Theorem 1124.5 (Reality-constrained model-audit fit separation)**.** *Two accepted* RealityConstrainedModelAudit$^{\uparrow}$ *packets may agree on source traces and observation bundles while remaining separated as physical audit certificates whenever their declared physical-fit comparison, failure surface, or strength row is not preserved by the classifier. This separation is visible at the certificate level and does not require a host-side judgment that either model is false.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelAuditUp.RealityConstrainedModelAuditFitSeparation`

Proof. Use the classifier definition. Agreement of H and Π supplies only the source and observation-bundle transports.

The same classifier also requires preservation of the observed and model-generated signatures, the physical-fit comparison, the tower, the ledger, the failure surface, and the strength row. If any of the comparison, failure, or strength rows is not preserved, the classifier relation fails even when the source rows agree.

The failure of classifier transport is an audit separation, not a truth judgment. It says that the two packets do not present the same licensed physical-fit certificate. □

Theorem 1124.6 (Reality-constrained model-audit signature exactness)**.** *Every accepted* RealityConstrainedModelA *audit route for*

$$A = (H, \Pi, O, M, C, T, L, F, S)$$

reads exactly the observed row O and the model row M extracted from the same source trace H and observation bundle Π. No alternative observed signature, model signature, classifier input, approximation witness, ledger entry, failure row, or strength row can be substituted without leaving the accepted packet.

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelAuditUp.RealityConstrainedModelAuditSignatureExactness`

Proof. Start with carrier admission in Definition 1124.3. It identifies the accepted object with the nine displayed rows of Definition 1124.1, so the audit route has no coordinate from which a second observed or model-generated signature can be read.

The classifier of Definition 1124.2 then binds the signature comparison to the same H and Π transports. Since classifier stability preserves the displayed comparison row C, any route using different signature inputs fails to be the same accepted classifier route.

Ledger non-escape in Definition 1124.4 excludes a hidden replacement through compression, translation, or idealization. The fit-separation theorem shows that a changed comparison row is an audit separation rather than another certificate for the same route. □

Theorem 1124.7 (Reality-constrained model-audit failure-surface exhaustion)**.** *For an accepted* RealityConstrainedModelAudit$^{\uparrow}$ *fit claim on* $A = (H, \Pi, O, M, C, T, L, F, S)$*, every defeating observation and every signature mismatch used against the claim is named in the finite failure-surface row* F*. A defeat that requires an observation route or mismatch row absent from* F *is outside the displayed audit certificate.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelAuditUp.RealityConstrainedModelAuditFailureSurfaceExhaustio`

Proof. The NameCert obligation surface fixes F as one of the carrier rows and makes non-escape part of the accepted audit. Thus a defeating test used by the certificate must be a projection from A, not an extra host-side objection added after acceptance.

Classifier stability requires the failure-surface rows of compared packets to name the same defeating tests. If a mismatch is not present in F, the classifier has no component on which to transport it as part of the accepted fit comparison.

Ledger non-escape also blocks hiding the missing defeat inside L. The ledger may expose provenance, compression, translation, and idealization rows, but it does not create an unlisted failure coordinate. Hence the finite row F exhausts the defeating observations and signature mismatches licensed by the audit route. □

Theorem 1124.8 (Reality-constrained model-audit strength-row transport)**.** *Whenever* RealityConstrainedModelAu *holds for*

$$A = (H, \Pi, O, M, C, T, L, F, S) \quad \textit{and} \quad A' = (H', \Pi', O', M', C', T', L', F', S'),$$

the classifier transports the audit-strength row S *to* S'*. Therefore classifier agreement cannot upgrade the evidential grade of a fit claim unless the transported strength row already presents that grade.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelAuditUp.RealityConstrainedModelAuditStrengthRowTransport`

Proof. Unpack the classifier definition. Alongside the source, observation, signature, tower, ledger, and failure rows, it includes preservation of the declared strength comparison.

The NameCert obligations and ledger non-escape prevent the strength grade from being imported through an unrecorded coordinate. The accepted packet has only the displayed row S for audit strength, and any grade used by the fit claim must be read from that row.

Finally apply Definition 1124.5. If strength is not preserved, the packets are separated as physical audit certificates even when their source and observation rows agree. Thus transported classifier agreement carries S; it does not manufacture a stronger evidential grade. □

The later Lean file `lean4/BEDC/Derived/RealityConstrainedModelAuditUp/TasteGate.lean` must provide `Nontrivial RealityConstrainedModelAuditUp` with two distinct audit packets and `FieldFaithful RealityConstrainedModelAuditUp` by `.mk` projections from $H, \Pi, O, M, C, T, L, F, S$ and injection on the displayed field surface.

Falsifiable prediction: A model-audit packet with an unledgered compression row cannot pass the acceptance gate for any fit claim whose signature depends on the hidden row.

Independence witness: Compare largemodelauditchannel, largemodelcorpussupply, physicalfit, finitewindowenvelope, and streamname: those siblings supply channel, corpus, window, and stream rows, but none carries the ten-field physical audit certificate with failure-surface and strength coordinates, so no bijection preserves the obligation rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedModelAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ packet is generated from a finite source-trace history, observation bundle, observed signature, model-generated signature, classifier comparison, approximation tower, audit ledger, failure surface, and audit-strength row. Its composite dependency surface is the source-trace, observation-bundle, signature-comparison, approximation-tower, audit-ledger, failure-surface, and audit-strength surfaces.

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelAuditUp.taste gate`

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealityConstrainedModelAudit}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1124.1, Definition 1124.2, Definition 1124.3, Definition 1124.4, Definition 1124.5, Definition 1124.6, Definition 1124.7, and Definition 1124.8 bind the finite carrier, classifier, NameCert obligations, ledger non-escape, fit separation, and exact audit rows for signatures, failures, and strength.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealityConstrainedModelAudit}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.RealityConstrainedModelAuditUp.RealityConstrainedModelAuditTasteGate\_single\_carrier\_`

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove host-level model truth, unbounded physical validation, continuous experimental adequacy, hidden-source recovery, axiom-clean audit, or bridge checking for $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$.

Upgrade path: No further paper-side theory upgrade is pending; bridge checking remains a separate verification-axis matter.

Chapter 1125

A Concrete Naming Certificate for $\mathsf{OnticState}^{\uparrow}$

The $\mathsf{OnticState}^{\uparrow}$ packet realizes the stable-signature source of section 9414.15 as a finite NameCert surface. It sits beside the observer-local packet $\mathsf{ConsciousObserverState}^{\uparrow}$ of chapter 578, the model-state packet $\mathsf{StateSpaceModel}^{\uparrow}$ of chapter 329, the support-and-budget packet $\mathsf{ObserverBudgetSupport}^{\uparrow}$ of chapter 1121, the observer-history identity packet $\mathsf{ObserverHistIdentity}^{\uparrow}$ of chapter 479, and the quantum-state packet $\mathsf{QuantumState}^{\uparrow}$ of chapter 217. Its role is narrower than a total ontology and wider than a model row: it binds the reality-facing signature source, the admissible observer-access route, and the residue ledger in one accepted carrier before any consumer treats a model as ontically adequate.

