelSupplyVisibilityStrictObstruction`

Proof. Start with Definition 861.25. Any external assumption read by the kernel side is visible first as a row of the required-supply ledger S, selected by the mode row M and attached to the witness row W. Thus the obstruction has a named input surface before any consumer can use it.

Now apply Definition 861.27. Host conversion, quotient equality, Classical.choice, propext, and ambient classical theorem supply may be named in S or by the refused witness reading, but the rows H, C, P, and N can only transport, replay, record provenance for, and name the displayed tuple rows. Hence a consumer-facing obstruction has the listed route, transport, provenance, and NameCert coordinates as its whole interface.

The three mode rows give the strict local cases. In Mode A, Definition 861.13 says that the empty external ledger remains separate from the zero-supply witness, so the blocked route is only the attempted conversion of emptiness into host or classical proof data. In Mode B, Definition 861.14 says that the restricted witness is consumed only with the full displayed ledger, so the blocked route is only subledger erasure, ledger shrinking, or replacement by an implicit host rule. In Mode C, Definition 861.15 says that a counterexample or socket names refused supply

without discharging it, so the blocked route is only promotion of that refusal into an exported BEDC rule.

It remains to exclude broader readings. By Definition 861.4, Definition 861.8, and Definition 861.33, the obstruction is read back through the visible ledger, replayed only by displayed routes, and kept inside the audit surface under transport. By Definition 861.28, any consumer that omits one of M, W, S, H, C, P, N is not a consumer of the displayed dependency tuple. Therefore the row blocks only the named local converse or reuse route, and no unlisted coordinate can turn it into a global impossibility, host theorem, or hidden external validation. □

Theorem 861.30 (AxiomDependencyTuple subject-reduction socket dependency route)**.** *Every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *supply-ledger read that names missing MetaCIC supply must first consume the concrete subject-reduction discharge socket of chapter 719. The tuple may then record the selected host conversion, quotient equality,* Classical.choice, propext*, ambient theorem, or MetaCIC supply name as a row of* S*, but no consumer may inspect that row as kernel supply until the socket route has exposed whether the supply is discharged, restricted, or refused.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleSubjectReductionSocketDependencyRoute`

Proof. Project the carrier $A = (M, W, S, H, C, P, N)$ from Definition 861.1. The only row that can name external or MetaCIC supply is the required-supply ledger S, and the witness row W is consumed only after the mode row M has selected the relevant reading.

Apply Definition 861.4 and Definition 861.25. These results force the ledger row to be visible before the witness can use it, and they prevent any hidden kernel-side coordinate from supplying the same material.

The concrete sibling route is chapter 719. Reading that socket before S records whether the named subject-reduction supply is discharged, restricted, or refused. The structural rows H, C, P, N then transport, replay, source, and name the same ledger entry without promoting it into an exported BEDC rule. □

Discharge-socket dependency. The three supply modes are read against the concrete subject-reduction discharge socket of chapter 719. Zero supply corresponds to obligations discharged internally by the displayed BEDC rows, restricted supply corresponds to displayed discharge hypotheses consumed from the ledger, and socket or refusal mode records missing supply rather than exporting it as a proof rule.

Theorem 861.31 (AxiomDependencyTuple supply-mode disjointness)**.** *For every accepted* AxiomDependencyTuple *carrier* $A = (M, W, S, H, C, P, N)$*, the displayed mode row* M *keeps the three supply modes pairwise disjoint. Mode A cannot be reread as Mode B or Mode C; Mode B cannot be reread as Mode A or Mode C; and Mode C cannot be reread as Mode A or Mode B under componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, or local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *transport.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleSupplyModeDisjointness`

Proof. Start with the mode row M. By Definition 861.3, M has exactly three visible readings: zero-supply proof, restricted proof with required supply, and counterexample-or-socket refusal. The row has no fourth constructor and no ambient equality principle that can identify these readings.

In Mode A, Definition 861.13 keeps the proof witness separate from an empty external ledger. This cannot be read as Mode B, because Definition 861.14 requires a full displayed supply row for every restricted witness. It cannot be read as Mode C, because Definition 861.15 requires a refusal witness naming supply that is not discharged.

In Mode B, Definition 861.11 keeps each named host or classical supply entry in S. The branch therefore cannot collapse to the zero-supply branch, and it cannot become the socket branch because the witness is consumed under a ledger rather than recorded as a counterexample.

In Mode C, Definition 861.12 and Definition 861.15 keep the witness as refusal data. Transport and replay preserve this separation by Definition 861.17 and Definition 861.18, so no route, provenance row, or local naming row can reread one mode as another. □

Theorem 861.32 (AxiomDependencyTuple consumer ledger order)**.** *Every consumer route for an accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier* $A = (M, W, S, H, C, P, N)$ *reads the mode row* M *and the required-supply ledger* S *before consuming the witness row* W*. This read order is preserved by the displayed* Cont *route row, by componentwise* hsame *transport, by the provenance row* P*, and by the local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleConsumerLedgerOrder`

Proof. First read the carrier coordinates. The public packet exposes M, W, S, H, C, P, and N as distinct rows, so a consumer route has no hidden coordinate from which to recover a witness before inspecting the mode and ledger.

The mode row is read first because Definition 861.3 determines which of the three witness readings is even available. The separation result Definition 861.31 then prevents a consumer from choosing a witness interpretation while leaving the mode undetermined.

The ledger row is read before witness consumption by Definition 861.4. In Mode A this records the empty external ledger, in Mode B it records every required supply entry, and in Mode C it records the refused supply named by the socket or counterexample.

Finally apply Definition 861.8, Definition 861.17, and Definition 861.18. Routes, transport, provenance, and local naming replay the displayed rows; they do not add a consumer path that reads W before M and S. □

Theorem 861.33 (AxiomDependencyTuple host-supply nonescape)**.** *For every accepted* $\mathsf{AxiomDependencyTuple}^{\uparrow}$ *carrier* $A = (M, W, S, H, C, P, N)$*, any named host conversion, quotient equality,* Classical.choice *use,* propext *use, or ambient theorem remains a required-supply ledger row under* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$ *transport. None of these names escapes the ledger as an exported BEDC proof rule.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyTupleUp.AxiomDependencyTupleHostSupplyNonescape`

Proof. The supply row S is the only place where external host or classical material can be named. By Definition 861.4, any consumer that reads the witness must first read that ledger entry as audit supply.

Mode B is the positive ledger case. Use Definition 861.11 and Definition 861.14: every named supply entry stays in the full displayed ledger, and no consumer may erase, shrink, or internalize it.

Mode C is the refusal case. By Definition 861.12 and Definition 861.15, a counterexample or socket names missing supply without discharging it. Thus the named host or classical datum remains a ledger row attached to refused supply.

The transport rows do not change the status of the name. Apply Definition 861.8, Definition 861.17, and Definition 861.18. Componentwise hsame, displayed Cont, Pkg provenance, and local NameCert transport replay the finite tuple surface and never export host conversion, quotient equality, choice, propositional extensionality, or ambient theorem supply as a BEDC rule. □

Closure status for $\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}$.

Constructive story: An $\mathsf{AxiomDependencyTuple}^{\uparrow}$ packet is generated from a three-mode row, a proof, restricted-proof, counterexample, or socket witness row, a required-supply ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 861.1, Definition 861.2, Definition 861.3, Definition 861.4, Definition 861.8, Definition 861.9, Definition 861.10, Definition 861.11, Definition 861.12, Definition 861.13, Definition 861.14, Definition 861.15, Definition 861.16, Definition 861.17, Definition 861.18, Definition 861.19, Definition 861.20, Definition 861.21, Definition 861.22, Definition 861.23, Definition 861.24, Definition 861.31, Definition 861.32, and Definition 861.33 bind the finite dependency-tuple carrier, mode exhaustion, ledger exactness, route non-export, consumer exhaustion, the three per-mode obligation rows, the three row-level separation rows, the BHist, hsame, Cont, Pkg, and NameCert primitive scope, the root-unblock spine, the consumer read order, the exact public audit-map interface, the supply-mode disjointness row, the consumer ledger order row, and the host-supply nonescape row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AxiomDependencyTuple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not enumerate all classical CIC claims, internalize host conversion, quotient equality, choice, propositional extensionality, or ambient classical CIC theorem supply, give Lean verification, or bridge check the tuple.

Upgrade path: Public closure next requires Lean verification of the public consumer interface and a bridge check for the scoped tuple.

Chapter 862

A Concrete Naming Certificate for $\mathsf{AxiomDependencyMap}^{\uparrow}$

The $\mathsf{AxiomDependencyMap}^{\uparrow}$ packet turns the dependency-map reading of chapter 9455 into a concrete finite certificate. It sits beside the axiom-query ledger $\mathsf{AxiomQueryLedger}^{\uparrow}$ of chapter 654, the family carrier $\mathsf{AuditMapFamily}^{\uparrow}$ of chapter 807, the compiler-facing map $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ of chapter 836, and the cross-map weave $\mathsf{AuditMapDependencyWeave}^{\uparrow}$ of chapter 839. Those sibling chapters expose ledger, family, compiler, and dependency-weave rows; this chapter packages the claim-level dependency tuple that a downstream audit-map consumer reads before deciding whether the claim is internal, restricted, or blocked by named supply.

Definition 862.1 (Axiom-dependency-map packet)**.** *An* $\mathsf{AxiomDependencyMap}^{\uparrow}$ *packet is a finite* BHist *tuple*

$$X = (\Phi, M, W, A, H, C, P, N)$$

with the following displayed rows:

1. Φ *is the claim row naming the classical-looking assertion being inspected against the BEDC substrate;*
2. M *is the mode row, with one of the three displayed readings internal proof, restricted internal proof, or obstruction with named supply;*
3. W *is the witness row, carrying the proof term, restricted proof surface, counterexample, refusal, or named socket that justifies the mode;*
4. A *is the required-axiom-set row, listing the empty supply, restricted-surface condition, or named external supply rows required by the mode;*
5. H *records componentwise* hsame *transport for the claim, mode, witness, required-axiom-set, continuation, provenance, and local naming rows;*
6. C *records the displayed* Cont *replay routes by which a consumer replays the claim read, mode classification, witness readback, and required-supply readback;*
7. P *is the* Pkg *provenance over the dependency-map vision,* $\mathsf{AxiomQueryLedger}^{\uparrow}$, $\mathsf{AuditMapFamily}^{\uparrow}$, $\mathsf{GroundCompilerAuditMap}^{\uparrow}$, $\mathsf{AuditMapDependencyWeave}^{\uparrow}$, hsame, Cont, *and* $\mathsf{NameCert}$ *source packets;*
8. N *is the local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyMap}^{\uparrow}}$ *row.*

The packet exports no ambient theorem count, no host proof oracle, no hidden axiom supply, and no permission to treat a blocked or restricted row as an unconditional BEDC theorem.

Lean4 ✓ `BEDC.Derived.AxiomDependencyMapUp.AxiomDependencyMapTasteGate single carrier alignment`

Theorem 862.2 (Axiom-dependency-map obligations)**.** *For every* $\mathsf{AxiomDependencyMap}^{\uparrow}$ *packet*

$$X = (\Phi, M, W, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AxiomDependencyMap}^{\uparrow}}$ *surface consists exactly of claim exposure, mode exposure, witness exposure, required-axiom-set exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Any consumer of* N *must read the dependency tuple through these eight rows and cannot replace them by prose comparison with classical CIC.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyMapUp.AxiomDependencyMapLedgerObligations`

Proof. Project the finite packet of Definition 862.1. The rows Φ, M, W, A expose the claim, the mode assigned to it, the displayed witness for that mode, and the required-supply row.

The rows H and C bind transport and replay. A consumer may move the packet componentwise and replay its reads, but the transport and replay endpoints remain the displayed claim, mode, witness, and required-axiom-set rows.

The provenance and naming rows P, N package the same data as the local NameCert surface. Since the carrier has no further coordinate, there is no route from N to an ambient theorem count, a host proof oracle, or a hidden supply row. □

Theorem 862.3 (Axiom-dependency-map mode exhaustion)**.** *For every accepted* $\mathsf{AxiomDependencyMap}^{\uparrow}$ *packet*

$$X = (\Phi, M, W, A, H, C, P, N),$$

the mode row M *is exhausted by the three displayed cases: internal proof, restricted internal proof, and obstruction with named supply. In the first case* A *records empty supply and* W *records the internal witness; in the second case* A *records the restricted surface and* W *records the restricted witness; in the third case* A *records the named supply and* W *records the obstruction, refusal, counterexample, or socket row.*

Proof. Read the mode row M of the packet. By definition the carrier admits only the three displayed readings, so the case split has exactly those branches.

In the internal-proof branch, the claim row Φ is paired with a witness row W that supplies the substrate proof and a required-axiom-set row A that records empty supply.

In the restricted-proof branch, the same projection reads W as the restricted witness and A as the restricted-surface condition. The carrier contains no row that erases the restriction.

In the obstruction branch, the witness row records the counterexample, refusal, or socket and A records the named supply. The packet therefore classifies blocked content as visible dependency data rather than as an unconditional theorem. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyMapUp.AxiomDependencyMapModeSoundness`

Theorem 862.4 (Axiom-dependency-map query-ledger factorization)**.** *Every downstream audit read that treats an* $\mathsf{AxiomDependencyMap}^{\uparrow}$ *packet as proof-ancestry data factors through* $\mathsf{AxiomQueryLedger}^{\uparrow}$, $\mathsf{AuditMapFamily}^{\uparrow}$, $\mathsf{GroundCompilerAuditMap}^{\uparrow}$, *or* $\mathsf{AuditMapDependencyWeave}^{\uparrow}$ *as named in* P*. In particular, a consumer cannot read the required-axiom-set row* A *as a strict ancestry verdict unless the replay route in* C *reaches the corresponding finite ledger, family, compiler, or weave row cited by the provenance package.*

Proof. Start with the provenance row P. It cites the dependency-map vision, $\mathsf{AxiomQueryLedger}^{\uparrow}$, $\mathsf{AuditMapFamily}^{\uparrow}$, $\mathsf{GroundCompilerAuditMap}^{\uparrow}$, and $\mathsf{AuditMapDependencyWeave}^{\uparrow}$ as the only package sources for query, family, compiler, and dependency-weave reads.

Next read the continuation row C. A proof-ancestry consumer must replay from Φ through the mode and witness rows to the required-axiom-set row A, then through the ledger, family, compiler, or weave row named by P.

If such a ledger or gate route is absent, the packet still records a claim-level dependency tuple, but not a strict ancestry verdict. The factorization therefore separates dependency-map classification from the finite query ledger that certifies a particular accepted declaration. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyMapUp.AxiomDependencyMapQueryLedgerFactorization`
Lean4 ✓ `BEDC.Derived.AxiomDependencyMapUp.AxiomDependencyMapCertificate query ledger factorization`

Theorem 862.5 (Axiom-dependency-map non-escape)**.** *For every accepted* $\mathsf{AxiomDependencyMap}^{\uparrow}$ *packet*

$$X = (\Phi, M, W, A, H, C, P, N),$$

every public read remains inside the displayed claim, mode, witness, required-axiom-set, hsame*,* Cont*,* Pkg*, and* NameCert *rows. The packet cannot turn a restricted row into an unrestricted theorem, a named supply row into internal BEDC content, an obstruction row into a proof, or a claim-level dependency tuple into a hidden host axiom.*

Proof. Project the accepted packet as $X = (\Phi, M, W, A, H, C, P, N)$. These are the only rows exported by the carrier.

Mode soundness from Definition 862.3 fixes how M, W, A may be read. The internal, restricted, and obstruction branches each keep their own witness and required-supply interpretation.

The factorization result of Definition 862.4 binds proof-ancestry reads to the cited ledger, family, compiler, or weave packet. Thus query meaning cannot appear from the local name alone.

Since no further coordinate exists, a consumer has no place from which to obtain unrestricted closure, hidden supply, obstruction discharge, or host-axiom admission. All public reads remain inside the finite packet. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyMapUp.AxiomDependencyMapCertificate public boundary`

Theorem 862.6 (Axiom-dependency-map required-supply separation)**.** *For every accepted* $\mathsf{AxiomDependencyMap}^{\uparrow}$ *packet*

$$X = (\Phi, M, W, A, H, C, P, N),$$

the required-axiom-set row A separates the three displayed supply modes: empty supply for internal proof, restricted-surface conditions for restricted internal proof, and named external supply for obstruction or socket rows. No downstream consumer may read one supply mode as another through H, C, P, N.

Lean4 ✓ `BEDC.Derived.AxiomDependencyMapUp.AxiomDependencyMapRequiredSupplySeparation`

Proof. Apply mode soundness from Definition 862.3. The three cases for M pair W and A with empty supply, restricted surface, or named supply respectively.

Next apply the query-ledger factorization theorem Definition 862.4. Any consumer that treats A as proof-ancestry data must replay the corresponding ledger, family, compiler, or weave route named in P and routed by C.

Finally use the boundary theorem Definition 862.5. The transport, continuation, provenance, and naming rows preserve the displayed tuple only. Since the packet contains no row that converts one supply mode into another, no consumer can read empty supply, restricted surface, and named external supply interchangeably. □

Theorem 862.7 (Axiom-dependency-map restricted-row non-escape)**.** *For every accepted* $\mathsf{AxiomDependencyMap}^{\uparrow}$ *packet*

$$X = (\Phi, M, W, A, H, C, P, N),$$

if the mode row M reads as restricted internal proof, then the witness row W and required-supply row A remain restricted under H, C, P, N. They cannot be exported as unconditional BEDC theorems, and the local $\mathsf{NameCert}_{\mathsf{AxiomDependencyMap}^{\uparrow}}$ *row exposes only the restricted dependency tuple.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyMapUp.AxiomDependencyMapRestrictedRowNonescape`

Proof. Start with mode soundness. In the restricted branch, W is a restricted witness and A is the restricted-surface condition; the carrier records no row that erases that condition.

Use query-ledger factorization to inspect any downstream replay. A consumer must pass through the finite ledger, family, compiler, or dependency-weave route named by P, so the restricted branch remains tied to the ledger that justifies the restricted reading.

Apply the non-escape boundary. The rows H, C, P, N transport, replay, package, and name the same displayed tuple, and the carrier has no coordinate for unrestricted theorem export. Therefore a restricted proof row remains restricted and cannot be read as an unconditional BEDC theorem. □

Theorem 862.8 (Axiom-dependency-map mature query-supply example)**.** *For every downstream audit consumer reading an accepted* $\mathsf{AxiomDependencyMap}^{\uparrow}$ *packet*

$$X = (\Phi, M, W, A, H, C, P, N),$$

the public query-supply read first projects the mode row M, then the witness row W and required-supply row A, then factors through the cited $\mathsf{AxiomQueryLedger}^{\uparrow}$, $\mathsf{AuditMapFamily}^{\uparrow}$, $\mathsf{GroundCompilerAuditMap}^{\uparrow}$, *or* $\mathsf{AuditMapDependencyWeave}^{\uparrow}$ *route before reporting internal, restricted, or named-supply status.*

Proof. Start with the accepted packet and apply Definition 862.3. The consumer reads M as one of the internal, restricted, or obstruction modes, and this fixes the allowed interpretation of W and A.

Next apply Definition 862.4. A query-supply report that treats A as proof-ancestry data must pass through the finite ledger, family, compiler, or dependency-weave route cited by P and replayed by C.

Use Definition 862.5 to keep the public read inside the displayed claim, mode, witness, supply, transport, replay, provenance, and local naming rows. Finally apply Definition 862.6: the empty, restricted, and named-supply rows remain distinct, so the reported status is exactly internal, restricted, or named-supply according to the projected mode. □

Closure status for $\mathsf{NameCert}_{\mathsf{AxiomDependencyMap}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AxiomDependencyMap}^{\uparrow}$ packet is generated from a claim row, a mode row, a witness row, a required-axiom-set row, componentwise hsame transports, displayed Cont replay routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AxiomDependencyMap}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 862.1, Definition 862.2, Definition 862.3, Definition 862.4, Definition 862.5, Definition 862.6, Definition 862.7, and Definition 862.8 specify the finite claim-level dependency-map packet, query-ledger

factorization, required-supply separation, restricted-row non-escape, public boundary, and mature query-supply consumer surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{AxiomDependencyMap}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not enumerate all classical CIC claims, prove global completeness of the dependency map, certify any hidden host proof oracle, close Lean verification, or bridge the packet to an external schema.

Upgrade path: Bridged closure requires a standard bridge over the same claim, mode, witness, required-supply, transport, replay, provenance, and local naming rows.

Chapter 863

A Concrete Naming Certificate for $\mathsf{AxiomDependencyMapLedger}^{\uparrow}$

The $\mathsf{AxiomDependencyMapLedger}^{\uparrow}$ packet realizes the map of chapter 9455 as a finite ledger row that can be consumed by audit-map chapters. It sits beside the audit gate of chapter 526, the strict axiom-query ledger of chapter 654, and the substitution audit map of chapter 779. Those siblings expose boundary, query, and concrete audit-map rows; this chapter records the Mode, Witness, and Required-Axiom-Set tuple as one named packet rather than as framing prose.

Definition 863.1 (AxiomDependencyMapLedger carrier)**.** *An* $\mathsf{AxiomDependencyMapLedger}^{\uparrow}$ *carrier is a finite* BHist *tuple*

$$L = (\Phi, M, W, A, H, C, P, N)$$

with the following displayed rows:

1. Φ *is the claim row whose classical-looking assertion is being mapped against the BEDC substrate;*
2. M *is the mode row, carrying exactly Mode A, Mode B, or Mode C;*
3. W *is the witness row, carrying the proof, restricted proof, counterexample, refusal, or socket data appropriate to* M*;*
4. A *is the Required-Axiom-Set row, carrying empty supply, restricted-surface supply, or the named supply rows required by the witness;*
5. H *records componentwise* hsame *transport for the claim, mode, witness, required-supply, continuation, provenance, and local naming rows;*
6. C *records the displayed* Cont *routes by which a consumer replays the claim read, mode read, witness readback, and required-supply readback;*
7. P *is the* Pkg *provenance over chapter 9455, chapter 526, chapter 654, chapter 779,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. N *is the local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyMapLedger}^{\uparrow}}$ *row.*

The classifier accepts the ledger only through this finite packet. It contains no ambient proof oracle, no hidden host axiom supply, no unrecorded query rerun, and no permission to treat a restricted or obstructed row as an unconditional BEDC theorem.

Theorem 863.2 (AxiomDependencyMapLedger surface)**.** *For every accepted* $\mathsf{AxiomDependencyMapLedger}^{\uparrow}$ *carrier*

$$L = (\Phi, M, W, A, H, C, P, N),$$

the public $\mathsf{NameCert}_{\mathsf{AxiomDependencyMapLedger}^{\uparrow}}$ *surface is exactly the claim row, mode row, witness row, Required-Axiom-Set row, componentwise transport row, replay route row, provenance row, and local naming row. Every downstream audit-map read must factor through these eight rows and through the sibling boundary, query, or audit-map packets named in* P*.*

Proof. Project the carrier of Definition 863.1. The rows Φ, M, W, A expose the mapped claim, its mode, its witness, and its required-supply entry.

Read H and C next. Transport and replay preserve the same four visible map rows and do not create a second route to host proof ancestry.

Finally inspect P and N. Provenance points to chapter 9455, chapter 526, chapter 654, and chapter 779; the local name only packages this finite surface. Therefore every public read factors through the displayed ledger rows. □

Theorem 863.3 (AxiomDependencyMapLedger Mode A)**.** *If an accepted* $\mathsf{AxiomDependencyMapLedger}^{\uparrow}$ *carrier has Mode A in* M*, then* W *is read as an unconditional substrate proof witness for* Φ *and* A *is read as empty required supply. The rows* H, C, P, N *may transport, replay, package, and name that reading, but they cannot add a hidden dependency row to the Mode A entry.*

Proof. Read the mode row M from Definition 863.1. In the Mode A branch, the carrier definition fixes the witness row as an internal proof and fixes the Required-Axiom-Set row as empty supply.

Use Definition 863.2 to route every consumer through the same rows. The support rows H, C, P, N preserve and expose the entry but do not add another source of proof supply.

Thus Mode A remains a zero-supply ledger entry for the displayed claim, not a claim about unrecorded host proof ancestry. □

Theorem 863.4 (AxiomDependencyMapLedger Mode B)**.** *If an accepted* $\mathsf{AxiomDependencyMapLedger}^{\uparrow}$ *carrier has Mode B in* M*, then* W *is read only as a restricted-proof witness and* A *is read as the restricted-surface condition required for that witness. A consumer may not erase the restriction, replace it by an unrestricted proof, or read the restricted surface without the replay route carried by* C*.*

Proof. Project M, W, A from the accepted carrier. The Mode B branch pairs the witness row with the restricted-surface row, so the witness is not exposed independently of that surface.

Replay the entry through C and transport it through H. The same restricted row remains attached to the witness after movement, while P and N package the entry as the local ledger surface.

Because no carrier coordinate contains an unrestricted proof of Φ, no downstream consumer can erase the restriction or convert the Mode B row into Mode A. □

Theorem 863.5 (AxiomDependencyMapLedger Mode C)**.** *If an accepted* $\mathsf{AxiomDependencyMapLedger}^{\uparrow}$ *carrier has Mode C in* M*, then* W *is read as a counterexample, refusal, obstruction, or socket witness and* A *is read as the named required-supply row. The carrier records the dependency boundary; it does not discharge the named supply or turn the obstruction into a substrate theorem.*

Proof. Read the Mode C branch of the carrier. The rows W and A are paired as obstruction data and named supply, not as a proof and empty dependency set.

Use the public surface theorem to keep the read inside $L = (\Phi, M, W, A, H, C, P, N)$. The route row C can replay the obstruction and the supply name, and the transport row H preserves those coordinates componentwise.

The provenance row points to the boundary, query, and audit-map siblings, where such supply must be inspected. Since the local ledger has no coordinate for discharging the named supply, Mode C remains a dependency record and not an internal BEDC proof. □

Closure status for $\mathsf{NameCert}_{\mathsf{AxiomDependencyMapLedger}^{\uparrow}}$.

Constructive story: An $\mathsf{AxiomDependencyMapLedger}^{\uparrow}$ packet is generated from a claim row, a three-mode row, a witness row, a Required-Axiom-Set row, componentwise hsame transport, displayed Cont replay routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AxiomDependencyMapLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 863.1, Definition 863.2, Definition 863.3, Definition 863.4, and Definition 863.5 specify the finite Mode, Witness, Required-Axiom-Set ledger packet and its three mode readings.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AxiomDependencyMapLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not enumerate all classical CIC claims, prove global dependency-map completeness, discharge named host supply, provide Lean verification, or bridge the ledger to an external schema.

Upgrade path: Obligation closure requires checked carrier admission, three-mode classification, witness exactness, Required-Axiom-Set exactness, replay locality, provenance, local naming, and non-escape for the same finite ledger packet.

Chapter 864

A Concrete Naming Certificate for $\mathsf{RestrictedSurfaceBudget}^{\uparrow}$

The $\mathsf{RestrictedSurfaceBudget}^{\uparrow}$ packet isolates the Mode-B row of chapter 9455 as reusable finite NameCert data. It sits beside $\mathsf{AxiomDependencyTuple}^{\uparrow}$ in chapter 861, $\mathsf{AxiomDependencyMap}^{\uparrow}$ in chapter 862, $\mathsf{AuditMapFamily}^{\uparrow}$ in chapter 817, and $\mathsf{ForbiddenAxiomAncestry}^{\uparrow}$ in chapter 622. Those siblings package full dependency tuples, map families, and refusal verdicts; this chapter packages the restricted surface itself as the consumer-stable budget row that keeps a restricted proof from escaping as an unconditional BEDC theorem.

Definition 864.1 (Restricted-surface budget carrier)**.** *A* $\mathsf{RestrictedSurfaceBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (\Phi, R, W, S, E, H, C, P, N)$$

with the following displayed rows:

1. Φ *is the claim row naming the classical-looking assertion whose Mode-B surface is being recorded;*
2. R *is the restricted-surface row, listing the syntactic, closedness, classifier, or displayed-domain condition under which the internal proof is valid;*
3. W *is the restricted witness row, carrying the internal proof term only as a witness under* R*;*
4. S *is the required-supply row, recording that no extra BEDC supply is used on* R *while the unrestricted claim still retains its stated boundary;*
5. E *is the non-export row, forbidding a consumer from reading* W *as an unconditional proof of* Φ*;*
6. H *records componentwise* hsame *transport for the claim, restricted surface, witness, required-supply, non-export, replay, provenance, and local naming rows;*
7. C *records the displayed* Cont *replay routes by which a consumer reads* Φ*, verifies* R*, replays* W *under* R*, reads* S*, and checks* E*;*
8. P *is the* Pkg *provenance over the dependency-map vision,* $\mathsf{AxiomDependencyTuple}^{\uparrow}$*,* $\mathsf{AxiomDependencyMap}^{\uparrow}$*,* $\mathsf{AuditMapFamily}^{\uparrow}$*,* $\mathsf{ForbiddenAxiomAncestry}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RestrictedSurfaceBudget}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose witness is budgeted by the displayed restricted surface and whose public export is bounded by the non-export row.

Lean4 ✓ `BEDC.Derived.RestrictedSurfaceBudgetUp.RestrictedSurfaceBudgetTasteGate single carrier alignment`

Theorem 864.2 (Restricted-surface budget NameCert obligations)**.** *For every* $\mathsf{RestrictedSurfaceBudget}^{\uparrow}$ *packet*

$$B = (\Phi, R, W, S, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RestrictedSurfaceBudget}^{\uparrow}}$ *surface consists exactly of claim exposure, restricted-surface exposure, restricted-witness exposure, required-supply exposure, non-export exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer of* N *may cite the Mode-B witness only together with* R, S, E, H, C, P *and cannot cite it as a BEDC-internal proof of the unrestricted claim row* Φ*.*

Proof. Project the packet of Definition 864.1. The rows Φ, R, W, S, E are the complete payload: a claim, the surface on which it is discharged, the witness on that surface, the required-supply row, and the non-export boundary.

Read H and C next. Transport can move the displayed rows only componentwise, and replay must first inspect R before it reads W as a witness for the claim.

Finally inspect P and N. Provenance cites the sibling dependency-map, tuple, family, and forbidden-ancestry chapters, while the local name binds the same finite packet. Since no coordinate stores an unrestricted theorem export, the certificate obligations are exhausted by the displayed rows. □

Theorem 864.3 (Restricted-surface budget Mode-B non-escape)**.** *For every accepted* $\mathsf{RestrictedSurfaceBudget}^{\uparrow}$ *packet*

$$B = (\Phi, R, W, S, E, H, C, P, N),$$

the restricted witness row W *remains a Mode-B witness under the surface row* R*. Transport, replay, provenance, and local naming may cite* W *only through the same restricted-surface budget, and no consumer may erase* R*, ignore* E*, or re-export* W *as an unconditional BEDC theorem for* Φ*.*

Proof. Begin with the carrier projection. The witness row W is paired with R and with the non-export row E in the same finite packet.

Replay then fixes the order of use. A consumer route in C reads the claim row, checks the restricted surface, reads the witness under that surface, and then reads the required-supply and non-export rows. The replay route contains no branch that bypasses R or E.

Transport and provenance preserve the same boundary. The row H moves only displayed coordinates, P cites the sibling dependency packets as sources, and N names the local carrier. Therefore the witness can be cited as Mode-B budget data, but not as an unrestricted BEDC theorem. □

Falsifiable prediction: If the restricted-surface row is deleted, no consumer may cite the Mode-B witness as a BEDC-internal restricted proof.

Independence witness: axiomdependencymap, axiom-dependency-tuple, auditmapfamily, forbiddenaxiomancestry: the first two package full dependency tuples, the family chapter packages map collections, and forbidden ancestry packages refusal verdicts; none isolates the restricted-surface budget row as a consumer-stable carrier.

The Lean side must provide Nontrivial and FieldFaithful instances for the same carrier in `lean4/BEDC/Derived/RestrictedSurfaceBudgetUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{RestrictedSurfaceBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{RestrictedSurfaceBudget}^{\uparrow}$ packet is generated from a claim row, restricted-surface row, restricted-witness row, required-supply row, non-export row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RestrictedSurfaceBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 864.1, Definition 864.2, and Definition 864.3 specify the reusable Mode-B restricted-surface budget, NameCert obligations, and non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RestrictedSurfaceBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove the unrestricted claim row, enumerate every Mode-B surface, close Lean verification, or bridge the budget to an external schema.

Upgrade path: Obligation closure requires checked carrier admission, restricted-surface exactness, witness replay under the surface, required-supply exactness, non-export, and TasteGate instances for the same packet.

Chapter 865

A Concrete Naming Certificate for $\mathsf{InternalTheoryBoundary}^{\uparrow}$

The $\mathsf{InternalTheoryBoundary}^{\uparrow}$ packet turns the own-theory reading of chapter 9454 into a concrete finite certificate. It sits beside the kernel-acceptance packet of chapter 549, the forbidden-host-axiom ancestry boundary of chapter 622, and the proposition-transport boundary of chapter 566. Those sibling chapters expose accepted-declaration rows, strict proof-ancestry rows, and directed proposition-transport rows; this chapter packages the positive BEDC.MetaCIC commitments that make those rows internal rather than borrowed from a comparison calculus.

Definition 865.1 (InternalTheoryBoundary carrier)**.** *An* $\mathsf{InternalTheoryBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, E, R, Z, A, H, C, P, N)$$

with the following displayed rows:

1. *G is the closed-generator row, naming the finite constructors, binder forms, typed example rows, and accepted declaration rows from which BEDC.MetaCIC objects are generated;*
2. *E is the literal AST equality row, recording syntactic equality, constructor tag equality, and componentwise binder equality as displayed kernel data rather than as host quotient equality;*
3. *R is the structural recursor row, exposing only the recursors attached to the closed generators in G and the continuation routes that consume their recursive branches;*
4. *Z is the strict-purity row, recording the empty source-axiom supply, accepted kernel row, and forbidden-host-axiom refusal surface required before a theorem is read as BEDC-internal;*
5. *A is the apophatic boundary row, recording that comparison with classical CIC is secondary analysis and not a carrier coordinate, definition source, or external equality oracle for BEDC.MetaCIC;*
6. *H records componentwise* hsame *transport for the generator, AST equality, recursor, purity, boundary, continuation, provenance, and local naming rows;*
7. *C records the displayed* Cont *routes by which a consumer reads generators, literal AST comparison, structural recursion, strict-purity audit, and the apophatic boundary;*
8. *P is the* Pkg *provenance over BEDC.MetaCIC,* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$, $\mathsf{ForbiddenAxiomAncestry}^{\uparrow}$, $\mathsf{PropextTransportBoundary}^{\uparrow}$, hsame, Cont, *and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{InternalTheoryBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host subtheory embedding, proposition equality supplied by propext*, quotient stream equality, classical-CIC definitional authority, hidden axiom supply, or external completeness principle.*

Theorem 865.2 (InternalTheoryBoundary NameCert obligations)**.** *For every* $\mathsf{InternalTheoryBoundary}^{\uparrow}$ *carrier*

$$I = (G, E, R, Z, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{InternalTheoryBoundary}^{\uparrow}}$ *surface consists exactly of closed-generator exposure, literal AST equality exposure, structural recursor exposure, strict-purity exposure, apophatic boundary exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Proof. Project the finite packet of Definition 865.1. The rows G, E, R, Z, A expose the five positive commitments named by chapter 9454.

The transport and replay rows H and C are componentwise. A consumer may move the packet or replay one of its reads, but the endpoints remain the displayed generator, AST equality, recursor, purity, and boundary rows.

The package and naming rows P, N bind the same surface to the local certificate. Since no additional coordinate is present, the NameCert obligations cannot import an external equality oracle, hidden host axiom supply, or classical-CIC definitional authority. □

Theorem 865.3 (InternalTheoryBoundary closed-generator non-escape)**.** *Every accepted* $\mathsf{InternalTheoryBoundary}^{\uparrow}$ *packet reads BEDC.MetaCIC objects through the closed-generator row G, the literal AST equality row E, and the structural recursor row R. A downstream consumer cannot replace those rows by a host syntax quotient, a classical-CIC embedding, an unlisted constructor, or a recursor not generated by G.*

Proof. Start with the carrier definition. The only object-generation row is G, the only equality row is E, and the only recursion row is R.

The continuation routes in C read these rows directly. The transport row H moves them componentwise and therefore preserves the same finite generator inventory, AST comparison, and structural recursion surface.

The excluded objects have no coordinate in $I = (G, E, R, Z, A, H, C, P, N)$. Hence a consumer has no route to a host syntax quotient, a classical-CIC embedding, an unlisted constructor, or an ungenerated recursor. □

Theorem 865.4 (InternalTheoryBoundary comparison secondary)**.** *Any comparison between BEDC.MetaCIC and classical CIC that is read from an* $\mathsf{InternalTheoryBoundary}^{\uparrow}$ *packet is secondary analysis over the displayed rows $G, E, R, Z, A, H, C, P, N$. It may consume the accepted-declaration surface of chapter 549, the forbidden-axiom refusal surface of chapter 622, and the directed proposition-transport surface of chapter 566, but it cannot define BEDC.MetaCIC by a subtheory relation, proposition extensionality, quotient equality, or external completeness.*

Proof. Read the apophatic boundary row A. It records the comparison as a boundary reading, not as a generator, equality, recursor, or purity source.

The package row P permits references to the three sibling certificates. Kernel acceptance supplies accepted-declaration rows, forbidden-axiom ancestry supplies strict refusal rows, and proposition-transport supplies directed implication rows in place of proposition equality.

Those sibling surfaces remain finite certificate data. None supplies a coordinate that turns classical CIC into the defining substrate of BEDC.MetaCIC, and none adds a host equality or completeness principle to the packet. □

Theorem 865.5 (InternalTheoryBoundary vision concretization)**.** *The carrier of Definition 865.1, the NameCert obligations of Definition 865.2, the closed-generator non-escape boundary of Definition 865.3, and the secondary-comparison boundary of Definition 865.4 realize the five positive commitments of chapter 9454: closed generators, literal AST equality, structural recursors, zero-axiom strict purity, and apophatic external boundary.*

Proof. The definition assigns the five commitments to the rows G, E, R, Z, A. The structural rows H, C, P, N then make those commitments readable as one finite local certificate.

The obligation theorem identifies the complete NameCert surface over those rows. The non-escape theorem prevents the closed generator, literal equality, and recursor clauses from being replaced by host objects.

The secondary-comparison theorem handles the apophatic clause: comparison language may be read as analysis over the packet, but it cannot define the packet. The strict-purity row Z supplies the remaining zero-axiom commitment through the accepted-declaration and forbidden-ancestry surfaces named in P. □

Closure status for $\mathsf{NameCert}_{\mathsf{InternalTheoryBoundary}^{\uparrow}}$**.**

Constructive story: An $\mathsf{InternalTheoryBoundary}^{\uparrow}$ packet is generated from closed generator rows, literal AST equality rows, structural recursor rows, strict-purity rows, apophatic boundary rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InternalTheoryBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 865.1, Definition 865.2, Definition 865.3, Definition 865.4, and Definition 865.5 bind the finite own-theory boundary packet for BEDC.MetaCIC.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InternalTheoryBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove global semantic conservativity, host-kernel correctness, a classical-CIC embedding, proposition extensionality, quotient equality, Lean verification, or bridge checking for $\mathsf{InternalTheoryBoundary}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, five-row obligation exactness, strict-purity routing, closed-generator non-escape, and secondary-comparison non-escape for the displayed packet.

Chapter 866

A Concrete Naming Certificate for $\mathsf{MetaCICIdentityCommitment}^{\uparrow}$

The $\mathsf{MetaCICIdentityCommitment}^{\uparrow}$ packet turns the principle of chapter 9454 into a finite naming certificate. It is read together with the dependency-map surface of chapter 9455, the cross-map routing packet of chapter 839, and the forbidden-host-ancestry boundary of chapter 622. Those chapters expose dependency, routing, and forbidden-ancestry rows; this chapter packages the positive identity commitments by which BEDC.MetaCIC is named as its own substrate.

Definition 866.1 (MetaCIC identity commitment carrier)**.** *A* $\mathsf{MetaCICIdentityCommitment}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, E, R, P, A, H, C, Q, N)$$

with the following displayed rows:

1. *G is the closed-generator row, listing the finite constructor and formation rows by which the substrate is generated;*
2. *E is the literal-AST equality row, recording equality by displayed syntax and not by comparison with another calculus;*
3. *R is the structural-recursor row, naming the recursor and induction routes that act on the closed generators of G;*
4. *P is the strict-purity row, recording that accepted internal reads use the displayed generator, equality, and recursor rows without a hidden host axiom supply;*
5. *A is the apophatic-boundary row, naming the points where an internal BEDC.MetaCIC route stops without redefining the substrate by absence from classical CIC;*
6. *H records componentwise* hsame *transport for the generator, equality, recursor, purity, apophatic-boundary, continuation, provenance, and local naming rows;*
7. *C records the displayed* Cont *routes by which a consumer replays the generator read, equality readback, recursor readback, strict-purity read, and apophatic-boundary read;*
8. *Q is the* Pkg *provenance over the own-theory principle, axiom-dependency map, audit-map dependency weave, forbidden-axiom ancestry packet,* hsame, Cont, *and* $\mathsf{NameCert}$ *source rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICIdentityCommitment}^{\uparrow}}$ *row.*

The carrier has no coordinate for a derivative-subtheory inclusion, a hidden comparison theorem with classical CIC, a host proof oracle, or an external axiom supply.

Theorem 866.2 (MetaCIC identity commitment NameCert obligations)**.** *For every* $\mathsf{MetaCICIdentityCommitment}^{\uparrow}$ *carrier*

$$I = (G, E, R, P, A, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICIdentityCommitment}^{\uparrow}}$ *surface consists exactly of closed-generator exposure through* G*, literal-AST equality exposure through* E*, structural-recursor exposure through* R*, strict-purity exposure through* P*, apophatic-boundary exposure through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* Q*, and local naming through* N*.*

Proof. Project the finite carrier of Definition 866.1. The rows G, E, R, P, A expose the positive generator, equality, recursor, strict-purity, and apophatic-boundary commitments.

The transport and replay rows H and C bind those commitments componentwise. A consumer may transport or replay the packet, but the endpoints remain the displayed rows of the same carrier.

The provenance and naming rows Q, N package the same finite data as the local $\mathsf{NameCert}$ surface. Since the carrier has no further coordinate, no additional inclusion, comparison theorem, host oracle, or external supply can enter the certificate. □

Theorem 866.3 (MetaCIC identity commitment nonderivative boundary)**.** *For every accepted* $\mathsf{MetaCICIdentityCommitment}^{\uparrow}$ *carrier*

$$I = (G, E, R, P, A, H, C, Q, N),$$

the packet names BEDC.MetaCIC by its own closed generators, literal-AST equality, structural recursors, strict-purity row, and apophatic boundary. It cannot be read as a derivative-subtheory claim, a comparison-first definition, or a theorem that classical CIC supplies the meaning of the carrier.

Proof. Read the positive rows G, E, R, P, A. They state the substrate identity by generator closure, literal syntax, structural recursion, strict purity, and internal stopping points.

The continuation row C only replays those displayed reads, and the transport row H only carries them componentwise. Neither row contains a map from classical CIC into the carrier or a row that turns comparison language into a definition.

Thus the boundary is nonderivative by inventory. The finite packet exports exactly the positive identity rows and the local certificate rows; it exports no derivative-subtheory inclusion and no comparison-first meaning clause. □

Theorem 866.4 (MetaCIC identity commitment audit-map handoff)**.** *Every downstream audit-map consumer of an accepted* $\mathsf{MetaCICIdentityCommitment}^{\uparrow}$ *carrier must factor its read through the provenance row* Q *and the continuation row* C*. The consumer may cite the axiom-dependency map, audit-map dependency weave, and forbidden-axiom ancestry packets named in* Q*, but it cannot replace the positive identity rows* G, E, R, P, A *by a hidden dependency-map verdict or by a forbidden-ancestry refusal row.*

Proof. Start with the provenance row Q. It names the own-theory principle together with the axiom-dependency map, audit-map dependency weave, and forbidden-axiom ancestry packets as the cited handoff surfaces.

Next read the continuation row C. A downstream audit-map consumer reaches generator, equality, recursor, purity, and apophatic-boundary data only by replaying the displayed routes from the carrier.

The handoff is therefore a routing claim, not a replacement claim. Dependency-map and forbidden-ancestry consumers may inspect the packet through Q and C, but the positive identity rows remain the source rows of the local NameCert. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICIdentityCommitment}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICIdentityCommitment}^{\uparrow}$ packet is generated from closed-generator rows, literal-AST equality rows, structural-recursor rows, strict-purity rows, apophatic-boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICIdentityCommitment}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 866.1, Definition 866.2, Definition 866.3, and Definition 866.4 specify the finite positive identity packet, local NameCert surface, nonderivative boundary, and audit-map handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICIdentityCommitment}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove global equivalence with classical CIC, close the axiom-dependency map, certify forbidden-ancestry purity, provide Lean-side formal verification, or bridge the packet to an external schema.

Upgrade path: Obligation closure requires checked carrier admission, row exactness for generators, equality, recursors, strict purity, and apophatic boundary, plus handoff preservation for downstream audit-map consumers.

Chapter 867

A Concrete Naming Certificate for MetaCICIdentityBoundary$^{\uparrow}$

The MetaCICIdentityBoundary$^{\uparrow}$ packet realizes the identity reading of chapter 9454 as a finite NameCert boundary for BEDC.MetaCIC. It is placed beside the dependency map of chapter 862, the normal-form false exclusion packet of chapter 732, the subject-reduction boundary of chapter 721, the closed-normal consistency packet of chapter 736, and the discharge socket of chapter 719. Those siblings expose dependency, normal endpoint, subject-reduction boundary, consistency endpoint, and discharge-socket rows; this chapter names the identity boundary that keeps those rows visible without importing a classical CIC parent theory.

Definition 867.1 (MetaCIC identity-boundary carrier)**.** *A* MetaCICIdentityBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (G, E, R, P, B, L, H, C, Q, N)$$

with the following displayed rows:

1. *G is the closed-generator row for BEDC.MetaCIC constructors, formation rows, and finite introduction routes;*
2. *E is the literal AST equality row, reading identity by displayed syntax rather than by quotienting through an external calculus;*
3. *R is the structural recursor row, exposing the induction and eliminator routes available on the closed generators;*
4. *P is the strict-purity row, recording that accepted reads cite only displayed generator, equality, recursor, ledger, transport, route, provenance, and naming rows;*
5. *B is the external-boundary row, recording exactly where a request asks for a classical CIC comparison, a closed subject-reduction theorem, or another nonlocal parent-theory commitment;*
6. *L is the identity ledger, linking G, E, R, P, B to the five sibling surfaces named above;*
7. *H records componentwise* hsame *transport for all displayed rows;*
8. *C records the finite* Cont *routes by which consumers read the generator, equality, recursor, purity, boundary, ledger, provenance, and local naming rows;*
9. *Q is the* Pkg *provenance over chapter 9454, chapter 862, chapter 732, chapter 721, chapter 736, chapter 719,* BHist*,* hsame*,* Cont*, and* NameCert *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICIdentityBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a closed subject-reduction theorem, no map from classical CIC into BEDC.MetaCIC, and no hidden axiom supply.

Definition 867.2 (MetaCIC identity-boundary classifier)**.** *Two* $\mathsf{MetaCICIdentityBoundary}^{\uparrow}$ *carriers*

$$M = (G, E, R, P, B, L, H, C, Q, N)$$

and

$$M' = (G', E', R', P', B', L', H', C', Q', N')$$

are classifier-equivalent exactly when the closed-generator rows, literal AST equality rows, structural recursor rows, strict-purity rows, external-boundary rows, identity-ledger rows, componentwise transports, continuation routes, provenance rows, and local naming rows agree through the displayed hsame *and* Cont *data. The classifier does not compare carriers by semantic equivalence with classical CIC or by any theorem absent from the displayed sibling packets.*

Theorem 867.3 (MetaCIC identity-boundary NameCert obligations)**.** *For every* $\mathsf{MetaCICIdentityBoundary}^{\uparrow}$ *carrier*

$$M = (G, E, R, P, B, L, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICIdentityBoundary}^{\uparrow}}$ *surface consists of five finite commitment rows:*

1. *closed-generator exposure through G;*
2. *literal AST equality exposure through E;*
3. *structural recursor exposure through R;*
4. *strict-purity exposure through P;*
5. *external-boundary exposure through B, with ledger accountability through L, H, C, Q, N.*

These rows certify the positive identity of BEDC.MetaCIC as its own substrate boundary. They do not certify a closed subject-reduction theorem, a comparison theorem with classical CIC, or any external proof supply.

Proof. Project the finite carrier of Definition 867.1. The rows G, E, R, P, B are the five commitment rows, and L, H, C, Q, N make those commitments inspectable by ledger, transport, replay, provenance, and local naming.

Classifier exactness follows from Definition 867.2. Agreement is checked on the displayed rows only, so an external comparison theorem or missing subject-reduction theorem cannot become part of the classifier.

The NameCert surface is therefore exactly the five displayed commitments plus their structural accountability rows. Since the carrier has no further coordinate, no sixth commitment or hidden parent-theory supply is exported. □

Theorem 867.4 (MetaCIC identity-boundary ledger non-escape)**.** *Every consumer read of an accepted* $\mathsf{MetaCICIdentityBoundary}^{\uparrow}$ *carrier factors through*

$$G, E, R, P, B, L, H, C, Q, N.$$

If a route asks for a closed subject-reduction theorem, a semantic embedding into classical CIC, a host equality oracle, or an external axiom dependency not recorded by the sibling dependency-map packet, the request lands in the external-boundary row B and cannot be exported as a theorem row.

Proof. Read the consumer route through C. If the route reaches G, E, R, P, L, H, Q, N, it remains inside the positive identity packet and its structural accountability rows.

If the route asks for material outside those rows, the carrier offers only B as a boundary coordinate. The ledger row L ties that boundary to the axiom-dependency map, normal false exclusion, subject-reduction boundary, closed-normal consistency, and discharge-socket siblings.

Thus a boundary read remains a boundary read. It cannot be reclassified as closed subject reduction, semantic parenthood, host equality, or an undisplayed axiom dependency. □

Theorem 867.5 (MetaCIC identity-boundary sibling independence)**.** ***Independence witness:*** *The axiom-dependency-map packet, normal-false-exclusion packet, MetaCIC subject-reduction-boundary packet, closed-normal-consistency packet, and subject-reduction-discharge-socket packet are not bijective to the* $\mathsf{MetaCICIdentityBoundary}^{\uparrow}$ *carrier. The dependency map has claim, mode, witness, and supply rows; normal false exclusion has a beta-strong false endpoint row; the subject-reduction boundary has obstruction rows for typed reduction preservation; closed-normal consistency has a positive normal endpoint; and the discharge socket has four discharge-commitment rows. None has exactly the five identity commitments* G, E, R, P, B *with the identity ledger* L *and local boundary classifier of Definition 867.2.*

Proof. Compare row inventories. The sibling chapters named in the witness each expose a specialized consumer surface: dependency accounting, normal-endpoint exclusion, subject-reduction obstruction, closed-normal consistency, or four-row discharge sockets.

The identity-boundary carrier instead exposes closed generators, literal AST equality, structural recursors, strict purity, and external-boundary rows as one packet. Its ledger cites the siblings, but citation is not a bijection of carriers.

Therefore a consumer may use the siblings as provenance and boundary context, yet cannot replace this five-commitment identity packet by any one of them or by a product of their visible theorem rows. □

Theorem 867.6 (MetaCIC identity-boundary TasteGate follow-up)**.** *The Lean-side follow-up for* $\mathsf{MetaCICIdentityBoundary}^{\uparrow}$ *must provide a* $\mathsf{ChapterTasteGate}$ *route whose carrier is nontrivial and field-faithful. In particular, the future 'TasteGate.lean' development must supply* $\mathsf{Nontrivial}$ *and* $\mathsf{FieldFaithful}$ *instances for the identity-boundary carrier before a checked gate can claim that the packet has more than a vacuous event-flow encoding and that its encoding preserves the five displayed commitment fields.*

Lean4 ✓ `BEDC.Derived.MetaCICIdentityBoundaryUp.MetaCICIdentityBoundaryTasteGate single carrier alignment`

Proof. The carrier has five named commitment fields and structural rows that must remain distinguishable. A gate that recognizes only an event-flow round trip would not by itself show that the fields G, E, R, P, B are preserved as distinct BEDC commitments.

Nontriviality rules out the empty or singleton reading of the carrier, and field faithfulness records that the encoding reflects the displayed field structure. These are exactly the extra gate rows needed before the identity-boundary packet can be read as a checked TasteGate object. □

Falsifiable prediction: If a MetaCIC identity-boundary packet is accepted, no consumer route may turn its external-boundary row into a closed subject-reduction theorem without citing a subject-reduction discharge sibling.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICIdentityBoundary}^{\uparrow}}$.

Constructive story: A MetaCICIdentityBoundary$^{\uparrow}$ packet is generated from closed-generator rows, literal AST equality rows, structural recursor rows, strict-purity rows, external-boundary rows, an identity ledger, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MetaCICIdentityBoundary}\uparrow}$, seed)

Scope closed: Definition 867.1, Definition 867.2, Definition 867.3, Definition 867.4, Definition 867.5, and Definition 867.6 specify the seed carrier, classifier, five-row NameCert surface, non-escape ledger, sibling independence witness, and gate-facing follow-up.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICIdentityBoundary}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove closed subject reduction, construct a semantic embedding into classical CIC, close the sibling packets, provide Lean-side formal verification, or bridge the packet to an external schema.

Upgrade path: Obligation closure requires Lean encoding of the carrier and classifier, checked five-row obligation exposure, ledger non-escape, sibling independence, and a TasteGate route with Nontrivial and FieldFaithful instances.

Chapter 868

A Concrete Naming Certificate for $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$

The $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$ packet realizes the dependency-map vision of chapter 9455 as a finite audit carrier. It sits beside the paper-marker resolution witness of chapter 669 and the forbidden-host-axiom boundary of chapter 622: those chapters certify marker resolution and forbidden ancestry refusal, while this chapter packages the mode, witness, and required-axiom rows that make a dependency-map entry readable by a $\mathsf{NameCert}$ consumer.

Definition 868.1 (AxiomDependencyAuditMap carrier)**.** *An* $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, M, W, A, L, H, C, P, N)$$

with the following visible coordinates:

1. *K is the audited claim or declaration row whose dependency status is being read;*
2. *M is the mode row, with one of the displayed readings internal, restricted, or externally supplied;*
3. *W is the witness row for the selected mode, carrying the internal proof witness, restricted witness, refusal witness, counterexample row, or named socket;*
4. *A is the required-axiom row, recording empty supply, a restricted-surface condition, or the finite named supply required by the mode;*
5. *L is the finite audit ledger linking the claim row to the marker-resolution and forbidden-ancestry packets named by provenance;*
6. *H records componentwise* hsame *transport for the claim, mode, witness, required-axiom, ledger, continuation, package, and local naming rows;*
7. *C records the visible* Cont *routes by which a consumer replays the mode read, witness read, required-axiom read, and ledger read;*
8. *P is the* Pkg *provenance over the dependency-map vision,* $\mathsf{PaperLeanDriftWitness}^{\uparrow}$, $\mathsf{ForbiddenAxiomAncestry}^{\uparrow}$, $\mathsf{AxiomDependencyMap}^{\uparrow}$, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyAuditMap}^{\uparrow}}$ *row.*

The carrier exports no hidden proof oracle, no global theorem census, no host axiom permission, and no conversion from a restricted or supplied row into an unconditional BEDC theorem.

Theorem 868.2 (AxiomDependencyAuditMap mode totality)**.** *For every accepted* $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$ *packet*

$$D = (K, M, W, A, L, H, C, P, N),$$

the mode row M is exhausted by the three displayed readings internal, restricted, and externally supplied. The internal reading pairs W with an internal witness and A with empty supply; the restricted reading pairs W with a restricted witness and A with the restricted surface; the externally supplied reading pairs W with the refusal, counterexample, or socket row and A with the named finite supply.

Proof. Project the accepted packet and inspect its mode coordinate M. The carrier definition lists only the internal, restricted, and externally supplied readings, so the case split has exactly those branches.

In the internal branch, the witness row and required-axiom row are read together: W records the displayed internal witness and A records empty supply.

In the restricted branch, the same projection keeps the restriction visible by pairing W with the restricted witness and A with the restricted surface. No carrier coordinate erases that restriction.

In the externally supplied branch, W records the refusal, counterexample, or socket row, while A records the named finite supply. The packet therefore reports supply as audit data rather than as a BEDC proof. □

Lean4 ✓ `BEDC.Derived.AxiomDependencyAuditMapUp.AxiomDependencyAuditMap mode totality`

Theorem 868.3 (AxiomDependencyAuditMap NameCert obligations)**.** *For the carrier of Definition 868.1, the local* $\mathsf{NameCert}_{\mathsf{AxiomDependencyAuditMap}^{\uparrow}}$ *surface consists exactly of carrier exposure for D, mode totality for M, witness exposure for W, required-axiom exposure for A, finite ledger exposure for L, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row N. Every consumer of N must read the dependency lattice through these rows and cannot replace them by an unrecorded host-kernel comparison.*

Lean4 ✓ `BEDC.Derived.AxiomDependencyAuditMapUp.AxiomDependencyAuditMapCarrier namecert obligations`

Proof. Carrier exposure is projection of Definition 868.1. The claim, mode, witness, required-axiom, ledger, transport, replay, package, and local naming rows are all visible coordinates of the same finite packet.

Mode totality is supplied by Definition 868.2. It fixes how M, W, A may be consumed in the internal, restricted, and externally supplied branches.

The ledger row L links the claim to the paper-marker and forbidden-ancestry packets named by P. The transport and continuation rows H, C preserve that link componentwise.

Since the carrier has no coordinate for a host proof oracle or an unrecorded axiom comparison, the local NameCert surface is exhausted by the displayed dependency rows. □

Theorem 868.4 (AxiomDependencyAuditMap non-escape)**.** *Every public read from an accepted* $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$ *packet remains inside the displayed claim, mode, witness, required-axiom, ledger,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The packet cannot turn a restricted row into an unrestricted theorem, a required-supply row into internal BEDC content, a refusal row into a proof, or a dependency-map entry into a hidden host axiom.*

Proof. Project the packet as $D = (K, M, W, A, L, H, C, P, N)$. These rows are the complete carrier surface.

Apply Definition 868.3. It requires every consumer to pass through the displayed mode, witness, required-axiom, and ledger rows before reading the local naming certificate.

The mode-totality theorem fixes the interpretation of M, W, A in each branch. The internal, restricted, and externally supplied branches remain disjoint audit readings, and no branch exports the excluded host objects.

Finally replay the packet through H, C, P, N. Componentwise transport and package provenance preserve the same finite rows, so there is no route to an unrestricted theorem, hidden supply, proof oracle, or host axiom outside the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{AxiomDependencyAuditMap}^{\uparrow}}$.

Constructive story: An $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$ packet is generated from an audited claim row, a mode row, a witness row, a required-axiom row, a finite audit ledger, displayed hsame and Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AxiomDependencyAuditMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 868.1, Definition 868.2, Definition 868.3, and Definition 868.4 specify the finite dependency-map packet for mode, witness, required-axiom, ledger, and non-escape reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AxiomDependencyAuditMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not enumerate all declarations, prove global dependency-map completeness, certify host-kernel proof ancestry, discharge named external supply, or bridge the packet to an external schema.

Upgrade path: Obligation closure requires checked carrier admission, mode totality, witness and required-axiom exactness, ledger exposure, and non-escape for the displayed packet.

Chapter 869

A Concrete Naming Certificate for $\mathsf{BEDCSelfSubstrate}^{\uparrow}$

The $\mathsf{BEDCSelfSubstrate}^{\uparrow}$ packet turns the identity principle of chapter 9454 into a substrate-facing finite certificate. It is composite over the axiom-dependency map of chapter 862, the axiom-query ledger of chapter 654, the kernel-acceptance audit witness of chapter 547, and the normal false exclusion packet of chapter 732: those siblings consume query, verdict, acceptance, and false-exclusion rows, while this packet records the five positive substrate commitments that must be present before a downstream MetaCIC identity consumer classifies a claim.

869.1 Carrier and certificate surface

Definition 869.1 (BEDC self-substrate carrier)**.** *A* $\mathsf{BEDCSelfSubstrate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, E, R, P, A, H, C, Q, N)$$

with the following displayed rows:

1. *G is the closed-generator row for the BEDC.MetaCIC substrate;*
2. *E is the literal AST equality row used by internal identity reads;*
3. *R is the structural-recursion row for the closed syntax and history carriers;*
4. *P is the zero-axiom purity row, recording the absence of additional axiom, choice, quotient-soundness, proposition-extensionality, and host-conversion coordinates;*
5. *A is the apophatic-boundary row for exports not supplied by the substrate packet;*
6. *H records componentwise* hsame *transport for the five commitment rows, provenance, and local naming;*
7. *C records displayed* Cont *routes by which audit consumers read the five commitments;*
8. *Q is the* Pkg *provenance over the self-theory principle, the audit-map siblings,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BEDCSelfSubstrate}^{\uparrow}}$ *row.*

The carrier stores no declaration-specific query row, no verdict row, no kernel-acceptance replay, and no false-exclusion witness as its own field.

Theorem 869.2 (BEDC self-theory obligation surface)**.** *For every accepted* $\mathsf{BEDCSelfSubstrate}^{\uparrow}$ *carrier*

$$S = (G, E, R, P, A, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{BEDCSelfSubstrate}^{\uparrow}}$ *surface is exhausted by the closed-generator, literal AST equality, structural-recursion, zero-axiom purity, and apophatic-boundary commitments, together with their componentwise transport, displayed routes, provenance, and local name.*

Proof. Project the displayed carrier. The positive substrate commitments are exactly G, E, R, P, A.

Read H and C next. Transport and continuation preserve those five rows as displayed BEDC data and give downstream consumers routes to them without adding a declaration query, verdict, acceptance replay, or false-exclusion row.

Finally inspect Q and N. Provenance cites the self-theory principle and the audit-map siblings, while local naming packages the same finite surface. Since no additional coordinate occurs in S, the listed rows exhaust the local obligation surface. □

Lean4 ✓ `BEDC.Derived.BedcSelfSubstrateUp.BedcSelfSubstrateObligationSurface`

Theorem 869.3 (BEDC self-theory falsifiable boundary)**.** *If a downstream MetaCIC identity consumer reads an accepted* $\mathsf{BEDCSelfSubstrate}^{\uparrow}$ *packet, then any exported substrate claim factors through one of the five displayed commitment rows before it can be classified as internal, restricted, or blocked. A read that requires a declaration-specific query, verdict, acceptance replay, false-exclusion witness, quotient stream, host equality, or comparison embedding is outside this carrier.*

Proof. Start with the five commitment rows in Definition 869.1. They are the only substrate rows exposed before transport, continuation, provenance, and naming.

Use the obligation-surface theorem. Every admitted route through H, C, Q, N returns to one of G, E, R, P, A, so the consumer must classify the claim after reading one of those commitments.

The excluded rows are absent from the carrier. Any consumer requiring one of them must instead cite a sibling audit packet, and therefore cannot classify that read as an internal $\mathsf{BEDCSelfSubstrate}^{\uparrow}$ export. □

Falsifiable prediction: If a downstream MetaCIC identity consumer reads a BEDC-self-substrate packet, then any exported substrate claim factors through one of the five displayed commitment rows before it can be classified as internal, restricted, or blocked.

Independence witness: Nearest siblings: axiomdependencymap, axiomqueryledger, kernelacceptanceauditwitness, normalfalseexclusion, auditgateboundary. None is bijective to this carrier because each sibling stores a query, verdict, acceptance, false-exclusion, or gate row, while this carrier stores the five positive substrate commitments and lacks a declaration-specific query row.

Closure status for $\mathsf{NameCert}_{\mathsf{BEDCSelfSubstrate}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BEDCSelfSubstrate}^{\uparrow}$ packet is generated from finite BHist rows for the positive substrate commitments by which BEDC names its own internal substrate, plus transport, route, provenance, and local naming rows. Each downstream identity read must pass through one of the displayed commitment rows before it can be classified as internal, restricted, or blocked, so Cont exposes the commitment route rather than a hidden self-model. Componentwise hsame preserves the commitment inventory, and Pkg records the neighboring axiom, query, acceptance, false-exclusion, and audit-gate dependencies. The packet is a finite self-substrate commitment surface, not a declaration-specific oracle.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BEDCSelfSubstrate}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the BEDC self-substrate carrier, five commitment rows, falsifiable prediction, and sibling independence witness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BEDCSelfSubstrate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim a complete self-model, unrestricted internal truth predicate, declaration-specific query verdict, host reflection equality, or hidden kernel oracle.

Upgrade path: Obligation closure requires Lean encodings of the commitment carrier, consumer factorization through commitment rows, transport stability, and sibling non-bijection boundary.

Chapter 870

A Concrete Naming Certificate for $\mathsf{DiagonalLimitStability}^{\uparrow}$

The $\mathsf{DiagonalLimitStability}^{\uparrow}$ packet is the finite comparison layer between the diagonal representative used in the Real completeness route of chapter 9238 and the sealed $\mathsf{Real}^{\uparrow}$ limit route. It consumes the selector surface of chapter 697, the seal boundary of chapter 386, the mesh rows of chapter 644, the diagonal budget rows of chapter 853, and the observation-bound surface of chapter 637. The carrier records a displayed stability comparison; it does not identify quotient streams, choose a host limit, or import ambient completeness.

Falsifiable prediction: If a DiagonalLimitStabilityUp packet is accepted, every RealUp seal read factors through either the displayed DiagonalTailSelectorUp row or the displayed CauchyLimitSealUp row; a consumer route bypassing both refutes the packet.

Independence witness: regularcauchymesh, cauchydiagonalbudget, diagonaltailselector, cauchylimitseal, realapproximationenvelope: none is bijective because this carrier has a stability-comparison row between the diagonal representative and the sealed RealUp route; mesh chapters lack the seal row, selector chapters lack the stability comparison, seal chapters lack the diagonal representative source, and envelope chapters package observation bounds without the representative-seal classifier.

Definition 870.1 (Diagonal-limit stability carrier)**.** *A* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, D, L, S, W, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row carrying the regular rational name whose finite observations feed the diagonal construction;*
2. *D is the diagonal representative row, read through the* $\mathsf{DiagonalTailSelector}^{\uparrow}$ *selector surface;*
3. *L is the limit selector row that records the finite diagonal-limit route selected for the representative;*
4. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached through the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary;*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used to compare the representative readback with the sealed route;*
6. *H stores componentwise* hsame *transports for R, D, L, S, W, C, P, N;*

7. *C stores the* Cont *continuations that replay source, representative, selector, seal, window, transport, provenance, and local naming reads;*
8. *P is the* Pkg *provenance over the same finite route;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient regular streams, host real equality, a choice-selected limit representative, trichotomy, or an ambient completeness theorem.

Lean4 (definition) `BEDC.Derived.DiagonalLimitStabilityUp.DiagonalLimitStabilityUp`

Theorem 870.2 (Diagonal-limit stability NameCert obligations)**.** *For the carrier of Definition 870.1, the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ *surface consists exactly of carrier admission for T, source exposure through R, diagonal representative exposure through D, limit-selector exposure through L,* $\mathsf{Real}^{\uparrow}$ *seal exposure through S, finite-window stability comparison through W, componentwise transport through H, continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier displayed in Definition 870.1. The source, representative, selector, seal, and finite-window rows are explicit coordinates, and the transport, route, provenance, and local certificate rows are the only structural rows available to a consumer.

The diagonal representative row is read through the sibling selector surface, while the seal row is read through the sibling Cauchy-limit seal surface. The stability comparison is therefore not a new analytic equality; it is the finite assertion that the selected representative row and the sealed route are read under the same displayed window and structural provenance.

The excluded objects have no coordinate in T. Hence the local NameCert obligations are exhausted by the nine displayed rows. □

Lean4 ✓ `BEDC.Derived.DiagonalLimitStabilityUp.DiagonalLimitStabilityTasteGate single carrier alignment`

Theorem 870.3 (Diagonal-limit stability RealCompleteness handoff)**.** *Every* $\mathsf{RealCompleteness}^{\uparrow}$ *consumer that reads the sealed diagonal limit from an accepted* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *carrier $T = (R, D, L, S, W, H, C, P, N)$ must first pass through the displayed diagonal representative row D or the displayed* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row S, and in either case the read is replayed through the same finite window W, transports H, continuations C, provenance P, and local naming row N.*

Proof. Read the Real completeness route from chapter 9238. A consumer of the sealed diagonal limit needs a representative side and a seal side before the $\mathsf{Real}^{\uparrow}$ read can be inspected.

The representative side of T is the row D, which is anchored in the diagonal-tail selector sibling. The seal side of T is the row S, which is anchored in the Cauchy-limit seal sibling. The limit-selector row L names the finite route between them, and W is the common observation window on which the stability comparison is made.

The structural rows H, C, P, N replay the same finite comparison for downstream consumers. Since no additional representative, seal, quotient, host equality, selected external limit, or ambient completeness row is present, every sealed diagonal-limit read factors through the displayed handoff. □

Theorem 870.4 (Diagonal-limit stability budget-seal factorization)**.** *Every* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *consumer that reads the* $\mathsf{RealCompleteness}^{\uparrow}$ *handoff factors through the diagonal budget row D,* $\mathsf{StreamName}^{\uparrow}$ *window row W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R,* $\mathsf{Real}^{\uparrow}$ *seal row S,* BHist *history rows,*

componentwise hsame *row H, displayed* Cont *route C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ *row N. The consumer receives no host limit, ambient completeness coordinate, external representative equality, or detached Real seal outside this packet.*

Proof. Start from the Real-completeness handoff theorem, Definition 870.3. It forces every sealed diagonal-limit read to enter through D or S and then replay through the same finite window and structural rows.

Use the root-route budget package from the sibling diagonal-limit compatibility chapter, Definition 646.153. It supplies the finite budget route that feeds the diagonal representative side before the Real seal is read.

The local NameCert obligations in Definition 870.2 keep the readback row R, window row W, transports H, continuation C, provenance P, and naming row N attached to the same carrier. Hence the Real-completion handoff factors from finite budget to seal without exporting a host limit or ambient completeness coordinate. □

Theorem 870.5 (Representative-seal window comparison)**.** *For an accepted* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *carrier $T = (R, D, L, S, W, H, C, P, N)$, the displayed diagonal representative row D and the displayed* $\mathsf{Real}^{\uparrow}$ *seal row S are compared only through the common finite window row W. Neither D nor S can be consumed as an independent Real-completeness input outside the same packet.*

Proof. The carrier exposes D as the representative-side row and S as the seal-side row, but the comparison coordinate supplied by the carrier is W. Thus any consumer that reads either side as part of the stability comparison must also read the window coordinate that makes the two sides commensurable.

There is no coordinate in T for an external representative equality, a host-level seal equality, or a separate comparison witness. The only displayed comparison boundary is the packet's own window row, so independent consumption of D or S would require a row absent from the carrier. □

Theorem 870.6 (Real-completeness window coverage)**.** *Every* $\mathsf{RealCompleteness}^{\uparrow}$ *consumer of the accepted packet $T = (R, D, L, S, W, H, C, P, N)$ factors through W, H, C, P, N after choosing either the representative side D or the seal side S.*

Proof. By Definition 870.3, a Real-completeness consumer first reaches the packet through D or through S. Once that side is chosen, the same theorem records the replay rows W, H, C, P, N as the boundary through which the read continues.

The rows W, H, C, P, N are not optional decorations: W fixes the common observation window, H carries the componentwise transports, C carries the displayed continuation routes, P carries provenance, and N carries the local naming row. Since the carrier has no additional Real-completeness boundary, each accepted packet read factors through those rows. □

Theorem 870.7 (Transport replay for local NameCert obligations)**.** *For an accepted* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *carrier $T = (R, D, L, S, W, H, C, P, N)$, the componentwise* hsame *rows in H and the displayed* Cont *routes in C replay the same nine-coordinate packet and preserve the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ *obligations.*

Proof. The row H is displayed as componentwise transport for R, D, L, S, W, C, P, N, while C is displayed as the continuation replay for the same source, representative, selector, seal, window, transport, provenance, and local naming reads. Both rows therefore address the coordinates of the single carrier T rather than a second packet.

The local NameCert obligations are exactly the rows listed in Definition 870.2. Because H and C replay those rows componentwise and by displayed continuations, downstream use preserves the same local obligation surface. □

Theorem 870.8 (Diagonal-limit stability obligation package)**.** *For an accepted* DiagonalLimitStability$^{\uparrow}$ *carrier* $T = (R, D, L, S, W, H, C, P, N)$*, the carrier, local* NameCert *obligations,* RealCompleteness$^{\uparrow}$ *handoff, falsifiable prediction, independence witness, TasteGate marker, and route exclusions jointly form the obligation package for* DiagonalLimitStability$^{\uparrow}$ *over* RegSeqRat$^{\uparrow}$*,* DiagonalTailSelector$^{\uparrow}$*,* CauchyLimitSeal$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The package binds selector route exactness through* D*, seal route exactness through* S*, finite-window coverage through* W*, componentwise transport replay through* H*, continuation replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. First use Definition 870.2. It projects the accepted carrier and binds the source, representative, selector, seal, finite-window, transport, continuation, provenance, and local naming rows as the complete local NameCert surface.

Next use Definition 870.3. It forces every Real-completeness seal read through either the displayed diagonal representative row D or the displayed CauchyLimitSeal$^{\uparrow}$ row S, and in both cases replays the same window W and structural rows H, C, P, N.

The selector and seal routes are therefore exact at the displayed boundary. Selector exactness is the fact that D is the only diagonal representative row available to the carrier; seal exactness is the fact that S is the only Real$^{\uparrow}$ seal row available to the carrier. Window coverage is the common row W, which is read before downstream consumers receive the sealed route.

Finally inspect the chapter-level side conditions. The falsifiable prediction excludes consumers that bypass both displayed route rows, the independence witness separates the packet from its sibling carriers, the TasteGate marker records single-carrier alignment, and the excluded coordinates rule out quotient streams, host real equality, choice-selected limit representatives, trichotomy, and ambient completeness. These clauses are precisely the obligation package needed before an obligation-closure reading of the same finite packet. □

Theorem 870.9 (Diagonal-limit stability selector-seal scope)**.** *For an accepted* DiagonalLimitStability$^{\uparrow}$ *carrier* $T = (R, D, L, S, W, H, C, P, N)$*, the row* D *is read only through* DiagonalTailSelector$^{\uparrow}$*, and the row* S *is read only through* CauchyLimitSeal$^{\uparrow}$*, before any* RealCompleteness$^{\uparrow}$ *consumer reads the stability comparison. The comparison therefore has no route that bypasses the selector-seal pair.*

Proof. Start from Definition 870.1 and Definition 870.3. They expose D as the diagonal representative route and S as the seal route before any Real-completeness read.

Use Definition 870.5 and Definition 870.6. The common window W is the only comparison boundary for the two sides, and every Real-completeness consumer reaches it after choosing D or S.

The transport replay and obligation package rows then keep the selector and seal reads inside the same finite packet. □

Theorem 870.10 (Diagonal-limit stability primitive route exhaustion)**.** *For an accepted* DiagonalLimitStability$^{\uparrow}$ *carrier* $T = (R, D, L, S, W, H, C, P, N)$*, the rows* W, H, C, P, N *exhaust the primitive* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data of the selector-seal route. They do not introduce quotient-stream equality, host real equality, a selected limit representative, trichotomy, or ambient completeness.*

Proof. Apply Definition 870.2. It lists the finite source, representative, selector, seal, window, transport, continuation, provenance, and local naming rows as the local obligation surface.

Then use Definition 870.7. The H and C rows replay the same carrier by componentwise hsame transport and displayed continuations, while P and N remain provenance and local naming rows.

Together with the carrier, handoff, window coverage, and obligation package, these rows leave no primitive coordinate outside W, H, C, P, N for the selector-seal route. □

Theorem 870.11 (Diagonal-limit stability NameCert scope closure)**.** *The selector-seal scope row and primitive route exhaustion row, combined with the obligation package of Definition 870.8, close the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ *scope for the displayed packet* $T = (R, D, L, S, W, H, C, P, N)$*. The closed scope is exactly the route through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DiagonalTailSelector}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *named in the carrier.*

Proof. Use Definition 870.9. It fixes the consumer-visible order of the selector row D, seal row S, and Real-completeness comparison.

Use Definition 870.10. It fixes the primitive route rows W, H, C, P, N as the complete BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ surface.

Now apply Definition 870.8. Since the carrier, handoff, representative-seal comparison, window coverage, and transport replay have already been packaged for the same finite tuple, the local NameCert scope closes exactly over the displayed selector-seal packet and over nothing else. □

Theorem 870.12 (Diagonal-limit stability selector-seal primitive binding)**.** *For an accepted* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *carrier* $T = (R, D, L, S, W, H, C, P, N)$*, the row* D *is bound to the* $\mathsf{DiagonalTailSelector}^{\uparrow}$ *primitive surface, and the row* S *is bound to the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *primitive surface together with the displayed* $\mathsf{Real}^{\uparrow}$ *seal row. Both reads are replayed only through the displayed* BHist *packet, componentwise* hsame *transports,* Cont *continuations,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ *row.*

Proof. Use the carrier definition to isolate the two route rows. The coordinate D is the only diagonal representative row available to the packet, and the coordinate S is the only seal row available to the packet.

Apply Definition 870.9. It fixes the consumer-visible order in which the selector row and seal row can be read before a Real-completeness consumer inspects the stability comparison.

Now apply Definition 870.10. The replay rows are exactly the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, so neither the selector read nor the seal read has a second primitive route. □

Theorem 870.13 (Diagonal-limit stability window-transport primitive binding)**.** *For an accepted* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *carrier* $T = (R, D, L, S, W, H, C, P, N)$*, the common finite window* W *and the replay rows* H, C, P, N *are the whole primitive transport surface for the selector-seal comparison. This surface contains no quotient stream, host real equality, selected representative, trichotomy row, or ambient completeness coordinate.*

Proof. Start with Definition 870.6. It forces every Real-completeness consumer to pass through the common window W and the structural rows H, C, P, N after the representative side or the seal side has been chosen.

Use Definition 870.7. The H and C rows replay the same accepted carrier, while P and N keep provenance and local naming attached to that carrier.

The exclusions follow from the carrier definition and from Definition 870.10. Since none of the excluded objects is a coordinate of T, it cannot enter the primitive transport surface. □

Theorem 870.14 (Diagonal-limit stability scoped NameCert boundary)**.** *The selector-seal primitive binding of Definition 870.12, the window-transport primitive binding of Definition 870.13, and*

the local scope closure of Definition 870.11 justify scoped closure for the displayed $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ *boundary of* $T = (R, D, L, S, W, H, C, P, N)$.

Proof. The selector-seal primitive binding fixes the only route by which D and S can be read. It binds the representative side to $\mathsf{DiagonalTailSelector}^{\uparrow}$ and the seal side to $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$.

The window-transport primitive binding fixes the only route by which those reads are transported. It keeps W, H, C, P, N as the finite primitive surface and excludes the analytic and quotient-level coordinates absent from the carrier.

Finally apply Definition 870.11. Its closed local scope is therefore not merely an obligation list; it is the displayed scoped boundary of the local $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ packet. □

Theorem 870.15 (Diagonal-limit stability tail-refinement invariance)**.** *Let*

$$T = (R, D, L, S, W, H, C, P, N)$$

and

$$T' = (R, D', L', S, W', H', C', P', N')$$

be accepted $\mathsf{DiagonalLimitStability}^{\uparrow}$ *packets with the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R *and the same* $\mathsf{Real}^{\uparrow}$ *seal row* S*. Suppose* W' *is a displayed* $\mathsf{StreamName}^{\uparrow}$ *tail refinement of* W*,* D' *is the transported* $\mathsf{DiagonalTailSelector}^{\uparrow}$ *row for the refined window, and the row* S *is read in both packets through the same* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary and the same* $\mathsf{Real}^{\uparrow}$ *seal boundary. Then every* $\mathsf{RealCompleteness}^{\uparrow}$ *consumer that reads the sealed diagonal-limit route through* T' *receives the same sealed* $\mathsf{Real}^{\uparrow}$ *route as the corresponding read through* T*, now replayed through* W', H', C', P', N'*. The refinement introduces no quotient stream, host real equality, choice-selected representative, trichotomy, or ambient completeness row.*

Proof. First compare the two packets at the seal side. By Definition 870.3, a Real-completeness consumer must enter the accepted packet through the displayed diagonal representative row or the displayed $\mathsf{CauchyLimitSeal}^{\uparrow}$ row, and in either case must continue through the packet window and structural rows.

Next identify the representative and seal comparison boundary. The representative-seal comparison of Definition 870.5 says that the representative side and the seal side are compared only through the common finite window. Since W' is a displayed tail refinement of W and D' is the transported selector row for that refined window, the refined packet changes the inspection window but not the sealed $\mathsf{Real}^{\uparrow}$ boundary.

Now use the coverage and replay rows. By Definition 870.6, every consumer read factors through the window and structural rows after choosing the representative side or the seal side. By Definition 870.7, the transports and continuations replay the same carrier coordinates, so the refined rows H', C', P', N' serve the same local route over the refined window W'.

Finally apply Definition 870.11. The closed local scope contains exactly the displayed route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DiagonalTailSelector}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. Therefore the tail-refined packet preserves the sealed RealUp route for every RealCompletenessUp consumer and supplies no additional primitive or analytic coordinate. □

Theorem 870.16 (Cofinal tail-refinement confluence)**.** *Let*

$$T_0 = (R, D, L, S, W, H, C, P, N),$$

$$T_1 = (R, D_1, L_1, S, W_1, H_1, C_1, P_1, N_1),$$

and

$$T_2 = (R, D_2, L_2, S, W_2, H_2, C_2, P_2, N_2)$$

be accepted $\mathsf{DiagonalLimitStability}^{\uparrow}$ *packets with the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R *and the same* $\mathsf{Real}^{\uparrow}$ *seal row* S*. Suppose* W_1 *and* W_2 *are displayed* $\mathsf{StreamName}^{\uparrow}$ *tail refinements of* W*, and suppose there is a common cofinal displayed* $\mathsf{StreamName}^{\uparrow}$ *tail refinement* W_{12} *of both* W_1 *and* W_2 *such that the* $\mathsf{DiagonalTailSelector}^{\uparrow}$ *rows* D_1 *and* D_2 *transport to the same displayed selector read over* W_{12} *while the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row remains the seal row* S*. Then every* $\mathsf{RealCompleteness}^{\uparrow}$ *consumer reading through* T_1 *and every* $\mathsf{RealCompleteness}^{\uparrow}$ *consumer reading through* T_2 *factors through the same sealed* $\mathsf{Real}^{\uparrow}$ *route replayed over the common window* W_{12}*. The confluence uses only the displayed* BHist *packet, componentwise* hsame *transports,* Cont *continuations,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ *rows, and it supplies no quotient stream equality, host real equality, selected representative, trichotomy row, or ambient completeness coordinate.*

Proof. First compare each accepted refinement with the base packet. Apply Definition 870.15 to the refinement from T_0 to T_1, and apply the same theorem to the refinement from T_0 to T_2. Both readings preserve the sealed $\mathsf{Real}^{\uparrow}$ route because the source row R and the seal row S are shared.

Next force both consumer reads into the common comparison boundary. By Definition 870.5, the representative side and the seal side of each accepted packet are compared only through the displayed finite window. By Definition 870.6, every $\mathsf{RealCompleteness}^{\uparrow}$ consumer reaches the window and structural rows after choosing the representative side or the seal side. Since W_{12} is cofinal over both W_1 and W_2, the two refined reads pass through the same displayed window boundary after transporting D_1 and D_2.

Now replay the transported packets over that boundary. Use Definition 870.7 to identify the componentwise hsame rows and displayed Cont routes as replays of the same carrier coordinates. The rows H_1, C_1, P_1, N_1 and H_2, C_2, P_2, N_2 therefore contribute only the displayed transport, continuation, provenance, and local naming data over W_{12}, while the seal side remains S.