Definition 1125.1 (OnticState carrier)**.** *An* $\mathsf{OnticState}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, A, K, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite reality-facing signature-source row, naming the stable signatures exposed by the accepted bundle family.*
2. *A is the observer-access route row, recording which* $\mathsf{ConsciousObserverState}^{\uparrow}$ *and* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *surfaces are allowed to inspect the signatures.*
3. *K is the classifier row comparing exposed signatures under the admissible observer bundle.*
4. *R is the residue ledger, recording reality-facing content not captured by the displayed* $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, *or* $\mathsf{QuantumState}^{\uparrow}$ *sibling rows.*
5. *H records componentwise* hsame *transport for the signature source, observer-access route, classifier, residue ledger, provenance, and local naming rows.*
6. *C records displayed* Cont *replay through S, A, K, R, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{OnticState}^{\uparrow}$, $\mathsf{ConsciousObserverState}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{ObserverBudgetSupport}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{QuantumState}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$ *row.*

The classifier for O reads only the displayed signature source, observer-access route, signature classifier, residue ledger, transport, replay, provenance, and local name. It has no coordinate for

a total physical object, hidden global observer, unregistered model state, quotient observer identity, or host-level quantum state.

Definition 1125.2 (OnticState classifier)**.** *The* $\mathsf{OnticState}^{\uparrow}$ *classifier identifies two accepted packets only when their displayed signature-source rows agree through* K*, their observer-access routes agree through the same admitted observer and support surfaces, and their residue ledgers preserve the same hidden or unqueried reality-facing rows under componentwise* hsame *transport. Agreement of model coordinates alone is not enough to classify two* $\mathsf{OnticState}^{\uparrow}$ *packets as the same.*

Theorem 1125.3 (OnticState signature stability)**.** *Let* $O = (S, A, K, R, H, C, P, N)$ *be an accepted* $\mathsf{OnticState}^{\uparrow}$ *carrier. If the displayed signature source* S *is transported along the componentwise* hsame *rows in* H *and replayed through the route* C*, then the resulting packet remains classified by the same* $\mathsf{OnticState}^{\uparrow}$ *surface exactly when* A*,* K*, and* R *are transported with it. In particular, signature stability is not a property of* S *alone; it is a property of the source together with observer access, classifier, and residue ledger.*

Proof. Start with the carrier of Definition 1125.1. The signature source S is admitted only as part of the packet $O = (S, A, K, R, H, C, P, N)$.

Transport through H is componentwise. Thus a transported source row must be accompanied by the transported observer-access row A, classifier row K, residue ledger R, replay row C, provenance row P, and local name N.

The classifier of Definition 1125.2 then reads the transported packet through all four content rows S, A, K, R. A consumer that keeps S while dropping A, K, or R has left the accepted $\mathsf{OnticState}^{\uparrow}$ classifier surface. □

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateSignatureStability`

Theorem 1125.4 (OnticState residue-ledger exactness)**.** *Every accepted* $\mathsf{OnticState}^{\uparrow}$ *public read factors through the finite route*

$$S, A, K, R, H, C, P, N.$$

The route may expose the reality-facing signature source, admitted observer access, classifier comparison, and residue ledger. It cannot replace R *by a bare* $\mathsf{StateSpaceModel}^{\uparrow}$ *state, a* $\mathsf{ConsciousObserverState}^{\uparrow}$ *state, an* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *support row, an* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *identity row, or a* $\mathsf{QuantumState}^{\uparrow}$ *state.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateResidueLedgerExactness`

Proof. Use the displayed carrier $O = (S, A, K, R, H, C, P, N)$. Public reads reach the local name only after the signature source, access route, classifier, residue ledger, transport row, replay row, and provenance row have been displayed.

The residue ledger R is a content row of the carrier. It records what is not captured by the displayed model, observer, support, history-identity, or quantum-state sibling rows.

Replacing R by any one sibling would delete the ledger coordinate that distinguishes ontic source from model interface. Such a replacement has no row in O, so it is outside the accepted packet. □

Definition 1125.5 (OnticState access route)**.** *The admitted observer-access route row* A *of an* $\mathsf{OnticState}^{\uparrow}$ *packet is the finite route through the observer-local state surface of* $\mathsf{ConsciousObserverState}^{\uparrow}$ *and the support-and-budget surface of* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *before any source signature in* S *is public. It records which observer-facing read may inspect the signature source, which budget support*

makes the read admissible, and how that read remains tied to the classifier row K, residue ledger R, transport row H, replay row C, provenance row P, and local $\mathsf{NameCert}_{\mathsf{OnticState}^\uparrow}$ *row N.*

Theorem 1125.6 (OnticState model-residue noncollapse)**.** *No* $\mathsf{StateSpaceModel}^\uparrow$ *row or* $\mathsf{QuantumState}^\uparrow$ *row can replace the residue ledger R of an accepted* $\mathsf{OnticState}^\uparrow$ *carrier while preserving the* $\mathsf{OnticState}^\uparrow$ *classifier. Any such replacement loses the record of hidden or unqueried reality-facing content required by the classifier and by residue-ledger exactness.*

Proof. Use the carrier of Definition 1125.1. The row R is displayed as a residue ledger distinct from the model-state and quantum-state sibling rows.

The classifier of Definition 1125.2 reads equality through the joint rows S, A, K, R. Replacing R by a model row or a quantum row changes the packet read by the classifier, so the resulting tuple is outside the same accepted classifier surface.

Finally apply Definition 1125.4. It states that every public read factors through R and cannot replace it by a bare $\mathsf{StateSpaceModel}^\uparrow$ or $\mathsf{QuantumState}^\uparrow$ row. The claimed collapse therefore deletes a required ledger coordinate. □

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateModelResidueNoncollapse`

Theorem 1125.7 (OnticState observer-support factorization)**.** *Every observer-facing public read of an accepted* $\mathsf{OnticState}^\uparrow$ *packet factors through*

$$A, K, R, H, C, P, N$$

after the signature source S is displayed and before any model adequacy claim can be made. A read that reaches a $\mathsf{StateSpaceModel}^\uparrow$ *or* $\mathsf{QuantumState}^\uparrow$ *adequacy judgment without this access, classifier, residue, transport, replay, provenance, and naming route is outside the accepted* $\mathsf{OnticState}^\uparrow$ *public surface.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateObserverSupportFactorization`

Proof. Begin with the access route of Definition 1125.5. It forces every observer-facing read through $\mathsf{ConsciousObserverState}^\uparrow$ and $\mathsf{ObserverBudgetSupport}^\uparrow$ before the source signature is treated as public.

Apply Definition 1125.3. The source row is stable only when the observer-access row and classifier row are transported with it.

Use Definition 1125.4 and Definition 1125.6. The public route keeps the residue ledger before any model or quantum adequacy claim is considered, so the read factors through A, K, R, H, C, P, N rather than through a detached model surface. □

Theorem 1125.8 (OnticState NameCert obligation surface)**.** *For the carrier of Definition 1125.1, the local* $\mathsf{NameCert}_{\mathsf{OnticState}^\uparrow}$ *surface consists exactly of five rows:*

1. *carrier admission for $O = (S, A, K, R, H, C, P, N)$;*
2. *classifier exposure through the signature-source row S, observer-access row A, and classifier row K;*
3. *signature stability through componentwise transport and displayed replay of S, A, K;*
4. *residue-ledger exactness through R and its componentwise transport;*
5. *public obligation surface through H, C, P, N, with no hidden total-state, global-observer, quotient-identity, or host quantum-state coordinate.*

These five rows are the complete public obligation surface for using $\mathsf{OnticState}^{\uparrow}$ *as an ontic-state certificate.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateNameCertObligationSurface`

Proof. Carrier admission is the first projection from Definition 1125.1. Classifier exposure is the content of Definition 1125.2, read through S, A, K.

Signature stability follows from Definition 1125.3: the source row remains stable only with the access and classifier rows transported alongside it. Residue-ledger exactness follows from Definition 1125.4: R cannot be replaced by any single sibling surface.