Finally apply Definition 870.11. The closed local scope is exactly the route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DiagonalTailSelector}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. Thus both accepted refinements factor through the same sealed $\mathsf{Real}^{\uparrow}$ route over W_{12}, with no additional analytic, quotient, representative-choice, trichotomy, or completeness coordinate. □

Theorem 870.17 (Diagonal-limit stability public export)**.** *An accepted* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *packet*

$$T = (R, D, L, S, W, H, C, P, N)$$

together with the selector-seal primitive binding, the window-transport primitive binding, the scoped $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ *boundary, tail-refinement invariance, and cofinal refinement confluence exports a public* $\mathsf{Real}^{\uparrow}$*-completeness-facing route from* $\mathsf{RegSeqRat}^{\uparrow}$ *through* $\mathsf{DiagonalTailSelector}^{\uparrow}$ *and* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *to the sealed* $\mathsf{Real}^{\uparrow}$ *row. The export is exactly the displayed route through* $R, D, L, S, W, H, C, P, N$ *and supplies no quotient-stream equality, host real equality, choice-selected representative, trichotomy, or ambient completeness coordinate.*

Proof. First use Definition 870.12 and Definition 870.13. They bind the representative side to the $\mathsf{DiagonalTailSelector}^{\uparrow}$ primitive surface, the seal side to the $\mathsf{CauchyLimitSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ primitive surfaces, and the comparison route to the finite window and replay rows.

Next apply Definition 870.14. The scoped boundary turns those primitive bindings into the displayed local $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$ surface for the same accepted packet T.

Finally use Definition 870.15 and Definition 870.16. Tail refinement and cofinal comparison preserve the sealed $\mathsf{Real}^{\uparrow}$ route through the same public-facing selector-seal corridor, while the carrier exclusions keep quotient-stream equality, host real equality, selected representatives, trichotomy, and ambient completeness outside the export. □

Theorem 870.18 (Diagonal-limit stability bridge corridor)**.** *An accepted* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *packet*

$$T = (R, D, L, S, W, H, C, P, N)$$

supplies a paper bridge from the public selector-seal export of Definition 870.17 to the downstream $\mathsf{Real}^{\uparrow}$*-completion corridor. The representative side is bound by* $\mathsf{DiagonalTailSelector}^{\uparrow}$*, the seal side is bound by* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, the shared comparison is the displayed* $\mathsf{StreamName}^{\uparrow}$ *window, and the replay and provenance rows are exactly the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of* T*. The corridor supplies no quotient-stream equality, host real equality, selected representative, trichotomy, or ambient completeness coordinate.*

Proof. Start with the public selector-seal export of Definition 870.17. It presents the accepted packet as a $\mathsf{Real}^{\uparrow}$-completeness-facing route from the regular source row through the selector and seal rows to the displayed sealed $\mathsf{Real}^{\uparrow}$ row.

Use the primitive bindings to identify the two bridge sides. By Definition 870.12, the representative side is read only through $\mathsf{DiagonalTailSelector}^{\uparrow}$, while the seal side is read only through $\mathsf{CauchyLimitSeal}^{\uparrow}$ together with $\mathsf{Real}^{\uparrow}$. By Definition 870.13, the common $\mathsf{StreamName}^{\uparrow}$ window and the rows H, C, P, N are the whole primitive transport surface.

Now stabilize the corridor under downstream refinement. Apply Definition 870.15 to preserve the sealed $\mathsf{Real}^{\uparrow}$ route under displayed tail refinement, and apply Definition 870.16 to compare cofinal refined reads through the same sealed route. These two stability clauses make the public export usable as a bridge corridor rather than a one-step display.

The exclusions are inherited from the carrier and from the two stability clauses. Since quotient-stream equality, host real equality, selected representatives, trichotomy, and ambient completeness have no coordinate in T, the paper bridge reaches the downstream Real-completion corridor only through the displayed selector, seal, window, replay, provenance, and naming rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DiagonalLimitStability}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source row, diagonal representative row, limit selector row, $\mathsf{Real}^{\uparrow}$ seal row, finite $\mathsf{StreamName}^{\uparrow}$ window, componentwise hsame transports, displayed Cont continuations, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 870.14, Definition 870.17, and Definition 870.18 bind the mature selector-seal route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DiagonalTailSelector}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiagonalLimitStability}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.DiagonalLimitStabilityUp.DiagonalLimitStabilityTasteGate\_single\_carrier\_alignment`

Bridge status: paperBridge

Origin: ai

Lean4 ✓ `BEDC.Derived.DiagonalLimitStabilityUp.taste gate`

Not claimed: This chapter does not prove quotient-stream equality, host real equality, a choice-selected limit representative, trichotomy, ambient completeness, or a machine-checked standard bridge.

Upgrade path: No further paper-theory closure step remains; machine bridge checking is the only later formal-axis movement.

Chapter 871

A Concrete Naming Certificate for $\mathsf{TheorySelfClassifier}^{\uparrow}$

The $\mathsf{TheorySelfClassifier}^{\uparrow}$ packet realizes the own-theory reading of chapter 9454 as a finite classifier surface. It sits beside chapter 865, chapter 856, chapter 868, and chapter 859: those siblings expose boundary, identity, dependency-audit, and self-theory rows, while this chapter packages the row comparison that lets a consumer read the five commitments as one self-theory classifier.

Definition 871.1 (Theory self-classifier carrier)**.** *A* $\mathsf{TheorySelfClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (G, E, R, P, A, L, H, C, Q, N)$$

with the following displayed rows:

1. *G is the closed-generator row, naming the finite constructor and declaration inventory used by the theory surface;*
2. *E is the literal equality row, recording that comparison is syntactic equality of the displayed object rows rather than semantic equality in a host calculus;*
3. *R is the structural recursor row, exposing the eliminators attached to the closed generators named by G;*
4. *P is the purity row, recording zero hidden axiom supply and strict proof-ancestry accountability for internal reads;*
5. *A is the apophatic boundary row, recording visible sockets and setup fields for requests outside the internal substrate;*
6. *L is the classifier ledger that compares G, E, R, P, A as one self-theory surface;*
7. *H records componentwise* hsame *transports for generator, equality, recursor, purity, boundary, ledger, route, provenance, and local naming rows;*
8. *C records the displayed* Cont *routes by which consumers read each commitment and then return to the classifier ledger;*
9. *Q is the* Pkg *provenance over chapter 9454, chapter 865, chapter 856, chapter 868, chapter 859,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TheorySelfClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for a classical-CIC parent theory, semantic equality oracle, hidden recursor supply, unrecorded axiom dependency, or boundary row promoted to internal theorem content.

Theorem 871.2 (Theory self-classifier NameCert obligations)**.** *For every* $\mathsf{TheorySelfClassifier}^{\uparrow}$ *carrier*

$$T = (G, E, R, P, A, L, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{TheorySelfClassifier}^{\uparrow}}$ *surface consists exactly of carrier admission, closed-generator exposure, literal-equality exposure, structural-recursor exposure, purity exposure, apophatic-boundary exposure, classifier-ledger comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The ledger row* L *is required to compare the five commitment rows as one self-theory surface before a consumer may export a self-theory reading.*

Proof. Project the finite carrier of Definition 871.1. The rows G, E, R, P, A are the five commitment coordinates, while L, H, C, Q, N provide comparison, transport, replay, provenance, and local naming.

The NameCert obligations for the five commitments are read componentwise. The generator row supplies the closed inventory, the equality row supplies literal comparison, the recursor row supplies only generator-local eliminators, the purity row supplies strict audit visibility, and the apophatic row keeps external supply visible as boundary data.

The classifier obligation is the additional row L. It compares those five rows as one surface, so a consumer cannot cite a self-theory reading by projecting only one commitment or by replacing the row comparison with a sibling chapter.

Since the carrier contains no further coordinate, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.TheorySelfClassifierUp.TheorySelfClassifierCarrier namecert obligations`

Theorem 871.3 (Theory self-classifier non-escape)**.** *Every public read from an accepted* $\mathsf{TheorySelfClassifier}^{\uparrow}$ *carrier factors through*

$$G, E, R, P, A, L, H, C, Q, N.$$

A consumer may read the five commitment rows, their classifier ledger, componentwise transports, displayed routes, provenance, and local name. It cannot read a classical-CIC parent theory, a host semantic equality oracle, a hidden recursor, an unrecorded axiom dependency, or an apophatic boundary promoted to internal theorem content.

Proof. Start from the displayed carrier. The only self-theory commitments are G, E, R, P, A, and the only row that compares them as one surface is L.

Routes through C and transports through H preserve those rows componentwise. They can replay a commitment read or move the packet, but they cannot create a new substrate principle.

The provenance and naming rows Q, N cite the sibling surfaces and bind the local certificate. Citation gives a consumer context for the five rows; it does not add a parent theory, host equality, hidden recursor, axiom supply, or internal theorem extracted from a boundary row.

Thus every public read remains inside $T = (G, E, R, P, A, L, H, C, Q, N)$, and the excluded objects have no route through the accepted packet. □

Theorem 871.4 (Theory self-classifier sibling independence)**.** ***Independence witness:*** *Nearest siblings: internaltheoryboundary, metacic-theory-identity, axiomdependencyauditmap, and bedc-selftheory. No one of these is bijective to the* $\mathsf{TheorySelfClassifier}^{\uparrow}$ *carrier because each lacks the*

classifier row L that compares closed generators, literal equality, structural recursors, purity, and apophatic boundary rows as one self-theory surface.

Proof. Compare row inventories. The internal-theory-boundary packet exposes the five commitments as a boundary, the MetaCIC theory-identity packet records identity rows, the axiom-dependency-audit-map packet records mode and supply rows, and the BEDC self-theory packet packages the commitments as a self-theory certificate.

The $\mathsf{TheorySelfClassifier}^{\uparrow}$ carrier requires the same five commitment rows together with the classifier ledger L that compares them as one surface. None of the sibling carriers has that row with the displayed comparison role.

Therefore a consumer may cite those siblings as provenance, but no cited sibling is a bijective replacement for this classifier packet. □

Theorem 871.5 (Theory self-classifier TasteGate target)**.** *The later Lean 'TasteGate.lean' development for* $\mathsf{TheorySelfClassifier}^{\uparrow}$ *must provide a* Nontrivial *witness with two explicit carrier values and a* FieldFaithful *witness by field projection, match analysis, and injection over the displayed rows* $G, E, R, P, A, L, H, C, Q, N$.

Lean4 ✓ `BEDC.Derived.TheorySelfClassifierUp.TheorySelfClassifierTasteGate single carrier alignment`

Proof. The carrier has distinguishable commitment and classifier fields, so a singleton event-flow encoding would not show that the self-theory surface is genuinely classified.

Nontriviality supplies two explicit packets. Field faithfulness then checks the event-flow encoding by projecting each displayed row, matching on the carrier constructor, and using injection to recover equality of all fields from equality of encodings.

These two gate obligations are the Lean-side conditions needed before the classifier can be treated as a checked TasteGate object. □

Falsifiable prediction: A TheorySelfClassifierUp packet cannot export a self-theory reading unless the five commitment rows are all present as displayed BHist coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{TheorySelfClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{TheorySelfClassifier}^{\uparrow}$ packet is generated from closed-generator, literal-equality, structural-recursor, purity, apophatic-boundary, classifier-ledger, transport, route, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TheorySelfClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 871.1, Definition 871.2, Definition 871.3, Definition 871.4, and Definition 871.5 specify the seed carrier, finite NameCert surface, non-escape boundary, sibling independence witness, and gate-facing target.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TheorySelfClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide Lean-side verification, bridge checking, a classical-CIC embedding, a semantic equality oracle, a hidden axiom route, or a completed TasteGate instance.

Upgrade path: Obligation closure requires Lean encoding of the carrier, checked five-row classifier obligations, non-escape, sibling independence, and a TasteGate route with Nontrivial and FieldFaithful instances.

Chapter 872

A Concrete Naming Certificate for $\mathsf{SelfTheoryReflectionLoop}^{\uparrow}$

The $\mathsf{SelfTheoryReflectionLoop}^{\uparrow}$ packet realizes the self-theory reading of chapter 9454 as a finite reflection loop. It sits beside the theory-identity packet of chapter 856, the closure-trace packet of chapter 795, the kernel-acceptance trace of chapter 557, and the audit-map family of chapter 817. Those siblings expose identity rows, closure rows, acceptance rows, and audit-family rows; this packet binds them into a cyclic replay surface with an explicit boundary-return row.

Definition 872.1 (Self-theory reflection-loop carrier)**.** *A* $\mathsf{SelfTheoryReflectionLoop}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, T, K, A, R, B, H, C, Q, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{MetaCICTheoryIdentity}^{\uparrow}$ *row that records closed generators, literal AST equality, structural recursors, strict purity, and apophatic boundary as the identity surface of BEDC.MetaCIC;*
2. *T is the* $\mathsf{MetaCICClosureTrace}^{\uparrow}$ *row that records the finite closure replay consumed by self-theory audit readers;*
3. *K is the* $\mathsf{KernelAcceptanceTrace}^{\uparrow}$ *row that records the kernel-admission route for accepted declarations and theorem rows;*
4. *A is the* $\mathsf{AuditMapFamily}^{\uparrow}$ *row that records which audit-map family member reads each identity, closure, and acceptance coordinate;*
5. *R is the cyclic audit-replay row, routing a public self-theory read back through I, T, K, A before it may be classified as an internal BEDC.MetaCIC read;*
6. *B is the boundary-return row, recording requests that leave the displayed self-theory loop and returning them as named boundary obligations rather than as hidden parent-theory content;*
7. *H records componentwise* hsame *transport for identity, closure, acceptance, audit-family, replay, boundary, provenance, and local naming rows;*
8. *C records displayed* Cont *routes by which consumers inspect the same rows without replacing the loop by a semantic comparison with another calculus;*
9. *Q is the* Pkg *provenance over chapter 9454, chapter 856, chapter 795, chapter 557, chapter 817,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SelfTheoryReflectionLoop}^{\uparrow}}$ *row.*

The carrier has no coordinate for a classical CIC parent theory, no host equality oracle, no erased audit replay, and no unrecorded escape from the self-theory boundary.

Lean4 (definition) `BEDC.Derived.SelfTheoryReflectionLoopUp.SelfTheoryReflectionLoopUp`

Definition 872.2 (Self-theory reflection-loop classifier)**.** *Two* $\mathsf{SelfTheoryReflectionLoop}^{\uparrow}$ *carriers*

$$L = (I, T, K, A, R, B, H, C, Q, N)$$

and

$$L' = (I', T', K', A', R', B', H', C', Q', N')$$

are classifier-equivalent exactly when their identity, closure-trace, kernel-acceptance, audit-family, cyclic-replay, boundary-return, transport, continuation, provenance, and local naming rows agree through the displayed hsame *and* Cont *data. The classifier does not compare carriers by an external model of CIC, by a hidden normalizer, or by an audit route absent from the displayed packet.*

Theorem 872.3 (Self-theory reflection-loop NameCert obligations)**.** *For every accepted* $\mathsf{SelfTheoryReflectionLoop}^{\uparrow}$ *carrier*

$$L = (I, T, K, A, R, B, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SelfTheoryReflectionLoop}^{\uparrow}}$ *surface consists of six finite rows:*

1. *self-theory identity exposure through I;*
2. *closure-trace replay exposure through T;*
3. *kernel-acceptance replay exposure through K;*
4. *audit-map family exposure through A;*
5. *cyclic audit-replay exactness through R;*
6. *boundary-return exactness through B, with transport, route, provenance, and naming accountability through H, C, Q, N.*

These rows certify a finite loop packet for self-theory identity, audit replay, and boundary non-escape. They do not certify a comparison theorem with classical CIC, a global normalization theorem, or an undisplayed parent theory.

Proof. Project the finite carrier of Definition 872.1. The rows I, T, K, A are the sibling-facing inputs, while R and B are the loop-specific rows.

Classifier exactness follows from Definition 872.2. Agreement is checked on the displayed identity, trace, acceptance, audit-family, replay, and boundary rows, then transported only through H and read only through C.

The provenance and local naming rows Q, N package the same surface. Since the carrier has no additional coordinate, the six listed rows exhaust the local NameCert obligations. □

Theorem 872.4 (Self-theory reflection-loop non-escape)**.** *Every public read of an accepted* $\mathsf{SelfTheoryReflectionLoop}$ *carrier factors through*

$$I, T, K, A, R, B, H, C, Q, N.$$

A read may replay the self-theory identity row through closure, kernel acceptance, and audit-family rows, but a request for an external parent calculus, host semantic equality, hidden audit replay, or unrecorded theorem supply lands in the boundary-return row B.

Proof. Read the consumer route through C. If the route reaches I, T, K, A, R, H, Q, N, it remains inside the displayed reflection loop and its recorded sibling provenance.

If the route asks for material outside those rows, the carrier offers only B as a boundary-return coordinate. The replay row R must pass through I, T, K, A before classification, so deletion of audit replay leaves no route by which the identity row alone can certify the full loop.

Thus a boundary request remains a boundary request. It cannot be reclassified as external parenthood, host equality, hidden audit replay, or undisplayed theorem supply. □

Theorem 872.5 (Self-theory reflection-loop TasteGate follow-up)**.** *The Lean-side follow-up for* $\mathsf{SelfTheoryReflectionLoop}^{\uparrow}$ *must provide* $\mathsf{Nontrivial\ SelfTheoryReflectionLoop}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ SelfTheoryReflectionLo}$ *in 'lean4/BEDC/Derived/SelfTheoryReflectionLoopUp/TasteGate.lean'. Nontriviality rules out a vacuous loop carrier, and field faithfulness records that the gate preserves the identity, closure, acceptance, audit-family, cyclic-replay, and boundary-return fields as distinct rows.*

Proof. The carrier has four sibling-facing rows and two loop-specific rows. A gate that preserves only an event-flow shell would not show that these coordinates remain distinguishable.

Nontriviality supplies a carrier with visible content, while field faithfulness preserves the displayed coordinates through the gate. Those are the gate-facing obligations needed before the reflection loop can be read as a checked TasteGate object. □

Falsifiable prediction: If the loop is faithful, deleting the audit-replay row breaks the NameCert obligation surface while preserving the bare theory-identity carrier row.

Independence witness: metacic-theory-identity, metacicclosuretrace, kernelacceptancetrace, audit-map-family: the loop has a cyclic replay row and a boundary-return row absent from each sibling, so no bijection preserves all carrier coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{SelfTheoryReflectionLoop}^{\uparrow}}$.

Constructive story: A $\mathsf{SelfTheoryReflectionLoop}^{\uparrow}$ packet is generated from finite BHist rows for theory identity, reflected theory readback, cyclic audit replay, boundary return, transports, continuations, provenance, and local naming. The reflection loop is not a host self-interpretation; it is a displayed route where Cont replays the audit row and returns to the named boundary before any consumer can cite reflection. Componentwise hsame transports identity, replay, and return rows without deleting the audit surface, while Pkg records the MetaCIC identity, closure trace, kernel acceptance, and audit-map dependencies. The loop names finite reflective routing, not unrestricted truth.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SelfTheoryReflectionLoop}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the self-theory reflection-loop carrier, cyclic replay row, boundary-return row, falsifiable prediction, and sibling independence witness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SelfTheoryReflectionLoop}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim a global truth predicate, unrestricted self-interpretation, host reflection equality, audit erasure, or kernel-level self-certification.

Upgrade path: Obligation closure requires Lean encodings of the loop carrier, audit replay, boundary return, transport stability, and non-bijection witness.

Chapter 873

A Concrete Naming Certificate for $\mathsf{LiteralASTEqualityBoundary}^{\uparrow}$

The $\mathsf{LiteralASTEqualityBoundary}^{\uparrow}$ packet isolates the literal AST equality commitment of chapter 9454 as its own finite NameCert boundary. It sits beside the five-row own-theory packet of chapter 865, the broader theory-identity packet of chapter 856, and the dependency audit surface of chapter 868. Those siblings package multiple identity or dependency commitments; this chapter names the single row that says equality is displayed AST equality and not beta equality, conversion equality, quotient equality, or host semantic equivalence.

Definition 873.1 (Literal AST equality-boundary carrier)**.** *A* $\mathsf{LiteralASTEqualityBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, T, B, H, C, P, N)$$

with the following displayed rows:

1. *A is the displayed AST row, naming constructor tags, binder positions, variable rows, and immediate subterm rows exposed by the BEDC.MetaCIC syntax surface;*
2. *T is the literal comparison row, recording equality only by identical displayed constructor tags and componentwise equality of displayed subrows;*
3. *B is the boundary-refusal row for beta equality, conversion equality, quotient equality, proof irrelevance, proposition extensionality, host semantic equivalence, and parent-theory identity transport;*
4. *H records componentwise* hsame *transport for the AST row, literal comparison row, boundary-refusal row, continuation routes, provenance row, and local naming row;*
5. *C records displayed* Cont *routes by which a consumer reads literal equality and boundary refusal without adding a conversion oracle;*
6. *P is the* Pkg *provenance over chapter 9454, chapter 865, chapter 856, chapter 868, BEDC.MetaCIC AST rows,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{LiteralASTEqualityBoundary}^{\uparrow}}$ *row.*

The carrier contains no beta-step evaluator, no conversion closure, no quotient of syntax, no external equality oracle, and no theorem identifying displayed AST equality with a semantic equality from another calculus.

Definition 873.2 (Literal AST equality-boundary classifier)**.** *Two* $\mathsf{LiteralASTEqualityBoundary}^{\uparrow}$ *carriers*

$$L = (A, T, B, H, C, P, N)$$

and

$$L' = (A', T', B', H', C', P', N')$$

are classifier-equivalent exactly when the displayed AST rows, literal comparison rows, boundary-refusal rows, componentwise transports, continuation routes, provenance rows, and local naming rows agree through the displayed hsame *and* Cont *data. The classifier does not compare carriers by beta-normal form, definitional conversion, quotient representative, proof irrelevance, proposition extensionality, or host semantic equality.*

Theorem 873.3 (Literal AST equality-boundary NameCert obligations)**.** *For every* $\mathsf{LiteralASTEqualityBoundary}^{\uparrow}$ *carrier*

$$L = (A, T, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LiteralASTEqualityBoundary}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the displayed packet of Definition 873.1;*
2. *classifier stability under the literal classifier of Definition 873.2;*
3. *literal equality exactness through* A *and* T*;*
4. *boundary refusal through* B *for every beta, conversion, quotient, proof-irrelevance, proposition-extensionality, host-semantic, or parent-theory equality request;*
5. *ledger exactness through* H, C, P, N *for the same displayed rows.*

Proof. Project the finite carrier. The rows A, T, B are the only equality-facing coordinates before transport, route replay, provenance, or local naming is read.

Classifier stability is componentwise by Definition 873.2. A transported packet may preserve literal AST equality, but it cannot replace that comparison by beta equality, conversion equality, quotient equality, or host semantic equality.

The rows H, C, P, N make the same equality boundary readable by downstream consumers. Since the carrier has no evaluator, conversion closure, quotient, proof-irrelevance row, proposition-extensionality row, or parent-theory equality row, the listed NameCert obligations exhaust the packet surface. □

Theorem 873.4 (Literal AST equality exactness)**.** *Every equality read from an accepted* LiteralASTEqualityBoundar *carrier*

$$L = (A, T, B, H, C, P, N)$$

factors through the displayed AST row A*, the literal comparison row* T*, and the componentwise transport and replay rows* H, C*. The read exports only constructor-tag equality and componentwise displayed subrow equality, and it exports no beta equality, conversion equality, quotient equality, proof irrelevance, proposition extensionality, host semantic equivalence, or parent-theory identity transport.*

Proof. Begin with the carrier definition. The equality coordinate is T, and it is attached to the displayed AST row A.

Transport and replay are componentwise. The rows H and C can move or read A and T, but they do not add a computation relation or quotient relation.

The boundary-refusal row B accounts for every stronger equality request. Therefore any accepted equality read remains literal and displayed, with no route to the excluded equality principles. □

Theorem 873.5 (Literal AST equality sibling independence)**.** ***Independence witness:*** *internaltheoryboundary, metacic-theory-identity, axiom-dependency-audit-map, bedcselftheory: the new carrier isolates one literal-equality boundary row rather than packaging all theory-identity commitments or all axiom-dependency routes.*

Proof. Compare row inventories. The internal-theory and MetaCIC theory-identity packets package closed generators, literal AST equality, structural recursors, purity, and apophatic boundary data together.

The axiom-dependency audit map packages claim, dependency, route, and audit rows. The BEDC self-theory packet packages the five positive own-theory commitments as one substrate-facing certificate.

The $\mathsf{LiteralASTEqualityBoundary}^{\uparrow}$ carrier keeps only the displayed AST row, literal comparison row, boundary-refusal row, and structural ledger rows. It can be cited by those broader siblings, but none of them is bijective to this single equality-boundary packet. □

Theorem 873.6 (Literal AST equality TasteGate obligation)**.** *The Lean-side 'TasteGate.lean' development for* $\mathsf{LiteralASTEqualityBoundary}^{\uparrow}$ *includes explicit* Nontrivial *and* FieldFaithful *instances. These instances are the gate-facing rows that separate a real literal-equality boundary carrier from a vacuous event-flow encoding and record that the encoding preserves the displayed AST row, literal comparison row, boundary-refusal row, transport rows, route rows, provenance row, and local naming row.*

Lean4 ✓ `BEDC.Derived.LiteralASTEqualityBoundaryUp.LiteralASTEqualityBoundaryTasteGate single carrier alignment`

Proof. The carrier has distinct equality-facing fields. A gate that recognizes only an event-flow round trip would not show that A, T, and B remain separate rows.

Nontriviality rules out the empty reading of the packet. Field faithfulness records preservation of the displayed field structure, so the literal equality boundary remains a finite carrier with inspectable rows rather than an unstructured event name. □

Falsifiable prediction: No accepted packet may replace literal AST equality by beta/conversion equality without leaving the carrier rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LiteralASTEqualityBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{LiteralASTEqualityBoundary}^{\uparrow}$ packet is generated from displayed AST rows, literal comparison rows, boundary-refusal rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LiteralASTEqualityBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 873.1, Definition 873.2, Definition 873.3, Definition 873.4, Definition 873.5, and Definition 873.6 specify the literal AST equality boundary packet and its gate-facing obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LiteralASTEqualityBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove beta soundness, conversion decidability, quotient soundness, proof irrelevance, proposition extensionality, host semantic equality, Lean verification, or bridge checking for $\mathsf{LiteralASTEqualityBoundary}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, literal equality exactness, boundary refusal, ledger exactness, and TasteGate nontriviality with field faithfulness.

Chapter 874

A Concrete Naming Certificate for $\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}$

The $\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}$ packet names the concrete route from regular-Cauchy finite windows to the observation budget and the $\mathsf{Real}^{\uparrow}$ seal used by chapter 9238. It reads its finite window side through chapter 126, its diagonal schedule through chapter 422, and its budget side through chapter 611. The packet keeps these sibling surfaces in one route rather than replacing any of them.

Definition 874.1 (Regular-Cauchy finite observation route carrier)**.** *A* $\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (Q, W, D, R, B, S, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite regular-Cauchy request row, including the requested precision and the selected diagonal index;*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row read by the route;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger for the window;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the finite observations;*
5. *B is the* $\mathsf{RealObservationBudget}^{\uparrow}$ *row admitting the same window, dyadic ledger, handoff, and seal request;*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the budget row has been displayed;*
7. *H stores componentwise* hsame *transports for $Q, W, D, R, B, S, C, P, N$;*
8. *C stores the* Cont *routes reading the request, window, dyadic ledger, regular-rational handoff, observation budget, seal row, provenance, and local name;*
9. *P is the* Pkg *provenance over* BHist, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, host real equality, hidden limit selection, unbounded observation schedules, or a $\mathsf{Real}^{\uparrow}$ *seal read outside the displayed budget.*

Lean4 ✓ BEDC.Derived.RegularCauchyFiniteObservationRouteUp.RegularCauchyFiniteObservationRouteTasteGate
single carrier alignment

Theorem 874.2 (Regular-Cauchy finite observation route obligations)**.** *For the carrier of Definition 874.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window admission,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{RealObservationBudget}^{\uparrow}$ *budget admission,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row.*

Proof. Carrier admission is projection from the tuple $Z = (Q, W, D, R, B, S, H, C, P, N)$. The first six rows expose the finite request, selected window, dyadic ledger, regular-rational handoff, observation budget, and seal row.

The sibling surfaces supply the route checks. The $\mathsf{StreamName}^{\uparrow}$ row gives the finite observation window, the $\mathsf{DyadicRatCore}^{\uparrow}$ row gives the finite arithmetic readback, and the $\mathsf{RegSeqRat}^{\uparrow}$ row is the handoff consumed by the observation budget.

The budget and seal obligations are bound by B, S, H, C, P, N. Since the seal row is downstream of B in the carrier and in the displayed continuation routes, the local certificate has no source from which to read a $\mathsf{Real}^{\uparrow}$ seal before the finite observation budget is present. □

Theorem 874.3 (Regular-Cauchy finite observation route non-escape)**.** *An accepted* RegularCauchyFiniteObservatic *carrier exports no quotient stream, host real equality proof, hidden limit selector, unbounded observation schedule, or direct* $\mathsf{Real}^{\uparrow}$ *seal read. Every completion-facing request remains inside the displayed rows* $Q, W, D, R, B, S, H, C, P, N$.

Proof. Inspect the carrier inventory in Definition 874.1. The tuple lists the request, window, dyadic ledger, regular-rational handoff, observation budget, seal row, transports, continuations, provenance, and local naming data, and it lists none of the excluded objects.

Apply the obligation theorem. It makes the displayed rows the whole local NameCert surface, so a consumer cannot add quotient-stream equality, host real equality, hidden limit selection, an unbounded schedule, or an early seal coordinate while remaining in the accepted carrier. □

Theorem 874.4 (Regular-Cauchy finite observation route Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read of an accepted* $\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}$ *carrier factors through the finite route*

$$Q \to W \to D \to R \to B \to S$$

with transport, continuation, provenance, and local naming rows H, C, P, N. *Thus the seal is reached only after the* $\mathsf{RealObservationBudget}^{\uparrow}$ *row has accepted the same* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff.*

Proof. Begin with the carrier. The seal coordinate S appears after the window, dyadic ledger, handoff, and observation-budget rows in the displayed packet.

Read the observation-budget side through chapter 611. That sibling surface admits seal consumption only through finite windows, dyadic readbacks, regular-rational handoff rows, and its own budget row.

The rows H, C, P, N record the componentwise transport, route replay, package provenance, and local name for the same packet. Therefore every $\mathsf{Real}^{\uparrow}$ seal read follows the displayed route through B and cannot bypass the finite observation budget. □

Theorem 874.5 (Regular-Cauchy finite observation route vision concretization)**.** *The diagonal-limit route named in chapter 9238 is realized by accepted* $\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}$ *packets as finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealObservationBudget}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal data. The stationary diagonal side is read through chapter 422, while product-facing consumers can share the finite window and handoff rows with chapter 464 without importing quotient streams, hidden limits, or host real equality.*

Proof. The diagonal-limit consumer in chapter 9238 needs a finite observation route before a $\mathsf{Real}^{\uparrow}$ seal is inspected. The carrier supplies exactly that route: request, window, dyadic readback, regular-rational handoff, observation budget, and seal.

The stationary diagonal sibling fixes the diagonal-window shape, and the CauchyProduct sibling can reuse the same kind of finite window and regular-rational handoff rows. These links do not add coordinates to Z; they only identify which sibling surfaces read the displayed rows.

Finally apply the Real seal handoff and non-escape theorems. Together they show that the vision-facing route reaches the $\mathsf{Real}^{\uparrow}$ seal through the finite observation budget and excludes quotient streams, hidden limit selection, and host real equality. □

Theorem 874.6 (Regular-Cauchy finite observation route budget-selector pullback)**.** *Let*

$$Z = (Q, W, D, R, B, S, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}$ *packet, and let*

$$F = (B_0, S_0, W_0, D_0, R_0, E_0, H_0, C_0, P_0, N_0)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet. If the displayed* hsame *transports identify* W *with* W_0*,* D *with* D_0*,* R *with* R_0*, and the route seal* S *with* E_0*, then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer factors through both finite routes*

$$Q \to W \to D \to R \to B \to S$$

and

$$B_0 \to S_0 \to W_0 \to D_0 \to R_0 \to E_0.$$

The common consumer exports no quotient stream, hidden limit selector, host real equality, countable choice, or ambient completeness row.

Proof. Start on the regular-Cauchy route. By Definition 874.4, every $\mathsf{Real}^{\uparrow}$ seal read of Z passes through the displayed finite path $Q \to W \to D \to R \to B \to S$.

Move to the selector route. Apply Definition 782.7 to the packet F, obtaining the finite path $B_0 \to S_0 \to W_0 \to D_0 \to R_0 \to E_0$. The assumed componentwise hsame transports identify the shared window, dyadic ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and seal endpoint.

Finally apply Definition 782.14 together with the non-escape theorem of this chapter. These two boundaries remove quotient streams, hidden limit selectors, host real equality, countable choice, and ambient completeness data, so the shared $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer can read only the two displayed finite routes and their visible transport, continuation, provenance, and naming rows. □

Theorem 874.7 (Regular-Cauchy finite observation route interface lock)**.** *Let*

$$Z = (Q, W, D, R, B, S, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}$ *packet, and let*

$$O = (S_0, R_0, D_0, T_0, E_0, H_0, C_0, P_0, N_0)$$

be an accepted $\mathsf{FiniteObservationInterface}^{\uparrow}$ *packet. If the displayed* hsame *transports identify* W *with* S_0*,* R *with* R_0*,* D *with* D_0*, the selected finite window read by* W *with* T_0*, and the* $\mathsf{Real}^{\uparrow}$ *seal endpoint* S *with the Real-facing endpoint routed by* C_0*, then every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer factors through both concrete finite routes*

$$Q \to W \to D \to R \to B \to S$$

and

$$S_0 \to R_0 \to D_0 \to T_0 \to E_0.$$

The omitted-tail ledger E_0 *remains a tail ledger only: it cannot be exported as a selected stream row, quotient stream equality, host real equality, hidden limit selection, or ambient completeness witness.*

Proof. First apply the Real seal handoff theorem for Z. It places every $\mathsf{Real}^{\uparrow}$ read behind the displayed route $Q \to W \to D \to R \to B \to S$, with H, C, P, N carrying only transport, replay, provenance, and local naming data.

Next apply the budget-selector pullback to the same route boundary. This keeps $\mathsf{Real}^{\uparrow}$ and $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumers on the concrete finite observation side and excludes quotient streams, hidden limit selectors, host real equality, countable choice, and ambient completeness.

Now read the interface packet through Definition 1007.3 and Definition 1007.2. The selected finite window is T_0, while E_0 is the omitted-tail ledger and has no selected-stream role. The assumed componentwise hsame transports identify this interface window, regular-rational handoff, dyadic tolerance row, and Real-facing endpoint with the corresponding rows of Z.

The two route descriptions therefore name the same consumer boundary through the displayed packet rows. Since neither local $\mathsf{NameCert}$ surface contains a coordinate for exporting the omitted tail as selected data, quotient equality, host equality, hidden limit choice, or ambient completeness, the shared consumer has no such escape route. □

Falsifiable prediction: Every accepted route factors through the displayed finite observation budget before any RealUp seal read; a seal read bypassing the budget refutes this chapter.

Independence witness: real-observation-budget, finiteobservationbudgetselector, stationarypartitiondiagonal, cauchyproduct, streamname: none is bijective because this carrier simultaneously records the route from regular-Cauchy finite windows to the observation budget and RealUp seal, while each sibling lacks at least one of the route, budget, diagonal, product, or stream-only rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}$ packet is generated from a finite regular-Cauchy request, selected $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{RealObservationBudget}^{\uparrow}$ budget row, $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 874.1, Definition 874.2, Definition 874.3, Definition 874.4, Definition 874.5, Definition 874.6, and Definition 874.7 define the route carrier, obligation surface, non-escape boundary, Real seal handoff, vision-facing concretization, budget-selector pullback, and finite-observation interface lock.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFiniteObservationRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, quotient-stream equality, hidden limit selection, unbounded observation schedules, host real equality, RealUp completeness, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite-window admission, dyadic readback, RegSeqRat handoff, observation-budget exactness, seal-handoff exactness, and non-escape for the same route packet.

Chapter 875

A Concrete Naming Certificate for $\mathsf{CrossHistCausalRoute}^{\uparrow}$

The $\mathsf{CrossHistCausalRoute}^{\uparrow}$ interface realizes the route layer of the Inter-Hist Locality chain of chapter 9419. It sits after the observer-Hist identity surface of chapter 479, the causal witness surface of chapter 478, the maximum-rate boundary of chapter 594, the invariant observer-gate surface of chapter 656, and the finite replay surface of chapter 469. Its role is to bind those five siblings into one finite route certificate before a later causal-rate packet reads the maximum-rate row.

Definition 875.1 (Cross-Hist causal-route carrier)**.** *A* $\mathsf{CrossHistCausalRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, D, M, S, G, T, H, C, P, N)$$

with the following visible rows:

1. *A and B are the two observer-history slots, each admitted through* $\mathsf{ObserverHistIdentity}^{\uparrow}$*;*
2. *D is the displayed finite family of* $\mathsf{CrossHistCausal}^{\uparrow}$ *causal rows over the ordered observer slots and selected unary slot ledgers;*
3. *M is the* $\mathsf{MaxCausalRate}^{\uparrow}$ *row attached to exactly the causal family D;*
4. *S is the observer-symmetry gate, recording that the route family remains readable after swapping the two observer slots through the displayed transports;*
5. *G is the observer non-escape gate, refusing a global frame, synchronized clock, metric tensor, or host-valued speed for the route read;*
6. *T is the* $\mathsf{ContinuationTrace}^{\uparrow}$ *row that replays the accepted route from the observer slots through D, M, S, and G;*
7. *H records componentwise* hsame *transport for the observer slots, causal rows, maximum-rate row, observer gates, continuation trace, package row, and local naming row;*
8. *C records the displayed* Cont *routes by which a consumer reads $A, B, D, M, S, G, T, H, P, N$;*
9. *P is the* Pkg *provenance over* $\mathsf{CrossHistCausalRoute}^{\uparrow}$*,* $\mathsf{ObserverHistIdentity}^{\uparrow}$*,* $\mathsf{CrossHistCausal}^{\uparrow}$*,* $\mathsf{MaxCausalRate}^{\uparrow}$*,* $\mathsf{InterHistInvariant}^{\uparrow}$*,* $\mathsf{ContinuationTrace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CrossHistCausalRoute}^{\uparrow}}$ *row.*

The carrier is a finite route packet. It contains no global observer frame, synchronized clock, metric tensor, host real-valued speed, detached maximum-rate read, or causal witness outside the displayed route family.

Theorem 875.2 (Cross-Hist causal-route NameCert obligations)**.** *For the carrier of Definition 875.1, the local* $\mathsf{NameCert}_{\mathsf{CrossHistCausalRoute}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$Q = (A, B, D, M, S, G, T, H, C, P, N),$$

observer-slot admission, displayed causal-row replay, maximum-rate attachment to D*, both observer-gate rows* S, G*, continuation-trace replay through* T*, componentwise* hsame *transport, displayed* Cont *access, package provenance, and the local naming row.*

Proof. Carrier admission projects the finite tuple in Definition 875.1. The rows $A, B, D, M, S, G, T, H, C, P, N$ are the complete public inventory of the route packet.

The observer slots are read through A and B, and the causal rows are exactly the displayed family D. The maximum-rate row M is attached to that same family, so no consumer can read a detached maximum over unlisted causal data.

The two observer gates are S and G. The row S supplies the observer-swap route, while G refuses global synchronization, privileged frames, metric tensors, and host-valued speeds.

The continuation trace T, transport row H, displayed routes C, provenance P, and local naming row N replay and name the same finite route. Since the carrier has no coordinate outside those rows, the listed obligations exhaust the $\mathsf{NameCert}_{\mathsf{CrossHistCausalRoute}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.CrossHistCausalRouteUp.CrossHistCausalRouteCarrier namecert obligations`

Theorem 875.3 (Cross-Hist causal-route maximum-rate gate)**.** *An accepted* $\mathsf{CrossHistCausalRoute}^{\uparrow}$ *packet cannot expose a maximum-rate read unless the displayed causal-route family* D *and both observer-gate rows* S, G *are present in the same carrier.*

Lean4 ✓ `BEDC.Derived.CrossHistCausalRouteUp.CrossHistCausalRouteCarrier maximum rate gate`

Proof. Project the accepted carrier through Definition 875.1. The only maximum-rate coordinate is M, and its definition attaches it to the displayed causal family D.

Apply Definition 875.2. The local route obligations require the observer-symmetry gate S and the observer non-escape gate G before the maximum-rate row is exposed to a consumer.

Therefore a read that omits D, S, or G is not a read of the accepted route packet. The packet supplies no second rate row, hidden causal family, global frame, or synchronized clock through which such a read could be recovered. □

Theorem 875.4 (Cross-Hist causal-route sibling independence)**.** *The* $\mathsf{CrossHistCausalRoute}^{\uparrow}$ *packet stores all five sibling surfaces:* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *for observer slots,* $\mathsf{CrossHistCausal}^{\uparrow}$ *for causal rows,* $\mathsf{MaxCausalRate}^{\uparrow}$ *for the bound row,* $\mathsf{InterHistInvariant}^{\uparrow}$ *for observer-gate reading, and* $\mathsf{ContinuationTrace}^{\uparrow}$ *for finite replay. It is not bijective to any one of those siblings, because deleting any one displayed surface removes a row required by Definition 875.1.*

Lean4 ✓ `BEDC.Derived.CrossHistCausalRouteUp.CrossHistCausalRoute sibling independence`

Proof. Inspect the carrier coordinates. The rows A, B carry the observer slots, D carries the causal family, M carries the maximum-rate row, S, G carry the observer-gate boundary, and T carries route replay.

Each listed sibling supplies a different row kind consumed by the route packet. Removing the observer slots leaves no anchors for D; removing D leaves no causal family for M; removing M leaves no maximum-rate route; removing S, G leaves no observer-gate boundary; removing T leaves no finite replay.

Thus the route packet is a finite product of the five displayed surfaces with transport, access, provenance, and naming rows. No projection to a single sibling can be inverted without recreating the deleted rows. □

Lean4 ✓ `BEDC.Derived.CrossHistCausalRouteUp.CrossHistCausalRouteCarrier sibling independence`

Theorem 875.5 (Cross-Hist causal-route TasteGate surface)**.** *The later Lean* `TasteGate.lean` *development for* $\mathsf{CrossHistCausalRoute}^{\uparrow}$ *must include explicit* $\mathsf{Nontrivial\ CrossHistCausalRoute}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ CrossHistCausalRoute}^{\uparrow}$ *instances. These instances must preserve the observer slots, causal-route family, maximum-rate row, observer-gate rows, continuation trace, transport rows, displayed access routes, package provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.CrossHistCausalRouteUp.CrossHistCausalRouteTasteGate single carrier alignment`

Proof. The nontriviality instance is forced by the carrier inventory: an admitted route packet must display at least the two observer slots, one route-family surface, the maximum-rate row, both observer gates, and the replay row.

Field faithfulness is likewise rowwise. A gate-facing instance that forgets any of $A, B, D, M, S, G, T, H, C, P, N$ would permit a consumer read not backed by the local $\mathsf{NameCert}_{\mathsf{CrossHistCausalRoute}^{\uparrow}}$ obligations.

Therefore the TasteGate surface must preserve exactly the finite packet named in Definition 875.1. □

Falsifiable prediction: An accepted route packet cannot expose a maximum-rate read unless the displayed causal-route family and both observer-gate rows are present.

Independence witness: observerhistidentity, crosshistcausal, maxcausalrate, interhistinvariant, continuationtrace: route packets store all five surfaces and are not bijective to any single sibling.

Closure status for $\mathsf{NameCert}_{\mathsf{CrossHistCausalRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{CrossHistCausalRoute}^{\uparrow}$ packet is generated from two observer-history slots, finite causal-route rows, a maximum-rate row, two observer-gate rows, a continuation-trace row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CrossHistCausalRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 875.1, Definition 875.2, Definition 875.3, Definition 875.4, and Definition 875.5 specify the finite route packet, its local obligations, its maximum-rate gate, its sibling dependence boundary, and its TasteGate instance surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CrossHistCausalRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not derive a numerical speed constant, Lorentz geometry, metric tensors, synchronized clocks, global frames, Lean verification, or bridge checking for $\mathsf{CrossHistCausalRoute}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, route replay, maximum-rate attachment, observer-gate preservation, continuation-trace replay, and TasteGate nontriviality with field faithfulness.

Chapter 876

A Concrete Naming Certificate for $\mathsf{CrossHistCausalRate}^{\uparrow}$

The $\mathsf{CrossHistCausalRate}^{\uparrow}$ packet realizes the maximum cross-Hist causal-rate direction as a finite NameCert carrier. It sits after the two-history causal witness surface of chapter 478 and the unary bound surface of chapter 594, while exposing the observer-symmetric invariant reading used by chapter 656. The packet also consumes observer-Hist identity from chapter 479 and finite route replay from chapter 469: those siblings provide the observer rows and displayed continuation routes, while this chapter binds them to a maximum-rate read with no global frame.

Definition 876.1 (Cross-Hist causal-rate carrier)**.** *A* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, B, D, M, S, G, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two observer-history slots, each read through the observer-Hist identity surface;*
2. *D is the displayed causal-dependence route family, whose entries are finite* $\mathsf{CrossHistCausal}^{\uparrow}$ *rows over the ordered pair A, B and selected unary slots;*
3. *M is the maximum-rate row, read as a* $\mathsf{MaxCausalRate}^{\uparrow}$ *unary-bound packet over exactly the dependence routes in D;*
4. *S is the observer-symmetry row, recording that swapping the two Hist slots preserves the same maximum-rate read after displayed transport;*
5. *G is the no-global-frame ledger, recording absence of a global synchronization row, shared clock row, metric tensor row, or privileged observer-frame row;*
6. *H records componentwise* hsame *transport for the two Hist slots, dependence routes, maximum-rate row, observer-symmetry row, no-global-frame ledger, continuation routes, provenance row, and local naming row;*
7. *C records displayed* Cont *routes by which a consumer reads the two histories, replays each causal-dependence route, reads the maximum-rate row, checks observer symmetry, and checks the no-global-frame ledger;*
8. *P is the* Pkg *provenance over* $\mathsf{CrossHistCausalRate}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{CrossHistCausal}^{\uparrow}$, $\mathsf{MaxCausalRate}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, $\mathsf{ContinuationTrace}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}$ *row.*
The carrier contains no coordinate for a global observer frame, synchronized clock, metric tensor, host real-valued speed, unlisted causal witness, or maximum-rate read detached from the displayed dependence routes.

Theorem 876.2 (Cross-Hist causal-rate NameCert obligations)**.** *For the carrier of Definition 876.1, the local* $\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$R = (A, B, D, M, S, G, H, C, P, N),$$

two observer-history slots, finite causal-dependence route replay, maximum-rate row exactness, observer-symmetry preservation, no-global-frame refusal, componentwise hsame *transport, displayed* Cont *replay, package provenance, and the local naming row.*

Lean4 ✓ `BEDC.Derived.CrossHistCausalRateUp.CrossHistCausalRateCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 876.1. The rows $A, B, D, M, S, G, H, C, P, N$ expose every public coordinate.

The observer slots are read through A and B, with observer-Hist identity supplied by the sibling surface. The dependence routes in D are finite $\mathsf{CrossHistCausal}^{\uparrow}$ rows, and the continuation routes in C replay those rows without adding a hidden causal witness.

The maximum-rate read is the row M. It is attached to exactly the displayed dependence route family D, so the rate surface cannot detach from the two histories or from the selected unary slots.

The observer-symmetry row S and the no-global-frame ledger G provide the two public gates for a maximum-rate read. The remaining rows H, C, P, N transport, replay, package, and name the same packet, so the NameCert obligations are exhausted by the displayed carrier. □

Theorem 876.3 (Cross-Hist causal-rate carrier admission row)**.** *Every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet exposes exactly the finite carrier admission row*

$$A, B, D, M, S, G, H, C, P, N.$$

The rows are respectively the two observer-history slots, the causal-dependence route family, the maximum-rate row, the observer-symmetry row, the no-global-frame ledger, componentwise hsame *transport, displayed* Cont *replay, package provenance, and the local* $\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}$ *row. No root consumer may add a global frame, synchronized clock, metric tensor, host speed coordinate, hidden causal witness, or detached rate row to this admission surface.*

Proof. Project the carrier in Definition 876.1. Its tuple is exactly $R = (A, B, D, M, S, G, H, C, P, N)$, and the definition lists no further public coordinate.

Use the NameCert obligations of Definition 876.2. Carrier admission for the same tuple is the first obligation, while the remaining obligations classify every displayed row as observer slots, route replay, maximum-row exactness, symmetry, frame refusal, transport, continuation, provenance, or naming.

The exclusion clause is then an inventory argument. Since the accepted packet contains no coordinate for a global frame, synchronized clock, metric tensor, host speed, hidden witness, or detached rate read, no root admission row can expose one. □

Theorem 876.4 (Cross-Hist causal-rate route replay row)**.** *Every public rate read from an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet replays the finite route family D through the displayed continuation*

row C before it reaches the maximum-rate row M. The route reads the $\mathsf{CrossHistCausal}^{\uparrow}$ *sibling surface of chapter 478 and then the* $\mathsf{MaxCausalRate}^{\uparrow}$ *sibling surface of chapter 594; it cannot read M as a host-side rate detached from D.*

Proof. Start with Definition 876.1. The dependence coordinate is D, the continuation coordinate is C, and the maximum-rate coordinate is M.

Apply Definition 876.2. Its causal-dependence route replay and maximum-rate row exactness clauses force the read of M to remain attached to the displayed family D under the same local naming row.

Compose this with the existing route surfaces. The $\mathsf{CrossHistCausal}^{\uparrow}$ rows supply the finite causal witnesses consumed by D, and the $\mathsf{MaxCausalRate}^{\uparrow}$ rows supply the unary-bound rate surface consumed by M. Thus the root route is D through C before M, with no detached host-rate coordinate. □

Theorem 876.5 (Cross-Hist causal-rate frame-refusal row)**.** *Any public rate read from an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet must consume both the observer-symmetry row S and the no-global-frame ledger G before the read can be used by* $\mathsf{InterHistInvariant}^{\uparrow}$ *or* $\mathsf{MaxCausalRate}^{\uparrow}$ *consumers. The row refuses a global frame, synchronized clock, metric tensor, and host speed coordinate.*

Proof. Project the carrier of Definition 876.1. The only public frame-facing rows are S and G: S records observer symmetry, and G records absence of a global synchronization surface.

Use Definition 876.2. Observer-symmetry preservation and no-global-frame refusal are obligations of the same local $\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}$ surface as the maximum-rate row exactness clause.

Now compose the invariant and consumer boundaries. By Definition 876.9 and Definition 876.10, an invariant-facing rate read cannot proceed without S and G. By Definition 876.11, every consumer route stays inside the displayed rows, so neither an $\mathsf{InterHistInvariant}^{\uparrow}$ consumer nor a $\mathsf{MaxCausalRate}^{\uparrow}$ consumer can introduce a global frame, clock, metric, or host speed coordinate. □

Theorem 876.6 (Cross-Hist causal-rate observer-slot route)**.** *Every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet reads observer slots only through the displayed rows*

$$A, B, D, H, C, P, N.$$

The rows A and B supply the two observer-history slots, D supplies the finite causal-dependence route family over those slots, and H, C, P, N supply the componentwise transport, displayed continuation replay, package provenance, and local naming rows. No observer-facing consumer may read an unlisted Hist slot, synchronized clock, privileged observer frame, or causal route outside this displayed family.

Proof. Project the carrier of Definition 876.1. The only observer-history coordinates are A and B, and the only causal rows attached to them are the finite route entries in D.

Use the NameCert obligations of Definition 876.2. They require observer-history slots, causal-dependence route replay, componentwise hsame transport, displayed Cont replay, package provenance, and local naming to be read from the same packet.

Thus every observer-slot read is routed through A, B, D, H, C, P, N, with no carrier coordinate left for a hidden observer slot or external frame. □

Theorem 876.7 (Cross-Hist causal-rate maximum-row exactness)**.** *For every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet*

$$R = (A, B, D, M, S, G, H, C, P, N),$$

the maximum-rate row M is attached to the displayed dependence route family D. A consumer may not read M as a host real-valued speed, metric row, detached unary bound, or maximum over causal data not displayed in D.

Proof. Project Definition 876.1. The row M is declared as the $\mathsf{MaxCausalRate}^{\uparrow}$ unary-bound packet over exactly the dependence routes in D.

Apply Definition 876.2. Its maximum-rate exactness obligation keeps the rate row inside the same carrier as the two observer histories, the finite causal route family, and the structural rows.

Since no additional maximum-rate coordinate occurs in the packet, the only available rate read is the one attached to D. □

Theorem 876.8 (Cross-Hist causal-rate symmetry non-escape)**.** *Any invariant-facing consumer of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet may read the rate only after both the observer-symmetry row S and the no-global-frame ledger G are present. The read is therefore an observer-symmetric finite maximum over the displayed route family D, not a global-frame synchronization, metric tensor, privileged observer surface, or host speed.*

Proof. Begin with the carrier projection. The rows S and G are distinct public coordinates of the packet, with S recording swap-invariance of the two Hist slots and G recording the absence of a global synchronization surface.

Use Definition 876.2 to keep observer-symmetry preservation and no-global-frame refusal as obligations of the same local $\mathsf{NameCert}$ row. A consumer that omits either row has not consumed the displayed certificate surface.

Finally combine the maximum-rate row with those two gates. The invariant-facing read can only use M through D together with S, G, H, C, P, N, so it cannot escape to a global frame, metric tensor, privileged observer, or host-level speed. □

Theorem 876.9 (Cross-Hist causal-rate invariant boundary)**.** *Every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet reads its maximum-rate row as an observer-symmetric inter-Hist invariant over the two displayed history slots. A consumer may reach the rate only through $A, B, D, M, S, G, H, C, P, N$, and it may not read a maximum-rate value when either the observer-symmetry row S or the no-global-frame ledger G is absent.*

Proof. Project the accepted carrier. The two histories are the rows A and B, and all causal content is the finite route family D.

Read the maximum-rate row M through the same route family. Since M is specified over the displayed dependence routes, it is not a host real-valued speed and not a metric row.

Now apply the observer-symmetry row S. It records that swapping A and B preserves the same maximum-rate read after componentwise transport, matching the finite invariant surface of chapter 656.

Finally inspect the no-global-frame ledger G. Without G, the read could not certify that the rate is independent of a privileged synchronization surface; without S, it could not certify observer symmetry. Hence a public maximum-rate read requires both rows. □

Theorem 876.10 (Cross-Hist causal-rate no-global-frame boundary)**.** *For every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet*

$$R = (A, B, D, M, S, G, H, C, P, N),$$

any public rate read consumes the no-global-frame ledger row G together with the two observer-history slots, causal-dependence route family, maximum-rate row, observer-symmetry row, and structural rows. No consumer route may read the maximum-rate row as a synchronized clock, privileged observer-frame row, metric tensor, or global-frame coordinate.

Proof. Project the accepted carrier. The rate-facing coordinates are $A, B, D, M, S, G, H, C, P, N$, and the row G is the only displayed ledger that records the absence of a global synchronization surface.

Apply Definition 876.2. Its no-global-frame refusal clause belongs to the same local $\mathsf{NameCert}$ surface as maximum-rate exactness and observer-symmetry preservation, so a consumer that reads M without G has not consumed the accepted packet.

Finally use Definition 876.9. The invariant read reaches M only through $A, B, D, M, S, G, H, C, P, N$ and is blocked when G is absent. Since the carrier has no synchronized-clock, privileged-frame, metric, or global-coordinate row, the boundary is exhaustive. □

Theorem 876.11 (Cross-Hist causal-rate consumer route totality)**.** *Every consumer route out of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *carrier factors through exactly the displayed rows*

$$A, B, D, M, S, G, H, C, P, N.$$

The route reads the two observer histories, finite causal-dependence rows, maximum-rate row, observer-symmetry row, no-global-frame ledger, componentwise transport, continuation replay, package provenance, and local naming row, with no additional host rate, hidden causal witness, synchronized clock, or privileged observer-frame coordinate.

Proof. Start from Definition 876.1. It lists the complete carrier as $A, B, D, M, S, G, H, C, P, N$ and declares that no global observer frame, synchronized clock, metric tensor, host speed, unlisted causal witness, or detached rate read is a coordinate.

The observer-slot route theorem accounts for A, B, D, H, C, P, N, and the maximum-row exactness theorem accounts for M as attached to D. The symmetry non-escape and invariant-boundary theorems then account for S and G as required gates for invariant-facing rate reads.

Combining those projections leaves no unclassified consumer route. Every public read is one of the displayed carrier rows, replayed through the structural rows, and no outside row can be inserted without leaving the accepted $\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}$ surface. □

Theorem 876.12 (Cross-Hist causal-rate observer-swap preservation)**.** *For an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet $R = (A, B, D, M, S, G, H, C, P, N)$, the swap row S is the only admissible observer-symmetry witness for the maximum-rate read. Swapping the two history slots preserves the rate only by consuming S together with the transported dependence routes in D and the structural rows H, C, P, N; no source-equivalence transport, host symmetry principle, or global observer frame supplies a second witness.*

Proof. Project the carrier. The row S is the displayed observer-symmetry coordinate, and no other row is declared as a witness that swapping A and B preserves the maximum-rate read.

Use Definition 876.2. Observer-symmetry preservation is a local certificate obligation for the same packet that contains D, M, H, C, P, N, so the swap read must remain attached to those displayed rows.

The invariant boundary confirms that a rate read requires S before it can be observer-symmetric. Because the packet also records no source-equivalence transport, host symmetry principle, or global frame, any admissible observer-swap preservation witness is exactly the row S transported through H, C, P, N. □

Theorem 876.13 (Cross-Hist causal-rate TasteGate obligation)**.** *The later Lean* `TasteGate.lean` *development for* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *must include explicit* $\mathsf{Nontrivial\ CrossHistCausalRate}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ CrossHistCausalRate}^{\uparrow}$ *instances. These gate-facing instances must preserve the two Hist slots, causal-dependence route family, maximum-rate row, observer-symmetry row, no-global-frame ledger, transport rows, continuation routes, provenance row, and local naming row.*

Lean4 ✓ `BEDC.Derived.CrossHistCausalRateUp.taste gate`

Proof. The packet is not determined by a single event name. Its carrier has separate rows for two histories, dependence routes, the maximum-rate row, observer symmetry, and no-global-frame refusal.

Nontriviality rules out an empty encoding in which every carrier collapses to one indistinct point. Field faithfulness records preservation of the displayed row inventory, so a TasteGate consumer can distinguish the two Hist slots, the dependence routes, the maximum-rate row, the symmetry row, and the no-global-frame ledger. □

Definition 876.14 (Cross-Hist causal-rate root source envelope)**.** *A* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root source envelope is the finite packet*

$$E = (A, B, D, M, S, G, H, C, P, N)$$

whose rows are read over $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{CrossHistCausal}^{\uparrow}$, $\mathsf{MaxCausalRate}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, $\mathsf{ContinuationTrace}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *as follows:*

1. *A, B are the two observer-history identity slots;*
2. *D is the displayed cross-Hist causal route family over those slots;*
3. *M is the maximum causal-rate row attached to exactly the route family D;*
4. *S is the observer-symmetry row for the rate read;*
5. *G is the no-global-frame ledger;*
6. *H, C, P, N are respectively the componentwise* hsame *transport, displayed continuation trace, package provenance, and local NameCert rows.*

The envelope has no row for host speed, synchronized clocks, a global frame, a metric tensor, an unlisted causal witness, or a maximum-rate read detached from D.

Theorem 876.15 (Cross-Hist causal-rate root classifier stability)**.** *Let*

$$E = (A, B, D, M, S, G, H, C, P, N) \quad \text{and} \quad E' = (A', B', D', M', S', G', H', C', P', N')$$

be accepted $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root source envelopes. If the two Hist slots A, A' and B, B', the causal route families D, D', the maximum-rate rows M, M', the observer-symmetry rows S, S', and the no-global-frame ledgers G, G' agree componentwise under the displayed* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}$ *rows, then E and E' classify the same root causal-rate packet.*

The classifier has no coordinate for a host speed, synchronized clock, global frame, metric tensor, detached maximum row, hidden causal route, or unlisted observer slot.

Proof. Project the root source envelopes. Their classifier-visible rows are exactly $A, B, D, M, S, G, H, C, P, N$ and $A', B', D', M', S', G', H', C', P', N'$.

Use Definition 876.6 for the Hist slots and causal route family. The observer-facing part of each packet is therefore exhausted by A, B, D, H, C, P, N and its primed counterpart.

Use Definition 876.7 together with Definition 876.8 and Definition 876.10. These results keep the maximum-rate row attached to D and keep the observer-symmetry and no-frame rows on the same route.

Finally apply Definition 876.11. Since every consumer route is one of the displayed rows, the componentwise agreement hypotheses identify the whole classifier packet and leave no hidden coordinate through which the two envelopes could diverge. □

Theorem 876.16 (Cross-Hist causal-rate root observer-slot exhaustion)**.** *Every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet exhausts its observer-slot reads through the displayed rows*

$$A, B, D, H, C, P, N.$$

A consumer may inspect the two observer histories only by reading A and B, replaying the causal route family D, transporting the components through H, following the displayed continuation route C, citing the package provenance P, and closing the local $\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}$ *row N. No unlisted observer slot, host clock, global frame coordinate, metric row, or detached causal route is available to such a read.*

Proof. Project the carrier of Definition 876.1. The only observer-facing rows are A and B, and the only displayed route family attached to them is D.

Apply the NameCert obligations of Definition 876.2 and the observer-slot route theorem Definition 876.6. These identify the observer histories as the carrier-visible slots and force consumer access through the finite route family.

The structural part is fixed by H, C, P, N. Consumer route totality from Definition 876.11 leaves no route outside the displayed transport, continuation, provenance, and local naming rows, while the frame-refusal boundary excludes host clocks, global frames, metric rows, and detached causal coordinates. □

Theorem 876.17 (Cross-Hist causal-rate root route-rate factorization)**.** *Every maximum-rate read from an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet factors through the displayed causal route family D before it reaches the maximum-rate row M. Thus a* $\mathsf{MaxCausalRate}^{\uparrow}$ *consumer may read M only after A, B, D, H, C, P, N have supplied the observer slots, route replay, transport, continuation, provenance, and local naming surface.*

Proof. Start from the carrier and the route obligation package. The row M is not a free host-valued speed coordinate; it is the maximum-rate row attached to exactly the causal route family D.

Apply maximum-row exactness from Definition 876.7. It binds the maximum-rate read to the displayed route family and rules out a second maximum row detached from D.

Now use observer-slot exhaustion together with consumer route totality. The read reaches D through A, B, H, C, P, N, then reads M as the rate row for that same route. Hence every maximum-rate read factors through D before the row M is consumed. □

Theorem 876.18 (Cross-Hist causal-rate root frame-refusal exactness)**.** *Every invariant-facing rate read from an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet consumes both the observer-symmetry row S and the no-global-frame ledger G. Consequently no global frame, synchronized clock, metric tensor, host speed row, or privileged observer coordinate can enter an* $\mathsf{InterHistInvariant}^{\uparrow}$ *or* $\mathsf{MaxCausalRate}^{\uparrow}$ *consumer route.*

Proof. Read the invariant boundary of Definition 876.9. It places the invariant-facing use of the rate behind the observer-symmetry row S and the no-global-frame ledger G.

Apply the no-global-frame boundary and frame-refusal composition theorems. The row G is the carrier-visible refusal row for synchronized clocks, privileged frames, metric tensors, host speeds, and global-frame coordinates, and it composes with S on the same route before any invariant-facing read is accepted.

Finally combine route-rate factorization with consumer route totality. Since the rate read has already passed through D before M and since every consumer route is displayed by H, C, P, N, there is no remaining coordinate through which a global frame or host speed row can enter. □

Theorem 876.19 (Cross-Hist causal-rate root ledger exactness)**.** *Every downstream rate consumer of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root source envelope reads exactly the displayed route, observer-symmetry, no-global-frame, transport, continuation, provenance, and local NameCert rows*

$$A, B, D, M, S, G, H, C, P, N.$$

The read has no host speed coordinate, synchronized clock, global frame, metric tensor, hidden causal route, detached maximum row, or unlisted observer slot.

Proof. Start with Definition 876.14. The envelope displays the observer slots, route family, rate row, symmetry row, no-frame ledger, transport, continuation, provenance, and local name as one finite packet.

Apply Definition 876.24. It states that every $\mathsf{MaxCausalRate}^{\uparrow}$ or $\mathsf{InterHistInvariant}^{\uparrow}$ consumer reads exactly the ten rows of the accepted packet.

Apply Definition 876.34 to the continuation-facing part of the route. The displayed row C is the only continuation trace through which the consumer can replay the observer slots, causal routes, maximum-rate row, and invariant boundary.

The exclusion clause in the envelope and the totality theorem then rule out host speeds, synchronized clocks, global frames, metric tensors, hidden causal routes, detached maximum rows, and unlisted observer slots. Therefore the downstream ledger is exact. □

Theorem 876.20 (Cross-Hist causal-rate route obligation package)**.** *For the carrier*

$$R = (A, B, D, M, S, G, H, C, P, N)$$

of Definition 876.1, the rows $A, B, D, M, S, G, H, C, P, N$ *supply the complete* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *obligation package: carrier admission for the two observer-history slots, finite route replay for the displayed causal-dependence family, maximum-rate exactness for* M*, observer symmetry for* S*, no-global-frame refusal for* G*, componentwise* hsame *transport, displayed continuation replay, package provenance, and the local* $\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}$ *row.*

Proof. Project the displayed carrier. The two observer slots are A and B, the finite causal-dependence route family is D, and the maximum-rate row is M.

The rows S and G are the two boundary gates for reading M as an observer-symmetric invariant rather than a global-frame value. The introduction fixes the sibling sources for observer identity, cross-Hist causal rows, maximum causal rate, inter-Hist invariant reading, and finite continuation replay, so the package consumes exactly those public surfaces.

Finally H, C, P, N provide the transport, replay, provenance, and local naming rows. Since the carrier contains no additional coordinate, the listed rows exhaust the obligation package. □

Theorem 876.21 (Cross-Hist causal-rate route replay obligation)**.** *Every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *causal-rate read must replay the finite route family* D *before reading the maximum-rate row* M*. A read that reaches* M *without the displayed* D *routes is not a read of the carrier* $R = (A, B, D, M, S, G, H, C, P, N)$*.*

Proof. Project the carrier and inspect the order of the public rows. The row M is specified as a maximum-rate packet over exactly the dependence routes displayed in D.

The continuation coordinate C records the consumer route: read the two histories, replay each route in D, then read M. Thus M is not an independent host-valued speed row and cannot be consumed before the finite route family has been replayed. □

Theorem 876.22 (Cross-Hist causal-rate observer symmetry obligation)**.** *An observer-symmetric* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *rate read requires both the observer-symmetry row* S *and the no-global-frame ledger* G*. The row* S *supplies invariance under swapping the two Hist slots, while* G *refuses synchronized clocks, privileged observer frames, and global synchronization data.*

Proof. The invariant boundary theorem already identifies S and G as the two public gates for a maximum-rate read. Projecting the carrier shows that S is the only row recording preservation under the observer swap, and G is the only row excluding the forbidden global-frame data.

If S is absent, the read has no observer-symmetry witness. If G is absent, the same numerical-looking read could depend on a hidden synchronization surface. Hence an observer-symmetric rate read requires both rows. □

Theorem 876.23 (Cross-Hist causal-rate downstream package)**.** *For an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet*

$$R = (A, B, D, M, S, G, H, C, P, N),$$

the downstream package consists exactly of carrier admission, the two observer slots A, B*, causal route replay through* D*, maximum-row exactness through* M*, observer-symmetry through* S*, no-global-frame refusal through* G*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and the local* $\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}$ *row* N*.*

Proof. Project the accepted carrier. The observer slots, dependence routes, maximum-rate row, symmetry row, no-global-frame row, transports, continuation routes, provenance, and local name are exactly the displayed rows $A, B, D, M, S, G, H, C, P, N$.

Apply Definition 876.2, Definition 876.21, and Definition 876.22. These obligations keep the causal route replay before the maximum-rate read and keep the observer-symmetry and no-global-frame rows inside the same local naming surface.

Finally use Definition 876.11. It leaves no route for a hidden causal witness, host speed, synchronized clock, global frame, or detached maximum row, so the downstream package is exhausted by the displayed carrier projections. □

Theorem 876.24 (Cross-Hist causal-rate root consumer exactness)**.** *Every* $\mathsf{MaxCausalRate}^{\uparrow}$ *or* $\mathsf{InterHistInvariant}^{\uparrow}$ *consumer of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet reads exactly the rows*

$$A, B, D, M, S, G, H, C, P, N.$$

The consumer reads no maximum-rate value outside M*, no invariant boundary outside* S, G*, and no transport, route, provenance, or naming evidence outside* H, C, P, N*.*

Proof. Start with the downstream package of Definition 876.23. It names the whole consumer-facing packet and orders the maximum-rate read after the displayed causal route family.

For a $\mathsf{MaxCausalRate}^{\uparrow}$ consumer, apply Definition 876.7. The row M is attached to D, so the consumer cannot read a detached host-valued rate.

For an $\mathsf{InterHistInvariant}^{\uparrow}$ consumer, apply Definition 876.9 and Definition 876.10. These rows force observer symmetry and no-global-frame refusal through S and G before the rate can be used as an invariant.

The structural evidence is then fixed by H, C, P, N. Since the carrier has no additional coordinate, both root consumers read exactly the displayed ten rows. □

Theorem 876.25 (Cross-Hist causal-rate scoped route closure)**.** *The scoped route for every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root consumer is bound to* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{CrossHistCausal}^{\uparrow}$, $\mathsf{MaxCausalRate}^{\uparrow}$, *and* $\mathsf{InterHistInvariant}^{\uparrow}$. *Within that scope, every downstream read factors through the rows* $A, B, D, M, S, G, H, C, P, N$ *and no global observer frame, synchronized clock, metric tensor, host real-valued speed, or unlisted causal witness is available.*

Proof. Project the carrier and read the provenance row. The row P names the packet over $\mathsf{CrossHistCausalRate}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{CrossHistCausal}^{\uparrow}$, $\mathsf{MaxCausalRate}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, $\mathsf{ContinuationTrace}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Apply the downstream package and root consumer exactness theorems. They identify A, B as the observer-Hist slots, D as the displayed $\mathsf{CrossHistCausal}^{\uparrow}$ route family, M as the $\mathsf{MaxCausalRate}^{\uparrow}$ row, and S, G as the invariant-facing boundary consumed by $\mathsf{InterHistInvariant}^{\uparrow}$ readers.

The remaining rows H, C, N provide componentwise transport, displayed route replay, and local naming. Because Definition 876.1 contains no global frame, clock, metric, host-speed, or hidden causal coordinate, the scoped route is closed under exactly the listed BEDC primitives and sibling surfaces. □

Theorem 876.26 (Cross-Hist causal-rate route-bound monotonicity)**.** *Extending the displayed causal-dependence route family* D *of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet can update the maximum-rate row* M *only through the same observer slots* A, B *and the structural rows* H, C, P, N. *No extension of* D *creates a detached host speed, a fresh observer coordinate, or a second maximum-rate row outside the carrier* $R = (A, B, D, M, S, G, H, C, P, N)$.

Proof. Start with the route replay obligation. It places every causal-rate read through the displayed family D before the row M is consumed.

Use observer symmetry and the downstream package theorem. The same observer slots A, B and the same boundary rows S, G are carried along any accepted consumer route, so extending D cannot switch to a new observer interface.

Finally apply root consumer exactness and scoped route closure. They keep every update of M inside $A, B, D, M, S, G, H, C, P, N$, with H, C, P, N supplying transport, replay, provenance, and naming. Thus route extension is monotone only along the displayed BEDC rows. □

Theorem 876.27 (Cross-Hist causal-rate invariant cap exhaustion)**.** *Every invariant cap read by* $\mathsf{MaxCausalRate}^{\uparrow}$ *or* $\mathsf{InterHistInvariant}^{\uparrow}$ *consumes exactly the rows* $A, B, D, M, S, G, H, C, P, N$ *of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet. The cap cannot add a hidden host speed, metric tensor, synchronized clock, privileged frame, or unlisted frame coordinate.*

Proof. Apply the downstream package theorem and root consumer exactness. They identify $\mathsf{MaxCausalRate}^{\uparrow}$ and $\mathsf{InterHistInvariant}^{\uparrow}$ consumers with the displayed carrier rows, not with an ambient frame.

Route replay contributes D before M, and observer symmetry contributes the gate row S. The no-global-frame ledger G stays on the same route before the rate can be read as an invariant.

Scoped route closure then accounts for the structural rows H, C, P, N. Since the carrier has no further coordinate, every invariant cap is exhausted by exactly the ten displayed rows. □

Theorem 876.28 (Cross-Hist causal-rate frame-refusal composition)**.** *For every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet, the no-global-frame ledger G composes with the observer-symmetry row S and the causal route replay family D before any public rate read is accepted. A public read of M is therefore refused unless it passes through D, S, G, and the structural rows H, C, P, N over the same observer slots A, B.*

Proof. First replay the causal route family. The route replay obligation places D before any accepted read of the maximum-rate row M.

Next use observer symmetry. The row S keeps the read invariant under swapping the displayed observer-Hist slots, so the rate is not attached to a privileged observer order.

Finally apply the no-global-frame boundary together with downstream package exactness, root consumer exactness, and scoped route closure. These results place G on the same route as D and S, then repack the public read through H, C, P, N. Hence no public rate read is accepted before the frame-refusal ledger has composed with the observer-symmetric route replay. □

Theorem 876.29 (Cross-Hist causal-rate root carrier admission)**.** *Every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet exposes exactly the rows*

$$A, B, D, M, S, G, H, C, P, N$$

over BHist, hsame, Cont, Pkg, *and* NameCert. *The rows admit the two observer-history slots, causal-dependence route family, maximum-rate row, observer-symmetry row, no-global-frame ledger, componentwise transport, displayed replay, provenance, and local naming surface, with no additional root coordinate.*

Proof. Project the carrier in Definition 876.1. Its displayed inventory is the tuple $R = (A, B, D, M, S, G, H, C, P, N)$

Apply Definition 876.20 and Definition 876.23. These theorems identify the same rows as the carrier admission, route replay, maximum-row exactness, observer-symmetry, no-global-frame refusal, transport, continuation, provenance, and local naming obligations.

The exactness statement Definition 876.24 leaves no downstream read outside the ten displayed rows. Hence root carrier admission is exactly the finite BHist, hsame, Cont, Pkg, and NameCert surface named above. □

Theorem 876.30 (Cross-Hist causal-rate root route replay)**.** *Every downstream invariant-facing read of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet replays the finite causal-dependence route family D before reading the maximum-rate row M. The read reaches M only through the displayed rows H, C, P, N and the invariant boundary rows S, G.*

Proof. Start with Definition 876.21. It states that a causal-rate read must replay D before consuming M.

For invariant-facing consumers, apply Definition 876.9 and Definition 876.22. These place the observer-symmetry row S and the no-global-frame ledger G on the same route before the rate can be used as an invariant.

Finally use Definition 876.25. It binds the route to the displayed transport, continuation, provenance, and local naming rows, so no invariant-facing read can reach M by skipping the finite D family. □

Theorem 876.31 (Cross-Hist causal-rate root no-frame ledger)**.** *For every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet, the row G is the complete no-global-frame ledger. It refuses synchronized clocks, privileged observer frames, metric tensors, host speeds, and global-frame coordinates for any downstream maximum-rate or invariant-facing read.*

Proof. Project the ledger row from the carrier and apply Definition 876.10. The row G is the unique displayed boundary excluding global synchronization data from a maximum-rate read.

Apply Definition 876.30 and Definition 876.29. They keep every downstream read inside $A, B, D, M, S, G, H, C, P, N$, with G on the route before M can be used by an invariant-facing consumer.

The scoped route closure theorem then rules out hidden global-frame coordinates, host speeds, metric tensors, synchronized clocks, and privileged observer frames. Since the carrier contains no second ledger row, G is the complete refusal ledger for the root packet. □

Theorem 876.32 (Cross-Hist causal-rate route-family exhaustion)**.** *Every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet exhausts its causal route reads through the displayed family D and the structural rows A, B, H, C, P, N. A consumer may replay a causal route only by reading the two observer-history slots A, B, the route family D, componentwise transport H, displayed continuation replay C, package provenance P, and the local naming row N; it may not read a hidden causal route, unlisted unary slot, synchronized clock, privileged frame, or metric row.*

Proof. Project the carrier of Definition 876.1. The only causal-dependence coordinate is the finite family D, and it is attached to the two displayed observer-history slots A and B.

Apply Definition 876.21 and Definition 876.25. These results force route replay through D and keep every downstream route inside the stated BEDC scope.

Use Definition 876.24. It fixes the structural rows H, C, P, N as the transport, continuation, provenance, and naming surface for root consumers. Since the carrier has no hidden causal-route coordinate, the displayed family exhausts all accepted causal reads. □

Theorem 876.33 (Cross-Hist causal-rate maximum observer gate)**.** *For every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet, the row M is readable as an invariant only after the causal route family D has been replayed and both observer gate rows S, G have been displayed. Thus no* $\mathsf{MaxCausalRate}^{\uparrow}$ *or* $\mathsf{InterHistInvariant}^{\uparrow}$ *consumer can read M as an invariant from a route that omits the observer-symmetry row, the no-global-frame ledger, or the displayed causal replay.*

Proof. Start from Definition 876.30. It places replay of D before every invariant-facing read of M.

Apply Definition 876.9 and Definition 876.22. They identify S and G as the two observer-facing gates needed before a rate read can be used as an invariant.

Finally use Definition 876.31 and Definition 876.24. These results keep the gate rows on the same root consumer route and exclude synchronized clocks, privileged frames, metric tensors, host speeds, and detached maximum rows. □

Theorem 876.34 (Cross-Hist causal-rate continuation-trace factorization)**.** *Every continuation-facing read of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet factors through the* $\mathsf{ContinuationTrace}^{\uparrow}$ *row C after the observer identity rows A, B, the* $\mathsf{CrossHistCausal}^{\uparrow}$ *route family D, the* $\mathsf{MaxCausalRate}^{\uparrow}$ *row M, and the* $\mathsf{InterHistInvariant}^{\uparrow}$ *boundary rows S, G have been displayed. The factorization has no route through a hidden continuation, global frame, host speed, unlisted causal witness, or detached invariant boundary.*

Proof. Read the displayed packet $R = (A, B, D, M, S, G, H, C, P, N)$ from Definition 876.1. The continuation coordinate C is the only row that records the consumer route through the observer slots, route family, maximum-rate row, and invariant boundary.

Apply Definition 876.32. It forces the causal part of the read through A, B, D, H, C, P, N and rules out hidden causal routes.

Apply Definition 876.33. It places the maximum-rate row M behind the displayed route replay and the two observer gate rows S, G.

Use Definition 876.25 and Definition 876.24 to repack the read as a root consumer route. The structural factor is therefore exactly C together with H, P, N, and no continuation-facing consumer can bypass the displayed route. □

Theorem 876.35 (Cross-Hist causal-rate root observer-gate totality)**.** *Every invariant-facing read of the maximum-rate row M from an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet must pass through the displayed causal route family D, the observer gate rows S, G, and the structural rows H, C, P, N. Thus a* $\mathsf{MaxCausalRate}^{\uparrow}$ *or* $\mathsf{InterHistInvariant}^{\uparrow}$ *consumer never reads M directly from the observer slots A, B, from a hidden frame row, or from a detached host-speed coordinate.*

Proof. Read the carrier $R = (A, B, D, M, S, G, H, C, P, N)$ from Definition 876.1. The carrier gives the two observer slots and names D, M, S, G, H, C, P, N as the only route, rate, gate, transport, replay, provenance, and naming rows.

Apply Definition 876.30. It places the finite route family D before any invariant-facing read of M and keeps the structural rows on the same route.

Apply Definition 876.33. It adds the observer-symmetry row S and the no-global-frame ledger G before M can be consumed by $\mathsf{MaxCausalRate}^{\uparrow}$ or $\mathsf{InterHistInvariant}^{\uparrow}$.

Finally use Definition 876.34. The continuation-facing read factors through C after the observer slots, route family, maximum-rate row, and gate rows have been displayed, so no invariant-facing consumer can bypass D, S, G, H, C, P, N. □

Theorem 876.36 (Cross-Hist causal-rate root route-family field faithfulness)**.** *For an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet, the rows*

$$A, B, D, M, S, G, H, C, P, N$$

remain distinguishable as the two observer-history slots, causal route family, maximum-rate row, observer-symmetry row, no-global-frame ledger, componentwise transport, continuation replay, provenance, and local naming row. Any future field-faithful TasteGate encoding must preserve these rows as separate carrier fields and may not identify D with M, S with G, or the structural rows H, C, P, N with the observer slots A, B.

Proof. Project the carrier definition. It lists $A, B, D, M, S, G, H, C, P, N$ as separate displayed coordinates, and each coordinate has a different consumer role in the packet.

Use Definition 876.30 to separate D from M: the route family is replayed before the maximum-rate row is read, so the two rows cannot collapse without losing the replay obligation.

Use Definition 876.31 and Definition 876.33 to separate S and G from the rate row and from each other. The former records observer symmetry, while the latter refuses global-frame coordinates before the invariant-facing read.

The factorization theorem Definition 876.34 keeps C as the continuation trace, with H, P, N supplying transport, provenance, and naming. Since those structural rows govern access to the packet rather than serving as observer slots, field faithfulness must keep the full displayed row inventory distinct. □

Theorem 876.37 (Cross-Hist causal-rate root no-frame consumer cut)**.** *For every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet, the no-global-frame ledger* G *is a consumer cut between valid* $\mathsf{MaxCausalRate}^{\uparrow}$ *or* $\mathsf{InterHistInvariant}^{\uparrow}$ *reads and any hidden clock, privileged frame, metric tensor, speed coordinate, or global-frame row. A consumer route that reaches* M *as a rate or invariant must pass through* G *together with* D, S, H, C, P, N*.*

Proof. Start with Definition 876.31. It identifies G as the complete ledger refusing synchronized clocks, privileged observer frames, metric tensors, host speeds, and global-frame coordinates.

Apply Definition 876.30. The valid consumer route reaches M only after replaying the finite causal route family D through the structural rows.

Apply Definition 876.33. It places S and G before the maximum-rate row can be read as an invariant-facing value by $\mathsf{MaxCausalRate}^{\uparrow}$ or $\mathsf{InterHistInvariant}^{\uparrow}$.

Finally use Definition 876.34. Since the displayed continuation factor is C and the carrier has no hidden clock, frame, metric, speed, or global-coordinate row, G separates accepted consumers from every forbidden frame-facing read. □

Theorem 876.38 (Cross-Hist causal-rate root observer-slot totality)**.** *For every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root consumer, the first observer-history read is exhausted by the two displayed slots* A, B *through* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *and by the rows* D, H, C, P, N *of the carrier*

$$R = (A, B, D, M, S, G, H, C, P, N).$$

The consumer therefore cannot begin from an unlisted observer slot, a hidden history identity witness, or a detached causal route outside the $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet.*

Proof. Read the carrier of Definition 876.1. It presents A, B as the only observer-history slots and gives D, H, C, P, N as the route, transport, continuation, provenance, and local naming rows around those slots.

Apply Definition 876.6. It forces every observer-slot read through the displayed $\mathsf{ObserverHistIdentity}^{\uparrow}$ surface and the route rows of the packet.

Next apply Definition 876.30. The replay step keeps the consumer on the same finite D route before any downstream maximum-rate read, matching the causal witness surface of chapter 478.

Since chapter 594 and chapter 656 consume the rate only after the route has been displayed, the root consumer has no earlier observer source than A, B, D, H, C, P, N. □

Theorem 876.39 (Cross-Hist causal-rate root dependence-route exhaustion)**.** *Every dependence read of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet is exhausted by the displayed* $\mathsf{CrossHistCausal}^{\uparrow}$ *route family* D *replayed through the continuation row* C*. The replay may pass through* A, B, H, P, N*, but it cannot introduce a hidden causal witness, an unlisted dependence edge, a host clock, or a frame-side causal row.*

Proof. Project the packet $R = (A, B, D, M, S, G, H, C, P, N)$. The only dependence-family coordinate is D, and the only continuation-facing replay coordinate is C.

Apply Definition 876.30. It places every downstream dependence read on the finite route family D before the rate row M can be consumed.

Now use Definition 876.6. The route is anchored in the two observer slots A, B and is transported only through the displayed structural rows H, C, P, N.

Finally apply Definition 876.37. The no-frame cut excludes clocks, privileged frames, metric tensors, host speeds, and global-frame rows, so the replay through C cannot acquire an extra causal witness outside the $\mathsf{CrossHistCausal}^{\uparrow}$ route family cited by chapter 478. □

Theorem 876.40 (Cross-Hist causal-rate root maximum-invariant handoff)**.** *An accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root packet may hand the maximum-rate row* M *to* $\mathsf{MaxCausalRate}^{\uparrow}$ *or* $\mathsf{InterHistInvariant}^{\uparrow}$ *only after the dependence route family* D*, the observer-symmetry row* S*, and the no-global-frame ledger* G *are visible on the same root route. Thus* M *is never exported as a detached rate value before the causal route, observer symmetry, and no-frame refusal rows have been displayed.*

Proof. Start with Definition 876.30. It makes D the finite route that precedes any invariant-facing read of M.

Apply Definition 876.33. This places S and G before a $\mathsf{MaxCausalRate}^{\uparrow}$ or $\mathsf{InterHistInvariant}^{\uparrow}$ consumer may read M as an invariant-facing value.

Use Definition 876.37. The cut keeps the handoff away from hidden clocks, privileged frames, metric tensors, host speeds, and global-frame rows.

The handoff therefore matches the sibling consumer surfaces of chapter 594 and chapter 656: both receive M only after the displayed D, S, G route has been exposed by the $\mathsf{CrossHistCausalRate}^{\uparrow}$ carrier. □

Theorem 876.41 (Cross-Hist causal-rate invariant-rate ledger)**.** *For an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet with carrier*

$$R = (A, B, D, M, S, G, H, C, P, N)$$

as in Definition 876.1, any $\mathsf{MaxCausalRate}^{\uparrow}$ *or* $\mathsf{InterHistInvariant}^{\uparrow}$ *consumer that reads* M *as a rate or invariant first passes through the displayed route rows* D, S, G, H, C, P, N*. The ledger is the same finite root route supplied by route replay, observer-gate totality, and the no-frame consumer cut; it has no coordinate for a hidden causal route, synchronized clock, privileged frame, metric tensor, host speed, or detached maximum row.*

Proof. Read the carrier displayed in Definition 876.1. The only rows downstream of the observer slots and upstream of the local name are the causal route family D, maximum-rate row M, observer-symmetry row S, no-frame ledger G, and structural rows H, C, P, N.

Apply Definition 876.30. It places D before every invariant-facing read of M and keeps the read inside the displayed structural route.

Now apply Definition 876.33 and Definition 876.37. These results add S and G as mandatory gates before a $\mathsf{MaxCausalRate}^{\uparrow}$ or $\mathsf{InterHistInvariant}^{\uparrow}$ consumer can use M.

The route is then closed by Definition 876.24. Since the carrier has no extra frame-facing coordinate, the invariant-rate ledger is exactly D, S, G, H, C, P, N before M is consumed. □

Theorem 876.42 (Cross-Hist causal-rate observer-symmetry totality)**.** *Every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *root consumer that exports the maximum row* M *to* $\mathsf{MaxCausalRate}^{\uparrow}$ *or* $\mathsf{InterHistInvariant}^{\uparrow}$ *exposes both observer-facing gates* S *and* G *on the same route as* D, H, C, P, N*. Thus observer symmetry and no-frame refusal are total for rate consumers: neither can be omitted, split into a second packet, or supplied by a host frame outside the carrier of Definition 876.1.*

Proof. Start from Definition 876.41. It already places every invariant-rate read behind the displayed route D, S, G, H, C, P, N.

Use Definition 876.22. The row S records the observer-symmetry obligation for the two history slots, so a consumer that omits S has no local certificate for invariant comparison.

Use Definition 876.31. The row G is the finite refusal ledger for global-frame data, so a consumer that omits G has no certified refusal of hidden clocks, privileged frames, metrics, or host speeds.

Finally apply Definition 876.24. It keeps S and G on the same root route as D, H, C, P, N, giving totality for the observer-symmetry and no-frame gates. □

Theorem 876.43 (Cross-Hist causal-rate consumer boundary)**.** *The consumer boundary for an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet is exact for* $\mathsf{MaxCausalRate}^{\uparrow}$ *and* $\mathsf{InterHistInvariant}^{\uparrow}$ *reads: before reading* M*, the consumer must pass through*

$$D, S, G, H, C, P, N.$$

Consequently the root boundary is generated by the displayed carrier of Definition 876.1, route replay, observer-symmetry totality, and no-frame refusal, not by any off-carrier frame, external speed comparison, hidden causal route, or detached invariant source.

Proof. Begin with Definition 876.37. It states that the no-frame ledger G separates valid maximum-rate or invariant reads from hidden clocks, privileged frames, metric tensors, and host speeds.

Apply Definition 876.42. This puts S and G on the same root route as D, H, C, P, N for every consumer that exports M.

Now use Definition 876.41. The invariant-rate ledger fixes the route before M is read, so the consumer boundary cannot be shortened to D alone or to the observer slots alone.

The exactness claim follows from Definition 876.24. The accepted packet contains no remaining coordinate from which a $\mathsf{MaxCausalRate}^{\uparrow}$ or $\mathsf{InterHistInvariant}^{\uparrow}$ consumer could recover an alternate read of M. □

Theorem 876.44 (Cross-Hist causal-rate observer identity dependence)**.** *For an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet* $R = (A, B, D, M, S, G, H, C, P, N)$*, the observer slots* A *and* B *must be read through the* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *identity surface before any route family* D *is admissible. A route family detached from that identity read is not a valid causal-rate route.*

Proof. Apply the observer-slot route theorem Definition 876.6. It makes the two observer histories the entrance to the displayed causal route family.

Use Definition 876.38 and Definition 876.39. They place every admissible D behind the same observer-slot read and prevent a hidden route outside A, B, H, C, P, N.

The no-global-frame boundary, root consumer exactness, and consumer boundary of Definition 876.10, Definition 876.24, and Definition 876.43 then keep the identity dependence inside the packet rather than in a host frame. □

Theorem 876.45 (Cross-Hist causal-rate falsifiability and independence surface)**.** *For an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet*

$$R = (A, B, D, M, S, G, H, C, P, N),$$

the carrier has a falsifiable consequence: a maximum-rate read is rejected unless both the observer-symmetry row S *and the no-global-frame ledger* G *are present on the same displayed route as* D, M, H, C, P, N*. Its independence surface is witnessed by the simultaneous presence of the two* Hist *slots* A, B*, causal-dependence route family* D*, maximum-rate row* M*, observer-symmetry row* S*, no-global-frame ledger* G*, componentwise transport* H*, continuation row* C*, provenance row* P*, and local name* N*. This surface is not bijective to any listed sibling surface* $\mathsf{InterHistInvariant}^{\uparrow}$*,* $\mathsf{ObserverHistIdentity}^{\uparrow}$*,* $\mathsf{HistTimeStream}^{\uparrow}$*,* $\mathsf{ContinuationTrace}^{\uparrow}$*, or* $\mathsf{SupplyKindRouter}^{\uparrow}$*.*

Proof. Read the carrier definition Definition 876.1. It displays the two history slots, route family, maximum-rate row, observer-symmetry row, no-frame ledger, and structural rows as simultaneous fields of one packet.

Apply maximum-row exactness from Definition 876.7. The maximum-rate row M is attached to the finite dependence family D, not to a detached host speed or metric coordinate.

Use the invariant boundary and no-global-frame boundary of Definition 876.9 and Definition 876.10. Together with observer identity dependence from Definition 876.44, they require the observer-symmetry and no-frame rows before a public maximum-rate read can pass to an invariant-facing consumer.

Finally use route-family field faithfulness from Definition 876.36. The separate fields $A, B, D, M, S, G, H, C, P, N$ cannot collapse to the inventory of any one sibling surface, so the packet exposes a distinct independence surface while keeping the falsifiable maximum-rate rejection tied to its carrier rows. □

Theorem 876.46 (Cross-Hist causal-rate MaxCausalRate dependence)**.** *The row M of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet is a* $\mathsf{MaxCausalRate}^{\uparrow}$ *row only over the already displayed route family D. It is not a detached maximum, a host speed, or a rate read available before D, S, G, H, C, P, N.*

Proof. Start with the maximum-row exactness theorem Definition 876.7. It binds M to the carrier route rather than to an ambient speed comparison.

Apply Definition 876.17, Definition 876.33, and Definition 876.41. These rows put the route family D and the gates S, G, H, C, P, N before any maximum-rate consumer reads M.

The root consumer exactness and consumer boundary theorems finish the dependence claim by excluding every off-carrier source for a maximum-rate row. □

Theorem 876.47 (Cross-Hist causal-rate InterHistInvariant dependence)**.** *An* $\mathsf{InterHistInvariant}^{\uparrow}$ *consumer of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet receives the maximum row M only after the displayed route and structural rows D, S, G, H, C, P, N. Thus the invariant-facing read is downstream of observer identity, causal route exposure, observer symmetry, no-frame refusal, transport, continuation replay, provenance, and local naming.*

Proof. Use the invariant boundary theorem Definition 876.9. It already treats invariant consumption as downstream of the displayed Cross-Hist packet.

Then apply Definition 876.40, Definition 876.41, and Definition 876.43. These force an invariant-facing consumer to pass through D, S, G, H, C, P, N before M is handed off.

Finally, Definition 876.24 prevents a second invariant source, so the $\mathsf{InterHistInvariant}^{\uparrow}$ dependence is exactly the displayed packet route. □

Theorem 876.48 (Cross-Hist causal-rate root source-channel totality)**.** *Every accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet exposes its two observer-history source slots, finite causal-dependence route, observer-symmetry row, and no-global-frame row through the displayed route*

$$A, B, D, S, G, H, C, P, N$$

before any consumer reads the maximum-rate row M. Thus the source channel for a maximum-rate read is the packet's finite BHist *route with componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *certification, not hidden frame data or an ambient clock.*

Proof. Start from the observer-slot route of Definition 876.6. It makes A and B the only entrance for the causal-dependence family D.

Apply Definition 876.38 and Definition 876.39. These force every accepted route row to pass through the same finite observer-history slots before M is available.

Use Definition 876.42 and Definition 876.10. The first supplies the observer-symmetry row S, and the second keeps the no-global-frame row G inside the displayed packet.

Finally apply Definition 876.43. It places H, C, P, N on the same route before any maximum-rate read, giving totality for the displayed source channel. □

Theorem 876.49 (Cross-Hist causal-rate max-bound ledger)**.** *For an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet, the maximum-rate row* M *is ledger-bound by the route rows*

$$A, B, D, S, G, H, C, P, N.$$

No consumer may replace this ledger with metric tensors, synchronized clocks, host speeds, a privileged frame, or any off-carrier maximum-rate primitive.

Proof. Use maximum-row exactness from Definition 876.7. It binds M to the displayed packet rather than to an external speed comparison.

The invariant boundary and no-global-frame boundary of Definition 876.9 and Definition 876.10 exclude hidden frame data, synchronized clocks, metric tensors, and host speeds from the consumer route.

Apply Definition 876.48. Since every maximum-rate read first exposes $A, B, D, S, G, H, C, P, N$, the ledger for M is exactly the displayed root route. □

Theorem 876.50 (Cross-Hist causal-rate downstream factorization)**.** *Every* $\mathsf{MaxCausalRate}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, *or* $\mathsf{LorentzFrameRate}^{\uparrow}$ *consumer of an accepted* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *packet factors through the same displayed route*

$$A, B, D, S, G, H, C, P, N$$

before reading M*. The downstream consumer may specialize the rate, invariant, or frame-facing interpretation only after that route has been exposed.*

Proof. For $\mathsf{MaxCausalRate}^{\uparrow}$, apply Definition 876.46. It reads M only after the displayed causal route and structural gates.

For $\mathsf{InterHistInvariant}^{\uparrow}$, apply Definition 876.47. It places invariant-facing consumption downstream of observer identity, route exposure, observer symmetry, no-frame refusal, transport, continuation, provenance, and naming.

For $\mathsf{LorentzFrameRate}^{\uparrow}$, use the same max-bound ledger of Definition 876.49. Since a frame-facing rate consumer has no permitted off-carrier metric, clock, host-speed, or privileged-frame coordinate, it must factor through the displayed route before reading M.

The consumer boundary of Definition 876.43 closes the three cases by preventing a second route for downstream reads. □

Falsifiable prediction: An accepted $\mathsf{CrossHistCausalRate}^{\uparrow}$ packet admits no maximum-rate read unless both observer-symmetry and no-global-sync rows are present.

Independence witness: interhistinvariant, observerhistidentity, histtimestream, continuationtrace, supplykindrouter: $\mathsf{CrossHistCausalRate}^{\uparrow}$ has two Hist slots, a causal-dependence route, a maximum-rate row, and no-global-frame refusal data; these rows are not bijective with invariant-only, identity-only, time-stream-only, trace-only, or socket-router packets.

Closure status for $\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CrossHistCausalRate}^{\uparrow}$ packet is generated from two observer-history slots, finite causal-dependence route rows, a maximum-rate row, an observer-symmetry row, a no-global-frame ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CrossHistCausalRate}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 876.1, Definition 876.2, Definition 876.6, Definition 876.7, Definition 876.8, Definition 876.9, Definition 876.10, Definition 876.11, Definition 876.12, Definition 876.13, Definition 876.48, Definition 876.49, Definition 876.50, Definition 876.45, and the recorded TasteGate packet bridge the public carrier, causal route, maximum-rate exactness, observer-symmetry row, no-global-frame refusal, downstream factorization, falsifiable prediction, independence witness, and TasteGate packet as one paper-side consumer surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{CrossHistCausalRate}^{\uparrow}}$, theoremChecked)
Lean target: `BEDC.Derived.CrossHistCausalRateUp.taste\_gate`
Bridge status: none
Origin: ai
Not claimed: This chapter does not derive a numerical speed constant, Lorentz geometry, metric tensors, synchronized clocks, global frames, or bridge checking for CrossHistCausalRate$^{\uparrow}$.
Upgrade path: No further paper-side theory closure grade remains; only independent verification-axis and bridge-axis checks can strengthen the recorded status.

Chapter 877

A Concrete Naming Certificate for $\mathsf{ObserverAccumulationClock}^{\uparrow}$

The $\mathsf{ObserverAccumulationClock}^{\uparrow}$ packet makes the time-as-accumulation reading of chapter 9420 into a finite NameCert carrier. It reads its state side through chapter 578, its observer-history identity side through chapter 477, and its order side through chapter 664. Unlike the state, identity, locality, order, or frame siblings, the packet stores a named transition witness that produces the next public clock tick only when the accumulated-record edge is displayed.

Definition 877.1 (ObserverAccumulationClock carrier)**.** *An* $\mathsf{ObserverAccumulationClock}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S_0, S_1, A, G, H, R, P, N)$$

with the following displayed rows:

1. S_0 *is the present observer-state row, read through the* $\mathsf{ConsciousObserverState}^{\uparrow}$ *surface;*
2. S_1 *is the successor observer-state row, carrying the records visible after the next accepted accumulation step;*
3. A *is the accumulation-edge row, naming the retained-record inclusion from* S_0 *to* S_1 *and producing the public tick;*
4. G *is the* Gap *residue row for demanded tick reads whose accumulation edge, retained-record comparison, or successor state is absent;*
5. H *records componentwise* hsame *transport for present state, successor state, accumulation edge, gap residue, route, package, and local naming rows;*
6. R *records displayed* Cont *routes by which consumers read* S_0*, then* S_1*, then* A*, and only then the clock-read result;*
7. P *is the* Pkg *provenance over* $\mathsf{ConsciousObserverState}^{\uparrow}$*,* $\mathsf{ObserverHistoryIdentity}^{\uparrow}$*,* $\mathsf{ObservationTimeOrder}^{\uparrow}$*,* BHist*,* Gap*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*
8. N *is the local* $\mathsf{NameCert}_{\mathsf{ObserverAccumulationClock}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host scalar clock, global synchronization map, direct state-to-clock read, reversible tick, or time read detached from the displayed accumulation edge.

Theorem 877.2 (ObserverAccumulationClock NameCert obligations)**.** *For the carrier of Definition 877.1, the local* $\mathsf{NameCert}_{\mathsf{ObserverAccumulationClock}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the finite packet* $C = (S_0, S_1, A, G, H, R, P, N)$*;*
2. *successor-record exposure, requiring* S_1 *to be read as a successor observer-state row of the same observer-history identity surface as* S_0*;*
3. *accumulation-edge exactness, requiring* A *to witness retained-record accumulation from* S_0 *to* S_1 *before any tick can be exported;*
4. Gap *residue exactness, requiring* G *to classify any demanded tick lacking* S_1 *or* A *as outside the accepted clock surface;*
5. *stability and non-escape under the componentwise* hsame *row* H*, displayed route row* R*, package provenance* P*, and local naming row* N*.*

Proof. Carrier admission is projection from Definition 877.1. The displayed packet exposes the two observer-state rows, the accumulation edge, the gap residue, transport, route, provenance, and local name.

The successor-record clause uses the conscious-state and observer-history identity siblings. The row S_1 is not a free clock value; it is another observer-state row on the same identity surface as S_0.

The accumulation-edge clause then reads A. By the observation-time-order sibling, a time comparison is record retention between displayed states, so a public tick is obtained only after the route has exposed the retained-record edge from S_0 to S_1.

The gap-residue row G handles failed tick demands. If a consumer asks for a tick without a successor state or without the accumulation edge, the request remains a residue rather than an accepted clock read.

Finally H, R, P, N transport, replay, package, and name the same finite packet. Since no displayed row stores a host scalar clock, direct state-to-clock function, global synchronization map, or reversible tick, the local certificate exports none. □

Theorem 877.3 (ObserverAccumulationClock falsifiable boundary)**.** *Every accepted* ObserverAccumulationClock$^{\uparrow}$ *consumer that claims a time tick factors through the displayed route*

$$S_0 \to S_1 \to A$$

and then through the transport, package, and local naming rows H, R, P, N*. A direct read from a single observer-state row to a clock value, or a tick read that bypasses the accumulation-edge row* A*, is a counter-witness to the accepted packet.*

Proof. Inspect the carrier rows. The only two state coordinates are S_0 and S_1, and the only row that relates them as a tick-producing transition is A.

The displayed route row R fixes the consumer order: read the present state, read the successor state, then read the accumulation edge. The transport row H preserves those coordinates componentwise, while P and N bind the route to the local package and name.

Thus a claimed clock read that starts and ends at a single state has no carrier coordinate that can justify it. Likewise a read from S_0 to S_1 that omits A has not displayed the accumulation witness required by the packet. □

Theorem 877.4 (ObserverAccumulationClock TasteGate obligation)**.** *The later Lean target in* `lean4/BEDC/Derived/ObserverAccumulationClockUp/TasteGate.lean` *must provide* Nontrivial ObserverAccumu *and* FieldFaithful ObserverAccumulationClock$^{\uparrow}$ *using explicit witness pairs and field projections. These instances must distinguish the present state, successor state, accumulation-edge row,* Gap *residue, transport row, displayed route, package provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.ObserverAccumulationClockUp.ObserverAccumulationClockTasteGate single carrier alignment`

Proof. Nontriviality is forced by the two-state edge shape. A packet that collapses S_0, S_1, and A into one indistinct point cannot witness a tick-producing accumulation edge.

Field faithfulness is forced by the carrier inventory. The field projections must preserve the state rows, the edge row, the residue row, and the structural rows separately so a consumer can reject a direct state-to-clock read. □

Falsifiable prediction: Any accepted ObserverAccumulationClockUp consumer that claims a time tick must factor through the displayed accumulation-edge row; a direct state-to-clock read is a counter-witness.

Independence witness: Nearest siblings: consciousobserverstate, observerhistoryidentity, observerlocalitycell, observationtimeorder, observercoordinateframe. The clock packet is not bijective to any of them because it carries a tick-producing accumulation-edge and clock-read row; the siblings carry state, identity, locality, order, or frame rows without this named transition witness.

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverAccumulationClock}\uparrow}$.

Constructive story: An $\mathsf{ObserverAccumulationClock}^{\uparrow}$ packet is generated from present observer-state, successor observer-state, accumulation-edge, GAP-residue, componentwise hsame transport, displayed route, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObserverAccumulationClock}\uparrow}, \mathsf{seed})$

Scope closed: Definition 877.1, Definition 877.2, Definition 877.3, and Definition 877.4 specify the finite observer-accumulation clock packet and its tick boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObserverAccumulationClock}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, host scalar time, global synchronization, reversible ticks, or direct state-to-clock reads.

Upgrade path: Obligation closure requires checked carrier admission, successor-record exposure, accumulation-edge exactness, GAP-residue exactness, and TasteGate nontriviality with field faithfulness.

Chapter 878

A Concrete Naming Certificate for $\mathsf{FableMachineBoundary}^{\uparrow}$

The $\mathsf{FableMachineBoundary}^{\uparrow}$ interface gives the Empty Fable Machine of chapter 9399 a finite boundary packet. It combines the Empty-fable ledger of chapter 516, the single-branch witness of chapter 585, the local-clock row of chapter 623, and the selector-ledger consumer surface of chapter 494. The packet is not a subject behind the observer and not a hidden chooser; it is the displayed boundary at which a finite selector ledger, enacted boundary row, and no-hidden-subject condition are read together.

Definition 878.1 (FableMachineBoundary carrier)**.** *A* $\mathsf{FableMachineBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (H, E, L, S, W, K, T, C, P, N)$$

with the following visible rows:

1. *H is the generated* Hist *row whose constructor spine supplies the observer sequence;*
2. *E is the empty-boundary slot row above the displayed source history;*
3. *L is the finite Empty-fable selector ledger read from the same* Hist *row;*
4. *S is the enacted selector row, including the selected mark and its displayed* Ext *edge;*
5. *W is the local fable-branch witness tying the enacted selector row to the boundary slot;*
6. *K is the local fable-machine clock row for the same finite step surface;*
7. *T records componentwise* hsame *transports for the history, boundary, ledger, selector, branch-witness, and clock rows;*
8. *C records the* Cont *routes by which consumers read those rows;*
9. *P records* Pkg *provenance over* BHist, Ext, *selector-ledger, fable-branch, fable-clock,* hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FableMachineBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through this displayed tuple. It has no coordinate for a hidden observer-substance, global branch chooser, host trace quotient, truth oracle, or selector rule outside the finite ledger.

Lean4 ✓ `BEDC.Derived.FableMachineBoundaryUp.FableMachineBoundaryTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.FableMachineBoundaryUp.FableMachineBoundaryUp`

Theorem 878.2 (FableMachineBoundary NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{FableMachineBoundary}^{\uparrow}}$ *surface for the carrier of Definition 878.1 consists exactly of five finite obligations:*

1. *carrier admission for* $B = (H, E, L, S, W, K, T, C, P, N)$*;*
2. *empty-boundary admission tying* E *to the displayed source* Hist *row and its enacted* Ext *edge;*
3. *selector-ledger exactness tying* L *and* S *to the same finite Empty-fable trace;*
4. *branch and clock compatibility tying* W *and* K *to the enacted selector row rather than to an external chooser;*
5. *consumer non-escape through* T, C, P, N *for every history, boundary, ledger, selector, witness, and clock read.*

Every obligation is read from the displayed BHist*,* Ext*,* hsame*,* Cont*,* Pkg*, selector-ledger, fable-branch, fable-machine-clock, and* NameCert *rows. No obligation introduces a hidden subject coordinate or a chooser row not already visible in the packet.*

Lean4 ✓ `BEDC.Derived.FableMachineBoundaryUp.FableMachineBoundaryNameCertObligations`

Proof. Project the carrier rows. The empty-boundary slot E, selector ledger L, enacted selector row S, branch witness W, and local clock K are separate coordinates of the same finite packet.

Use the Empty-fable ledger and selector-ledger surfaces to read the trace and enacted selector from L and S. The branch witness then attaches the selected mark to the displayed Ext edge, while the fable-machine clock records the same local step order.

The transport, continuation, package, and naming rows T, C, P, N replay those reads componentwise. Since the carrier contains no observer-substance, global chooser, host trace quotient, or truth oracle coordinate, the five obligations exhaust the boundary certificate. □

Theorem 878.3 (FableMachineBoundary selector non-escape)**.** *Every consumer read of an accepted* $\mathsf{FableMachineBoundary}^{\uparrow}$ *packet factors through*

$$H, E, L, S, W, K, T, C, P, N.$$

In particular, the selected branch can be read only as the displayed selector row S *together with the fable-branch witness* W *and the finite selector ledger* L*. No consumer route reaches a hidden chooser row, observer-substance coordinate, global branch policy, or host-level trace equality.*

Lean4 ✓ `BEDC.Derived.FableMachineBoundaryUp.FableMachineBoundarySelectorNonescape`

Proof. Read the consumer request through C. If it asks for the generated history, empty-boundary row, selector ledger, enacted selector row, branch witness, clock row, transport row, provenance row, or local name, the carrier supplies exactly the corresponding displayed coordinate.

For any request for a hidden chooser, observer-substance coordinate, global branch policy, or host trace equality, inspect the carrier inventory. None of those objects occurs in $B = (H, E, L, S, W, K, T, C, P, N)$, and the NameCert obligations admit selector data only through L, S, W, K.

Thus every accepted read remains inside the finite boundary packet, and the enacted selector cannot escape as an undisplayed chooser. □

Theorem 878.4 (FableMachineBoundary inscription non-escape)**.** *Every Empty Fable Machine inscription read accepted by a* $\mathsf{FableMachineBoundary}^{\uparrow}$ *carrier must pass through the displayed rows*

$$H, E, L, S, W, K, T, C, P, N$$

and through the sibling surfaces $\mathsf{EmptyFableLedger}^{\uparrow}$, $\mathsf{FableBranchWitness}^{\uparrow}$, $\mathsf{FableMachineClock}^{\uparrow}$, *and* $\mathsf{SelectorLedger}^{\uparrow}$ *before it exports a boundary name. The inscription route exposes only the generated history row, empty-boundary slot, selector ledger, enacted selector, branch witness, local clock, componentwise transport, replay, provenance, and local naming rows; it has no route to a hidden subject coordinate, global branch chooser, host trace quotient, or truth oracle.*

Proof. Project the carrier of Definition 878.1. The inscription request can inspect only the history row H, boundary row E, selector ledger L, enacted selector S, branch witness W, local clock K, and the structural rows T, C, P, N.

Read the sibling surfaces in order. The Empty-fable ledger supplies the finite trace, the selector ledger supplies the enacted selector row, the branch witness attaches that selector to the displayed boundary branch, and the local clock records the finite step at which the read is made.

Finally replay the inscription through T, C, P, N. These rows preserve and name the already displayed finite route, so they cannot add a hidden observer, global chooser, host trace quotient, or truth oracle. The exported boundary name is therefore exhausted by the visible inscription rows and their sibling surfaces. □

Theorem 878.5 (FableMachineBoundary obligation closure)**.** *The* $\mathsf{FableMachineBoundary}^{\uparrow}$ *chapter has the following obligation surface: carrier admission for* $B = (H, E, L, S, W, K, T, C, P, N)$*, empty-boundary admission through* E*, selector-ledger exactness through* L *and* S*, branch and clock compatibility through* W *and* K*, inscription non-escape by Definition 878.4, and consumer non-escape by Definition 878.3. These obligations are finite rows over* BHist, Ext, $\mathsf{EmptyFableLedger}^{\uparrow}$, $\mathsf{FableBranchWitness}^{\uparrow}$, $\mathsf{FableMachineClock}^{\uparrow}$, $\mathsf{SelectorLedger}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

Proof. Carrier admission and empty-boundary admission are the first two projections of Definition 878.1: the displayed history H and empty-boundary slot E determine the boundary at which a read can occur.

Selector-ledger exactness and branch/clock compatibility are the middle projections. Rows L and S display the selector ledger and enacted selector, while rows W and K tie that selector to the local branch witness and finite clock row.

Inscription non-escape is supplied by Definition 878.4. Consumer non-escape is supplied by Definition 878.3. The remaining rows T, C, P, N only transport, replay, source, and name this finite route, so the listed clauses exhaust the obligation surface. □

Theorem 878.6 (FableMachineBoundary scoped kernel route)**.** *Every boundary, inscription, selector, branch, and clock consumer accepted by a* $\mathsf{FableMachineBoundary}^{\uparrow}$ *packet factors through the displayed rows*

$$H, E, L, S, W, K, T, C, P, N$$

and through the sibling surfaces $\mathsf{EmptyFableLedger}^{\uparrow}$, $\mathsf{FableBranchWitness}^{\uparrow}$, $\mathsf{FableMachineClock}^{\uparrow}$, *and* $\mathsf{SelectorLedger}^{\uparrow}$. *The closed scope is limited to the generated* BHist *row, the displayed* Ext *edge, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}$ *naming, and the four sibling surfaces; it does not include a hidden chooser row, observer-substance coordinate, host trace quotient, global branch policy, or truth oracle.*

Proof. Begin with the obligation-closure theorem Definition 878.5. It fixes carrier admission, empty-boundary admission, selector-ledger exactness, branch and clock compatibility, inscription non-escape, and consumer non-escape as the complete finite obligation surface over $H, E, L, S, W, K, T, C, P, N$.

Next apply the selector non-escape theorem Definition 878.3. It confines every selector-facing read to the displayed ledger row L, enacted selector row S, fable-branch witness W, local clock K, and the structural rows that transport and name them.

Finally use the inscription non-escape theorem Definition 878.4. Its sibling route through $\mathsf{EmptyFableLedger}^{\uparrow}$, $\mathsf{FableBranchWitness}^{\uparrow}$, $\mathsf{FableMachineClock}^{\uparrow}$, and $\mathsf{SelectorLedger}^{\uparrow}$ supplies the same finite surface for boundary inscriptions, so no consumer route leaves the displayed kernel scope. □

Falsifiable prediction: Any accepted FableMachineBoundaryUp packet factors through the displayed empty-boundary selector ledger and admits no consumer route to a hidden chooser row.

Independence witness: Nearest siblings: empty-fable-ledger, fablebranchwitness, fablemachineclock, selectorledger, emptyboundaryselector. FableMachineBoundaryUp is not bijective to any of them because it simultaneously carries the empty-boundary slot, enacted selector row, and no-hidden-chooser boundary; each sibling lacks at least one of those obligation rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FableMachineBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{FableMachineBoundary}^{\uparrow}$ packet is generated from a displayed Hist row, empty-boundary slot, finite selector ledger, enacted selector row, fable-branch witness, local fable-clock row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FableMachineBoundary}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 878.6 closes the displayed boundary, inscription, selector, branch, and clock consumer scope over $H, E, L, S, W, K, T, C, P, N$ and the sibling Empty-fable surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FableMachineBoundary}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.FableMachineBoundaryUp.FableMachineBoundaryTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close standard bridging, global branch selection, host trace equality, observer-substance, or truth-oracle semantics.

Upgrade path: Scoped closure requires checked classifier-stability and field-faithfulness for the displayed finite boundary packet.

Chapter 879

A Concrete Naming Certificate for $\mathsf{BetaReductionAuditTrail}^{\uparrow}$

The $\mathsf{BetaReductionAuditTrail}^{\uparrow}$ packet realizes the beta audit map of chapter 9384 as a finite audit trail. It sits beside the typed congruence trigger of chapter 760, the beta audit packet of chapter 761, the beta-step boundary of chapter 754, and the subject-reduction discharge socket of chapter 719. Those siblings expose trigger, audit, boundary, and discharge surfaces; the present packet records the ordered finite trail by which a consumer reads them without turning reduction into typed preservation.

Definition 879.1 (Beta-reduction audit-trail carrier)**.** *A* $\mathsf{BetaReductionAuditTrail}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, V, O, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the ordered* BetaStep *ledger, separating the direct redex row from application, lambda, and Pi congruence rows;*
2. *V is the* BetaConv *common-reduct ledger read after the single-step ledger and before any typing-boundary row;*
3. *O is the obstruction-trigger ledger for beta substitution, application-argument stability, lambda-domain preservation, and Pi-domain preservation;*
4. *D is the subject-reduction discharge-socket row that records whether a typed-preservation discharge is present for the displayed trigger;*
5. *H stores componentwise* hsame *transports for the step, conversion, obstruction, discharge, route, provenance, and name rows;*
6. *C stores the displayed* Cont *route through the ordered stages S, V, O, D;*
7. *P is the* Pkg *provenance over chapter 9384, chapter 760, chapter 761, chapter 754, chapter 719,* BHist, hsame, Cont, *and* NameCert *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BetaReductionAuditTrail}^{\uparrow}}$ *row.*

The carrier contains no direct typing-preservation row, no closed subject-reduction theorem, no hidden conversion rule for typing, and no terminal audit escape outside H, C, P, N.

Lean4 ✓ `BEDC.Derived.BetaReductionAuditTrailUp.BetaReductionAuditTrailTasteGate single carrier alignment`

Theorem 879.2 (Beta-reduction audit-trail NameCert obligations)**.** *For the carrier of Definition 879.1, the local* $\mathsf{NameCert}_{\mathsf{BetaReductionAuditTrail}^{\uparrow}}$ *surface consists exactly of carrier admission for* $R = (S, V, O, D, H, C, P, N)$*, beta-step stage readback through* S*, common-reduct conversion readback through* V*, obstruction-trigger readback through* O*, subject-reduction socket readback through* D*, componentwise* hsame *transport through* H*, displayed continuation replay through* C*, package provenance through* P*, and terminal naming through* N*.*

Lean4 ✓ `BEDC.Derived.BetaReductionAuditTrailUp.BetaReductionAuditTrailNameCertObligations`

Proof. Project the carrier of Definition 879.1. Its only stage coordinates are the beta-step ledger S, the conversion ledger V, the obstruction ledger O, and the discharge-socket row D.

Read the siblings in the displayed order. The typed congruence trigger supplies the constructor-facing boundary, the MetaCIC beta audit packet separates reduction and conversion, the beta-step boundary keeps obstruction triggers visible, and the subject-reduction discharge socket records whether a typed preservation discharge has been supplied.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same finite trail. Since no coordinate contains an unguarded typing rule, a closed subject-reduction theorem, or an external audit ledger, the local NameCert obligations are exhausted by the displayed rows. □

Theorem 879.3 (Beta-reduction audit-trail Stage F falsifiability)**.** *Every accepted* $\mathsf{BetaReductionAuditTrail}^{\uparrow}$ *packet has a falsifiable terminal ledger: a consumer that reads a direct typing-preservation row must also read the subject-reduction discharge socket* D *for the same ordered trail* S, V, O, D*. If* D *is absent, the accepted trail may still expose beta-step, conversion, and obstruction-trigger rows, but it cannot export typed preservation.*

Proof. Start from the ordered carrier. A typing-facing read can only occur after the consumer has passed through S, then V, then O, because those are the displayed step, conversion, and obstruction stages.

The only row after the obstruction stage that can mention typed-preservation discharge is D. The transport, continuation, package, and name rows H, C, P, N keep the same coordinate order and do not add a new discharge row.

Thus any accepted trail lacking D lacks a direct typing-preservation read. The packet remains readable as a beta audit trail, but its terminal ledger falsifies any attempted escape from reduction and conversion into typed preservation. □

Falsifiable prediction: Every accepted trail lacks a direct typing-preservation row unless a subject-reduction discharge socket is present.

Independence witness: typedbetacongruencetrigger, metacicbetaaudit, betastepboundary, subjectreductiondischargesocket: the trail carrier has ordered reduction-conversion-obstruction stages and a terminal audit ledger, while each sibling omits at least one stage or the terminal non-escape ledger, so no carrier bijection preserves the displayed NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BetaReductionAuditTrail}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BetaReductionAuditTrail}^{\uparrow}$ packet is generated from an ordered BetaStep ledger, a BetaConv common-reduct ledger, obstruction-trigger rows, a subject-reduction discharge-socket row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BetaReductionAuditTrail}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 879.1, Definition 879.2, and Definition 879.3 bind the finite ordered beta audit trail and its terminal falsifiability ledger.

Formal verification: FormalStatus(NameCert$_{\mathsf{BetaReductionAuditTrail}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close typed beta preservation, closed subject reduction, conversion typing, confluence, normalisation, closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ordered stage readback, discharge-socket readback, transport, route replay, provenance, naming, and terminal falsifiability for the same finite trail.

Chapter 880

A Concrete Naming Certificate for $\mathsf{TypedExampleAuditBudget}^{\uparrow}$

The $\mathsf{TypedExampleAuditBudget}^{\uparrow}$ packet realizes the TypedExamples audit-map vision of chapter 9382 as a finite regression-spend certificate. It sits beside the MetaCIC gallery of chapter 775, the typed-example gallery of chapter 756, the worked-example seal of chapter 753, and the beta-step boundary of chapter 754: those siblings expose gallery rows, checker rows, seal rows, and reduction-boundary rows, while this chapter records which accepted rows have regression budget and which consumer spends may read that budget.

Definition 880.1 (TypedExampleAuditBudget carrier)**.** *A* $\mathsf{TypedExampleAuditBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (G, C, B, Z, R, H, K, P, N)$$

with the following displayed rows:

1. *G is the finite gallery-row inventory inherited from the accepted TypedExamples and MetaCIC gallery packets;*
2. *C is the checker-row inventory recording the accepted local type-checker reads for the same gallery rows;*
3. *B is the beta-row inventory recording the selected beta computations and boundary steps that the gallery spends;*
4. *Z is the closedness-row inventory recording the closed term, context, and well-scoped inputs required by the checker rows;*
5. *R is the regression-budget row, naming the accepted gallery rows that count as covered and the consumer-spend boundary attached to each row;*
6. *H records componentwise* hsame *transports for gallery, checker, beta, closedness, regression-budget, provenance, and local naming rows;*
7. *K records the displayed* Cont *routes by which downstream checker-audit consumers reach exactly the rows G, C, B, Z, R;*
8. *P is the* Pkg *provenance over the sibling gallery, seal, beta-boundary, transport, continuation, and regression-budget rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TypedExampleAuditBudget}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global checker-completeness theorem, a subject-reduction theorem, a normalization theorem, an arbitrary beta closure, or an unbudgeted consumer spend.

Theorem 880.2 (TypedExampleAuditBudget NameCert obligations)**.** *For the carrier of Definition 880.1, the local* $\mathsf{NameCert}_{\mathsf{TypedExampleAuditBudget}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier admission for* $A = (G, C, B, Z, R, H, K, P, N)$*;*
2. *gallery-row exactness through* G *against the sibling gallery packets of chapter 775 and chapter 756;*
3. *checker, beta, and closedness exposure through* C*,* B*, and* Z*;*
4. *regression-budget non-escape through* R*, including the consumer-spend boundary attached to accepted rows;*
5. *transport and provenance through* H*,* K*,* P*, and the local name row* N*.*

Proof. Carrier admission is projection of the displayed finite packet. Every public row that a checker-audit consumer may inspect is present before the local NameCert row is read.

Gallery exactness is sibling-bounded. The row G names the gallery entries, while C, B, and Z expose the checker, beta, and closedness evidence that the gallery and seal packets already make visible.

The regression-budget row R is separate from gallery acceptance. A consumer that reads an accepted gallery row must still pass through R to learn whether that row is counted as covered and which spend boundary it carries.

Finally H, K, P, and N bind the row reads to displayed transport, continuation, provenance, and local naming. Since no coordinate names a global checker theorem, subject reduction, normalization, arbitrary beta closure, or unbudgeted spend, the certificate cannot export one. □

Theorem 880.3 (TypedExampleAuditBudget regression non-escape)**.** *Every checker-audit consumer of an accepted* $\mathsf{TypedExampleAuditBudget}^{\uparrow}$ *packet can read gallery acceptance only together with the displayed checker, beta, closedness, regression-budget, transport, continuation, provenance, and local naming rows. Removing the regression-budget row* R *destroys the consumer's ability to distinguish accepted gallery entries from entries counted as regression coverage, and no sibling gallery, seal, or beta-boundary packet can reconstruct that distinction.*

Proof. Project an accepted carrier $A = (G, C, B, Z, R, H, K, P, N)$. The rows G, C, B, Z expose gallery acceptance, checker reads, selected beta computations, and closedness inputs, but only R records regression coverage and consumer-spend boundaries.

Use the transport and continuation rows H and K for downstream checker-audit reads. They route the consumer through the displayed coordinates and therefore preserve the separation between gallery admission and regression coverage.

The sibling packets do not identify these two readings. The MetaCIC and typed-example galleries name accepted rows, the seal names worked-example closure of the gallery surface, and the beta-step boundary names reduction-boundary rows; none of them carries the regression-budget coordinate R together with its spend boundary. Thus removing R erases precisely the coverage distinction claimed by the packet. □

Falsifiable prediction: If the regression-budget row is removed from an accepted TypedExampleAuditBudget packet, a downstream checker-audit consumer can no longer distinguish gallery acceptance from regression coverage.

Independence witness: Nearest siblings: metacictypedexamplesgallery, typedexamplegallery, metacic-typedexamples-seal, betastepboundary. The budget packet is not bijective with any sibling because it carries a regression-budget row and a consumer-spend boundary that gallery and seal packets do not expose, while BetaStepBoundary carries reduction-boundary rows rather than typed-example gallery spend rows.

The proposed Lean follow-up for namespace BEDC.Derived.TypedExampleAuditBudgetUp places the taste-gate surface in BEDC.Derived.TypedExampleAuditBudgetUp.TasteGate. Its file lean4/BEDC/Derived/Typed includes both Nontrivial TypedExampleAuditBudget$^{\uparrow}$ with an explicit witness pair and FieldFaithful TypedExampleAud with mk-field projections and an injection proof.

Closure status for NameCert$_{\text{TypedExampleAuditBudget}^{\uparrow}}$ ·

Constructive story: A TypedExampleAuditBudget$^{\uparrow}$ packet is generated from finite gallery rows, checker rows, beta rows, closedness rows, regression-budget rows, componentwise transports, continuation routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{TypedExampleAuditBudget}^{\uparrow}}$, seed)

Scope closed: Definition 880.1, Definition 880.2, and Definition 880.3 bind the finite gallery, checker, beta, closedness, regression-budget, consumer-spend, transport, provenance, and local naming surface.

Formal verification: FormalStatus(NameCert$_{\text{TypedExampleAuditBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close checker completeness, subject reduction, normalization, global beta closure, arbitrary gallery soundness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, gallery-row exactness, checker exposure, beta exposure, closedness exposure, regression-budget non-escape, consumer-spend boundary visibility, componentwise transport, displayed continuation, provenance, and local naming rows.

Chapter 881

A Concrete Naming Certificate for $\mathsf{BetaCriticalPair}^{\uparrow}$

The $\mathsf{BetaCriticalPair}^{\uparrow}$ packet concretizes the beta audit map of chapter 9384 as a finite local-overlap certificate. It sits beside the closed-normal route certificate of chapter 858, the beta-reduction audit trail of chapter 879, and the beta-step boundary of chapter 754: those siblings display normal-route, ordered audit, and step-boundary surfaces, while this packet displays two competing beta branches and the common-reduct witness that a local-join consumer may read.

Definition 881.1 (Beta critical-pair carrier)**.** *A* $\mathsf{BetaCriticalPair}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (O, L, R, J, B, H, C, P, N)$$

with the following displayed rows:

1. *O is the local-overlap row identifying the shared redex context and the finite neighborhood in which the two beta branches are compared;*
2. *L is the left branch* BetaStep *readback from the overlap row;*
3. *R is the right branch* BetaStep *readback from the same overlap row;*
4. *J is the displayed common-reduct witness, read only after both branch rows have been displayed;*
5. *B is the consumer-boundary row separating local joining from subject reduction, closed confluence, normalization, or typed preservation;*
6. *H stores componentwise* hsame *transports for the overlap, branch, common-reduct, boundary, route, provenance, and name rows;*
7. *C stores the displayed* Cont *routes by which a consumer reads O, then the two branch readbacks L, R, then the common-reduct witness J, and finally the boundary row B;*
8. *P is the* Pkg *provenance over chapter 9384, chapter 858, chapter 879, chapter 754,* BHist, hsame, Cont, *and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BetaCriticalPair}^{\uparrow}}$ *row.*

The carrier has no coordinate for subject reduction, closed Church–Rosser, global confluence, normalization, host evaluation, or a hidden join not displayed by J.

Lean4 ✓ `BEDC.Derived.BetaCriticalPairUp.BetaCriticalPairTasteGate single carrier alignment`

Theorem 881.2 (Beta critical-pair NameCert obligations)**.** *For the carrier of Definition 881.1, the local* $\mathsf{NameCert}_{\mathsf{BetaCriticalPair}^{\uparrow}}$ *surface consists exactly of carrier admission for* $K = (O, L, R, J, B, H, C, P, N)$*, left branch readback through* L*, right branch readback through* R*, common-reduct witness readback through* J*, local non-escape through* B*, displayed continuation replay through* C*, componentwise classifier transport through* H*, package provenance through* P*, and terminal naming through* N*.*

Lean4 ✓ `BEDC.Derived.BetaCriticalPairUp.BetaCriticalPairNameCertObligations`

Proof. Project the carrier of Definition 881.1. The overlap row O is the only source row, and the branch rows L and R are both read from that same displayed neighborhood.

The common-reduct row J is downstream of the two branch rows. A consumer cannot read a joined endpoint before both branch readbacks have been displayed, because the continuation row C records the route through O, L, R, J in that order.

The local boundary row B then blocks escape from local joining into subject reduction, closed confluence, normalization, typed preservation, or host evaluation. The rows H, P, N transport, source, and name this same finite surface without adding a hidden join coordinate. □

Theorem 881.3 (Beta critical-pair local-join boundary)**.** *Every accepted* $\mathsf{BetaCriticalPair}^{\uparrow}$ *packet exposes a local join only through the displayed branch rows* L, R *and the common-reduct witness row* J*. A consumer may use the packet to read the common endpoint of the two local beta branches, but it may not reread the packet as subject reduction, closed Church–Rosser, normalization, conversion typing, or a global confluence theorem.*

Proof. Begin with an accepted packet $K = (O, L, R, J, B, H, C, P, N)$. The two branch rows share the same overlap row O, so the packet is a local-overlap certificate rather than an arbitrary pair of unrelated beta steps.

The join endpoint is exactly the row J. Since J is a displayed coordinate, local joining is falsifiable by inspecting the carrier: if the row is absent, the joined endpoint is absent from the packet.

Finally read the boundary row B. It records the non-escape side of the carrier and prevents any consumer from replacing the local common-reduct witness by subject reduction, global confluence, normalization, conversion typing, or host evaluation. □

Theorem 881.4 (Beta critical-pair local-join route)**.** *Every beta-audit consumer reading a* $\mathsf{BetaCriticalPair}^{\uparrow}$ *packet must pass through the shared overlap row* O*, both branch rows* L, R*, the displayed common-reduct witness* J*, and the non-escape boundary* B *before any local-join conclusion is available. The route realizes the finite local-overlap and common-reduct surface of chapter 9384 and is constrained by Definition 881.2 and Definition 881.3.*

Proof. Start with the NameCert obligations of Definition 881.2. They expose the shared overlap row O, the left and right branch readbacks L, R, the common-reduct witness J, and the local boundary row B as distinct displayed coordinates of the same carrier.

Apply Definition 881.3. It permits a local join only through the branch rows and the common-reduct row, while B blocks rereading that local fact as subject reduction, closed Church–Rosser, normalization, conversion typing, or global confluence.

The beta audit map of chapter 9384 is therefore reached through the finite route O, L, R, J, B and the structural rows H, C, P, N. No consumer can obtain a local-join conclusion from the packet before those overlap, branch, witness, and boundary rows have been displayed. □

Falsifiable prediction: If a BetaCriticalPairUp packet has no displayed common-reduct row, then no local-join consumer can read a joined endpoint from the packet.

Independence witness: closednormalroutecertificate, literalastequalityboundary, metaciciden-tity, selftheoryreflectionloop: the carrier has two reduction branches plus a common-reduct witness, while these siblings respectively carry normal-route, literal equality, identity, or reflection-loop rows and admit no bijection preserving both branch rows and the join row.

The Lean TasteGate obligation surface for this carrier requires a non-singleton carrier and faithful field exposure: it is discharged only by instances witnessing Nontrivial $\mathsf{BetaCriticalPair}^{\uparrow}$ and FieldFaithful $\mathsf{BetaCriticalPair}^{\uparrow}$ for the same finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BetaCriticalPair}^{\uparrow}}$.

Constructive story: A $\mathsf{BetaCriticalPair}^{\uparrow}$ packet is generated from a local-overlap row, two beta-step branch readbacks, a displayed common-reduct witness, a local non-escape boundary, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BetaCriticalPair}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 881.1, Definition 881.2, and Definition 881.3 bind the finite local-overlap carrier, the two branch readbacks, the common-reduct witness, and the consumer boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BetaCriticalPair}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, closed Church–Rosser, global confluence, normalization, conversion typing, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch readback exactness, common-reduct witness readback, local non-escape, route replay, provenance, local naming, and the Nontrivial and FieldFaithful TasteGate instances for the same finite carrier.

Chapter 882

A Concrete Naming Certificate for $\mathsf{ObserverDistinctionTrace}^{\uparrow}$

The $\mathsf{ObserverDistinctionTrace}^{\uparrow}$ packet realizes the distinction-trace face of chapter 9418 as a finite BEDC carrier. It reads observer-history identity through chapter 479, the subject boundary through chapter 615, and local stream rows through chapter 603. Unlike those siblings, it stores the ordered distinction-step trace itself: the displayed Hist growth rows, the Cont route rows that generate them, the hsame transports that preserve their order, and the no-subject provenance that prevents the trace from exporting an observer-substance coordinate.

Definition 882.1 (ObserverDistinctionTrace carrier)**.** *An* $\mathsf{ObserverDistinctionTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (H, T, K, C, L, P, N)$$

with the following displayed rows:

1. *H is the observed* Hist *source row whose distinction trace is being read;*
2. *T is the finite ordered trace of* $\mathsf{E1}$ *and* $\mathsf{E0}$ *distinction-step rows above the source surface;*
3. *K is the trace-growth ledger, recording the successive* Hist *rows reached by the ordered distinction steps;*
4. *C records the displayed* Cont *routes that read each step of T into the corresponding growth row in K;*
5. *L records componentwise* hsame *transport for the source, trace, growth, route, provenance, and local naming rows;*
6. *P is the* Pkg *provenance over* $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{ObserverSubjectBoundary}^{\uparrow}$, $\mathsf{HistTimeStream}^{\uparrow}$, $\mathsf{LocalClockBudget}^{\uparrow}$, BHist, Hist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{ObserverDistinctionTrace}^{\uparrow}}$ *row.*

The carrier has no coordinate for an observer-substance, a host equality of observers, a global clock, or a trace value detached from the displayed Hist *and* Cont *rows.*

Theorem 882.2 (ObserverDistinctionTrace NameCert obligations)**.** *For the carrier of Definition 882.1, the local* $\mathsf{NameCert}_{\mathsf{ObserverDistinctionTrace}^{\uparrow}}$ *surface consists exactly of carrier admission for $D = (H, T, K, C, L, P, N)$, ordered distinction-step exposure,* Hist *growth-row exactness, displayed* Cont *route replay, componentwise* hsame *transport, no-subject provenance, and local naming exactness.*

Lean4 ✓ `BEDC.Derived.ObserverDistinctionTraceUp.ObserverDistinctionTraceNameCert obligations`

Proof. Carrier admission is projection from the finite packet. The rows H, T, K, C, L, P, N display the observed source, the ordered distinction steps, the growth ledger, the continuation routes, transport, provenance, and local name.

The ordered trace rows T and K are read together. Each listed E1 or E0 step is attached to a displayed growth row, so the packet records a finite trace rather than an unindexed observer state.

The route row C supplies the only permitted reads of those steps, and L preserves the same trace componentwise under hsame. The package row P ties the trace to observer-history identity, subject-boundary exclusion, local stream, and clock-budget surfaces without adding any new observer-substance coordinate. □

Theorem 882.3 (ObserverDistinctionTrace temporal factorization)**.** *Every accepted* ObserverDistinctionTrace$^{\uparrow}$ *consumer route factors through the displayed temporal rows*

$$H \to T \to K \to C$$

and then through the transport, provenance, and local naming rows L, P, N. Thus the trace is read as ordered Hist *growth by distinction steps and displayed* Cont *routes, not as an ambient time parameter or a detached clock value.*

Lean4 ✓ `BEDC.Derived.ObserverDistinctionTraceUp.ObserverDistinctionTrace temporal factorization`

Proof. Project the carrier rows. The only temporal data are the source history H, the ordered distinction list T, the growth ledger K, and the displayed continuation routes C.

Use the Hist time-stream sibling of chapter 603 and the local clock-budget sibling of chapter 665. They read time through finite Cont rows and local step budgets, so a consumer of the distinction trace must pass through the same displayed rows.

Finally transport and name the route through L, P, N. Since the carrier contains no global clock or detached time coordinate, every accepted temporal read factors through the displayed Hist and Cont trace rows. □

Theorem 882.4 (ObserverDistinctionTrace non-escape)**.** *Every accepted* ObserverDistinctionTrace$^{\uparrow}$ *packet exports only the finite rows*

$$H, T, K, C, L, P, N.$$

No consumer can extract from the packet an observer-substance carrier, subject identity row, hidden owner of the trace, host equality of observers, global clock, or trace coordinate outside the displayed distinction-step ledger.

Proof. Begin with the observer-history identity sibling. chapter 479 permits observer-facing reads only through displayed history, observation, transport, route, package, and naming rows.

Next apply the subject-boundary sibling. chapter 615 excludes an additional subject carrier behind the observation rows, so the distinction trace cannot be assigned to a hidden owner outside Hist.

The remaining carrier coordinates are exactly H, T, K, C, L, P, N. Thus any accepted consumer receives a finite ordered distinction-step packet and no observer-substance, host equality, global clock, or off-packet trace object. □

Lean4 ✓ `BEDC.Derived.ObserverDistinctionTraceUp.ObserverDistinctionTrace nonescape`

Theorem 882.5 (ObserverDistinctionTrace TasteGate obligation)**.** *The later Lean target in* `lean4/BEDC/Derived` *must provide* Nontrivial ObserverDistinctionTrace$^{\uparrow}$ *and* FieldFaithful ObserverDistinctionTrace$^{\uparrow}$ *instances. The witnesses must distinguish the source* Hist *row, ordered distinction trace, growth ledger, displayed* Cont *routes,* hsame *transport, no-subject provenance, and local naming row.*

Lean4 ✓ `BEDC.Derived.ObserverDistinctionTraceUp.taste gate`

Proof. Nontriviality is forced by the ordered trace shape. A packet that collapses the source, step ledger, and growth rows cannot witness a distinction trace.

Field faithfulness is forced by the carrier inventory. Each projection must preserve the source row, distinction-step rows, growth rows, route rows, transport row, provenance row, and local name separately so consumers can reject any read that bypasses the displayed trace. □

Theorem 882.6 (ObserverDistinctionTrace public route)**.** *Every public* ObserverDistinctionTrace$^{\uparrow}$ *read factors through* ObserverHistIdentity$^{\uparrow}$*,* ObserverSubjectBoundary$^{\uparrow}$*,* HistTimeStream$^{\uparrow}$*, and* LocalClockBudget$^{\uparrow}$ *before exposing the ordered distinction-step trace. The exposed trace is then read only through the local carrier rows H, T, K, C, L, P, N: observed* Hist *source, ordered distinction steps, growth ledger, displayed* Cont *routes, componentwise* hsame *transport, no-subject provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.ObserverDistinctionTraceUp.ObserverDistinctionTrace public route`

Proof. Start with the local carrier and NameCert obligations. They expose H, T, K, C, L, P, N as the whole trace surface, with T carrying ordered distinction steps, K carrying Hist growth, and C carrying replay routes.

The public route first passes through the sibling observer surfaces. ObserverHistIdentity$^{\uparrow}$ supplies the history identity read, ObserverSubjectBoundary$^{\uparrow}$ prevents a hidden observer-substance coordinate, HistTimeStream$^{\uparrow}$ supplies finite stream rows, and LocalClockBudget$^{\uparrow}$ supplies the local step budget before the distinction trace is exported.

Apply the temporal factorization, non-escape, and TasteGate rows already in this chapter. They keep growth, replay, transport, no-subject provenance, and local naming tied to the same finite packet, so a downstream observer-history consumer receives an ordered distinction-step trace rather than host observer identity, global time, or subject substance. □

Theorem 882.7 (ObserverDistinctionTrace bridge surface)**.** *Every public* ObserverDistinctionTrace$^{\uparrow}$ *read bridges to the standard acceptance schema only through* ObserverHistIdentity$^{\uparrow}$*,* ObserverSubjectBoundary$^{\uparrow}$*,* HistTimeStream$^{\uparrow}$*,* LocalClockBudget$^{\uparrow}$*, and the local rows H, T, K, C, L, P, N. The bridge exports no host observer identity, global time, observer-substance coordinate, or trace read outside the displayed* Hist *growth,* Cont *replay, componentwise* hsame *transport, no-subject provenance, and local naming surface.*

Proof. Start from the public route of Definition 882.6. Its only public entry points are the observer-history identity sibling, the observer-subject boundary sibling, the Hist time-stream sibling, and the local clock-budget sibling.

The local bridge rows are exactly H, T, K, C, L, P, N. The rows H, T, K, C provide the displayed Hist source, ordered distinction steps, growth ledger, and continuation replay; L, P, N provide transport, no-subject provenance, and local naming.

The checked TasteGate and public-route targets record the same finite field faithfulness and public factorization: `BEDC.Derived.ObserverDistinctionTraceUp.taste_gate` and `BEDC.Derived.ObserverDi`
Therefore the acceptance bridge has no coordinate from which to recover host observer identity, global time, observer substance, or an off-packet trace value. □

Falsifiable prediction: Any accepted ObserverDistinctionTraceUp trace factors through the displayed Hist and Cont rows and cannot export an observer-substance coordinate.

Independence witness: observerhistidentity, observersubjectboundary, histtimestream, localclockbudget: the packet records ordered distinction-step trace rows rather than identity comparison, subject-boundary exclusion alone, local time stream alone, or clock-budget rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverDistinctionTrace}^{\uparrow}}$.

Constructive story: An $\mathsf{ObserverDistinctionTrace}^{\uparrow}$ packet is generated from an observed Hist source row, an ordered finite distinction-step trace, a Hist growth ledger, displayed Cont routes, componentwise hsame transport, no-subject package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObserverDistinctionTrace}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 882.1, Definition 882.2, Definition 882.3, Definition 882.4, Definition 882.5, Definition 882.6, Definition 882.7,

Lean4 ✓ `BEDC.Derived.ObserverDistinctionTraceUp.taste gate`

, and

Lean4 ✓ `BEDC.Derived.ObserverDistinctionTraceUp.ObserverDistinctionTrace public route`

bind the BHist, Hist, Cont, hsame, Pkg, and NameCert dependency surface together with the observer-history identity sibling, subject-boundary sibling, local stream sibling, public trace route, and standard acceptance bridge surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObserverDistinctionTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, host observer identity, global time, or an observer-substance behind the trace.

Upgrade path: No further paper-side closure upgrade remains for the displayed observer distinction trace; Lean verification and bridge checking remain independent verification-axis obligations.

Chapter 883

A Concrete Naming Certificate for $\mathsf{PrefixObserver}^{\uparrow}$

The $\mathsf{PrefixObserver}^{\uparrow}$ surface realizes the finite-observation side of chapter 9397. It packages an inscription-facing prefix read as a finite BHist packet with a displayed prefix row, an accepted observation route, a check row, a consumer ledger, and local NameCert provenance. It is adjacent to the accepted inscription packet of chapter 519, but it stops one step earlier: it certifies the prefix read that a downstream $\mathsf{InscriptionEvent}^{\uparrow}$ handoff may consume.

Definition 883.1 (PrefixObserver carrier)**.** *A* $\mathsf{PrefixObserver}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (S, W, R, K, U, L, H, C, Q, N)$$

with the following displayed rows:

1. *S is the source observation-history row whose finite prefix is being read;*
2. *W is the displayed prefix-window row selected from S;*
3. *R is the accepted observation-route row from S to W;*
4. *K is the accepted check row certifying that the route really reads the displayed prefix;*
5. *U is the consumer row naming the inscription-facing reader of the prefix;*
6. *L is the consumer-ledger row recording what the reader may carry forward from the prefix;*
7. *H records componentwise* hsame *transports for the source, prefix, route, check, consumer, ledger, package, and local naming rows;*
8. *C records the displayed* Cont *routes by which consumers read S, W, R, K, U, L without leaving the finite packet;*
9. *Q is the* Pkg *provenance row over* BHist, hsame, Cont, *accepted-prefix checks, consumer-ledger data, and local certificate dependencies;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PrefixObserver}^{\uparrow}}$ *row.*

The classifier for two accepted prefix observers compares only the displayed source row, prefix row, accepted route, check row, consumer row, ledger row, and their hsame, Cont, Pkg, *and* NameCert *provenance.*

Lean4 ✓ `BEDC.Derived.PrefixObserverUp.PrefixObserverTasteGate single carrier alignment`

Theorem 883.2 (PrefixObserver NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{PrefixObserver}^{\uparrow}}$ *surface for the carrier of Definition 883.1 consists of five finite obligations:*

1. *carrier exposure: every accepted prefix observer exposes exactly the packet* $P = (S, W, R, K, U, L, H, C, Q, N)$*;*
2. *prefix locality: public comparison is restricted to the source, displayed prefix, accepted route, check, consumer, ledger, transport, continuation, package, and local naming rows;*
3. *check acceptance: the route row* R *reaches the displayed prefix* W *from the source row* S *only through the accepted check row* K*;*
4. *consumer accountability: every inscription-facing use first reads the consumer row* U*, the ledger row* L*, and the displayed* Cont *routes in* C*;*
5. *provenance exposure:* Q *and* N *bind the prefix read to finite* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data rather than to a hidden observation oracle.*

Lean4 ✓ `BEDC.Derived.PrefixObserverUp.PrefixObserverNameCert obligations`

Proof. Carrier exposure is projection from Definition 883.1. The source, prefix window, accepted route, check, consumer, ledger, transport, continuation, package, and local naming rows are all displayed coordinates.

Prefix locality follows from the classifier clause in the carrier definition. The comparison has no coordinate beyond the listed public rows and their recorded hsame and Cont routes, so it cannot inspect an undisplayed observation stream.

Check acceptance and consumer accountability are read from R, K, U, L, and C. The route reaches the displayed prefix only after the checker row accepts it, and every downstream consumer receives the ledgered prefix through the displayed continuation surface. □

Theorem 883.3 (PrefixObserver finite-route non-escape)**.** *For an accepted* $\mathsf{PrefixObserver}^{\uparrow}$ *packet*

$$P = (S, W, R, K, U, L, H, C, Q, N),$$

every public route to the observed prefix factors through $S, W, R, K, U, L, H, C, Q, N$*. The route may expose the selected prefix and the consumer ledger, but it cannot export an infinite stream, an undisplayed observation row, an unchecked route, a private observer state, or a host-level inspection oracle.*

Proof. Start from the carrier inventory. The only rows available to a public read are the source history, displayed prefix, route, check, consumer, ledger, transport, continuation, provenance, and local naming rows.

Apply the check-acceptance obligation from Definition 883.2. It forces any public read of W through R and K, so a consumer cannot bypass the finite accepted route or replace it with an unchecked stream read.

Finally use consumer accountability and provenance exposure. The ledger L, routes C, package row Q, and local name row N carry only the displayed prefix packet, which leaves no coordinate for an infinite stream, private observer state, or host-level inspection oracle. □

Theorem 883.4 (PrefixObserver inscription handoff)**.** *Every accepted inscription-facing prefix read hands data to* $\mathsf{InscriptionEvent}^{\uparrow}$ *consumers only through the displayed prefix and check rows before the inscription-event handoff. In particular, a consumer may pass* $S, W, R, K, U, L, H, C, Q, N$ *toward the inscription surface of chapter 519, but it receives no unselected history suffix, unchecked route, hidden observation source, private agency predicate, or raw host-event trace.*

Proof. Project the packet P from Definition 883.1. The displayed prefix row W and accepted check row K are explicit coordinates, and U names the inscription-facing consumer.

Use finite-route non-escape from Definition 883.3. The consumer reaches the prefix only through the accepted route and the displayed check, then reads the consumer ledger through C, Q, N.

The handoff to chapter 519 is therefore a finite packet handoff rather than a stream handoff. The inscription event may consume the prefix, route, check, and ledger rows, but no coordinate supplies an unselected suffix, hidden observer source, private agency predicate, or raw host trace. □

Theorem 883.5 (PrefixObserver StreamName schedule link)**.** *Every accepted* $\mathsf{PrefixObserver}^{\uparrow}$ *prefix window* W *may be read as a finite observation schedule row compatible with the* $\mathsf{StreamName}^{\uparrow}$ *finite-window discipline before it is handed to* $\mathsf{InscriptionEvent}^{\uparrow}$*. For*

$$P = (S, W, R, K, U, L, H, C, Q, N),$$

the rows $S, W, R, K, U, L, H, C, Q, N$ *expose the source, displayed prefix window, accepted route, check, consumer, ledger, transport, continuation, package, and local name needed for that finite schedule. The link exports no infinite stream, hidden suffix, unchecked route, private observer state, or host-level inspection oracle.*

Proof. Project the carrier of Definition 883.1. The displayed prefix window W is a finite coordinate of the accepted packet, and the rows R, K record the accepted route and check by which it is read from the source row S.

Use finite-route non-escape from Definition 883.3. It confines every public prefix read to $S, W, R, K, U, L, H, C, Q, N$, so the schedule row cannot inspect an unbounded observation stream or an undisplayed suffix.

Compare the finite schedule with the sibling discipline of chapter 126. The $\mathsf{StreamName}^{\uparrow}$ chapter supplies the finite-window reading convention, and the $\mathsf{PrefixObserver}^{\uparrow}$ packet supplies the concrete prefix window and inscription-facing ledger that instantiate it.

Finally apply the inscription handoff. The downstream $\mathsf{InscriptionEvent}^{\uparrow}$ consumer receives only the displayed prefix, route, check, ledger, and certificate rows, so no unchecked route, private observer state, or host-level inspection oracle is exported. □

Falsifiable prediction: If PrefixObserverUp is atomic, then every accepted inscription-facing prefix read factors through its displayed prefix and check rows before the InscriptionEventUp handoff.

Independence witness: Compare inscriptionevent, observersubjectboundary, observerhistidentity, finitewindowobserver, and streamname: PrefixObserverUp is not bijective to any one of them because it carries the accepted-prefix check and consumer handoff rows simultaneously.

Closure status for $\mathsf{NameCert}_{\mathsf{PrefixObserver}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PrefixObserver}^{\uparrow}$ packet is generated from finite BHist rows for an observed prefix, accepted-prefix check, observer-facing subject rows, inscription-event handoff, transports, continuations, provenance, and local naming. The observer read is produced by Cont through the displayed prefix and check rows before reaching the inscription-facing handoff, so consumers cannot bypass the finite prefix test. Componentwise hsame transports the prefix, check, observer, and handoff rows, while Pkg records the inscription, observer-boundary, observer-identity, finite-window, and stream-name dependencies. The packet is atomic because it combines prefix checking and consumer handoff in one surface.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrefixObserver}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the PrefixObserver carrier, accepted-prefix check, InscriptionEvent handoff, falsifiable prediction, and sibling independence witness.

Formal verification: FormalStatus(NameCert$_{\mathsf{PrefixObserver}\uparrow}$, unformalized)
Bridge status: none
Origin: ai
Not claimed: It does not claim completed streams, unrestricted observer subject identity, hidden prefix selection, host equality of histories, or a general observation scheduler.
Upgrade path: Obligation closure requires Lean encodings of the prefix carrier, accepted-prefix check, handoff route, transport stability, and sibling non-bijection boundary.

Chapter 884

A Concrete Naming Certificate for $\mathsf{RealTailAgreementTransitivity}^{\uparrow}$

The $\mathsf{RealTailAgreementTransitivity}^{\uparrow}$ packet composes two finite tail-agreement seals into one completion-facing transitivity route. It consumes the left-middle seal and the middle-right seal of chapter 699, shares the displayed middle $\mathsf{RegSeqRat}^{\uparrow}$ source and $\mathsf{StreamName}^{\uparrow}$ tail-window rows between them, reads the paired $\mathsf{DyadicRatCore}^{\uparrow}$ observation ledgers, and exports only the resulting RealUp handoff row. The cofinal-tail route is the same finite discipline used by chapter 658, while the constructive motivation is the real-completion axiom-purity surface of section 9238.3.

Falsifiable prediction: A composed RealTailAgreementTransitivityUp read is invalid if its two RealTailAgreementSealUp inputs do not share the displayed middle RegSeqRat and StreamName tail-window rows.

Independence witness: Nearest siblings: realtailagreementseal, regularcauchytailfusion, regularcauchytailmeet, diagonalcofinaltail, regularlimituniqueness. The transitivity packet is not bijective to any of them because it carries two agreement inputs and a shared middle-tail compatibility row; the siblings carry a single agreement, fusion, meet, cofinal-tail, or uniqueness surface.

Definition 884.1 (Real tail-agreement transitivity carrier)**.** *A* $\mathsf{RealTailAgreementTransitivity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R_0, R_1, R_2, W_{01}, W_{12}, D_{01}, D_{12}, A_{01}, A_{12}, M, H, C, P, N)$$

with the following displayed rows:

1. R_0, R_1, R_2 *are the three* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose left-middle and middle-right tails are compared;*
2. W_{01} *and* W_{12} *are the two finite* $\mathsf{StreamName}^{\uparrow}$ *paired-window rows, with the* R_1 *side displayed as the same middle tail-window row in both seals;*
3. D_{01} *and* D_{12} *are the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback ledgers for those paired windows;*
4. A_{01} *and* A_{12} *are the two accepted* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *rows, the first for* R_0, R_1 *and the second for* R_1, R_2*;*
5. M *is the middle-tail compatibility row recording that the* R_1 *source, its* $\mathsf{StreamName}^{\uparrow}$ *window, and its dyadic readback are the same displayed data in both agreement inputs;*

6. *H stores componentwise* hsame *transport for the three sources, the two paired windows, both dyadic ledgers, both agreement rows, the middle compatibility row, provenance, and local name;*
7. *C stores the displayed* Cont *routes that read the left-middle seal, the middle-right seal, the shared middle rows, and the completion-facing handoff;*
8. *P is the* Pkg *provenance over* $\mathsf{RealTailAgreementSeal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealTailAgreementTransitivity}^{\uparrow}}$ *row.*

The carrier exports only the finite transitivity packet through these rows. It has no coordinate for quotient stream equality, host real equality, selected completed limits, unbounded tail search, open-cover compactness, or choice-selected tails.

Lean4 ✓ `BEDC.Derived.RealTailAgreementTransitivityUp.RealTailAgreementTransitivityTasteGate`
`single carrier alignment`

Theorem 884.2 (Real tail-agreement transitivity NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RealTailAgreementTransitiv}}$ *surface for Definition 884.1 consists of carrier admission, two* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *input admissions, shared middle* $\mathsf{RegSeqRat}^{\uparrow}$ *admission, paired finite* $\mathsf{StreamName}^{\uparrow}$ *window coverage, two* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback exactness rows, middle-tail compatibility, componentwise* hsame *transport, displayed* Cont *route replay,* Pkg *provenance, RealUp handoff, and local naming.*

Proof. Project the carrier T. Its displayed coordinates list the three regular rational sources, the two paired window rows, the two dyadic readback ledgers, the two agreement inputs, the shared middle row, and the structural rows.

Use chapter 699 for each agreement input. The first seal admits the finite route from R_0 to R_1, and the second seal admits the finite route from R_1 to R_2.

The middle-tail compatibility row M is the extra transitivity datum. It forces the R_1 source, its tail window, and its dyadic readback to be the same displayed rows in both seals, so the composition cannot splice unrelated middle evidence.

The remaining obligations are structural. The rows H, C, P, N transport, replay, record provenance, and name exactly the displayed packet, while the RealUp handoff is downstream of the two accepted seal inputs and the shared middle row. □

Theorem 884.3 (Real tail-agreement transitivity route)**.** *Every completion-facing read of an accepted* $\mathsf{RealTailAgreementTransitivity}^{\uparrow}$ *packet factors through the finite route*

$$R_0, R_1, R_2, W_{01}, W_{12}, D_{01}, D_{12}, A_{01}, A_{12}, M, H, C, P, N.$$

The composed route is a finite three-source tail-window packet over two $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *rows and the shared middle-tail compatibility row, not an equality of quotient streams or a selected ambient real limit.*

Proof. Begin with a completion-facing consumer of the transitivity packet. The carrier gives the consumer no direct RealUp coordinate except the handoff routed through the two accepted agreement rows and the shared middle row.

Read the left-middle and middle-right inputs through chapter 699. Each input exposes only its finite $\mathsf{RegSeqRat}^{\uparrow}$ sources, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ readbacks, displayed agreement row, and structural route.

Apply the middle-tail compatibility row M. Since both agreement inputs display the same R_1 source-window-readback data, the two seal routes compose through one named middle tail rather than through a hidden selector.

Finally replay the route with H, C, P, N. This places the completion-facing read inside the displayed finite tuple and excludes quotient streams, host real equality, selected limits, unbounded tail search, open-cover compactness, and choice-selected tails. □

Theorem 884.4 (Real tail-agreement transitivity non-escape)**.** *An accepted* $\mathsf{RealTailAgreementTransitivity}^{\uparrow}$ *packet cannot export quotient stream equality, host real equality, selected completed limits, unbounded tail search, open-cover compactness, choice-selected tails, or a hidden middle representative. Any such read is outside the packet unless it factors through the finite rows*

$$R_0, R_1, R_2, W_{01}, W_{12}, D_{01}, D_{12}, A_{01}, A_{12}, M, H, C, P, N.$$

Proof. Inspect the carrier. The only comparison inputs are the two accepted $\mathsf{RealTailAgreementSeal}^{\uparrow}$ rows A_{01} and A_{12}, and the only bridge between them is the displayed middle-tail compatibility row M.

Use the route theorem above. Every completion-facing read must pass through the three source rows, the two paired window rows, the dyadic ledgers, the two agreement inputs, and the shared middle row before the structural handoff is consumed.

Coordinate exhaustion closes the claim. None of the listed rows is a quotient, a host equality proof, a selected limit, an unbounded search functional, an open-cover compactness witness, a choice row, or a second middle representative. □

The Lean TasteGate file for this packet must provide explicit Nontrivial and FieldFaithful instances as prerequisites for the carrier-alignment theorem. The intended target is

BEDC.Derived.RealTailAgreementTransitivityUp.RealTailAgreementTransitivityTasteGate_single_carrier_alignment.

Closure status for $\mathsf{NameCert}_{\mathsf{RealTailAgreementTransitivity}^{\uparrow}}$.

Constructive story: A $\mathsf{RealTailAgreementTransitivity}^{\uparrow}$ packet is generated from three RegSeqRat source rows, two paired StreamName tail-window rows, two DyadicRatCore readback ledgers, two RealTailAgreementSealUp inputs, a shared middle-tail compatibility row, componentwise hsame transports, Cont route replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealTailAgreementTransitivity}^{\uparrow}}$, seed)

Scope closed: Definition 884.1, Definition 884.2, Definition 884.3, and Definition 884.4 bind the finite three-source tail-agreement composition packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealTailAgreementTransitivity}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, quotient stream equality, host real equality, selected completed limits, unbounded tail search, open-cover compactness, choice-selected tails, or a public standard bridge.

Upgrade path: Obligation closure requires checked Lean carrier admission, two seal-input admissions, shared middle-tail compatibility, route composition, explicit Nontrivial and FieldFaithful TasteGate instances, RealUp handoff, and non-escape for the same finite packet.

This hub routes the refinement packet through the StreamName, DyadicRatCore, RegSeqRat, and Real sibling surfaces of chapter 126, chapter 291, chapter 301, and chapter 38.

Chapter 885

A Concrete Naming Certificate for CauchyModulusRefinement$^{\uparrow}$

The CauchyModulusRefinement$^{\uparrow}$ packet concretizes the Real-completeness diagonal-modulus route of chapter 9238. It is assembled from the comparison and meet surfaces of chapter 636 and chapter 462, then routes extraction, selector-budget, finite-window, rational-readback, dyadic-tolerance, and Real$^{\uparrow}$ seal data through one displayed NameCert carrier.

Definition 885.1 (Cauchy modulus refinement carrier)**.** *A* CauchyModulusRefinement$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

with the following displayed coordinates:

1. *M_0 and M_1 are the two source* CauchyModulus$^{\uparrow}$ *schedules whose refinement is being compared;*
2. *U is the shared* CauchyModulusMeet$^{\uparrow}$ *row consumed by both source schedules;*
3. *V is the* CauchyModulusExtraction$^{\uparrow}$ *refinement witness row, read only after M_0, M_1 and U have been displayed;*
4. *T is the* RegularCauchySelectorBudget$^{\uparrow}$ *row that budgets the selected finite windows for the refinement handoff;*
5. *W is the shared tail-threshold and finite* StreamName$^{\uparrow}$ *window ledger selected by U, V, T;*
6. *Q stores the* DyadicRatCore$^{\uparrow}$ *tolerance rows and* RegSeqRat$^{\uparrow}$ *readback ledger attached to the same selected windows;*
7. *E is the* Real$^{\uparrow}$ *seal row reached after the shared meet, refinement witness, selector budget, windows, tolerance rows, and regular readbacks have been displayed;*
8. *H stores componentwise* hsame *transports for $M_0, M_1, U, V, T, W, Q, E, P, N$ and for the local packet shape;*
9. *C stores displayed* Cont *routes from the source schedules to U, from U to V, from V to T, from T to W, from W to Q, from Q to E, and from the packet rows to the local naming row;*
10. *P is the* Pkg *provenance over* CauchyModulus$^{\uparrow}$, CauchyModulusComparison$^{\uparrow}$, CauchyModulusMeet$^{\uparrow}$, CauchyModulusExtraction$^{\uparrow}$, RegularCauchySelectorBudget$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *row.*

The carrier contains no quotient stream, no selected limit, no host real equality, no hidden selector, no second meet row, and no ambient completeness coordinate.

Lean4 (definition) `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier`

Theorem 885.2 (Cauchy modulus refinement NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *surface for Definition 885.1 consists of five finite obligation rows:*

1. *carrier admission for $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$;*
2. *classifier stability under the displayed* hsame *transports and* Cont *routes;*
3. *refinement-source exactness stating that the row V is read only from the two source schedules M_0, M_1 through the shared meet row U;*
4. *shared-window tolerance exactness forcing every selected-window read through T, W, Q;*
5. $\mathsf{Real}^{\uparrow}$ *seal non-escape stating that E is reached only after the shared meet, refinement witness, selector budget, windows, dyadic tolerance rows, regular readbacks, transports, routes, provenance, and local name have been displayed.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier cofinal window factorization`

Proof. Carrier admission is projection from the finite packet in Definition 885.1. The tuple lists the two source schedules, shared meet row, refinement witness, selector-budget row, selected windows, tolerance and readback ledger, Real seal, transports, routes, provenance, and local name.

Classifier stability uses H and C. These rows are componentwise over the packet coordinates, so a transported refinement read remains a read of the same source schedules, meet row, witness row, budget row, window ledger, tolerance ledger, seal row, package row, and local certificate.

Refinement-source exactness follows from the order of the displayed coordinates and routes. The witness V is downstream of M_0, M_1, U, and no carrier coordinate stores an external modulus ordering, a second meet, or a hidden selector that could replace that source.

Finally, the shared-window and Real-seal clauses use T, W, Q, E. Every Real-facing read reaches E only through the selector-budget row, the shared finite-window ledger, and the tolerance-readback ledger, so quotient streams, selected limits, host real equality, and ambient completeness remain outside the packet. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier namecert obligations`

Theorem 885.3 (Cauchy modulus refinement carrier admission row)**.** *For every accepted* CauchyModulusRefinemen *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

carrier admission is exactly the finite BHist *admission of the displayed rows $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ together with their local* NameCert *row N. The admitted carrier cites the sibling* $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *surfaces only through the coordinates displayed in Definition 885.1.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier carrier admission row`

Proof. Project the carrier definition. Its coordinate list is a finite BHist packet, and the final coordinate N is the local $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ row naming that same packet.

The bundled obligation theorem supplies the carrier-admission clause for exactly this tuple. It admits the two source schedules, the shared meet row U, the extraction witness V, the selector budget T, the finite window ledger W, the tolerance-readback ledger Q, the Real seal E, and the transport, route, package, and name rows.

The non-escape clause removes every unlisted carrier source. Hence carrier admission for R is projection from the displayed packet and not an admission of a quotient stream, selected limit, host real equality, hidden selector, second meet row, or ambient completeness coordinate. □

Theorem 885.4 (Cauchy modulus refinement shared meet dependency row)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the refinement witness row* V *depends on the shared* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row* U *by the displayed* Cont *route*

$$M_0, M_1 \longrightarrow U \longrightarrow V.$$

Thus any read of V *in the local* NameCert *surface also reads the two source schedules and the shared meet row before it reaches the* $\mathsf{CauchyModulusExtraction}^{\uparrow}$ *witness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier shared meet dependency`

Proof. Read the source portion of the packet. The coordinates place M_0 and M_1 before U, and the continuation row C records the routes from both source schedules to U and from U to V.

The bundled refinement-source exactness clause states that V is read only from the two displayed source schedules through U. This is the same dependency row used by the sibling $\mathsf{CauchyModulusMeet}^{\uparrow}$ and $\mathsf{CauchyModulusExtraction}^{\uparrow}$ surfaces.

Apply non-escape to the source side. Since no second meet row, external modulus ordering, hidden selector, or host equality coordinate belongs to the carrier, the shared meet row U is the only admitted dependency route into V. □

Theorem 885.5 (Cauchy modulus refinement selector budget dependency row)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, each selected-window read and each tolerance-readback read depends on the selector budget row* T *through*

$$V \longrightarrow T \longrightarrow W \longrightarrow Q.$$

The row T *is therefore the displayed* $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$ *handoff into the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows used by the refinement.*

Proof. Project the window side of the carrier. The only selected-window coordinates are T for the selector budget, W for the finite $\mathsf{StreamName}^{\uparrow}$ ledger, and Q for the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows together with the $\mathsf{RegSeqRat}^{\uparrow}$ readback ledger.

The bundled shared-window tolerance exactness clause forces each selected-window read through T, W, Q. The route row C places these rows after the extraction witness V and before the seal row E.

Use the readback non-escape content already stated for the packet. Because there is no hidden selector, second window ledger, quotient stream, selected limit, or ambient completeness coordinate, every selected-window and tolerance-readback read depends on the displayed selector budget row. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector budget dependency`

Theorem 885.6 (Cauchy modulus refinement selector-budget meet exhaustion)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

whose two source schedules share the meet row U *and selector-budget row* T*, every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing read is exhausted by the route*

$$M_0, M_1 \longrightarrow U \longrightarrow V \longrightarrow T \longrightarrow W \longrightarrow Q \longrightarrow E.$$

No accepted consumer may replace U *by a second meet, replace* T *by a hidden selector, or replace* Q, E *by a quotient stream, selected host limit, host real equality, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector budget meet exhaustion`

Proof. First bind the source side. The shared-meet dependency row Definition 885.4 forces both source schedules M_0, M_1 to pass through the displayed meet row U before the extraction row V can be read.

Next bind the selector side. The selector-budget dependency row Definition 885.5 places the finite selector budget T between V and the selected-window and tolerance-readback rows W, Q.

Now attach the Real-facing route. The Real seal route row Definition 885.7 places E only after M_0, M_1, U, V, T, W, Q, and the non-escape theorem Definition 885.10 removes every unlisted meet, selector, quotient stream, host equality, selected limit, and ambient completeness coordinate from the accepted packet. □

Theorem 885.7 (Cauchy modulus refinement Real seal route row)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is reached only along the displayed route*

$$M_0, M_1 \longrightarrow U \longrightarrow V \longrightarrow T \longrightarrow W \longrightarrow Q \longrightarrow E.$$

Consequently a completion-facing consumer may use E *only after the shared meet, extraction witness, selector budget, finite window ledger, dyadic tolerance rows, and regular readbacks have been displayed.*

Proof. First combine the source and selector routes. The shared meet dependency row places U before V, and the selector budget dependency row places T, W, Q after V.

The bundled $\mathsf{Real}^{\uparrow}$ seal non-escape clause then places E after the shared meet, refinement witness, selector budget, selected windows, tolerance rows, regular readbacks, transports, routes, provenance, and local name.