The remaining rows H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no further coordinate, the listed five rows exhaust the public NameCert obligation surface. □

Definition 1125.9 (OnticState access-residue boundary)**.** *The accepted access-residue boundary for* $\mathsf{OnticState}^{\uparrow}$ *is the displayed tuple*

$$(S, A, K, R, H, C, P, N).$$

A public read is boundary-respecting only when it reaches the local name through the signature source S, observer-access row A, classifier row K, residue ledger R, componentwise transport row H, displayed replay row C, provenance row P, and local $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$ *row N. The boundary has no coordinate for observer access without residue, residue without an admitted observer route, or a model-facing substitute for the reality-facing signature source.*

Theorem 1125.10 (OnticState access-residue coupling)**.** *Let $O = (S, A, K, R, H, C, P, N)$ be an accepted* $\mathsf{OnticState}^{\uparrow}$ *carrier, and let a public read of O preserve the signature source S through the componentwise* hsame *rows in H and the displayed replay row C. Then the read preserves the observer-access row A and the residue-ledger row R as displayed coordinates of the same packet. In particular, preserving the source signature while dropping either admitted observer access or the residue ledger is not an accepted* $\mathsf{OnticState}^{\uparrow}$ *public read.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.onticState access residue boundary fields`

Proof. Begin with the boundary of Definition 1125.9. The public read reaches N only through the full tuple (S, A, K, R, H, C, P, N), so a source-preserving read is still evaluated inside the same displayed packet.

Apply Definition 1125.3 to the transported source. The theorem makes source stability depend on transporting the observer-access route and classifier alongside S.

Apply Definition 1125.4 to the public route. The residue ledger is an exposed coordinate of every accepted read and cannot be replaced by a sibling surface. Thus A and R remain coupled to any accepted preservation of the signature source. □

Theorem 1125.11 (OnticState sibling noncollapse)**.** *No sibling surface among* $\mathsf{ConsciousObserverState}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{ObserverBudgetSupport}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, *or* $\mathsf{QuantumState}^{\uparrow}$ *can replace an accepted* $\mathsf{OnticState}^{\uparrow}$ *packet. Any such replacement loses at least one displayed coordinate from the boundary (S, A, K, R, H, C, P, N): the reality-facing signature source, admitted observer-access route, classifier row, residue ledger, componentwise transport, displayed replay, provenance, or local* $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateSiblingNoncollapse`

Proof. Inspect the carrier in Definition 1125.1. Its coordinates bind the signature source, observer access, classifier, residue ledger, transport, replay, provenance, and local name in one finite packet.

The observer-state, model-state, budget-support, history-identity, and quantum-state siblings each expose one neighboring surface, not the complete boundary of Definition 1125.9. Replacing O by any one sibling therefore deletes a coordinate required by the accepted $\mathsf{OnticState}^{\uparrow}$ classifier or public read.

By Definition 1125.4, the residue row in particular cannot be supplied by a bare model, observer, support, history-identity, or quantum-state row. Hence the sibling replacement is outside the accepted packet. □

Theorem 1125.12 (OnticState transport scope)**.** *Let $O = (S, A, K, R, H, C, P, N)$ be an accepted* $\mathsf{OnticState}^{\uparrow}$ *carrier. The primitive transport scope of O is the componentwise* BHist *and* hsame *route over the signature source S, observer-access row A, classifier row K, residue ledger R, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$ *row N. A transported public read of O cannot keep only S or only S, K while dropping access, residue, replay, provenance, or local naming.*

Proof. Begin with the carrier of Definition 1125.1. The row H is displayed as componentwise transport for the same finite packet $O = (S, A, K, R, H, C, P, N)$, not as a free equality on the signature source alone.

Apply Definition 1125.2 and Definition 1125.3. The classifier reads S, A, K, R together, and signature stability requires the access route, classifier, and residue ledger to travel with the source row.

Finally use Definition 1125.10 and Definition 1125.11. Access and residue remain packet coordinates under source preservation, while each sibling surface omits at least one coordinate of O. Hence the primitive transport scope is exactly the displayed BHist, hsame, Cont, Pkg, and NameCert route on the full carrier. □

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateCarrier transport scope`

Theorem 1125.13 (OnticState observer-access scope)**.** *For an accepted* $\mathsf{OnticState}^{\uparrow}$ *carrier $O = (S, A, K, R, H, C, P, N)$, the observer-access row A is scoped only through the admitted observer and support route, the classifier row K, the residue ledger R, and the support rows H, C, P, N. It is not a detachable observer permission, a global observer row, or a model-facing access token independent of the* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$ *surface of O.*

Proof. Start from the access route of Definition 1125.5. The row A records which $\mathsf{ConsciousObserverState}^{\uparrow}$ and $\mathsf{ObserverBudgetSupport}^{\uparrow}$ surfaces may inspect the source signatures before those signatures become public.

Use Definition 1125.9 and Definition 1125.10. They keep A inside the full boundary (S, A, K, R, H, C, P, N) and force accepted source-preserving reads to preserve the residue row R with the access row.

Apply Definition 1125.7 and Definition 1125.11. Observer-facing reads factor through A, K, R, H, C, P, N, and no sibling-only observer, model, support, history-identity, or quantum surface exposes all required coordinates. Thus observer access has the stated primitive scope. □

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateObserverAccessScope`

Theorem 1125.14 (OnticState residue ledger scope)**.** *For an accepted* $\mathsf{OnticState}^{\uparrow}$ *carrier $O = (S, A, K, R, H, C, P, N)$, the residue ledger R is scoped as the reality-facing residual row of the same* BHist *packet, transported through H, replayed through C, sourced by P, and named by N. The row*

R cannot be replaced by a $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{ConsciousObserverState}^{\uparrow}$, $\mathsf{ObserverBudgetSupport}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, *or* $\mathsf{QuantumState}^{\uparrow}$ *sibling row, and it cannot be read without the classifier and observer-access rows that determine the accepted packet.*

Proof. Inspect Definition 1125.1. The residue ledger R is a displayed coordinate of O, adjacent to the signature source, observer-access route, classifier, transport, replay, provenance, and local naming rows.

Apply Definition 1125.4. Every accepted public read factors through R, and none of the listed sibling rows can replace it as the ledger of hidden or unqueried reality-facing content.

Finally combine Definition 1125.6, Definition 1125.10, and Definition 1125.11. Model or quantum rows do not collapse the residue ledger, access and residue remain coupled under source preservation, and sibling surfaces omit the complete carrier. The residue scope is therefore the displayed BHist, hsame, Cont, Pkg, and NameCert ledger row of O. □

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateResidueLedgerScope`

Theorem 1125.15 (OnticState obligation-closure package)**.** *The* $\mathsf{OnticState}^{\uparrow}$ *obligation surface is the package consisting of carrier admission, classifier exposure, signature stability, access-residue coupling, sibling noncollapse, and the TasteGate-facing nontrivial and field-faithful obligations for the same tuple* (S, A, K, R, H, C, P, N)*. This package is sufficient for obligation closure of the paper-side* $\mathsf{OnticState}^{\uparrow}$ *NameCert surface: every accepted public use must preserve the displayed carrier, read classification through* S, A, K, R*, keep the access and residue rows coupled under source preservation, avoid sibling replacement, and expose a nontrivial field-faithful packet to downstream TasteGate consumers.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateObligationClosurePackage`

Proof. Carrier admission and classifier exposure are Definition 1125.1 and Definition 1125.2. Signature stability is Definition 1125.3.

The access-residue boundary is fixed by Definition 1125.9, and source-preserving public reads preserve both access and residue by Definition 1125.10. Sibling noncollapse is Definition 1125.11.