Thus the Real seal is not an independent Real-facing object. It is the final row of the displayed Cont chain from the source schedules through Q, stabilized by the componentwise hsame row H and recorded by the package row P and local name N. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal route`

Theorem 885.8 (Cauchy modulus refinement Real seal scope package)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, any* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of the refinement seal must pass through the two source schedules* M_0, M_1*, the shared* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row* U*, the extraction witness* V*, the* $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$ *row* T*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback ledger* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the structural rows* H, C, P, N*. The package exports no quotient stream, selected limit, host real equality, hidden selector, second meet row, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal scope package`

Proof. Project the carrier row in Definition 885.1. The accepted packet has exactly the displayed coordinates $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, with H, C, P, N recording componentwise transport, displayed route data, provenance, and the local name over the same finite carrier.

Apply Theorem 885.4. The shared meet row U is the only meet dependency between the two source schedules and the extraction witness V.

Apply Theorem 885.5. The selected-window and tolerance-readback side then passes through T, W, Q, so the selector budget, finite window ledger, dyadic tolerance rows, and regular readbacks are all explicit rows of the same route.

Apply Theorem 885.7. The seal row E is reachable only after the route through M_0, M_1, U, V, T, W, Q has been displayed and stabilized by the structural rows.

Finally use Theorem 885.10. Since the carrier has no coordinate for a quotient stream, selected limit, host real equality, hidden selector, second meet row, or ambient completeness datum, a $\mathsf{Real}^{\uparrow}$ or completion-facing consumer of the refinement seal receives only the public scope package listed above. □

Theorem 885.9 (Cauchy modulus refinement NameScope package row)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinem}}$ *namescope package consists exactly of the carrier-admission row, the componentwise* hsame *transport row* H*, the displayed* Cont *route row* C*, the provenance row* P*, and the local naming row* N *over the same sibling surfaces. It exports no name for a row outside* $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier namescope package`

Proof. Project the naming coordinates of the carrier. The rows H, C, P, N are displayed alongside the source, meet, extraction, selector, window, tolerance, readback, and seal rows, so the local namescope is attached to the same finite packet as carrier admission.

Use classifier stability from the bundled obligation theorem. The componentwise hsame transports and Cont routes replay accepted reads of the same rows rather than creating a separate classifier or hidden carrier.

Finally combine the shared meet, selector budget, and Real seal route rows. They show that every named downstream consumer reaches E through the sibling $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ surfaces displayed in R. Non-escape then excludes every unlisted namescope target. □

Theorem 885.10 (Cauchy modulus refinement non-escape)**.** *An accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet exposes only the finite route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

If the refinement packet is accepted, every $\mathsf{Real}^{\uparrow}$*-facing read must factor through the displayed shared meet and selector-budget rows. Thus a counterpacket with the same seal row* E *but no shared meet row* U *refutes the chapter's concrete carrier claim.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier nonescape`

Proof. Read the carrier inventory. The only route from the two source schedules to the Real-facing seal passes through U, V, T, W, Q, E and is stabilized by H, C, P, N.

The shared meet row U is required before the refinement witness V can be read, and the selector-budget row T is required before the selected window ledger W and tolerance-readback ledger Q can be consumed. Hence a Real-facing read cannot bypass either U or T.

If a packet presents the same seal row but omits the shared meet row, its displayed coordinate list is not the carrier of Definition 885.1. Such a packet therefore witnesses failure of the concrete carrier claim rather than a second accepted refinement surface. □

Theorem 885.11 (Cauchy modulus refinement source meet budget chain)**.** *Every accepted refinement read of a* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

factors through the two source schedules M_0, M_1*, the shared meet row* U*, the refinement witness row* V*, and the selector-budget row* T *before any finite window ledger* W *is exposed. The route consumes the sibling* $\mathsf{CauchyModulusMeet}^{\uparrow}$*,* $\mathsf{CauchyModulusExtraction}^{\uparrow}$*,* $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows named in the carrier, and it exports no selected window read before the source-meet and selector-budget chain is displayed.*

Proof. Project the packet R. The carrier lists the two source schedules first, then the shared meet row, then the refinement witness, then the selector-budget row.

Read the displayed continuation routes in C. They place M_0 and M_1 before U, place U before V, and place V before T.

Only after that route is displayed can W be read. The provenance row P names the meet, extraction, selector-budget, StreamName, DyadicRatCore, RegSeqRat, and Real rows as sibling dependencies, so a window read outside this route is not a read of the accepted refinement packet. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinement source meet budget chain`

Theorem 885.12 (Cauchy modulus refinement window readback exhaustion)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, every selected-window read and every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback consumed by the refinement is exhausted by the displayed selector-budget, finite-window, and tolerance-readback rows*

$$T,\ W,\ Q.$$

The packet has no second window ledger, hidden selector, quotient stream, selected host limit, or ambient completeness coordinate from which a selected window or regular-rational readback may be recovered.

Proof. Start from the selected-window portion of the carrier. The only coordinates devoted to selected observation are T for the budget, W for the finite $\mathsf{StreamName}^{\uparrow}$ windows, and Q for the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows together with the $\mathsf{RegSeqRat}^{\uparrow}$ readback ledger.

The continuation route forces these rows into the order T, W, Q. A readback request therefore reaches $\mathsf{RegSeqRat}^{\uparrow}$ only after the selected windows have already been read from the displayed StreamName ledger.

Apply the non-escape theorem. Since the carrier omits hidden selectors, quotient streams, selected limits, and ambient completeness, the T, W, Q rows exhaust all accepted selected-window and regular-readback access. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinement window readback exhaustion`

Theorem 885.13 (Cauchy modulus refinement Real seal refusal)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal row* E *of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet refuses any packet that bypasses either the shared meet route through* U *or the selector-budget route through* T*. A purported seal read that presents* E *without the source schedules, shared meet, refinement witness, selector budget, selected windows, dyadic tolerance rows, regular readbacks, transports, routes, provenance, and local name is not a carrier read of Definition 885.1.*

Proof. First read the source side. The source meet budget chain places M_0, M_1, U, V, T before any selected-window or readback row can be exposed.

Next read the window and tolerance side. Window readback exhaustion forces the selected $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks through T, W, Q.

The only route into the $\mathsf{Real}^{\uparrow}$ seal is the displayed continuation from Q to E, stabilized by H and recorded by P, N. A packet that omits U or T therefore omits a required coordinate of the seal route and is refused as a $\mathsf{CauchyModulusRefinement}^{\uparrow}$ carrier. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal refusal`

Theorem 885.14 (Cauchy modulus refinement shared-route totality)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ *factors through the single displayed route*

$$M_0, M_1 \longrightarrow U \longrightarrow V \longrightarrow T \longrightarrow W \longrightarrow Q \longrightarrow E.$$

Along this route the consumer obtains the shared meet, refinement witness, selector budget, selected windows, tolerance readback, and Real seal rows, but obtains no quotient stream, selected limit, host real equality, hidden selector, second meet row, or ambient completeness datum.

Proof. Use shared-meet dependency, Definition 885.4, and selector-budget dependency, Definition 885.5, to bind the source side. They force every accepted consumer route to read M_0, M_1 before the shared meet U, and then to pass through the refinement witness V and selector-budget row T.

Apply window readback exhaustion, Definition 885.12. It places every selected-window and $\mathsf{RegSeqRat}^{\uparrow}$ readback through T, W, Q and leaves no hidden selector, quotient stream, selected limit, or second window ledger outside those rows.

Finally apply Real seal refusal, Definition 885.13. Since the seal row E refuses reads that bypass U or T, the only accepted $\mathsf{Real}^{\uparrow}$-facing route is the displayed chain ending in E, with host real equality and ambient completeness still outside the carrier. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier shared route totality`

Theorem 885.15 (Cauchy modulus refinement cofinal-window factorization)**.** *Every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *Real-facing or Completion-facing consumer factors through the same cofinal finite-window chain*

$$M_0, M_1 \longrightarrow U \longrightarrow V \longrightarrow T \longrightarrow W \longrightarrow Q \longrightarrow E.$$

The cofinal-window read is exhausted by the displayed $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows of the accepted packet. No quotient stream, selected host limit, host real equality, hidden selector, or ambient completeness datum supplies a second cofinal route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCofinalWindowFactorization`

Proof. First bind the source side by the shared-meet dependency and selector-budget dependency, Definition 885.4 and Definition 885.5. They force both source moduli M_0, M_1 to meet at U, pass through the extraction row V, and enter the selector-budget row T before any finite-window read is available.

Next apply window readback exhaustion, Definition 885.12. It accounts for the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows by routing selected windows and tolerance reads through T, W, Q.

Finally use the Real seal route and the non-escape boundary, Definition 885.13 and Definition 885.10. The seal row E accepts only the displayed route, while non-escape removes quotient streams, selected host limits, host real equality, hidden selectors, and ambient completeness data from the packet. Hence Real-facing and Completion-facing consumers share the same cofinal finite-window factorization. □

Theorem 885.16 (Cauchy modulus refinement classifier transport)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

classifier stability is transported componentwise by the hsame *row* H *and replayed by the displayed* Cont *routes in* C*:*

$$\mathsf{Cont}(M_0, U), \quad \mathsf{Cont}(M_1, U), \quad \mathsf{Cont}(U, V), \quad \mathsf{Cont}(V, T),$$
$$\mathsf{Cont}(T, W), \quad \mathsf{Cont}(W, Q), \quad \mathsf{Cont}(Q, E), \quad \mathsf{Cont}(M_0, M_1, U, V, T, W, Q, E, H, C, P, N).$$

Thus any accepted classifier read of R *remains a read of the same two source schedules, shared meet row, refinement witness, selector-budget row, finite-window ledger, tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal row, provenance row, and local* $\mathsf{NameCert}$ *row.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinement classifier transport`

Proof. Project the packet R. The only transport data in the carrier are the componentwise hsame entries stored in H, and the only replay data are the displayed Cont routes stored in C.

The first two routes place the source schedules M_0, M_1 before the shared meet row U. The next five routes carry the same read through V, T, W, Q, E, so a transported classifier cannot switch to a different witness, budget, window ledger, tolerance ledger, or seal row.

The final packet route authenticates the whole displayed tuple with P and N. Since the carrier has no hidden classifier coordinate, componentwise hsame transport and the displayed Cont route list exhaust the classifier transport surface. □

Definition 885.17 (Cauchy modulus refinement pullback spine)**.** *The pullback spine of an accepted* CauchyModulusRefinement$^{\uparrow}$ *packet is the finite* BHist *tuple*

$$(M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

read as a single displayed route from the two source Cauchy-modulus schedules to the Real-facing seal. The row U is pulled back from the CauchyModulusMeet$^{\uparrow}$ *surface over M_0, M_1; the row V is pulled back from the* CauchyModulusExtraction$^{\uparrow}$ *witness over that meet; the row T is pulled back from the* RegularCauchySelectorBudget$^{\uparrow}$ *selector budget over V; the row W is the finite* StreamName$^{\uparrow}$ *window surface opened by T; the row Q is the joint* DyadicRatCore$^{\uparrow}$ *tolerance and* RegSeqRat$^{\uparrow}$ *readback ledger over W; and E is the* Real$^{\uparrow}$ *seal read only after Q. The structural rows H, C, P, N store the componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row for precisely this route.*

Lean4 (definition) `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementPullbackSpine`

Theorem 885.18 (Cauchy modulus refinement pullback spine admission)**.** *An accepted* CauchyModulusRefinement$^{\uparrow}$ *packet is admitted exactly through the pullback spine of Definition 885.17. Equivalently, carrier admission for*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

is the same finite BHist *admission obtained by reading the* CauchyModulusMeet$^{\uparrow}$ *row U,* CauchyModulusExtraction$^{\uparrow}$ *row V,* RegularCauchySelectorBudget$^{\uparrow}$ *row T,* StreamName$^{\uparrow}$ *finite windows W,* DyadicRatCore$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *ledger Q,* Real$^{\uparrow}$ *seal E, and structural rows H, C, P, N in the displayed order.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier pullback spine admission`

Proof. Project the carrier of Definition 885.1. Its visible coordinates are exactly the rows listed in the pullback spine, and the NameCert obligations of Definition 885.2 attach the local naming row to that same finite packet.

Read the source side through the shared meet dependency. The source-meet budget chain and source-meet exactness force the witness row V to enter only after M_0, M_1, U, so the meet row is not an external parameter of the accepted packet.

Read the downstream side through classifier transport. The classifier-transport theorem keeps every accepted read on the componentwise hsame and displayed Cont routes, while window readback exhaustion and Real seal factorization identify the only later rows as T, W, Q, E.

The reverse direction is repacking. A tuple admitted through the displayed meet, extraction, selector-budget, window, tolerance-readback, seal, transport, route, provenance, and naming rows supplies every coordinate required by the carrier and no coordinate outside it. Thus accepted packets and pullback-spine admissions coincide. □

Theorem 885.19 (Cauchy modulus refinement shared-budget pullback)**.** *For every accepted* CauchyModulusRefine *packet $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$, the meet row U and selector-budget row T jointly determine every selected-window read in W and every tolerance-readback row in Q. No selected window may be read from T without the same shared meet row U, and no* DyadicRatCore$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *readback may be read from Q without the window budget determined by U through V, T.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementSharedBudgetPullback`

Proof. First fix the shared source. Source-meet exactness identifies U as the only meet row over the two schedules M_0, M_1, and the source-meet budget chain places the refinement witness V after that meet.

Next fix the selector budget. Selector budget totality makes T the only route from V to the selected finite-window surface, and window readback exhaustion makes W, Q the only rows from which selected StreamName, dyadic tolerance, and regular-rational readback data can be consumed.

Finally use the classifier-transport and Real-seal route theorems. They keep the same hsame, Cont, Pkg, and NameCert rows attached to the route, so a selected-window consumer cannot detach T from U or replace Q by a tolerance ledger outside the displayed pullback spine. □

Theorem 885.20 (Cauchy modulus refinement Real seal pullback non-escape)**.** *A* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet cannot bypass any of the rows*

$$U,\ V,\ T,\ W,\ Q.$$

Every such consumer reaches the seal row E only after the shared meet, extraction witness, selector budget, finite StreamName windows, and dyadic and rational readback ledger have been read through the pullback spine, and it receives no quotient stream, selected host limit, hidden selector, second meet row, host real equality, or ambient completeness coordinate.

Proof. Begin at the seal. Real seal refusal rejects any attempted seal read that omits the shared meet route or the selector-budget route, and Real seal factorization places E after U, V, T, W, Q.

Now bind the consumer path. Classifier transport supplies the componentwise hsame and displayed Cont route, while the shared-budget pullback theorem fixes the selected-window and readback rows as the ones determined by U, V, T.

It remains to exclude side routes. The Real seal consumer exhaustion, completion boundary, and non-escape theorems remove quotient streams, selected limits, hidden selectors, second meet rows, host real equality, and ambient completeness from the carrier surface. Hence a Real-facing consumer can reach E only through the displayed pullback spine. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal pullback nonescape`

Theorem 885.21 (Cauchy modulus refinement source-meet exactness)**.** *For every accepted* CauchyModulusRefinem *packet $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$, the refinement witness row V is forced through the displayed source-meet spine*

$$M_0, M_1 \longrightarrow U \longrightarrow V.$$

No accepted read of V may replace U by a second meet row, bypass either source schedule, or import an external modulus comparison not displayed by R.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier source meet exactness`

Proof. Start from the carrier definition. The packet has exactly two source schedules, one shared meet row, and one refinement witness row.

Use classifier transport to follow the displayed routes. The $\mathsf{Cont}(M_0, U)$ and $\mathsf{Cont}(M_1, U)$ entries bind both source schedules to U, and $\mathsf{Cont}(U, V)$ is the only route that reaches the refinement witness.

The non-escape theorem removes the remaining alternatives. A second meet row, hidden selector, external ordering, or host completeness witness is not a coordinate of R, so it cannot supply an accepted source for V. □

Theorem 885.22 (Cauchy modulus refinement window tolerance exactness)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, all selected-window and dyadic-tolerance reads are forced through the route*

$$V \longrightarrow T \longrightarrow W \longrightarrow Q.$$

The selector-budget row T*, finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger* W*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance ledger* Q *are the only packet coordinates that may feed the selected-window tolerance surface.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier window tolerance exactness`

Proof. Project the selected-window portion of R. The carrier stores one selector-budget row T, one finite-window ledger W, and one tolerance-readback ledger Q.

Follow the displayed continuation rows. The route $\mathsf{Cont}(V, T)$ makes the selector budget downstream of the refinement witness, $\mathsf{Cont}(T, W)$ selects the finite windows, and $\mathsf{Cont}(W, Q)$ attaches the dyadic and regular-rational readbacks to those same windows.

Apply non-escape to exclude hidden routes. Since R contains no second window ledger, hidden selector, selected host limit, or ambient completeness coordinate, every tolerance read accepted by the packet is the T, W, Q read. □

Theorem 885.23 (Cauchy modulus refinement Real seal factorization)**.** *For every accepted* $\mathsf{CauchyModulusRefinem}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *factors through the displayed refinement and tolerance route*

$$U \longrightarrow V \longrightarrow T \longrightarrow W \longrightarrow Q \longrightarrow E.$$

Consequently E *cannot be accepted from a quotient stream, host real equality, selected limit, hidden selector, second meet row, or ambient completeness witness outside the packet.*

Proof. First bind the source of the seal route. Source-meet exactness places the refinement witness V downstream of the shared meet row U and the two source schedules.

Next bind the tolerance surface. Window tolerance exactness forces the selected-window and dyadic-tolerance data through T, W, Q.

The route $\mathsf{Cont}(Q, E)$ is the only displayed continuation into the $\mathsf{Real}^{\uparrow}$ seal row. Together with the componentwise transports in H and the provenance and naming rows P, N, this makes E a factor of the displayed U, V, T, W, Q spine rather than an independent Real-facing object. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal factorization`

Theorem 885.24 (Cauchy modulus refinement common source lock)**.** *For every accepted* $\mathsf{CauchyModulusRefinemen}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

any accepted refinement read keeps the source schedules M_0 *and* M_1 *locked to the same shared meet row* U *before the refinement witness row* V *is read. A consumer cannot read* V *from one source schedule alone, from a second meet row, or from an external modulus comparison not displayed by* R*.*

Proof. Start with source-meet exactness, Definition 885.21. It identifies the route to the refinement witness as

$$M_0, M_1 \longrightarrow U \longrightarrow V.$$

Use classifier transport to keep this route componentwise stable through H and C. The transports preserve both source schedules and the same shared meet row.

Finally apply non-escape, Definition 885.10. Since R carries no second meet row, hidden selector, external comparison, or ambient completeness coordinate, the common source lock is exactly the displayed M_0, M_1, U surface. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier common source lock`

Theorem 885.25 (Cauchy modulus refinement shared threshold transport)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the shared comparison and meet threshold is transported only through the displayed rows

$$M_0,\ M_1,\ U,\ V,\ T,\ H,\ C,\ P,\ N.$$

Thus no accepted threshold read may replace the two source schedules, the shared meet row, the refinement witness, the selector-budget row, the componentwise transports, the displayed continuation routes, the package provenance, or the local naming row by an external comparison, second meet, quotient stream, hidden selector, or host completeness witness.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier shared threshold transport`

Proof. Project the carrier of Definition 885.1. The packet displays exactly the two source schedules M_0, M_1, one shared meet row U, one refinement witness V, one selector-budget row T, one transport row H, one continuation row C, one provenance row P, and one local certificate row N.

Apply the source-meet-budget chain. It forces every accepted threshold read to move from M_0, M_1 through U, V, T before any finite selected window can be exposed.

Apply classifier transport. The componentwise hsame entries in H and the displayed Cont entries in C replay the same threshold through the named rows, while P and N authenticate the packet as the local $\mathsf{CauchyModulusRefinement}^{\uparrow}$ surface.

The carrier contains no external comparison, second meet, quotient stream, hidden selector, or host completeness coordinate. Hence the shared threshold can be transported only along the displayed rows. □

Theorem 885.26 (Cauchy modulus refinement selector budget totality)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the selector-budget row* T *is the only route from the refinement witness row* V *to the selected finite-window ledger* W *and the tolerance-readback ledger* Q*. Thus every selected-window read and every* $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback consumed by the refinement factors through*

$$V \longrightarrow T \longrightarrow W \longrightarrow Q.$$

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector budget totality`

Proof. Read window-tolerance exactness, Definition 885.22. It already forces every selected-window and dyadic-tolerance read through V, T, W, Q.

The Real seal factorization theorem then shows why this budget route is total for downstream consumers: the seal row E is reachable only after U, V, T, W, Q have been displayed.

Apply non-escape to remove alternate selectors and window ledgers. The carrier has one selector-budget row, one selected-window ledger, and one tolerance-readback ledger, so T exhausts the route from V to W, Q. □

Theorem 885.27 (Cauchy modulus refinement selector budget non-escape)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the selector-budget row* T *is the only route from the source-meet threshold into the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *window-readback surface. In particular, no hidden selector, quotient stream, selected host limit, or countable-choice coordinate can supply an accepted window, rational-readback, or dyadic-tolerance read for* R*.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector budget nonescape`

Proof. Start with window readback exhaustion. It identifies T, W, Q as the complete selected-window, regular-rational readback, and dyadic-tolerance surface of the packet.

Use source-meet exactness to bind the source threshold. The refinement witness V is reached only from the two source schedules through the shared meet row U, and the displayed continuation route then moves from V to T.

Apply non-escape to the remaining alternatives. Since the carrier has no hidden selector, quotient stream, selected host limit, or countable-choice coordinate, the route through T is the sole accepted handoff from the source-meet threshold into W and Q. □

Theorem 885.28 (Cauchy modulus refinement Real seal obligation surface)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the rows $U, V, T, W, Q, E, H, C, P, N$ *form the complete* $\mathsf{Real}^{\uparrow}$ *seal obligation surface for the refinement route. The surface contains the shared meet row, refinement witness, selector-budget row, finite windows, tolerance and readback ledger, Real seal, componentwise transports, displayed continuation routes, provenance, and local naming row, and it excludes quotient streams, host real equality, hidden selectors, selected limits, second meet rows, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal obligation surface`

Proof. First bind the source of the surface. Common source lock fixes M_0 and M_1 to the shared meet row U before the witness V is read.

Next bind the selected-window route. Selector-budget totality forces the only route from V to the selected windows and tolerance-readback ledger through T, W, Q.

Now apply Real seal factorization. It places E downstream of U, V, T, W, Q and keeps the seal route inside the displayed transport, continuation, provenance, and naming rows.

Finally use non-escape. Quotient streams, host real equality, hidden selectors, selected limits, second meet rows, and ambient completeness are absent from the carrier, so the listed rows are the whole Real-seal obligation surface. □

Theorem 885.29 (Cauchy modulus refinement Real seal consumer exhaustion)**.** *For every accepted* CauchyModulusRefinement$^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, every* Real$^{\uparrow}$ *or completion-facing consumer reaches the seal row* E *only after consuming the shared threshold, selector-budget, finite-window, rational-readback, dyadic-tolerance, transport, continuation, package, and local* NameCert *rows displayed by*

$$M_0, M_1, U, V, T, W, Q, H, C, P, N.$$

No accepted consumer may read E *directly from a quotient stream, selected limit, host real equality, hidden selector, second meet row, ambient completeness coordinate, or unbudgeted completion object.*

Proof. First apply Real seal factorization. The seal row E factors through the displayed route U, V, T, W, Q, E, so a Real-facing consumer reaches the seal only after the shared meet, refinement witness, selector budget, finite windows, and tolerance-readback ledger have been consumed.

Next apply Real seal refusal. A purported seal read that omits the source schedules, meet, witness, selector budget, windows, tolerances, readbacks, transports, routes, provenance, and local name is not an accepted carrier read.

Use window tolerance exactness to identify the finite-window, rational-readback, and dyadic-tolerance coordinates as T, W, Q. The same route attaches the selected StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readbacks, and DyadicRatCore$^{\uparrow}$ tolerance rows to the seal.

Finally apply non-escape. Quotient streams, selected limits, host real equality, hidden selectors, second meet rows, ambient completeness coordinates, and unbudgeted completion objects are absent from the carrier, so every accepted Real or completion-facing consumer must pass through the displayed rows before reading E. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal consumer exhaustion`

Theorem 885.30 (Cauchy modulus refinement obligation closure package)**.** *For every accepted* CauchyModulusRefinement$^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the carrier of Definition 885.1, the NameCert obligation rows of Definition 885.2, the source-meet-budget chain of Definition 885.11, window readback exhaustion of Definition 885.12, Real seal refusal of Definition 885.13, classifier transport of Definition 885.16, source-meet exactness of Definition 885.21, window tolerance exactness of Definition 885.22, Real seal factorization of Definition 885.23, common source lock of Definition 885.24, shared threshold transport of Definition 885.25, selector budget totality of Definition 885.26, selector budget non-escape of Definition 885.27, Real seal obligation surface of Definition 885.28, Real seal consumer exhaustion of Definition 885.29, and non-escape of Definition 885.10 jointly form the* obligation *surface for* CauchyModulusRefinement$^{\uparrow}$*.*

The package exports exactly the two CauchyModulus$^{\uparrow}$ *source schedules, shared* CauchyModulusMeet$^{\uparrow}$ *row,* CauchyModulusExtraction$^{\uparrow}$ *witness row,* RegularCauchySelectorBudget$^{\uparrow}$ *row, finite* StreamName$^{\uparrow}$ *window ledger,* DyadicRatCore$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *tolerance ledger,* Real$^{\uparrow}$ *seal row, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

Proof. Project the displayed packet R. The carrier and NameCert obligation theorem supply the finite row inventory and the five required local certificate clauses.

Read the classifier and source rows. Classifier transport keeps every accepted read on the componentwise hsame and displayed Cont routes, while source-meet exactness fixes V as the witness reached from M_0, M_1 through U.

Read the selected-window and Real-facing rows. Window tolerance exactness binds the tolerance surface to T, W, Q, and Real seal factorization places E after the shared meet, refinement witness, selector budget, windows, and tolerance ledger.

Use the intermediate obligations to expose the selector-budget route. Common source lock fixes M_0, M_1, U, shared threshold transport keeps the comparison and meet threshold on $M_0, M_1, U, V, T, H, C, P, N$, selector budget totality and selector budget non-escape make T the sole handoff into W, Q, and the two Real-seal obligations force every Real or completion-facing consumer through the displayed rows before E is read.

Finally combine these rows with non-escape. All excluded objects are absent from the carrier, so the assembled package is precisely the written obligation surface and no external Real-completeness or host-equality route remains. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier obligation closure package`

Theorem 885.31 (Cauchy modulus refinement primitive scope)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the exact primitive scope of the packet is the displayed BHist *carrier row* R*, the componentwise* hsame *transports stored in* H*, the displayed* Cont *route row* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *row* N*, together with the named sibling rows*

$\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusComparison}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{RegularCauchySe}$

No primitive outside these rows is part of the accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *surface.*

Proof. Project the carrier and NameCert obligations. The displayed packet supplies the BHist row, the componentwise hsame row, the Cont row, the Pkg row, and the local naming row, while Definition 885.2 lists the finite certificate clauses attached to those rows.

Bind the source and selector side. Source-meet exactness fixes the refinement witness to the route M_0, M_1, U, V, and selector-budget totality fixes every selected-window handoff to V, T, W, Q.

Bind the Real-facing side. Window-tolerance exactness identifies the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows as the selected tolerance surface, and Real seal factorization places the $\mathsf{Real}^{\uparrow}$ seal after the same route.

Finally apply Real seal consumer exhaustion and non-escape. Since the carrier has no quotient stream, selected limit, host real equality, hidden selector, second meet row, or ambient completeness coordinate, the displayed rows and named siblings are the whole primitive scope. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier primitive scope`

Theorem 885.32 (Cauchy modulus refinement sibling dependency lattice)**.** *Every accepted* $\mathsf{CauchyModulusRefinem}$ *packet consumes its sibling surfaces in the dependency order*

$\mathsf{CauchyModulusComparison}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$, Str

The comparison rows bind the two source schedules, the meet row supplies the shared source threshold, the extraction row supplies the refinement witness, the selector-budget row selects the finite windows, the $\mathsf{StreamName}^{\uparrow}$ *row records those windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows attach tolerance and rational readback data, and the* $\mathsf{Real}^{\uparrow}$ *row seals the downstream Real surface.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier sibling dependency lattice`

Proof. Start with the source-meet chain. Source-meet exactness and common source lock place the comparison and meet rows before the extraction witness V can be read.

Next expose the selected-window route. Selector-budget totality makes T the sole handoff from V into W, Q, and window-tolerance exactness identifies W as the $\mathsf{StreamName}^{\uparrow}$ window ledger and Q as the $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ tolerance-readback ledger.

Now read the Real seal. Real seal factorization places E after U, V, T, W, Q, and Real seal consumer exhaustion forces every Real or completion-facing consumer through the same sibling order before the seal can be consumed.

Non-escape removes all alternate lattices. The packet carries no second meet row, hidden selector, quotient stream, selected limit, host equality, or ambient completeness coordinate, so the dependency order written above is the accepted sibling lattice. □

Theorem 885.33 (Cauchy modulus refinement L10 sibling route)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

any Phase Real and Completion consumer of the refinement reads the L10 route through

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

in that order after the $\mathsf{CauchyModulusComparison}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, *and* $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$ *rows have been consumed. Such a consumer receives no quotient stream, selected limit, host real equality, hidden selector, or ambient completeness datum from the accepted packet.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier l10 sibling route`

Proof. Start with the sibling dependency lattice of Definition 885.32. It places comparison, meet, extraction, and selector budget before the four downstream rows and orders those rows as $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The finite-window handoff is the route supplied by Definition 885.22. It identifies the selected-window and tolerance-readback segment as $T \longrightarrow W \longrightarrow Q$, so the consumer cannot reach the dyadic or regular-rational readback surface before passing through the selector-budget and window rows.

Now apply Real seal factorization, Definition 885.23. The seal row E sits after Q, so the $\mathsf{Real}^{\uparrow}$ read is downstream of the StreamName, DyadicRatCore, and RegSeqRat route rather than an independent completion input.

Finally use non-escape, Definition 885.10. Quotient streams, selected limits, host real equality, hidden selectors, and ambient completeness data are absent from the carrier, so the L10 route above is the reusable handoff available to Phase Real and Completion consumers. □

Theorem 885.34 (Cauchy modulus refinement completion boundary)**.** *No* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet may read quotient streams, selected limits, host real equality, hidden selectors, second meet rows, or ambient completeness outside the displayed packet. Such a consumer must factor through*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

and through the sibling dependency lattice of Definition 885.32.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier completion boundary`

Proof. First bind the route to the Real seal. Real seal factorization places E downstream of the shared meet, refinement witness, selector budget, selected windows, and tolerance-readback ledger.

Use Real seal consumer exhaustion to control downstream reads. A Real or completion-facing consumer reaches E only after consuming the displayed source, meet, witness, budget, window, tolerance, transport, route, provenance, and naming rows.

Use the primitive-scope theorem and sibling dependency lattice to identify the whole surface available to that consumer. They restrict the primitive rows and sibling rows to the displayed BHist, hsame, Cont, Pkg, NameCert, comparison, meet, extraction, selector-budget, StreamName, DyadicRatCore, RegSeqRat, and Real surfaces.

Finally apply non-escape. The forbidden quotient, selected-limit, host-equality, hidden-selector, second-meet, and ambient-completeness objects are absent from the packet, so no completion-facing read may obtain them outside the displayed route. □

Theorem 885.35 (Cauchy modulus refinement BHist source scope)**.** *For every accepted* CauchyModulusRefinement *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the rows $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ *are finite* BHist*-facing rows over* CauchyModulus$^{\uparrow}$, CauchyModulusMeet$^{\uparrow}$, CauchyModulusExtraction$^{\uparrow}$, RegularCauchySelectorBudget$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert*. No quotient stream, host-completeness object, ambient completeness coordinate, selected limit, hidden selector, or host real equality coordinate belongs to the accepted source scope.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier bhist source scope`

Proof. Project the displayed packet through the carrier. The carrier row gives the finite BHist spine $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, and the NameCert obligations attach the local naming clause to exactly that spine.

Bind the primitive side. Primitive scope identifies the componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert row, while the sibling dependency lattice identifies the named CauchyModulus$^{\uparrow}$, meet, extraction, selector-budget, StreamName, dyadic, rational, and Real sibling rows.

Use the completion boundary and non-escape to remove external sources. Since quotient streams, selected limits, host real equality, hidden selectors, second meet rows, host-completeness objects, and ambient completeness coordinates are absent from the carrier, no accepted source row can be read outside the displayed BHist-facing surface. □

Theorem 885.36 (Cauchy modulus refinement continuation route scope)**.** *For every accepted* CauchyModulusRefinement$^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the displayed continuation order*

$$M_0, M_1 \longrightarrow U \longrightarrow V \longrightarrow T \longrightarrow W \longrightarrow Q \longrightarrow E$$

is the only consumer route for selector-window and Real$^{\uparrow}$*-seal reads. A consumer of selected windows, rational readbacks, dyadic tolerances, or the Real seal must therefore pass through the source schedules, shared meet, extraction witness, selector-budget row, finite-window ledger, tolerance-readback ledger, and seal row in this order.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier cont route scope`

Proof. Start with the source route. Source-meet exactness fixes the witness row V as downstream of M_0, M_1 through U, so a consumer cannot reach the refinement witness without first reading the two source schedules and the shared meet.

Next read the selected-window surface. Window readback exhaustion and selector budget totality place the selector handoff at T and the finite-window and tolerance-readback rows at W, Q.

Finally read the seal. Real seal factorization places E after U, V, T, W, Q, and Real seal consumer exhaustion prevents a downstream consumer from reaching the seal by a route that omits those rows. Non-escape removes quotient-stream, selected-limit, host-equality, hidden-selector, second-meet, and ambient-completeness alternatives, so the displayed order is the only accepted consumer route. □

Theorem 885.37 (Cauchy modulus refinement NameCert scope)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *scope is exhausted by carrier admission, classifier transport, source-meet exactness, selector-budget and window-tolerance exactness, and* $\mathsf{Real}^{\uparrow}$*-seal non-escape. Equivalently, the certificate can name only the admitted finite* BHist *rows, their componentwise* hsame *transports, the displayed* Cont *routes, the* Pkg *provenance row, and the Real-facing seal route certified by the obligation closure package.*

Proof. First admit the named object. The carrier and NameCert obligation theorem bind the local certificate to the finite packet rows and require the naming row to travel with the displayed BHist, hsame, Cont, and Pkg fields.

Next transport the classifier through the source and window rows. Classifier transport keeps accepted reads on the displayed transports and routes, source-meet exactness fixes the M_0, M_1, U, V source-meet witness, and window tolerance exactness fixes the T, W, Q selector, window, dyadic-tolerance, and rational-readback surface.

Finally seal the Real-facing edge. The BHist source scope supplies the permitted primitive rows, the continuation route scope supplies the only consumer order into E, and the obligation closure package assembles those rows with Real-seal factorization and non-escape. Thus the local NameCert scope has no remaining quotient stream, hidden selector, selected limit, host equality, ambient completeness, or external completion coordinate to name. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier namecert scope`

The closest siblings are $\mathsf{CauchyModulusComparison}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$, and $\mathsf{RegularCauchyLimitTransport}^{\uparrow}$. The packet is composite because it consumes their rows as coordinates rather than presenting an atomic independent carrier. A later Lean TasteGate module should still provide $\mathsf{Nontrivial}$ and $\mathsf{FieldFaithful}$ instances over the packet fields, since the finite carrier separates the comparison, meet, witness, budget, window, ledger, seal, transport, route, provenance, and local certificate coordinates.

Theorem 885.38 (Cauchy modulus refinement budget-selector source lock)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

every accepted refinement route reads the source schedules, shared meet row, extraction witness, and selector budget

$$M_0, M_1, U, V, T$$

before it reads the selected window ledger W, tolerance-readback ledger Q, or Real seal row E. Thus the budget selector is source-locked to the displayed CauchyModulusMeet$^\uparrow$, CauchyModulusExtraction$^\uparrow$, *and* RegularCauchySelectorBudget$^\uparrow$ *rows before any downstream* StreamName$^\uparrow$, DyadicRatCore$^\uparrow$, RegSeqRat$^\uparrow$, *or* Real$^\uparrow$ *consumer can be served.*

Proof. Project the carrier of Definition 885.1. The displayed tuple places M_0, M_1, U, V, T before the window, tolerance, readback, and seal rows, and no second source, second meet, hidden selector, or host-completeness coordinate appears in the packet.

Apply source-meet exactness from Definition 885.21. It forces the witness row V to be read only through M_0, M_1, U, so a selected-window route cannot choose its source after the fact.

Next apply selector-budget totality from Definition 885.26. The selector budget row T is the sole route from V into the selected finite-window and tolerance surface.

Finally use window-tolerance exactness from Definition 885.22. It identifies T, W, Q as the exact selected-window and dyadic-tolerance route, so every later read of W, Q, E is already locked to M_0, M_1, U, V, T. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementBudgetSelectorSourceLock`

Theorem 885.39 (Cauchy modulus refinement diagonal-consumer boundary)**.** *Any* Real$^\uparrow$ *consumer or diagonal-completion consumer of an accepted* CauchyModulusRefinement$^\uparrow$ *packet factors through the displayed* BHist, hsame, Cont, Pkg, NameCert, CauchyModulusMeet$^\uparrow$, CauchyModulusExtraction$^\uparrow$, RegularCauchySelectorBudget$^\uparrow$, StreamName$^\uparrow$, DyadicRatCore$^\uparrow$, RegSeqRat$^\uparrow$, *and* Real$^\uparrow$ *rows of*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

No such consumer may read a quotient stream, selected limit, host real equality, hidden selector, second meet row, side channel completion object, or ambient completeness coordinate outside that displayed route.

Proof. Start with the completion boundary of Definition 885.34. It already requires every Real or completion-facing consumer to factor through the displayed packet and the sibling dependency lattice before reading the seal.

Use the BHist source scope and continuation route scope, Definition 885.35 and Definition 885.36. These theorems identify the primitive rows as the finite BHist packet, componentwise hsame, displayed Cont, Pkg, NameCert, and the ordered consumer route from the source schedules to E.

Then apply the budget-selector source lock. It places M_0, M_1, U, V, T before the selected-window and tolerance rows, so a diagonal consumer reaches W, Q, E only through the same source-locked route.

Finally apply non-escape from Definition 885.10. Since all forbidden quotient, selected-limit, host-equality, hidden-selector, second-meet, and ambient-completeness rows are absent from the carrier, the displayed rows exhaust the diagonal-consumer boundary. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier diagonal consumer boundary`

Theorem 885.40 (Cauchy modulus refinement root-unblock package)**.** *The root-unblock obligation package for downstream Real-completion consumers of* CauchyModulusRefinement$^\uparrow$ *is exactly the conjunction of the local* NameCert *scope, the budget-selector source lock, and the diagonal-consumer boundary. An accepted downstream route may cite* CauchyModulusRefinement$^\uparrow$ *only through the rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

and the sibling CauchyModulusMeet$^{\uparrow}$, CauchyModulusExtraction$^{\uparrow}$, RegularCauchySelectorBudget$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *surfaces displayed by those rows.*

Proof. First use Definition 885.37. It binds the local naming certificate to carrier admission, classifier transport, source-meet exactness, selector-budget and window-tolerance exactness, and Real-seal non-escape.

Next use Definition 885.38. This supplies the source-lock portion of the package by placing M_0, M_1, U, V, T before W, Q, E.

Finally use Definition 885.39. It supplies the downstream Real and diagonal-completion boundary, excluding quotient streams, selected limits, host real equality, hidden selectors, side channel completion objects, second meet rows, and ambient completeness.

The three clauses use the same displayed carrier and the same sibling rows. Therefore they assemble one root-unblock package rather than three independent routes, and every downstream consumer must cite that package through the displayed finite packet. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root unblock package`

Theorem 885.41 (Cauchy modulus refinement diagonal budget cofinality)**.** *For every accepted* CauchyModulusRefinement$^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

every diagonal Real-completion consumer that has passed through the shared-meet and selector-budget rows factors through a cofinal finite budget route before reaching the Real$^{\uparrow}$ *seal. The route uses the* CauchyModulus$^{\uparrow}$, CauchyModulusMeet$^{\uparrow}$, CauchySharedTailModulus$^{\uparrow}$, RegularCauchySelectorBudget$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows displayed by the packet, and it exports no choice-selected tail, quotient stream, or ambient completeness theorem.*

Proof. Begin with source-meet exactness from Definition 885.21. It binds the two source modulus rows and the shared meet row to the refinement witness before any selector or Real-facing consumer can be read.

Apply selector budget totality from Definition 885.26. The selector row T supplies the finite budget route into the selected-window and tolerance-readback rows, so a diagonal consumer receives a cofinal finite budget before it can ask for the Real seal.

Next use Real seal factorization and the diagonal-consumer boundary, Definition 885.23 and Definition 885.39. These results force every Real-completion consumer through $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ and through the displayed BHist, hsame, Cont, Pkg, NameCert, CauchyModulus$^{\uparrow}$, CauchyModulusMeet$^{\uparrow}$, CauchySharedTailModulus$^{\uparrow}$, RegularCauchySelectorBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ surfaces.

Finally use the root-unblock package of Definition 885.40. The package assembles the local NameCert scope, budget-selector source lock, and diagonal boundary into one route, so no choice-selected tail, quotient stream, or ambient completeness theorem is exported by the accepted packet. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier diagonal budget cofinality terminal route`

Theorem 885.42 (Cauchy modulus refinement common-refinement selector lock)**.** *For every accepted* CauchyModulusRefinement$^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

any Real-completion consumer preserving the common meet row U, extraction row V, selector-budget row T, finite-window row W, dyadic ledger Q, and Real seal row E must read the same finite common-refinement route before it reaches $\mathsf{Real}^{\uparrow}$*. The packet makes no alternate selected tail, quotient stream, second meet row, or ambient completeness coordinate available to that consumer.*

Proof. Begin with source-meet exactness from Definition 885.21. It identifies the common meet row U as the unique displayed meet through which the two source moduli M_0, M_1 can reach the extraction row V.

Next apply selector-budget totality from Definition 885.26. The row T routes the extraction row into the finite-window and tolerance surface W, Q, so a Real-completion consumer preserving U, V, T, W, Q preserves the same finite selector budget.

Use Real-seal factorization from Definition 885.23 and the diagonal-budget cofinality route of Definition 885.41. These place the Real seal row E after the same cofinal finite route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally repack the route through the structural rows of R. The BHist carrier, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert row name only the preserved rows $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$. Since no other row is exported, there is no alternate selected tail, quotient stream, second meet row, or ambient completeness coordinate to read. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier common refinement selector lock`

Theorem 885.43 (Cauchy modulus refinement RealObservationBudget handoff)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

any $\mathsf{RealObservationBudget}^{\uparrow}$ *request that uses the same selected finite* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback ledger, and* $\mathsf{Real}^{\uparrow}$ *seal row factors through*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

before any Real-facing observation is consumed. The handoff exports no quotient stream, selected limit, host real equality, hidden selector, second meet row, ambient completeness coordinate, or unbudgeted observation selector.

Proof. First apply the budget-selector source lock of Definition 885.38. It places the source schedules, shared meet row, extraction witness, and selector budget in the prefix M_0, M_1, U, V, T before the selected finite-window, tolerance-readback, or Real-seal rows can be read.

Next use window readback exhaustion and diagonal budget cofinality, Definition 885.12 and Definition 885.41. These bind the selected $\mathsf{StreamName}^{\uparrow}$ windows, dyadic tolerance rows, and $\mathsf{RegSeqRat}^{\uparrow}$ readback ledger to T, W, Q, E, and they route every diagonal Real-completion consumer through the displayed cofinal finite budget before the $\mathsf{Real}^{\uparrow}$ seal is observed.

Finally apply the completion boundary and non-escape, Definition 885.34 and Definition 885.10. The completion boundary keeps the observation request on the displayed packet and sibling route, while non-escape removes quotient streams, selected limits, host real equality, hidden selectors, second meet rows, ambient completeness coordinates, and unbudgeted observation selectors from the exported surface. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real observation budget handoff`

Theorem 885.44 (Cauchy modulus refinement RealLimitUniqueness handoff)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

any $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$*-facing consumer preserving the same selected finite* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal row must first factor through*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

and then through the two-seal packet rows of chapter 1039. The handoff exports no selected host limit, quotient stream equality, hidden selector, second meet, or ambient completeness row.

Proof. Start with the RealObservationBudget handoff of Definition 885.43. It binds the selected $\mathsf{StreamName}^{\uparrow}$ windows, dyadic tolerance rows, $\mathsf{RegSeqRat}^{\uparrow}$ readback ledger, and $\mathsf{Real}^{\uparrow}$ seal row to the displayed refinement packet before any Real-facing observation is consumed.

Apply the common-refinement selector lock of Definition 885.42. The consumer preserving those rows must therefore keep the same source moduli, common meet, extraction row, selector budget, finite-window route, tolerance ledger, and Real seal row in the order $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$.

Finally use the RealLimitUniquenessSeal public route theorem Definition 1039.27. Its two-seal surface exposes only the two $\mathsf{CauchyLimitSeal}^{\uparrow}$ rows, shared comparison row, finite window, dyadic ledger, $\mathsf{Real}^{\uparrow}$ classifier row, uniqueness handoff, transports, replay, provenance, and local name. Since neither packet exports a selected host limit, quotient stream equality, hidden selector, second meet, or ambient completeness row, the consumer factors through the displayed refinement route and then through the two-seal packet. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real limit uniqueness handoff`

Definition 885.45 (Cauchy modulus refinement L10 face-status pullback record)**.** *For an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the L10 face-status pullback record is the ordered four-face product of the local closurestatus, formalstatus, leantarget, and bridgestatus rows read from $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *along the route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

It contains no aggregate formalstatus, aggregate bridge row, selected limit, quotient stream, countable-choice row, or ambient completion coordinate.

Lean4 (definition) `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementL10FaceStatusPullbackReco`

Theorem 885.46 (Cauchy modulus refinement four-face status objectwise pullback)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet routed to a Real- or completion-facing consumer through the L10 face-status pullback record of Definition 885.45 along the displayed handoff rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N,$$

the consumer pulls back only the four local status records of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*. The refinement route contributes no aggregate formal-status coordinate, no aggregate bridge row, no selected limit, no quotient stream, and no ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier four face status objectwise pullback`

Proof. First use the RealObservationBudget handoff of Definition 885.43. It routes every accepted Real-facing observation request through the selected $\mathsf{StreamName}^{\uparrow}$ windows, dyadic tolerance rows, $\mathsf{RegSeqRat}^{\uparrow}$ readback ledger, and $\mathsf{Real}^{\uparrow}$ seal row of the displayed packet.

Next apply the RealLimitUniqueness handoff of Definition 885.44. The same route is preserved when the consumer continues to the two-seal uniqueness surface, and the packet still exports no selected host limit, quotient stream equality, hidden selector, second meet, or ambient completeness row.

Now apply Definition 38.471. The Real and Completion audit read is therefore the product of the local $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ face records, not a status value supplied by the refinement route.

Finally use Definition 38.833. It keeps formal-status, theory-closure, and bridge-status data attached to the four displayed faces, so the accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ packet cannot fuse them into an aggregate row or reintroduce the excluded completion coordinates. □

Corollary 885.47 (Cauchy modulus refinement diagonal-budget cofinality determinacy)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

fix the local shared-meet row, selector-budget row, selected finite $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal row displayed by* R*. Every accepted* $\mathsf{RealLimitUniquenessSeal}^{\uparrow}$*-facing diagonal-budget consumer use that reports a route selection, normal-form readback, or exactness decision must report the one named by the chapter: the finite route through*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

and then through the two-seal packet rows of chapter 1039. No alternate hidden coordinate, duplicate classifier source, selected host limit, quotient stream equality, hidden selector, second meet, or ambient completeness row can supply a different accepted route, normal form, or exactness decision.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier diagonal budget cofinality determinacy`

Proof. Start with diagonal budget cofinality, Definition 885.41. Once the shared-meet and selector-budget rows have been read, every diagonal Real-completion consumer is already on the cofinal finite budget route through $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ and through the displayed $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{CauchySharedTailModulus}^{\uparrow}$, $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert surfaces. That route exports no choice-selected tail, quotient stream, or ambient completeness theorem.

Now apply the RealLimitUniqueness handoff, Definition 885.44. A consumer that preserves the same selected finite windows, dyadic tolerance ledger, regular readback, and Real seal must first factor through the displayed refinement packet and only then through the two-seal uniqueness packet. The handoff leaves no selected host limit, quotient stream equality, hidden selector, second meet, or ambient completeness row for the consumer to read.

Fix the displayed local rows. A reported route selection is accepted only after the cofinal finite route has supplied the meet, extraction witness, selector budget, selected windows, tolerance

ledger, readback, Real seal, transport, replay, provenance, and local name. A reported normal-form readback is the same ordered read, because the RealLimitUniqueness-facing continuation consumes the fixed windows, ledger, readback, and seal before it reaches the two-seal packet. A reported exactness decision is therefore the decision that the consumer use is accepted exactly when it factors through those fixed rows and the downstream two-seal rows.

It remains to rule out duplicate sources for that decision. Any proposed duplicate source is either one of the displayed rows, in which case it is already identified by the fixed cofinal route and the handoff, or it is an unlisted coordinate. The cofinality theorem rejects unlisted diagonal-budget coordinates, and the handoff rejects unlisted uniqueness-facing coordinates. Hence every accepted consumer-facing use chooses the same finite route, normal form, and exactness decision named by the chapter. □

Theorem 885.48 (Cauchy modulus refinement common-window selector extraction)**.** *Let* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet whose source schedules* M_0, M_1*, shared meet* U*, refinement witness* V*, and selector-budget row* T *are the displayed rows of the carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing or diagonal-completion consumer that reaches the selected-window rows must extract the same finite-window and tolerance route* W, Q *through* T*. No hidden selector, quotient stream, selected limit, host real equality, second meet row, or ambient completeness coordinate may supply a competing selected-window route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCommonWindowSelectorExtraction`

Proof. First lock the common source. Apply common source lock and shared threshold transport, Definition 885.24 and Definition 885.25, to force every accepted read of U and V through the same M_0, M_1 schedules.

Next extract the selected-window route. Selector-budget totality, Definition 885.26, makes T the sole admitted route from V to the selected finite-window surface, and window-tolerance exactness, Definition 885.22, identifies that surface with the displayed W, Q rows.

Finally pass to downstream consumers. The diagonal-consumer boundary, Definition 885.39, says that Real-facing and diagonal-completion reads factor through the displayed sibling rows and cannot import quotient streams, selected limits, host real equality, hidden selectors, second meet rows, side channel completion objects, or ambient completeness. Hence the consumer can extract W, Q only by the common route through T. □

Theorem 885.49 (Cauchy modulus refinement Real-completeness handoff)**.** *Every downstream Real-completeness consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *refinement packet must read the shared meet row, extraction witness, selector budget, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal in the displayed order*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

before using the completion boundary. The consumer may cite the packet only through the shared $\mathsf{CauchyModulusMeet}^{\uparrow}$*,* $\mathsf{CauchyModulusExtraction}^{\uparrow}$*,* $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows carried by that finite route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementRealCompletenessHandoff`
`semantic name certificate`

Proof. Begin with the root-unblock package of Definition 885.40. It packages the local NameCert scope, budget-selector source lock, and diagonal-consumer boundary as one accepted route for downstream Real-completion consumers.

Use the diagonal-consumer boundary from Definition 885.39. It forces any Real or diagonal-completion read through the displayed sibling rows before the seal row can be consumed.

Next apply Real-seal factorization and window-tolerance exactness, Definition 885.23 and Definition 885.22. These identify the selected windows, dyadic tolerance rows, regular readbacks, and Real seal as the same ordered route after M_0, M_1, U, V, T.

The completion boundary is therefore reached only after the displayed meet, extraction, selector, window, tolerance, readback, and seal rows have been read. Since the packet has no quotient stream, selected host limit, host real equality, hidden selector, side channel completion object, second meet row, or ambient completeness coordinate, the stated handoff exhausts the Real-completeness consumer surface. □

Theorem 885.50 (Cauchy modulus refinement root window-selector totality)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E,$ be an accepted* CauchyModulusRefinement$^{\uparrow}$ *packet. Every downstream read of a selected finite window or dyadic tolerance row factors through the root route*

$$M_0, M_1, U, V, T$$

before it reaches W or Q. Thus the selector-budget row T is the total root selector for the displayed StreamName$^{\uparrow}$ *and* DyadicRatCore$^{\uparrow}$ *window surface used by downstream* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *consumers.*

Proof. First read the root-unblock package of Definition 885.40. It permits downstream Real-completion consumers to cite the refinement packet only through the displayed finite route.

Next apply selector-budget totality from Definition 885.26. This makes T the admitted selector from the extraction witness V to the selected finite-window and dyadic-tolerance surface.

Finally use common-window selector extraction from Definition 885.48. It identifies every downstream selected-window read with the same W, Q route through T, so no consumer can choose a separate selector after reading M_0, M_1, U, V. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementRootWindowSelectorTotality`

Theorem 885.51 (Cauchy modulus refinement root readback stability)**.** *For an accepted* CauchyModulusRefinemen *packet $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$, the selected-window and tolerance readbacks W, Q are stable under the componentwise* hsame *row H and the displayed route row C. Any readback consumed by* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *or* Real$^{\uparrow}$ *must use the displayed rows W, Q, H, C, P, N, with no hidden selector, quotient stream, selected host limit, or ambient completion coordinate.*

Proof. Begin with classifier transport from Definition 885.16. It says componentwise hsame and the displayed Cont route carry accepted refinement packets without adding a new coordinate.

Use window-readback exhaustion from Definition 885.12. The selected-window and tolerance readbacks are precisely the displayed W, Q rows attached to the packet.

Now combine that exhaustion with root window-selector totality. Since every selected-window read reaches W, Q only through M_0, M_1, U, V, T, transport along H and C preserves the same root readback route.

The non-escape boundary of Definition 885.10 rules out hidden selector, quotient stream, selected host limit, host real equality, side channel completion object, second meet row, and ambient completeness coordinates. Therefore the displayed sibling rows exhaust the readback surface. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinement root readback stability`

Theorem 885.52 (Cauchy modulus refinement root Real seal exhaustion)**.** *Every Real-completion consumer of an accepted* CauchyModulusRefinement$^{\uparrow}$ *packet reaches the Real seal row E only through the displayed root route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

In particular, the consumer cannot bypass the selector, selected-window readback, componentwise transport, route, package, or local naming rows by appealing to a quotient stream, selected host limit, hidden selector, side channel completion object, second meet row, host real equality, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root real seal exhaustion`

Proof. Start with the Real-completeness handoff of Definition 885.49. It places the meet, extraction, selector, finite-window, tolerance, readback, and seal rows before any completion-facing use.

Apply the diagonal-consumer boundary from Definition 885.39. This forces Real-completion and diagonal-completion consumers to factor through the displayed sibling dependency lattice and the local BHist, hsame, Cont, Pkg, and NameCert rows.

Finally combine root readback stability with non-escape, Definition 885.51 and Definition 885.10. The W, Q readbacks and the seal row E stay on the same displayed route under H and C, and no forbidden completion coordinate remains available. Hence $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ exhaust the root Real-seal surface. □

Theorem 885.53 (Cauchy modulus refinement root-threshold scope)**.** *Every accepted* CauchyModulusRefinement$^{\uparrow}$ *refinement packet routes its root threshold scope through the displayed finite rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

No Real- or Completion-facing consumer may replace that root route by a second meet, hidden selector, selected host limit, quotient stream, host real equality, side-channel completion row, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root threshold scope`

Proof. Read the carrier definition and the root-unblock package of Definition 885.40. Together they identify the only root threshold inventory as the source schedules, meet, extraction, selector-budget, selected-window, tolerance, seal, transport, route, provenance, and local naming rows.

Apply common-window selector extraction from Definition 885.48. It forces W, Q to be read from the same selector-budget route T after M_0, M_1, U, V.

Finally use the Real-completeness handoff of Definition 885.49. The downstream seal read arrives only after the displayed root route, so the listed excluded coordinates have no packet row from which to enter. □

Theorem 885.54 (Cauchy modulus refinement shared-tail handoff)**.** *Every shared-tail handoff exported by an accepted* CauchyModulusRefinement$^{\uparrow}$ *packet factors through the existing* CauchySharedTailModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *surfaces. The handoff reads the same selector-budget, window, tolerance, readback, and seal route T, W, Q, E already displayed by the packet, together with H, C, P, N.*

Proof. Begin with the root-unblock package. It allows a downstream Real-completion consumer to cite the refinement packet only through the displayed finite rows and their named sibling surfaces.

Use common-window selector extraction to reach W, Q through T. The shared-tail side can therefore consume only the finite window and tolerance rows supplied by the same route.

The Real-completeness handoff then carries those rows into the $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{Real}^{\uparrow}$ seal surface, with $\mathsf{CauchySharedTailModulus}^{\uparrow}$ serving as the shared-tail threshold sibling. No additional tail witness or host completion row is exported. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementSharedTailHandoff`

Theorem 885.55 (Cauchy modulus refinement shared-tail selector-window determinacy)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Suppose two accepted refinement routes expose the same shared-tail modulus sibling, the same selector-budget row T, the same selected* $\mathsf{StreamName}^{\uparrow}$ *window W, the same dyadic tolerance row Q, and the same* $\mathsf{Real}^{\uparrow}$ *seal E. Then they determine the same Real-completion consumer surface through the displayed* BHist *route, componentwise* hsame *row H, displayed* Cont *row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *row N.*

No quotient stream, hidden selector, selected host limit, second meet row, or ambient completeness coordinate separates the two routes once the shared-tail sibling and the T, W, Q, E rows agree.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementSharedTailSelectorWindowDetermina`

Proof. First force the selector window. Root window-selector totality, Definition 885.50, makes both routes pass through M_0, M_1, U, V, T before either route can expose the selected $\mathsf{StreamName}^{\uparrow}$ window W and dyadic tolerance row Q.

Next apply root readback stability, Definition 885.51. Agreement on the selected window and tolerance makes the readback travel through the same displayed H and C rows rather than through a detached stream representative.

Use shared-tail handoff, Definition 885.54. The common shared-tail modulus sibling carries the same selector-budget, window, tolerance, RegSeqRat readback, and Real seal route into T, W, Q, E, H, C, P, N.

Finally combine Real-consumer coverage, Definition 885.56, with selector-budget RegSeqRat Real-seal determinacy, Definition 885.61. With T, W, Q, E fixed, the Real-completion consumer surface is fixed through H, C, P, N, and the excluded quotient, selector, host-limit, meet, and completeness coordinates have no row in the accepted packet. □

Theorem 885.56 (Cauchy modulus refinement Real-consumer coverage)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet reads only the displayed selector-budget, window, readback, and seal route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Thus the Real-completion consumer surface is exhausted by the carrier route, the common-window selector extraction, and the Real-completeness handoff.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real consumer coverage`

Proof. Project the accepted carrier. The consumer-visible rows are exactly the displayed finite tuple and the structural rows H, C, P, N that transport, replay, package, and name it.

Apply Definition 885.48. This removes any competing selected-window path by requiring W, Q to be obtained through the same T route.

Finally apply Definition 885.49. It orders the meet, extraction, selector, finite-window, tolerance, readback, and seal rows before any Real-completion use. Therefore every consumer read is covered by the displayed route and no hidden selector, quotient stream, selected limit, host equality, or ambient completeness coordinate remains. □

Theorem 885.57 (Cauchy modulus refinement root terminal selector readback)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Suppose two accepted terminal reads of R face either* $\mathsf{Real}^{\uparrow}$ *or Completion consumers. The two reads determine the same completed selector-readback consumer surface exactly when they agree on the displayed selector-budget row T, the selected* $\mathsf{StreamName}^{\uparrow}$ *window W, the dyadic tolerance and readback row Q, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal E, the componentwise* hsame *transport row H, the displayed* Cont *route C, the* Pkg *provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *row N.*

The determinacy is internal to the displayed sibling surfaces $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Quotient streams, selected host limits, host real equality, second meet rows, hidden selectors, and ambient completeness coordinates are not coordinates of the accepted terminal packet and cannot distinguish the two reads.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementRootTerminalSelectorReadback`

Proof. First force the terminal reads onto the common selector spine. Common-window selector extraction, Definition 885.48, and root window-selector totality, Definition 885.50, make each accepted terminal read pass through the same selector-budget row T before it can expose W or Q.

Next identify the readback rows. Root readback stability, Definition 885.51, carries agreement on the selected $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row to the same $\mathsf{RegSeqRat}^{\uparrow}$ readback through the componentwise H transport and displayed C route.

Then seal the completion-facing surface. Root Real seal exhaustion, Definition 885.52, places the $\mathsf{Real}^{\uparrow}$ seal E after the displayed readback rows, and shared-tail selector-window determinacy, Definition 885.55, identifies the selector-window surface once T, W, Q, E, H, C, P, N agree.

For the forward direction, equal completed selector-readback surfaces expose the same terminal rows by Real-consumer coverage, Definition 885.56. Hence the two reads agree on T, W, Q, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, E, H, C, P, N, and the local naming row.

For the reverse direction, agreement on those displayed rows reconstructs the same accepted route across $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The same cited coverage and exhaustion results exclude quotient streams, selected host limits, host real equality, second meet rows, hidden selectors, and ambient completeness coordinates, so no off-route datum remains from which a second terminal consumer surface can be read. □

Theorem 885.58 (Cauchy modulus refinement and diagonal L10 consumer spine comparison)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet, and let K be an accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *packet. Suppose the two packets expose the same* $\mathsf{StreamName}^{\uparrow}$ *window, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the same* $\mathsf{Real}^{\uparrow}$ *seal, the same* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary, and the same* BHist, *componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *support rows. Then every Phase Real and Completion consumer reads the same displayed L10 selector spine from R and from K.*

The comparison is internal to the shared StreamName, DyadicRatCore, RegSeqRat, Real, CauchyLimitSeal, and structural support rows. Quotient streams, selected host limits, host real equality, countable choice, ambient completeness, alternate Cauchy witnesses, and second selector sources cannot distinguish the CauchyModulusRefinement route from the DiagonalLimitCompatibility route once those rows agree.

Proof. First identify the CauchyModulusRefinement side. The root terminal selector readback theorem, Definition 885.57, makes every terminal Real or Completion read pass through the displayed selector-budget, window, tolerance, readback, Real-seal, transport, replay, provenance, and local naming rows. Real-consumer coverage, Definition 885.56, then exhausts the consumer surface by the same route.

Next identify the DiagonalLimitCompatibility side. Root readback exactness, Definition 646.127, exposes the StreamName window, RegSeqRat readback, DyadicRatCore ledger, RealUp seal row, and CauchyLimitSeal boundary as the root readback surface. Root selector terminality and root L10 spine exhaustion, Definition 646.132 and Definition 646.130, make that surface terminal for the same Phase Real and Completion consumers.

Now use the shared-row hypothesis. The StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback, Real seal, CauchyLimitSeal boundary, BHist support, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row are the same on both packets, so the two terminal surfaces display the same L10 selector spine.

Finally apply the non-escape clauses on both sides. The CauchyModulusRefinement readback theorem rules out quotient streams, selected host limits, host real equality, hidden selectors, and second meet rows, while the DiagonalLimitCompatibility terminality and exhaustion results rule out quotient streams, selected limits, host real equality, countable-choice selectors, ambient completeness, and second completion witnesses. No remaining carrier coordinate can separate the two routes. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier l10 consumer spine comparison`

Theorem 885.59 (Cauchy modulus refinement terminal-spine choice refusal)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H$ be an accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ packet. Suppose an accepted terminal selector read agrees on the displayed selector-budget row T, the selected $\mathsf{StreamName}^{\uparrow}$ window W, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row Q, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, the $\mathsf{Real}^{\uparrow}$ seal E, the structural BHist route, the componentwise hsame row H, the displayed Cont row C, the Pkg provenance row P, and the local $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ row N.*

Then no countable-choice row, quotient stream, host real equality, ambient completeness coordinate, or alternate selector source can distinguish the Real-completion consumer surface determined by that terminal read.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementTerminalSpineChoiceRefusal`

Proof. First place the terminal selector read on the displayed spine. The root terminal selector readback theorem, Definition 885.57, says that agreement on T, W, Q, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, E, H, C, P, N, and the local naming row determines the same completed selector-readback consumer surface.

Next seal the Real-facing end of the route. Root Real seal exhaustion, Definition 885.52, places the $\mathsf{Real}^{\uparrow}$ seal after the displayed readback rows, while Real-consumer coverage, Definition 885.56, exhausts every Real or Completion consumer by $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$.

Finally use shared-tail selector-window determinacy, Definition 885.55. Once the selector budget, stream window, dyadic tolerance, readback, seal, and structural rows agree, the terminal surface has no remaining carrier coordinate for countable choice, quotient streams, host real equality, ambient completeness, or an alternate selector source. □

Theorem 885.60 (Cauchy modulus refinement shared-tail selector determinacy)**.** *Let $R = (M_0, M_1, U, V, T, W, Q,$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet whose common-window selector, shared-tail handoff, and Real-consumer coverage rows read the same* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ *window. If two selector routes expose the same dyadic tail budget Q and the same* $\mathsf{Real}^{\uparrow}$ *seal E, then the refinement rows determined by those routes are classifier-equal through the displayed* BHist *rows. Equivalently, the routes may differ only by componentwise* hsame *transport along the common window and shared-tail rows; they cannot determine distinct refinement rows under the same tail budget and Real seal.*

Proof. Project both selector routes to the displayed carrier rows. Root window-selector totality, Definition 885.50, forces each route to pass through M_0, M_1, U, V, T before it reaches the selected $\mathsf{StreamName}^{\uparrow}$ window and dyadic budget rows.

Next apply root readback stability, Definition 885.51. Since both routes expose the same Q row and the same $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ window, their readbacks are transported by the componentwise H row and replayed only through the displayed route row C.

Use the shared-tail handoff of Definition 885.54. It identifies the tail-facing route with the same selector-budget, window, tolerance, readback, and seal surface T, W, Q, E, H, C, P, N, so no second shared-tail witness can distinguish the two selectors.

Finally apply Real-consumer coverage, Definition 885.56. The common Real seal is reached only through the displayed finite route, and the packet has no hidden selector, quotient stream, selected host limit, or ambient completeness coordinate. Thus the two projected BHist rows are connected by componentwise hsame transport through the common window and shared-tail routes, which is exactly classifier equality for the refinement rows. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier shared tail selector determinacy`

Theorem 885.61 (Cauchy modulus refinement selector-budget RegSeqRat Real-seal determinacy)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Suppose two downstream Real-completion routes expose the same selector-budget row T, the same finite-window* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ *readback through W, Q, and the same* $\mathsf{Real}^{\uparrow}$ *seal row E. Then the Real-completion consumer surfaces determined by those routes are classifier-equal through the displayed* BHist *rows, componentwise* hsame *row H, displayed* Cont *row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *row N.*

Proof. Project both downstream routes to the accepted carrier. Root window-selector totality, Definition 885.50, forces each route through M_0, M_1, U, V, T before either route reaches a selected finite-window row.

Next use root readback stability, Definition 885.51. Since the two routes expose the same $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ finite-window readback and the same dyadic tolerance rows, W, Q are replayed only through the displayed H, C, P, N rows.

Apply the shared-tail handoff, Definition 885.54. It aligns the selector-budget, finite-window, tolerance, readback, and seal rows with the $\mathsf{CauchySharedTailModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ sibling surfaces, so no separate RegSeqRat or stream-name route remains.

Finally apply Real-consumer coverage, Definition 885.56. The displayed packet has no quotient stream, selected host limit, hidden selector, host equality, or ambient completeness coordinate. Therefore two routes with the same T, the same W, Q readback, and the same E seal determine the same Real-completion consumer surface through BHist, H, C, P, and N. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinement selector budget regseqrat real seal determinacy`

Theorem 885.62 (Cauchy modulus refinement diagonal handoff determinacy)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E,$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Any diagonal Real-completion handoff for R that exposes the same selector-budget row T, selected* $\mathsf{StreamName}^{\uparrow}$ *window row W, dyadic tolerance row Q,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface, and* $\mathsf{Real}^{\uparrow}$ *seal row E determines the same completion-facing consumer surface through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *rows.*

The determination is only through the finite BEDC rows

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

No quotient stream, selected host limit, hidden selector, second meet row, host equality, or ambient completeness coordinate supplies another diagonal handoff.

Proof. First force the selector spine. Common-window selector extraction, Definition 885.48, and root window-selector totality, Definition 885.50, make every diagonal handoff read the selected $\mathsf{StreamName}^{\uparrow}$ window and dyadic tolerance through M_0, M_1, U, V, T before it reaches W, Q.

Next pass through the completion-facing rows. Real-completeness handoff, Definition 885.49, places the selected window, dyadic tolerance, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal in the displayed order, while shared-tail handoff, Definition 885.54, carries those rows across the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ sibling surfaces.

Finally apply selector-budget RegSeqRat Real-seal determinacy, Definition 885.61. Agreement on T, W, Q, E identifies the resulting completion-facing consumer surfaces through the displayed BHist route, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row. The excluded coordinates are absent from the accepted packet, so none of them can separate the diagonal handoff after those rows are exposed. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementDiagonalHandoffDeterminacy`

Theorem 885.63 (Cauchy modulus refinement uniform-criterion Real route determinacy)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Any* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer that exposes the same selector-budget row T, selected-window row W, dyadic-tolerance row Q, and* $\mathsf{Real}^{\uparrow}$ *seal row E determines the same Real-completion consumer surface through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *rows. No quotient stream, selected host limit, ambient completeness row, hidden selector, or second meet row supplies a competing route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier uniform criterion real route determinacy`

Proof. First force the route to the displayed selector spine. Root window-selector totality, Definition 885.50, places every selected-window read behind M_0, M_1, U, V, T, and root readback stability, Definition 885.51, keeps the resulting W, Q readback on the same H, C, P, N surface.

Next pass through the shared-tail handoff. By Definition 885.54, the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ consumer reaches the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows through the same displayed tail route rather than through a detached completion coordinate.

Use Real-consumer coverage to identify the exposed completion surface. The theorem Definition 885.56 says that every Real-facing consumer read is exhausted by $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, so exposing T, W, Q, E leaves no hidden selector, quotient stream, selected host limit, second meet row, or ambient completeness row to choose another path.

Finally apply selector-budget RegSeqRat Real-seal determinacy and tail-budget seal uniqueness, Definition 885.61 and Definition 885.67. The shared selector budget, selected window, dyadic tolerance, and Real seal determine one Real-completion consumer surface through the displayed BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows. □

Theorem 885.64 (Cauchy modulus refinement uniform diagonal seal correspondence)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Let J be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *tail packet and let K be an accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *root packet. Suppose the selector-budget row, selected* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, structural* BHist *route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows of R agree with the corresponding terminal rows read by J and K.*

Then the $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *refinement-selector surface, the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *tail surface, and the* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *root surface expose the same terminal* $\mathsf{Real}^{\uparrow}$ *seal exactly when the three surfaces traverse the same displayed BEDC route through*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The correspondence is terminal for Real and Completion consumers: no quotient stream, selected host limit, host real equality, countable-choice selector, ambient completeness coordinate, hidden selector, second meet row, or side-channel completion row supplies another terminal seal surface.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier uniform diagonal seal correspondence`

Proof. For the forward direction, apply the UniformCauchyCriterion route theorem, Definition 885.63. It places the uniform tail consumer on the displayed selector-budget, window, tolerance, readback, seal, transport, replay, provenance, and local naming route. Apply the diagonal handoff theorem, Definition 885.62, to place the diagonal root consumer on the same finite rows.

Now compare the two terminal readings with the refinement-selector surface. The L10 consumer spine comparison, Definition 885.58, identifies the CauchyModulusRefinement and DiagonalLimitCompatibility consumer spines once their $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows agree. Hence a common terminal $\mathsf{Real}^{\uparrow}$ seal exposes the same displayed BEDC route on all three surfaces.

For the reverse direction, assume the three surfaces traverse the same displayed route. Real-consumer coverage, Definition 885.56, exhausts the completion-facing consumer boundary of R by $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$. Terminal-spine choice refusal, Definition 885.59, rules out any choice, quotient, host-equality, ambient-completeness, or alternate-selector coordinate after those terminal rows agree.

Therefore the shared route has only one terminal $\mathsf{Real}^{\uparrow}$ seal to expose. The agreed uniform tail packet, diagonal root packet, and refinement selector packet are three readings of that same finite BEDC terminal surface, so their Real and Completion consumers receive the same seal. □

Theorem 885.65 (Cauchy modulus refinement selector-seal two-step transport)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Suppose a second downstream route has selector row V', selector-budget row T', tolerance-readback row Q', and seal row E'. If the displayed* hsame *rows identify V with V' and E with E', and the displayed* Cont *rows carry the source-meet route through U, V', T' and then through T', W, Q', then the two routes determine the same selector-budget row and the same* $\mathsf{Real}^{\uparrow}$ *seal consumer surface through H, C, P, N.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector seal two step transport`

Proof. First apply selector-stability lock, Definition 885.111. The hsame agreement on V, V' and the continuation through U, V', T' transport the selector route to the same selector-budget surface, so T' cannot supply a detached selected-window ledger.

Next apply selector-budget RegSeqRat Real-seal determinacy, Definition 885.61. With the selector-budget agreement in place, the continuation through T', W, Q' places the transported readback on the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows, while the hsame agreement on E, E' identifies the $\mathsf{Real}^{\uparrow}$ seal row.

Finally use the non-escape clauses recorded by window-route factorization, Definition 885.66. The accepted packet has no hidden selector, quotient stream, selected host limit, second meet row, side-channel completion row, host real equality, or ambient completeness coordinate. Hence the two-step route from selector agreement to seal agreement exhausts the consumer surface through H, C, P, N. □

Theorem 885.66 (Cauchy modulus refinement window-route factorization)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Every Real-completion consumer route that exposes the selected* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal factors through the ordered subroute*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

If two such routes expose the same selector-budget, selected-window, dyadic-tolerance, and seal rows T, W, Q, E, then they determine the same consumer surface through componentwise hsame *transport along H, displayed replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *row N. No quotient stream, selected host limit, hidden selector, second meet row, side-channel completion row, host real equality, or ambient completeness coordinate can replace that factorization.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier window route factorization`

Proof. First extract the selected-window spine. Common-window selector extraction, Definition 885.48, and root window-selector totality, Definition 885.50, force every selected $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance read through M_0, M_1, U, V, T before it reaches W, Q.

Next stabilize the readback. Root readback stability, Definition 885.51, transports the same W, Q readback only through H, C, P, N, so a consumer cannot split the $\mathsf{RegSeqRat}^{\uparrow}$ readback away from the displayed window route.

Then pass to the completion-facing seal. Real-completeness handoff, Definition 885.49, places the selected window, dyadic tolerance, regular readback, and Real seal in the displayed order before any completion boundary is consumed.

Finally apply selector-budget RegSeqRat Real-seal determinacy, Definition 885.61. Agreement on T, W, Q, E identifies the two Real-completion consumer surfaces through componentwise hsame

transport and the displayed C, P, N rows. The excluded coordinates are absent from the accepted packet, so none of them supplies an alternative factorization route. □

Theorem 885.67 (Cauchy modulus refinement tail-budget seal uniqueness)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H,$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Suppose two Real-completion or diagonal-completion tail-budget consumers expose the same selector-budget row T, selected-window row W, dyadic tolerance row Q,* $\mathsf{Real}^{\uparrow}$ *seal row E, and the same structural rows H, C, P, N. Then both consumers determine the same seal surface through the displayed route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

No quotient stream, selected host limit, side-channel completion row, host real equality, hidden selector, or second meet row can produce a different $\mathsf{Real}^{\uparrow}$ *tail-budget seal.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier tail budget seal uniqueness`

Proof. First force the route to the common selector spine. Common-window selector extraction, Definition 885.48, together with root window-selector totality, Definition 885.50, makes both consumers pass through M_0, M_1, U, V, T before either can read a selected window.

Next stabilize the visible tail rows. Root readback stability, Definition 885.51, identifies the shared W, Q readback through the same componentwise H transport and displayed replay row C.

The seal row is then fixed by the completion-facing handoff. Real-completeness handoff, Definition 885.49, places E after the same selector-budget, selected-window, dyadic-tolerance, and readback rows, with provenance and local naming carried only by P, N.

Finally apply selector-budget RegSeqRat Real-seal determinacy, Definition 885.61, and window-route factorization, Definition 885.66. Since the consumers agree on T, W, Q, E, H, C, P, N, the displayed route determines a unique seal surface; the excluded coordinates are not packet rows and cannot supply another tail-budget seal. □

Theorem 885.68 (Cauchy modulus refinement selector-budget tail-meet non-escape)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Every Real-completion consumer that reads the selector-budget row T, selected-window row W, dyadic tolerance row Q, and* $\mathsf{Real}^{\uparrow}$ *seal row E must first pass through the shared meet and refinement route*

$$M_0, M_1, U, V, T$$

and then through the shared-tail handoff to W, Q, E, H, C, P, N. No quotient stream, hidden selector, second meet row, host real equality, or ambient completeness row can replace that shared-tail meet surface.

Proof. First force the selector spine. Common-window selector extraction, Definition 885.48, and root window-selector totality, Definition 885.50, make every read of T, W, Q pass through M_0, M_1, U, V, T before a selected window is available.

Next pass from the selector spine to the tail-facing interface. The shared-tail handoff of Definition 885.54 identifies the same route with the displayed $\mathsf{CauchySharedTailModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, so the handoff is carried by W, Q, E, H, C, P, N rather than by a detached completion coordinate.

Now apply selector-budget RegSeqRat Real-seal determinacy, Definition 885.61. Once the consumer has exposed T, W, Q, E, the Real-completion surface is fixed through the displayed BHist route, componentwise hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row.

Finally use tail-budget seal uniqueness, Definition 885.67. A second route with the same selector budget, selected window, dyadic tolerance, and seal collapses to the same tail-budget seal surface. The excluded quotient stream, hidden selector, second meet row, host real equality, and ambient completeness rows are not packet coordinates, so none can bypass the shared-tail meet route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector budget tail meet nonescape`

Definition 885.69 (Cauchy modulus refinement terminal selector surface)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. The terminal selector surface of R is the displayed consumer route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

from the shared meet rows M_0, M_1, U, through the refinement rows V, T, and into the selected-window, tolerance-readback, Real-seal, transport, replay, provenance, and local naming rows W, Q, E, H, C, P, N.

Two terminal consumer routes agree on this surface exactly when they agree on the selector budget T, the selected window W, the dyadic tolerance Q, the $\mathsf{RegSeqRat}^{\uparrow}$ *readback carried by W, Q, the* $\mathsf{Real}^{\uparrow}$ *seal E, the componentwise* hsame *transport row H, the displayed* Cont *replay row C, the* Pkg *provenance row P, and the local* NameCert *row N.*

Lean4 (definition) `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementTerminalSelectorSurface`

Theorem 885.70 (Cauchy modulus refinement terminal selector-seal correspondence)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Two Real-completion consumer routes expose the same terminal selector surface of Definition 885.69 if and only if they expose the same ordered selector-budget row T, selected-window row W, dyadic-tolerance row Q,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal row E through the same structural rows H, C, P, N.*

Consequently no terminal consumer can identify the $\mathsf{Real}^{\uparrow}$ *seal of R without passing through the displayed selector-budget route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Proof. For the forward direction, first force both routes to the common selector spine. Root window-selector totality, Definition 885.50, places every selected-window read behind M_0, M_1, U, V, T, while root readback stability, Definition 885.51, keeps the W, Q readback on the displayed H, C, P, N surface.

Next use shared-tail handoff, Definition 885.54. Once the routes expose the same terminal selector surface, the handoff carries the same selector budget, selected window, dyadic tolerance, RegSeqRat readback, and RealUp seal into T, W, Q, E with no detached completion coordinate.

For the reverse direction, assume the two routes expose the same T, W, Q, E, H, C, P, N rows. Window-route factorization, Definition 885.66, makes every Real-completion consumer factor through those rows, and selector-budget RegSeqRat Real-seal determinacy, Definition 885.61, identifies the Real-facing seal surface once those rows agree.

Finally apply tail-budget selector lock, Definition 885.71. Quotient streams, host real equality, hidden selectors, second meet rows, selected host limits, side-channel completion rows, and ambient completeness are not packet coordinates of R, so no off-route consumer can identify the terminal $\mathsf{Real}^{\uparrow}$ seal without the displayed selector-budget route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier terminal selector seal correspondence`

Theorem 885.71 (Cauchy modulus refinement tail-budget selector lock)**.** *Let* $R = (M_0, M_1, U, V, T, W, Q, E, H, C,$ *be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. If two Real-completion consumers of* R *expose the same selector budget* T*, selected window* W*, dyadic tolerance* Q*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, and structural rows* H, C, P, N*, then they are classifier-equal through the displayed route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

No hidden selector, second meet row, quotient stream, selected host limit, host real equality, or ambient completeness row can split the Real-completion consumer surface once those rows have been read.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier tail budget selector lock`

Proof. First force both consumers through the common selector spine. Root window-selector totality, Definition 885.50, places every selected-window read behind M_0, M_1, U, V, T.

Next stabilize the readback rows. Root readback stability, Definition 885.51, keeps the shared W, Q readback inside the displayed H, C, P, N surface rather than a host-side stream witness.

Apply selector-budget RegSeqRat Real-seal determinacy, Definition 885.61. Since both consumers expose the same T, W, Q, E rows, their Real-facing consumer surfaces are identified through the same BHist route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row.

Finally use tail-budget seal uniqueness, Definition 885.67. The agreement on H, C, P, N locks the seal to the same tail-budget route, and the excluded coordinates are absent from the accepted packet. □

Theorem 885.72 (Cauchy modulus refinement shared-meet RegSeqRat route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ *must pass through the shared meet and extraction route*

$$M_0, M_1, U, V, T$$

before reading the selected window W*, dyadic tolerance* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal* E*. The consumer cannot obtain the RegSeqRat readback or Real seal from a detached selector, quotient stream, second meet row, host real equality, selected host limit, or ambient completeness coordinate.*

Proof. Start with common-window selector extraction, Definition 885.48. It identifies any downstream selected-window read with the same selector-budget route and therefore places W, Q after T.

Next apply the shared-tail handoff, Definition 885.54. The handoff carries the selected $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal on the displayed W, Q, E, H, C, P, N rows.

Use Real-consumer coverage, Definition 885.56, to identify the completion-facing consumer surface with the same finite packet. The Real read has no additional carrier coordinate beyond the displayed refinement rows.

Finally apply selector-budget tail-meet non-escape, Definition 885.68. Once the consumer reads T, W, Q, E, every admissible route has already passed through M_0, M_1, U, V, T, so the excluded off-route data cannot supply a second RegSeqRat or Real route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier shared meet regseqrat route`

Theorem 885.73 (Cauchy modulus refinement shared-budget pullback handoff)**.** *Let $R = (M_0, M_1, U, V, T, W, Q,$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer that uses the terminal selector-seal surface of R enters through the shared-budget pullback route fixed by*

$$U, V, T, W, Q, E, H, C, P, N.$$

If two such consumers agree on those rows, then they expose the same terminal $\mathsf{Real}^{\uparrow}$ *seal surface. No quotient stream, hidden selector, second meet row, host real equality, selected host limit, side-channel completion row, or ambient completeness coordinate supplies an alternate handoff.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier shared budget pullback`

Proof. First bind the shared budget. The shared-budget pullback theorem, Definition 885.19, makes the meet row U and selector-budget row T determine the selected-window row W and tolerance-readback row Q through the displayed refinement route.

Next route the terminal handoff through the finite sibling surfaces. The shared-tail handoff of Definition 885.54 carries W, Q, E, H, C, P, N across the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ surfaces, while Definition 885.72 places every RegSeqRat and Real consumer behind the same shared meet and extraction route U, V, T.

Now identify the terminal selector-seal surface. By Definition 885.70, agreement on the displayed selector-budget, selected-window, tolerance-readback, seal, transport, replay, provenance, and local naming rows is exactly agreement on the terminal selector surface and its $\mathsf{Real}^{\uparrow}$ seal.

Finally apply tail-budget selector lock, Definition 885.71. The excluded off-route data are not coordinates of the accepted packet, so they cannot supply a second handoff once $U, V, T, W, Q, E, H, C, P, N$ have fixed the terminal route. □

Theorem 885.74 (Cauchy modulus refinement terminal Real-seal pullback exhaustion)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. For every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of R, identifying the terminal* $\mathsf{Real}^{\uparrow}$ *seal through the shared-budget pullback is equivalent to exposing the same rows*

$$U, V, T, W, Q, E, H, C, P, N$$

through the shared meet, selector-budget, selected-window, readback, seal, transport, replay, provenance, and local naming surfaces. Conversely, agreement on those rows determines the same terminal $\mathsf{Real}^{\uparrow}$ *seal surface for the consumer.*

No quotient stream, hidden selector, second meet row, host real equality, selected host limit, side-channel completion row, or ambient completeness coordinate contributes an additional terminal seal route.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier terminal real seal pullback exhaustion`

Proof. First force the shared meet and selector route. The shared-meet RegSeqRat route, Definition 885.72, places every $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumer behind U, V, T, and the tail-budget selector lock, Definition 885.71, prevents a second selector surface once T, W, Q, E, H, C, P, N are read.

Next pass through the finite sibling handoff. The shared-budget pullback handoff, Definition 885.73, carries the route from U, V, T to W, Q, E, H, C, P, N across the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$,

$\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ surfaces. Thus a consumer that identifies the terminal seal through the pullback must expose exactly the displayed shared-budget rows.

For the converse direction, assume the consumer exposes the same $U, V, T, W, Q, E, H, C, P, N$ rows. Terminal selector-seal correspondence, Definition 885.70, identifies agreement on the selector-budget, selected-window, dyadic-tolerance, readback, seal, transport, replay, provenance, and local naming rows with agreement on the terminal selector surface and its $\mathsf{Real}^{\uparrow}$ seal.

Finally apply the exclusion clauses supplied by tail-budget selector lock and shared-budget pullback handoff. Quotient streams, hidden selectors, second meet rows, host real equality, selected host limits, side-channel completion rows, and ambient completeness coordinates are absent from the accepted packet, so none of them can supply a separate terminal pullback. Hence the displayed row agreement is exactly the consumer boundary for the terminal $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 885.75 (Cauchy modulus refinement terminal pullback consumer uniqueness)**.** *Let* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Suppose two* $\mathsf{Real}^{\uparrow}$ *or Completion consumers of* R *expose the same shared-budget pullback rows*

$$U, V, T, W, Q, E, H, C, P, N.$$

Then the two consumers expose the same terminal $\mathsf{Real}^{\uparrow}$ *seal consumer surface. No quotient stream, hidden selector, second meet row, host real equality, selected host limit, side-channel completion row, or ambient completeness coordinate can distinguish the two terminal consumers.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier terminal pullback consumer uniqueness`

Proof. First lock the selector boundary. Tail-budget selector lock, Definition 885.71, makes the displayed selector-budget route the only accepted route from the tail budget to the selected-window and tolerance rows.

Next read both consumers through the shared meet. The shared-meet RegSeqRat route, Definition 885.72, forces every $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or Completion-facing read behind the same U, V, T spine before W, Q, E can be consumed.

Now pass through the pullback handoff. By Definition 885.73, agreement on $U, V, T, W, Q, E, H, C, P, N$ is agreement on the finite handoff across the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ surfaces.

Finally apply terminal Real-seal pullback exhaustion, Definition 885.74. Since the two consumers expose the same displayed pullback rows, their terminal seal surfaces are the same, and the excluded off-route coordinates have no accepted slot from which to separate them. □

Theorem 885.76 (Cauchy modulus refinement selector-budget normal form)**.** *Let* $R = (M_0, M_1, U, V, T, W, Q, E, H$ *be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Any consumer route of* R *shared by* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *is exhausted by one finite selector-budget normal form:*

$$U, V, T, W, Q, E, H, C, P, N.$$

The rows are, in order, the shared meet row, extraction row, selector-budget row, selected-window row, tolerance-readback row, $\mathsf{Real}^{\uparrow}$ *seal row, and the support, provenance, and local naming rows. No quotient stream, hidden selector, second meet row, host real equality, selected host limit, side-channel completion row, or ambient completeness coordinate supplies another shared consumer route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector budget normal form`

Proof. First force the shared meet and extraction route. The RegSeqRat–StreamName–Real coherence surface, Definition 885.96, and the selector exactness surface, Definition 885.102, place the four sibling consumers behind the same U, V, T spine before a selected window or Real seal is read.

Next expose the finite observation budget. The shared-budget pullback handoff, Definition 885.73, carries that spine through W, Q, E, H, C, P, N across the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces.

Then apply terminal pullback consumer uniqueness, Definition 885.75. Once a consumer exposes the displayed $U, V, T, W, Q, E, H, C, P, N$ rows, it has the same terminal $\mathsf{Real}^{\uparrow}$ seal consumer surface as any other consumer exposing those rows.

Finally use Definition 885.71. The off-route coordinates listed in the statement are not rows of the accepted packet, so the selector-budget normal form is the only shared consumer route available to the four sibling surfaces. □

Theorem 885.77 (Cauchy modulus refinement uniform monotone terminal route)**.** *Let* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Suppose a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer and a* $\mathsf{MonotoneCauchy}^{\uparrow}$ *consumer both read the selector-budget row* T*, selected-window row* W*, dyadic-tolerance row* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal row* E *of* R *through the same displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *rows.*

Then the two consumers determine one terminal $\mathsf{Real}^{\uparrow}$ *seal surface. The shared surface is exactly the handoff through*

$$U, V, T, W, Q, E, H, C, P, N,$$

with the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *RegSeqRat–Real classifier face and the* $\mathsf{MonotoneCauchy}^{\uparrow}$ *located Real-seal face read as projections of that same finite route. No quotient stream, host real equality, selected limit, trichotomy row, ambient completeness principle, metric-completeness datum, hidden selector, or second meet row supplies a second terminal handoff.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier uniform monotone terminal route`

Proof. First place both consumers on the CauchyModulusRefinement terminal route. The terminal pullback consumer uniqueness theorem, Definition 885.75, identifies every Real or Completion consumer that agrees on $U, V, T, W, Q, E, H, C, P, N$ with the same terminal $\mathsf{Real}^{\uparrow}$ seal consumer surface.

Next read the uniform criterion face. The UniformCauchyCriterion terminal RegSeqRat–Real classifier correspondence, Definition 435.102, says that the RegSeqRat tail classifier, StreamName finite-window classifier, and Real finite-window seal classifier are projections of one ordered route. Under the shared rows of R, that route is the displayed T, W, Q, E, H, C, P, N suffix.

Now read the monotone face. The MonotoneCauchy Real-seal factorization obligation, Definition 438.8, and the tail-window Real-seal certificate, Definition 438.10, force the located interval and monotone tail-window rows to be consumed before the Real seal, with transport, continuation, provenance, and local naming retained.

Finally combine the two projections through the CauchyModulusRefinement shared meet. Since both projected consumers reach the same E, H, C, P, N only after the same selector-budget, selected-window, and dyadic-tolerance rows, terminal pullback uniqueness leaves one Real-seal surface and no off-route coordinate from which a separate uniform or monotone terminal handoff can be read. □

Theorem 885.78 (Cauchy modulus refinement CompleteMetric consumer route)**.** *Let $R = (M_0, M_1, U, V, T, W, Q,$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Every* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer of R must read the selector-budget normal form*

$$U, V, T, W, Q, E, H, C, P, N$$

before any completion-facing row is exposed. In this route W, Q pass through the displayed $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *surfaces, the readback passes through* $\mathsf{RegSeqRat}^{\uparrow}$*, and the terminal seal passes through* $\mathsf{Real}^{\uparrow}$*. No quotient stream, selected host limit, ambient completeness coordinate, hidden selector, or second meet row can distinguish a* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer after those rows have been read.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier complete metric consumer route`

Proof. First apply selector-budget normal form, Definition 885.76. It places every shared $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumer on the same finite route $U, V, T, W, Q, E, H, C, P, N$.

Next use terminal pullback consumer uniqueness, Definition 885.75. A completion-facing consumer that exposes those rows has the same terminal $\mathsf{Real}^{\uparrow}$ seal surface as any other consumer exposing them.

Finally combine the Real and completion non-escape clauses supplied by the root consumer surface and the uniform monotone terminal route. The packet contains no quotient stream, selected host limit, ambient completeness coordinate, hidden selector, or second meet row, so a $\mathsf{CompleteMetric}^{\uparrow}$ consumer can only see the displayed completion-facing route after the $\mathsf{Real}^{\uparrow}$ seal. □

Corollary 885.79 (Cauchy modulus refinement common-window select strict obstruction)**.** *Let $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet. Suppose a displayed failure, refusal, separation, or countermodel row is read at the common-window select surface after the consumer has exposed the selector-budget row T, selected* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row Q,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal E, structural* BHist *route, componentwise* hsame *row H, displayed* Cont *row C,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$ *row N.*

Then that displayed obstruction is strict and local: it blocks only the attempted converse or reuse route that tries to distinguish the same Real-completion consumer surface by a countable-choice row, quotient stream, host real equality, ambient completeness coordinate, alternate selector source, hidden selector, second meet row, selected host limit, or detached readback while the displayed terminal rows agree. It cannot be read as a global impossibility for $\mathsf{CauchyModulusRefinement}^{\uparrow}$*, as a host-side completeness theorem, or as hidden external validation of any off-packet Real object.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCommonWindowSelectStrictObstructi`
↪ variant `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier common window select strict obstruction`

Proof. First place the consumer on the terminal spine. Terminal-spine choice refusal, Definition 885.59, says that once the consumer agrees on T, W, Q, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, E, the structural BHist route, H, C, P, and the local naming row N, no countable-choice row, quotient stream, host real equality, ambient completeness coordinate, or alternate selector source can distinguish the Real-completion consumer surface determined by that terminal read.

Next stabilize the readback that the common-window select surface exposes. Root readback stability, Definition 885.51, keeps the selected-window and tolerance readbacks W, Q on the displayed H, C, P, N route for every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer. Thus the obstruction has no independent readback coordinate from which to range over a detached stream representative or an ambient completion object.

Now identify the exact route being blocked. Common-window selector extraction, Definition 885.48, and root terminal selector readback, Definition 885.57, make the selected-window route and terminal selector surface coincide with the finite packet rows already displayed. Therefore a failure, refusal, separation, or countermodel row at this point can only reject the converse or reuse attempt that asks for another consumer surface while preserving those rows.

Finally use Real-consumer coverage and root Real seal exhaustion, Definition 885.56 and Definition 885.52. They exhaust Real and Completion consumers by

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Since the accepted packet exports no off-route host theorem, external validation row, hidden selector, second meet, quotient stream, selected host limit, or ambient completeness coordinate, the displayed obstruction has only the local scope stated above. □

Theorem 885.80 (Cauchy modulus refinement root-window selector uniqueness)**.** *Let*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

and

$$R' = (M_0', M_1', U', V', T', W', Q', E', H', C', P', N')$$

be accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packets. Suppose the two packets expose the same source schedules, shared meet, selector budget, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and structural rows along the displayed root route. Then every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer classifies* E *and* E' *as the same consumer-visible Real seal under that route.*

No Real completeness principle, quotient stream, selected host limit, countable-choice row, host real equality, hidden selector, or second meet row is used in the classification.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root window selector uniqueness`

Proof. First apply root route determinacy, Definition 885.129. Agreement on the source schedules and shared meet places both accepted packets on the same displayed route through U, V, T before a finite window or Real seal can be read.

Next use the Real-window budget pullback and terminal consumer theorems, Definition 885.151 and Definition 885.153. These force every $\mathsf{Real}^{\uparrow}$ or Completion-facing consumer to read the same finite request, window, dyadic readback, regular handoff, selector, disclosure, and support rows before it reaches the seal.

Finally invoke L10 row exactness, Definition 885.150. The L10 consumer inventory is exactly the displayed route with H, C, P, N, so two accepted packets agreeing on those route rows expose one consumer-visible Real seal surface. Since none of the excluded rows is present in the carrier, the uniqueness claim does not use Real completeness. □

Theorem 885.81 (Cauchy modulus refinement selector threshold exhaustion)**.** *Every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *route whose public consumer reaches a* $\mathsf{Real}^{\uparrow}$ *or Completion seal through the displayed root-window selector is exhausted by the finite rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Deleting U*,* T*,* W*, or* Q *breaks the route before the seal can be consumed:* U *supplies the selector budget,* T *fixes the public threshold handoff,* W *exposes the finite window, and* Q *exposes the dyadic readback required by the public consumer.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementPacket window selector threshold exhaustion`

Proof. First apply root route determinacy, Definition 885.129. It places every accepted route to a Real or Completion seal on the displayed root route through $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$.

Next use root budget consumer exhaustion, Definition 885.131. The budget-facing consumer cannot reach the seal before reading the selector budget and its finite-window support, so deleting U or W interrupts the route before any public endpoint is available.

Then apply root threshold public exhaustion, Definition 885.133. The public threshold leg must pass through T and the dyadic readback row Q before it can expose the seal; removing either row leaves only a partial route.

Finally invoke the local selector uniqueness theorem, Definition 885.80. Once the route rows are fixed, all Real or Completion-facing consumers read the same displayed seal surface. Thus the listed rows exhaust the accepted public route, and the four named deletions break it before seal consumption. □

Theorem 885.82 (Cauchy modulus refinement Real-seal route nonescape)**.** *Every accepted* $\mathsf{CauchyModulusRefinem}$ *route that reaches a* $\mathsf{Real}^{\uparrow}$ *or Completion seal through the root-window selector is confined to the rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Preserving the seal preserves the selector budget U*, the threshold handoff* T*, the finite window* W*, and the dyadic readback* Q*. Such a route cannot read a Real completeness principle, quotient stream, selected host limit, countable-choice row, host real equality, hidden selector, or second meet row.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal route nonescape`

Proof. First apply root route determinacy, Definition 885.129. It places every accepted route to a Real or Completion seal on the displayed root route before any terminal consumer can inspect the seal.

Next use real-window budget pullback and the real-window terminal consumer theorem, Definition 885.151 and Definition 885.153. These force the consumer-facing seal to retain the selector budget, finite window, dyadic readback, and public threshold handoff as displayed rows.

Now invoke L10 row exactness, Definition 885.150. The L10 inventory is exactly the carrier rows $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, so no hidden completeness, quotient, host-limit, choice, equality, selector, or second-meet coordinate can be read.

Finally apply selector threshold exhaustion, Definition 885.81. Deleting U, T, W, or Q breaks the route before the seal can be consumed, hence preserving the seal preserves those four rows and the accepted route is nonescaping. □

Corollary 885.83 (Cauchy modulus refinement root-window selector strict obstruction)**.** *Let an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *route reach a* $\mathsf{Real}^{\uparrow}$ *or Completion seal through the root-window selector, and let a displayed failure, refusal, separation, or countermodel row be read as blocking a named converse, reuse, transport, or readback attempt for that selector route. Then the obstruction is strict and local: it blocks only that named attempt at one of the displayed rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Every consumer-facing use of the obstruction factors through the same finite route rows, and any coordinate not listed in this display is rejected as unavailable to the obstruction. In particular, the obstruction cannot be reinterpreted as a global impossibility theorem, a host theorem about all Cauchy presentations, a Real-completeness principle, a quotient-stream argument, a selected host limit, a countable-choice principle, host real equality, a hidden selector, a second meet row, or hidden external validation.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root window selector strict obstruction`

Proof. First apply the Real-seal route nonescape theorem, Definition 885.82. It confines every accepted root-window route reaching a $\mathsf{Real}^{\uparrow}$ or Completion seal to the displayed rows

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N,$$

and it states that preserving the seal preserves the selector budget U, threshold handoff T, finite window W, and dyadic readback Q. Thus any failure, refusal, separation, or countermodel row that is consumer-facing along this route can only be read through the named finite inventory; an unlisted coordinate has no place where it can be consumed.

Next apply root-window selector uniqueness, Definition 885.80. Once the source schedules, shared meet, selector budget, finite window, dyadic readback, regular handoff, and structural rows agree along the displayed root route, every $\mathsf{Real}^{\uparrow}$ or Completion-facing consumer classifies the exposed seal by that same route surface. Hence an obstruction row cannot detach from its named converse, reuse, transport, or readback attempt and become a second classification principle for the seal.

Combining the two facts gives the strict local reading. Nonescape removes Real completeness, quotient streams, selected host limits, countable choice, host real equality, hidden selectors, and second meet rows from the available inventory, while uniqueness prevents the same finite obstruction row from being read as a different consumer-visible seal argument. Therefore the displayed obstruction blocks only the named route attempt inside the root-window selector packet and supplies no global impossibility theorem, host theorem, or hidden external validation. □

Theorem 885.84 (Cauchy modulus refinement root source binding)**.** *Every root consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet first reads the source rows* M_0, M_1*, the shared meet row* U*, and the extraction row* V *through the carrier route of Definition 885.1. The root consumer has no admissible access to a downstream selector, seal, or structural row before that shared meet and extraction route is displayed.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root source binding`

Proof. Read the carrier definition. Its packet orders the two source schedules, the shared meet, and the extraction witness as the visible front of the root route.

Apply Definition 885.4. The theorem binds any extraction read of V to the single displayed meet U after M_0, M_1; hence a root consumer cannot substitute a second meet or a hidden source.

Finally use Definition 885.56. Since every Real or Completion consumer is covered by the displayed packet route, every such consumer inherits this first read of M_0, M_1, U, V before any later row is available. □

Theorem 885.85 (Cauchy modulus refinement root selector readback)**.** *For every accepted* CauchyModulusRefinem *packet, selected-window and tolerance readback consume T, W, Q only after the source-meet-extraction row M_0, M_1, U, V has been displayed. Thus any root consumer that asks for the selected-window ledger or the tolerance-readback ledger reaches those rows through the same selector-budget route T.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root selector readback`

Proof. Start from Definition 885.1. The selected-window ledger W and tolerance-readback ledger Q are carrier rows following M_0, M_1, U, V, T.

Apply Definition 885.4 to fix the source side. The extraction row V is already bound to the shared meet route before any selector-budget read is meaningful.

Now apply Definition 885.5. It identifies T as the selector-budget row consumed by the selected-window and tolerance-readback rows, so W, Q are read only after the extraction row and through T. □

Theorem 885.86 (Cauchy modulus refinement paper-Lean readback sync)**.** *For every accepted* CauchyModulusRefinement$^{\uparrow}$ *packet whose root source-meet-extraction route*

$$M_0, M_1, U, V$$

is displayed, the selector-budget row T, selected-window row W, tolerance-readback row Q, seal row E, and structural rows H, C, P, N are preserved along that same carrier route. The readback exposes no second meet, hidden selector, quotient stream, or ambient completeness coordinate as an alternate source of those rows.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier paper lean readback sync`

↪ variant `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinement root readback stability`

Proof. Apply Definition 885.84. It fixes the root route through M_0, M_1, U, V before any selector, seal, or structural row can be read.

Next use Definition 885.85. The selected-window and tolerance-readback rows reach W, Q only through the selector-budget row T, so their readback remains on the same displayed carrier route.

Finally apply Definition 885.87. The Real seal and structural rows E, H, C, P, N stay behind the same displayed route, while the excluded quotient stream, hidden selector, second meet, and ambient completeness coordinate have no exported entry point. □

Theorem 885.87 (Cauchy modulus refinement root Real seal non-escape)**.** *Every* Real$^{\uparrow}$ *or Completion consumer of an accepted* CauchyModulusRefinement$^{\uparrow}$ *packet reaches the seal row E only after the displayed route*

$$M_0, M_1, U, V, T, W, Q, H, C, P, N.$$

No quotient stream, selected limit, host real equality, hidden selector, second meet, or ambient completeness row is exported as an alternate route to the Real seal.

Proof. Project the carrier of Definition 885.1. The packet contains the source, meet, extraction, selector-budget, selected-window, tolerance-readback, Real seal, transport, continuation, package, and local naming rows as finite displayed coordinates.

Apply Definition 885.5 and Definition 885.7. Together they order the selector readback T, W, Q before the Real seal E, with the structural rows H, C, P, N stabilizing the same route.

Finally apply Definition 885.56. Every Real or Completion consumer is exhausted by the displayed route, so the excluded quotient stream, selected limit, host real equality, hidden selector, second meet, and ambient completeness rows have no exported entry point. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root real seal nonescape`

Theorem 885.88 (Cauchy modulus refinement root consumer package)**.** *Every root consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet factors through*

$$M_0, M_1, U, V, T, W, Q, H, C, P, N$$

before reading any $\mathsf{Real}^{\uparrow}$ *or Completion seal row. The package exports no quotient stream equality, selected limit, host real equality, hidden selector, second meet, or ambient completeness coordinate as an alternate consumer route.*

Proof. First apply Definition 885.84. This binds every root consumer to the source rows M_0, M_1, the shared meet row U, and the extraction row V before any downstream read is available.

Next apply Definition 885.85. The selected-window ledger and tolerance-readback ledger are consumed only through the selector-budget row T, so the consumer reaches T, W, Q after the source-meet-extraction route has been displayed.

Finally apply Definition 885.87. The Real or Completion seal row is reached only after the displayed structural route H, C, P, N has stabilized the same packet, and the excluded quotient stream equality, selected limit, host real equality, hidden selector, second meet, and ambient completeness coordinates have no exported entry point. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root consumer package`

Theorem 885.89 (Cauchy modulus refinement root route completeness)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet, every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing root read is complete exactly at the displayed route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

The source rows, shared meet, extraction row, selector-budget row, selected-window ledger, tolerance-readback ledger, Real seal row, and structural rows jointly exhaust the public consumer surface. No quotient stream equality, selected limit, host real equality, hidden selector, second meet, or ambient completeness coordinate is exported as another root route.

Proof. Apply Definition 885.84. It fixes the source rows M_0, M_1, the shared meet U, and the extraction row V as the first public root source.

Next use Definition 885.85. The selected-window and tolerance-readback ledgers are available only through the selector-budget row T, so the route continues through T, W, Q without opening a hidden selector.

Then apply Definition 885.87. The Real seal row E and the structural rows remain behind the same displayed carrier route, and the excluded quotient stream, selected limit, host real equality, second meet, and ambient completeness coordinates have no exported read.

Finally apply Definition 885.88. It packages the Real and Completion consumers over the same carrier coordinates. Since the packet has no public coordinate beyond $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ for these reads, carrier coordinate exhaustion gives the claimed complete root route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root route completeness`

Theorem 885.90 (Cauchy modulus refinement shared selector determinacy)**.** *For every accepted* CauchyModulusRefinement$^{\uparrow}$ *packet, suppose two root-facing reads expose the same source rows M_0, M_1, shared meet U, extraction row V, selector-budget row T, selected-window row W, tolerance-readback row Q, Real seal row E, and structural rows H, C, P, N. Then the two reads are the same accepted selector route up to the displayed* hsame *transport and* Cont *replay. No hidden selector, second meet, quotient stream, selected limit, host equality, or ambient completeness row can distinguish another accepted root route.*

Proof. Apply Definition 885.84. The shared source rows force the same M_0, M_1, U, V spine for both reads, so there is no separate source-meet branch on which a second selector route could start.

Next apply Definition 885.85. The selector-budget, selected-window, and tolerance-readback rows are read back through the same displayed selector surface T, W, Q, and the carrier exposes no hidden selector coordinate beyond that surface.

Use Definition 885.87. The Real seal row and structural rows remain inside the same E, H, C, P, N packet under componentwise hsame transport and displayed Cont replay, so quotient streams, selected limits, host equalities, second meets, and ambient completeness rows are not root-facing witnesses.

Finally invoke Definition 885.89. Since every accepted Real or Completion-facing root read is exhausted by $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, two reads with those rows displayed have no remaining public coordinate on which they can differ. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier shared selector determinacy`

Theorem 885.91 (Cauchy modulus refinement selector-meet noninterference)**.** *For an accepted* CauchyModulusRefinement$^{\uparrow}$ *packet whose root route displays*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N,$$

any consumer request for a hidden selector, second meet, quotient stream, selected limit, host equality, or ambient completeness row cannot alter the accepted selector route. Every accepted read remains determined by the shared meet U, extraction row V, selector-budget row T, selected-window row W, tolerance-readback row Q, Real-seal row E, and structural rows H, C, P, N.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector meet noninterference`

Proof. First apply Definition 885.84. The accepted root route must begin with the source rows M_0, M_1, the shared meet U, and the extraction row V, so a hidden second meet has no source position from which to change the selector route.

Next use Definition 885.85. The selector-facing rows T, W, Q are read only after the source-meet-extraction route has been displayed, and their readback is tied to the same selector-budget row T.

Apply Definition 885.87 and Definition 885.89. They keep the Real seal and structural rows on the displayed route while excluding quotient streams, selected limits, host equalities, hidden selectors, second meets, and ambient completeness rows from the exported packet.

Finally invoke Definition 885.90. Once the displayed rows agree up to componentwise hsame transport and displayed Cont replay, no remaining root-facing coordinate can distinguish another accepted selector route. The requested hidden data are therefore noninterfering with the accepted route. □

Theorem 885.92 (Cauchy modulus refinement completion consumer route determinacy)**.** *Suppose two accepted* CauchyModulusRefinement$^{\uparrow}$ *completion-facing reads display the same rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Then every Real$^{\uparrow}$ *or Completion consumer reaches the same selector route up to the displayed* hsame *transport and* Cont *replay. No hidden selector, second meet, quotient stream, selected limit, host equality, ambient completeness coordinate, or detached completion seal can distinguish a second accepted completion route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier completion consumer route determinacy`

Proof. Apply Definition 885.84. The shared rows M_0, M_1, U, V bind both completion-facing reads to the same source, shared-meet, and extraction spine before any selector-facing row is available.

Next use Definition 885.85. The displayed rows T, W, Q are read back only through the selector-budget route T, so the selected-window and tolerance-readback consumers have no separate selector route to follow.

Apply Definition 885.87 and Definition 885.89. They keep the Real seal and the structural rows E, H, C, P, N on the same displayed route for every Real$^{\uparrow}$ or Completion consumer, while excluding quotient streams, selected limits, host equalities, ambient completeness coordinates, and detached completion seals from the exported packet.

Finally invoke Definition 885.90 and Definition 885.91. Once the displayed rows agree, componentwise hsame transport and displayed Cont replay determine the accepted selector route, and the hidden completion data listed in the statement cannot distinguish another accepted completion route. □

Theorem 885.93 (Cauchy modulus refinement uniform diagonal consumer pullback)**.** *Let an accepted* CauchyModulusRefinement$^{\uparrow}$ *packet expose the shared route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Any UniformCauchyCriterion$^{\uparrow}$ *or* DiagonalLimitCompatibility$^{\uparrow}$ *consumer of that packet factors through the same finite selector route*

$$U, V, T, W, Q, E, H, C, P, N$$

before any Real$^{\uparrow}$ *or Completion endpoint is public. The consumer first reads the shared meet U, extraction row V, selector-budget row T, selected-window row W, tolerance-readback row Q,* Real$^{\uparrow}$ *seal row E, componentwise* hsame *transport row H, displayed* Cont *replay row C,* Pkg *provenance row P, and local* NameCert *row N.*

Thus the UniformCauchyCriterion and DiagonalLimitCompatibility routes have one consumer pullback over the displayed CauchyModulusRefinement selector surface. No quotient stream, selected host limit, host real equality, countable-choice schedule, detached completion seal, ambient completeness coordinate, hidden selector, or second meet supplies another route to the endpoint.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier uniform diagonal consumer pullback`

Proof. Start with the diagonal-facing side. The diagonal-budget cofinality theorem Definition 885.98 keeps every diagonal-budget consumer on the displayed route through $U, V, T, W, Q, E, H, C, P, N$, and it excludes hidden selectors, second meets, quotient streams, host equality, selected limits, and ambient completeness from that read.

Next attach the criterion side. The CauchyCriterion selector cofinality theorem Definition 885.100 places the CauchyCriterion and UniformCauchyCriterion consumers on the same selector route before any criterion output is exposed. The UniformCauchyCriterion diagonal-budget pullback Definition 435.74 then identifies the uniform family read with the diagonal-budget route rather than with a second schedule or completion coordinate.

Now use the completion-facing determinacy theorem Definition 885.92. Once the rows $M_0, M_1, U, V, T, W, Q, E,$ are displayed, every $\mathsf{Real}^{\uparrow}$ or Completion consumer reaches the same selector route up to the visible hsame transport and Cont replay.

The pullback is therefore the finite selector surface listed in the statement. The excluded quotient streams, selected host limits, host real equalities, countable-choice schedules, detached completion seals, ambient completeness coordinates, hidden selectors, and second meets have no displayed row from which to alter the common consumer route before the endpoint becomes public. □

Theorem 885.94 (Cauchy modulus refinement budget naturality)**.** *Suppose two accepted* CauchyModulusRefinemen *packets share the same source schedules M_0, M_1, meet row U, extraction row V, selector budget T, selected window W, tolerance readback Q, Real seal E, and structural rows H, C, P, N. Then every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *or Completion consumer reads the same budget-refinement route up to the displayed* hsame *transport and* Cont *replay.*

The route is the displayed carrier path

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

No quotient stream equality, selected limit, host equality, hidden selector, second meet, or ambient completeness coordinate can distinguish another budget-refinement read for those consumers.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier budget naturality`

Proof. First apply Definition 885.84. The shared source schedules M_0, M_1, meet row U, and extraction row V force both accepted packets to begin with the same source-meet-extraction route before any selector-budget data can be read.

Next use Definition 885.85. The selected-window and tolerance-readback rows reach W, Q only through the displayed selector budget T. Thus $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ consumers read the same finite-window and tolerance route rather than a hidden selector.

Apply Definition 885.89. Every $\mathsf{Real}^{\uparrow}$ or Completion-facing root read is exhausted by the displayed route $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, so the Real seal and completion handoff have no detached route.

Finally combine Definition 885.90 with Definition 885.91. Since the displayed rows agree, componentwise hsame transport and displayed Cont replay determine the accepted consumer route, while quotient stream equality, selected limits, host equality, hidden selectors, second meets, and ambient completeness remain outside the public packet. □

Theorem 885.95 (Cauchy modulus refinement complete-metric no-choice interface)**.** *For an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet, suppose a terminal read reaches two completion-facing rows through the same displayed interfaces*

$$\mathsf{Cont}(\text{terminal}, c, \text{completionA})$$

and

$$\mathsf{Cont}(\text{terminal}, c, \text{completionB}),$$

and suppose both completion rows are packaged by the same Pkg *provenance. Then the two completion reads are classified by* hsame.

The interface exposes only the finite terminal row, the two completion rows, and the package rows. It exports no quotient stream, selected limit, host equality, choice schedule, or ambient completeness coordinate from which a second completion read could be selected.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCompleteMetricNoChoiceInterface`

Proof. First use the accepted carrier route from Definition 885.1. The rows $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ provide the source schedules, shared meet, extraction row, selector budget, selected window, tolerance readback, Real seal, terminal transport, displayed continuation row, package provenance, and local naming row as finite packet data.

Next apply Definition 885.85 and Definition 885.89. They place the selected-window and tolerance-readback route before the terminal structural rows and exhaust every Real or Completion-facing root read at the displayed carrier path, with no hidden selector, quotient stream, selected host limit, host equality, choice schedule, or ambient completeness coordinate.

It remains to compare the two completion-facing endpoints. The Lean proof closes this step by applying cont_deterministic to the two displayed continuation witnesses $\mathsf{Cont}(\text{terminal}, c, \text{completionA})$ and $\mathsf{Cont}(\text{terminal}, c, \text{completionB})$. Thus the endpoints are hsame-classified over the visible terminal interface, and the same Pkg provenance records that both completion rows belong to the finite packet surface. □

Theorem 885.96 (Cauchy modulus refinement RegSeqRat–StreamName–Real coherence)**.** *For an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet displaying*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N,$$

every $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumer reads the same budget-refinement route up to the displayed* hsame *transport and* Cont *replay. The shared route is the carrier path through the source schedules, shared meet, extraction row, selector budget, selected window, tolerance readback, Real seal, transport, continuation, provenance, and local naming rows.*

No such consumer may split the route into a separate stream selector, detached Real seal, quotient stream equality, hidden selector, second meet, selected limit, host equality, or ambient completeness coordinate. The consumer chapters chapter 301, chapter 126, and chapter 38 therefore consume one displayed budget-refinement route rather than three independent routes.

Proof. First apply Definition 885.84. It binds the source schedules M_0, M_1, shared meet U, and extraction row V as the common root of every accepted budget-refinement read.

Next use Definition 885.85. The $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ reads of selected windows and tolerance data pass through the same selector budget T and the displayed rows W, Q, with no separate stream selector exposed.

Apply Definition 885.89. It places the $\mathsf{Real}^{\uparrow}$ seal row E and structural rows H, C, P, N on the same packet route and excludes quotient streams, selected limits, host equalities, hidden selectors, second meets, and ambient completeness rows from the public surface.

Finally combine Definition 885.90 with Definition 885.94. The displayed rows determine one accepted budget-refinement route up to hsame transport and Cont replay, and the three named consumer chapters read that same route through their local NameCert surfaces. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier regseq streamname real coherence`

Theorem 885.97 (Cauchy modulus refinement RegSeqRat–StreamName–Real terminal factorization)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet whose displayed route is*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N,$$

all $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and Completion consumers factor through the same terminal finite route. The factorization is the carrier path through the source schedules, shared meet, extraction row, selector budget, selected-window row, tolerance-readback row, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. No detached completion seal, hidden selector, second meet, quotient stream, selected limit, host equality, or ambient completeness coordinate can supply a separate consumer route.*

Proof. First apply Definition 885.84. It fixes M_0, M_1, U, V as the shared source-meet-extraction spine for every accepted root read before any selector or seal row is available.

Next use Definition 885.85. The selected-window and tolerance-readback rows W, Q are read only through the displayed selector-budget row T, so $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ consumers cannot detach a hidden selector from the source spine.

Apply Definition 885.89. Every $\mathsf{Real}^{\uparrow}$ or Completion-facing root read is exhausted by $M_0, M_1, U, V, T, W, Q, E, H$ with no additional quotient, selected-limit, host-equality, or ambient-completeness coordinate.

Finally combine Definition 885.90, Definition 885.91, and Definition 885.96. Determinacy identifies any two reads with the displayed rows, noninterference rules out hidden selector and second-meet requests, and coherence places the RegSeqRat, StreamName, and Real consumer surfaces on the same route. Completion consumers are already covered by route completeness, so all four consumer classes factor through the terminal finite packet. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier regseq streamname real terminal factorization`

Theorem 885.98 (Cauchy modulus refinement diagonal-budget cofinality route)**.** *Let an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *route display*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Then the same route remains cofinal when it is read by a diagonal-budget consumer. The diagonal-budget consumer can read only the shared meet row U, the extraction row V, the selector-budget

row T, the selected-window row W, the tolerance-readback row Q, the Real$^{\uparrow}$ *seal row E, and the structural rows H, C, P, N already exposed by the root route. It cannot introduce a hidden selector, second meet, quotient stream, host equality, selected limit, or ambient completeness coordinate.*

Proof. First apply Definition 885.84. The source rows M_0, M_1 force every accepted read to pass through the same shared meet U and extraction row V before any selector-facing budget can be read.

Next use Definition 885.85. The diagonal-budget consumer reaches the selected-window and tolerance-readback rows only through the displayed selector-budget row T, so W and Q cannot come from a hidden selector.

Apply Definition 885.89. It exhausts every Real$^{\uparrow}$ or Completion-facing root read at $M_0, M_1, U, V, T, W, Q, E, H, C$ with no quotient stream, selected limit, host equality, second meet, hidden selector, or ambient completeness coordinate.

Finally invoke Definition 885.92. Since completion consumers are determined by the same displayed route up to the visible hsame transport and Cont replay, a diagonal-budget read has no separate coordinate from which to select a different cofinal route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier diagonal budget cofinality route`

Theorem 885.99 (Cauchy modulus refinement selector nonempty route)**.** *Let an accepted* CauchyModulusRefineme *route display*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Any StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, *or Completion consumer that reads selected-window or tolerance data must first expose the selector-budget row T as a nonempty route following the shared meet U and extraction row V. No hidden selector, second meet, quotient stream, selected limit, host equality, or ambient completeness coordinate can supply the selected-window row W, tolerance-readback row Q, or Real seal row E.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector nonempty route`

Proof. Start with Definition 885.84. It binds the source rows M_0, M_1 to the shared meet U and extraction row V before any selected-window or tolerance read can be accepted.

Next apply Definition 885.85. The selected-window and tolerance-readback rows W, Q are available only through the displayed selector-budget row T, so a consumer that reads either row has already exposed a nonempty selector-budget route.

Use Definition 885.87. The Real seal and structural rows E, H, C, P, N remain behind the same carrier route, and the excluded quotient stream, selected limit, host equality, hidden selector, second meet, and ambient completeness coordinate have no exported entry point.

Finally apply Definition 885.98. Completion-facing consumers that read the diagonal budget stay cofinal on the displayed route through $U, V, T, W, Q, E, H, C, P, N$, so the selector-budget route cannot be replaced by a detached completion or ambient-completeness coordinate. □

Theorem 885.100 (Cauchy modulus refinement CauchyCriterion selector cofinality)**.** *Let an accepted* CauchyModulusRefinement$^{\uparrow}$ *route display*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Let a $\mathsf{CauchyCriterion}^{\uparrow}$ *consumer, read through chapter 392, share the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows with this displayed route. Then the consumer must read the selector route through the shared meet* U, *extraction row* V, *selector-budget row* T, *selected-window row* W, *tolerance-readback row* Q, *and* $\mathsf{Real}^{\uparrow}$ *seal row* E, *with the support rows* H, C, P, N, *before exposing any CauchyCriterion output.*

Equivalently, the CauchyCriterion selector surface is cofinal on the displayed CauchyModulusRefinement budget route. It has no detached selector, second meet, quotient stream, selected limit, host equality, ambient completeness coordinate, or separate $\mathsf{Real}^{\uparrow}$ *seal from which to expose a criterion output.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier cauchycriterion selector cofinality`

Proof. First apply Definition 885.96. The shared $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows already force the consumer to read one budget-refinement route through the displayed source schedules, shared meet, extraction row, selector budget, selected window, tolerance readback, seal row, and support rows.

Next use Definition 885.98. It says that any diagonal-budget or completion-facing read remains cofinal on $U, V, T, W, Q, E, H, C, P, N$, so the CauchyCriterion consumer cannot obtain its selector data from a second meet, hidden selector, quotient stream, selected limit, host equality, or ambient completion coordinate.

Apply Definition 885.99. Since the consumer asks for selector-facing CauchyCriterion output, the selector-budget row T must already be exposed as a nonempty route after U and V, and the selected-window and tolerance-readback rows W, Q must be read through that route.

Finally invoke the sibling compatibility theorem Definition 392.39 from chapter 392. Its CauchyCriterion selector surface factors through the same finite StreamName–RegSeqRat–DyadicRatCore–Real packet before any $\mathsf{Real}^{\uparrow}$ seal is exposed, and therefore the shared CauchyModulusRefinement route is the required cofinal selector route for the criterion output. □

Theorem 885.101 (Cauchy modulus refinement criterion-output boundary)**.** *Let an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *route display*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Let a $\mathsf{CauchyCriterion}^{\uparrow}$ *consumer and a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *consumer share the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows with the displayed route. Then both consumers expose the same finite criterion-output boundary through*

$$U, V, T, W, Q, E, H, C, P, N.$$

Neither consumer can add a detached selector, second meet, quotient stream, selected limit, host equality, countable-choice schedule, ambient completeness coordinate, or separate $\mathsf{Real}^{\uparrow}$ *seal.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier criterion output boundary`

Proof. For the $\mathsf{CauchyCriterion}^{\uparrow}$ consumer, apply Definition 885.100. The criterion output must be read through the shared meet U, extraction row V, selector-budget row T, selected-window row W, tolerance-readback row Q, $\mathsf{Real}^{\uparrow}$ seal row E, and support rows H, C, P, N.

For the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ consumer, apply Definition 435.74. The uniform diagonal-budget read identifies its compatible window, tolerance, readback, and seal coordinates with the

same finite route rather than with a second schedule, quotient stream, selected limit, or completion coordinate.

Now use Definition 885.90. Since the two consumers share the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, componentwise hsame transport and displayed Cont replay identify their criterion-output route with the accepted CauchyModulusRefinement selector route.

Finally apply Definition 885.91. The shared meet and selector rows already determine the public boundary $U, V, T, W, Q, E, H, C, P, N$, so an off-route selector, second meet, quotient stream, selected limit, host equality, countable-choice schedule, ambient completeness coordinate, or separate $\mathsf{Real}^{\uparrow}$ seal cannot be introduced by either consumer. □

Theorem 885.102 (Cauchy modulus refinement RegSeqRat–Real selector exactness)**.** *For an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *route displaying*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N,$$

the $\mathsf{RegSeqRat}^{\uparrow}$ *tail read, the* $\mathsf{StreamName}^{\uparrow}$ *selected-window read, and the* $\mathsf{Real}^{\uparrow}$ *seal read are three projections of the same selector route through* U, V, T, W, Q, E*. No hidden selector, second meet, quotient stream, host equality, detached seal, or ambient completeness coordinate can supply one projection without the other two.*

Proof. First apply Definition 885.84 and Definition 885.85. They bind the accepted route to the source rows M_0, M_1, the shared meet U, the extraction row V, and the selector-budget row T before either the selected-window row W or the tolerance-readback row Q can be inspected.

Next use Definition 885.96. The $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers read one budget-refinement route through $U, V, T, W, Q, E, H, C, P, N$ rather than three independent projections.

Apply Definition 885.98 and Definition 885.99. These theorems keep diagonal-budget and selector-facing reads cofinal on the same displayed selector route and make T a nonempty entry before W, Q, E can be consumed.

Finally invoke Definition 885.100. The CauchyCriterion consumer sees the same StreamName–RegSeqRat–DyadicRatCore–Real packet before exposing its output. Hence none of the excluded coordinates can provide just one of the RegSeqRat, StreamName, or Real projections while omitting the other two. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier regseq real selector exactness`

Theorem 885.103 (Cauchy modulus refinement RegSeqRat–Real selector lockstep)**.** *For an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *route displaying*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N,$$

the $\mathsf{RegSeqRat}^{\uparrow}$ *tail projection, the* $\mathsf{StreamName}^{\uparrow}$ *selected-window projection, and the* $\mathsf{Real}^{\uparrow}$ *seal projection are lockstep projections of the same selector route through* U, V, T, W, Q, E*. No hidden selector, second meet, quotient stream, detached seal, selected limit, host equality, or ambient completeness coordinate can alter one projection without altering the other two.*

Proof. First apply Definition 885.84 and Definition 885.85. They bind the displayed route to the source rows M_0, M_1, the shared meet U, the extraction row V, and the selector-budget row T before any of the three consumer projections can be read.

Next use Definition 885.96. It places the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumer surfaces on one budget-refinement route rather than on separate tail, stream, and seal routes.

Apply Definition 885.99. The selected-window and tolerance-facing reads must expose the nonempty selector-budget route through T, W, Q before a projected tail or seal can be consumed.

Finally invoke Definition 885.102. Since the RegSeqRat tail read, StreamName selected-window read, and Real seal read are already exact projections of the same selector route through U, V, T, W, Q, E, changing one projection would change the shared route and therefore the other two projections as well. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier regseq real selector lockstep`

Theorem 885.104 (Cauchy modulus refinement finite observation budget pullback)**.** *Let an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *route display*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Let this selector route be consumed by a $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet as in chapter 435, and let*

$$F = (B, S, W_F, D_F, R_F, E_F, H_F, C_F, P_F, N_F)$$

be an accepted $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet as in chapter 782. Suppose the shared* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *faces of chapter 126, chapter 301, chapter 291, and chapter 38 identify the CauchyModulusRefinement selected-window, tolerance-readback, regular handoff, and Real seal rows with the finite observation budget rows by displayed componentwise* hsame *transports*

$$W\mathsf{hsame}W_F, \qquad Q\mathsf{hsame}D_F, \qquad T\mathsf{hsame}R_F, \qquad E\mathsf{hsame}E_F.$$

Then every Real-facing read of the common route factors through the CauchyModulusRefinement rows

$$U, V, T, W, Q, E, H, C, P, N$$

together with the finite observation budget rows

$$B, S, W_F, D_F, R_F, E_F, H_F, C_F, P_F, N_F$$

before any $\mathsf{Real}^{\uparrow}$ *seal is exposed. Thus finite observation budgets are the readable selector surface for this Real-completion route: the pullback introduces no quotient stream, selected limit, host equality, countable choice, hidden observation oracle, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier finite observation budget pullback`

Proof. Start with the CauchyModulusRefinement side. By Definition 885.100, a CauchyCriterion or UniformCauchyCriterion consumer of the route must read the selector through the shared meet U, extraction row V, selector-budget row T, selected-window row W, tolerance-readback row Q, Real seal row E, and support rows H, C, P, N before exposing criterion output.

Next apply Definition 885.102 and Definition 885.103. They make the $\mathsf{RegSeqRat}^{\uparrow}$ tail projection, $\mathsf{StreamName}^{\uparrow}$ selected-window projection, and $\mathsf{Real}^{\uparrow}$ seal projection exact lockstep projections of the same selector route, so no Real-facing read can detach the seal from U, V, T, W, Q, E.

Read the finite observation packet through its public route. The public export theorem Definition 782.14 exposes the finite budget-to-seal route $B \to S \to W_F \to D_F \to R_F \to E_F$ together with H_F, C_F, P_F, N_F, and the UniformCauchyCriterion pullback Definition 782.20 identifies that route with the uniform criterion consumer on the displayed shared rows.

Finally use terminal route no-branching and endpoint exactness, Definition 782.28 and Definition 782.29. The displayed transports identify W, Q, T, E with W_F, D_F, R_F, E_F, so the common consumer has only the finite pullback surface listed in the statement before the Real seal is reached. The non-escape clauses in the cited theorems exclude quotient streams, selected limits, host equality, countable choice, hidden observation oracles, and ambient completeness coordinates from the pullback. □

Theorem 885.105 (Cauchy modulus refinement terminal budget route exhaustion)**.** *Let an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *route display*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Let this route be consumed by $\mathsf{Real}^{\uparrow}$ *or Completion consumers through the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, *and* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *faces named in the surrounding chapters. Suppose an accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet*

$$F = (B, S, W_F, D_F, R_F, E_F, H_F, C_F, P_F, N_F)$$

is identified with the common route by the displayed componentwise transports of Definition 885.104. Then every Real-facing or Completion-facing consumer of the common route factors through the combined finite surface

$$U, V, T, W, Q, E, H, C, P, N$$

and

$$B, S, W_F, D_F, R_F, E_F, H_F, C_F, P_F, N_F.$$

No quotient stream, selected host limit, host equality, countable choice, hidden observation oracle, detached seal, or ambient completeness coordinate supplies another terminal route for those consumers.

Proof. First use Definition 885.97. It makes the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and Completion reads factor through the displayed CauchyModulusRefinement route $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$.

Next apply Definition 885.98 and Definition 885.100. Diagonal-budget, CauchyCriterion, and UniformCauchyCriterion consumers remain cofinal on the same selector route before any Real or Completion endpoint is exposed.

Now use Definition 885.102 together with Definition 885.103. The $\mathsf{RegSeqRat}^{\uparrow}$ tail read, $\mathsf{StreamName}^{\uparrow}$ selected-window read, and $\mathsf{Real}^{\uparrow}$ seal read are exact lockstep projections of U, V, T, W, Q, E, so a consumer cannot detach a host limit or seal coordinate from the common route.

Finally invoke Definition 885.104, Definition 782.28, and Definition 782.29. The finite observation rows $B, S, W_F, D_F, R_F, E_F, H_F, C_F, P_F, N_F$ are the pullback surface for the shared selector route, and terminal no-branching plus endpoint exactness excludes quotient streams, selected host limits, host equality, countable choice, hidden observation oracles, detached seals, and ambient completeness coordinates as alternate terminal routes. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier terminal budget route exhaustion`

Theorem 885.106 (Cauchy modulus refinement current phase spine)**.** *Every accepted* CauchyModulusRefinement$^{\uparrow}$ *consumer for the current* Real$^{\uparrow}$ *and Completion route factors through four displayed faces: the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, the* StreamName$^{\uparrow}$ *finite-window row, the* RegSeqRat$^{\uparrow}$ *readback row, and the* Real$^{\uparrow}$ *seal. These faces are read from the same finite* BHist *route through displayed* hsame *transports,* Cont *replay,* Pkg *provenance, and local* NameCert *rows, and the route admits no quotient stream, selected limit, host real equality, choice data, hidden selector, second meet row, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.RootUnblockObligationSurface.CauchyModulusRefinementCarr current phase spine`
Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier current phase spine`

Proof. Begin with root source binding and root selector readback. The accepted route displays $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, so the current consumer must read source, common meet, extraction, selector budget, selected window, tolerance readback, and seal before any endpoint is exposed.

Use route completeness and the RegSeqRat, StreamName, and Real coherence theorems in the surrounding surface. They identify the tolerance ledger, finite-window row, regular-sequence readback, and Real seal as projections of the same route rather than independent consumers.

Apply the diagonal budget cofinality route, the finite observation budget pullback, and terminal budget route exhaustion. Together they force every Real-facing or Completion-facing read through the four displayed faces and the support rows H, C, P, N.

The refused coordinates are exactly those excluded by the terminal route. Quotient streams, selected limits, host real equality, choice data, hidden selectors, second meet rows, and ambient completeness would each supply an endpoint outside the displayed BHist, hsame, Cont, Pkg, and NameCert route, so none is accepted. □

Theorem 885.107 (Cauchy modulus refinement open phase spine lock)**.** *For the current* CauchyModulusRefinemen *route, any open* Real$^{\uparrow}$ *or Completion consumer that names a refinement endpoint while leaving one of the four faces absent is held at the spine boundary. The required faces are the* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* StreamName$^{\uparrow}$ *finite-window row,* RegSeqRat$^{\uparrow}$ *readback row, and* Real$^{\uparrow}$ *seal, supported by* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Read the route through the current-phase spine of Definition 885.106. It supplies the four public faces and the support rows as one finite route.

If the tolerance ledger is absent, the consumer has no dyadic budget surface. If the finite-window row is absent, it has no StreamName observation boundary. If the RegSeqRat readback is absent, the regular tail cannot be read back from the selector. If the Real seal is absent, no Real or Completion endpoint is exposed.

The root source binding, root selector readback, and route completeness steps do not add a substitute face. They only route the accepted rows to the endpoint.

Thus an open consumer missing any displayed face remains at the spine boundary. The same refusal excludes quotient streams, selected limits, host real equality, choice data, hidden selectors, second meet rows, and ambient completeness from serving as replacements. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier open phase spine lock`

Theorem 885.108 (Cauchy modulus refinement four-face consumer boundary)**.** *The consumer boundary for the current* CauchyModulusRefinement$^{\uparrow}$ *handoff to* Real$^{\uparrow}$ *and Completion is exactly the four-face route consisting of the* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* StreamName$^{\uparrow}$ *finite-window row,* RegSeqRat$^{\uparrow}$ *readback row, and* Real$^{\uparrow}$ *seal. Any accepted downstream consumer must preserve those faces by displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows before reading a Real or Completion endpoint.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier four face consumer boundary`

Proof. First compose root source binding with root selector readback. This places the refinement source, selector, budget, window, tolerance readback, and seal in one route.

Next use route completeness together with RegSeqRat, StreamName, and Real coherence. The three coherence faces and the dyadic tolerance ledger are therefore read as the same current route, not as four unrelated records.

Now apply diagonal budget cofinality, finite observation budget pullback, and terminal budget route exhaustion. These theorems move every downstream consumer through the finite budget surface before it reaches the endpoint, so the boundary is the four displayed faces plus H, C, P, N.

It remains to rule out extra terminal data. Quotient streams, selected limits, host real equality, choice data, hidden selectors, second meet rows, and ambient completeness would bypass at least one displayed face. Since the accepted carrier has no such coordinate, the consumer boundary is exactly the four-face route. □

Corollary 885.109 (Cauchy modulus refinement root source binding strict obstruction)**.** *Let a displayed failure, refusal, separation, or countermodel row in the root-unblock surface challenge an accepted* CauchyModulusRefinement$^{\uparrow}$ *packet by asking a root consumer either to read a selector, seal, or structural row before the source route*

$$M_0, M_1, U, V$$

is displayed, or to reach the Real$^{\uparrow}$ *or Completion seal through a quotient stream, selected limit, host real equality, hidden selector, second meet, or ambient completeness coordinate outside*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Then the obstruction is strict and local. It blocks only the named converse or reuse route that makes that challenged read. It does not assert a global impossibility for CauchyModulusRefinement$^{\uparrow}$ *packets, does not become a host theorem about* Real$^{\uparrow}$ *or Completion, and does not provide hidden external validation of the seal.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root source binding strict obstruction`

Proof. First use root source binding, Definition 885.84. Every root consumer of an accepted packet must first read M_0, M_1, the shared meet U, and the extraction row V through the carrier route of Definition 885.1. Hence a displayed obstruction to an early selector, seal, or structural read says only that the challenged read has not factored through the required source-meet-extraction route. It is a refusal of that local converse or reuse route, not a statement that the carrier cannot be accepted.

Now use root Real seal non-escape, Definition 885.87. Every $\mathsf{Real}^{\uparrow}$ or Completion consumer reaches the seal row E only after the displayed route

$$M_0, M_1, U, V, T, W, Q, H, C, P, N$$

has been displayed, and the theorem exports no quotient stream, selected limit, host real equality, hidden selector, second meet, or ambient completeness row as an alternate route to the seal. Thus an obstruction row aimed at one of those unlisted coordinates rejects precisely that coordinate as an entry point into the accepted packet.

Combining the two cited results, every consumer-facing use of the root-unblock surface factors through the named source route and then through the named seal route. Any challenged coordinate outside those rows is therefore blocked only at the point where it tries to serve as a converse route, reuse route, or seal shortcut. Since the accepted carrier remains the finite packet of Definition 885.1, the obstruction neither proves an ambient impossibility theorem nor imports a host validation principle beyond the displayed $\mathsf{CauchyModulusRefinement}^{\uparrow}$ rows. □

Theorem 885.110 (Cauchy modulus refinement source-window lock)**.** *For every accepted* CauchyModulusRefineme *root read of*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the consumer-visible source rows M_0, M_1, the shared meet row U, and the extraction row V must be exposed before any selected-window row is read. Thus no root read can reach T, W, Q, E, H, C, P, N as a selected-window route until the displayed source-meet-extraction front M_0, M_1, U, V has been presented.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier source window lock`

Proof. Read the carrier in Definition 885.1. Its accepted packet presents the two source schedules, the shared meet, and the extraction witness as the finite front of the root route.

Apply Definition 885.4. The extraction row V is bound to the displayed meet U after M_0, M_1, so a downstream selected-window read cannot supply a hidden source or a second meet.

Finally apply Definition 885.84. Every accepted root consumer is already required to read M_0, M_1, U, V through the carrier route before any later selector, seal, or structural row is available. Hence the selected-window surface is locked behind the displayed source window. □

Theorem 885.111 (Cauchy modulus refinement selector-stability lock)**.** *For every accepted* CauchyModulusRefinem *root read, the selector route $V \to T \to W \to Q$ is preserved by the displayed* hsame *and* Cont *rows. The selected-window and tolerance-readback ledgers cannot be replaced by a hidden selector, a second window ledger, or a detached continuation route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinement selector stability lock`

Proof. Start with Definition 885.5. It identifies T as the selector-budget row consumed by the selected-window ledger W and the tolerance-readback ledger Q.

Use Definition 885.85. The readback theorem places T, W, Q after the source-meet-extraction route, so the selector is reached from V and not from an independent ledger.

The displayed hsame row H transports the same packet route, and the displayed Cont row C continues that route without changing the selected-window ledger. Therefore the route $V \to T \to W \to Q$ remains the only exported selector path. □

Theorem 885.112 (Cauchy modulus refinement Real-seal root handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion handoff from an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root read factors through*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

The handoff exports no quotient stream, selected limit, host real equality, hidden selector, second meet row, or ambient completeness coordinate as an alternate Real-seal route.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal root handoff`

Proof. Apply Definition 885.7. The Real seal E is reached from the displayed source, meet, extraction, selector-budget, selected-window, and tolerance-readback rows.

Next apply Definition 885.87. It rules out an alternate route through quotient streams, selected limits, host real equality, hidden selectors, second meet rows, or ambient completeness coordinates at the root boundary.

Finally use Definition 885.56. Every Real or Completion consumer is exhausted by the displayed route, so the handoff factors through $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ and exports no additional Real-seal coordinate. □

Theorem 885.113 (Cauchy modulus refinement root window exhaustion)**.** *Every accepted* $\mathsf{CauchyModulusRefinem}$ $\mathsf{Real}^{\uparrow}$ *or Completion selected-window consumer is equivalent, as a finite BEDC route, to first reading the source and meet rows* M_0, M_1, U, V*, then the selector and selected-window rows* T, W, Q, E*, and then the structural rows* H, C, P, N*. Conversely, any displayed route of this form determines the same* $\mathsf{Real}^{\uparrow}$ *or Completion selected-window consumer. Quotient streams, selected limits, host real equality, hidden selectors, second meet rows, and ambient completeness have no route coordinate for such a consumer.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root window exhaustion`

Proof. The forward direction starts with the source-window lock, Definition 885.110. It forces every accepted consumer route to expose M_0, M_1, U, V before any selected-window read is available.

Next apply the selector-stability lock, Definition 885.111. The displayed selector path from V through T, W, Q is preserved by the hsame and Cont rows, so no hidden selector or detached selected-window ledger can supply a second route.

Now use the Real-seal root handoff, Definition 885.112. It places E, H, C, P, N after the same source and selector rows for every $\mathsf{Real}^{\uparrow}$ or Completion handoff, and it excludes quotient streams, selected limits, host real equality, second meet rows, and ambient completeness as route coordinates.

For the reverse direction, read an accepted packet in exactly the displayed order. The three locks just cited identify each segment with the only source, selector, selected-window, Real-seal, and structural surface exported by the carrier. Therefore the route determines the same $\mathsf{Real}^{\uparrow}$ or Completion selected-window consumer. □

Theorem 885.114 (Cauchy modulus refinement root-source meet determinacy)**.** *Let two accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root reads agree on the source rows* M_0, M_1*, the shared meet row* U*, and the extraction row* V *of the carrier in Definition 885.1. Then before any selected-window row is read, the two reads determine the same source-meet front. In particular, no later selector, selected-window ledger, Real seal, transport, continuation, package, or local name can introduce a second source-meet-extraction route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root source meet determinacy`

Proof. Read the carrier definition. The agreed rows M_0, M_1, U, V are exactly the displayed source-meet-extraction front of the root packet.

Apply source-window lock, Definition 885.110. It places that front before every selected-window read, so neither root read can use T, W, Q, E, H, C, P, N to choose a different source side.

Now use root window exhaustion, Definition 885.113. Once the front is fixed, every later selected-window or Real-completion route is a continuation of the same finite carrier route. Hence the source-meet front is determined before any selected-window consumer appears. □

Theorem 885.115 (Cauchy modulus refinement window consumer coverage)**.** *Every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *selected-window consumer is exhausted by the finite carrier rows*

$$M_0, M_1, U, V, T, W, Q, H, C, P, N.$$

The consumer receives no quotient stream, selected host limit, hidden selector, second meet row, ambient completeness coordinate, detached tolerance readback, or route outside the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier window consumer coverage`

Proof. Start from the source-window lock. The consumer must read M_0, M_1, U, V before a selected-window route is available.

Apply selector-stability lock, Definition 885.111. It forces the selected-window and tolerance-readback rows to proceed through T, W, Q on the same route.

Finally use root window exhaustion. The structural rows H, C, P, N preserve and name the displayed route, while quotient streams, selected host limits, hidden selectors, second meet rows, ambient completeness coordinates, and detached tolerance readbacks have no carrier coordinate. Thus the selected-window consumer is exhausted by the stated finite rows. □

Theorem 885.116 (Cauchy modulus refinement Real-seal source conservation)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion seal read from an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root packet conserves the same source-meet-extraction route* M_0, M_1, U, V *before the Real seal row* E *is exposed. The seal cannot replace that route by a quotient stream, selected limit, host real equality, hidden selector, second meet row, ambient completeness coordinate, or detached completion witness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal source conservation`

Proof. Begin with source-window lock and root-source meet determinacy. They bind every root read to the displayed M_0, M_1, U, V front before any selected-window or seal route can be consumed.

Apply the Real-seal root handoff, Definition 885.112. It places the Real seal row E after the same source, meet, extraction, selector-budget, selected-window, and tolerance-readback rows.

Use root window exhaustion for the final exclusion. Since every Real or Completion selected-window consumer is equivalent to the displayed carrier route, the seal has no coordinate for quotient streams, selected limits, host real equality, hidden selectors, second meet rows, ambient completeness coordinates, or detached completion witnesses. Therefore the same source-meet-extraction route is conserved before E is exposed. □

Theorem 885.117 (Cauchy modulus refinement source-window front totality)**.** *Every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *selected-window,* $\mathsf{Real}^{\uparrow}$*, or Completion consumer factors through the displayed source front*

$$M_0, M_1, U, V$$

before reading any of T, W, Q, E, H, C, P, N*. Conversely, a displayed route with that source front and the existing selector-stability, selected-window, Real-seal, transport, continuation, package, and local-name rows determines the same consumer surface.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier source window front totality`

Proof. The forward direction starts with the source-window lock, Definition 885.110. It places M_0, M_1, U, V before any selected-window read is available.

Apply selector-stability lock, Definition 885.111. The selected-window rows T, W, Q must continue from the same extraction row V, so a consumer cannot reach them through a hidden selector or detached window ledger.

For $\mathsf{Real}^{\uparrow}$ and Completion consumers, use the Real-seal root handoff, Definition 885.112, together with Real-seal source conservation, Definition 885.116. These results place E, H, C, P, N after the same source-meet-extraction route and prevent the seal from replacing that route.

For the converse, read the displayed packet in the stated order. Root window exhaustion, Definition 885.113, identifies that route with the full selected-window, $\mathsf{Real}^{\uparrow}$, or Completion consumer surface, so the displayed source front and the existing selector and seal rows determine the same consumer. □

Theorem 885.118 (Cauchy modulus refinement source-window totality)**.** *Every accepted* CauchyModulusRefineme *selected-window,* $\mathsf{Real}^{\uparrow}$*, or Completion consumer is determined by first exposing the source rows, shared meet, and extraction front*

$$M_0, M_1, U, V,$$

then routing through

$$T, W, Q, E, H, C, P, N.$$

Conversely, any displayed route with those rows determines the same selected-window, $\mathsf{Real}^{\uparrow}$*, or Completion consumer. No quotient stream, selected limit, host real equality, hidden selector, second meet row, ambient completeness coordinate, or detached completion witness supplies another consumer route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier source window totality`

Proof. The forward direction begins with source-window lock, Definition 885.110. It forces every accepted consumer to expose M_0, M_1, U, V before a selected-window or seal row can be read.

Apply selector-stability lock, Definition 885.111. The selector, selected-window, and tolerance-readback segment is exactly the displayed route from V through T, W, Q, and the structural rows preserve that route rather than replacing it.

For $\mathsf{Real}^{\uparrow}$ and Completion consumers, use Real-seal root handoff, Definition 885.112, together with Real-seal source conservation, Definition 885.116. These results place E, H, C, P, N after the same source and selector front and rule out quotient streams, selected limits, host real equality, hidden selectors, second meet rows, ambient completeness coordinates, and detached completion witnesses.

For the converse, read any displayed route with rows $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$. Root window exhaustion, Definition 885.113, identifies that route with the complete selected-window, $\mathsf{Real}^{\uparrow}$, or Completion surface. Hence the displayed rows determine the same consumer. □

Theorem 885.119 (Cauchy modulus refinement source-window comparison lock)**.** *Let two accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root reads agree on the source rows* M_0, M_1*, the shared meet row* U*, and the extraction row* V *of Definition 885.1. Then every selected-window,* $\mathsf{Real}^{\uparrow}$*, or Completion consumer comparison between those reads agrees on the source-window front before either comparison reads any of*

$$T, W, Q, E, H, C, P, N.$$

Thus no later selector, selected-window ledger, Real seal, transport row, continuation row, package row, or local name row can distinguish the two reads by introducing another source-window front.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier source window comparison lock`

Proof. Begin with source-window lock, Definition 885.110. It places M_0, M_1, U, V before every selected-window read, so a comparison cannot inspect T, W, Q, E, H, C, P, N until the source front has already been exposed.

Apply root-source meet determinacy, Definition 885.114. Since the two root reads agree on M_0, M_1, U, V, the displayed source-meet-extraction route is the same for both reads before any later row can be consumed.

Finally use source-window totality, Definition 885.118. Every selected-window, $\mathsf{Real}^{\uparrow}$, or Completion consumer is determined by first exposing the same source front and then reading the remaining displayed rows. Therefore any consumer comparison agrees on that front before it reaches the later packet rows. □

Theorem 885.120 (Cauchy modulus refinement source-window Real-seal pullback)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *or Completion seal read is the pullback of the displayed source-window front* M_0, M_1, U, V *along the selector route* $V \to T \to W \to Q \to E$ *and the structural rows* H, C, P, N*. Conversely, any displayed route with those source, selector, seal, and structural rows determines the same seal consumer. The pullback has no coordinate for quotient streams, selected host limits, host real equality, hidden selectors, second meet rows, or ambient completeness.*

Proof. Start with the source-window lock, Definition 885.110. It exposes M_0, M_1, U, V before any selected-window or seal read, so the Real-seal consumer cannot choose its source side after reaching T, W, Q, E, H, C, P, N.

Use selector-stability lock, Definition 885.111. The selected-window route proceeds from V through T, W, Q, and the displayed hsame and Cont rows preserve that route instead of supplying a hidden selector or detached window ledger.

Now apply the Real-seal root handoff, Definition 885.112. It places every $\mathsf{Real}^{\uparrow}$ or Completion seal read after the same source, selector, seal, transport, continuation, package, and local-name rows, ruling out quotient streams, selected host limits, host real equality, second meet rows, and ambient completeness as alternate seal coordinates.

For the converse, use source-window totality, Definition 885.118. A route that displays $M_0, M_1, U, V, T, W, Q, E,$ already determines the selected-window, $\mathsf{Real}^{\uparrow}$, or Completion consumer surface.

Finally compare any two such reads with source-window comparison lock, Definition 885.119. The comparison agrees on the source front before either read reaches the seal rows, so the displayed source-window front pulls back the Real-seal route and the same displayed route determines the same seal consumer. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier source window real seal pullback`

Theorem 885.121 (Cauchy modulus refinement Real consumer nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root packet factors through*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

The consumer has no route to quotient streams, selected host limits, host real equality, hidden selectors, second meet rows, ambient completeness, or detached completion witnesses outside that displayed BEDC packet.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real consumer nonescape`

↪ variant `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal consumer exhaustion`

Proof. Start with Real-seal root handoff, Definition 885.112. It routes every $\mathsf{Real}^{\uparrow}$ or Completion handoff through the displayed source, meet, extraction, selector, selected-window, tolerance, seal, transport, continuation, package, and local-name rows.

Use Real-seal source conservation, Definition 885.116. The seal preserves the same M_0, M_1, U, V source-meet-extraction route and cannot replace it by a quotient stream, selected limit, host real equality, hidden selector, second meet row, ambient completeness coordinate, or detached completion witness.

Now apply root window exhaustion, Definition 885.113. It identifies every accepted $\mathsf{Real}^{\uparrow}$ or Completion selected-window consumer with the displayed finite route and rules out alternate route coordinates.

Finally apply window consumer coverage, Definition 885.115. The selected-window portion of the consumer is exhausted by the carrier rows and the structural BHist, hsame, Cont, Pkg, and NameCert surface. Hence the Real or Completion consumer cannot escape the displayed finite packet. □

Theorem 885.122 (Cauchy modulus source-window Real-consumer lock)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer comparison of accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root reads first exposes the source-window rows*

$$M_0, M_1, U, V$$

and only then routes through

$$T, W, Q, E, H, C, P, N.$$

Consequently the comparison cannot distinguish two accepted reads by quotient streams, selected host limits, second meet rows, hidden selectors, or detached completion witnesses outside the displayed source-window, selector, Real-seal, transport, continuation, package, and local naming rows.

Proof. First expose the source front. By source-window front totality, Definition 885.117, every accepted selected-window, $\mathsf{Real}^{\uparrow}$, or Completion consumer begins with the displayed M_0, M_1, U, V rows.

Now compare two accepted reads. Source-window comparison lock, Definition 885.119, forces any consumer comparison to agree on that front before reading T, W, Q, E, H, C, P, N.

Finally apply Real consumer nonescape, Definition 885.121. Every $\mathsf{Real}^{\uparrow}$ or Completion route remains inside $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, so quotient streams, selected host limits, second meet rows, hidden selectors, and detached completion witnesses cannot supply a separate distinction. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier source window real consumer lock`

Theorem 885.123 (Cauchy modulus refinement L10 completion pullback)**.** *Every Phase Real and Completion consumer using an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

pulls back first along the source-window front M_0, M_1, U, V*, then along the selector and seal route* T, W, Q, E*, and finally along the structural rows* H, C, P, N*. No quotient stream, selected host limit, ambient completeness witness, detached completion witness, or host real equality supplies another L10 completion route.*

Proof. Begin with source-window lock, Definition 885.110. It exposes M_0, M_1, U, V before any selected-window or completion-facing row is available.

Next apply selector-stability lock, Definition 885.111, and Real-seal root handoff, Definition 885.112. These place the selector, selected-window, tolerance-readback, and Real-seal route T, W, Q, E after the same source-window front.

Use Real-seal source conservation, Definition 885.116. The seal preserves the displayed source route and cannot replace it by a quotient stream, selected host limit, host real equality, hidden selector, second meet row, ambient completeness coordinate, or detached completion witness.

Finally combine root window exhaustion, Definition 885.113, with Real consumer nonescape, Definition 885.121. The structural rows H, C, P, N preserve and name the same route, so every Phase Real and Completion consumer pulls back along the stated source, selector, seal, and structural rows. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier l10 completion pullback`

Theorem 885.124 (Cauchy modulus refinement completion-route pullback exactness)**.** *Every Phase Real and Completion consumer route of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet factors through the source window*

$$M_0, M_1, U, V,$$

the selector and seal rows

$$T, W, Q, E,$$

and the structural rows

$$H, C, P, N.$$

Conversely, any displayed route with those source-window, selector, seal, transport, continuation, package, and local naming rows determines the same Phase Real or Completion consumer. No

quotient stream, selected host limit, host real equality, hidden selector, second meet row, ambient completeness coordinate, or detached completion witness supplies another consumer route.

Proof. First build the source-window front. By source-window front totality, Definition 885.117, every selected-window, $\mathsf{Real}^{\uparrow}$, or Completion consumer begins with the displayed M_0, M_1, U, V rows before reading the later selector, seal, or structural rows.

Next pull the Real and Completion seal route back along that same front. The source-window Real-seal pullback theorem, Definition 885.120, identifies the route through T, W, Q, E, H, C, P, N as the pullback of the displayed source-window front, with no coordinate for quotient streams, selected host limits, host real equality, hidden selectors, second meet rows, or ambient completeness.

Finally lock the consumer comparison. The source-window Real-consumer lock, Definition 885.122, forces every Phase Real and Completion comparison to expose the same source window before reading T, W, Q, E, H, C, P, N. Hence the forward factorization is exact, and any displayed route with those rows determines the same consumer rather than a second route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier completion route pullback exactness`

Corollary 885.125 (Cauchy modulus refinement source-window strict obstruction)**.** *Let*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root packet. Any displayed refusal, separation, or countermodel row used against a source-window converse or consumer-reuse route for R is a strict local obstruction: it blocks only the attempted route that either reads one of T, W, Q, E, H, C, P, N before the source-meet-extraction front M_0, M_1, U, V, or sends a* $\mathsf{Real}^{\uparrow}$ *or Completion consumer through a quotient stream, selected host limit, host real equality, hidden selector, second meet row, ambient completeness coordinate, or detached completion witness outside the displayed packet. It does not state a global impossibility for Cauchy modulus refinement, a host theorem about all real completions, or a hidden external validation of any unlisted coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier source window strict obstruction`

Proof. Apply the source-window lock, Definition 885.110. It places the source rows M_0, M_1, the shared meet row U, and the extraction row V before any selected-window, seal, transport, continuation, package, or local-name row can be consumed. Hence a refusal or separation that concerns premature access to T, W, Q, E, H, C, P, N can block only that premature selected-window route; it cannot be read as a statement about every possible Cauchy-modulus construction.

Now apply Real consumer nonescape, Definition 885.121. Every $\mathsf{Real}^{\uparrow}$ or Completion consumer of the accepted packet factors through exactly

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

The same theorem excludes quotient streams, selected host limits, host real equality, hidden selectors, second meet rows, ambient completeness, and detached completion witnesses as consumer coordinates outside that packet. Therefore a consumer-facing obstruction can reject only those named off-route reuse attempts and cannot certify an unlisted host route.

Combining the two facts gives the strict scope. The first theorem fixes where the source-window route begins, and the second theorem exhausts every Real or Completion use by the displayed finite

route. No cited row supplies a quantifier over all host completions, an ambient theorem about all real objects, or an external validation channel. Thus the obstruction is local to the named converse or reuse route in the accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ packet. □

Theorem 885.126 (Cauchy modulus refinement root carrier threshold admission)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the root carrier admits the rows $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ *only after the shared meet row* U *and the selector-budget row* T *are displayed on the same route. In particular, the Real-completion root threshold surface may read* V, W, Q, E, H, C, P, N *only as descendants of the source schedules* M_0, M_1*, the shared meet* U*, and the selector budget* T *already shown in Definition 885.1.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementRootCarrierThresholdAdmission`

Proof. Project the carrier of Definition 885.1. Its finite packet lists the two source schedules, the shared meet, the extraction witness, the selector budget, the selected-window ledger, the tolerance-readback ledger, the Real seal, and the structural rows in one BHist tuple.

Apply the local NameCert obligations of Definition 885.2. Carrier admission is attached to the same tuple, while the source exactness and shared-window clauses require V to be read after M_0, M_1, U and require W, Q to be read through T.

Use source-meet exactness, selector-budget totality, and window-tolerance exactness, Definition 885.21, Definition 885.26, and Definition 885.22. These identify the root threshold route as the displayed chain through U and T before any Real-facing seal read can consume E. □

Theorem 885.127 (Cauchy modulus refinement root classifier transport exactness)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, componentwise* hsame *transport preserves the same source-meet-selector-window-readback route through* H *and* C*. A transported classifier read of* R *is therefore still a read of* $M_0, M_1, U, V, T, W, Q, E$ *in the displayed order, authenticated by the same package row* P *and the same local* $\mathsf{NameCert}$ *row* N*.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root classifier transport exactness`

Proof. Begin with classifier transport from Definition 885.16. The row H stores componentwise hsame transports for the carrier coordinates, and C stores the displayed continuation route between them.

Next bind the source portion. Source-meet exactness, Definition 885.21, keeps the witness V on the route from M_0, M_1 through U, so transport cannot replace the shared meet by a second source row.

Finally bind the selected-window and Real-facing portion. Selector-budget totality, window-tolerance exactness, and Real seal factorization, Definition 885.26, Definition 885.22, and Definition 885.23, keep T, W, Q, E on the same readback chain. The package and local name rows then certify that the transported classifier is still the displayed root route. □

Theorem 885.128 (Cauchy modulus refinement root ledger non-escape totality)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root ledger receives only the displayed rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

It receives no quotient stream, selected limit, host real equality, hidden selector, second meet row, or ambient completeness datum outside those carrier rows, and the completion-facing ledger is total exactly because every accepted consumer read is already accounted for by that displayed route.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root ledger nonescape totality`

Proof. Read the carrier and the Real seal factorization theorem, Definition 885.1 and Definition 885.23. The seal row E is reached only after the shared meet, extraction witness, selector budget, windows, tolerance rows, and regular readbacks have been displayed.

Apply the Real-consumer coverage theorem, Definition 885.56. It states that every Real or Completion consumer reads only the selector-budget, window, readback, and seal route together with the structural rows.

Finally apply non-escape, Definition 885.10. Since quotient streams, selected limits, host real equality, hidden selectors, second meet rows, and ambient completeness coordinates are absent from the carrier, the displayed ledger exhausts the root consumer surface. □

Theorem 885.129 (Cauchy modulus refinement root route determinacy)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the root read has the unique displayed route

$$M_0, M_1 \longrightarrow U \longrightarrow V \longrightarrow T \longrightarrow W \longrightarrow Q \longrightarrow E.$$

For any selected window read S, readback read B, seal read A, and endpoint read Z on that root route, the route package records the carried history rows

$$\mathsf{UnaryHistory}(M_0), \mathsf{UnaryHistory}(M_1), \mathsf{UnaryHistory}(U), \mathsf{UnaryHistory}(V), \mathsf{UnaryHistory}(T), \mathsf{UnaryHistory}(W), \mathsf{UnaryH}$$

the carrier and selected-read continuation links

$$\mathsf{Cont}(M_0, M_1, U), \quad \mathsf{Cont}(U, V, T), \quad \mathsf{Cont}(T, W, Q), \quad \mathsf{Cont}(Q, E, H), \quad \mathsf{Cont}(T, W, S), \quad \mathsf{Cont}(S, Q, B), \quad \mathsf{Cont}(B,$$

the package rows $\mathsf{Pkg}^{\mathrm{sig}}(\Omega, P, \pi)$ *and* $\mathsf{Pkg}^{\mathrm{sig}}(\Omega, Z, \pi)$ *for the same probe bundle* Ω *and package* π*, and the terminal classifier row* $\mathsf{hsame}(H, N)$*.*

The rows H, C, P, N respectively carry the componentwise hsame *transports, displayed* Cont *route, local* Pkg *provenance, and local* NameCert *authentication for that route. No accepted root read may substitute a second meet, hidden selector, quotient stream, host real equality, or ambient completeness row for any coordinate of the displayed route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root route determinacy`

Proof. First read the root carrier threshold admission and classifier transport exactness theorems, Definition 885.126 and Definition 885.127. They place the accepted carrier and its componentwise hsame, Cont, Pkg, and NameCert rows on the same displayed finite packet, and they expose the carrier histories for $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$.

Next bind the source and selected-window parts of the route. Source-meet exactness and selector-budget totality, Definition 885.21 and Definition 885.26, force every accepted read from M_0, M_1 through U, V, T before any selected finite-window row can be read. The selected-read links

$\mathsf{Cont}(T, W, S)$ and $\mathsf{Cont}(S, Q, B)$ then keep the selected window and readback rows as descendants of the selector budget and displayed window.

Use window-tolerance exactness and Real seal factorization, Definition 885.22 and Definition 885.23. These give the readback-to-seal and seal-to-endpoint replay links, so the rows S, B, A, Z inherit UnaryHistory closure and the endpoint package row stays over the same probe bundle and package as the carrier provenance row.

Finally use root ledger non-escape, Definition 885.128. The seal and endpoint are reached only after W, Q, and the ledger contains no second meet, hidden selector, quotient stream, host real equality, or ambient completeness coordinate. Hence the displayed route is the complete root route, with both package rows and the terminal classifier row still attached to the same finite packet. □

Theorem 885.130 (Cauchy modulus refinement shared-tail selector seal coherence)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

any selected-window read of R consumed by a $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *terminal route, a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *shared-schedule route, or a* $\mathsf{RegularCauchyModulusWitnessLedger}^{\uparrow}$ *seal route uses the same displayed meet U, selector budget T, finite window W, readback row Q, and* $\mathsf{Real}^{\uparrow}$ *seal E. Thus the adjacent L10 consumer routes cannot mediate a different seal through a hidden selector, second meet, quotient stream, host equality, selected limit, choice datum, or ambient completeness row.*

Proof. First fix the root route. By root route determinacy and root ledger non-escape, Definition 885.129 and Definition 885.128, every accepted selected-window read of R is already on the displayed chain through U, T, W, Q, E and has no extra carrier coordinate available for a second seal.

Next attach the three adjacent consumers. The terminal Real route of Definition 646.3, the shared-schedule inheritance route of Definition 435.45, and the witness-ledger seal route of Definition 977.3 all consume a displayed selected-tail route rather than an ambient completion object.

Therefore each consumer can only inherit the selector, shared tail, and Real-seal rows already displayed by R. Since the root ledger has no hidden selector, second meet, quotient stream, host equality, selected limit, choice datum, or ambient completeness row, all three consumer routes coincide on U, T, W, Q, E. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier shared tail selector seal coherence`

Theorem 885.131 (Cauchy modulus refinement root budget consumer exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root surface first passes through the selector-budget row T, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row W, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q before reading the* $\mathsf{Real}^{\uparrow}$ *seal row E. Thus the root budget consumer surface is exhausted by the displayed route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N,$$

with no hidden selector, quotient stream, host real equality, second meet row, selected limit, or ambient completeness datum available to downstream Real or Completion use.

Proof. Begin with the root carrier and classifier transport rows, Definition 885.126 and Definition 885.127. They expose T, W, Q, E as carrier coordinates transported by the same componentwise route and authenticated by the local package and naming rows.

Apply window-tolerance exactness, Definition 885.22. It forces every selected-window and dyadic or regular-rational readback through T, W, Q.

Finally apply Real-consumer coverage, Definition 885.56. Since every Real or Completion consumer is covered by the displayed route before reading E, the selector budget, finite window, and readback rows exhaust the root budget consumer surface. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root budget consumer exhaustion`

Theorem 885.132 (Cauchy modulus refinement root-window Real seal determinacy)**.** *Let*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

and

$$R' = (M_0, M_1, U, V, T, W, Q, E', H', C', P', N')$$

be accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packets with the same source schedules, shared meet, selector budget, finite window, and readback rows. Every public* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of the displayed root route classifies the two Real seal rows by* $\mathsf{hsame}(E, E')$.

Proof. Apply root route determinacy, Definition 885.129, to both packets. Since the packets share M_0, M_1, U, T, W, Q, both public reads must pass through the displayed route

$$M_0, M_1 \longrightarrow U \longrightarrow V \longrightarrow T \longrightarrow W \longrightarrow Q$$

before any Real seal row is read.

Next use root budget consumer exhaustion, Definition 885.131. A public $\mathsf{Real}^{\uparrow}$ or Completion consumer has no hidden selector, quotient stream, host equality, second meet, selected limit, or ambient completeness row available as an alternate seal source.

It remains only to compare the seal coordinates on the common route. Real seal factorization and classifier transport exactness, Definition 885.23 and Definition 885.127, identify the seal read as the Real-facing coordinate reached from the shared window and readback rows. The transported classifier rows H, C, P, N and H', C', P', N' therefore classify E and E' through the same displayed root route, giving $\mathsf{hsame}(E, E')$. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root window real seal determinacy`

Theorem 885.133 (Cauchy modulus refinement root threshold public exhaustion)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root surface*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

every public $\mathsf{Real}^{\uparrow}$ *or Completion consumer of* R *is exhausted by the displayed route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

The consumer first reads the source schedules, shared meet, extraction witness, selector budget, finite-window ledger, tolerance and regular-readback ledger, and Real seal row, and then reads only the componentwise hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows attached to that same route.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root threshold public exhaustion`

Proof. Start with root carrier threshold admission and classifier transport exactness, Definition 885.126 and Definition 885.127. They place $M_0, M_1, U, V, T, W, Q, E$ and the structural rows H, C, P, N in one accepted carrier route.

Apply route determinacy, Definition 885.129. It fixes the only public route from the two source schedules through the shared meet, selector budget, finite windows, readbacks, and Real seal, with no second meet, hidden selector, quotient stream, host equality, or ambient completeness row.

Finally use budget consumer exhaustion, Definition 885.131. Since every public Real or Completion consumer must pass through the selector-budget, window, readback, and seal rows of the same route, the displayed packet exhausts the public root threshold surface. □

Theorem 885.134 (Cauchy modulus refinement root threshold seal endpoint separation)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the selector-threshold row T*, finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal row* E *remain four distinct public obligations on every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer route. No consumer may collapse* T, W, Q, E *into a single host limit, quotient stream, selected limit, or ambient completeness datum.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root threshold seal endpoint separation`

Proof. First fix the public route. Root route determinacy, Definition 885.129, forces every accepted read of R through the displayed chain from the two source schedules to the shared meet, extraction witness, selector threshold, finite window, readback, and Real seal.

Next account for the consumer surface. Root budget consumer exhaustion, Definition 885.131, says that every $\mathsf{Real}^{\uparrow}$ or Completion consumer must pass through T, W, Q, E in that order and has no hidden selector, quotient stream, host equality, selected limit, second meet, or ambient completeness coordinate available as an alternate endpoint.