The Lean follow-up file named below supplies the TasteGate-facing nontrivial and field-faithful rows for the same finite packet. Together these clauses cover the carrier, classifier, source transport, access-residue boundary, noncollapse, and downstream TasteGate obligations named by the $\mathsf{OnticState}^{\uparrow}$ NameCert surface. □

Theorem 1125.16 (OnticState componentwise transport scope)**.** *Let* $O = (S, A, K, R, H, C, P, N)$ *be an accepted* $\mathsf{OnticState}^{\uparrow}$ *carrier. Any accepted public read of* O *that preserves the source signature* S *transports the full packet componentwise: the observer-access route* A*, classifier row* K*, residue ledger* R*, transport history* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$ *row* N *remain the coordinates of the same packet. The transport is read through the* hsame *rows in* H*, the displayed* Cont *replay, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$ *witness; it is not a public read of* S *alone.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateComponentwiseTransportScope`

Proof. Begin with the accepted carrier of Definition 1125.1. The tuple stores S, A, K, R, H, C, P, N as one finite public packet, so a public read preserving S is still evaluated against that tuple.

Apply Definition 1125.3 to the source-preserving read. Its stability clause requires the signature source, observer-access route, classifier row, componentwise hsame transport, displayed replay, provenance, and local naming row to remain aligned.

Apply Definition 1125.10 for the exposed access and residue coordinates. The residue ledger and observer-access route are preserved as packet coordinates, not as independent sibling rows. Hence every accepted source-preserving read transports the eight displayed fields componentwise through H, C, P, N. □

Theorem 1125.17 (OnticState TasteGate field scope)**.** *The TasteGate-facing nontrivial and field-faithful rows for* $\mathsf{OnticState}^{\uparrow}$ *are scoped to the same eight-field packet* (S, A, K, R, H, C, P, N)*. They cannot be discharged by a sibling-only surface among* $\mathsf{ConsciousObserverState}^{\uparrow}$*,* $\mathsf{StateSpaceModel}^{\uparrow}$*,* $\mathsf{ObserverBudgetSupport}^{\uparrow}$*,* $\mathsf{ObserverHistIdentity}^{\uparrow}$*, or* $\mathsf{QuantumState}^{\uparrow}$*, because each such surface omits at least one of the signature source, observer access, classifier, residue ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, or local* $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateTasteGateFieldScope`

Proof. The TasteGate rows named for this chapter are attached to $\mathsf{OnticState}^{\uparrow}$, whose carrier is the packet of Definition 1125.1. The nontrivial witness separates two accepted packets inside that carrier, and field faithfulness reads the same packet coordinates.

By Definition 1125.11, no listed sibling exposes all eight coordinates of the ontic-state carrier. A sibling-only surface therefore lacks the public boundary required by Definition 1125.9.

The TasteGate rows must consequently be interpreted over the full $\mathsf{OnticState}^{\uparrow}$ packet, with the source, access, classifier, residue, transport, replay, provenance, and local name rows kept together. □

Theorem 1125.18 (OnticState scoped-closure package)**.** *The* $\mathsf{OnticState}^{\uparrow}$ *paper-side boundary is scoped closed by the carrier, classifier, residue exactness, access-residue coupling, sibling noncollapse, componentwise transport scope, and TasteGate field scope. Thus every accepted public use of* $\mathsf{OnticState}^{\uparrow}$ *must remain inside the single packet* (S, A, K, R, H, C, P, N)*, preserve source transport through the displayed* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$ *rows, and reject any sibling-only substitute for the ontic-state packet.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateScopedClosurePackage`

Proof. Carrier admission and classifier exposure are fixed by Definition 1125.1 and Definition 1125.2. Residue exactness is supplied by Definition 1125.4.

Access and residue remain coupled under source preservation by Definition 1125.10. Sibling replacement is excluded by Definition 1125.11.

The transport boundary is Definition 1125.16, which keeps all eight coordinates inside the same packet. The TasteGate obligations are scoped to that packet by Definition 1125.17.

Combining these clauses gives the public boundary claimed here: accepted uses preserve the complete ontic-state packet and cannot discharge the chapter through a model, observer, support, history-identity, or quantum-state sibling alone. □

Theorem 1125.19 (OnticState mature consumer completeness)**.** *Every downstream consumer of an accepted* $\mathsf{OnticState}^{\uparrow}$ *packet* $O = (S, A, K, R, H, C, P, N)$ *is complete exactly over the same displayed source, access, classifier, residue, transport, replay, provenance, and local naming rows. A consumer may use the access-residue coupling, sibling noncollapse, componentwise transport scope, and TasteGate field scope, but it cannot add a total physical ontology row, detach observer access from residue, collapse the packet to a sibling surface, or discharge the TasteGate obligations on any carrier other than* O*.*

Lean4 ✓ `BEDC.Derived.OnticStateUp.OnticStateUp StdBridge`

Proof. Start with the carrier and scoped-closure package. The carrier of Definition 1125.1 gives the eight rows S, A, K, R, H, C, P, N, and Definition 1125.18 binds accepted public use to that packet.

Apply access-residue coupling from Definition 1125.10. Any source-preserving consumer keeps the observer-access row A and residue ledger R as coordinates of the same public read.

Next use sibling noncollapse and componentwise transport scope. By Definition 1125.11, no neighboring observer, model, support, history-identity, or quantum surface replaces O; by Definition 1125.16, every accepted source-preserving read transports the full packet through H, C, P, N.

Finally apply the TasteGate field scope of Definition 1125.17. Its nontrivial and field-faithful rows are scoped to the same carrier, so a downstream consumer has no remaining paper-side row to add. Consumer completeness is therefore exactly the displayed packet O and its accepted public route. □

The Lean follow-up path is `lean4/BEDC/Derived/OnticStateUp/TasteGate.lean`. That file must provide explicit Nontrivial $\mathsf{OnticState}^{\uparrow}$ and FieldFaithful $\mathsf{OnticState}^{\uparrow}$ instances preserving the signature source, observer-access route, classifier, residue ledger, componentwise transport, displayed replay, provenance, and local naming rows.

Falsifiable prediction: An accepted $\mathsf{OnticState}^{\uparrow}$ packet cannot be reduced to $\mathsf{StateSpaceModel}^{\uparrow}$ without losing either the residue-ledger row or the observer-access route.

Independence witness: consciousobserverstate, statespacemodel, observerbudgetsupport, observerhistidentity, quantumstate: none is bijective because $\mathsf{OnticState}^{\uparrow}$ carries the reality-facing signature source and residue ledger together, while those siblings carry observer state, model state, budget support, history identity, or quantum-state rows separately.

Closure status for $\mathsf{NameCert}_{\mathsf{OnticState}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OnticState}^{\uparrow}$ packet is generated from a finite reality-facing signature source, observer-access route, classifier row, residue ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Lean4 ✓ `BEDC.Derived.OnticStateUp.taste gate`

Chapter 1126

A Concrete Naming Certificate for $\mathsf{ObservationReflectionPacket}^{\uparrow}$

The $\mathsf{ObservationReflectionPacket}^{\uparrow}$ packet realizes the observation–reflection equivalence thesis of chapter 9414 as a finite BEDC NameCert surface. It sits beside the finite observation route of chapter 1007, the closed observation packet of chapter 616, the observation conservation ledger of chapter 607, and the runtime checkpoint packet of chapter 997. Those siblings provide finite observation windows, closed observation ledgers, monotone record preservation, and runtime checkpoint boundaries; this packet binds the shared observation–reflection roles into one local carrier without identifying physical reality with MetaCIC.