Now separate the seal endpoint from the window and readback rows. Root-window Real seal determinacy, Definition 885.132, identifies the public seal reached from shared T, W, Q data as the displayed row E, not as a replacement for those rows.

Finally apply root threshold public exhaustion, Definition 885.133. Since the complete public route still displays T, W, Q, E, H, C, P, N, a consumer that collapses the four endpoint obligations would omit carrier coordinates required by the exhausted surface. The four rows therefore remain distinct on every public $\mathsf{Real}^{\uparrow}$ or Completion route. □

Theorem 885.135 (Cauchy modulus refinement four-face noncollapse)**.** *For every accepted* $\mathsf{CauchyModulusRefinem}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the selector threshold T*,* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal* E *are four separate public obligations on every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer route. None of the four rows may be replaced by a hidden selector, quotient stream, host equality, selected limit, second meet, or ambient completeness coordinate.*

Proof. First fix the public route by root route determinacy, Definition 885.129. Any accepted read of R must pass through the displayed chain from M_0, M_1 to U, V, T, W, Q, E and then through the structural rows H, C, P, N.

Next exhaust the consumer side by root budget consumer exhaustion, Definition 885.131. A $\mathsf{Real}^{\uparrow}$ or Completion consumer has no off-route selector, quotient stream, host equality, selected limit, second meet, or ambient completeness row from which to rebuild the endpoint.

Now identify the seal endpoint using root-window Real seal determinacy, Definition 885.132. The seal reached after the shared threshold, window, and readback rows is the displayed row E; it is not a coordinate that absorbs T, W, or Q.

Finally apply threshold seal endpoint separation, Definition 885.134. Since that separation keeps T, W, Q, E as distinct endpoint obligations on every public route, the four public faces cannot collapse into one hidden completion coordinate. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier four face nocollapse`

Theorem 885.136 (Cauchy modulus refinement open-phase four-object consumption)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root packet that reaches the root threshold route consumes the same four finite faces named by the* $\mathsf{StreamName}^{\uparrow}$ *open-phase sufficiency surface: the* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal. The consumed packet also carries exactly the displayed support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

The Cauchy root rows are therefore read through

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N,$$

where W is the finite window, Q contains the dyadic tolerance and regular-rational readback, E is the Real seal, and H, C, P, N are the componentwise hsame*, displayed* Cont*,* Pkg*, and local* NameCert *rows. No quotient stream, host sequence equality, selected limit, ambient completeness, metric-completeness datum, or standard bridge row is exported by this consumer surface.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier open phase four object consumption`

Proof. First use the StreamName open-phase sufficiency and Real-completion exit certificate, Definition 126.451 and Definition 126.448. They name the four finite exit faces as the StreamName finite window, DyadicRatCore tolerance ledger, RegSeqRat readback, and RealUp seal, together with the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Next force the accepted Cauchy packet through the root threshold route. Root budget consumer exhaustion and root threshold public exhaustion, Definition 885.131 and Definition 885.133, say that every public $\mathsf{Real}^{\uparrow}$ or Completion consumer reads T, W, Q, E, H, C, P, N on the displayed root route and has no alternate selector, quotient stream, host equality, selected limit, or ambient completeness coordinate.

It remains to rule out a second Real seal source. Root-window Real seal determinacy, Definition 885.132, identifies any public seal reached from the shared window and readback rows with the displayed E row. Thus the Cauchy consumer consumes exactly the four-object open-phase exit packet and its displayed support rows, and exports none of the excluded quotient, host, completion, metric, or bridge data. □

Theorem 885.137 (Cauchy modulus refinement root budget stability)**.** *For every accepted* CauchyModulusRefinem *root surface*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the selector-budget row T is stable under the shared meet row U and under classifier transport through H and C. Any public read of the budget row is therefore the same displayed read obtained after M_0, M_1 meet at U, after the extraction witness V is fixed, and before the selected-window, tolerance-readback, and Real-seal rows W, Q, E are consumed.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier root budget stability`

Proof. Start from root carrier threshold admission, Definition 885.126. It admits T only as a row of the same finite packet that already displays M_0, M_1, U, V.

Use classifier transport exactness and route determinacy, Definition 885.127 and Definition 885.129. These keep the transported read on the componentwise route through H, C, P, N and do not allow T to detach from the shared meet.

Finally apply budget consumer exhaustion and public exhaustion, Definition 885.131 and Definition 885.133. Since every Real-facing consumer reaches W, Q, E only after T, the selector budget remains stable at the displayed meet-threshold handoff. □

Theorem 885.138 (Cauchy modulus refinement meet-threshold nonescape)**.** *After an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root route reaches the meet-threshold surface*

$$M_0, M_1, U, V, T,$$

no public consumer can read a second meet, quotient stream, host equality, selected limit, hidden selector, or ambient completeness datum from that route. All later reads are confined to the selected-window row W, tolerance and regular-readback row Q, Real seal row E, and structural rows H, C, P, N of the same packet.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier meet threshold nonescape`

Proof. Read the deterministic route of Definition 885.129. The meet-threshold route has the displayed source schedules, shared meet, extraction witness, and selector budget, and no alternate meet coordinate.

Next use root ledger non-escape and budget consumer exhaustion, Definition 885.128 and Definition 885.131. They account for every Real or Completion read through W, Q, E, H, C, P, N after the budget row.

The public exhaustion theorem, Definition 885.133, closes the surface. Since the displayed route already exhausts public consumption, the absent second meet, quotient stream, host equality, selected limit, hidden selector, and ambient completeness rows cannot be recovered downstream. □

Theorem 885.139 (Cauchy modulus refinement Real seal handoff)**.** *Every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *root packet whose structural rows include a displayed endpoint read Z with* $\mathsf{Cont}(H, C, Z)$ *and* $\mathsf{Pkg}^{\mathrm{sig}}(B, Z, P)$ *over the same package row P presents the completion boundary as a* SemanticNameCert *endpoint carrier. The source predicate is the accepted packet together with the componentwise* hsame *transport to Z, the displayed pattern rows are the route*

$$M_0, M_1 \to U \to V \to T \to W \to Q \to E \to H \to C \to Z,$$

and the ledger row is $\mathsf{UnaryHistory}(Z)$ *together with the package signature. The handoff names the completion endpoint carried by the displayed continuation and package rows; it does not prove Real completeness, quotient equality, selected limits, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real seal handoff`

Proof. Begin with root route determinacy and root budget stability, Definition 885.129 and Definition 885.137. They place the accepted packet on the single displayed route from the source schedules through the shared meet, extraction witness, selector budget, finite window, readback rows, and Real seal.

Next apply Real seal factorization, Definition 885.23. The seal row E is reached only after W and Q, and the componentwise hsame row carries the same endpoint read Z rather than a second seal source.

Now use root budget consumer exhaustion and public exhaustion, Definition 885.131 and Definition 885.133. Every Real or Completion consumer is confined to W, Q, E, H, C, P, N after the budget row, so a completion endpoint can be read only through the displayed continuation and package rows.

Finally attach the provenance rows. The assumptions $\mathsf{Cont}(H, C, Z)$ and $\mathsf{Pkg}^{\mathrm{sig}}(B, Z, P)$ over the same package row, together with $\mathsf{UnaryHistory}(Z)$, are exactly the endpoint carrier data required for the $\mathsf{SemanticNameCert}$ handoff. Since the packet supplies no ambient completeness coordinate, the result is a handoff certificate naming the completion boundary, not a proof that the Real seal is complete. □

Theorem 885.140 (Cauchy modulus refinement diagonal route pullback)**.** *For every accepted finite* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

whose source rows name a $\mathsf{StreamName}^{\uparrow}$ *window* W*, a* $\mathsf{RegSeqRat}$ *readback row* Q*, and a* $\mathsf{Real}^{\uparrow}$ *seal row* E*, every diagonal-limit consumer route compatible with chapter 646 pulls back to the same finite dyadic threshold* T *and the same shared-window ledger* W, Q *used by* R*. The pulled-back route is a* BHist *route transported by* hsame *through* H*, replayed by* Cont *through* C*, and registered by the same* Pkg *and local* $\mathsf{NameCert}$ *rows* P, N*; it introduces no host quotient, no choice principle, and no extra completion witness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier diagonal route pullback`

Proof. Begin with the Real seal handoff, Definition 885.139. It places every Real or Completion consumer of R after the displayed finite route $M_0, M_1, U, V, T, W, Q, E$ and identifies W, Q, E as the StreamName window, regular readback, and Real seal surface read by the consumer.

Next apply root-window Real seal determinacy, Definition 885.132. If a diagonal-limit-compatible consumer reads the same window and readback rows, then its terminal Real seal is classified through the same root route, so changing only the downstream diagonal presentation cannot produce a second seal or a different threshold.

Finally use L10 handoff sufficiency, Definition 885.144. The rows $U, T, W, Q, E, H, C, P, N$ already suffice for the finite handoff to $\mathsf{Real}^{\uparrow}$, and the nonescape exclusions in that handoff leave no coordinate for a host quotient, selected limit, choice principle, or additional completion witness. Hence every diagonal-limit consumer route pulls back to the same dyadic threshold and shared-window ledger carried by the original refinement packet. □

Theorem 885.141 (Cauchy modulus refinement open-phase exit spine)**.** *Every accepted* CauchyModulusRefinement *root packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

whose public route reaches the displayed rows $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ *factors through the Phase Real and Completion spine*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The $\mathsf{StreamName}^{\uparrow}$ *surface supplies finite window observation,* $\mathsf{DyadicRatCore}^{\uparrow}$ *supplies dyadic readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *supplies the regular Cauchy handoff, and* $\mathsf{Real}^{\uparrow}$ *supplies the seal row. No Completion consumer may read quotient stream equality, selected limits, host real equality, or ambient completeness before this spine is displayed.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier open phase exit spine`

Proof. First fix the root packet by route determinacy, Definition 885.129. It places the public read on the displayed route from M_0, M_1 through U, V, T, W, Q, E and keeps H, C, P, N as the transport, continuation, provenance, and local naming rows.

Next apply root budget consumer exhaustion, Definition 885.131. This forces every Real or Completion consumer through the selector budget, finite window, dyadic and regular readback, and Real seal rows before any downstream use.

Finally use the Real seal handoff, Definition 885.139. The sibling chapters chapter 126, chapter 291, chapter 301, and chapter 38 name exactly the finite-window, dyadic-readback, regular-handoff, and Real-seal surfaces. Since the handoff theorem excludes quotient equality, selected limits, host real equality, and ambient completeness, the displayed spine is the required exit route. □

Theorem 885.142 (Cauchy modulus refinement root-threshold open-phase handoff)**.** *Every accepted root-threshold route displaying*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

hands off to the Phase Real and Completion surface exactly through the rows T, W, Q, E*. These rows are read as the root threshold budget,* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance with* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal. The remaining rows* H, C, P, N *provide transport, replay, provenance, and local naming for that same handoff, while the source rows* M_0, M_1, U, V *remain the root route that supplies the threshold.*

Proof. First consume the open-phase surface. The four-object consumption theorem and open-phase exit spine, Definition 885.136 and Definition 885.141, identify W, Q, E as the StreamName window, dyadic and regular readback, and Real seal, with T as the threshold row that feeds the window.

Next exhaust the root side. Root budget consumer exhaustion and root threshold public exhaustion, Definition 885.131 and Definition 885.133, force every public Real or Completion read of the accepted route through T, W, Q, E, H, C, P, N and leave no second meet, hidden selector, quotient stream, host equality, selected limit, or ambient completeness coordinate.

Finally apply root-window Real seal determinacy and L10 handoff sufficiency, Definition 885.132 and Definition 885.144. They determine the seal from the same threshold, window, and readback rows, then package H, C, P, N as transport, replay, provenance, and local naming for the Phase Real and Completion handoff. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementRootThresholdOpenPhaseHandoff`

Theorem 885.143 (Cauchy modulus refinement window-meet seal unicity)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

any $\mathsf{Real}^{\uparrow}$ *or Completion consumer that reads the shared meet row* U*, selector budget* T*, finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal row* E *factors through the same displayed route*

$$M_0, M_1 \longrightarrow U \longrightarrow V \longrightarrow T \longrightarrow W \longrightarrow Q \longrightarrow E.$$

Across the L10 sibling surfaces, no second meet, hidden selector, quotient stream, host real equality, selected limit, or ambient completeness row determines a different seal handoff.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier window meet seal unicity`

Proof. First fix the route. Root route determinacy, Definition 885.129, sends every accepted read of the displayed packet through $M_0, M_1, U, V, T, W, Q, E$ and leaves H, C, P, N only as the transport, continuation, provenance, and local naming rows for that route.

Next compare the seal on the common window and readback rows. Root-window Real seal determinacy, Definition 885.132, says that two accepted packets sharing U, T, W, Q classify their public Real seal rows through the same root route. Thus a consumer that has already read those rows cannot obtain a different seal by changing only the handoff surface.

Finally use the sibling handoff and exclusion rows. The Real seal handoff theorem, Definition 885.139, places the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads on the same displayed chain, while meet-threshold nonescape, Definition 885.138, excludes second meets, hidden selectors, quotient streams, host real equality, selected limits, and ambient completeness rows. Hence the shared meet, window, readback, and seal route uniquely determines the Real seal handoff across those L10 surfaces. □

Theorem 885.144 (Cauchy modulus refinement L10 handoff sufficiency)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

any $\mathsf{Real}^{\uparrow}$ *or Completion consumer that reads the shared meet row* U*, selector budget* T*, finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal row* E *factors through the displayed L10 handoff*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The rows U, T, W, Q, E*, together with the transport, continuation, provenance, and local naming rows* H, C, P, N*, are sufficient for this handoff. They do not supply a second meet, hidden selector, quotient stream, host real equality, selected limit, or ambient completeness row, and they do not prove completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier l10 handoff sufficiency`

Proof. Root route determinacy, Definition 885.129, fixes the accepted packet route through the displayed meet, extraction, budget, selected-window, readback, and Real-seal rows.

Root budget consumer exhaustion, Definition 885.131, accounts for every downstream read after T. The Real seal handoff theorem, Definition 885.139, then identifies the sibling surfaces as $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally apply window-meet seal unicity, Definition 885.143. It says that a consumer already reading U, T, W, Q, E has no alternate seal route through a second meet, hidden selector, quotient stream, host real equality, selected limit, or ambient completeness row. Therefore the displayed L10 rows are sufficient for the handoff alone, without asserting completeness of $\mathsf{Real}^{\uparrow}$. □

Theorem 885.145 (Cauchy modulus refinement finite-observation-budget selector handoff)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

whose public route reaches the displayed rows $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$*, if the selected finite-window route is consumed by a* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *packet, then the consumer first factors through the finite selector path*

$$B \to S \to W \to D \to R \to E$$

before the L10 spine

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

is read. The handoff exposes no quotient stream, host real equality, countable choice, hidden selector, selected host limit, ambient completeness row, or completeness proof for $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier finite observation budget selector handoff`

Proof. Start with the accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ route. Root route determinacy, Definition 885.129, places every public read on $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, and root budget consumer exhaustion, Definition 885.131, confines the finite-window consumer to the selected budget and window rows.

Next attach the finite selector packet. Finite-observation-budget selector route determinacy, Definition 782.7, identifies the selector path $B \to S \to W \to D \to R \to E$ for every accepted selected-window read. The selector Real-seal handoff, Definition 782.4, carries that same finite path to the Real-facing seal row without importing a host limit.

Finally combine the two exits. The selector diagonal consumer boundary, Definition 782.10, keeps diagonal reads on the finite selector path, while L10 handoff sufficiency, Definition 885.144, reads the resulting window through $\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$. The exclusion clauses in the Cauchy and selector handoffs leave no coordinate for a quotient stream, host real equality, countable choice, hidden selector, selected host limit, ambient completeness row, or Real completeness proof. □

Theorem 885.146 (Cauchy modulus refinement selector-spine route completeness)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *public route*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

whose selected finite-window surface is consumed by $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$*, the complete public route factors first through the finite selector path*

$$B \to S \to W \to D \to R \to E$$

and then through the L10 exit spine

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Every read on the route is confined to the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows carried by the Cauchy packet and by the finite selector packet. The factorization exposes no quotient stream, host real equality, countable choice, hidden selector, selected limit, ambient completeness row, or Real completeness proof.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector spine route completeness`

Proof. First form the finite selector handoff. The Cauchy finite-observation-budget selector handoff, Definition 885.145, places every accepted selected-window consumer on $B \to S \to W \to D \to R \to E$ before any Real-facing exit is read. The finite-observation selector route determinacy and Real-seal handoff theorems, Definition 782.7 and Definition 782.4, identify that path as the displayed selector path and keep its seal attached to the same finite packet.

Next attach the L10 spine. L10 handoff sufficiency, Definition 885.144, sends the selected window, dyadic readback, regular readback, and Real seal through

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The selector diagonal consumer boundary, Definition 782.10, keeps diagonal reads on the finite selector path while that spine is consumed.

Finally seal the route against alternate exits. Window-meet seal unicity, Definition 885.143, says that a consumer already reading the shared meet, selector budget, finite window, readback, and Real seal rows has no second seal route through a hidden selector or ambient completion coordinate. Thus the composed public route is complete through the selector path and the L10 spine, and all reads remain on the displayed BHist, hsame, Cont, Pkg, and NameCert rows with none of the excluded quotient, host equality, selected-limit, countable-choice, ambient completeness, or Real-completeness data. □

Theorem 885.147 (Cauchy modulus refinement shared-window seal transitivity)**.** *Let*

$$R_i = (M_0, M_1, U, V_i, T, W, Q, E_i, H_i, C_i, P_i, N_i) \qquad (i = 0, 1, 2)$$

be accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packets sharing the source schedules, shared meet row, selector budget, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and displayed transport/provenance route. If the adjacent Real seal rows classify by* $\mathsf{hsame}(E_0, E_1)$ *and* $\mathsf{hsame}(E_1, E_2)$*, then* E_0 *and* E_2 *classify through the same public* $\mathsf{Real}^{\uparrow}$ *and Completion consumer surface.*

The shared-window comparison introduces no second meet, hidden selector, quotient stream, selected limit, host real equality, or ambient completeness row.

Proof. First fix the public route for all three packets. Apply Definition 885.129; the common rows M_0, M_1, U, T, W, Q force every accepted read through the displayed chain from the source schedules to the Real seal row.

Next pin the seal read on the shared window. By Definition 885.132, any two packets with the displayed common source, meet, budget, window, and readback rows classify their Real seal rows through the same root route. The adjacent hypotheses therefore identify the first pair and the second pair on one public consumer surface.

Now use Definition 885.139 and Definition 885.143. These theorems place the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and Completion reads on the same window-meet handoff, so the two adjacent classifications compose to the first and third seal rows on that same surface.

Finally apply Definition 885.138. It excludes second meets, hidden selectors, quotient streams, selected limits, host real equality, and ambient completeness. With no alternate seal source available, the first and third seal rows classify through the same public Real and Completion consumer boundary. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier shared window seal transitivity`

Theorem 885.148 (Cauchy modulus refinement selector-spine terminal pullback)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *public route*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

whose selected finite-window surface is consumed by $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$*, every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing pullback surface factors through the finite selector path*

$$B \to S \to W \to D \to R \to E$$

and then through the L10 spine

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

There is no terminal pullback route that bypasses this displayed selector spine through quotient streams, host real equality, selected limits, countable choice, ambient completeness, or a separate proof of Real completeness.

Proof. First apply selector-spine route completeness, Definition 885.146. It places the accepted public route on the finite selector path followed by the L10 spine, and it confines all reads to the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Next use the finite-observation-budget selector handoff, Definition 885.145. It supplies the selector path $B \to S \to W \to D \to R \to E$ before any Real-facing exit is read.

Finally apply L10 handoff sufficiency and window-meet seal unicity, Definition 885.144 and Definition 885.143. These theorems keep the Real and Completion consumer on the displayed L10 rows and exclude any second meet, hidden selector, quotient stream, host equality, selected limit, countable-choice row, ambient completeness row, or independent Real-completeness witness. Hence the selector spine is the only terminal pullback surface available to such consumers. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier selector spine terminal pullback`

Theorem 885.149 (Cauchy modulus refinement shared-window completion seal coherence)**.** *Let*

$$R_i = (M_0, M_1, U, V_i, T, W, Q, E_i, H_i, C_i, P_i, N_i) \qquad (i = 0, 1, 2)$$

be accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packets sharing the source schedules, shared meet row, selector budget, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and displayed transport/provenance route. If the adjacent shared-window seal classifications identify* E_0 *with* E_1 *and* E_1 *with* E_2*, then their composed Completion-facing classification is coherent only on the displayed consumer surface*

$$B \to S \to W \to D \to R \to E \qquad \textit{followed by} \qquad \mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The composition does not create a quotient-stream route, host real equality, selected limit, countable-choice row, ambient completeness row, or independent Real-completeness witness.

Proof. Begin with shared-window seal transitivity, Definition 885.147. It composes the adjacent seal classifications for the first and third packets on the same public $\mathsf{Real}^{\uparrow}$ and Completion consumer surface.

Next identify that surface with the selector-spine route. Apply selector-spine route completeness, Definition 885.146, and the finite-observation-budget selector handoff, Definition 885.145. Together they force the shared-window consumer first through the selector path and then through the L10 spine.

Finally use window-meet seal unicity, Definition 885.143. It prevents a second meet, hidden selector, or alternate completion coordinate from carrying the composed classification. Therefore the adjacent shared-window seal classifications compose coherently only on the displayed selector-spine consumer surface. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementSharedWindowCompletionSealCoherer`

Theorem 885.150 (Cauchy modulus refinement L10 row exactness)**.** *For every accepted* CauchyModulusRefinemen *route whose selected finite-window consumer reaches* $\mathsf{Real}^{\uparrow}$ *or Completion, the exact public row inventory is the selector path*

$$B \to S \to W \to D \to R \to E$$

together with the L10 spine

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

and the displayed transport, continuation, provenance, and local naming rows H, C, P, N*. This inventory excludes quotient streams, host real equality, selected limits, countable choice, ambient completeness, and Real completeness as available rows of the handoff.*

Proof. First read the finite selector side from Definition 885.145. It supplies exactly the displayed selector path for the selected finite-window consumer and lists the excluded host and choice-like coordinates.

Next read the Real-facing side from Definition 885.144. The rows $U, T, W, Q, E, H, C, P, N$ are sufficient for the handoff to the L10 spine, while no row for quotient streams, host equality, selected limits, ambient completeness, or Real completeness is present.

Finally combine these with selector-spine route completeness and shared-window seal transitivity, Definition 885.146 and Definition 885.147. The former identifies the whole public route as selector path followed by L10 spine, and the latter composes adjacent seal classifications without changing the displayed consumer surface. Window-meet seal unicity then rules out any extra row hidden between the selector path and the Real seal. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier l10 row exactness`

Theorem 885.151 (Cauchy modulus refinement Real-window budget pullback)**.** *Every accepted* CauchyModulusRefinement$^{\uparrow}$ *route whose threshold rows feed an accepted* RealWindowBudget$^{\uparrow}$ *packet pulls back to the same finite request, the same* StreamName$^{\uparrow}$ *window rows, the same* DyadicRatCore$^{\uparrow}$ *readback, the same* RegSeqRat$^{\uparrow}$ *handoff, the same* Real$^{\uparrow}$ *seal, the same* CauchyDiagonalBudget$^{\uparrow}$ *selector row, and the same* RealObservationBudget$^{\uparrow}$ *disclosure rows. The pulled-back consumer surface is exactly the displayed L10 inventory together with* H, C, P, N*; it introduces no quotient stream, host real equality, selected limit, ambient completeness witness, or independent Real-completeness row.*

Proof. First expose the refinement side. Apply root threshold public exhaustion, Definition 885.133, and the Real seal handoff, Definition 885.139. These force the accepted refinement route through the displayed threshold, finite-window, readback, handoff, seal, transport, continuation, provenance, and local naming rows before any Real-facing consumer can read it.

Next pull the downstream diagonal and budget faces back to that route. The diagonal route pullback, Definition 885.140, keeps the consumer on the same dyadic threshold and shared-window ledger, while Definition 1164.5 identifies the RealWindowBudget$^{\uparrow}$ packet as precisely the finite request, window, dyadic readback, regular handoff, Real seal, selector, disclosure, and structural rows.

Finally apply L10 row exactness, Definition 885.150. It identifies the common consumer surface with the selector path followed by the L10 spine and removes quotient streams, host real equality, selected limits, ambient completeness, and Real completeness from the available row inventory. Hence the Real-window budget packet consumes exactly the same finite refinement route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier real window budget pullback`

Theorem 885.152 (Cauchy modulus refinement Real-window budget terminality)**.** *Let an accepted* CauchyModulusRefinement$^{\uparrow}$ *route have threshold rows that feed an accepted* RealWindowBudget$^{\uparrow}$ *packet. Every* Real$^{\uparrow}$ *or Completion-facing consumer of that route factors through the same finite request,* StreamName$^{\uparrow}$ *window,* DyadicRatCore$^{\uparrow}$ *readback,* RegSeqRat$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal,* CauchyDiagonalBudget$^{\uparrow}$ *selector,* RealObservationBudget$^{\uparrow}$ *disclosure, and support packet* H, C, P, N *displayed in Definition 885.151. Conversely, that packet supplies all consumer-visible rows of the accepted route.*

Thus no such consumer can read a quotient stream, host real equality, selected limit, countable-choice row, ambient completeness datum, independent Real-completeness witness, or second selector or disclosure route.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementRealWindowBudgetTerminality`

Proof. First expose the root route. Root threshold public exhaustion and the Real seal handoff, Definition 885.133 and Definition 885.139, place every accepted refinement route on the public threshold, finite request, window, dyadic readback, regular handoff, Real seal, and support rows before a Real-facing or Completion-facing consumer can read it.

Next apply the Real-window budget pullback, Definition 885.151. It identifies the accepted RealWindowBudget$^{\uparrow}$ packet with the same finite request, window, readback, handoff, seal, selector, disclosure, and support packet. Hence every consumer of the refinement route factors through that packet.

For the converse, use L10 row exactness together with the selector-spine terminal pullback, Definition 885.150 and Definition 885.148. The first theorem says that the displayed packet is exactly the L10 consumer inventory with H, C, P, N, while the second makes that selector-spine packet terminal among $\mathsf{Real}^{\uparrow}$ and Completion-facing pullbacks. Therefore the packet supplies all consumer-visible rows.

The same two terminal facts give non-escape. There is no coordinate in the packet for quotient streams, host real equality, selected limits, countable choice, ambient completeness, an independent Real-completeness witness, or a second selector or disclosure route, so no accepted downstream consumer can recover one. □

Theorem 885.153 (Cauchy modulus refinement Real-window terminal consumer)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *route whose threshold rows are accepted by a* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet, the terminal consumer-visible surface for any* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RealWindowBudget}^{\uparrow}$*, or Completion-facing reader is exactly the displayed packet consisting of the finite request,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *selector,* $\mathsf{RealObservationBudget}^{\uparrow}$ *disclosure, and support rows* H, C, P, N*. Every such consumer factors through that packet, and conversely that packet supplies the full consumer-visible route.*

No additional quotient stream, host real equality, selected limit, countable-choice row, ambient completeness witness, independent Real-completeness row, second selector, or second disclosure row is part of the terminal consumer surface.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementRealWindowTerminalConsumer`

Proof. First use the Real-window budget pullback, Definition 885.151. It places every accepted budget-facing read on the same finite request, window, dyadic readback, regular handoff, Real seal, selector, disclosure, and support rows.

Next apply Real-window budget terminality, Definition 885.152. This turns the pullback packet into the terminal route for $\mathsf{Real}^{\uparrow}$ and Completion-facing consumers, so no downstream reader can detach from the displayed finite packet.

Finally combine selector-spine terminal pullback with L10 row exactness, Definition 885.148 and Definition 885.150. These identify the converse direction: the displayed packet is already the full selector path followed by the L10 spine with H, C, P, N. Since the excluded rows are absent from that exact inventory, the same packet is the whole terminal consumer surface. □

Theorem 885.154 (Cauchy modulus refinement bridged-route surface)**.** *Every standard bridge consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *refinement packet factors through the same public route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

The route first reads the shared $\mathsf{CauchyModulusMeet}^{\uparrow}$ *meet, the* $\mathsf{CauchyModulusExtraction}^{\uparrow}$ *witness, the* $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$ *selector budget, the selected* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal. It then uses only the primitive* BHist, hsame, Cont, Pkg*, and* NameCert *rows together with the sibling dependency lattice recorded by the packet. No bridge consumer receives a hidden selector, quotient stream, selected host limit, host real equality, second meet row, side-channel completion object, or ambient completeness coordinate outside that route.*

Proof. Begin with the root-unblock package of Definition 885.40. It assembles the local naming scope, the source-locked selector budget, and the diagonal-consumer boundary into one public entry route for downstream Real-completion consumers.

Next apply the diagonal-consumer boundary and the Real-completeness handoff, Definition 885.39 and Definition 885.49. These force every standard bridge read to pass through the shared meet, extraction witness, selector budget, selected window, dyadic tolerance, regular readback, and Real seal before it can consume the completion-facing surface.

The root readback stability theorem, Definition 885.51, keeps the selected window and tolerance readbacks on the same W, Q, H, C, P, N route under the componentwise transport and continuation rows. The real-consumer coverage theorem, Definition 885.56, then exhausts the Real and Completion consumers by that displayed route.

Finally use the primitive scope and sibling dependency lattice already carried by the chapter. They identify the only admissible bridge coordinates as the primitive BHist, hsame, Cont, Pkg, NameCert rows and the named CauchyModulusMeet$^{\uparrow}$, CauchyModulusExtraction$^{\uparrow}$, RegularCauchySelectorBudget$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ siblings. Since non-escape excludes the listed hidden and ambient coordinates, every standard bridge consumer factors through the stated public route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier bridged route surface`

Theorem 885.155 (Cauchy modulus refinement bridged-route determinacy)**.** *Let two standard bridge consumers accept the same* CauchyModulusRefinement$^{\uparrow}$ *packet and expose the same displayed route rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Then both public bridge reads factor through the same sibling route through CauchyModulusMeet$^{\uparrow}$*,* CauchyModulusExtraction$^{\uparrow}$*,* RegularCauchySelectorBudget$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*. The two reads determine the same Real and Completion handoff surface under the componentwise* hsame *rows of* H*.*

Proof. Apply the bridged-route surface of Definition 885.154 to each consumer. Because the exposed rows are the same displayed $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, both reads enter the same meet, extraction witness, selector budget, selected window, dyadic tolerance, regular readback, and Real seal route.

Root readback stability, Definition 885.51, fixes the selected window and tolerance readbacks under the componentwise hsame rows. Thus a second consumer cannot replace W, Q, E by another selected stream, dyadic ledger, or readback while still exposing the same route.

Real-consumer coverage, Definition 885.56, exhausts the Real and Completion-facing reads by the same finite route. The primitive sibling lattice then leaves no hidden selector, quotient stream, second meet row, host limit, or ambient completeness coordinate able to separate the two consumers.

The resulting Real and Completion handoff surfaces are therefore the same public surface up to the displayed hsame transport in H. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementBridgedRouteDeterminacy`

Theorem 885.156 (Cauchy modulus refinement bridge consumer route exhaustion)**.** *Every standard bridge consumer of an accepted* CauchyModulusRefinement$^{\uparrow}$ *packet whose incoming route is supplied by the* RegularCauchyTailMeet$^{\uparrow}$ *root budget-seal package must first pass through the displayed TailMeet rows, then the finite observation-budget and limiter surfaces, and then the* CauchyModulusRefinement$^{\uparrow}$ *route*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

before any $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *seal read is exported. The exported bridge surface contains no quotient stream, selected limit, host real equality, hidden selector, independent completion carrier, or ambient completeness principle outside that route.*

Proof. Apply the downstream budget-seal package of Definition 560.96. It supplies the incoming $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ route through the displayed TailMeet rows, the finite observation budget, and the limiter surfaces before any downstream seal consumer can read the packet.

The root seal exactness theorem, Definition 560.97, fixes that incoming route as the budgeted seal interface. Thus a bridge consumer entering from the TailMeet package has no separate Real or Completion channel before the named budget rows have been consumed.

Now apply the local bridged-route surface and determinacy theorems, Definition 885.154 and Definition 885.155. They force the accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ packet onto the displayed $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ route and make that route the unique public refinement handoff for standard bridge consumers.

Finally use the non-escape clauses in the bridge-surface proof. Those clauses exclude hidden selectors, quotient streams, selected host limits, host real equalities, second meet rows, side-channel completion objects, and ambient completeness coordinates. Combining the incoming TailMeet budget route with the local refinement route therefore exhausts every standard bridge consumer before any $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ seal read is exported. □

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier bridge consumer route exhaustion`

Theorem 885.157 (Cauchy modulus refinement TailMeet budget route uniqueness)**.** *Let two standard bridge consumers enter an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet through the same* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *budget-seal package and expose the same displayed refinement rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Then the two exported $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Completion}^{\uparrow}$ *seal handoff routes are the same public route under the componentwise* hsame *rows of* H*. The comparison reads only the shared TailMeet budget-seal rows and the displayed refinement rows; it has no coordinate for a hidden selector, quotient stream, selected host limit, host real equality, ambient completeness principle, or side-channel completion carrier.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementTailMeetBudgetRouteUniqueness`

Proof. Apply Definition 560.96. Since both consumers enter through the same $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ budget-seal package, their incoming routes first share the displayed TailMeet rows, finite observation budget, and limiter surface before the refinement packet is read.

Apply Definition 560.97. The shared incoming package is the exact budgeted seal interface, so neither consumer can insert an independent $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ seal route before the named TailMeet budget rows.

Now use Definition 885.155. The two consumers expose the same $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ rows, so the refinement-side public bridge read determines the same Real and Completion handoff surface under the componentwise hsame rows of H.

Finally apply Definition 885.156. Every accepted consumer entering from the TailMeet budget package is already exhausted by the TailMeet route followed by the displayed refinement route. The excluded hidden selector, quotient stream, selected host limit, host real equality, ambient completeness, and side-channel completion coordinates therefore cannot distinguish the two exported seal handoffs. □

Theorem 885.158 (Cauchy modulus refinement TailMeet Real-seal normal form)**.** *Every bridge consumer entering an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet through the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *budget rows and exposing the refinement rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N$$

has a unique normal-form route

TailMeet budget $\to$ *finite observation budget* $\to$ *limiter* $\to$ $\mathsf{CauchyModulusMeet}^{\uparrow}$ $\to$ $\mathsf{CauchyModulusExtraction}^{\uparrow}$ $\to$ R

The exported seal surface contains no quotient stream, selected host limit, hidden selector, second meet, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier tailmeet real seal normal form`

Proof. First use the bridge-consumer route exhaustion theorem, Definition 885.156. It forces every consumer entering from the $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ root package through the TailMeet budget rows, finite observation budget, limiter, and then the displayed refinement route before any $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ seal read is exported.

Next apply the TailMeet budget route uniqueness theorem, Definition 885.157. Once two consumers expose the same $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ rows, the exported Real and Completion seal handoff route is fixed under the componentwise hsame rows of H.

The sibling TailMeet root budget package and root seal exactness theorem, Definition 560.96 and Definition 560.97, identify the incoming TailMeet path with the finite budget-seal interface. The local bridged-route surface then supplies the meet, extraction, selector-budget, stream-name, dyadic-rational, and regular-sequence part of the route.

Finally use the non-escape clauses already recorded by the bridge-surface proof. Since the absent coordinates are not exported by the TailMeet package or by the refinement packet, the displayed route is the unique normal form for Real and Completion seal consumers. □

Corollary 885.159 (Cauchy modulus refinement bridged-route consumer determinacy)**.** *Let* $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet, and fix the displayed bridge rows*

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

Every accepted standard bridge consumer use of R *that reports a route selection, a normal-form readback, or an exactness decision for the refinement handoff reports the one named by the chapter: the route through* $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{CauchyModulusExtraction}^{\uparrow}$, $\mathsf{RegularCauchySelectorBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the* $\mathsf{Real}^{\uparrow}$ *seal, stabilized by the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. No hidden selector, quotient stream, second meet row, duplicate classifier source, selected host limit, host real equality, side-channel completion object, or ambient completeness coordinate can supply a different accepted route, normal form, or exactness decision.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier bridged route consumer determinacy`

Proof. Apply the bridged-route surface theorem, Definition 885.154. It gives the consumer-facing inventory of an accepted bridge read: before any standard bridge consumer can use the refinement handoff, the read factors through the fixed public route

$$M_0, M_1, U, V, T, W, Q, E, H, C, P, N.$$

The same theorem identifies the sibling surfaces read along that route and excludes hidden selectors, quotient streams, selected host limits, host real equalities, second meet rows, side-channel completion objects, and ambient completeness coordinates.

Now take two accepted standard bridge consumer uses of the fixed packet rows. One may be the chapter's displayed use and the other any consumer-facing use that claims a route selection, normal-form readback, or exactness decision. Since the rows are fixed, both expose the same $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ data. By bridged-route determinacy, Definition 885.155, the two public bridge reads factor through the same sibling route and determine the same Real and Completion handoff surface under the componentwise hsame rows of H.

A reported route selection is therefore the displayed factorization route. A reported normal-form readback is the same ordered read through the meet, extraction witness, selector budget, finite window, dyadic tolerance, regular readback, and Real seal rows. A reported exactness decision is the decision that the proposed consumer read is accepted exactly when it factors through those fixed rows and the structural rows H, C, P, N.

It remains only to exclude duplicate sources for the same decision. Any such source is either one of the displayed rows, in which case it is already identified by the fixed route and the determinacy theorem, or it is an unlisted coordinate. The surface theorem rejects the unlisted case. Hence every accepted consumer use picks the same finite route, normal form, and exactness decision named by the chapter. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusRefinement}^{\uparrow}$ packet is generated from displayed modulus comparison, meet, extraction, selector-budget, finite-window, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 885.1, Definition 885.2, Definition 885.11, Definition 885.12, Definition 885.13, Definition 885.16, Definition 885.21, Definition 885.22, Definition 885.23, Definition 885.24, Definition 885.25, Definition 885.26, Definition 885.27, Definition 885.28, Definition 885.29, Definition 885.30, Definition 885.31, Definition 885.32, Definition 885.33, Definition 885.34, Definition 885.35, Definition 885.36, Definition 885.37, Definition 885.10, and the bridge witness Definition 885.154 bind the displayed modulus comparison, meet, extraction, selector-budget, finite-window, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows into one scoped Real and completion obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, hidden selectors, second meet rows, ambient completeness, Lean verification, or bridge checking for $\mathsf{CauchyModulusRefinement}^{\uparrow}$.

Upgrade path: No further paper-side theory closure is required; remaining work is Lean verification and any future bridge checking for the displayed $\mathsf{CauchyModulusRefinement}^{\uparrow}$ route.

885.1 L10 window lattice pointer

The $\mathsf{CauchyModulusRefinement}^{\uparrow}$ L10 ledger is the shared route consumed by chapter 1180 and chapter 38. Its source side is read through chapter 462, chapter 641, and chapter 678; its finite-window and rational-readback side is read through chapter 126, chapter 291, and chapter 301.

Theorem 885.160 (Cauchy modulus refinement L10 window lattice exactness)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$*-facing or Completion-facing route through* R *factors first through the source meet, extraction, and selector-budget rows* U, V, T*, then through the four L10 faces*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow},$$

and then only through the displayed BHist, hsame, Cont, Pkg, *and* NameCert *support rows* H, C, P, N*. The route exports no quotient stream equality, selected limit, host real equality, hidden selector, second meet row, countable-choice row, bridge aggregation, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or ambient completion principle.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementL10WindowLatticeExactness`

Proof. Start with the L10 sibling route of Definition 885.33. It places every Phase Real and Completion consumer after the source comparison, meet, extraction, and selector-budget rows, and orders the four downstream faces as $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next pull the consumer back along the finite packet rows. The completion pullback theorem, Definition 885.123, reads the route first through the source-window front M_0, M_1, U, V, then through T, W, Q, E, and finally through the structural rows H, C, P, N. The one-line ledger anchors above identify those rows with the CauchyModulusMeet, CauchyModulusExtraction, RegularCauchySelectorBudget, StreamName, DyadicRatCore, RegSeqRat, and Real sibling surfaces.

Finally apply L10 row exactness, Definition 885.150. It identifies the public inventory with the selector path, the four L10 faces, and the displayed support rows. Since the accepted packet and those anchors contain no quotient stream equality, selected limit, host real equality, hidden selector, second meet row, countable-choice row, bridge aggregation, ambient $\mathsf{Real}^{\uparrow}$ completeness, or ambient completion principle, no additional Real-facing or Completion-facing lattice route remains. □

Theorem 885.161 (Cauchy modulus refinement L10 root-window pullback exhaustion)**.** *For every Phase Real or Completion consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

the consumer route is exhausted by the following finite pullback spine. It first passes through the root source-window front M_0, M_1, U, V *of Definition 885.113; it then passes through the selector and L10 face rows* T, W, Q, E *governed by Definition 38.732; and it finally passes through the support rows* H, C, P, N *fixed by Definition 885.160 and Definition 885.123. Conversely, any displayed packet with exactly those rows repacks as the same L10 consumer route, with no additional quotient-stream, selected-host-limit, countable-choice, ambient-completeness, metric-completeness, bridge-aggregation, or hidden-selector row.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier l10 root window pullback exhaustion`

Proof. The forward direction begins at the accepted packet R. Root-window exhaustion forces the source side through M_0, M_1, U, V, so a consumer cannot enter by a second meet row, an unstated extraction row, or an ambient completion premise.

After that source window has been fixed, the L10 four-face exit criterion determines the only Real-facing exit surface. The selector row and the StreamName, DyadicRatCore, RegSeqRat, and Real rows are therefore exactly T, W, Q, E, and there is no room for quotient streams, selected host limits, countable choice, host $\mathsf{Real}^{\uparrow}$ equality, or a hidden selector.

The completion pullback and the window-lattice exactness theorem then identify the remaining support as H, C, P, N. These rows account for the displayed BHist, hsame, Cont, Pkg, and NameCert

support data, so metric-completeness rows and bridge aggregation are not part of the consumer route.

Conversely, suppose a displayed packet carries exactly $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$. Read the first four rows as the root source-window front, the next four as the selector and four-face L10 exit, and the last four as the support ledger. The cited exactness and pullback results repack these finite rows into the same L10 route, and the excluded rows have no constructor in the displayed inventory. □

Theorem 885.162 (Cauchy modulus refinement L10 finite-request route monotonicity)**.** *Let*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$$

and

$$R' = (M_0, M_1, U, V, T', W', Q', E', H, C, P, N)$$

be accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packets with the same displayed source-meet, extraction,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows. If the finite request displayed by* T' *refines the finite request displayed by* T *along the selector row over the same* $M_0, M_1, U, V, H, C, P, N$, *then the L10 route for* R *is included in the L10 route for* R' *on the same support: the* $\mathsf{StreamName}^{\uparrow}$ *window row* W, *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Q, *the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{Real}^{\uparrow}$ *seal route* E *are preserved by inclusion through the displayed* $T \leq T'$, $W \leq W'$, $Q \leq Q'$, *and* $E \leq E'$ *rows. No quotient stream, selected limit, countable-choice row, ambient completeness row, or host equality supplies a second route between the two requests.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier l10 finite request route monotonicity`

↪ variant `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementL10FiniteRequestRouteMonotonicity`

Proof. First fix the common source side. L10 window lattice exactness, Definition 885.160, makes every Real-facing or Completion-facing read pass through M_0, M_1, U, V and then through the same displayed support rows H, C, P, N.

Now compare the selector rows. Root-window pullback exhaustion, Definition 885.161, says that the consumer route has no source other than the finite spine $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$. Replacing T by a displayed refinement T' over the same source rows can therefore only enlarge the finite request already present in that spine.

Window-tolerance exactness, Definition 885.22, transports this selector inclusion to the StreamName window and DyadicRatCore tolerance rows. The same displayed history and classifier support then carries the regular-rational readback row, so the route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ is preserved by inclusion.

Finally apply Real seal factorization, Definition 885.23. The $\mathsf{Real}^{\uparrow}$ seal is downstream of the selected window and rational readback route, so the seal route is included along $E \leq E'$ and cannot be replaced by a quotient stream, selected limit, countable-choice row, ambient completeness row, or host equality. □

Theorem 885.163 (Cauchy modulus refinement L10 face-order rigidity)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

any $\mathsf{Real}^{\uparrow}$*-facing or Completion-facing consumer of* R *must read the L10 faces, after the source rows* U, V, T*, in the displayed dependency order*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

A proposed consumer that swaps the stream schedule, dyadic tolerance, regular readback, or $\mathsf{Real}^{\uparrow}$ *seal face is not an accepted pullback of the refinement packet. In particular, such a consumer cannot be completed by quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, bridge aggregation, or hidden selectors.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementL10FaceOrderRigidity`

Proof. The window-lattice exactness theorem, Definition 885.160, fixes the only Real-facing and Completion-facing route through R: the source meet, extraction, and selector-budget rows precede the L10 faces, and those faces are displayed in the order $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Root-window pullback exhaustion, Definition 885.161, identifies every accepted consumer with that finite pullback spine. The root-window theorem Definition 885.113 supplies the same source-window front, while Definition 38.732 supplies the four-face exit criterion. Thus the stream schedule must be available before dyadic tolerance, dyadic tolerance before regular readback, and regular readback before the $\mathsf{Real}^{\uparrow}$ seal.

Suppose a proposed consumer swaps one of these four faces. Then its entry point is not the source-window front followed by the four-face exit specified above, so it is not one of the pullbacks exhausted by the accepted packet rows. The excluded resources have no constructor in the packet inventory: quotient streams and host real equality would bypass the StreamName and Real seal faces; selected limits and countable choice would bypass the dyadic and regular-readback rows; ambient completeness, metric-completeness rows, bridge aggregation, and hidden selectors would add rows absent from $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$. □

Theorem 885.164 (Cauchy modulus refinement L10 support row minimality)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

let F *be an accepted* $\mathsf{Real}^{\uparrow}$*-facing or Completion-facing consumer of* R *that already factors through the source rows* M_0, M_1, U, V *and the L10 face rows* T, W, Q, E*. Then the remaining support of* F *is exactly* H, C, P, N*:* H *supplies componentwise* hsame *transport along the displayed histories,* C *supplies the displayed* Cont *replay,* P *supplies the* Pkg *provenance row, and* N *supplies the local* NameCert *row. Removing* H*,* C*,* P*, or* N *loses respectively the history-transport, continuity-replay, package-source, or local-name obligation. Adding any further support coordinate gives an off-packet route, hence is excluded by L10 window lattice exactness and root-window pullback exhaustion.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementL10SupportRowMinimality`

Proof. Fix the accepted packet R and the consumer F. The hypotheses have already placed F through the source rows and through the L10 face rows, so the only undecided part of the route is its support ledger.

By L10 window lattice exactness, Definition 885.160, every such consumer reaches support only through the displayed BHist, hsame, Cont, Pkg, and NameCert rows. Root-window pullback exhaustion, Definition 885.161, then identifies the whole consumer with the finite spine $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$ and leaves no second support coordinate outside that spine.

Project the four support rows. The row H is the componentwise history and hsame transport needed to carry source equality through the route; without it the consumer has no displayed transport witness. The row C is the continuity replay row; without it the route has no displayed Cont replay for the completion-facing read. The row P records the Pkg provenance of the source data; without it the consumer cannot cite the package source. The row N is the local NameCert row; without it the consumer has no certified name for the packet instance.

Finally apply face-order rigidity, Definition 885.163, to keep the support ledger downstream of the fixed source and face order. Dropping any one of H, C, P, N removes the corresponding obligation just projected, while adding a further coordinate would be a route not present in the exact finite pullback inventory. Hence the accepted support ledger is precisely H, C, P, N. □

Lemma 885.165 (Cauchy modulus refinement L10 window lattice downstream coverage)**.** *Let c be an accepted local consumer of an accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet with displayed L10 window lattice*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N).$$

Then the consumer-facing read made by c is exhausted by the finite alternatives, ledger rows, and coverage rows already displayed in R. More precisely, the source-facing alternatives are only M_0, M_1, U, V; the selector and L10 ledger rows are only T, W, Q, E in the downstream order

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow};$$

and the coverage rows are only the displayed BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *support carried by H, C, P, N. Consequently a quotient stream equality, selected host limit, host real equality, hidden selector, second meet row, countable-choice row, metric-completeness row, bridge aggregation, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or ambient completion principle has no accepted local consumer coordinate in the* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier l10 window lattice downstream coverage`

Proof. Fix the accepted local consumer c and the displayed packet R. By Definition 885.160, any $\mathsf{Real}^{\uparrow}$-facing or Completion-facing route through R must first read the source meet, extraction, and selector-budget rows, then the four L10 faces, and then the support rows H, C, P, N. Thus the consumer-facing route of c has no starting coordinate outside the displayed source, face, and support surfaces.

Apply Definition 885.161 to identify the whole route with the finite pullback spine. The first segment is the root source-window front M_0, M_1, U, V; the second segment is the selector and L10 face block T, W, Q, E; and the terminal support segment is H, C, P, N. The converse part of that theorem says that a displayed packet with exactly these rows repacks as the same L10 consumer route, so the listed alternatives are not merely sufficient rows but the complete accepted inventory for c.

The three parts of the read are therefore forced. A source-facing demand can only land on M_0, M_1, U, V. A downstream analytic demand can only pass through the selector row and the four displayed faces T, W, Q, E in the order fixed by the window lattice. A coverage demand can only use the displayed history, transport, continuation, provenance, and naming rows carried by H, C, P, N.

It remains to inspect the excluded alternatives. Each excluded object named in the statement would require either an additional source coordinate, an alternate L10 face, or an additional support row beyond $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$. The exactness theorem excludes

such additions from every $\mathsf{Real}^{\uparrow}$-facing or Completion-facing route, and the pullback exhaustion theorem excludes them from the repacked finite spine. Hence every accepted local consumer is covered by the displayed finite rows, and every excluded alternative remains outside the accepted $\mathsf{CauchyModulusRefinement}^{\uparrow}$ packet. □

Theorem 885.166 (Cauchy modulus refinement L10 face-status noncollapse)**.** *For every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *packet*

$$R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N),$$

a $\mathsf{Real}^{\uparrow}$*-facing or Completion-facing consumer cannot replace the four L10 face rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

by a single aggregate closurestatus, formalstatus, or bridge-status row. The consumer must preserve the separate face-status reads determined by the L10 window lattice, the root-window pullback, the face order, the support-row ledger, and downstream coverage. This theorem only prevents cross-face status aggregation; it does not upgrade the verification axis of any individual face.

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier l10 face status noncollapse`

Proof. First apply L10 window lattice exactness, Definition 885.160. Every accepted $\mathsf{Real}^{\uparrow}$-facing or Completion-facing route through R must pass through the source rows and then through the displayed L10 face surface before it reaches the support rows.

Next apply root-window pullback exhaustion, Definition 885.161. It identifies the consumer route with the finite spine $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, so an aggregate status row outside that spine cannot be a hidden replacement for the face rows.

Face-order rigidity, Definition 885.163, then keeps the downstream read ordered through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. A single aggregate row would erase that order and therefore would not be an accepted pullback of the packet.

Support-row minimality, Definition 885.164, fixes the remaining rows as H, C, P, N. These support rows transport, replay, source, and name the displayed packet; none of them stores a combined closurestatus, formalstatus, or bridge-status value for all four faces.

Finally use downstream coverage, Definition 885.165. Every accepted local consumer is already covered by the displayed source, face, and support rows. Hence the four face-status rows remain separate, and the theorem records only this noncollapse discipline, not a stronger verification claim for any face. □

Theorem 885.167 (Cauchy modulus refinement formal target surface)**.** *Every accepted* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *window-lattice consumer reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed finite route*

$$\mathsf{CauchyModulusMeet}^{\uparrow}, \mathsf{CauchyModulusExtraction}^{\uparrow}, \mathsf{RegularCauchySelectorBudget}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}$$

Equivalently, for a packet $R = (M_0, M_1, U, V, T, W, Q, E, H, C, P, N)$*, the consumer route is exhausted by the modulus-meet rows* M_0, M_1, U*, extraction row* V*, selector-budget row* T*, StreamName window row* W*, DyadicRatCore tolerance row* Q*, RegSeqRat readback and Real seal row* E*, and the support rows* H, C, P, N*. No quotient stream equality, selected host limit, host real equality, hidden selector, second meet row, countable-choice row, metric-completeness row, bridge aggregation, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or ambient completion principle supplies an alternate formal target surface.*

Lean4 ✓ `BEDC.Derived.CauchyModulusRefinementUp.CauchyModulusRefinementCarrier formal target surface`

Proof. First use L10 window lattice exactness. It places every Real-facing or Completion-facing read through the source meet, extraction, and selector-budget rows before the four L10 faces and support rows are available.

Next apply root-window pullback exhaustion and finite-request route monotonicity. The pullback theorem identifies the finite spine $M_0, M_1, U, V, T, W, Q, E, H, C, P, N$, while monotonicity says refinements enlarge only the displayed request route and do not create a second source of Real-facing data.

Then use face-order rigidity and support-row minimality. The faces must be read in the order $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and the remaining support is exactly H, C, P, N for hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Finally apply downstream coverage. Every accepted local consumer is already covered by those source, face, and support rows, so the excluded quotient, selection, host-equality, hidden-selector, second-meet, choice, completeness, bridge, and ambient-completion alternatives have no coordinate in the formal target surface. □

Chapter 886

A Concrete Naming Certificate for $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$

The $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ packet realizes the Real and Completion route of chapter 9238 as a single finite synchronization surface. It joins the seal boundary of chapter 386, the budget selector of chapter 853, and the observation-budget route of chapter 611 before a $\mathsf{Real}^{\uparrow}$ consumer reads a completion-facing seal. The packet has no coordinate for quotient streams, host real equality, selected external limits, countable choice, or ambient completeness.

Definition 886.1 (Cauchy seal-budget synchronizer carrier)**.** *A* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (E, S, B, T, D, L, H, C, P, N)$$

with the following displayed rows:

1. *E is the finite precision and selected-observation request entering the Real and Completion read;*
2. *S is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row whose* $\mathsf{Real}^{\uparrow}$ *seal is the completion-facing endpoint;*
3. *B is the* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *or* $\mathsf{RealObservationBudget}^{\uparrow}$ *budget row that exposes the finite selected window, dyadic ledger, regular handoff, and seal boundary;*
4. *T is the* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *or shared-tail schedule row supplying the cofinal tail witness used by the same request;*
5. *D is the* $\mathsf{DiagonalTailSelector}^{\uparrow}$ *row naming the selected diagonal tail consumed by the budget and seal;*
6. *L is the joint compatibility row tying D, B, the shared threshold from T, and the seal row S into one finite route;*
7. *H stores componentwise* hsame *transports for $E, S, B, T, D, L, C, P, N$;*
8. *C stores the* Cont *routes by which consumers read the request, selector, budget, shared threshold, compatibility row, seal row, provenance, and local naming row;*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{CauchyDiagonalBudget}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{DiagonalTailSelector}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}}$ *row.*

Lean4 ✓ BEDC.Derived.CauchySealBudgetSynchronizerUp.CauchySealBudgetSynchronizerTasteGate single carrier alignment

Theorem 886.2 (Cauchy seal-budget synchronizer NameCert obligations)**.** *For the carrier of Definition 886.1, the local* $\mathsf{NameCert}_{\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}}$ *surface consists exactly of carrier admission for* Z*, selector exposure through* D*, budget exposure through* B*, shared-tail exposure through* T*, seal exposure through* S*, joint compatibility through* L*, classifier stability under the componentwise* hsame *rows in* H*, displayed route replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is the displayed tuple $Z = (E, S, B, T, D, L, H, C, P, N)$. The request, seal, budget, tail schedule, selector, compatibility, transport, route, provenance, and naming rows are all explicit coordinates.

Selector, budget, and shared-tail exposure are projections from the same tuple. The selector row D names the diagonal tail, the budget row B supplies either the Cauchy diagonal budget or the observation-budget route, and T supplies the shared tail threshold consumed by the same request.

The seal and compatibility clauses are also finite projections. The row S is not read as an isolated seal; it is tied by L to the selected diagonal row, budget row, and shared threshold. Componentwise transports in H and continuation routes in C can replay these displayed rows, but they cannot introduce a second selector, budget, threshold, or seal. □

Lean4 ✓ BEDC.Derived.CauchySealBudgetSynchronizerUp.CauchySealBudgetSynchronizerTasteGate obligation surface

Theorem 886.3 (Cauchy seal-budget synchronizer non-escape)**.** *Every accepted* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet read by a* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer factors through both the displayed seal row* S *and a displayed budget row* B *that is supplied by* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *or* $\mathsf{RealObservationBudget}^{\uparrow}$*. If the read uses the tail schedule, it must also pass through the displayed selector* D*, shared threshold* T*, and compatibility row* L*. No accepted read can bypass both the budget row and the selector-threshold compatibility row while still exporting the seal.*

Proof. Start from the carrier inventory. The only seal-facing coordinate is S, and the only budget-facing coordinate is B.

Apply the NameCert obligation theorem. It requires every admitted consumer route to expose D, B, T, L, and S through the displayed transport and continuation rows before the local name can be consumed.

Thus a seal read that omits the budget row has no route to B, and a seal read that omits both the selector row and the shared-threshold compatibility row has no route to D, T, L. Since the carrier contains no quotient stream, host real equality, selected external limit, countable-choice row, or ambient completeness theorem, no omitted analytic object can be repacked as a second seal route. □

Theorem 886.4 (Cauchy seal-budget synchronizer shared budget lock)**.** *Every accepted* $\mathsf{CauchySealBudgetSynchron}$ *packet fixes one request row, one seal row, one displayed budget row, one selector row, one shared-tail row, one compatibility row, and one structural family before any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer can read the seal. In the notation of Definition 886.1, the locked rows are*

$$E, S, B, T, D, L, H, C, P, N,$$

where B is supplied by chapter 853 or chapter 611, and S is supplied by chapter 386. A consumer route that changes any one of these rows before reading S is outside the local $\mathsf{NameCert}_{\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}}$ *surface.*

Proof. Project the carrier displayed in Definition 886.1. Its ten coordinates are exactly the request, seal, budget, tail schedule, selector, compatibility, componentwise transport, displayed continuation, provenance, and local naming rows.

Apply Definition 886.2. The obligation surface exposes D, B, T, L, and S through the same H, C, P, N structural rows, so the request and the consumer route read one displayed packet rather than separately chosen sibling certificates.

Finally use Definition 886.3. A $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ read that reaches the seal must factor through both the displayed seal row from chapter 386 and the displayed budget route from chapter 853 or chapter 611. Therefore replacing any locked row destroys the accepted synchronizer route. □

Lean4 ✓ `BEDC.Derived.CauchySealBudgetSynchronizerUp.CauchySealBudgetSynchronizerUp StdBridge`

Theorem 886.5 (Cauchy seal-budget synchronizer tail-selector compatibility)**.** *In every accepted* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet, the tail schedule row T and selector row D are consumed together through the compatibility row L. Hence a* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer cannot combine the seal row S with an alternate selector or an alternate tail source while remaining inside the carrier*

$$Z = (E, S, B, T, D, L, H, C, P, N).$$

Proof. Start with the compatibility coordinate in Definition 886.1. The row L is the only displayed place where D, B, the shared threshold from T, and the seal row S are tied into one finite route.

Apply Definition 886.2. The local $\mathsf{NameCert}$ obligations require selector exposure, shared-tail exposure, budget exposure, seal exposure, and joint compatibility, and they replay these rows through the same componentwise hsame, Cont, Pkg, and local naming surface.

Use Definition 886.3. Since a seal read must pass through the displayed budget row and through the selector-threshold compatibility row, a consumer that substitutes another selector or tail source no longer reads the synchronizer packet. The sibling seal, diagonal-budget, and observation-budget chapters provide the displayed rows, but the synchronizer admits them only through the shared L row. □

Theorem 886.6 (Cauchy seal-budget synchronizer real-seal budget exhaustion)**.** *The* $\mathsf{Real}^{\uparrow}$*-facing seal route of an accepted* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *packet is exhausted by*

$$E, S, B, T, D, L, H, C, P, N.$$

It contains the displayed request, seal, budget, tail schedule, selector, compatibility, transport, continuation, provenance, and local naming rows, and it excludes quotient streams, host real equality, selected external limits, countable choice, and ambient completeness as seal-exporting resources.

Proof. Begin with the carrier inventory of Definition 886.1. The $\mathsf{Real}^{\uparrow}$-facing route has exactly the ten displayed rows $E, S, B, T, D, L, H, C, P, N$.

Apply Definition 886.2. These rows account for carrier admission, selector exposure, budget exposure, shared-tail exposure, seal exposure, joint compatibility, componentwise transport, displayed route replay, package provenance, and local naming.

Now apply Definition 886.3. Any $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer must read the seal through the displayed chapter 386 row and through the displayed budget route of chapter 853 or chapter 611.

There is no coordinate in the carrier for quotient streams, host real equality, selected external limits, countable choice, or ambient completeness. Those resources therefore cannot be recovered as hidden seal exporters, and the finite row list exhausts the Real-facing seal route. □

Theorem 886.7 (Cauchy seal-budget synchronizer scoped row grounding)**.** *For an accepted packet*

$$Z = (E, S, B, T, D, L, H, C, P, N),$$

every scoped obligation of $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *is grounded by exactly the displayed request, seal, budget, tail schedule, diagonal selector, compatibility, transport, route, provenance, and* $\mathsf{NameCert}$ *rows. The seal row S is consumed from chapter 386; the budget row B is consumed from chapter 853 or chapter 611; the tail schedule row T is consumed from chapter 681; the selector row D is consumed from chapter 697; and the seal read ends at the* $\mathsf{Real}^{\uparrow}$ *row named in the provenance package. No additional scoped obligation is discharged by quotient streams, host real equality, selected external limits, countable choice, or ambient completeness.*

Proof. Begin with the carrier definition. The packet has exactly the ten displayed coordinates $E, S, B, T, D, L, H, C, P, N$, so a scoped obligation can only be admitted through one of those rows.

Apply the local obligation package in Definition 886.2. Carrier admission gives Z; selector, budget, shared-tail, seal, and compatibility exposure give D, B, T, S, L; classifier stability and route replay give H and C; package provenance and local naming give P and N.

Next apply the shared budget lock and tail-selector compatibility theorems. They force the sibling rows to be consumed together: S comes from the Cauchy limit seal surface, B comes from the diagonal-budget or observation-budget surface, T supplies the tail schedule, D supplies the selected diagonal tail, and L ties these rows to the Real-facing seal read.

Finally project P. Its provenance list names the sibling dependency rows over $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{CauchyDiagonalBudget}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{DiagonalTailSelector}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Use the non-escape theorem to close the scope. Since the accepted carrier contains no coordinate for quotient streams, host real equality, selected external limits, countable choice, or ambient completeness, none of those objects can discharge a hidden synchronizer obligation. Thus the scoped obligation surface is exhausted by the displayed rows. □

Falsifiable prediction: If an accepted synchronizer packet is read by a RealCompleteness consumer, the read factors through both a displayed CauchyLimitSealUp row and a displayed CauchyDiagonalBudgetUp or RealObservationBudgetUp row; a seal read bypassing both refutes the packet.

Independence witness: cauchylimitseal, cauchydiagonalbudget, realobservationbudget, tailcofinalityschedule, diagonaltailselector: none is bijective because the synchronizer has one joint compatibility row tying selector, observation budget, shared threshold, and seal rows; each sibling lacks at least one of these rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ packet is generated from a finite precision request, completion-facing seal row, budget row, tail schedule row, diagonal selector row, joint compatibility row, componentwise transports, displayed routes, package provenance, and local naming row.

Theory closure: TheoryGate(NameCert$_{\text{CauchySealBudgetSynchronizer}\uparrow}$, maturePackageClosed)

Scope closed: Definition 886.1, Definition 886.2, Definition 886.3, Definition 886.4, Definition 886.5, Definition 886.6, Definition 886.7, and the checked TasteGate marker bind the synchronizer carrier, finite obligation package, row lock, selector-tail compatibility boundary, Real-facing budget exhaustion, scoped row grounding, and non-escape surface.

Formal verification: FormalStatus(NameCert$_{\text{CauchySealBudgetSynchronizer}\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.CauchySealBudgetSynchronizerUp.CauchySealBudgetSynchronizerTasteGate\_single\_carrier\_`

Bridge status: bridgeChecked

Not claimed: This chapter does not close Real completeness, quotient streams, host real equality, selected external limits, countable choice, or ambient completeness.

Upgrade path: No further verification-axis bridge upgrade remains for this finite synchronizer surface.

Chapter 887

A Concrete Naming Certificate for $\mathsf{RealSealComparison}^{\uparrow}$

The $\mathsf{RealSealComparison}^{\uparrow}$ packet is the equality-facing comparison surface for two sealed $\mathsf{Real}^{\uparrow}$ routes in the Real completeness target of chapter 9238. It consumes two Cauchy-limit seal packets from chapter 386, the separated uniqueness row of chapter 427, and the diagonal stability route of chapter 870. The packet records a finite comparison between the two sealed routes; it is not a quotient stream, a host real equality, a selected limit, or an ambient completeness principle.

Falsifiable prediction: If a $\mathsf{RealSealComparison}^{\uparrow}$ route is accepted, it factors through two displayed $\mathsf{CauchyLimitSeal}^{\uparrow}$ public route packets and one separated comparison row. A route requiring quotient streams, host real equality, selected limits, or ambient completeness is outside the carrier.

Independence witness: cauchylimitseal, regularlimituniqueness, diagonallimitstability, realobservationbudget, regularcauchycomparison: none is bijective to $\mathsf{RealSealComparison}^{\uparrow}$ because this carrier contains two seal routes and one equality-facing separated comparison between them. CauchyLimitSeal, RealObservationBudget, and DiagonalLimitStability are single-route or representative-to-seal packets; RegularLimitUniqueness supplies the separated row without the two public seal routes; RegularCauchyComparison compares regular sources before the paired seal-comparison package is assembled.

Definition 887.1 (Real seal comparison carrier)**.** *A* $\mathsf{RealSealComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S_0, S_1, U, D_0, D_1, K, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are two public* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route packets, each already exposing its regular source, finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, continuation, provenance, and local naming rows;*
2. *U is the separated* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *comparison row between the two* $\mathsf{Real}^{\uparrow}$ *seal outputs;*
3. *D_0 and D_1 are the* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *rows that attach the two seal routes to their displayed diagonal representatives;*
4. *K is the equality-facing comparison verdict read only after S_0, S_1, and U have been displayed;*
5. *H records componentwise* hsame *transport for the two seal packets, the separated comparison row, the diagonal-stability rows, the verdict, route replay, provenance, and local naming;*

6. *C records the displayed* Cont *routes that replay the two seal packets, the separated comparison, the diagonal-stability handoffs, and the verdict;*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{RegularLimitUniqueness}^{\uparrow}$, $\mathsf{DiagonalLimitStability}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSealComparison}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host real equality, a selected host limit, countable choice, trichotomy, or an ambient Real completeness theorem.

Lean4 ✓ `BEDC.Derived.RealSealComparisonUp.RealSealComparisonTasteGate single carrier alignment`

Theorem 887.2 (RealSealComparison NameCert obligations)**.** *For every* $\mathsf{RealSealComparison}^{\uparrow}$ *carrier*

$$Q = (S_0, S_1, U, D_0, D_1, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealSealComparison}^{\uparrow}}$ *surface consists of carrier exposure for the two* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *route packets, exposure of the separated* $\mathsf{RegularLimitUniqueness}^{\uparrow}$ *comparison row, exposure of the two* $\mathsf{DiagonalLimitStability}^{\uparrow}$ *handoff rows, equality-facing verdict exposure through K, component-wise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 887.1. The two seal packets, separated comparison row, diagonal-stability rows, verdict row, transports, continuations, provenance, and local name are explicit coordinates of one finite BHist packet.

Read the two seal routes through the Cauchy-limit seal public boundary. Each side must already present its regular source, finite windows, readback, and $\mathsf{Real}^{\uparrow}$ seal before the comparison route can inspect it.

Then read U through the separated uniqueness surface and D_0, D_1 through diagonal-limit stability. These rows make the equality-facing verdict a finite comparison between displayed seal routes, not a host equality between completed reals.

The structural rows H, C, P, N transport, replay, authenticate, and name exactly those displayed rows. Since the carrier contains no quotient, host equality, selected limit, choice, trichotomy, or ambient-completeness coordinate, the local NameCert obligations are exhausted by the listed packet. □

Lean4 ✓ `BEDC.Derived.RealSealComparisonUp.RealSealComparisonCarrier namecert obligations`

Theorem 887.3 (RealSealComparison uniqueness handoff)**.** *Any accepted* $\mathsf{RealSealComparison}^{\uparrow}$ *packet that exports equality of the two sealed* $\mathsf{Real}^{\uparrow}$ *routes must factor the export through the two displayed* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *packets S_0, S_1 and the separated comparison row U. The verdict K is determined only after those three rows and the diagonal-stability handoffs D_0, D_1 have been replayed through the displayed* hsame, Cont, Pkg, *and* NameCert *rows.*

Proof. Start with the two seal packets. The Cauchy-limit seal boundary forces each $\mathsf{Real}^{\uparrow}$ route to expose its public route packet before a downstream consumer reads the seal.

Next apply the separated uniqueness row. The comparison between the two seal outputs is the row U, so the equality-facing verdict cannot be read before both S_0 and S_1 have reached their displayed seals.

The diagonal-stability rows attach the seal routes to their representatives, while H, C, P, N replay and authenticate the same finite route. Thus the handoff to equality is the displayed two-seal and one-separated-row route, with no independent host equality or selected limit available. □

Theorem 887.4 (RealSealComparison non-escape)**.** *Downstream consumers of an accepted* RealSealComparison$^{\uparrow}$ *packet receive only the finite comparison surface*

$$S_0, S_1, U, D_0, D_1, K, H, C, P, N.$$

They receive no quotient stream, host real equality, selected limit, countable-choice selector, trichotomy row, or ambient completeness theorem.

Proof. Project the accepted carrier. The public comparison surface contains exactly the two seal route packets, separated comparison row, diagonal-stability handoffs, verdict, transports, continuations, provenance, and local naming row.

Use the uniqueness handoff to route any equality-facing consumer through S_0, S_1, U, D_0, D_1 before it reaches K. This makes the displayed finite comparison the only consumer-visible equality boundary.

Finally inspect the excluded data. No coordinate in the carrier stores quotient stream equality, host real equality, a selected limit, countable choice, trichotomy, or ambient completeness. The downstream export therefore cannot escape the finite two-seal comparison surface. □

Closure status for NameCert$_{\text{RealSealComparison}^{\uparrow}}$**.**

Constructive story: A RealSealComparison$^{\uparrow}$ packet is generated from two CauchyLimitSeal$^{\uparrow}$ public route packets, a separated RegularLimitUniqueness$^{\uparrow}$ comparison row, two DiagonalLimitStability$^{\uparrow}$ handoff rows, an equality-facing verdict, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RealSealComparison}^{\uparrow}}$, seed)

Scope closed: Definition 887.1, Definition 887.2, Definition 887.3, and Definition 887.4 specify the finite two-seal comparison carrier, local NameCert rows, separated uniqueness handoff, and non-escape boundary.

Formal verification: FormalStatus(NameCert$_{\text{RealSealComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove host real equality, quotient-stream equality, selected-limit existence, ambient Real completeness, Lean verification, or bridge checking for RealSealComparison$^{\uparrow}$.

Upgrade path: Obligation closure requires checked two-seal carrier admission, separated comparison exactness, diagonal-stability replay, equality-verdict determinacy, transport preservation, and consumer non-escape for the same finite packet.

Chapter 888

A Concrete Naming Certificate for $\mathsf{ObserverTraceKernel}^{\uparrow}$

The $\mathsf{ObserverTraceKernel}^{\uparrow}$ packet realizes the observer-history identity vision of chapter 9418 as a finite kernel trace-row surface. It is the row-level companion of chapter 640 and chapter 882: the former exposes observer identity through a finite kernel trace, while the latter orders distinction steps. This chapter binds those two readings into one NameCert packet whose consumer sees only BHist, hsame, Cont, observation, provenance, and no-subject rows.

Definition 888.1 (ObserverTraceKernel carrier)**.** *An* $\mathsf{ObserverTraceKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (H, T, Q, O, L, C, P, N)$$

with the following displayed rows:

1. *H is the finite source-history ledger, whose entries are* BHist *rows available to the observer-facing consumer;*
2. *T is the kernel trace row recording the ordered finite observation route above H;*
3. *Q is the componentwise* hsame *transport row for source histories, trace rows, observation rows, provenance rows, and the local name;*
4. *O is the finite observation ledger, including the displayed* ProbeBundle *and* SigRel *reads licensed for the same trace;*
5. *L is the no-subject ledger recording that every exported observer read is one of the displayed rows of K;*
6. *C records the displayed* Cont *routes from H through T, O, L to the local naming row;*
7. *P is the* Pkg *provenance over* $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{ObserverKernelTrace}^{\uparrow}$, $\mathsf{ObserverDistinctionTrace}^{\uparrow}$, $\mathsf{ObserverSubjectBoundary}^{\uparrow}$, BHist, hsame, Cont, *observation, and* NameCert *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ObserverTraceKernel}^{\uparrow}}$ *row.*

The carrier has no coordinate for an observer-substance type, host equality of observers, hidden owner of observations, or trace object outside the displayed finite kernel rows.

Lean4 ✓ `BEDC.Derived.ObserverTraceKernelUp.ObserverTraceKernelTasteGate single carrier alignment`

Theorem 888.2 (ObserverTraceKernel carrier row)**.** *For the carrier of Definition 888.1, the local* $\mathsf{NameCert}_{\mathsf{ObserverTraceKernel}^{\uparrow}}$ *surface consists exactly of carrier admission for* $K = (H, T, Q, O, L, C, P, N)$*, kernel trace-row exposure, componentwise* hsame *transport, finite observation readback, displayed* Cont *route replay, no-subject ledger exactness,* Pkg *provenance, and local naming exactness.*

Proof. Carrier admission is projection from the displayed tuple K. The rows H, T, Q, O, L, C, P, N list the source histories, kernel trace, transports, observations, no-subject ledger, continuation routes, provenance, and local name.

The trace-row and observation clauses are read together. The kernel trace T records the finite route over the histories in H, while O records only the licensed observation rows attached to that same route.

Transport and replay are also componentwise. The row Q preserves the displayed coordinates under hsame, and C gives the only permitted reads from source histories to observation and naming rows. Since the tuple has no further coordinate, the listed clauses exhaust the local certificate surface. □

Theorem 888.3 (ObserverTraceKernel no-subject ledger)**.** *Every accepted* $\mathsf{ObserverTraceKernel}^{\uparrow}$ *packet exports observer-history identity only through the finite rows* H, T, Q, O, L, C, P, N*. No consumer can extract an observer-substance carrier, subject identity row, hidden owner of the trace, host equality of observers, or observation truth predicate outside* BHist*,* hsame*,* Cont*, observation,* Pkg*, and* NameCert *rows.*

Proof. Project the accepted carrier and inspect the no-subject ledger L. It records each exported observer-facing read as a row already listed in H, T, Q, O, C, P, N.

Apply Definition 888.2. The local certificate surface admits only kernel trace rows, transports, finite observation rows, route replay, provenance, and local naming.

An observer-substance carrier or hidden owner would require an additional coordinate outside K. Because no such coordinate is present, every accepted consumer remains inside the displayed trace rows and cannot export subject identity or host equality data. □

Theorem 888.4 (ObserverTraceKernel composition boundary)**.** *Every consumer route from an accepted* $\mathsf{ObserverTraceKernel}^{\uparrow}$ *packet to an observer-history identity read factors through the finite composition*

$$H \longmapsto T \longmapsto O \longmapsto L \longmapsto C \longmapsto P \longmapsto N.$$

The route composes the $\mathsf{ObserverKernelTrace}^{\uparrow}$ *trace surface, the* $\mathsf{ObserverDistinctionTrace}^{\uparrow}$ *distinction-step surface, the* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *observation surface, and the* $\mathsf{ObserverSubjectBoundary}^{\uparrow}$ *exclusion surface without adding a new observer carrier, quotient observer identity, ambient time parameter, or host equality of subjects.*

Proof. Begin with the kernel trace sibling chapter 640. It confines observer trace reads to finite BHist, hsame, Cont, probe, signature, provenance, and naming rows.

Next use the distinction-trace sibling chapter 882. It orders distinction-step reads through displayed Hist growth and Cont routes, so the trace row T remains a finite kernel row rather than a detached observer state.

Finally apply the observer-history identity and subject-boundary surfaces. chapter 479 supplies the observation readback, and chapter 615 prevents the route from exporting a subject coordinate. The displayed route through H, T, O, L, C, P, N is therefore the whole consumer boundary. □

The later Lean target in `lean4/BEDC/Derived/ObserverTraceKernelUp.lean` must provide $\mathsf{Nontrivial\ ObserverTraceKernel}^{\uparrow}$ and $\mathsf{FieldFaithful\ ObserverTraceKernel}^{\uparrow}$ instances. The witnesses must distinguish the source-history ledger, kernel trace row, hsame transports, observation ledger, no-subject ledger, displayed Cont routes, provenance, and local name.

Falsifiable prediction: Any accepted ObserverTraceKernelUp consumer route factors through the displayed kernel trace, observation, Cont, provenance, and no-subject rows before reading the local NameCert row.

Independence witness: observerkerneltrace, observerdistinctiontrace, observerhistidentity, observersubjectboundary: the packet records a kernel trace-row composition rather than trace exposure alone, distinction ordering alone, observation identity alone, or subject-boundary exclusion alone.

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverTraceKernel}^{\uparrow}}$.

Constructive story: An $\mathsf{ObserverTraceKernel}^{\uparrow}$ packet is generated from source-history rows, a finite kernel trace row, componentwise hsame transports, observation rows, a no-subject ledger, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObserverTraceKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 888.1, Definition 888.2, Definition 888.3, and Definition 888.4 bind the finite kernel trace-row packet for observer-history identity.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObserverTraceKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, a host observer model, quotient observer identity, ambient time, or an observer-substance behind the trace.

Upgrade path: Obligation closure requires checked carrier admission, trace-row exposure, hsame transport, observation readback, Cont route replay, provenance, no-subject exactness, and the stated Nontrivial and FieldFaithful instances.

Chapter 889

A Concrete Naming Certificate for $\mathsf{ObserverLocalityTransport}^{\uparrow}$

The $\mathsf{ObserverLocalityTransport}^{\uparrow}$ packet realizes the transport boundary in the Inter-Hist Locality chain of chapter 9419. It sits after the observer-locality cell surface of chapter 513, the causal-route surface of chapter 478, and the unary-bound surface of chapter 594; it is the route-level sibling read by the cross-Hist causal-rate packet of chapter 876. The packet records the finite path by which a consumer transports locality-cell data through causal rows and maximum-rate rows without entering a global observer frame.

Definition 889.1 (Observer-locality transport carrier)**.** *An* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (O, D, R, L, H, Q, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{ObserverLocalityCell}^{\uparrow}$ *row that supplies the two-observer locality cell being transported;*
2. *D is the finite family of* $\mathsf{CrossHistCausal}^{\uparrow}$ *rows that records the causal route through which the locality-cell read is moved between the two displayed histories;*
3. *R is the* $\mathsf{MaxCausalRate}^{\uparrow}$ *row whose unary bound is read only after the causal routes in D have been exposed;*
4. *L is the no-global-frame ledger, recording that the transport route contains no privileged observer frame, synchronized clock, metric tensor, Lorentz-geometry coordinate, or host real-valued speed row;*
5. *H records componentwise* hsame *transport for the locality cell, causal rows, maximum-rate row, no-global-frame ledger, probe-stability row, continuation routes, provenance row, and local naming row;*
6. *Q records* psame *stability for the probe reads used by the locality-cell row, causal rows, and maximum-rate row;*
7. *C records displayed* Cont *routes by which a consumer reads O, replays each row of D, reads R, checks L, and transports the same packet through H and Q;*
8. *P is the* Pkg *provenance over* $\mathsf{ObserverLocalityTransport}^{\uparrow}$, $\mathsf{ObserverLocalityCell}^{\uparrow}$, $\mathsf{CrossHistCausal}^{\uparrow}$, $\mathsf{MaxCausalRate}^{\uparrow}$, $\mathsf{CrossHistCausalRate}^{\uparrow}$, BHist, hsame, psame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{ObserverLocalityTransport}^{\uparrow}}$ *row.*

The carrier exports only the displayed locality cell, causal rows, maximum-rate row, no-global-frame ledger, transport rows, continuation routes, provenance, and local naming data.

Theorem 889.2 (Observer-locality transport NameCert obligations)**.** *For the carrier of Definition 889.1, the local* $\mathsf{NameCert}_{\mathsf{ObserverLocalityTransport}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the displayed packet $T = (O, D, R, L, H, Q, C, P, N)$;*
2. *locality-cell source exactness, requiring the transported row to be the* $\mathsf{ObserverLocalityCell}^{\uparrow}$ *row O and not a detached observer-frame coordinate;*
3. *causal-route handoff, requiring every transport route to pass through the displayed* $\mathsf{CrossHistCausal}^{\uparrow}$ *family D before the maximum-rate row R is read;*
4. *transport stability through componentwise* hsame *in H, probe stability in Q, and displayed* Cont *replay in C;*
5. *non-escape, excluding global frames, synchronized clocks, metric tensors, Lorentz geometry, host real-valued speed, and any locality read not routed through $O, D, R, L, H, Q, C, P, N$.*

Proof. Carrier admission is projection from Definition 889.1. The rows $O, D, R, L, H, Q, C, P, N$ display the locality cell, causal family, maximum-rate row, no-global-frame ledger, transports, routes, provenance, and local name.

Locality-cell source exactness reads O first. The packet has no separate observer-frame coordinate, so the transported locality surface is the finite cell row rather than an ambient frame.

Causal-route handoff then reads D before R. Each maximum-rate read is attached to the displayed causal family, so a consumer cannot replace the route witness by a bare unary bound.

Transport stability is componentwise through H, Q, C, and the non-escape claim is the carrier inventory. Since no excluded structure is a coordinate of T, no local certificate projection can export one. □

Theorem 889.3 (Observer-locality transport boundary)**.** *Every public consumer of an accepted* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *packet reads the locality-cell row only through*

$$O, D, R, L, H, Q, C, P, N.$$

In particular, the consumer must pass from the $\mathsf{ObserverLocalityCell}^{\uparrow}$ *row O through the* $\mathsf{CrossHistCausal}^{\uparrow}$ *rows D before it reads the* $\mathsf{MaxCausalRate}^{\uparrow}$ *row R or the cross-Hist causal-rate surface of chapter 876.*

Proof. Project the accepted carrier. The locality-cell source is the row O, and the only displayed route family connecting it to rate data is D.

Use the causal-route handoff in Definition 889.2. It places the $\mathsf{CrossHistCausal}^{\uparrow}$ rows before the maximum-rate row R, so the rate read is not a substitute for the transport route.

Finally route through H, Q, C, P, N and check the no-global-frame ledger L. The consumer remains inside the finite packet and cannot read a global frame, metric tensor, Lorentz geometry, synchronized clock, or host real-valued speed. □

Theorem 889.4 (Observer-locality transport rate pullback)**.** *Every rate-facing consumer of an accepted* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *packet factors through the same finite tuple*

$$O, D, R, L, H, Q, C, P, N.$$

In particular, the consumer must read the $\mathsf{ObserverLocalityCell}^{\uparrow}$ *row* O*, the* $\mathsf{CrossHistCausal}^{\uparrow}$ *route family* D*, the* $\mathsf{MaxCausalRate}^{\uparrow}$ *row* R*, and the* $\mathsf{CrossHistCausalRate}^{\uparrow}$ *consumer surface through one transport packet. The packet exports no global frame, synchronized clock, metric tensor, Lorentz geometry, host real-valued speed, or detached rate row.*

Proof. Project the accepted carrier from Definition 889.1. The tuple $O, D, R, L, H, Q, C, P, N$ lists the locality cell, causal family, maximum-rate row, no-global-frame ledger, structural rows, provenance, and local naming row available to a rate-facing consumer.

Apply Definition 889.2. The NameCert surface places locality-cell exactness before causal-route handoff, and it requires every maximum-rate read to pass through the displayed causal family.

Now use Definition 889.3. It keeps the public consumer inside the same tuple and routes any cross-Hist causal-rate read through the locality cell, causal routes, maximum-rate row, and transport rows.

The non-escape clause follows from the ledger L and carrier inventory. Since no listed coordinate is a global frame, synchronized clock, metric tensor, Lorentz geometry, host real-valued speed, or detached rate row, the accepted transport packet cannot export one. □

Theorem 889.5 (Observer-locality transport TasteGate obligation)**.** *The later Lean* `TasteGate.lean` *development for* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *must include explicit* $\mathsf{Nontrivial\ ObserverLocalityTransport}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ ObserverLocalityTransport}^{\uparrow}$ *instances. These instances must preserve the locality-cell row, causal-route family, maximum-rate row, no-global-frame ledger,* hsame *transport,* psame *stability,* Cont *routes, package provenance, and local naming row.*

Proof. The packet is not determined by a single locality cell or a single rate row. It carries a route-level transport witness between the cell and the maximum-rate surface.

Nontriviality rules out a collapsed carrier in which the route witness is indistinguishable from the cell or rate rows. Field faithfulness records preservation of all displayed coordinates $O, D, R, L, H, Q, C, P, N$, so a TasteGate consumer can distinguish the route-level transport row from the sibling surfaces it connects. □

Lean4 ✓ `BEDC.Derived.ObserverLocalityTransportUp.ObserverLocalityTransportTasteGate single carrier alignment`

Theorem 889.6 (Observer-locality transport obligation carrier admission)**.** *For every accepted* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *carrier*

$$T = (O, D, R, L, H, Q, C, P, N),$$

the finite local $\mathsf{NameCert}_{\mathsf{ObserverLocalityTransport}^{\uparrow}}$ *surface admits exactly the displayed transport packet. The admitted rows are the* $\mathsf{ObserverLocalityCell}^{\uparrow}$ *source row* O*, the* $\mathsf{CrossHistCausal}^{\uparrow}$ *route family* D*, the* $\mathsf{MaxCausalRate}^{\uparrow}$ *rate row* R*, the no-global-frame ledger* L*, componentwise transport* H*, probe stability* Q*, continuation replay* C*, package provenance* P*, and the local naming row* N*.*

Proof. Project the carrier displayed in Definition 889.1. Its coordinates are precisely $O, D, R, L, H, Q, C, P, N$, and each coordinate already has the named transport role used by the local certificate.

Apply the boundary theorem, Definition 889.3. It says every public consumer reads the locality-cell row only through the same tuple, so carrier admission cannot add an external frame, clock, metric, or detached rate coordinate.

Finally apply the rate pullback theorem, Definition 889.4. The rate-facing surface also factors through the same packet, which makes the admitted carrier the complete finite NameCert row for later promotion. □

Theorem 889.7 (Observer-locality transport obligation causal-route handoff)**.** *For every accepted* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *carrier* $T = (O, D, R, L, H, Q, C, P, N)$*, any consumer that reads the maximum-rate row* R *or the cross-Hist causal-rate surface must first pass through the displayed route family* D *from the locality-cell row* O*. The handoff is transported only by* H*, stabilized only by* Q*, replayed only by* C*, packaged only by* P*, and locally named only by* N*.*

Proof. Begin with the local NameCert obligations of Definition 889.2. Their handoff row places every maximum-rate read after the displayed $\mathsf{CrossHistCausal}^{\uparrow}$ family D.

Use Definition 889.3 to identify the public route. The consumer starts at the locality-cell row O, moves through D, and only then reaches R or a cross-Hist causal-rate read.

The rate pullback theorem, Definition 889.4, keeps this handoff inside T. Thus H, Q, C, P, N preserve and replay the same finite route instead of manufacturing a second causal path or detached rate row. □

Theorem 889.8 (Observer-locality transport route composition determinacy)**.** *For every accepted* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *carrier*

$$T = (O, D, R, L, H, Q, C, P, N),$$

any two public consumers that read the same $\mathsf{ObserverLocalityCell}^{\uparrow}$ *row* O *and the same* $\mathsf{CrossHistCausal}^{\uparrow}$ *family* D *before reading the* $\mathsf{MaxCausalRate}^{\uparrow}$ *row* R *have the same displayed transport route through* H, Q, C, P, N*. No such consumer can splice in a detached causal row, detached rate row, global frame, synchronized clock, metric tensor, Lorentz coordinate, or host real-valued speed.*

Proof. Project the accepted carrier from Definition 889.1. The only displayed route from the locality cell to the rate row is the finite packet $O, D, R, L, H, Q, C, P, N$.

Apply causal-route handoff, Definition 889.7. It forces both consumers to read O, then the same family D, and only then the rate row R.

Use rate pullback, Definition 889.4. Since every rate-facing consumer remains inside the same tuple, the continuation, transport, stability, provenance, and naming rows are exactly H, Q, C, P, N for both reads.

Finally apply non-global-frame exhaustion, Definition 889.9. The excluded coordinates have no carrier row in T, so they cannot be spliced into the displayed route. □

Theorem 889.9 (Observer-locality transport obligation non-global-frame exhaustion)**.** *For every accepted* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *carrier* $T = (O, D, R, L, H, Q, C, P, N)$*, the no-global-frame ledger* L *exhausts every request for a privileged observer frame, synchronized clock, metric tensor, Lorentz-geometry coordinate, host real-valued speed, or locality read not routed through* $O, D, R, L, H, Q, C, P, N$*. Later promotion reads the existing* `BEDC.Derived.ObserverLocalityTransportUp.ObserverLocalityTransport` *marker together with the* $\mathsf{Nontrivial\ ObserverLocalityTransport}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ ObserverLocalityTransport}^{\uparrow}$ *instances, so the AI-origin TasteGate discipline is attached to this same finite carrier rather than to a global frame.*

Proof. Read the ledger coordinate L in the carrier definition. It records exactly the exclusions for global frame, synchronized clock, metric tensor, Lorentz geometry, host real-valued speed, and off-route locality access.

Apply Definition 889.3. Since every public locality read stays inside T, any request for a global frame has no coordinate except the refusal recorded by L.

Apply Definition 889.4 for rate-facing consumers. The rate row is available only after the causal route and never as a host real-valued speed or Lorentz coordinate, so the exhaustion covers both locality and rate interfaces.

The TasteGate marker already checked in this chapter is then read as a single-carrier alignment condition. Nontriviality separates the transport packet from its sibling rows, and field faithfulness preserves all coordinates $O, D, R, L, H, Q, C, P, N$ during promotion. □

Theorem 889.10 (Observer-locality transport public export)**.** *For every accepted* $\mathsf{ObserverLocalityTransport}^{\uparrow}$ *carrier*

$$T = (O, D, R, L, H, Q, C, P, N),$$

the public export surface of T is exactly the finite route $O, D, R, L, H, Q, C, P, N$. The row O is exported as the $\mathsf{ObserverLocalityCell}^{\uparrow}$ *source, D as the finite* $\mathsf{CrossHistCausal}^{\uparrow}$ *route family, R as the* $\mathsf{MaxCausalRate}^{\uparrow}$ *rate row, L as the no-global-frame ledger, H as componentwise* hsame *transport, Q as probe stability, C as continuation replay, P as package provenance, and N as the local* $\mathsf{NameCert}_{\mathsf{ObserverLocalityTransport}^{\uparrow}}$ *row. The provenance path runs through* $\mathsf{ObserverLocalityCell}^{\uparrow}$, $\mathsf{CrossHistCausal}^{\uparrow}$, $\mathsf{MaxCausalRate}^{\uparrow}$, $\mathsf{CrossHistCausalRate}^{\uparrow}$, *and the checked single-carrier TasteGate marker* `BEDC.Derived.ObserverLocalityTransportUp.ObserverLocalityTransportTasteGate_single_carri` *no public export coordinate lies outside that route.*

Proof. Apply Definition 889.6. It identifies the accepted carrier with precisely the displayed packet $O, D, R, L, H, Q, C, P, N$ and supplies the local NameCert row for that packet.

Apply Definition 889.7. The export reads the locality cell through O, the route family through D, and the maximum-rate or cross-Hist causal-rate surface only after that handoff.

Apply Definition 889.8. Once the public consumer has read the same O and D before R, the displayed transport through H, Q, C, P, N is determined, so the export cannot splice in a detached route or detached rate row.

Finally apply Definition 889.9. The ledger L exhausts requests for global-frame or host-geometry data, while the checked TasteGate single-carrier marker attaches promotion to the same finite packet. □

Falsifiable prediction: If the transport packet is atomic, a consumer cannot replace the displayed locality-cell row by a MaxCausalRate row without passing through CrossHistCausal transport.

Independence witness: Nearest siblings: observerlocalitycell, crosshistcausal, maxcausalrate, crosshistcausalrate. The transport packet is not bijective to any of them because it carries a route-level transport row between sibling surfaces, while those siblings carry cell, causal, bound, or rate rows without this route witness.

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverLocalityTransport}^{\uparrow}}$.

Constructive story: An $\mathsf{ObserverLocalityTransport}^{\uparrow}$ packet is generated from an observer-locality cell, finite cross-Hist causal route rows, a maximum-rate row, a no-global-frame ledger, componentwise hsame transport, psame stability, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{ObserverLocalityTransport}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 889.1, Definition 889.2, Definition 889.3, Definition 889.5, Definition 889.10, Lean4 ✓ `BEDC.Derived.ObserverLocalityTransportUp.taste gate`, and the checked single-carrier marker `BEDC.Derived.ObserverLocalityTransportUp.ObserverLocalityTransportTasteGate_sing` bind the public finite route $O, D, R, L, H, Q, C, P, N$ with the kernel rows BHist, hsame, psame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\mathsf{ObserverLocalityTransport}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.ObserverLocalityTransportUp.ObserverLocalityTransportTasteGate\_single\_carrier\_alignm`

Bridge status: none

Origin: ai

Not claimed: This chapter does not derive Lorentz geometry, metric tensors, synchronized clocks, global frames, host real-valued speed, Lean verification of the public export theorem, or bridge checking for $\mathsf{ObserverLocalityTransport}^{\uparrow}$.

Upgrade path: No further paper-side theory closure grade remains; only independent verification-axis and bridge-axis checks can strengthen the recorded status.

Chapter 890

A Concrete Naming Certificate for $\mathsf{RuntimeReflectionBoundary}^{\uparrow}$

The $\mathsf{RuntimeReflectionBoundary}^{\uparrow}$ packet realizes the runtime half of the reflection limit in chapter 9461. It sits beside the truth-total obstruction packet of chapter 472 and the certificate-indexed self-reference branch packet of chapter 667: those siblings record truth-total and branch-query refusals, while this packet records the concrete runtime-request surface that separates structural self-description from external kernel execution.

Definition 890.1 (Runtime-reflection boundary carrier)**.** *A* $\mathsf{RuntimeReflectionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, Q, E, V, H, C, P, N)$$

with the following displayed rows:

1. *S is the structural self-description row over the internal* CIC^* *presentation, including formation, replay, and certificate-shape data;*
2. *Q is the runtime-request route, naming the object-level request that a consumer wants to treat as validation of the same structural presentation;*
3. *E is the execution-refusal row, recording that external kernel execution is not a carrier coordinate and cannot be supplied by the described object language;*
4. *V is the displayed runtime-boundary report, separating structural replay through S from the refused validator route through Q and E;*
5. *H records componentwise* hsame *transport for structural self-description, runtime requests, execution refusal, boundary reports, routes, provenance, and local names;*
6. *C records displayed* Cont *routes by which consumers read S, inspect Q, receive E, replay V, and transport the same packet through H;*
7. *P is the* Pkg *provenance over chapter 9461, chapter 472, chapter 667,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RuntimeReflectionBoundary}^{\uparrow}}$ *row.*

The carrier stores no BEDC-internal runtime validator, no truth-total classifier, no certificate-indexed truth branch, and no route that turns structural self-description into host execution.

Theorem 890.2 (Runtime-reflection boundary NameCert obligations)**.** *For the carrier of Definition 890.1, the local* $\mathsf{NameCert}_{\mathsf{RuntimeReflectionBoundary}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the displayed packet* $R = (S, Q, E, V, H, C, P, N)$*;*
2. *structural self-description exactness, requiring every admitted description read to factor through* S*;*
3. *runtime-request accountability, requiring every attempted validator read to enter through the displayed route* Q*;*
4. *execution refusal and report exactness, requiring the refusal row* E *and boundary report* V *to be the only runtime-facing exports;*
5. *transport and provenance closure, requiring all comparisons, consumer routes, package provenance, and local naming to be exactly the displayed rows* H, C, P, N*.*

Thus a consumer can read structural self-description and the refused runtime request, but it cannot obtain a BEDC-internal runtime validator from the packet.

Proof. Carrier admission is projection from Definition 890.1. The rows S, Q, E, V, H, C, P, N are the complete finite packet.

Structural self-description exactness reads S first. The row displays formation, replay, and certificate-shape data, so a consumer may inspect the structural copy described in chapter 9461.

Runtime-request accountability reads Q before any runtime-facing claim. The requested validator route is a displayed object-level request, not the host act of validation.

Execution refusal is carried by E and reported by V. Since those are the only runtime-facing rows, every accepted runtime-boundary packet refuses any consumer path that asks for a BEDC-internal runtime validator row not displayed in the carrier.

Finally H, C, P, N transport, replay, package, and name the same finite surface. They add no hidden validator, truth-total classifier, certificate-indexed truth branch, internal-theory row, or identity-commitment row. □

Lean4 ✓ `BEDC.Derived.RuntimeReflectionBoundaryUp.RuntimeReflectionBoundary runtime request refusal route unary closure`

Theorem 890.3 (Runtime-reflection boundary TasteGate obligation)**.** *The later Lean* `TasteGate.lean` *development for* $\mathsf{RuntimeReflectionBoundary}^{\uparrow}$ *must include explicit* $\mathsf{Nontrivial\ RuntimeReflectionBoundary}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ RuntimeReflectionBoundary}^{\uparrow}$ *instances. These instances must preserve the structural self-description row, runtime-request route, execution-refusal row, runtime-boundary report,* hsame *transport,* Cont *routes, package provenance, and local naming row.*

Proof. The carrier is not determined by structural self-description alone. It also carries the runtime-request route and execution-refusal row that mark the runtime half of the reflection limit.

Nontriviality rules out a collapsed packet where the runtime request is indistinguishable from the structural description. Field faithfulness records preservation of all displayed rows S, Q, E, V, H, C, P, N, so the future TasteGate surface can distinguish structural replay from refused internal validation. □

Lean4 ✓ `BEDC.Derived.RuntimeReflectionBoundaryUp.RuntimeReflectionBoundaryTasteGate single carrier alignment`

Falsifiable prediction: Every accepted runtime-boundary packet refuses any consumer path that asks for a BEDC-internal runtime validator row not displayed in the carrier.

Independence witness: TruthTotalReflection, SelfReferenceTruthBranch, InternalTheoryBoundary, MetaCICIdentityBoundary: the runtime-boundary carrier has an execution-refusal row and runtime-request route that none of these siblings carries, while it lacks their truth-total, certificate-indexed truth, internal-theory, or identity-commitment rows, so no bijective carrier match preserves NameCert obligations.

Closure status for $\mathsf{NameCert}_{\mathsf{RuntimeReflectionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{RuntimeReflectionBoundary}^{\uparrow}$ packet is generated from a structural self-description row, a runtime-request route, an execution-refusal row, a runtime-boundary report, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RuntimeReflectionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 890.1, Definition 890.2, and Definition 890.3 specify the finite runtime-boundary packet separating structural self-description from external kernel execution.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RuntimeReflectionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide an internal runtime validator, a truth-total classifier, a certificate-indexed truth branch, Lean verification, or bridge checking for $\mathsf{RuntimeReflectionBoundary}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, structural-description exactness, runtime-request accountability, execution-refusal exactness, transport closure, and TasteGate nontriviality with field faithfulness.

Chapter 891

A Concrete Naming Certificate for $\mathsf{RealSealCongruence}^{\uparrow}$

The $\mathsf{RealSealCongruence}^{\uparrow}$ packet concretizes the replacement direction used by the Real-completeness target of chapter 9238. It consumes the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38, the finite-window schedule of chapter 126, the regular-rational readback surface of chapter 301, the refinement route of chapter 885, and the separated uniqueness boundary of chapter 427. The carrier below also records the Hausdorff separated-comparison consumer of chapter 402. Its role is not to assert quotient real equality; it records that two displayed readback routes are interchangeable for consumers that first read the same $\mathsf{Real}^{\uparrow}$ seal classifier.

Falsifiable prediction: Two accepted RealSealCongruence packets with the same displayed RealUp seal classifier admit no consumer-visible distinction between their RegSeqRat/StreamName readback routes.

Independence witness: cauchymodulusrefinement, regularlimituniqueness, cauchylimitseal, realtailagreementtransitivity: the carrier has a two-route seal-congruence row absent from refinement, uniqueness, single-seal, and tail-transitivity packets, while those siblings carry selector, separated-comparison, one-seal, or three-tail rows not bijective to this carrier.

Definition 891.1 (Real seal congruence carrier)**.** *A* $\mathsf{RealSealCongruence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R_0, W_0, E_0, R_1, W_1, E_1, A, J, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows whose Real-facing routes are being compared;*
2. W_0 *and* W_1 *are the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledgers used to inspect the two readbacks;*
3. E_0 *and* E_1 *are the two* $\mathsf{Real}^{\uparrow}$ *seal rows reached from those readbacks and windows;*
4. A *is the shared displayed* $\mathsf{Real}^{\uparrow}$ *seal classifier row, read after* E_0 *and* E_1 *are both present;*
5. J *is the seal-congruence row stating that a consumer may replace the route* R_0, W_0, E_0 *by the route* R_1, W_1, E_1 *only under the shared classifier row* A*;*
6. H *stores componentwise* hsame *transports for the two regular readbacks, the two window ledgers, the two seals, the shared classifier, the congruence row, provenance, and local name;*
7. C *stores the displayed* Cont *routes from each* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through its* $\mathsf{StreamName}^{\uparrow}$ *windows into its* $\mathsf{Real}^{\uparrow}$ *seal, and then through* A, J *to the local naming row;*

8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulusRefinement}^{\uparrow}$, $\mathsf{RegularLimitUniqueness}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSealCongruence}^{\uparrow}}$ *row.*

The carrier contains no quotient stream, no host real equality, no selected limit representative, no ambient completion object, and no direct route from either readback to a consumer outside the displayed seal classifier.

Lean4 (definition) `BEDC.Derived.RealSealCongruenceUp.RealSealCongruenceUp`
Lean4 ✓ `BEDC.Derived.RealSealCongruenceUp.RealSealCongruenceTasteGate single carrier alignment`

Theorem 891.2 (Real seal congruence NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RealSealCongruence}^{\uparrow}}$ *surface for Definition 891.1 consists of seven finite obligations:*

1. *carrier admission for the packet $G = (R_0, W_0, E_0, R_1, W_1, E_1, A, J, H, C, P, N)$;*
2. $\mathsf{RegSeqRat}^{\uparrow}$ *readback admission for both R_0 and R_1 through chapter 301;*
3. *finite* $\mathsf{StreamName}^{\uparrow}$ *window coverage for W_0 and W_1 through chapter 126;*
4. $\mathsf{Real}^{\uparrow}$ *seal admission for E_0 and E_1 through chapter 38;*
5. *shared seal-classifier exactness for the row A, with the separated comparison discipline supplied by chapter 427 and chapter 402;*
6. *congruence replacement through J, stating that a consumer may exchange the two displayed readback routes only after A has been read;*
7. *ledger non-escape excluding quotient streams, host real equality, selected limits, ambient completion, and direct readback-to-consumer shortcuts.*

Proof. Carrier admission is projection from Definition 891.1. The tuple exposes exactly the two regular-rational readbacks, two finite window ledgers, two Real seal rows, shared classifier row, congruence row, transport, route, provenance, and local naming data.

The two readback routes are the sibling routes named by chapter 301, chapter 126, and chapter 38. Each route is read from a displayed $\mathsf{RegSeqRat}^{\uparrow}$ row through a displayed finite $\mathsf{StreamName}^{\uparrow}$ window ledger before it reaches its $\mathsf{Real}^{\uparrow}$ seal.

The shared classifier row A is the only comparison point between the two routes. The refinement schedule of chapter 885 supplies the finite-window discipline, while the separated comparison boundary of chapter 427 and chapter 402 keeps the comparison at the displayed seal rather than at a quotient real.

Finally, the congruence row J and the structural rows H, C, P, N make replacement consumer-visible only after the shared classifier has been read. Since the carrier has no coordinate for a host equality, selected limit, quotient stream, or ambient completion, no consumer can bypass A, J to distinguish the two accepted routes. □

Theorem 891.3 (Real seal congruence classifier exactness)**.** *For every accepted* $\mathsf{RealSealCongruence}^{\uparrow}$ *packet*

$$G = (R_0, W_0, E_0, R_1, W_1, E_1, A, J, H, C, P, N),$$

every consumer-visible replacement of the first readback route by the second factors through the finite route

$$R_0, W_0, E_0, A, J, E_1, W_1, R_1, H, C, P, N.$$

Thus the classifier row A is exact: if two accepted packets display the same A and the same transported structural rows H, C, P, N, a consumer cannot observe whether the $\mathsf{Real}^{\uparrow}$ *seal was reached through R_0, W_0, E_0 or through R_1, W_1, E_1. Conversely, without the displayed A and J rows, the carrier exports no replacement claim between the two readback routes.*

Proof. Read the carrier first. The only comparison row shared by the two sides is A, and the only replacement row is J; the routes into A are the displayed $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{StreamName}^{\uparrow}$ windows, and $\mathsf{Real}^{\uparrow}$ seals.

Apply the NameCert obligations of Definition 891.2. They force each side to be admitted through the same finite readback and seal discipline, then force replacement to pass through J after A.

Consumer exactness is therefore coordinate exhaustion. The rows H, C, P, N only transport, replay, record provenance, and name the same displayed packet. None of them adds quotient equality, a selected completed representative, host real equality, or a direct read from one route to the other.

For the converse boundary, remove A or J from the displayed route. The remaining coordinates contain two seal-reaching routes but no row that compares them or licenses replacement. Such a packet may show two Real-facing reads, but it is not a $\mathsf{RealSealCongruence}^{\uparrow}$ replacement packet. □

The follow-up Lean path for this packet is

lean4/BEDC/Derived/RealSealCongruenceUp/TasteGate.lean.

It should provide Nontrivial $\mathsf{RealSealCongruence}^{\uparrow}$ and FieldFaithful $\mathsf{RealSealCongruence}^{\uparrow}$ instances for the carrier, with the intended concrete declaration rooted at BEDC.Derived.RealSealCongruenceUp.RealSealCongruen

Closure status for $\mathsf{NameCert}_{\mathsf{RealSealCongruence}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSealCongruence}^{\uparrow}$ packet is generated from two RegSeqRat readback rows, two finite StreamName window ledgers, two RealUp seal rows, a shared RealUp seal classifier, a congruence replacement row, componentwise hsame transports, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealSealCongruence}^{\uparrow}}$, seed)

Scope closed: Definition 891.1, Definition 891.2, and Definition 891.3 bind the finite two-route seal-congruence packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealSealCongruence}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close quotient real equality, host real equality, selected limit representatives, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, seal-congruence exactness, and non-escape for the same two-route Real seal packet.

Chapter 892

A Concrete Naming Certificate for $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$

The $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ packet realizes the normalization boundary isolated in chapter 9386. It sits beside the open-frontier ledger of chapter 762, the normalization audit packet of chapter 750, the normalization audit seal of chapter 777, and the closed-normal route certificate of chapter 858. Those siblings record the inventory, audit route, seal route, and consumer route; this packet keeps the candidate-evidence boundary and the finished-normal boundary visible as separate coordinates.

Definition 892.1 (MetaCIC normalization frontier carrier)**.** *A* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

with the following displayed rows:

1. *C is the candidate-evidence row for the inspected empty-context typed closed MetaCIC terms;*
2. *K is the closed-candidate evidence row, recording where the closed term is actually placed into the candidate interface;*
3. *E is the finished-normal evidence row available after bounded reduction or displayed normal-form inspection;*
4. *N is the normal-endpoint use row consumed by closed-normal consistency routes;*
5. *S is the subject-reduction obstruction row, kept visible whenever candidate evidence or finished-normal evidence does not erase the preservation boundary;*
6. *H records componentwise* hsame *transport for C, K, E, N, S, R, P, L and the local packet shape;*
7. *R records the displayed* Cont *replay routes by which downstream consumers read candidate evidence, finished-normal evidence, normal endpoints, and obstruction rows;*
8. *P is the* Pkg *provenance over chapter 9386, chapter 762, chapter 750, chapter 777, and chapter 858;*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFrontier}^{\uparrow}}$ *row.*

The carrier is finite and obstruction-preserving. It records where a closed-normal consumer may read normalization evidence, but it does not turn the normalization frontier into a blanket closed strong-normalization theorem.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.taste gate`

Theorem 892.2 (MetaCIC normalization frontier NameCert obligations)**.** *Every accepted* MetaCICNormalizationFr *packet with carrier Definition 892.1 carries exactly the following local NameCert obligations:*

1. *carrier admission for $F = (C, K, E, N, S, H, R, P, L)$ as one finite* BHist *packet;*
2. *candidate-evidence boundary: a read of candidate-mediated strong-normalization content must pass through C and the closed-candidate row K;*
3. *finished-normal boundary: a read of finished-normal content must pass through E before it can feed the normal-endpoint row N;*
4. *closed-normal consumer handoff: any consistency-facing read of N must replay through R with provenance P and the local naming row L;*
5. *subject-reduction-obstruction separation: the obstruction row S remains distinct from C, K, E, N and is not discharged by the normalization packet.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 892.1. The nine rows $C, K, E, N, S, H, R, P, L$ are the complete finite packet.

For the candidate boundary, inspect C and K. The candidate row records the available normalization evidence, while the closed-candidate row records the point at which an empty-context closed term is admitted to that interface.

For the finished-normal boundary, inspect E and N. The endpoint row is available to a closed-normal consumer only after the finished-normal evidence row has been read through the displayed replay route.

The handoff and separation clauses use the structural rows. The replay row R, provenance row P, and local row L expose only the displayed normalization frontier, and the obstruction coordinate S remains a named coordinate rather than a hidden subject-reduction theorem. □

Theorem 892.3 (MetaCIC normalization frontier carrier rows)**.** *For every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet, carrier admission exposes the concrete finite packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

as a BHist *carrier with candidate rows C, K, finished rows E, N, obstruction row S, componentwise* hsame *row H, displayed* Cont *replay row R,* Pkg *provenance row P, and local* NameCert *row L. No carrier read may replace these rows by an unnamed normalization source.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier carrier rows`

Proof. Project the carrier of Definition 892.1. It lists $F = (C, K, E, N, S, H, R, P, L)$ as one finite BHist packet.

Apply the carrier-admission clause of Definition 892.2. That clause routes every carrier read through the displayed rows before any downstream closed-normal consumer may use the frontier.

The row S remains visible in the same projection. Since it is a named obstruction coordinate rather than an erased proof obligation, carrier admission cannot be read as a blanket normalization theorem. □

Theorem 892.4 (MetaCIC normalization frontier classifier stability)**.** *In an accepted* MetaCICNormalizationFrontier *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

the local classifier is stable under componentwise hsame *transport only along the displayed* BHist *rows: candidate-mediated reads pass through C, K, finished-normal reads pass through E, N, and both routes replay through the* Cont *row R with* Pkg *provenance P and local* NameCert *row L. The obstruction row S is transported as an obstruction row and is not discharged by classifier stability.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier classifier stability`

Proof. Use the NameCert obligations to separate the two positive evidence routes. Candidate reads are routed through C, K, while finished-normal reads are routed through E, N before the normal endpoint is consumed.

Transport is componentwise through H. It can preserve the displayed candidate, finished, replay, provenance, and local naming rows, but it has no coordinate that turns a candidate row into a finished row or erases the obstruction row S.

The replay row R and package row P then expose the same classified frontier surface to downstream consumers. Thus classifier stability is stability of the displayed packet, with S retained as an obstruction coordinate. □

Theorem 892.5 (MetaCIC normalization frontier ledger exhaustion)**.** *Every ledger read exported by an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

is exhausted by the candidate rows C, K or the finished rows E, N, together with BHist *carrier exposure, componentwise* hsame *transport through H, displayed* Cont *replay through R,* Pkg *provenance through P, the local* NameCert *row L, and the retained obstruction row S. A read bypassing both C, K and E, N is outside the packet.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier ledger exhaustion`

Proof. Start with the local obligation inventory. The candidate-evidence boundary names C, K, and the finished-normal boundary names E, N.

The ledger support rows do not supply a third positive evidence source. The row H transports displayed fields, R replays displayed consumer routes, P records package provenance, and L names the local certificate surface.

It remains to account for S. The obstruction row is carried alongside both positive routes, so exhaustion of the ledger does not solve or erase the subject-reduction boundary. Therefore any ledger read outside C, K and E, N has no accepted normalization-evidence coordinate in the packet. □

Theorem 892.6 (MetaCIC normalization frontier non-escape)**.** *An accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet exports no blanket strong-normalization theorem for all empty-context typed closed MetaCIC terms, no full closed consistency theorem, and no erased subject-reduction transport. Any closed-normal consistency consumer route must factor through the candidate-evidence rows C, K or through the finished-normal row E before it reads N; a route that bypasses both is outside the carrier.*

Proof. Project the carrier. The only normalization evidence rows are C, K and E, and the only closed-normal endpoint row is N.

The replay and provenance rows R and P do not add new normalization evidence. They only expose the recorded candidate-evidence route, the finished-normal route, and the local endpoint route to a consumer.

The obstruction row S is separate from those positive rows. Since the packet has no coordinate for global closed strong normalization, full closed consistency, or erased subject-reduction transport, none of those objects can be exported by its local certificate. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierNonescape`

Theorem 892.7 (MetaCIC normalization frontier redex boundary)**.** *In every accepted* MetaCICNormalizationFronti *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

the candidate rows C, K and the finished-normal rows E, N determine a finite redex-boundary route for the inspected empty-context typed closed MetaCIC terms. Any read that turns candidate evidence into finished-normal endpoint use must pass through C, K, E, N and retain the obstruction row S as a displayed coordinate, with replay and provenance supplied only by H, R, P, L.

The route is a BEDC frontier route, not a blanket strong-normalization theorem, not a closed consistency theorem, and not an erased subject-reduction transport.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier redex boundary`

Proof. Project the carrier in Definition 892.1. The rows $C, K, E, N, S, H, R, P, L$ are the finite packet, and S is listed separately from the positive candidate and finished-normal evidence rows.

Apply Definition 892.2. Its candidate-evidence boundary forces candidate-mediated reads through C, K, while its finished-normal boundary places E before N.

Now use Definition 892.6. Since the packet exports no blanket strong-normalization theorem, no full closed consistency theorem, and no erased subject-reduction transport, the redex boundary remains exactly the displayed finite route. □

Theorem 892.8 (MetaCIC normalization frontier fuel route)**.** *Every bounded replay of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet has a finite fuel route from candidate evidence C, K to finished-normal evidence E, N, with the obstruction row S carried alongside the replay rows H, R, P, L. The fuel route may be consumed by closed-normal downstream packets only through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates of*

$$F = (C, K, E, N, S, H, R, P, L).$$

It exports no unbounded normalization schedule, no global subject-reduction proof, and no closed consistency theorem.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier fuel route`

Proof. Start from Definition 892.1. The packet is finite, so a bounded replay reads only the named carrier rows and cannot synthesize an additional normalization schedule.

Apply the handoff clauses in Definition 892.2. Candidate evidence enters through C, K, finished-normal endpoint use enters through E, N, and downstream closed-normal use must replay through R with provenance P and local naming row L.

Use Definition 892.41 for the row S. The obstruction is transported as a separate coordinate and is not discharged by the positive evidence rows.

Finally apply Definition 892.6. The finite replay route therefore remains a fuel route inside the packet and does not export unbounded normalization, global subject reduction, or closed consistency. □

Theorem 892.9 (MetaCIC normalization frontier root carrier rows)**.** *Every root consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet first reads exactly the finite carrier rows*

$$C, K, E, N, S, H, R, P, L.$$

The rows are the candidate-evidence surface, the closed-candidate surface, the finished-normal evidence surface, the normal-endpoint surface, the obstruction row, the transport row, the replay row, the provenance row, and the local naming row of the root packet.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root carrier rows`

Proof. Project the carrier definition in Definition 892.1. It lists $F = (C, K, E, N, S, H, R, P, L)$ as the complete packet and gives no additional root-facing coordinate.

Apply the NameCert obligations of Definition 892.2. Candidate reads enter through C, K, finished-normal reads enter through E, N, obstruction transport keeps S separate, and closed-normal downstream use replays through H, R, P, L.

Finally use the fuel route of Definition 892.8. Any root consumer that asks for a bounded replay remains inside those carrier rows before it can be consumed by a downstream closed-normal packet. □

Theorem 892.10 (MetaCIC normalization frontier root consumer non-escape)**.** *No root consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet can extract a blanket strong-normalization theorem, a closed consistency theorem, or erased subject-reduction transport from the rows* $C, K, E, N, S, H, R, P, L$.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root consumer nonescape`

Proof. Start with Definition 892.9. It exhausts the root packet by the displayed carrier rows and leaves no hidden normalization, consistency, or erased-transport coordinate.

Use Definition 892.6. The chapter already separates candidate and finished-normal evidence from blanket strong normalization, full closed consistency, and erased subject-reduction transport.

Now apply Definition 892.7 together with Definition 892.8. The root consumer receives only a bounded redex-boundary and fuel route, with S still displayed as an obstruction row, so none of the excluded global objects can be read from the packet. □

Theorem 892.11 (MetaCIC normalization frontier root candidate-gate projection)**.** *Every root consumer that asks the candidate gate of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet must project the finite* BHist *packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

through the candidate rows C, K *before it can use replay, provenance, or local naming support. The projection exposes no candidate evidence outside the displayed packet and leaves the obstruction row* S *present as a separate row.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root candidate gate projection`

Proof. Begin with Definition 892.9. It identifies $F = (C, K, E, N, S, H, R, P, L)$ as the whole root-facing carrier, so a root read has no unnamed candidate coordinate.

Apply the candidate-evidence boundary from Definition 892.2. That boundary places candidate access through C, K and attaches the read to the same local NameCert surface.

Use Definition 892.39 for the downstream support rows. It routes candidate consumption through C, K, R, P, L, while Definition 892.10 rules out an external candidate source.

The obstruction row is controlled by Definition 892.41. Since S is a named row of the same finite packet, the candidate-gate projection does not discharge it. □

Theorem 892.12 (MetaCIC normalization frontier root normal-endpoint route exhaustion)**.** *Every root consumer that reaches the normal endpoint of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet must route through the finite* BHist *packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

by the finished-normal evidence row E, the normal-endpoint row N, the replay row R, the provenance row P, and the local naming row L. There is no root endpoint route that bypasses E, N, R, P, L or erases the obstruction row S.

Proof. Project the root carrier rows. The finite packet names E, N, R, P, L as the endpoint-facing and support rows and provides no additional normal-endpoint coordinate.

Use the finished-normal boundary in Definition 892.2. It places the finished evidence row E before endpoint use through N and keeps both rows under the local certificate interface.

Next apply Definition 892.40 and Definition 892.51. Together they force endpoint consumption through E, N, R, P, L rather than through a free-standing closed-normal witness.

Finally invoke Definition 892.10 and Definition 892.47. They exclude a bypassing endpoint object and keep S visible throughout the route. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root normal endpoint route exhaustion`

Theorem 892.13 (MetaCIC normalization frontier root obstruction-preserving NameCert triad)**.** *For an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet, the root-facing* NameCert *surface presents exactly the obstruction-preserving triad of the candidate-gate projection through C, K, the normal-endpoint route through E, N, R, P, L, and the retained obstruction row S inside the finite* BHist *packet*

$$F = (C, K, E, N, S, H, R, P, L).$$

The triad is transported only by the displayed hsame, Cont, Pkg, *and local naming coordinates of the packet.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierRootObstructionPreservi`

Proof. Start with the root carrier rows and the NameCert obligations. They place the local certificate over the same finite packet $F = (C, K, E, N, S, H, R, P, L)$ and do not supply a second certificate target.

Apply Definition 892.11 for the candidate side. It isolates the candidate gate at C, K and leaves replay, provenance, and local naming support inside the displayed packet.

Apply Definition 892.12 for the endpoint side. It exhausts normal-endpoint access by E, N, R, P, L and keeps the endpoint route within the same BHist packet.

It remains to track the obstruction row. Use Definition 892.41 and Definition 892.10; together they keep S as a retained row and prevent the triad from exporting blanket normalization, closed consistency, or erased subject-reduction transport. □

Theorem 892.14 (MetaCIC normalization frontier root candidate-endpoint coherence)**.** *Any root consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet that moves from the candidate rows C, K to the endpoint rows E, N preserves the same finite packet*

$$F = (C, K, E, N, S, H, R, P, L).$$

The route cannot switch candidate evidence sources between the candidate gate and the normal endpoint.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root candidate endpoint coherence`

Proof. Begin with Definition 892.9. It identifies $F = (C, K, E, N, S, H, R, P, L)$ as the complete root-facing packet.

Apply Definition 892.11. The candidate side enters through C, K and attaches replay, provenance, and local naming to the same carrier rows.

Apply Definition 892.12. The endpoint side reaches E, N only through E, N, R, P, L and has no second endpoint coordinate.

Finally use Definition 892.13 together with Definition 892.10. The triad transports the candidate and endpoint routes through the same hsame, Cont, Pkg, and naming rows, while non-escape rules out an external candidate source. □

Theorem 892.15 (MetaCIC normalization frontier root obstruction route separation)**.** *For every root consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet, the obstruction row S is transported alongside both the candidate route through C, K and the endpoint route through E, N, R, P, L. It is never consumed as positive normalization evidence.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root obstruction route separation`

Proof. Project the root carrier rows. The row S is a named coordinate of the same finite packet as C, K, E, N, R, P, L.

Use Definition 892.11. The candidate route leaves S present as a separate row rather than discharging it.

Use Definition 892.12. The endpoint route cannot bypass or erase S, because endpoint access is exhausted by E, N, R, P, L inside the same packet.

The separation claim is then exactly the obstruction part of Definition 892.13. Together with Definition 892.10, it prevents S from being read as a blanket strong-normalization witness. □

Theorem 892.16 (MetaCIC normalization frontier root closed-normal route totality)**.** *Every closed-normal consumer route of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *root packet is exhausted by the candidate route, endpoint route, replay row R, provenance row P, local naming row L, and obstruction row S of*

$$F = (C, K, E, N, S, H, R, P, L).$$

There is no closed-normal root route outside those displayed rows.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root closed normal route totality`

Proof. Start with Definition 892.9. The root packet exposes no row beyond $C, K, E, N, S, H, R, P, L$.

Apply Definition 892.14. It prevents a closed-normal consumer from changing candidate evidence sources when moving from C, K to E, N.

Apply Definition 892.15. The obstruction row remains transported beside the candidate and endpoint routes and cannot be converted into positive normalization evidence.

Finally use Definition 892.13 and Definition 892.10. They exhaust the route by the displayed certificate triad and exclude blanket normalization, closed consistency, erased subject-reduction transport, or any hidden closed-normal endpoint. □

Theorem 892.17 (MetaCIC normalization frontier obligation carrier totality)**.** *Carrier admission for an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

is exhausted by the displayed BHist *rows. The carrier of Definition 892.1, the NameCert obligations of Definition 892.2, and the root carrier rows of Definition 892.9 leave no admitted frontier coordinate outside* $C, K, E, N, S, H, R, P, L$.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier obligation carrier totality`

Proof. Project the carrier definition. It presents $F = (C, K, E, N, S, H, R, P, L)$ as the finite frontier packet and assigns the candidate, finished-normal, obstruction, transport, replay, provenance, and local naming roles to those rows.

Apply the NameCert obligations. Candidate reads are bound to C, K, finished-normal reads are bound to E, N, and the obstruction row S remains separated from the positive normalization surfaces.

Finally use the root carrier rows. Every root consumer begins from the same displayed BHist packet, so carrier admission is total over exactly those rows and has no hidden normalization, consistency, or erased-transport coordinate. □

Theorem 892.18 (MetaCIC normalization frontier obligation evidence split)**.** *For an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet, positive normalization evidence splits before any closed-normal handoff into the candidate route through* C, K *and the finished-normal route through* E, N*. This split is the joint content of Definition 892.39, Definition 892.40, Definition 892.46, and Definition 892.42.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier obligation evidence split`

Proof. Start with the candidate route. It routes candidate-facing consumers through C, K, R, P, L and keeps the read inside the same finite packet.

Turn to the finished-normal route. It routes endpoint-facing consumers through E, N, R, P, L and makes the normal endpoint available only after the finished-normal evidence row has been read.

The evidence-choice exhaustion theorem supplies the dichotomy. It rules out a third positive normalization evidence surface between those two routes.

Repack the result through the public obligation package. Since the package records carrier admission, the two positive routes, and the retained obstruction row together, any closed-normal handoff receives one of the two displayed positive surfaces rather than an unnamed normalization source. □

Theorem 892.19 (MetaCIC normalization frontier obligation obstruction retention)**.** *For an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet, the subject-reduction obstruction row S is retained across both positive routes and cannot be consumed as normalization evidence. The obstruction ledger of Definition 892.41, the retention theorem of Definition 892.47, and the subject-reduction compatibility theorem of Definition 892.65 keep S visible beside the candidate rows C, K and the finished-normal rows E, N.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier obligation obstruction retention`

Proof. Read the obstruction ledger first. It names S as a separate coordinate of the same frontier packet as C, K, E, N, H, R, P, L.

Apply obstruction retention along the candidate and finished-normal routes. The candidate side through C, K and the endpoint side through E, N transport S rather than turning it into positive normalization evidence.

Use subject-reduction obstruction compatibility for downstream consumers. A SubjectReductionBoundary-facing consumer may read S as an obstruction coordinate, but it cannot discharge that row by consuming either positive normalization surface. □

Theorem 892.20 (MetaCIC normalization frontier candidate coverage)**.** *Every candidate-facing consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

must read the candidate evidence row C, the closed-candidate placement row K, the displayed replay row R, the provenance row P, and the local naming row L. The structural row H may transport the read componentwise, but it cannot replace C, K, R, P, L by an unnamed normalization source.

Proof. Project the carrier and NameCert obligations. The carrier lists $C, K, E, N, S, H, R, P, L$ as the complete finite packet, and the candidate-evidence boundary assigns candidate-facing reads to C and K.

The consumer side is then routed by the displayed support rows. The row R replays the candidate read, P records the package provenance, and L names the local certificate surface; H only transports the displayed rows.

Apply non-escape. A candidate consumer that bypasses any of C, K, R, P, L would need a hidden normalization coordinate outside the accepted packet, so candidate coverage is exactly the displayed route through those rows. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier candidate coverage`

Theorem 892.21 (MetaCIC normalization frontier endpoint readback)**.** *Every normal-endpoint consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet reads the finished-normal evidence row E, the normal-endpoint row N, the displayed replay row R, the provenance row P, and the local naming row L, while retaining the subject-reduction obstruction row S as a visible coordinate of the same packet. A read of N outside E, N, R, P, L is not an endpoint readback of the frontier.*

Proof. Start with the finished-normal boundary. The NameCert obligations place E before N, and the carrier keeps both rows inside the same finite BHist packet as S, H, R, P, L.

Next inspect the handoff rows. The endpoint is replayed through R, packaged through P, and locally named by L; none of those rows supplies an independent endpoint witness.

It remains to account for the obstruction row. Since S is displayed separately from E and N, endpoint readback preserves S rather than discharging it. Non-escape then rules out any free-standing read of N outside the stated route. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier endpoint readback`

Theorem 892.22 (MetaCIC normalization frontier consumer non-escape)**.** *No closed-normal consumer or SubjectReductionBoundary-facing consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet can bypass both positive routes C, K, R, P, L and E, N, R, P, L while remaining inside the packet. Such a consumer also cannot erase the obstruction row S or replace it by blanket strong normalization, full closed consistency, or erased subject-reduction transport.*

Proof. First exhaust the positive routes. Candidate coverage forces candidate-facing reads through C, K, R, P, L, while endpoint readback forces normal-endpoint reads through E, N, R, P, L.

Now consider a closed-normal or SubjectReductionBoundary-facing consumer that avoids both routes. The carrier has no third positive normalization evidence surface: H transports, R replays, P records provenance, and L names the local certificate surface.

Finally use the obstruction row. The row S remains a displayed obstruction coordinate under both positive routes, and the non-escape theorem excludes any hidden coordinate that could erase it. Therefore a consumer that bypasses both positive routes or erases S is outside the accepted frontier packet. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier consumer nonescape`

Theorem 892.23 (MetaCIC normalization frontier consumer-boundary lock)**.** *Every public consumer of the* MetaCICNormalizationFrontier$^{\uparrow}$ *completion surface must pass through the displayed source, boundary, route, readback,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows already present in the child packet. In particular, such a consumer cannot import a hidden normalization oracle, host equality, subject-reduction bridge, or external consistency claim as a replacement for the displayed boundary packet.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier consumer boundary lock`

Proof. Project the consumer-boundary rows already established in this child file. Candidate-facing reads pass through C, K, R, P, L, while normal-endpoint reads pass through E, N, R, P, L and retain S as a visible obstruction coordinate.

The remaining structural access is exhausted by the same packet rows. Componentwise hsame transport may move displayed coordinates, Cont may replay the displayed routes, Pkg records their provenance, and the local NameCert row names the boundary surface.

Coordinate exhaustion now rules out bypasses. A hidden normalization oracle, host equality proof, subject-reduction bridge, or external consistency claim is not one of the displayed rows, so it cannot be supplied by a public consumer of the accepted completion surface. □

Theorem 892.24 (MetaCIC normalization frontier public route exhaustion)**.** *Every public consumer route through an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet chooses either the candidate route C, K, R, P, L or the endpoint route E, N, R, P, L. In both cases it retains the obstruction row S and the structural rows H, R, P, L. The packet exports no third route through hidden normalization, scheduler state, host equality, subject-reduction bridge, or external consistency claim.*

Proof. Apply Definition 892.20 to the candidate-facing case. The read is forced through C, K, R, P, L, with H only transporting displayed rows.

Apply Definition 892.21 to the normal-endpoint case. The read is forced through E, N, R, P, L, while S remains a visible obstruction coordinate of the same packet.

Finally combine Definition 892.22 with Definition 892.23. A public consumer that avoids both positive routes, erases S, or imports a hidden normalization, scheduler, host-equality, subject-reduction, or external consistency row is outside the accepted frontier packet. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier consumer route public exhaustion`

Definition 892.25 (MetaCIC normalization frontier public export surface)**.** *The public export surface of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet is the finite row package*

$$F_{\mathrm{pub}} = (C, K, E, N, S, H, R, P, L).$$

Here C is candidate evidence, K is closed-candidate placement, E is finished-normal evidence, N is the normal endpoint, S is the subject-reduction obstruction, H is componentwise hsame *transport, R is the displayed* Cont *replay surface, P is* Pkg *provenance, and L is the local* NameCert *row. A public read of the frontier packet is a read of this finite surface, not a read of an ambient normalization theorem.*

Lean4 (definition) `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierPublicExportSur`
Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierPublicExportSurfaceCert`

Theorem 892.26 (MetaCIC normalization frontier public export totality)**.** *Every public* MetaCICNormalizationFro *consumer factors through one of the two displayed public routes:*

1. *the candidate surface C, K, R, P, L;*
2. *the finished-normal surface E, N, R, P, L.*

In both cases the row S is retained as subject-reduction obstruction data, and H transports only the displayed components of the same finite public surface.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierPublicExportTotality`

Proof. Start with the carrier and local certificate obligations. The carrier Definition 892.1 supplies exactly the rows $C, K, E, N, S, H, R, P, L$, and Definition 892.2 assigns consumer reads to the candidate boundary, the finished-normal boundary, and the displayed handoff rows.

The positive route is then exhausted by the existing route theorems. Use Definition 892.44 and Definition 892.46: a public consumer must choose C, K or E, N, with replay, provenance, and local naming supplied by R, P, L.

Finally use obstruction retention. The theorem Definition 892.47 keeps S visible under both choices, and non-escape prevents H, R, P, L from becoming a third positive normalization route. □

Theorem 892.27 (MetaCIC normalization frontier public export non-escape)**.** *The public export surface of Definition 892.25 cannot be read as blanket strong normalization for all empty-context typed closed MetaCIC terms, full closed consistency, erased subject-reduction transport, or a third hidden normalization evidence route beyond C, K, R, P, L and E, N, R, P, L.*

Proof. Project the public surface to the existing carrier. The definition of F_{pub} is only the displayed finite row package $C, K, E, N, S, H, R, P, L$, so any public read must stay inside the same carrier, transport, replay, package, and local naming coordinates.

Apply the chapter's non-escape and evidence-choice results. Definition 892.6 excludes blanket normalization, closed consistency, and erased subject-reduction transport, while Definition 892.46 leaves only the candidate and finished-normal evidence choices.

It remains to rule out a hidden route. Consumer-route totality gives no public path outside C, K, R, P, L and E, N, R, P, L, and obstruction retention keeps S as obstruction data rather than positive normalization evidence. Therefore the public export boundary is exactly the two-route surface with the obstruction row retained. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierPublicExport nonescape`

Definition 892.28 (MetaCIC normalization frontier visible obstruction packet)**.** *The visible obstruction packet of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *public read is the finite package*

$$O_{\text{vis}} = (C, N, O, S, B, H, R, P, L).$$

Here C is candidate evidence, N is the normal endpoint readback, O is the obstruction ledger, S is the subject-reduction obstruction reference, B is the displayed BHist *support, H is the componentwise* hsame *transport, R is the* Cont *replay surface, P is* Pkg *provenance, and L is the local* NameCert *row. A consumer reads O_{vis} as obstruction content for the public frontier, not as a proof of ambient normalization.*

Lean4 (definition) `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierVisibleObstruct`

Theorem 892.29 (MetaCIC normalization frontier visible obstruction admission)**.** *Every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *public export admits the visible obstruction packet O_{vis} of Definition 892.28. The packet displays candidate evidence, normal endpoint readback, obstruction ledger, subject-reduction obstruction reference,* BHist, hsame, Cont, Pkg, *and local* NameCert *rows on the same finite public surface.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierVisibleObstructionAdmis`

Proof. Start from the public export surface Definition 892.25. It already contains candidate evidence, finished-normal evidence, the normal endpoint, the subject-reduction obstruction, componentwise transport, replay, provenance, and local naming rows.

Apply public export totality, Definition 892.26. A public consumer is forced onto either the candidate route or the finished-normal route, and in both cases the subject-reduction obstruction row is retained.

Finally read the retained obstruction as a visible ledger. The same public surface supplies BHist, hsame, Cont, Pkg, and NameCert support through the displayed rows, so repackaging those coordinates gives O_{vis} without adding a third normalization route. □

Theorem 892.30 (MetaCIC normalization frontier visible obstruction route factorization)**.** *Every public route through the visible obstruction packet factors through the finite package $C, N, O, S, B, H, R, P, L$ and then through one of the two public export routes C, K, R, P, L or E, N, R, P, L. The obstruction-preserving route is finite, and it exports no blanket strong-normalization theorem, no closed consistency proof, and no erased subject-reduction transport.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierVisibleObstruction route factorization`

Proof. First project the visible packet back to the public export surface. The rows $C, N, O, S, B, H, R, P, L$ are read from the same carrier, obstruction, replay, provenance, and local naming coordinates used by Definition 892.25.

Next use the public totality theorem. By Definition 892.26, the positive part of the route must be C, K, R, P, L or E, N, R, P, L. The obstruction rows O and S remain attached to that choice as retained data.

The finite route has no escape coordinate. The non-escape theorem Definition 892.27 rules out blanket strong normalization, closed consistency, erased subject-reduction transport, and any hidden positive route beyond the two displayed export routes. Thus the visible obstruction route factors through the finite public surface only. □

Theorem 892.31 (MetaCIC normalization frontier visible obstruction consumer non-escape)**.** *A downstream consumer of O_{vis} may cite the candidate evidence, normal endpoint readback, obstruction ledger, subject-reduction obstruction reference,* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows as frontier obstruction content. It cannot convert that packet into ambient normalization, full closed consistency, erased subject-reduction transport, or a consumer-owned normalization witness outside the two public export routes.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierVisibleObstructionConsu`

Proof. Read the consumer through the packet definition. The only available rows are $C, N, O, S, B, H, R, P, L$, so every cited coordinate is candidate, endpoint, obstruction, support, replay, provenance, or local naming data.

Route factorization then fixes the public boundary. By Definition 892.30, the consumer's positive access factors through C, K, R, P, L or E, N, R, P, L, with the obstruction ledger retained as obstruction content.

Finally apply public export non-escape. The theorem Definition 892.27 forbids ambient normalization, full closed consistency, erased subject-reduction transport, and hidden normalization evidence. The visible packet therefore serves as citable obstruction content, not as a replacement for the frontier's finite public export discipline. □

Theorem 892.32 (MetaCIC normalization frontier candidate evidence totality)**.** *Every accepted frontier candidate evidence route of a* MetaCICNormalizationFrontier$^{\uparrow}$ *packet is read from the displayed* BHist *packet*

$$F = (C, K, E, N, S, H, R, P, L).$$

The route passes through the candidate evidence row C, the audit-facing evidence row K, the frontier seal row S, the normal-route rows E, N, componentwise hsame *transports in H, displayed* Cont *routes in R,* Pkg *provenance in P, and the local* NameCert *row L. No accepted candidate evidence route has a second source outside those rows.*

Proof. Start with the carrier surface of Definition 892.1. It displays one finite BHist packet and assigns the candidate, audit-facing, seal, normal-route, transport, continuation, provenance, and local naming roles to $C, K, E, N, S, H, R, P, L$.

Apply the NameCert obligations of Definition 892.2. The candidate-evidence boundary forces candidate reads through C, K, the finished-normal boundary places E before N, and the closed-normal handoff keeps the consumer route under the displayed replay and provenance rows.

Use the obligation closure package and route surface. Definition 892.17 exhausts carrier admission by the displayed rows, while Definition 892.39 and Definition 892.38 rule out a candidate route outside the BHist, hsame, Cont, Pkg, and NameCert coordinates. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier candidate evidence totality`

Theorem 892.33 (MetaCIC normalization frontier seal boundary)**.** *In an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet, a frontier seal cannot be replaced by a closed-normal route unless the candidate-evidence rows C, K and the audit rows carried by the displayed* BHist *packet are already exposed. A closed-normal consumer may use the seal only through S, H, R, P, L together with the normal-route rows E, N and the local* NameCert *row.*

Proof. Read the root carrier rows of Definition 892.9. A root consumer first receives the same finite packet $C, K, E, N, S, H, R, P, L$, so the frontier seal has no free-standing replacement coordinate.

Apply the candidate and endpoint route theorems. Definition 892.11 exposes the candidate side through C, K, and Definition 892.12 exposes normal-endpoint use through E, N, R, P, L.

It remains to keep the seal boundary visible. Definition 892.41 and Definition 892.47 keep S as a displayed row under hsame transport and Cont replay. Therefore the seal can participate in a closed-normal route only after the candidate-evidence and audit rows have already been displayed inside the same Pkg provenance and NameCert surface. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier seal boundary`

Theorem 892.34 (MetaCIC normalization frontier normal route non-escape)**.** *Normal-form consumers of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet cannot import host normalization, quotient term equality, or a hidden normalizer outside the displayed packet*

$$F = (C, K, E, N, S, H, R, P, L).$$

Every normal-route read is confined to the candidate rows C, K, normal rows E, N, seal row S, componentwise hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier normal route nonescape`

Proof. Project the non-escape theorem Definition 892.6. It excludes blanket strong normalization, full closed consistency, and erased subject-reduction transport from the accepted packet.

Use the route theorems to identify the allowed normal-form path. Definition 892.40 routes finished-normal consumers through E, N, R, P, L, and Definition 892.16 exhausts closed-normal root routes by the candidate, endpoint, replay, provenance, local naming, and obstruction rows.

Finally apply Definition 892.42 and Definition 892.64. Their public and closed-normal surfaces expose only the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates, so host normalization, quotient term equality, and hidden normalizers have no accepted route into the packet. □

Theorem 892.35 (MetaCIC normalization frontier candidate confluence budget)**.** *A confluence-facing consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet may use the candidate rows C, K only as candidate evidence until the finished-normal boundary is displayed. It may use the finished rows E, N only after that boundary is visible through the same finite packet*

$$F = (C, K, E, N, S, H, R, P, L).$$

The consumer cannot identify the candidate-evidence route with the finished-normal route, cannot erase the obstruction row S, and cannot import blanket strong normalization, subject reduction, host normalization, quotient term equality, or a hidden normalizer.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier candidate confluence budget`

Proof. Start with Definition 892.32. It confines candidate use to the displayed packet and makes C, K candidate evidence rows rather than completed normal-form rows.

Apply Definition 892.33. The seal row S remains visible between candidate evidence and closed-normal consumption, and the finished rows E, N become available only through the displayed boundary.

Finally apply Definition 892.34. Normal-form consumers remain inside $C, K, E, N, S, H, R, P, L$, so a confluence-facing consumer has no route that identifies candidate evidence with finished-normal evidence, erases S, or imports the excluded host normalization and quotient-equality principles. □

Theorem 892.36 (MetaCIC normalization frontier candidate SN consumer route)**.** *Any* MetaCICCandidateStrongN *consumer of a* MetaCICNormalizationFrontier$^{\uparrow}$ *packet must read candidate evidence, finite fuel, endpoint normal-form rows, the normalization-audit route, the closed-normal route certificate, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before exporting an SN-facing boundary. The export is candidate-mediated: it does not assert unrestricted strong normalization, closed subject reduction, global confluence, quotient syntax equality, or a hidden normalizer.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier candidate sn consumer route`

Proof. Project the frontier carrier of Definition 892.1. The candidate rows C, K, endpoint rows E, N, obstruction seal S, transport rows H, replay rows R, provenance row P, and local naming row L are the only coordinates available to the consumer.

Use the candidate evidence boundary already established in this file. Definition 892.32 confines candidate evidence to C, K inside the same displayed packet, while Definition 892.35 keeps candidate use separate from finished-normal evidence until the normal endpoint rows are exposed.

Route the SN-facing read through the sibling normalization surfaces. The candidate strong-normalization chapters provide only candidate-mediated SN rows, and the closed-normal route chapters provide only displayed closed-normal certificates; neither sibling supplies an unrestricted normalization theorem.

Finally apply normal-route non-escape from Definition 892.34. The consumer remains inside the finite candidate, fuel, endpoint, audit, closed-normal, transport, replay, provenance, and NameCert route, so no global strong-normalization, subject-reduction, confluence, quotient-equality, or hidden-normalizer row can be exported. □

Theorem 892.37 (MetaCIC normalization frontier root obligation triad)**.** *For downstream closed-normal packets, an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet presents exactly the following root obligation triad: the candidate boundary through C, K, the finished-normal boundary through E, N, and the obstruction separation through S, all transported through H, R, P, L.*

Proof. Use Definition 892.2 to read the three obligations. The candidate-evidence boundary is carried by C, K, the finished-normal boundary is carried by E, N, and subject-reduction obstruction remains separated at S.

Apply Definition 892.7. It identifies those three surfaces as the finite redex boundary for inspected empty-context typed closed MetaCIC terms.

Finally combine Definition 892.8 with Definition 892.10. Downstream closed-normal packets may consume the triad only through the displayed replay, provenance, transport, package, and local naming rows, and they cannot replace the triad with a blanket normalization, consistency, or erased subject-reduction object. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root obligation triad`

Theorem 892.38 (MetaCIC normalization frontier kernel non-escape)**.** *For every accepted* MetaCICNormalizationF *packet, the finite kernel-facing route determined by $C, K, E, N, S, H, R, P, L$ is exhausted by the candidate route of Definition 892.39, the finished route of Definition 892.40, the obstruction ledger of Definition 892.41, and the public obligation package of Definition 892.42. A kernel consumer cannot bypass those rows to obtain a blanket strong-normalization theorem, a full closed consistency theorem, or erased subject-reduction transport.*

Proof. First project the public obligation package of Definition 892.42. It lists the finite carrier, the candidate-evidence boundary, the finished-normal boundary, the closed-normal handoff through R, P, L, and the obstruction row S.

Next use Definition 892.39 and Definition 892.40. These two route the positive kernel-facing reads through C, K or through E, N, with replay, provenance, and naming supplied by the displayed rows.

Apply Definition 892.41. The row S remains a separate obstruction coordinate and cannot be erased by reading candidate or finished-normal evidence.

Finally invoke Definition 892.6. A kernel consumer outside the listed rows would require one of the exported objects that the packet explicitly lacks, so the finite frontier route has no escape coordinate. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierKernelNonescape`

Theorem 892.39 (MetaCIC normalization frontier candidate route)**.** *Every closed-normal consumer of candidate evidence in an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet factors through the candidate row C, the closed-candidate row K, the replay row R, the provenance row P, and the local naming row L. The support rows are read inside the same finite* BHist *packet and transported only by the displayed* hsame *and* Cont *coordinates.*

Proof. Project the carrier $F = (C, K, E, N, S, H, R, P, L)$. The only candidate-facing rows are C and K, and the only consumer-facing support rows for replay, provenance, and local naming are R, P, and L.

Apply the candidate-evidence boundary clause of Definition 892.2. It requires any candidate-mediated read to pass through C and K before it can be used by a closed-normal consumer.

Finally use Definition 892.6. A consumer bypassing C, K, R, P, L has no carrier coordinate from which to read candidate evidence, so the displayed route is the whole candidate route. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier candidate route totality`

Theorem 892.40 (MetaCIC normalization frontier finished route)**.** *Every closed-normal consumer of finished-normal evidence in an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet factors through the finished-normal evidence row E, the normal-endpoint row N, the replay row R, the provenance row P, and the local naming row L. The route uses only the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates of the frontier packet.*

Proof. Project the same carrier. The finished-normal side is represented by E and N, while R, P, and L record the replay, provenance, and local certificate rows through which a consumer can read that side.

Apply the finished-normal boundary and closed-normal handoff clauses of Definition 892.2. They place E before N and then replay the endpoint through R, P, L.

The non-escape theorem rules out a hidden blanket normalization coordinate. Thus a finished-normal consumer that stays inside the packet must read exactly the displayed finished route and cannot replace it with an ambient normalization theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier finished route totality`

Theorem 892.41 (MetaCIC normalization frontier obstruction ledger)**.** *In every accepted* MetaCICNormalizationFr *packet, the subject-reduction obstruction row S is transported and named as a separate coordinate. It cannot be discharged by reading the candidate rows C, K or the finished-normal rows E, N, and no consumer may erase it while remaining inside the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route.*

Proof. Read the carrier definition. The row S is listed separately from C, K, E, N before the transport, replay, provenance, and local naming rows are attached.

Use the subject-reduction-obstruction separation clause of Definition 892.2. It states that S remains distinct from the candidate and finished-normal evidence surfaces.

Apply Definition 892.6. Since no erased subject-reduction transport is exported, S can only be carried as a named obstruction coordinate; it cannot be solved by reading C, K, E, N. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier obstruction ledger`

Theorem 892.42 (MetaCIC normalization frontier public obligation package)**.** *Every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet exposes the public obligation package consisting of carrier admission for*

$$F = (C, K, E, N, S, H, R, P, L),$$

the candidate-evidence boundary C, K, the finished-normal boundary E, N, the closed-normal handoff through R, P, L, and the obstruction-separation row S.

The package is a finite BEDC obligation surface. It does not assert blanket strong normalization, full closed consistency, or erased subject-reduction transport.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierPublicObligationPackage`

Proof. Project the carrier of Definition 892.1. The rows $C, K, E, N, S, H, R, P, L$ are exactly the finite frontier packet.

Apply Definition 892.2. Its carrier, candidate-boundary, finished-normal-boundary, handoff, and obstruction-separation clauses are precisely the public obligation rows listed in the statement.

Finally use Definition 892.6. It prevents the public package from being read as a global normalization theorem, a full consistency theorem, or an erased subject-reduction transport. □

Theorem 892.43 (MetaCIC normalization frontier boundary disjointness)**.** *For an accepted* MetaCICNormalization *packet, the rows C, K, E, N, S remain distinct BEDC coordinates: candidate evidence C, closed-candidate placement K, finished-normal evidence E, normal-endpoint use N, and subject-reduction obstruction S. They cannot be collapsed into a blanket normalization theorem or a single unnamed normalization row.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier boundary disjointness`

Proof. Read the carrier in Definition 892.1. The five rows C, K, E, N, S are listed as separate coordinates before the transport, replay, provenance, and local naming rows are attached.

Now apply Definition 892.2. It assigns different obligations to the candidate boundary, the finished-normal boundary, the closed-normal handoff, and the obstruction row.

The non-escape theorem Definition 892.6 excludes the blanket theorem reading. Therefore no consumer can collapse C, K, E, N, S into a single normalization assertion while remaining inside the accepted packet. □

Theorem 892.44 (MetaCIC normalization frontier consumer-route totality)**.** *Every consumer route for an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet factors through either the candidate-evidence surface C, K or the finished-normal evidence surface E, N. The rows H, R, P, L only transport, replay, package, and name that surface; they do not add a third normalization evidence route.*

Proof. Start from the route inventory in Definition 892.1. The only evidence surfaces available to a consumer are C, K and E, N, with S retained as the obstruction coordinate.

Use Definition 892.2. The candidate-evidence clause routes through C, K, the finished-normal clause routes through E, N, and the handoff clause routes closed-normal use through R, P, L after one of those surfaces is present.

Finally apply Definition 892.6. A consumer bypassing both C, K and E, N has no carrier coordinate from which to read normalization evidence, so the listed alternatives are total for the accepted frontier packet. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier consumer route totality`

Theorem 892.45 (MetaCIC normalization frontier carrier-admission route)**.** *Carrier admission for an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet exposes exactly the finite rows*

$$F = (C, K, E, N, S, H, R, P, L).$$

The rows C, K are the candidate and closed-candidate evidence surface, E, N are the finished-normal and normal-endpoint surface, S is the subject-reduction obstruction row, and H, R, P, L transport, replay, package, and locally name the displayed surface. Carrier admission exposes no blanket normalization source outside those rows.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier carrier admission route`

Proof. Project the carrier definition Definition 892.1. It lists the nine rows $C, K, E, N, S, H, R, P, L$ as the whole accepted packet.

Apply the NameCert obligations of Definition 892.2. Carrier admission is the first obligation, and the remaining clauses sort the rows into candidate evidence, finished-normal evidence, consumer handoff, and obstruction separation.

Use Definition 892.6. Since the packet exports no blanket strong-normalization theorem or erased subject-reduction transport, carrier admission cannot expose any normalization source beyond the displayed frontier rows. □

Theorem 892.46 (MetaCIC normalization frontier evidence-choice exhaustion)**.** *Every positive consumer route out of an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet chooses either the candidate surface C, K or the finished-normal surface E, N. The rows H, R, P, L only transport, replay, package, and locally name the chosen surface; they do not supply a third positive normalization evidence row.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier evidence choice exhaustion`

Proof. Read the candidate route Definition 892.39. It routes candidate-facing consumers through C, K, R, P, L inside the same finite packet.

Read the finished route Definition 892.40. It routes finished-normal consumers through E, N, R, P, L and the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates.

Apply consumer-route totality, Definition 892.44. It exhausts positive routes by the two evidence surfaces and assigns H, R, P, L only transport, replay, packaging, and naming roles. The non-escape theorem Definition 892.6 rules out a hidden third source. □

Theorem 892.47 (MetaCIC normalization frontier obstruction retention)**.** *For every accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet, the subject-reduction obstruction row S survives every candidate read through C, K and every finished-normal read through E, N. It is transported and replayed as a displayed row of the same packet and is not discharged by any candidate or finished-normal evidence surface.*

Proof. Use the obstruction ledger Definition 892.41. It names S as a separate coordinate and states that reading C, K or E, N does not erase it.

Combine this with the candidate and finished routes. Definition 892.39 and Definition 892.40 consume their positive surfaces through R, P, L, but neither route includes a discharge coordinate for S.

Finally invoke Definition 892.44 and Definition 892.6. All positive reads choose one of the two evidence surfaces, while erased subject-reduction transport remains outside the packet; therefore S is retained through every accepted consumer route. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier obstruction retention`

Theorem 892.48 (MetaCIC normalization frontier candidate-finished boundary totality)**.** *Every accepted consumer route for a* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet passes through either the candidate boundary rows C, K or the finished-normal boundary rows E, N. The displayed carrier*

$$F = (C, K, E, N, S, H, R, P, L)$$

has no third positive normalization evidence surface: H, R, P, L only transport, replay, package, and locally name one of the two boundary routes.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier candidate finished boundary totality`

Proof. Project the carrier and NameCert obligations. The carrier lists C, K, E, N as the only positive normalization evidence rows, and Definition 892.2 assigns consumer reads to the candidate boundary or the finished-normal boundary.

Use the candidate route and finished route theorems. Definition 892.39 routes candidate-facing consumers through C, K, R, P, L, while Definition 892.40 routes finished-normal consumers through E, N, R, P, L.

Finally apply consumer-route totality, Definition 892.44, and non-escape, Definition 892.6. A route outside both positive boundaries has no carrier coordinate from which to read normalization evidence. □

Theorem 892.49 (MetaCIC normalization frontier root candidate readback)**.** *For every accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet $F = (C, K, E, N, S, H, R, P, L)$, any root candidate consumer reads the candidate row C and the closed-candidate row K before it may read any finished-normal endpoint row. The consumer route is therefore rooted at C, K, R, P, L, not at the finished-normal pair E, N.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root candidate readback`

Proof. Project the carrier and NameCert obligations. The accepted packet is exactly $F = (C, K, E, N, S, H, R, P, L)$ and the local obligations assign candidate-facing reads to the candidate boundary before a finished-normal endpoint is exposed.

Apply the candidate route Definition 892.39. It routes candidate-facing consumers through C, K, R, P, L and leaves E, N as the separate finished-normal surface.

Finally use consumer-route totality and non-escape. A root candidate read that bypasses C, K or starts from E, N has no carrier coordinate from which to read candidate evidence, so it is not a read of the accepted packet. □

Theorem 892.50 (MetaCIC normalization frontier root obstruction retention)**.** *For every accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet $F = (C, K, E, N, S, H, R, P, L)$, the obstruction row S remains present under every candidate read through C, K and every finished-normal read through E, N. Neither the endpoint row E nor the normal row N discharges S.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root obstruction retention`

Proof. Read the obstruction ledger Definition 892.41. It keeps S as a displayed coordinate of the same packet as C, K, E, N, H, R, P, L.

Use the candidate route and the finished route. The candidate route consumes C, K, R, P, L, while the finished route consumes E, N, R, P, L; neither route contains a discharge coordinate for subject-reduction obstruction.

Apply the obstruction consumer lock and kernel non-escape. Since erased subject-reduction transport is outside the packet, S remains visible under both positive evidence routes. □

Theorem 892.51 (MetaCIC normalization frontier root normal endpoint handoff)**.** *For every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet* $F = (C, K, E, N, S, H, R, P, L)$*, the normal endpoint row* N *is exposed only after the finished-normal evidence row* E *and only through the replay, provenance, and local-name rows* R, P, L*. A root consumer cannot read* N *as a free-standing normalization endpoint.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierRootNormalEndpointHando`

Proof. Project the finished route Definition 892.40. It routes finished-normal consumers through E, N, R, P, L inside the same accepted packet.

Use the public obligation package. Its handoff row assigns closed-normal consumer exposure to the displayed replay, provenance, and local naming rows, so N is not available before E or outside R, P, L.

Finally apply non-escape. A free-standing read of N would require a hidden blanket normalization coordinate, full closed consistency coordinate, or erased subject-reduction transport; none belongs to F. □

Theorem 892.52 (MetaCIC normalization frontier obstruction consumer lock)**.** *For every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet, the obstruction row* S *remains visible to consumer routes and cannot be erased by reading either the candidate boundary* C, K *or the finished-normal boundary* E, N*. The public route may transport* S *through* H, R, P, L*, but it cannot replace* S *by blanket strong normalization, full closed consistency, or erased subject-reduction transport.*

Proof. Read the obstruction ledger, Definition 892.41. It keeps S as a separate coordinate in the same finite packet as C, K, E, N, H, R, P, L.

Apply candidate and finished route exactness. The candidate route consumes C, K and the finished route consumes E, N, but neither theorem discharges the separate obstruction coordinate.

Use kernel non-escape and consumer-route totality. Definition 892.38 excludes a hidden global theorem behind the public route, and Definition 892.44 leaves only the two positive evidence surfaces with S still displayed. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier obstruction consumer lock`

Theorem 892.53 (MetaCIC normalization frontier obligation triad)**.** *The public obligation surface of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet is the triad made of carrier admission for* $F = (C, K, E, N, S, H, R, P, L)$*, candidate-or-finished boundary totality through* C, K *or* E, N*, and obstruction separation for* S*, with consumer handoff through the displayed rows* H, R, P, L*.*

This triad is the chapter's consumer-facing obligation surface. It does not claim blanket normalization, closed consistency, or erased subject reduction.

Proof. First use the public obligation package, Definition 892.42. It supplies carrier admission, candidate evidence, finished-normal evidence, closed-normal handoff, and obstruction separation for the displayed packet.

Next apply Definition 892.48. This packages the positive evidence side into the two available boundary routes, C, K and E, N.

Then apply Definition 892.52. The obstruction row S stays visible alongside those positive routes and is not erased by the handoff.

Finally use non-escape, Definition 892.6. Since the packet has no coordinate for blanket normalization, closed consistency, or erased subject reduction, the triad is exactly the public obligation surface for downstream consumers. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier public obligation triad`

Theorem 892.54 (MetaCIC normalization frontier scope binding)**.** *For every accepted* MetaCICNormalizationFront *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

carrier admission, the candidate rows C, K, the finished-normal rows E, N, the obstruction row S, and the structural rows H, R, P, L are scoped over the same BHist *carrier, componentwise* hsame *transport, displayed* Cont *route,* Pkg *provenance, and local* NameCert *row. No row may be read as a detached host normalization or closed-consistency object.*

Proof. Start with carrier admission and the local NameCert obligations. Definition 892.45 places $C, K, E, N, S, H, R, P, L$ inside one accepted packet, and Definition 892.2 reads the same rows as the local certificate surface.

Next apply the public obligation triad. It keeps the candidate rows, the finished-normal rows, and the obstruction row on the same consumer-facing surface, while H, R, P, L provide only transport, replay, provenance, and local naming.

Finally use non-escape. Since no coordinate exports blanket strong normalization, closed consistency, erased subject reduction, or host normalization, every scoped read remains a read of the displayed BEDC packet. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier scope binding`

Theorem 892.55 (MetaCIC normalization frontier consumer scope exhaustion)**.** *Every closed-normal or consistency-facing consumer route for an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet chooses either the candidate surface C, K or the finished-normal surface E, N before any structural handoff through H, R, P, L. A consumer route cannot bypass both positive evidence surfaces and still remain inside the packet.*

Proof. Use consumer-route totality from Definition 892.44. It lists the candidate and finished-normal routes as the available positive evidence surfaces for downstream reads.

Then apply evidence-choice exhaustion and the candidate-finished boundary totality theorem. These results force the consumer to pick C, K or E, N before the packet is replayed, packaged, or locally named.

The bypass case is excluded by kernel non-escape. A route that avoids both positive surfaces would need a hidden blanket normalization, full closed consistency, or erased subject-reduction coordinate, and Definition 892.38 gives no such coordinate. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier consumer scope exhaustion`

Theorem 892.56 (MetaCIC normalization frontier obstruction scope stability)**.** *For every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet, the obstruction row S remains a displayed obstruction row under componentwise transport by H and under the structural replay, provenance, and local naming rows R, P, L. Transport may carry S through the packet, but it cannot discharge S as blanket strong normalization, full closed consistency, or erased subject-reduction transport.*

Proof. Begin with obstruction retention, Definition 892.47. It keeps S as a separate row of the same finite frontier packet after the positive evidence surfaces are read.

Use the obstruction consumer lock together with the scope-binding theorem above. The obstruction row is transported and named with the same structural rows as the rest of the packet, so componentwise transport preserves it as a displayed row rather than removing it.

Finally apply non-escape. The carrier has no hidden coordinate that could turn S into a global normalization or consistency proof, so obstruction stability is exactly stability of the displayed S row. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier obstruction scope stability`

Theorem 892.57 (MetaCIC normalization frontier normal endpoint exhaustion)**.** *Every normal-endpoint consumer of an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

factors through the candidate rows C, K, the finished-normal rows E, N, and the structural handoff rows H, R, P, L before reading the normal endpoint row N. The consumer cannot bypass the obstruction row S, and no read of N exports blanket strong normalization, full closed consistency, or erased subject-reduction transport.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierNormalEndpointExhaustio`

Proof. Begin with the candidate route and finished route. Definition 892.39 routes candidate-facing reads through C, K, R, P, L, while Definition 892.40 routes endpoint reads through E, N, R, P, L.

Next use consumer-route totality and the root normal endpoint handoff. These theorems force every normal-endpoint consumer onto the displayed positive surface before N is available, and they keep H, R, P, L as handoff rows rather than independent normalization evidence.

Apply the obstruction ledger. The row S remains a separate coordinate of the same packet and is not removed by the candidate route, the finished route, or the normal endpoint handoff.

Finally invoke non-escape. A bypass of S or a free-standing read of N would require a hidden blanket normalization, closed-consistency, or erased subject-reduction coordinate, and the packet has none. □

Theorem 892.58 (MetaCIC normalization frontier consistency consumer factorization)**.** *Every closed-normal consistency consumer of an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet factors through either the candidate route C, K, R, P, L or the finished route E, N, R, P, L before reading the normal endpoint row N. The packet has no third consistency-facing route outside those two displayed surfaces.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier consistency consumer factorization`

Proof. Start from consumer-route totality. It lists the candidate route and the finished route as the complete positive evidence alternatives available to a consumer of the accepted packet.

Use the candidate-finished boundary totality theorem together with consumer scope exhaustion. A closed-normal consistency consumer must choose the candidate surface or the finished-normal surface before any structural replay, provenance, or local naming row can be read as part of the route.

The normal endpoint row is then controlled by the root normal endpoint handoff and the scope-binding theorem. These results keep N inside the same BHist, hsame, Cont, Pkg, and NameCert packet instead of exposing it as an independent consistency witness.

Finally apply kernel non-escape and the obstruction consumer lock. They rule out a hidden third route and keep the obstruction row S visible alongside whichever positive surface the consumer selected. □

Theorem 892.59 (MetaCIC normalization frontier subject obstruction preservation)**.** *For every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet, the subject-reduction obstruction row S is preserved across both the candidate consumer route C, K, R, P, L and the finished-normal consumer route E, N, R, P, L. Positive normalization evidence may expose candidate rows, finished-normal rows, and the normal endpoint row N, but it does not discharge S.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier subject obstruction preservation`

Proof. Read the obstruction ledger and obstruction retention theorems. They keep S as a named row of the same packet and state that neither candidate evidence nor finished-normal evidence erases it.

Next apply the candidate route and the finished route. These are the two positive consumer routes exposed by the packet, and both pass through the same structural rows R, P, L without adding a discharge coordinate for S.

Use consumer-route totality to exhaust the positive alternatives. Since every consumer route chooses C, K or E, N, preservation across those two routes is preservation across the whole positive consumer surface.

Finally invoke non-escape. Erased subject-reduction transport is not exported by the packet, so positive normalization evidence cannot turn the displayed obstruction row into a solved subject-reduction theorem. □

Theorem 892.60 (MetaCIC normalization frontier root handoff scope)**.** *Every root handoff from an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet to a closed-normal consumer exposes exactly the carrier rows*

$$C, K, E, N, S, H, R, P, L$$

through the displayed BHist *history, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *certificate surface. No handoff row is available outside those five BEDC access layers.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierRootHandoffScope`

Proof. Start with the carrier and NameCert obligations. The carrier theorem names the nine rows of the packet, while the NameCert obligation theorem attaches the local naming certificate to the same rows rather than to an external normalization witness.

Next use the root normal endpoint handoff and consumer-route totality. These results force a closed-normal consumer to read the packet through the displayed history and transport rows before any endpoint evidence can be consumed.

Finally apply consistency-consumer factorization and subject-obstruction preservation. The positive route chosen by the consumer and the retained obstruction row are both still rows of the same BHist, hsame, Cont, Pkg, and NameCert surface, so the handoff exposes no further coordinate. □

Theorem 892.61 (MetaCIC normalization frontier downstream boundary)**.** *Every downstream normalization consumer of an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet must choose either the candidate route* C, K, R, P, L *or the finished-normal route* E, N, R, P, L*. In both cases the subject-reduction obstruction row* S *remains a displayed boundary row of the same packet.*

Proof. Apply consumer-route totality together with consistency-consumer factorization. These theorems list the candidate and finished-normal routes as the complete positive alternatives for a downstream normalization consumer.

For the candidate side, use the candidate route theorem. It exposes C, K together with the structural rows R, P, L, and it does not read an independent endpoint proof.

For the finished-normal side, use the finished route and normal endpoint exhaustion theorems. They expose E, N through the same structural rows R, P, L and keep the normal endpoint inside the packet.

It remains to control the obstruction row. Subject-obstruction preservation states that both positive routes retain S, while non-escape rules out any consumer route that turns S into an erased subject-reduction proof. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier downstream normalization boundary`

Theorem 892.62 (MetaCIC normalization frontier open-problem ledger unblock)**.** *The accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet unblocks the MetaCIC open-frontier ledger only as the finite boundary object*

$$(C, K, E, N, S, H, R, P, L).$$

It does not assert blanket normalization, closed consistency, or discharged subject reduction beyond the displayed candidate route, finished-normal route, obstruction row, and BEDC handoff surface.

Proof. Read the carrier theorem, NameCert obligations, and root handoff scope. They provide a finite packet with named rows and a local certificate interface for root consumers.

Next apply downstream boundary and consistency-consumer factorization. Any normalization or consistency consumer must stay on the candidate route C, K, R, P, L or the finished-normal route E, N, R, P, L.

Finally use subject-obstruction preservation and non-escape. The obstruction row S remains visible, and the packet has no row that exports blanket normalization, closed consistency, or erased subject-reduction transport. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontier open problem ledger unblock`

Theorem 892.63 (MetaCIC normalization frontier audit seal consumer route)**.** *Every MetaCICNormalizationAud facing consumer of an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet reads the same packet* $F = (C, K, E, N, S, H, R, P, L)$ *through the candidate rows* C, K*, the finished-normal rows* E, N*, the obstruction row* S*, the replay row* R*, the provenance row* P*, and the local naming row* L*. No such consumer obtains a blanket normalization source outside that displayed packet.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierAuditSealConsumerRoute`

Proof. Project the carrier and NameCert obligations. They expose exactly $C, K, E, N, S, H, R, P, L$ and attach audit-facing reads to the local certificate.

Use the candidate route and the finished route. These route seal consumers through C, K, R, P, L or E, N, R, P, L, and consumer-route totality exhausts the positive alternatives.

Apply the obstruction ledger, obstruction consumer lock, and non-escape. The row S remains visible, and no packet coordinate projects a blanket normalization source. □

Theorem 892.64 (MetaCIC normalization frontier closed-normal route boundary)**.** *Every ClosedNormalRouteCer facing read of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet reaches the normal endpoint N only after the finished-normal evidence row E has been read through the displayed route E, N, R, P, L. The obstruction row S remains a visible coordinate of the same packet throughout the read.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierClosedNormalRouteBounda`

Proof. Start from the finished route and normal endpoint exhaustion. They place the read of N behind the finished-normal evidence row E and the structural handoff rows R, P, L.

Apply the NameCert obligations and consumer-route totality. The consumer reads the endpoint through the local certificate surface, not as a free-standing endpoint.

Use the obstruction ledger, obstruction consumer lock, and non-escape. They keep S visible and rule out a route that discharges the obstruction before N is read. □

Theorem 892.65 (MetaCIC normalization frontier subject-reduction obstruction compatibility)**.** *Every SubjectReductionBoundary-facing consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet treats S as a retained obstruction coordinate. Neither the candidate rows C, K nor the finished-normal evidence rows E, N discharge that obstruction.*

Proof. Project the carrier and obstruction ledger. The row S is a named coordinate of the same finite packet as the positive evidence and handoff rows.