Definition 1126.1 (ObservationReflectionPacket carrier)**.** *An* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, H, \Sigma, C, P, L, E, T, R, N)$$

with the following displayed rows:

1. *S is the source trace row, recording the reality-facing or MetaCIC-facing source access that starts the inquiry;*
2. *H is the finite* BHist *carrier of observations, generated traces, and replayable inquiry events;*
3. *Σ is the signature extraction row, listing the finite signature read from S through H;*
4. *C is the classifier row comparing the extracted signature with the displayed model, package, or checkpoint claim;*
5. *P is the package row naming the finite* Pkg *provenance for the source, trace, signature, classifier, ledger, and route rows;*
6. *L is the ledger row recording accepted matches, open gaps, rejected identity claims, and conservation constraints;*
7. *E is the open-continuation row, recording the prediction horizon or open meta-continuation that remains after the finite certificate is read;*
8. *T is the transport row carrying componentwise* hsame *comparisons between the observation side and the reflection side;*
9. *R is the route row of displayed* Cont *consumers through $S, H, \Sigma, C, P, L, E, T$;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ObservationReflectionPacket}^{\uparrow}}$ *row naming exactly this packet.*

The carrier has no coordinate for an ontological identity between physical reality and MetaCIC, no final truth oracle, and no host-level physical law beyond the finite inquiry rows shown above.

Theorem 1126.2 (ObservationReflectionPacket NameCert obligations)**.** *For the carrier of Definition 1126.1, the local* $\mathsf{NameCert}_{\mathsf{ObservationReflectionPacket}\uparrow}$ *surface consists exactly of six finite obligations:*

1. *carrier admission for the displayed packet* $Q = (S, H, \Sigma, C, P, L, E, T, R, N)$*;*
2. *source-trace exactness, requiring every inquiry read to start from* S *and pass through the finite history row* H*;*
3. *signature-classifier fit, requiring every accepted comparison to expose* Σ *and* C *before any package read;*
4. *package and ledger exactness, requiring* P *and* L *to name the finite provenance, accepted matches, open gaps, and rejected identity claims;*
5. *open-continuation preservation, requiring* E *to remain an open continuation rather than a final oracle;*
6. *transport, route, and local naming closure through* T, R, N*, requiring all observation-side and reflection-side reads to remain inside the displayed packet.*

Thus the observation–reflection thesis is certified as a finite role correspondence and not as an identity of source domains.

Lean4 ✓ `BEDC.Derived.ObservationReflectionPacketUp.ObservationReflectionPacketTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1126.1. The ten rows $S, H, \Sigma, C, P, L, E, T, R, N$ are the complete finite packet visible to a consumer.

Source-trace exactness uses the first two rows. The source row S records the inquiry access point, while H records only the finite trace available from that source. This matches the finite-trace side of chapter 9414 and the finite observation interface of chapter 1007.

Signature-classifier fit is then read through Σ and C. The packet does not classify a hidden source directly; it classifies only the displayed signature extracted from the finite trace. Package and ledger exactness attach P and L to that same read, so accepted matches, open gaps, and rejected identity claims remain part of the local NameCert packet.

The open-continuation row E records the non-final horizon. It agrees with the reflection checkpoint boundary of chapter 997: checkpoint and inquiry rows can be inspected, but neither side exports total truth or host validation from the finite packet.

Finally T, R, N transport, route, and name the same rows. Since those rows add no source-domain equality, final oracle, or host physical-law coordinate, the six obligations exhaust the local certificate surface. □

Theorem 1126.3 (ObservationReflectionPacket non-escape boundary)**.** *Every accepted* ObservationReflectionPacke *packet exports only the displayed rows* $S, H, \Sigma, C, P, L, E, T, R, N$*. A consumer may read the source trace, finite history, extracted signature, classifier fit, package provenance, ledgered gaps, open continuation, transport, route, and local naming row. It cannot recover an ontological identity between physical reality and MetaCIC, a final truth oracle, a host-level physical law, an unbounded observation stream, or a runtime validator outside those rows.*

Proof. Inspect the carrier of Definition 1126.1. Its only source-facing rows are S and H, its only pattern-facing rows are Σ and C, and its only boundary-facing rows are P, L, E, T, R, N.

Apply the NameCert obligations of Definition 1126.2. Every legal read starts with source-trace exactness, passes through signature-classifier fit, and then records package provenance, ledger status, and open continuation before transport and local naming.

The sibling closed-observation packets make the same inventory boundary explicit. chapter 616 exposes only finite observation records plus a gap socket, while chapter 607 preserves displayed records without adding an oracle for unseen witnesses.

Thus any demand for source-domain identity, final truth, host physical law, unbounded observation, or runtime validation has no coordinate in the accepted packet. It is recorded as a non-exported demand at the ledger or continuation boundary rather than as a readable row. □

Lean4 ✓ `BEDC.Derived.ObservationReflectionPacketUp.ObservationReflectionPacket nonescape fields`

Theorem 1126.4 (ObservationReflectionPacket public export surface)**.** *The public export surface of an accepted* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *packet is exactly*

$$Q = (S, H, \Sigma, C, P, L, E, T, R, N).$$

It exports the source trace, finite history, signature extraction, classifier, package, ledger, open continuation, transport, route, and local NameCert *rows. It does not export ontological identity, a final oracle, host physical law, or an unbounded observation stream.*

Lean4 ✓ `BEDC.Derived.ObservationReflectionPacketUp.ObservationReflectionPacketUp StdBridge`

Proof. Project the carrier of Definition 1126.1. Its ten displayed rows are precisely $S, H, \Sigma, C, P, L, E, T, R, N$.

Apply the local NameCert obligations from Definition 1126.2. Source trace, finite history, signature extraction, classifier fit, package provenance, ledger status, open continuation, transport, route, and local naming are the rows made available to a public consumer.

Finally use the non-escape boundary of Definition 1126.3. Since the accepted packet has no coordinate for source-domain identity, final truth, host physical law, or unbounded observation, the public export surface is exactly the displayed finite packet. □

Falsifiable prediction: No accepted $\mathsf{ObservationReflectionPacket}^{\uparrow}$ packet exports an ontological identity between physical reality and MetaCIC, a final truth oracle, or a host-level physical law beyond its displayed finite inquiry rows.

Independence witness: finiteobservationinterface, closedobservationsystem, observationconservationledger, packagereflection, reflectionruntimecheckpoint: $\mathsf{ObservationReflectionPacket}^{\uparrow}$ is not bijective to any listed sibling because it simultaneously carries source trace, finite history, signature extraction, classifier fit, package provenance, ledgered gap status, open continuation, transport, route, and local naming rows. The finite observation sibling lacks the reflection-side classifier and open-continuation ledger; the closed observation and conservation siblings lack the signature-package reflection row; the package-reflection surface lacks observation-source and conservation rows; the runtime checkpoint sibling lacks the physical-inquiry source trace and empirical signature inventory.

The Lean follow-up in `lean4/BEDC/Derived/ObservationReflectionPacketUp/TasteGate.lean` should provide explicit Nontrivial $\mathsf{ObservationReflectionPacket}^{\uparrow}$ and FieldFaithful $\mathsf{ObservationReflectionPacket}^{\uparrow}$ instances preserving $S, H, \Sigma, C, P, L, E, T, R, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{ObservationReflectionPacket}^{\uparrow}}$.

Constructive story: An ObservationReflectionPacket$^{\uparrow}$ packet is generated from a source trace, finite history carrier, signature extraction row, classifier row, package provenance, ledger row, open continuation, componentwise transport, displayed route, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ObservationReflectionPacket}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1126.1, Definition 1126.2, Definition 1126.3, Definition 1126.4, and the TasteGate single-carrier alignment supply the paper-side bridge from the finite observation-reflection packet to the abstract interface by binding the carrier, non-escape boundary, public export surface, and alignment target together.