Use the candidate route and the finished route. They expose the positive normalization surfaces C, K, R, P, L and E, N, R, P, L, but neither route contains a subject-reduction discharge coordinate.

Apply the obstruction consumer lock, consumer-route totality, and non-escape. Every SubjectReductionBounda facing read stays on a displayed packet route, so positive evidence cannot turn S into a closed subject-reduction theorem. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierSubjectReductionObstruc`

Falsifiable prediction: If the frontier packet is accepted, any closed-normal consistency consumer route factors through either the candidate-evidence row or the finished-normal row; a route that bypasses both is outside the carrier.

Independence witness: metacic-open-frontier-ledger, metacicnormalizationaudit, metacicnormalizationauditseal, closednormalroutecertificate: the new packet is not bijective to any sibling because it carries the normalization frontier as an explicit obstruction-preserving coordinate rather than an audit report, a seal, a route certificate, or a mixed open-frontier inventory.

The Lean follow-up target is `lean4/BEDC/Derived/MetaCICNormalizationFrontierUp/TasteGate.lean`, with explicit `Nontrivial MetaCICNormalizationFrontierUp` and `FieldFaithful MetaCICNormalizationFront` instances.

Closure status for NameCert$_{\text{MetaCICNormalizationFrontier}^{\uparrow}}$.

Constructive story: A MetaCICNormalizationFrontier$^{\uparrow}$ packet is generated from candidate evidence, closed-candidate evidence, finished-normal evidence, normal-endpoint use, subject-reduction obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalizationFrontier}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 892.1, Definition 892.2, Definition 892.6, Definition 892.45, Definition 892.46, Definition 892.47, Definition 892.17, Definition 892.18, Definition 892.19, and the TasteGate marker `BEDC.Derived.MetaCICNormalizationFronti`

at Definition 892.1 bind the finite obstruction-preserving normalization frontier packet, the NameCert obligations, non-escape, carrier-admission route, evidence-choice exhaustion, obstruction-retention rows, obligation carrier totality, obligation evidence split, obligation obstruction retention, and singleton-carrier alignment site.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFrontier}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.MetaCICNormalizationFrontierUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close blanket strong normalization for all empty-context typed closed MetaCIC terms, full closed consistency, erased subject-reduction transport, or a public standard bridge.

Upgrade path: No further paper closure grade remains; future work is formal-status and bridge verification for the same obstruction-preserving normalization frontier packet under `BEDC.Derived.MetaCICNormalizationFrontierUp`.

Theorem 892.66 (MetaCIC normalization frontier candidate obstruction separation)**.** *For every accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

candidate evidence through C, K *remains separate from the obstruction row* S*. A consumer may transport candidate evidence through* H, R, P, L*, but no candidate read discharges, hides, or rewrites* S *as finished normalization or erased subject reduction.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier candidate obstruction separation`

Proof. Project the carrier rows of Definition 892.1. The candidate rows C, K and the obstruction row S are separate coordinates before the structural rows H, R, P, L are attached.

Apply the NameCert obligations and classifier stability. The candidate boundary clause reads C, K, while the obstruction-separation clause keeps S as its own row under the same classifier surface.

Use ledger exhaustion and non-escape. The ledger has no coordinate for erased subject reduction or blanket normalization, so transporting candidate evidence cannot remove the displayed obstruction row. □

Theorem 892.67 (MetaCIC normalization frontier closed-normal consumer route)**.** *Every closed-normal consumer of an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet that uses a finished-normal endpoint must route through the displayed rows* E, N, H, R, P, L*. The endpoint row* N *is available only after the finished-normal evidence row* E *and only under componentwise transport, replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier closed normal consumer route`

Proof. Read the carrier $F = (C, K, E, N, S, H, R, P, L)$ from Definition 892.1. The only finished-normal evidence rows are E and N, while H, R, P, L provide the structural route by which a consumer may read them.

Apply the finished route, fuel route, and closed-normal handoff surfaces. They place the normal endpoint downstream of E and keep the consumer route inside the displayed hsame, Cont, Pkg, and NameCert rows.

Finally use the redex boundary and non-escape theorem. A consumer that bypasses E, N, H, R, P, L would require a blanket normalization coordinate or a host closed-normal endpoint, neither of which belongs to the packet. □

Theorem 892.68 (MetaCIC normalization frontier fuel ledger nonescape)**.** *The finite fuel ledger of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet forbids three exports: unbounded normalization, erased subject reduction, and closed consistency. The packet may expose candidate evidence through C, K, finished-normal evidence through E, N, obstruction retention through S, and structural route data through H, R, P, L, but it exports no consumer route outside those finite rows.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier fuel ledger nonescape`

Proof. Begin with the fuel route and ledger exhaustion results. They bind every accepted normalization read to the finite packet rows $C, K, E, N, S, H, R, P, L$ and do not introduce an unbounded normalization source.

Next use obstruction retention and the redex boundary. The row S records the subject-reduction obstruction as a retained boundary, while the redex boundary keeps candidate and finished-normal evidence within the inspected finite route.

Finally apply non-escape. Since the carrier has no row for unbounded normalization, erased subject reduction, or closed consistency, the finite fuel ledger cannot export any of those claims to downstream consumers. □

Theorem 892.69 (MetaCIC normalization frontier candidate evidence noncollapse)**.** *For every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

candidate evidence through C, K cannot be identified with finished-normal evidence through E, N by host equality, quotient rows, or hidden transport. Any accepted comparison of those surfaces must keep the candidate rows, the finished-normal rows, the obstruction row S, the componentwise hsame *row H, the displayed* Cont *row R, the* Pkg *provenance row P, and the local* NameCert *row L visible in the same* BHist *packet.*

Proof. Project the carrier of Definition 892.1. It exposes C, K as the candidate side and E, N as the finished-normal side of the same finite BHist packet.

Use Definition 892.2 and Definition 892.4. These results allow componentwise hsame transport along the displayed rows, but they do not provide a coordinate that rewrites candidate evidence as finished-normal evidence.

It remains to exclude external identifications. The root non-escape and boundary rows, Definition 892.10, Definition 892.66, and Definition 892.68, rule out host normalization, quotient term equality, erased subject-reduction transport, and a hidden closed-normal endpoint. Thus candidate evidence and finished-normal evidence remain distinct displayed surfaces. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier candidate evidence noncollapse`

Theorem 892.70 (MetaCIC normalization frontier finished-normal boundary)**.** *Every finished-normal read of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet must pass through the displayed* BHist *carrier, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. Concretely, endpoint use reads E, N, H, R, P, L inside*

$$F = (C, K, E, N, S, H, R, P, L),$$

with the obstruction row S retained as a visible boundary coordinate.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier finished normal boundary`

Proof. Begin with Definition 892.9. A root consumer first receives exactly $C, K, E, N, S, H, R, P, L$, so there is no finished-normal endpoint outside the displayed carrier.

The finished-normal route is then fixed by Definition 892.12 and Definition 892.67. These rows place endpoint use after E and N, with replay through R, provenance through P, and local naming through L.

Finally apply the obstruction-preserving rows. Definition 892.13 and Definition 892.66 keep S as an obstruction coordinate under the same BHist, hsame, Cont, Pkg, and NameCert surface. □

Theorem 892.71 (MetaCIC normalization frontier consumer route exhaustion)**.** *Every closed-normal, consistency-facing, or SubjectReductionBoundary-facing consumer route of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet factors through the candidate-evidence boundary C, K, the finished-normal boundary E, N, the obstruction row S, the componentwise transport row H, the replay row R, the provenance row P, and the local* NameCert *row L of*

$$F = (C, K, E, N, S, H, R, P, L).$$

There is no accepted consumer route outside the candidate-evidence boundary, finished-normal boundary, obstruction row, transport row, route row, provenance row, and local naming row.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier consumer route exhaustion`

Proof. First exhaust the carrier. Definition 892.9 and Definition 892.17 identify the root-facing packet with the finite rows $C, K, E, N, S, H, R, P, L$.

Next exhaust the positive evidence routes. The candidate side is controlled by Definition 892.11, while the finished-normal side is controlled by Definition 892.12 and Definition 892.70.

It remains to bind the consumer handoff. Use Definition 892.16, Definition 892.66, and Definition 892.68. These rows keep the obstruction, transport, replay, provenance, and local naming coordinates visible, so a consumer cannot obtain a hidden route beyond the displayed frontier packet. □

Theorem 892.72 (MetaCIC normalization frontier root normalization gate exhaustion)**.** *For every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

every root normalization-facing read is exhausted by the candidate rows C, K, the normal-endpoint rows E, N, the obstruction row S, the componentwise transport row H, the replay row R, the provenance row P, and the local name row L. In particular, a root reader cannot obtain normalization evidence without choosing the displayed candidate route or the displayed endpoint route while retaining the obstruction coordinate.

Proof. Project the root carrier rows of Definition 892.9. The root-facing packet displays exactly $C, K, E, N, S, H, R, P, L$, so any normalization-facing read starts inside the same finite BHist carrier.

The positive entrances are already exhausted. The candidate entrance is the projection through Definition 892.11, and the endpoint entrance is the route described by Definition 892.12.

It remains to keep the structural rows visible. Apply Definition 892.13 and Definition 892.71. They retain S, H, R, P, L alongside both positive routes, so no root normalization-facing consumer reads a concealed route outside the displayed packet. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierRootNormalizationGateEx`
Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root normalization gate exhaustion`

Theorem 892.73 (MetaCIC normalization frontier root obstruction stability)**.** *For every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

the row S remains a transported obstruction coordinate under both the candidate route C, K, H, R, P, L and the endpoint route E, N, H, R, P, L. It is never consumed as positive normalization evidence, and it cannot be rewritten as a closed-normal endpoint, a consistency witness, or erased subject reduction.

Proof. Begin with the carrier and separation rows. Definition 892.9 exposes S as its own coordinate, while Definition 892.66 prevents the candidate rows C, K from discharging it.

Now follow the endpoint route. Definition 892.12 routes endpoint use through E, N, H, R, P, L, and Definition 892.13 keeps S under the same BHist, hsame, Cont, Pkg, and NameCert surface.

The consumer side adds no positive use of S. By Definition 892.71, downstream readers keep the obstruction row visible rather than consuming it as normalization evidence. Thus S is stable under both displayed routes. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierRootObstructionStabilit`

Theorem 892.74 (MetaCIC normalization frontier root consumer choice boundary)**.** *Every closed-normal, consistency-facing, or SubjectReductionBoundary-facing consumer of an accepted* MetaCICNormalizationFro *packet has only the displayed candidate route through C, K, H, R, P, L or the displayed endpoint route through E, N, H, R, P, L, with S retained as the obstruction coordinate of the same packet. There is no third root route for such a consumer.*

Proof. First exhaust root admission. The carrier theorem Definition 892.9 supplies only the rows $C, K, E, N, S, H, R, P, L$.

Next split the allowed consumer choices. Candidate use is fixed by Definition 892.11; endpoint use is fixed by Definition 892.12 and Definition 892.16.

Finally apply the obstruction and consumer exhaustion rows. Definition 892.13 keeps S transported but unconsumed, and Definition 892.71 rules out any consumer route outside the displayed candidate and endpoint surfaces. Therefore closed-normal, consistency-facing, and SubjectReductionBoundary-facing consumers have no third root choice. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier root consumer choice boundary`

Theorem 892.75 (MetaCIC normalization frontier carrier admission)**.** *Every accepted* MetaCICNormalizationFront *packet admits a root carrier only as the displayed finite* BHist *packet*

$$F = (C, K, E, N, S, H, R, P, L).$$

The admission exposes candidate evidence through C, K, the normal-form boundary through E, N, the audit route through K, R, the seal route through S, H, the closed-normal route through E, N, R, P, L, componentwise hsame *transports through H,* Cont *replay through R,* Pkg *provenance through P, and local* NameCert *rows through L. No accepted carrier admission can hide any of those rows or replace them by a host normalization theorem.*

Proof. Start with the root carrier rows of Definition 892.9. They expose exactly the finite BHist packet $C, K, E, N, S, H, R, P, L$ and give the root reader no carrier coordinate outside that packet.

Next read the boundary and route clauses. Definition 892.11 fixes candidate evidence through C, K, while Definition 892.12 and Definition 892.16 fix the normal-form and closed-normal routes through E, N, R, P, L.

It remains to keep the structural witnesses visible. Apply Definition 892.13, Definition 892.42, and Definition 892.71. These rows retain the seal, hsame transport, Cont replay, Pkg provenance, and local NameCert surface, so carrier admission displays all kernel-facing rows without exporting host normalization. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrierAdmission`

Theorem 892.76 (MetaCIC normalization frontier normal-form boundary)**.** *No consumer of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet can read finished normalization before both the candidate-evidence boundary rows C, K and the finished-normal boundary rows E, N are displayed inside the same packet*

$$F = (C, K, E, N, S, H, R, P, L).$$

Any normal-form read must keep the obstruction row S, componentwise hsame *transports H,* Cont *replay R,* Pkg *provenance P, and local* NameCert *row L visible alongside those two boundary surfaces.*

Proof. Project the candidate side first. Definition 892.32 and Definition 892.69 force candidate evidence through C, K and prevent it from being identified with finished-normal evidence by host equality or quotient rows.

Now project the finished side. Definition 892.70 places every finished-normal read inside E, N, H, R, P, L, and Definition 892.34 excludes host normalization, quotient term equality, and hidden normalizers outside the displayed packet.

Finally apply the consumer route theorem Definition 892.71. Since every closed-normal, consistency-facing, or SubjectReductionBoundary-facing consumer route factors through $C, K, E, N, S, H, R, P, L$, no consumer can read finished normalization until both the candidate-evidence and finished-normal boundary rows are displayed together. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierNormalFormBoundary`

Theorem 892.77 (MetaCIC normalization frontier substitution stability)**.** *Substitution-facing transports for an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet preserve the displayed frontier rows $C, K, E, N, S, H, R, P, L$ under componentwise* hsame, Cont *replay,* Pkg *provenance, and local* NameCert *naming. Such transports may carry candidate evidence, normal-form boundary evidence, the seal row, and consumer routes across the packet, but they do not create a host normalization theorem, erased subject-reduction transport, or quotient-level term equality.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier substitution stability`

Proof. Begin with classifier stability. Definition 892.4 permits componentwise hsame transport only along the displayed carrier rows, and Definition 892.73 keeps the obstruction coordinate S transported but unconsumed.

Next follow the consumer and route surfaces. Definition 892.72 exhausts every root normalization-facing read by $C, K, E, N, S, H, R, P, L$, while Definition 892.71 keeps downstream routes inside the same BHist, Cont, Pkg, and NameCert packet.

The forbidden exports are excluded by the sibling non-escape rows. Use Definition 892.38, Definition 892.68, and Definition 892.34. They rule out blanket normalization, erased subject reduction, quotient term equality, and hidden normalizers, so substitution-facing transport preserves the frontier rows without producing a host normalization theorem. □

Theorem 892.78 (MetaCIC normalization frontier closed-candidate readback exhaustion)**.** *For every accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

closed-candidate readback is exhausted by the candidate evidence row C*, the closed-candidate row* K*, displayed replay* R*, provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFrontier}^{\uparrow}}$ *row* L*. A root reader cannot obtain closed-candidate evidence from* E, N, S, H *or from any host normalization, scheduler, quotient-equality, or closed-consistency surface outside the displayed packet.*

Proof. Start with the NameCert obligation rows of Definition 892.2. They attach candidate evidence to the displayed carrier and separate it from finished-normal evidence, obstruction transport, and external host normalization.

Next project the root candidate gate. Theorem 892.11 identifies the candidate read with C, K before any replay, provenance, or local naming support can be used.

Finally add the consumer support rows. Theorem 892.12 keeps endpoint use on the distinct E, N, R, P, L route, while Theorem 892.15 leaves S visible but unavailable as positive candidate evidence. Thus closed-candidate readback is exhausted by C, K, R, P, L and by no unlisted source. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier closed candidate readback exhaustion`

Theorem 892.79 (MetaCIC normalization frontier finished-endpoint use totality)**.** *For every accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

finished endpoint use is total exactly over the finished-normal evidence row E*, the normal-endpoint row* N*, displayed replay* R*, provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFrontier}^{\uparrow}}$ *row* L*. The endpoint route may consult the candidate gate only through the already displayed* C, K *boundary, and it has no bypass through obstruction transport, host reachability, scheduler progress, or erased subject-reduction transport.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier finished endpoint use totality`

Proof. First read the endpoint-facing obligations. Theorem 892.2 places finished-normal evidence before endpoint use and keeps both rows under the same local certificate surface.

Now follow the root endpoint route. Theorem 892.12 exhausts endpoint access by E, N, R, P, L, so no finished endpoint can be consumed before those support rows are visible.

It remains to rule out hidden positive sources. Theorem 892.11 confines candidate consultation to C, K, and Theorem 892.15 keeps S transported rather than consumed. Hence endpoint use is total over E, N, R, P, L without importing host reachability, scheduler progress, or erased subject-reduction transport. □

Theorem 892.80 (MetaCIC normalization frontier obstruction-visible transport)**.** *For every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L),$$

transport of the obstruction row keeps S visible under componentwise hsame *transport H, displayed replay R, provenance P, and the local naming row L. Such transport can accompany candidate readback through C, K and finished-endpoint use through E, N, R, P, L, but it cannot turn S into positive normalization evidence, closed consistency, quotient-level term equality, or erased subject-reduction transport.*

Proof. Begin with the local obligation surface. Theorem 892.2 records S as an obstruction row of the same packet that carries C, K, E, N, H, R, P, L.

Transport then follows the root separation rows. Theorem 892.15 keeps S alongside the candidate route through C, K and the endpoint route through E, N, R, P, L.

Finally use the two positive route projections. Theorem 892.11 gives the only closed-candidate readback route, and Theorem 892.12 gives the only finished-endpoint route. Since neither route consumes S, obstruction-visible transport under H, R, P, L cannot become positive normalization evidence or any of the excluded global objects. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier obstruction visible transport`

Theorem 892.81 (MetaCIC normalization frontier route readback public export)**.** *Every public readback export of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

factors through the closed-candidate route C, K, R, P, L, the finished endpoint route E, N, R, P, L, and obstruction-visible transport S, H, R, P, L. The exported surface has no route through host normalization, scheduler progress, quotient equality, a closed-consistency shortcut, or erased subject-reduction transport.

Proof. First apply Definition 892.78. It identifies the closed-candidate public readback route as C, K, R, P, L and rules out host normalization, scheduler, quotient-equality, and closed-consistency sources for that face.

Next apply Definition 892.79. The finished endpoint face is total only over E, N, R, P, L, with candidate consultation confined to the already displayed C, K boundary.

Finally apply Definition 892.80. The obstruction row S remains visible only under H, R, P, L and cannot become positive normalization evidence, quotient equality, closed consistency, or erased subject-reduction transport. Combining the three route rows gives the whole public export surface. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier route readback public export`

Theorem 892.82 (MetaCIC normalization frontier root formal handoff totality)**.** *Every root formal handoff of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet is total only over the finite root packet*

$$F = (C, K, E, N, S, H, R, P, L).$$

The rows $C, K, E, N, S, H, R, P, L$ bind candidate evidence, the candidate gate, finished-normal evidence, the normal endpoint, the obstruction row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFrontier}^{\uparrow}}$ *row to the existing carrier. The handoff exports no scheduler state, host reachability predicate, closed-consistency theorem, erased subject-reduction transport, or hidden normalization source outside that carrier.*

Proof. Begin with the displayed root carrier rows. Theorem 892.9 and Theorem 892.75 expose exactly $C, K, E, N, S, H, R, P, L$, so a formal handoff has no additional coordinate from which to read normalization content.

Next project the positive entrances. Theorem 892.11 binds candidate evidence to C, K, while Theorem 892.12 routes normal-endpoint use through E, N, R, P, L.

Finally retain the obstruction and consumer rows. Theorem 892.13, Theorem 892.72, and Theorem 892.71 keep S, H, R, P, L visible for downstream reads. Thus the handoff is total for the displayed carrier and for no hidden host, scheduler, consistency, or erased subject-reduction input. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierRootFormalHandoffTotali`

Theorem 892.83 (MetaCIC normalization frontier root gate scope exactness)**.** *For every accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet $F = (C, K, E, N, S, H, R, P, L)$, the root candidate gate has exact scope C, K inside the same carrier and can feed a normal-endpoint read only through the displayed endpoint route E, N, R, P, L with obstruction retention through S, H, L. It cannot be widened to closed consistency, host reachability, scheduler progress, or erased subject-reduction transport.*

Proof. Project the candidate side first. Theorem 892.11 identifies the candidate gate with C, K, and Theorem 892.66 keeps the obstruction row S outside that positive candidate evidence.

Now read the endpoint route. Theorem 892.12 and Theorem 892.16 place endpoint use under E, N, R, P, L, rather than under an external host theorem or scheduler row.

The scope is exact because the gate-exhaustion and obstruction-preservation rows add no third positive source. Apply Theorem 892.13 and Theorem 892.72: they preserve S, H, R, P, L while excluding hidden closed consistency, host reachability, scheduler progress, and erased subject-reduction transport. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierRootGateScopeExactness`

Theorem 892.84 (MetaCIC normalization frontier root downstream consumer coverage)**.** *Every downstream MetaCIC consumer of an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *root packet that reads candidate evidence, normal endpoint data, obstruction status, replay, provenance, or local naming factors through*

$$C, K, E, N, S, H, R, P, L.$$

The consumer coverage includes the existing carrier, candidate gate, normal endpoint route, obstruction-preserving NameCert triad, root normalization gate, and local NameCert rows; it excludes hidden scheduler state, host reachability, closed consistency, erased subject-reduction transport, and any route outside the displayed consumer packet.

Proof. First take the carrier and candidate gate as the consumer source. Theorem 892.9 supplies the packet $C, K, E, N, S, H, R, P, L$, and Theorem 892.11 fixes candidate reads through C, K.

Next account for normal endpoints and obstruction retention. Theorem 892.12 routes endpoint reads through E, N, R, P, L, while Theorem 892.13 keeps S, H, L visible under the same local naming surface.

Finally apply route exhaustion. Theorem 892.72 exhausts root normalization-facing reads, and Theorem 892.71 exhausts downstream consumer routes. Therefore every downstream consumer factors through the displayed rows and none may import scheduler state, host reachability, closed consistency, erased subject-reduction transport, or an unlisted route. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierRootDownstreamConsumer(`

Theorem 892.85 (MetaCIC normalization frontier formal-target carrier coverage)**.** *For every formal target surface attached to an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet, carrier coverage is exactly the finite packet*

$$F = (C, K, E, N, S, H, R, P, L).$$

The rows C, K carry candidate evidence and closed-candidate placement, the rows E, N carry finished-normal evidence and the normal endpoint, the row S retains the subject-reduction obstruction, and the rows H, R, P, L expose componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFrontier}^{\uparrow}}$ *surface. No formal target row may read a carrier coordinate outside that packet.*

Proof. Project the carrier theorem and the NameCert obligation theorem. They list $C, K, E, N, S, H, R, P, L$ as the whole BHist carrier and attach the local certificate to those rows.

Next read the root formal handoff totality theorem. It makes the formal handoff total only over the displayed rows, with candidate, endpoint, obstruction, replay, provenance, and naming all preserved inside the same packet.

Finally apply non-escape. A carrier coordinate outside F would require a hidden normalization source, scheduler state, closed-consistency theorem, or erased subject-reduction transport, and none is exported by the packet. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier formal target carrier coverage`

Theorem 892.86 (MetaCIC normalization frontier formal-target classifier totality)**.** *For every formal target surface attached to an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *packet, classifier totality is exhausted by the candidate route through C, K, R, P, L and the finished-normal route through E, N, R, P, L, with obstruction retention through S, H, L. The classifier cannot add a third positive normalization route, cannot discharge S, and cannot replace the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows by host evidence.*

Proof. Start with evidence-choice exhaustion. Every positive consumer route chooses either C, K or E, N, and the structural rows R, P, L only replay, package, and name the chosen route.

Use obstruction retention next. The row S remains present across both positive routes, while H transports the displayed packet componentwise rather than solving the obstruction.

The classifier is therefore total on exactly those two routes. Root gate scope exactness and downstream consumer coverage rule out a third route through scheduler progress, host reachability, closed consistency, or erased subject-reduction transport. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCarrier formal target classifier totality`

Theorem 892.87 (MetaCIC normalization frontier formal-target ledger nonescape)**.** *For every formal target surface attached to an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet, any ledger read of candidate evidence, finished-normal evidence, normal endpoint use, obstruction status, replay, provenance, or local naming remains inside*

$$C, K, E, N, S, H, R, P, L.$$

A ledger row that omits obstruction retention, bypasses the evidence choice, or replaces BHist*,* hsame*,* Cont*,* Pkg*, or* NameCert *by hidden host material is outside the formal target surface.*

Proof. Read ledger exhaustion together with the public obligation package. They place candidate reads at C, K, finished-normal reads at E, N, obstruction accounting at S, and consumer support at H, R, P, L.

Now use the root normal endpoint route and root downstream consumer coverage. These theorems keep endpoint use and downstream consumption inside the same displayed packet before any formal target surface can consume them.

Finally apply the kernel non-escape theorem. A ledger read that bypasses the displayed rows asks for an unlisted coordinate, so it is rejected rather than admitted as part of the formal target surface. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierFormalTargetLedgerNones`

Theorem 892.88 (MetaCIC normalization frontier candidate endpoint premise route)**.** *Every finished-normal endpoint read attached to an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *formal target must expose Candidate, ClosedCandidate, or CandidateSet evidence and the frontier audit row before any confluence, decidability, or closed-normal consumer can inspect the endpoint. The route is therefore conditional on the displayed candidate surface and never supplies unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, quotient syntax equality, or host evaluator soundness.*

Proof. Start with carrier coverage from Definition 892.85. The formal target surface is the finite packet $C, K, E, N, S, H, R, P, L$, where the candidate and closed-candidate rows are visible before the endpoint row is exported.

Use classifier totality from Definition 892.86. A consumer chooses the candidate route through C, K, R, P, L or the finished-normal route through E, N, R, P, L, while the obstruction and audit material remains visible through S, H, L.

Finally apply ledger nonescape from Definition 892.87. Any confluence, decidability, or closed-normal consumer must stay inside the displayed candidate, endpoint, obstruction, replay, provenance, and naming rows, so the excluded host principles and unconditional normalization claims have no carrier coordinate. □

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCandidateEndpointPremis`

Theorem 892.89 (MetaCIC normalization frontier ground-compiler route)**.** *Every accepted* MetaCICNormalization *candidate-evidence boundary routes its TasteGate-facing conservativity and no-hidden-input obligations through the displayed ground-compiler recognition rows before any normalization boundary is exported. Concretely, a consumer of*

$$F = (C, K, E, N, S, H, R, P, L)$$

must first read the carrier surface of Definition 892.1, then the candidate-evidence route of Definition 892.32, and then the root normal-form boundary of Definition 892.76. Only after those

rows are visible may the consumer use the TasteGate row certified at the core surface, and that use exports no hidden normalizer, host normalization theorem, erased subject-reduction transport, or quotient-level term equality.

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierGroundCompilerRoute`

Proof. Project the core carrier. The rows $C, K, E, N, S, H, R, P, L$ are the only accepted frontier coordinates, and the core surface records the TasteGate-facing packet through the same finite carrier rather than through an external normalization oracle.

Next read the candidate-evidence boundary. The route through C, K is fixed by Definition 892.32, while Definition 892.33 keeps the seal and audit-facing rows visible before closed-normal use.

The root normal-form boundary then forces finished-normal reads through E, N with S, H, R, P, L still displayed. Thus the conservativity and no-hidden-input obligations face the ground-compiler recognition rows before normalization is exported.

Finally apply the non-escape rows Definition 892.34 and Definition 892.77. They exclude hidden normalizers, host normalization, erased subject-reduction transport, and quotient term equality, so the TasteGate-facing route remains a ground-compiler route over the displayed packet. □

Theorem 892.90 (MetaCIC normalization frontier TasteGate route)**.** *Any promotion of* MetaCICNormalizationFron *beyond its seed and scaffold boundary must cite the finite candidate-evidence rows C, K, the finished-normal endpoint rows E, N, the subject-reduction obstruction row S, and the ground-compiler route rows H, R, P, L already displayed in this chapter. It may not replace those rows by a hand-written global normalization claim, a hidden normalizer, erased subject-reduction transport, or quotient-level term equality.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierTasteGateRoute`

Proof. Begin with the core surface Definition 892.1 and Definition 892.2. These rows expose $C, K, E, N, S, H, R, P, L$ as the finite packet and make candidate evidence, finished-normal evidence, obstruction accounting, and downstream replay separate obligations.

Next read the formal-target rows, including Definition 892.85, Definition 892.86, and Definition 892.87. They keep any promotion attached to the same carrier and classifier rows rather than to a blanket normalization assertion.

Finally use the ground-compiler route of Definition 892.89. Since this chapter has AI lineage, the roadmap discipline requires TasteGate and ground-compiler evidence before the chapter leaves seed-level closure; the displayed route supplies exactly that evidence and excludes a hand-written global normalization replacement. □

Theorem 892.91 (MetaCIC normalization frontier discharge route)**.** *The candidate evidence rows C, K, endpoint rows E, N, obstruction row S, and ground-compiler rows H, R, P, L jointly discharge any* MetaCICNormalizationFrontier$^{\uparrow}$ *normalization-frontier consumer through the displayed packet. The discharge exports neither a hidden normalizer nor a host strong-normalization theorem, erased subject-reduction transport, or quotient-level term equality.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierDischargeRoute`

Proof. Start with the TasteGate route of Definition 892.90. It requires any promotion beyond the seed and scaffold boundary to cite $C, K, E, N, S, H, R, P, L$ together, so the consumer cannot isolate candidate evidence from endpoints, obstruction accounting, or the ground-compiler rows.

Now apply the ground-compiler route of Definition 892.89. That route reads the carrier, candidate-evidence boundary, and root normal-form boundary before exporting any normalization boundary, and it states the same exclusions for hidden normalizers, host normalization, erased subject-reduction transport, and quotient-level term equality.

Finally read the formal-target rows cited in the TasteGate proof, especially carrier coverage, classifier totality, and ledger nonescape. These rows keep the discharge attached to the finite packet rather than to an ambient normalizer. Hence the listed rows jointly discharge the local frontier consumer while preserving the chapter's no-hidden-input boundary. □

Definition 892.92 (MetaCIC normalization frontier ground-compiler formal target)**.** *A ground-compiler formal target for* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *is a finite packet*

$$F = (C, K, E, N, S, H, R, P, L)$$

whose carrier rows C, K *display candidate evidence, whose endpoint rows* E, N *display finished-normal evidence, whose obstruction row* S *retains subject-reduction failure data, whose ground-compiler rows* H, R *record recognition and replay, whose provenance row* P *names the source packet, and whose local ledger* L *binds the exported normalization boundary to the same displayed rows.*

Lean4 (definition) `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierGroundCompilerF`

Theorem 892.93 (MetaCIC normalization frontier ground-compiler target scope)**.** *Any formal target for the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *normalization frontier must read candidate evidence* C, K*, finished-normal endpoint evidence* E, N*, obstruction retention* S*, and ground-compiler rows* H, R, P, L *before exporting a normalization boundary. A target that exports the boundary without those rows is outside the displayed ground-compiler packet and does not inhabit the local formal-target surface.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierGroundCompilerTargetSco`

Proof. Begin with the ground-compiler route of Definition 892.89. It requires a consumer to read the carrier surface, candidate evidence, and root normal-form boundary before any normalization boundary is exported.

Next apply the TasteGate route in Definition 892.90. It keeps every promotion beyond the seed and scaffold boundary attached to $C, K, E, N, S, H, R, P, L$ and excludes a hand-written global normalization claim or hidden normalizer.

Finally use the discharge route of Definition 892.91. The discharge theorem joins candidate evidence, endpoint evidence, obstruction retention, and ground-compiler rows into the same packet, so the formal target of Definition 892.92 has exactly the stated scope. □

Theorem 892.94 (MetaCIC normalization frontier candidate-discharge stability)**.** *Let* $F = (C, K, E, N, S, H, R, P$ *be an accepted* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *carrier whose ground-compiler route of Definition 892.89 and TasteGate route of Definition 892.90 are displayed. If* F' *is obtained from* F *by component-wise* hsame *transport of* $C, K, E, N, S, H, R, P, L$ *and by displayed* Cont *replay of the same ground-compiler recognition and discharge rows, then* F' *preserves the same candidate-mediated discharge boundary. In particular, the transported packet may export only the local candidate evidence, endpoint evidence, obstruction-retention, route, replay, provenance, and ledger rows already visible in* F*; it does not acquire strong normalization, confluence, erased subject-reduction transport, quotient-level term equality, or a hidden normalizer.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCandidateDischargeStabi`

Proof. Start with the ground-compiler route. It makes the carrier surface, candidate-evidence boundary, and root normal-form boundary visible before any normalization boundary is exported.

Next use the TasteGate route. It requires the same rows $C, K, E, N, S, H, R, P, L$ for any promotion beyond the seed and scaffold boundary, so componentwise hsame transport can only rename displayed rows and cannot introduce a hidden normalizer or a global normalization assertion.

Now apply the discharge route and the target-scope theorem. The discharge route joins candidate evidence, endpoint evidence, obstruction retention, and ground-compiler rows inside the packet, while the target-scope theorem excludes targets that export a boundary without those rows.

Finally replay the displayed Cont route for F'. Since the replay reads exactly the transported recognition and discharge rows, the candidate-mediated boundary is preserved, and none of the excluded strong-normalization, confluence, subject-reduction, quotient-equality, or hidden-normalizer claims is added. □

Theorem 892.95 (MetaCIC normalization frontier residual-premise retention)**.** *Let $F = (C, K, E, N, S, H, R, P, L$ be an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet. Any candidate-mediated discharge that preserves the ground-compiler route must retain the obstruction row S as a visible residual premise until a separate subject-reduction row is supplied. The route may export candidate evidence, endpoint evidence, ground-compiler recognition, replay, provenance, and local ledger data, but it may not export hidden normalization, full strong normalization, confluence, erased subject reduction, quotient term equality, or a hidden normalizer.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierResidualPremiseRetentio`

Proof. Begin with the ground-compiler route of Definition 892.89. It requires a consumer to read the carrier surface, candidate-evidence route, and root normal-form boundary before any normalization boundary is exported.

Next apply the TasteGate route of Definition 892.90. That route keeps $C, K, E, N, S, H, R, P, L$ visible together, so the obstruction row S cannot be silently erased by a promotion that still claims to use the displayed frontier packet.

Use the discharge route of Definition 892.91. It joins candidate evidence, endpoint evidence, obstruction accounting, and ground-compiler rows in one packet, and it excludes hidden normalizers, host strong-normalization theorems, erased subject-reduction transport, and quotient-level term equality.

Finally apply candidate-discharge stability from Definition 892.94. Componentwise hsame transport and displayed Cont replay preserve exactly the same boundary, so the transported discharge still retains S until an independent subject-reduction row is displayed. □

Theorem 892.96 (MetaCIC normalization frontier subject-reduction residual budget)**.** *Let $F = (C, K, E, N, S, H, R, P, L)$ be an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet whose ground-compiler route is preserved. The subject-reduction obstruction row S remains a visible residual budget row until a separate subject-reduction certificate is supplied. Candidate evidence C, K, endpoint evidence E, N, and ground-compiler rows H, R, P, L may be consumed only as their displayed rows; they cannot be retyped as subject reduction, strong normalization, confluence, quotient term equality, evaluator equality, or a hidden normalizer.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierSubjectReductionResidua`

Proof. Begin with the ground-compiler route of Definition 892.89. It forces every normalization-boundary consumer to read the carrier surface, candidate-evidence route, and endpoint boundary before exporting any ground-compiler-facing result.

Apply the TasteGate and discharge routes of Definition 892.90 and Definition 892.91. These routes keep $C, K, E, N, S, H, R, P, L$ visible as separate rows, so the candidate and endpoint evidence cannot be promoted into subject reduction or a stronger normalization theorem.

Use candidate-discharge stability from Definition 892.94. Componentwise hsame transport and displayed Cont replay preserve the same row family, including the distinction between candidate evidence, endpoints, obstruction accounting, and ground-compiler replay.

Finally apply residual-premise retention from Definition 892.95. Since S is the only displayed subject-reduction obstruction row and no other coordinate has the required type, row exhaustion leaves S as an ordinary residual budget row until an independent subject-reduction certificate is supplied. □

Theorem 892.97 (MetaCIC normalization frontier ground-compiler readback)**.** *Let $F = (C, K, E, N, S, H, R, P, L$ be an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *carrier. Any normalization-frontier readback consumed by a MetaCIC audit or TasteGate consumer must pass through candidate evidence C, K, endpoint evidence E, N, residual premise S, and the ground-compiler rows H, R, P, L. Componentwise* hsame *transport and displayed* Cont *replay preserve that readback, and the route exports no strong normalization, confluence, erased subject reduction, quotient term equality, or hidden normalizer.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierGroundCompilerReadback`

Proof. Begin with the ground-compiler route of Definition 892.89. It requires every normalization-boundary consumer to read the carrier surface, candidate-evidence route, and root normal-form boundary before any frontier readback is exported.

Next apply the TasteGate route and discharge route of Definition 892.90 and Definition 892.91. These rows keep $C, K, E, N, S, H, R, P, L$ visible together, so an audit-facing readback cannot separate candidate evidence from endpoints, residual obstruction accounting, recognition, replay, provenance, or the local ledger.

Use candidate-discharge stability from Definition 892.94. Componentwise hsame transport only renames the displayed rows, and displayed Cont replay replays the same recognition and discharge route for the transported packet.

Finally retain the residual premise by Definition 892.95. Since S remains visible until a separate subject-reduction row is supplied, the readback exports none of the excluded strong-normalization, confluence, erased subject-reduction, quotient-equality, or hidden-normalizer claims. □

Theorem 892.98 (MetaCIC normalization frontier formal-target contract)**.** *Any formal target consumed from an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet must expose candidate evidence rows C, K, finished-normal endpoint rows E, N, residual premise S, and ground-compiler rows H, R, P, L before it may export a normalization boundary. A target is outside the contract if it drops S or replaces these rows by hidden strong normalization, confluence, erased subject reduction, quotient term equality, or a hidden normalizer.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierFormalTargetContract`

Proof. Begin with the ground-compiler route of Definition 892.89. It requires a consumer to read the carrier surface, candidate-evidence route, and root normal-form boundary before any normalization boundary is exported.

Apply the TasteGate route of Definition 892.90 and the discharge route of Definition 892.91. Together they keep $C, K, E, N, S, H, R, P, L$ visible as one packet rather than allowing a formal target to cite an ambient normalization principle.

Use candidate-discharge stability from Definition 892.94. Componentwise hsame transport and displayed Cont replay preserve the candidate-mediated discharge boundary and do not add confluence, erased subject reduction, quotient term equality, or a hidden normalizer.

Finally apply Definition 892.95 and Definition 892.97. The residual premise S remains visible until a separate subject-reduction row is supplied, and the readback exports the normalization boundary only through the displayed ground-compiler rows. Hence any target that drops S or substitutes hidden strong normalization lies outside the local contract. □

Theorem 892.99 (MetaCIC normalization frontier certificate-router handoff)**.** *Every accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet whose frontier rows name closed-normal candidates, bounded reduction windows, residual obstruction data, and classifier-stable proof certificates can be consumed by the normalization-certificate router only after those rows remain visible under* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *transport. The handoff refuses unconditional strong normalization, unrestricted confluence, and host equality.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierCertificateRouterHandof`

Proof. Project the carrier of Definition 892.1. Candidate evidence, endpoint evidence, residual obstruction, route recognition, replay, provenance, and local ledger rows are the only rows available to a router-facing consumer.

Use the ground-compiler route of Definition 892.89 and the target scope of Definition 892.93. They force every normalization-boundary read through the displayed carrier, candidate-evidence boundary, endpoint boundary, and ground-compiler rows before any certificate is exported.

Apply candidate-discharge stability, residual-premise retention, and ground-compiler readback. These theorems keep the same rows visible under componentwise hsame transport and displayed Cont replay, with Pkg provenance and the local NameCert ledger still attached to the packet.

The certificate router therefore receives only the displayed closed-normal candidate data, bounded window data, residual obstruction row, and classifier-stable proof certificate rows. Since no carrier coordinate stores unconditional strong normalization, unrestricted confluence, or host equality, the handoff cannot export those claims. □

Theorem 892.100 (MetaCIC normalization frontier L10 candidate-discharge route)**.** *Every candidate-normalization discharge read of an accepted* MetaCICNormalizationFrontier$^{\uparrow}$ *packet must display the four L10 Real and Completion source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

before the frontier rows are consumed as a normalization-facing discharge. The read must also pass through the existing normalization audit and closed-normal route siblings, including chapter 750, chapter 777, chapter 858, Definition 892.89, and Definition 892.91. The route exports no full strong normalization, global confluence, beta-conversion decidability, quotient term equality, selected limits, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetaCICNormalizationFrontierUp.MetaCICNormalizationFrontierL10CandidateDischargeRo`

Proof. Start with the displayed carrier $F = (C, K, E, N, S, H, R, P, L)$. The candidate rows C, K can be consumed only through the same frontier packet that also displays endpoint evidence, obstruction retention, replay, provenance, and local naming.

Read the ground-compiler route and the discharge route. They force the normalization-facing consumer through the carrier, candidate-evidence boundary, endpoint boundary, residual obstruction, and closed-normal handoff before any discharge is public.

Now attach the L10 faces as source rows for the discharge. $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the finite tolerance ledger, $\mathsf{StreamName}^{\uparrow}$ supplies finite observation windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular rational readback, and $\mathsf{Real}^{\uparrow}$ supplies the terminal Real seal. These faces are source displays, not selected limits or ambient completeness principles.

Finally use the audit and closed-normal route siblings named in the statement. They keep the candidate discharge tied to finite audit, seal, and route rows, so the consumer cannot replace it by full strong normalization, global confluence, beta-conversion decidability, quotient term equality, selected limits, or Real completeness. □

Chapter 893

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailFiber}^{\uparrow}$

The $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ packet records the common finite tail-fiber classifier used when two regular Cauchy source tails must feed one $\mathsf{Real}^{\uparrow}$ seal boundary. It sits between the shared-tail threshold packet of chapter 560, the tail-agreement seal of chapter 699, the finite stream windows of chapter 126, and the regular rational carrier of chapter 301. The packet is a Real-and-Completion diagonal route component; it is not a quotient of streams, a host real equality, or an ambient completeness principle.

Falsifiable prediction: If the shared tail fiber row is removed, the packet cannot factor both $\mathsf{RealTailAgreementSeal}^{\uparrow}$ and $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ consumer reads through one finite $\mathsf{Real}^{\uparrow}$ seal route.

Independence witness: regular-cauchy-tail-meet, realtailagreementseal, regularcauchytailfusion, modulus-indexed-tail-cover: these siblings expose threshold, agreement, fusion, or cover rows, while $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ exposes the common fiber classifier tying the two source tails to one $\mathsf{Real}^{\uparrow}$ seal boundary.

Definition 893.1 (Regular Cauchy tail fiber carrier)**.** *A* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose late regular-rational tails are being compared;*
2. W_0 *and* W_1 *are the finite* $\mathsf{StreamName}^{\uparrow}$ *windows through which the two source rows are observed;*
3. D_0 *and* D_1 *are* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-radius ledgers for the two observed tails;*
4. T *is the shared tail fiber row classifying the two source tails as one finite tail boundary;*
5. A *is the* $\mathsf{Real}^{\uparrow}$ *tail-agreement seal row reached through the shared fiber;*
6. H *records componentwise* hsame *transport for the source rows, windows, dyadic ledgers, shared fiber, seal, replay route, provenance, and local name;*
7. C *records displayed* Cont *routes for reading both source tails, both windows, both dyadic ledgers, the shared fiber row, and the seal row;*

8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFiber}^{\uparrow}}$ *row.*

The carrier accepts only packets whose two regular Cauchy source tails meet in the displayed shared fiber row before any $\mathsf{Real}^{\uparrow}$ *seal is read. It contains no quotient stream, no host real equality, no selected limit, and no completion theorem beyond the finite seal boundary.*

Theorem 893.2 (Regular Cauchy tail fiber NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFiber}^{\uparrow}}$ *surface consists exactly of source-row exposure for R_0, R_1, finite-window exposure for W_0, W_1, dyadic tail-radius exposure for D_0, D_1, shared tail-fiber exposure for T,* $\mathsf{Real}^{\uparrow}$ *tail-agreement seal exposure for A, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 893.1. The first six rows expose exactly the two source tails, their finite observation windows, and their dyadic tail-radius ledgers.

Next read the common fiber row T. This is the only row that identifies the two late-tail observations as one finite tail boundary before the seal row is available.

Finally read A, H, C, P, N. The seal row is reached only after the shared fiber has been displayed, and the transport, continuation, provenance, and naming rows replay that same finite packet. Thus the local NameCert obligations are exhausted by the listed carrier coordinates. □

Theorem 893.3 (Regular Cauchy tail fiber window projection)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read of an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier factors through the finite projection*

$$(R_0, R_1, W_0, W_1, D_0, D_1, T).$$

The read cannot reach the $\mathsf{Real}^{\uparrow}$ *tail-agreement seal row A without first passing through the shared tail fiber row T and the displayed continuation route C.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberWindowProjection changes packet`

Proof. Start with a source-facing consumer. Projection exposes R_0, R_1 as the only regular-rational source rows and W_0, W_1 as the only finite stream-name windows attached to them.

The dyadic-radius ledgers D_0, D_1 are then read at those same windows. A consumer has no separate radius or tolerance row outside the displayed packet.

The seal-facing step is forced through T and C. Since A is attached to the shared fiber route, a consumer cannot bypass the common fiber and read a detached $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 893.4 (Regular Cauchy tail fiber shared seal factorization)**.** *For an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier $F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$, the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *consumer route and the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *consumer route share the same finite factorization through T before reaching the* $\mathsf{Real}^{\uparrow}$ *seal row A.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiber shared fiber route changes packet`

Proof. Read the tail-meet side first. The meet route consumes $R_0, R_1, W_0, W_1, D_0, D_1$ and then exposes the shared threshold boundary as the fiber row T.

Read the tail-agreement side next. Its seal route uses the same T as the finite agreement boundary before the $\mathsf{Real}^{\uparrow}$ seal row A is available.

The administrative rows H, C, P, N transport, replay, package, and name this one route. Since no second fiber coordinate is present, both consumer routes factor through the same shared row. □

Theorem 893.5 (Regular Cauchy tail fiber non-escape)**.** *Every downstream read of an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *packet remains inside*

$$R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N.$$

It exports no quotient stream equality, no host real equality, no selected limit, no countable-choice selector, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier. The only source, window, radius, common-fiber, and seal rows are the coordinates listed in Definition 893.1.

Use the window projection and shared seal factorization. Any consumer first reads the two finite windows and dyadic-radius ledgers, then reaches the common fiber T, and only then reaches the seal row A.

Inspect the excluded data. No coordinate stores quotient stream equality, host real equality, a selected limit, choice, or ambient completeness. The packet therefore cannot export such data to a downstream Real-and-Completion route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberPacket nonescape`

Theorem 893.6 (Regular Cauchy tail fiber follow-up TasteGate contract)**.** *The Lean TasteGate follow-up for* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *must provide* $\mathsf{Nontrivial}\ \mathsf{RegularCauchyTailFiber}^{\uparrow}$ *and* $\mathsf{FieldFaithful}\ \mathsf{RegularCauchyTailFiber}^{\uparrow}$ *instances whose witnesses include an explicit* $\mathsf{witness_pair}$ *and constructor-field injection proofs for the two source rows, two windows, two dyadic-radius ledgers, shared fiber, seal row, transport, continuation, provenance, and local naming fields.*

Proof. The carrier has twelve displayed fields, and each field is observable by a NameCert obligation or by the non-escape boundary. A nontrivial instance must therefore exhibit two distinguishable accepted packets through a concrete witness pair rather than by host equality.

Field faithfulness must then inspect constructor fields. If two accepted packets agree under the public classifier, the proof has to inject through the source rows, windows, dyadic ledgers, fiber row, seal row, and administrative rows separately.

These are precisely the fields used by the window projection, shared seal factorization, and non-escape theorems. The TasteGate follow-up is therefore a fieldwise carrier proof for this packet, not a quotient-stream or host-real argument. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberTasteGate single carrier alignment`

Theorem 893.7 (Regular Cauchy tail fiber classifier stability)**.** *For an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N),$$

componentwise hsame *transport through the row H preserves the common fiber classifier on $R_0, R_1, W_0, W_1, D_0, D_1,$ In particular, a transported read still classifies the two regular Cauchy source tails through the same finite row T before reaching the* $\mathsf{Real}^{\uparrow}$ *seal row A, and the transport introduces neither quotient-stream equality nor host-real equality.*

Proof. Project the carrier of Definition 893.1. The row H is displayed as componentwise hsame transport for the two source rows, the two windows, the two dyadic ledgers, the shared fiber row, and the seal row.

Apply the window projection of Definition 893.3. Any source-facing read reaches $R_0, R_1, W_0, W_1, D_0, D_1$ before it can see a seal-facing row, so the transported classifier has the same finite source and window support.

Apply the shared seal factorization of Definition 893.4. The tail-meet route and the tail-agreement route both pass through the same row T before A is available.

Finally use non-escape from Definition 893.5. Since the accepted packet contains no quotient-stream equality and no host-real equality, componentwise transport along H cannot export either kind of equality. □

Theorem 893.8 (Regular Cauchy tail fiber paired-window exactness)**.** *For an accepted* RegularCauchyTailFiber$^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N),$$

every RegularCauchyTailMeet$^{\uparrow}$ *read and every* RealTailAgreementSeal$^{\uparrow}$ *read factors through the same finite tuple*

$$(R_0, R_1, W_0, W_1, D_0, D_1, T).$$

Thus the BEDC correspondence between the regular-tail meet route and the real-tail agreement route is witnessed by one paired-window tuple, not by an external equality of streams or host reals.

Proof. Start with a RegularCauchyTailMeet$^{\uparrow}$ consumer. By Definition 893.3, its source and window observations are exactly the two regular-rational rows, the two finite stream windows, and the two dyadic ledgers, followed by the shared fiber row T.

Now read a RealTailAgreementSeal$^{\uparrow}$ consumer. By Definition 893.4, the seal route uses the same shared fiber row T before it reaches the seal row A.

The two reads therefore have identical finite support up to T. The remaining rows H, C, P, N transport, replay, package, and name that support, so the correspondence is the displayed BEDC route through the paired-window tuple. □

Theorem 893.9 (Regular Cauchy tail fiber seal-consumer exhaustion)**.** *For an accepted* RegularCauchyTailFiber$^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N),$$

all downstream reads by RegSeqRat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegularCauchyTailMeet$^{\uparrow}$*,* RealTailAgreementSe *and* Real$^{\uparrow}$ *consumers remain inside*

$$R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N.$$

No listed consumer can read a detached source tail, detached stream window, detached dyadic radius, second fiber row, external seal, quotient-stream witness, host-real witness, selected limit, or ambient completeness theorem.

Proof. Use the carrier projection and the NameCert obligations of Definition 893.2. The only exposed rows are the two source rows, two windows, two dyadic ledgers, shared fiber, seal, transport, continuation, provenance, and local name.

For RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, and DyadicRatCore$^{\uparrow}$ consumers, apply Definition 893.3. Their reads are exhausted by $R_0, R_1, W_0, W_1, D_0, D_1, T$ before any seal boundary is available.

For RegularCauchyTailMeet$^{\uparrow}$, RealTailAgreementSeal$^{\uparrow}$, and Real$^{\uparrow}$ consumers, apply Definition 893.4 and Definition 893.5. The shared seal route reaches A only through T, and the packet exports no further equality, selector, or completeness data. □

Theorem 893.10 (Regular Cauchy tail fiber Real-completion route coverage)**.** *For an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N),$$

every current Real-and-Completion consumer route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *factors through the paired-window route*

$$R_0, R_1, W_0, W_1, D_0, D_1 \longmapsto T \longmapsto A$$

before any Real seal is read, together with the displayed transport, continuation, provenance, and local naming rows H, C, P, N*. The route-coverage surface exports no quotient stream, host real equality, selected limit, countable-choice selector, or ambient completeness theorem.*

Proof. Start with the window projection of Definition 893.3. It makes the two regular-rational rows, two stream windows, and two dyadic ledgers the only source route available before a seal-facing row can be reached.

Next apply shared seal factorization and seal-consumer exhaustion from Definition 893.4 and Definition 893.9. These place the shared fiber row T before the seal row A for each listed Real-and-Completion consumer.

Finally use classifier exactness and source-swap stability from Definition 893.11 and Definition 893.15. The classifier can only replay the displayed paired-window, fiber, seal, transport, continuation, provenance, and local naming rows, so no quotient stream, host equality, selector, choice row, or completeness theorem is exported. □

Theorem 893.11 (Regular Cauchy tail fiber classifier exactness)**.** *For accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carriers*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

and

$$F' = (R'_0, R'_1, W'_0, W'_1, D'_0, D'_1, T', A', H', C', P', N'),$$

the local classifier can identify the two packets only through common $\mathsf{StreamName}^{\uparrow}$ *windows, transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-radius rows, the shared fiber row, and the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *seal row. In particular, classifier agreement is exhausted by displayed agreement of* W_0, W_1, D_0, D_1, T, A *with* $W'_0, W'_1, D'_0, D'_1, T', A'$ *under the available* hsame *transports, and it does not use quotient equality of streams or host real equality.*

Proof. Project both carriers through Definition 893.1. The only rows available to the local classifier are the two source rows, two finite windows, two dyadic ledgers, shared fiber, seal, transport, continuation, provenance, and local name.

Apply the window projection of Definition 893.3. Any source-facing classification must first pass through the common finite windows and their dyadic tail-radius ledgers before a seal-facing row can be observed.

Use the classifier stability and paired-window exactness rows. The hsame transports in H and H' carry the displayed window, radius, fiber, and seal coordinates component by component, while the shared fiber row T is the unique route from the paired windows to the seal row A.

Finally apply non-escape. Since neither accepted packet contains quotient stream equality or host real equality, no such equality can participate in the classifier. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberPacket classifier exactness`

Theorem 893.12 (Regular Cauchy tail fiber RegSeqRat Real handoff lock)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *packet*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

must read the packet through the ordered handoff

$$R_0, R_1 \longrightarrow W_0, W_1 \longrightarrow D_0, D_1 \longrightarrow T \longrightarrow A.$$

Here R_0, R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows,* W_0, W_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *windows,* D_0, D_1 *are the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers,* T *is the shared tail-fiber row, and* A *is the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *row consumed at the* $\mathsf{Real}^{\uparrow}$ *boundary. The handoff cannot bypass these rows by using host real equality, quotient stream equality, selected limits, choice-like selectors, or ambient completeness.*

Proof. Project the carrier of Definition 893.1. The accepted packet exposes exactly the two source rows, two windows, two dyadic ledgers, shared fiber, seal row, transports, continuation, package provenance, and local $\mathsf{NameCert}$ row.

Apply the NameCert obligations and window projection from Definition 893.2 and Definition 893.3. They force any source-facing read to start at the two $\mathsf{RegSeqRat}^{\uparrow}$ rows and pass through the displayed $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ ledgers.

Use shared seal factorization and classifier exactness from Definition 893.4 and Definition 893.11. The common tail-fiber row T is the route from the window-ledger surface to the seal row A, and the classifier has no quotient-stream or host-real coordinate.

Close with non-escape from Definition 893.5. Since the packet exports no selected limit, choice-like selector, ambient completeness theorem, host real equality, or quotient stream equality, every $\mathsf{Real}^{\uparrow}$-facing handoff remains locked to the displayed ordered row sequence. □

Theorem 893.13 (Regular Cauchy tail fiber tail-agreement seal exactness)**.** *Let*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *packet. The tail-agreement seal consumed by* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *is exactly the displayed row* A *reached through the shared fiber row* T *from the paired windows and dyadic ledgers. No detached seal row, external tail-agreement certificate, quotient stream equality, host real equality, selected limit, or ambient completeness witness can replace* A*.*

Proof. Start from the carrier and the local $\mathsf{NameCert}$ obligations. They list a single seal row A together with the paired source, window, dyadic, fiber, transport, continuation, package, and name rows.

Use the window projection to identify the two source rows through W_0, W_1 and D_0, D_1. The seal-facing route therefore begins with the same displayed finite support as the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ consumers.

Apply shared seal factorization. It sends the paired window-ledger support through the common tail-fiber row T before the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ row is reachable, so the consumed seal is the displayed row A reached through T.

Finally combine classifier exactness with non-escape. The classifier has no detached seal coordinate, and the packet exports no quotient-stream equality, host real equality, selected limit, or ambient completeness witness; hence there is no second seal available to the consumer. □

Theorem 893.14 (Regular Cauchy tail fiber completion consumer nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *packet receives only the packet rows*

$$R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N.$$

In particular, the consumer receives no selected limit, choice-like selector, ambient completeness theorem, quotient stream equality, host equality of reals, detached tail, detached window, detached dyadic ledger, second fiber, or detached tail-agreement seal.

Proof. Project the carrier and read the NameCert obligations. The completion-facing surface is the displayed finite tuple: two $\mathsf{RegSeqRat}^{\uparrow}$ rows, two $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{DyadicRatCore}^{\uparrow}$ ledgers, one shared fiber row, one tail-agreement seal row, and the structural rows.

Apply window projection and shared seal factorization. They route all source, window, dyadic, tail meet, and seal reads through $R_0, R_1, W_0, W_1, D_0, D_1, T, A$ before any completion-facing consumer can inspect the packet.

Use classifier exactness to keep the local classifier on the displayed window, ledger, fiber, and seal rows. The classifier supplies no quotient stream coordinate and no host real coordinate.

Finally invoke non-escape. Since the carrier contains no selected limit, choice-like selector, ambient completeness theorem, host equality, detached tail, detached window, detached ledger, second fiber, or detached seal, the completion-facing consumer cannot receive any such datum. □

Theorem 893.15 (Regular Cauchy tail fiber source-swap stability)**.** *For an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N),$$

the packet obtained by swapping the two source rows together with their $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers,*

$$F^{\mathrm{op}} = (R_1, R_0, W_1, W_0, D_1, D_0, T, A, H, C, P, N),$$

has the same shared fiber route T *and reaches the same* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *row* A *through the same* Cont, Pkg, *and* NameCert *route. The source swap changes only the displayed order of the two source-window-radius triples; it does not create quotient-stream equality, host real equality, selected limits, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberPacket source swap stability`

Proof. Project the carrier of Definition 893.1. The source-facing coordinates occur as the two triples (R_0, W_0, D_0) and (R_1, W_1, D_1), while the fiber, seal, continuation, provenance, and local-name rows are the shared coordinates T, A, C, P, N.

Apply window projection from Definition 893.3. Reading the original order or the swapped order exposes the same two source-window-radius triples before either read reaches a seal-facing row.

Use shared seal factorization and paired-window exactness from Definition 893.4 and Definition 893.8. Both source orders pass through the common fiber row T before reaching the seal row A, and the continuation and package rows are reused without adding a second route.

Finally apply classifier exactness and non-escape from Definition 893.11 and Definition 893.5. The classifier sees only the displayed window, dyadic ledger, fiber, and seal coordinates, so the swap cannot introduce quotient-stream equality, host real equality, selected limits, or ambient completeness. □

Theorem 893.16 (Regular Cauchy tail fiber componentwise transport)**.** *For an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N),$$

componentwise hsame *transport of*

$$R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N$$

preserves carrier admission and preserves the local classifier on the transported packet. The transported carrier is read through the same displayed H *and* C *rows, so every source, window, radius, fiber, seal, provenance, and local-name coordinate remains part of the same finite packet.*

Proof. Start with the carrier projection. The row H is part of the accepted packet and lists componentwise hsame transport for every coordinate that the packet exposes.

Replay the displayed continuation row C. The transported source rows, windows, dyadic ledgers, shared fiber, and seal are read in the same order as the original carrier, so carrier admission is preserved by rebuilding the finite tuple with transported coordinates.

Apply classifier stability. Because the classifier reads only the window, radius, fiber, and seal coordinates transported by H, the transported packet has the same local classifier support and cannot introduce an external classifier coordinate. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberPacket componentwise transport`

Theorem 893.17 (Regular Cauchy tail fiber ledger exhaustion)**.** *Every downstream Real-and-Completion consumer of an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

is exhausted by the finite rows

$$R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N.$$

Such a consumer cannot read quotient stream equality, a selected limit, choice, ambient completeness, or host real equality from the packet.

Proof. Use the shared seal factorization of Definition 893.4. Every $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ or $\mathsf{RealTailAgreementSeal}^{\uparrow}$ route passes through the same shared fiber row T before it can reach the seal row A.

Apply the seal-consumer exhaustion theorem. The downstream Real-and-Completion consumers listed there are already confined to the two source rows, two windows, two dyadic ledgers, shared fiber, seal, transport, continuation, provenance, and local name.

Finish with non-escape. The carrier contains no quotient stream equality, selected limit, choice row, ambient completeness theorem, or host real equality, so none of these can be exported to a downstream consumer. □

Theorem 893.18 (Regular Cauchy tail fiber seal totality)**.** *Every* $\mathsf{RealTailAgreementSeal}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

is total exactly on

$$R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N.$$

The consumer reads no detached source row, detached window, second dyadic ledger, second fiber, external seal, selected limit, quotient stream equality, host real equality, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberPacket seal totality`

Proof. Start with paired-window exactness. It identifies the common support for $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ and $\mathsf{RealTailAgreementSeal}^{\uparrow}$ reads as the two source rows, two windows, two dyadic ledgers, and the shared fiber row T.

Apply shared seal factorization and seal-consumer exhaustion. The seal-facing consumers reach A only through the same finite packet, and the Real-facing consumers named there do not leave $R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N$.

Use classifier exactness to keep the visible classifier on the displayed window, ledger, fiber, and seal rows. This prevents a seal consumer from creating an additional source, window, dyadic ledger, or fiber coordinate.

Finally apply ledger exhaustion. The downstream Real-and-Completion route is already exhausted by the displayed tuple, so no selected limit, quotient stream equality, host real equality, or ambient completeness witness is exported. □

Theorem 893.19 (Regular Cauchy tail fiber source-seal ledger totality)**.** *Every accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

exposes exactly the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows* R_0, R_1*, the two* $\mathsf{StreamName}^{\uparrow}$ *windows* W_0, W_1*, the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-radius ledgers* D_0, D_1*, the shared fiber row* T*, the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row* A*, and the structural rows* H, C, P, N*. No other source, window, dyadic ledger, fiber, seal, transport, continuation, package, or local NameCert row is available to a consumer of the carrier.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberPacket source seal ledger totality`

Proof. Project the carrier of Definition 893.1. Its displayed coordinates list the two regular-rational source rows, the two stream windows, the two dyadic tail-radius ledgers, the shared fiber row, the seal row, and the four structural rows.

Use the NameCert obligations of Definition 893.2. They identify the same coordinates as the whole local certificate surface, so a consumer cannot obtain a detached source, window, ledger, fiber, or seal row from the local name.

Finally apply ledger exhaustion from Definition 893.17. Every downstream Real-and-Completion read is confined to the same finite list, which gives totality for the source-to-seal ledger. □

Theorem 893.20 (Regular Cauchy tail fiber window-fiber classifier coverage)**.** *Every local classifier read of an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier is covered by the paired windows* W_0, W_1*, the dyadic ledgers* D_0, D_1*, the shared fiber row* T*, and the seal row* A*. The classifier has no quotient stream coordinate and no host-real coordinate.*

Proof. Begin with the window projection of Definition 893.3. Any source-facing classifier read reaches the two source rows through the paired windows and their dyadic ledgers before it can see a seal-facing row.

Next use classifier stability and paired-window exactness from Definition 893.7 and Definition 893.8. These results keep the transported classifier on the same finite window, ledger, and fiber support.

Finally apply classifier exactness from Definition 893.11. The only equality data available to the classifier is displayed agreement of the window, ledger, fiber, and seal coordinates under componentwise transport, so quotient streams and host reals are outside its coverage. □

Theorem 893.21 (Regular Cauchy tail fiber completion handoff scope)**.** *Every downstream Real-and-Completion handoff from an accepted* $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier factors through*

$$(R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

before reaching the $\mathsf{Real}^{\uparrow}$ *seal boundary. The handoff cannot claim selected limits, ambient completeness, quotient streams, or host equality.*

Proof. Use the shared seal factorization of Definition 893.4. Both the regular-tail meet route and the tail-agreement route pass through the same shared fiber row T before the seal row A is reachable.

Apply seal-consumer exhaustion from Definition 893.9. The Real-and-Completion consumers named there read only the two source rows, two windows, two dyadic ledgers, shared fiber, seal, and structural rows.

Close with ledger exhaustion from Definition 893.17. Since the packet exports no selected limit, ambient completeness theorem, quotient stream equality, or host real equality, the handoff scope stops at the finite tuple and the seal boundary. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberPacket completion handoff scope`

Theorem 893.22 (Regular Cauchy tail fiber shared-window seal determinacy)**.** *Let*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

and

$$F' = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

be accepted $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carriers with the same displayed source rows, windows, dyadic ledgers, shared fiber, seal row, transports, continuations, package provenance, and local* $\mathsf{NameCert}$ *row. Every* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal read available from either carrier factors through the same finite shared-window route*

$$(W_0, W_1, D_0, D_1) \longrightarrow T \longrightarrow A$$

before it reaches the seal row A. No quotient stream, host equality, selected limit, or ambient completeness coordinate can distinguish the two seal routes.

Proof. Project the displayed rows of the two carriers. Since the tuples show the same $R_0, R_1, W_0, W_1, D_0, D_1, T, H, C$ rows, any source-facing read begins with the same finite support.

Use the window projection of Definition 893.3. It pins each source row to the corresponding displayed window and dyadic ledger, so the two carriers expose the same W_0, W_1, D_0, D_1 window surface before any seal-facing route is reached.

Apply shared seal factorization from Definition 893.4. The seal route must pass through the common fiber row T before it can reach A, so the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readings have the same finite path through the shared fiber.

Finally combine completion handoff scope with non-escape from Definition 893.21 and Definition 893.5. These results rule out detached seal paths, quotient-stream equality, host equality, selected limits, and ambient completeness coordinates; hence no external coordinate can separate the two displayed seal routes. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberPacket shared window seal determinacy`

Theorem 893.23 (Regular Cauchy tail fiber source non-escape)**.** *Every source-facing read of an accepted* RegularCauchyTailFiber$^{\uparrow}$ *packet that is later consumed by* RegularCauchyTailMeet$^{\uparrow}$, RealTailAgreementSeal$^{\uparrow}$, *or* Real$^{\uparrow}$ *remains inside*

$$R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N.$$

The packet exports no detached source tail, detached StreamName$^{\uparrow}$ *window, second fiber row, quotient stream witness, host-real witness, selected limit, or ambient completeness theorem.*

Proof. Project the carrier of Definition 893.1. Its source-facing data are exactly the two source rows, paired windows, dyadic ledgers, shared fiber row, seal row, and structural rows displayed in the theorem.

Apply paired-window exactness from Definition 893.8. Any source read that reaches a downstream meet, tail-agreement seal, or Real consumer must keep the two windows and two dyadic ledgers paired with the same shared fiber row.

Use seal-consumer exhaustion from Definition 893.9 and source-seal ledger totality from Definition 893.19. These rows account for every seal-facing read through $R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N$ before any downstream consumer can inspect the packet.

Finally apply shared-window seal determinacy from Definition 893.22. Since the finite route through the paired windows, ledgers, fiber, and seal row is already determined, no detached tail, detached window, second fiber, quotient witness, host-real witness, selected limit, or ambient completeness theorem can be exported. □

Theorem 893.24 (Regular Cauchy tail fiber meet route)**.** *Every accepted shared-window tail-fiber read of a* RegularCauchyTailFiber$^{\uparrow}$ *packet factors through the displayed* StreamName$^{\uparrow}$ *finite-window rows, the* RegSeqRat$^{\uparrow}$ *classifier rows, the* DyadicRatCore$^{\uparrow}$ *tolerance rows, and the* CauchyLimitSeal$^{\uparrow}$ *completion handoff before it may be consumed as a completion-facing fiber. The route exports no detached tail, detached finite window, second fiber, quotient stream witness, host-real equality, selected limit, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberPacket meet route`

Proof. Project the accepted carrier rows

$$R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N.$$

The two source rows are read only through the displayed windows, dyadic ledgers, shared fiber, seal row, histories, continuations, package provenance, and local naming row.

Apply the window projection theorem Definition 893.3. It places each RegSeqRat$^{\uparrow}$ source read behind the corresponding StreamName$^{\uparrow}$ finite-window row and DyadicRatCore$^{\uparrow}$ tolerance row.

Next use shared-window seal determinacy from Definition 893.22. The two accepted routes therefore meet at the same shared fiber row T before any seal-facing read can reach A.

Transport the classifier componentwise by Definition 893.16, then exhaust the ledger by Definition 893.17. These steps keep the classifier, finite windows, dyadic tolerance rows, and shared fiber on the displayed packet.

Finally apply completion handoff scope from Definition 893.21. The resulting completion-facing fiber is already routed through the finite-window, classifier, tolerance, shared-seal, and CauchyLimitSeal$^{\uparrow}$ handoff surface, so no external coordinate remains available to the consumer. □

Theorem 893.25 (Regular Cauchy tail fiber Real-seal determinacy)**.** *Let*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *packet. Any* $\mathsf{Real}^{\uparrow}$ *seal-facing consumer that agrees with the shared meet route through the displayed fiber row* T *reaches the unique displayed seal row* A*. Such a consumer cannot replace* A *by a second seal, quotient-stream equality, host real equality, selected limit, or ambient completeness witness.*

Proof. Project the carrier of Definition 893.1. The only seal-facing rows displayed by the accepted packet are the paired source rows, paired windows, dyadic ledgers, shared fiber row T, seal row A, transports, continuation, provenance, and local name.

Use the window projection theorem Definition 893.3 and shared seal factorization from Definition 893.4. Together they force every seal-facing read to pass through the displayed windows and then through T before reaching A.

Apply paired-window exactness from Definition 893.8 and classifier exactness from Definition 893.11. These rows identify the two window ledgers and the source classifiers with the same finite meet route, so an agreeing $\mathsf{Real}^{\uparrow}$ consumer has no second path to a different seal coordinate.

Finally invoke the meet route Definition 893.24 and non-escape from Definition 893.5. The meet route supplies the shared route through T, while non-escape excludes detached seal data, quotient-stream equality, host real equality, selected limits, and ambient completeness witnesses. Hence the displayed row A is the unique seal row available to the consumer. □

Theorem 893.26 (Regular Cauchy tail fiber limit-seal functor handoff)**.** *Let*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *packet. Let an accepted* $\mathsf{CauchyLimitFunctor}^{\uparrow}$ *consumer have carrier*

$$G = (S_G, T_G, M_G, W_0^G, W_1^G, R_G, D_G, K_G, E_G, H_G, C_G, P_G, N_G)$$

whose source seal row S_G *reads the same finite tail-agreement row* A*. Then the consumer must factor through the displayed finite route*

$$R_0, R_1 \longmapsto W_0, W_1 \longmapsto D_0, D_1 \longmapsto T \longmapsto A$$

before it can read its transport-map row M_G*, completion-seal classifier row* K_G*, terminal endpoint row* E_G*, or structural rows* H_G, C_G, P_G, N_G*. The handoff exports no quotient-stream equality, host real equality, selected limit, countable-choice selector, detached completion object, or ambient completeness principle.*

Proof. Project the accepted carrier of Definition 893.1. The source rows R_0, R_1 are visible only through their finite windows W_0, W_1 and dyadic ledgers D_0, D_1 before a seal-facing row can be inspected.

Apply the window projection, shared seal factorization, and Real-seal determinacy of Definition 893.3, Definition 893.4, and Definition 893.25. These results force every agreeing Real or seal-facing read through $R_0, R_1, W_0, W_1, D_0, D_1, T, A$, and they make A the only displayed tail-agreement seal reached from T.

Now read the $\mathsf{CauchyLimitFunctor}^{\uparrow}$ side through the carrier boundary of Definition 1116.1 and the consumer boundary of Definition 1116.7. Since its source seal S_G is the same finite row A,

the functor consumer cannot reach its transport-map, completion-classifier, endpoint, or structural rows until it has consumed that source seal along the displayed tail-fiber route.

The non-escape clauses in Definition 893.5, Definition 893.21, and Definition 1116.7 remove quotient-stream equality, host real equality, selected limits, countable-choice selectors, detached completion objects, and ambient completeness from both packets. Therefore the handoff is exactly the finite route through $R_0, R_1, W_0, W_1, D_0, D_1, T, A$ before the functor reads $M_G, K_G, E_G, H_G, C_G, P_G, N_G$. □

Theorem 893.27 (Regular Cauchy tail fiber finite-window Real-seal equivalence)**.** *Let*

$$F = (R_0, R_1, W_0, W_1, D_0, D_1, T, A, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ *carrier. The* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *route through the paired finite windows and the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *seal route describe the same completion-facing read exactly when both factor through the finite tuple*

$$(W_0, W_1, D_0, D_1, T, A)$$

under the displayed hsame *transports carried by* H *and the displayed continuations carried by* C*. This correspondence uses no quotient stream, host real equality, selected limit, or ambient completeness coordinate.*

Proof. Begin with the forward route. Apply the window projection of Definition 893.3; the two source reads are visible only through W_0, W_1 and their dyadic ledgers D_0, D_1 under the displayed transports.

Use shared seal factorization from Definition 893.4. The paired-window read reaches the shared fiber row T before it reaches the seal row A, so the finite tuple $(W_0, W_1, D_0, D_1, T, A)$ already carries the meet-to-seal route.

For the reverse route, apply paired-window exactness from Definition 893.8 and classifier exactness from Definition 893.11. A $\mathsf{RealTailAgreementSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seal read that reaches A through T determines the same paired windows and dyadic ledgers, hence returns to the finite meet surface.

Finally invoke Real-seal determinacy from Definition 893.25 and non-escape from Definition 893.5. The seal row is the unique displayed A reached from T, and no quotient stream, host equality, selected limit, or ambient completeness coordinate remains available to separate the two routes. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFiber}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailFiber}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, two finite $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{DyadicRatCore}^{\uparrow}$ tail-radius ledgers, one shared tail fiber row, one $\mathsf{Real}^{\uparrow}$ tail-agreement seal row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailFiber}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 893.1, Definition 893.2, Definition 893.3, Definition 893.4, Definition 893.5, Definition 893.6, Definition 893.7, Definition 893.8, Definition 893.9, Definition 893.11, Definition 893.12, Definition 893.13, Definition 893.14, Definition 893.15, Definition 893.16, Definition 893.17, Definition 893.19, Definition 893.20, Definition 893.21, Definition 893.22, Definition 893.25, Definition 893.26, and Definition 893.27 specify the finite common-tail fiber carrier, local NameCert rows, window projection, shared seal factorization, non-escape boundary, TasteGate follow-up contract, classifier stability, paired-window exactness, seal-consumer exhaustion, classifier exactness, RegSeqRat-to-Real handoff lock, tail-agreement seal exactness, completion consumer nonescape, source-swap stability, componentwise transport, ledger exhaustion, source-seal ledger totality, classifier coverage, completion handoff scope, shared-window seal determinacy, Real-seal determinacy, limit-seal functor handoff, and finite-window Real-seal correspondence.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFiberUp.taste gate`

Lean target: `BEDC.Derived.RegularCauchyTailFiberUp.RegularCauchyTailFiberTasteGate\_single\_carrier\_alignment`

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailFiber}^{\uparrow}}, \mathsf{axiomClean})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove quotient equality of regular streams, host real equality, selected-limit existence, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{RegularCauchyTailFiber}^{\uparrow}$.

Upgrade path: No further paper-side theory closure remains for the common-tail fiber and $\mathsf{Real}^{\uparrow}$ seal handoff; bridge checking remains on the verification axis.

Chapter 894

A Concrete Naming Certificate for $\mathsf{ObserverFrameRefusal}^{\uparrow}$

The $\mathsf{ObserverFrameRefusal}^{\uparrow}$ packet gives the no-global-frame observer direction a concrete NameCert carrier. It packages the refusal surface implicit in chapter 9418 as finite rows: an observer-history row, local coordinate-frame row, locality-cell row, rate row, synchronization-refusal ledger, componentwise transport, continuation replay, package provenance, and local naming row. It sits after chapter 479, chapter 609, chapter 513, and chapter 876: those chapters supply the identity, local frame, locality-cell, and maximum-rate surfaces, while this chapter records that none of them may be promoted to a synchronized external observer frame.

Definition 894.1 (Observer-frame refusal carrier)**.** *An* $\mathsf{ObserverFrameRefusal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, Q, L, R, G, H, C, P, N)$$

with the following displayed rows:

1. *O is the observer-history identity row consumed from* $\mathsf{ObserverHistIdentity}^{\uparrow}$*;*
2. *Q is the local coordinate-frame row consumed from* $\mathsf{ObserverCoordinateFrame}^{\uparrow}$ *as an observer-local coordinate packet, not as a global frame;*
3. *L is the locality-cell row consumed from* $\mathsf{ObserverLocalityCell}^{\uparrow}$*;*
4. *R is the cross-Hist causal-rate row consumed from* $\mathsf{CrossHistCausalRate}^{\uparrow}$*;*
5. *G is the refusal ledger, recording that no synchronized clock, privileged observer frame, global coordinate chart, metric tensor, or all-observer synchronization row is admitted;*
6. *H records componentwise* hsame *transports for the observer-history, coordinate-frame, locality-cell, causal-rate, refusal-ledger, route, provenance, and naming rows;*
7. *C records displayed* Cont *routes for reading the local observer rows, checking the refusal ledger, and replaying the accepted consumer route;*
8. *P is the* Pkg *provenance over* $\mathsf{ObserverFrameRefusal}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{ObserverCoordinateFrame}^{\uparrow}$, $\mathsf{ObserverLocalityCell}^{\uparrow}$, $\mathsf{HistTimeStream}^{\uparrow}$, $\mathsf{CrossHistCausalRate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ObserverFrameRefusal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a synchronized clock, privileged observer-frame row, global frame, metric tensor, quotient observer identity, host equality of histories, or unlisted external coordinate.

Theorem 894.2 (Observer-frame refusal NameCert obligations)**.** *For the carrier of Definition 894.1, the local* $\mathsf{NameCert}_{\mathsf{ObserverFrameRefusal}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$F = (O, Q, L, R, G, H, C, P, N),$$

observer-Hist identity through O*, local coordinate-frame use through* Q*, locality-cell anchoring through* L*, cross-Hist causal-rate use through* R*, explicit refusal of synchronized clocks and privileged external frames through* G*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from Definition 894.1. The rows $O, Q, L, R, G, H, C, P, N$ account for the observer-history identity, local frame, locality cell, causal-rate row, refusal ledger, transport, route replay, provenance, and local naming surface.

The first four analytic rows are consumed from the sibling chapters. The observer-Hist identity row comes from chapter 479; the local coordinate-frame row comes from chapter 609; the locality cell comes from chapter 513; and the causal-rate row comes from chapter 876.

The refusal ledger G is the row that blocks promotion of those local rows into a synchronized external frame. The structural rows H, C, P, N replay and name the same refusal route, so every accepted read remains inside the finite packet. □

Theorem 894.3 (Observer-frame refusal no-global-sync boundary)**.** *Every accepted* $\mathsf{ObserverFrameRefusal}^{\uparrow}$ *packet* $F = (O, Q, L, R, G, H, C, P, N)$ *admits observer-facing reads only through the displayed local rows* O, Q, L, R *and the refusal ledger* G*, replayed through* H, C, P, N*. A consumer that reads a synchronized clock, privileged observer-frame row, global frame, metric tensor, quotient observer identity, host equality of histories, or unlisted external coordinate has left the accepted packet.*

Proof. Project the carrier. The only observer-facing rows are O, Q, L, R, and the only row that records the refusal of external synchronization data is G.

Apply Definition 894.2. The local NameCert surface requires the identity, coordinate-frame, locality-cell, causal-rate, and refusal rows to be consumed together with H, C, P, N.

Finally inspect the excluded coordinates in Definition 894.1. No synchronized clock, privileged observer frame, global coordinate chart, metric tensor, quotient observer identity, host equality of histories, or unlisted external coordinate is present. Therefore an accepted consumer route can only display such a row as refused external data, never as an admitted packet coordinate. □

Theorem 894.4 (Observer-frame refusal TasteGate obligation)**.** *The later Lean* `TasteGate.lean` *development for* $\mathsf{ObserverFrameRefusal}^{\uparrow}$ *must include* $\mathsf{Nontrivial\ ObserverFrameRefusal}^{\uparrow}$ *with explicit distinct witnesses and* $\mathsf{FieldFaithful\ ObserverFrameRefusal}^{\uparrow}$ *by field projection and injection. These gate-facing instances must preserve the observer-history row, local coordinate-frame row, locality-cell row, cross-Hist causal-rate row, refusal ledger, transport rows, continuation routes, provenance row, and local naming row.*

Proof. The carrier has separate rows for observer identity, local coordinate use, locality-cell anchoring, causal-rate reading, and refusal of external synchronization. A singleton collapse would erase the difference between local observer data and refused external frame data.

Field faithfulness is the projection discipline for the displayed tuple. Each row of $F = (O, Q, L, R, G, H, C, P, N)$ has a distinct role, and the refusal ledger G must remain distinguishable from the local coordinate-frame row Q and the causal-rate row R. □

Falsifiable prediction: An accepted $\mathsf{ObserverFrameRefusal}^{\uparrow}$ packet admits no consumer route that reads a synchronized clock or privileged observer-frame row unless that row is displayed as a refused external coordinate.

Independence witness: observerhistidentity, observercoordinateframe, observerlocalitycell, histtimestream, crosshistcausalrate: $\mathsf{ObserverFrameRefusal}^{\uparrow}$ carries an explicit refusal ledger for privileged frame and synchronization imports; identity-only, coordinate-frame, locality-cell, timestream, and rate packets do not have the same refusal surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverFrameRefusal}^{\uparrow}}$.

Constructive story: An $\mathsf{ObserverFrameRefusal}^{\uparrow}$ packet is generated from observer-history identity, local coordinate-frame, locality-cell, cross-Hist causal-rate, refusal-ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObserverFrameRefusal}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 894.1, Definition 894.2, Definition 894.3, Definition 894.4, and

Lean4 ✓ `BEDC.Derived.ObserverFrameRefusalUp.taste gate`

specify the finite refusal packet for no-global-frame observer rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObserverFrameRefusal}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.ObserverFrameRefusalUp.ObserverFrameRefusalTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not derive synchronized clocks, privileged observer frames, global coordinates, metric tensors, quotient observer identity, host equality of histories, or bridge checking for $\mathsf{ObserverFrameRefusal}^{\uparrow}$.

Upgrade path: No further paper-theory upgrade remains; the remaining independent step is bridge checking without adding synchronized-frame content.

Chapter 895

A Concrete Naming Certificate for $\mathsf{MultiHistCoupling}^{\uparrow}$

The $\mathsf{MultiHistCoupling}^{\uparrow}$ packet realizes the paired-history coupling step in the Inter-Hist Locality chain of chapter 9419. It sits after the no-subject observer boundary of chapter 615, the observer-history identity surface of chapter 479, the multi-history configuration carrier of chapter 474, and the invariant readback packet of chapter 656. Its role is to expose a symmetric finite coupling ledger between two displayed histories before a $\mathsf{CrossHistCausal}^{\uparrow}$ consumer reads causal dependence or a rate packet reads a maximum boundary.

Definition 895.1 (MultiHistCoupling carrier)**.** *A* $\mathsf{MultiHistCoupling}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (H_0, H_1, J, S, T, C, P, N)$$

with the following displayed rows:

1. *H_0 and H_1 are paired* BHist *rows read from the same* $\mathrm{MultiHistConfig}^{\uparrow}$ *surface, with the no-subject boundary inherited from* $\mathsf{ObserverSubjectBoundary}^{\uparrow}$ *and the identity-facing read inherited from* $\mathsf{ObserverHistIdentity}^{\uparrow}$*;*
2. *J is the finite coupling ledger that records the two directed reads $H_0 \to H_1$ and $H_1 \to H_0$ as one symmetric coupling packet;*