Formal verification: FormalStatus(NameCert$_{\text{ObservationReflectionPacket}^{\uparrow}}$, bridgeChecked)

Not claimed: This chapter does not assert ontological identity between physical reality and MetaCIC, final truth, host-level physical laws, unbounded observation streams, or bridge checking.

Upgrade path: No further upgrade – chapter at top of formal axis.

Chapter 1127

A Concrete Naming Certificate for $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$

The $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$packet realizes the indexed approximation-tower discipline of chapter 9414 as a composite BEDC NameCert carrier. It sits after the observation reflection packet of chapter 1126, the ontic-state packet of chapter 1125, the approximation carrier of chapter 225, the finite Cauchy approximation carrier of chapter 601, the Real approximation envelope of chapter 637, and the observer-filter budget selector of chapter 1042. Those siblings provide observation readback, ontic-state naming, approximation rows, finite Cauchy windows, Real-facing envelope data, and selected observer budgets; this carrier binds them into one indexed reality-constrained tower without importing host equality, quotient reals, hidden limit selectors, or ambient completeness. As an ai packet, it bundles observation reflection, ontic-state naming, approximation, finite Cauchy approximation, Real-envelope, and observer-budget surfaces into one indexed tower ledger.

Definition 1127.1 (Reality-constrained approximation-tower carrier)**.** *A* $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ *c*
is a finite BHist *packet*

$$T = (O, D, M, S, C, F, L, H, R, P, N)$$

with the following displayed rows:

1. *O is the ontic source row naming the reality-facing source whose signatures are being approximated;*
2. *D is the observation-data row, containing the finite admissible observations selected for the tower and the displayed observation-reflection readback;*
3. *M is the model row, naming the visible mathematical model read from the observed source;*
4. *S is the physical-signature row extracted from O through D and read against M;*
5. *C is the reality-constrained classifier row comparing model-facing signatures with the reality-facing signature row S;*
6. *F is the GAP-admissible compression row, recording the indexed sequence of approximation, finite Cauchy, Real-envelope, observer-budget, and residue stages accepted by the displayed classifier;*
7. *L is the ledger row recording every hidden source, compressed stage, rejected signature omission, and open residue of the tower;*

8. *H records componentwise* hsame *transport among source, observation-data, model, signature, classifier, compression, ledger, provenance, and local-name rows;*
9. *R records the displayed* Cont *route from source observation to model readback, signature comparison, compression use, and ledger inspection;*
10. *P is the* Pkg *provenance over chapter 1126, chapter 1125, chapter 225, chapter 601, chapter 637, chapter 1042,* BHist, hsame, Cont, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedApproximationTower}^{\uparrow}}$ *row.*

The classifier admits T only when the physical signature, GAP-admissible compression, and ledger rows are all displayed on the same indexed tower. The carrier has no coordinate for mathematical approximation divorced from physical signature, compression without a listed GAP row, erased compression residue, quotient-real equality, selected host limits, host-level physical law, or ambient completeness.

Theorem 1127.2 (Reality-constrained approximation-tower NameCert obligations)**.** *For every accepted* $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ *carrier*

$$T = (O, D, M, S, C, F, L, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedApproximationTower}^{\uparrow}}$ *surface consists exactly of carrier admission for T, ontic source exposure through O, observation-data readback through D, model exposure through M, physical-signature display through S, reality-constrained classifier exactness through C, GAP-admissible compression through F, ledger coverage through L, componentwise* hsame *transport through H, displayed* Cont *route replay through R, dependency provenance through P, and local naming through N.*

Proof. Project the carrier definition. The positive route exposes the source row O, observation-data row D, model row M, physical-signature row S, classifier C, GAP-admissible compression row F, and ledger row L before the structural rows are read.

The structural rows are attached to that same route. Transport through H is componentwise over the displayed rows, replay through R follows the same tower ledger, provenance through P names the listed siblings, and N names no additional coordinate.

Thus the local NameCert surface is exhausted by the displayed rows. Since no additional coordinate exists for detached mathematical approximation, unledgered physical signature data, a hidden classifier, or an ambient completion principle, the obligations are exactly the ones listed. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedApproximationTowerUp.RealityConstrainedApproximationTowerTasteGa`
`single carrier alignment`

Theorem 1127.3 (Reality-constrained approximation-tower non-escape)**.** *Every mathematical approximation consumed through an accepted* $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ *packet factors through the displayed physical-signature row S, classifier row C, GAP-admissible compression row F, and tower ledger L. It cannot replace physical-fit signature data by using only the model row M, host equality, quotient-real equality, selected limits, or ambient completeness.*

Proof. Start with the carrier $T = (O, D, M, S, C, F, L, H, R, P, N)$. Its only approximation-facing coordinates after model readback are the physical-signature row S, classifier row C, compression row F, and ledger row L.

Apply the obligation surface of Definition 1127.2. Any mathematical classifier whose stability depends on hidden source history, omitted physical signature, or compressed residue must be recorded through S, C, F, L rather than silently transported across M.

It remains to exhaust the excluded routes. The model row M records the visible mathematical representation, and the structural rows H, R, P, N only transport, replay, package, and name displayed data. None of these rows contains host equality, quotient-real equality, selected limits, ambient completeness, or a second physical-fit channel. Thus mathematical approximation cannot replace the displayed physical-fit signature data. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedApproximationTowerUp.RealityConstrainedApproximationTowerNonesca`

Theorem 1127.4 (Reality-constrained approximation-tower sibling independence)**.** *The* RealityConstrainedApproxi *is not bijective to the observation-reflection-packet, ontic-state, finite-observation-interface, closed-observation-system, reflection-runtime-checkpoint, approximation, finite-Cauchy-approximation, Real-approximation-envelope, observer-filter-budget-selector, or residue surfaces named by its provenance. Each sibling lacks at least one of the joint ontic source, observation-data row, model row, physical-signature row, classifier row, GAP-admissible compression row, ledger row, transport, continuation, provenance, and local NameCert coordinates required by Definition 1127.1.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedApproximationTowerUp.RealityConstrainedApproximationTower sibling independence boundary`

Proof. Inspect the observation-facing siblings. The observation-reflection packet supplies a readback route but not the full GAP-admissible compression ledger. The ontic-state packet names source state but not the classifier and tower ledger. The finite-observation-interface, closed-observation-system, and reflection-runtime-checkpoint surfaces each isolate an interface, closure, or runtime checkpoint without carrying the full physical-fit classifier across the tower.

Inspect the approximation-facing siblings. The approximation carrier supplies approximation rows but not the full physical-signature and ledger inventory. The finite Cauchy approximation carrier supplies finite precision windows but not the ontic source and physical-signature classifier. The Real approximation envelope supplies Real-facing boundary rows but not the selected observation bundle with omitted-row residue. The observer-filter budget selector supplies selected and omitted observer rows but not the full indexed tower from ontic source to model readback.

The residue surface is also separated. It records what remains outside a given admission, while the tower carrier binds residue to the same packet that contains source, observation data, model, physical signature, classifier, GAP-admissible compression, ledger, transport, continuation, provenance, and local naming rows.

Therefore no listed sibling carries all coordinates of T and no coordinate of T can be deleted without changing the accepted NameCert surface. A bijection preserving the local obligations would have to preserve all displayed rows, which none of the siblings can do. □

Falsifiable prediction: An accepted $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ packet cannot identify two representations by a mathematical classifier unless their displayed physical signature rows agree through the same tower ledger.

Independence witness: observationreflectionpacket, onticstate, finiteobservationinterface, closedobservationsystem, reflectionruntimecheckpoint, approximation, finite-cauchy-approximation, real-approximation-envelope, observer-filter-budget-selector, residue: no listed sibling is bijective to $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ because only this packet carries ontic source, observation data, model row, physical signature, classifier, GAP-admissible compression, tower ledger, hsame

transport, Cont route, Pkg provenance, and local NameCert rows together. The tower ledger and physical-fit classifier separate these coordinates from every sibling surface.

The packet composes observationreflectionpacket, onticstate, finiteobservationinterface, closedobservationsystem, reflectionruntimecheckpoint, approximation, finite-cauchy-approximation, real-approximation-envelope, observer-filter-budget-selector, and residue into the displayed approximation-tower surface.

Lean development for this route must provide Nontrivial RealityConstrainedApproximationTower$^{\uparrow}$ and FieldFaithful RealityConstrainedApproximationTower$^{\uparrow}$ instances in `lean4/BEDC/Derived/RealityConstrainedA`

Theorem 1127.5 (Reality-constrained approximation-tower bridge surface)**.** *Every public* RealityConstrainedAppro *packet bridges the observation-reflection, ontic-state, approximation, finite-Cauchy approximation, Real-approximation envelope, and observer-filter budget rows into one BEDC carrier interface. The bridge preserves the physical-signature classifier and ledger nonescape while keeping the TasteGate handoff attached to the same finite tower packet.*

Proof. Start from the carrier of Definition 1127.1. Its displayed rows contain the ontic source, observation-data readback, model row, physical-signature row, classifier, GAP-admissible compression, ledger, transport, replay, provenance, and local naming data.

Apply Definition 1127.2 and Definition 1127.3. The obligation surface binds all six dependency families to the same packet, and nonescape keeps mathematical approximation behind the physical-signature classifier and tower ledger.

Use sibling independence, Definition 1127.4, to prevent any listed sibling from replacing the composite carrier. The existing TasteGate marker remains the Lean-facing witness that the displayed carrier alignment is the accepted public route. □

Closure status for NameCert$_{\text{RealityConstrainedApproximationTower}^{\uparrow}}$.

Constructive story: A RealityConstrainedApproximationTower$^{\uparrow}$ packet is generated from ontic source, observation-data, model, physical-signature, classifier, GAP-admissible compression, ledger, transport, continuation, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{RealityConstrainedApproximationTower}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1127.1, Definition 1127.2, Definition 1127.3, Definition 1127.4, Definition 1127.5, and

Lean4 ✓ `BEDC.Derived.RealityConstrainedApproximationTowerUp.taste gate`

bind the public carrier, NameCert surface, non-escape boundary, sibling-independence witness, paper bridge surface, and TasteGate handoff for the finite tower.

Formal verification: FormalStatus(NameCert$_{\text{RealityConstrainedApproximationTower}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RealityConstrainedApproximationTowerUp.RealityConstrainedApproximationTowerTasteGate\_s`

Bridge status: none

Origin: ai

Not claimed: This chapter does not claim machine bridge checking for the paper bridge surface.

Upgrade path: Bridge checking remains the next verification step for binding the same carrier, NameCert surface, non-escape boundary, sibling-independence witness, paper bridge surface, and TasteGate handoff.

Chapter 1128

A Concrete Naming Certificate for $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$

The $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ packet realizes the reality-constrained approximation tower of chapter 9414 as a finite NameCert carrier. It sits beside the ontic-state surface of chapter 1125, the finite stream window surface of chapter 126, the regular rational readback of chapter 301, the Real seal of chapter 38, and the dyadic observation ledger of chapter 291. When tower observations are exposed, the packet also consumes the methodology-ledger route of chapter 1145 because that sibling provides the finite audit and signature-residue rows that the tower packet packages. Those sibling chapters supply source, schedule, rational-window, completed-real, and dyadic-tolerance rows; this packet binds them to classifier adequacy, descent, ledger, residue, transport, and non-escape rows before any consumer treats approximation or completion as reality-facing fit.

Definition 1128.1 (Reality-constrained tower packet carrier)**.** *A* $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (O, S, R, E, D, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{OnticState}^{\uparrow}$ *source row naming the reality-facing source whose approximation is being read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the finite observation windows available to the packet.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled windows.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the regular rational readback.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and residue ledger row for the same finite windows.*
6. *L is the classifier-ledger row recording which approximation, completion, and physical-signature comparisons are asserted and which adequacy gaps remain visible.*
7. *Q is the descent row. A consumer may descend along a tower operation only when the corresponding permission is displayed in Q.*
8. *H records componentwise* hsame *transport for the source, schedule, readback, Real seal, dyadic ledger, classifier ledger, descent row, replay, provenance, and local name.*

9. *C records the displayed* Cont *replay through $O, S, R, E, D, L, Q, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$, $\mathsf{OnticState}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerPacket}^{\uparrow}}$ *row.*

The carrier has no coordinate for identifying mathematical classifier adequacy with physical fit, no route from a completed Real row to reality-facing equivalence without O, L, D, and no descent across the tower outside the displayed row Q.

Lean4 (definition) `BEDC.Derived.RealityConstrainedTowerPacketUp.RealityConstrainedTowerPacketCarrier`

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerPacketUp.RealityConstrainedTowerPacketCarrier route closure`

Theorem 1128.2 (Reality-constrained tower packet NameCert boundary)**.** *For the carrier of Definition 1128.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerPacket}^{\uparrow}}$ *boundary consists exactly of seven obligation surfaces:*

1. *carrier admission for $T = (O, S, R, E, D, L, Q, H, C, P, N)$;*
2. *source exposure through the* $\mathsf{OnticState}^{\uparrow}$ *row O;*
3. *finite-window classifier exposure through S, R, E, D in the displayed StreamName, RegSeqRat, Real, and DyadicRatCore order;*
4. *reality-facing classifier accountability through the ledger row L;*
5. *descent permission through Q;*
6. *componentwise transport and replay through H, C;*
7. *provenance and local naming through P, N.*

Any consumer that reads endpoint equivalence, completion adequacy, or tower descent from the packet must display these surfaces before exporting its conclusion.

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerPacketUp.TasteGate.RealityConstrainedTowerPacketNameCertBou`

Proof. Project the carrier. The only accepted packet is the finite tuple $O, S, R, E, D, L, Q, H, C, P, N$, so endpoint equivalence and tower descent have no source outside the displayed rows.

Read the sibling rows in order. The ontic source comes from chapter 1125, finite access comes through chapter 126, regular readback through chapter 301, Real sealing through chapter 38, and dyadic tolerance through chapter 291.

The ledger L records the reality-facing classifier and adequacy residue, while Q records the permitted descent rows. The transport, replay, provenance, and local name rows H, C, P, N preserve exactly that packet. Therefore the local certificate boundary is exhausted by the seven listed surfaces. □

Theorem 1128.3 (Reality-constrained tower packet non-escape)**.** *Every accepted* $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ *consumer read factors through*

$$O, S, R, E, D, L, Q, H, C, P, N.$$

In particular, a consumer cannot export endpoint equivalence, completion adequacy, physical fit, or tower descent from the mathematical approximation rows alone. The reality-facing classifier ledger L, dyadic residue row D, ontic source row O, and descent row Q remain mandatory boundary data.

Lean4 ✓ BEDC.Derived.RealityConstrainedTowerPacketUp.TasteGate.RealityConstrainedTowerPacketUp nonescape transport

Proof. Start with Definition 1128.2. It requires source exposure, finite-window classifier exposure, reality-facing classifier accountability, descent permission, transport, replay, provenance, and local naming before the packet can be consumed.

The mathematical rows S, R, E provide windowed readback and Real sealing, but they do not supply the ontic source O, dyadic residue ledger D, classifier ledger L, or descent row Q. Thus a route that keeps only mathematical approximation has lost rows required by the certificate.

Transport and replay do not add a hidden adequacy route. The rows H, C, P, N only preserve and name the displayed packet, so every accepted read remains inside $O, S, R, E, D, L, Q, H, C, P, N$. □

Theorem 1128.4 (Reality-constrained tower packet TasteGate obligation)**.** *The* RealityConstrainedTowerPacket$^{\uparrow}$ *TasteGate surface is obligated to keep one carrier alignment across the source, classifier, descent, ledger, residue, transport, provenance, and local-name rows of Definition 1128.1. A* Nontrivial *instance must distinguish at least one accepted source-ledger packet from a packet with missing reality-facing classifier, descent, or residue rows, and a* FieldFaithful *instance must preserve the row order*

$$O, S, R, E, D, L, Q, H, C, P, N$$

under every accepted field projection.

Proof. Use the NameCert boundary theorem to identify the carrier fields visible to the gate. The accepted gate has to read the source, schedule, regular readback, Real seal, dyadic residue, classifier ledger, descent permission, transport, replay, provenance, and local name as one packet.

Nontriviality is forced by the non-escape theorem: a packet that omits the reality-facing classifier, descent, or residue rows cannot export the same accepted consumer route. Field faithfulness is therefore the requirement that every gate projection preserve the displayed row order rather than replacing it by a detached mathematical classifier. □

Lean4 ✓ BEDC.Derived.RealityConstrainedTowerPacketUp.TasteGate.RealityConstrainedTowerPacketTasteGate single carrier alignment

Theorem 1128.5 (Reality-constrained tower packet classifier-ledger exactness)**.** *For every accepted* RealityConstrainedTowerPacket$^{\uparrow}$ *carrier* $T = (O, S, R, E, D, L, Q, H, C, P, N)$*, the row* L *is the only classifier-adequacy row visible to endpoint-equivalence and completion-adequacy consumers. The schedule, readback, Real-seal, and descent rows* S, R, E, Q *may be read only as finite access and permission data, while* D *records dyadic residue; none of* S, R, E, D *exports physical fit without the reality-facing classifier ledger* L *together with the source row* O *and the local certificate rows* P, N*.*

Lean4 ✓ BEDC.Derived.RealityConstrainedTowerPacketUp.TasteGate.RealityConstrainedTowerPacketClassifierL

Proof. Project the carrier through Definition 1128.1. The displayed classifier-adequacy coordinate is L, and the NameCert boundary of Definition 1128.2 lists reality-facing classifier accountability as its own obligation surface.

The finite-window rows S, R, E and the residue row D are therefore not alternative classifier witnesses. They supply schedule, readback, completion, and tolerance data inside the packet, but their consumer routes still pass through the seven-surface boundary.

Apply Definition 1128.3. Any endpoint-equivalence or completion-adequacy export that forgets O, L, D, Q, H, C, P, N has left the accepted packet. Hence L is exact as the ledger row for classifier adequacy, and S, R, E, D cannot by themselves export physical fit. □

Theorem 1128.6 (Reality-constrained tower packet descent permission stability)**.** *Let $T = (O, S, R, E, D, L, Q, H,$ and $T' = (O', S', R', E', D', L', Q', H', C', P', N')$ be accepted* $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ *carriers related by componentwise* hsame *transport preserving the displayed rows $O, S, R, E, D, L, Q, H, C, P, N$. If a descent is permitted for T' after transport, then its permission is already displayed in the transported row Q'. The transport and replay rows H', C' cannot add a descent outside Q'.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerPacketUp.TasteGate.RealityConstrainedTowerPacketDescentPerm`

Proof. Project the target carrier T'. By the carrier definition, descent permission is stored in the single displayed row Q', while H' records componentwise hsame transport and C' records replay through the same named rows.

Use the NameCert boundary to read descent permission as a separate obligation surface. Since the boundary exposes Q' before transport and replay are consumed, replay can only preserve the displayed permission surface.

Finally apply the non-escape theorem to the transported packet. A descent route outside Q' would export tower descent without the mandatory descent row of the accepted carrier, contradicting the stated consumer boundary. Thus componentwise transport preserves permitted descent and cannot create a hidden descent permission. □

Theorem 1128.7 (Reality-constrained tower packet Real-phase consumer boundary)**.** *Every consumer route that passes through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *before treating an endpoint as reality-facing must also display the rows*

$$O, L, Q, H, C, P, N.$$

Thus finite windows, regular rational readback, Real sealing, and dyadic tolerance are not sufficient for a reality-facing endpoint unless the source, classifier ledger, descent permission, transport, replay, provenance, and local NameCert rows remain present.

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerPacketUp.TasteGate.RealityConstrainedTowerPacketRealPhaseCo`

Proof. Read the sibling route in the order named in the chapter introduction. $\mathsf{StreamName}^{\uparrow}$ supplies finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular rational readback, $\mathsf{Real}^{\uparrow}$ supplies the completed seal, and $\mathsf{DyadicRatCore}^{\uparrow}$ supplies dyadic tolerance and residue.

The classifier-ledger exactness theorem then identifies L as the visible classifier-adequacy row for endpoint and completion consumers. The descent-permission stability theorem identifies Q as the only displayed descent row preserved under componentwise transport and replay.

Apply the non-escape theorem to the combined route. Since every accepted consumer read factors through $O, S, R, E, D, L, Q, H, C, P, N$, the Real-phase route may use S, R, E, D only while also retaining O, L, Q, H, C, P, N. Therefore no completed endpoint becomes reality-facing from the Real-phase rows alone. □

Falsifiable prediction: Any accepted RealityConstrainedTowerPacketUp consumer that exports endpoint equivalence without reality-facing classifier, descent, and residue-ledger rows refutes the packet.

Independence witness: onticstate, streamname, regseqrat, real, dyadicratcore: none is bijective because $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ binds source, classifier, descent, ledger, residue, transport, provenance, and local NameCert rows in one carrier, while each sibling supplies only one constituent surface.

The Lean `TasteGate.lean` development for $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ provides explicit $\mathsf{Nontrivial\ RealityConstrainedTowerPacket}^{\uparrow}$ and $\mathsf{FieldFaithful\ RealityConstrainedTowerPacket}^{\uparrow}$ instances, together with the target `BEDC.Derived.RealityConstrainedTowerPacketUp.TasteGate.RealityConstrainedT`

Theorem 1128.8 (Reality-constrained tower packet public export)**.** *The public* $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ *surface exposes exactly the carrier, NameCert boundary, non-escape, classifier-ledger exactness, descent-permission stability, and Real-phase consumer boundary rows of this chapter. A downstream public consumer may cite the packet as a reality-constrained approximation-tower object only while preserving the displayed source, schedule, readback, Real seal, dyadic residue ledger, classifier ledger, descent permission, transport, replay, provenance, and local NameCert rows.*

Proof. Start with the carrier and NameCert boundary. They present the finite tuple $O, S, R, E, D, L, Q, H, C, P, N$ and identify the seven obligation surfaces available to consumers.

Apply the non-escape, classifier-ledger exactness, descent-permission stability, and Real-phase consumer boundary theorems. Together they rule out public reads that forget the source, classifier ledger, residue ledger, descent permission, transport, replay, provenance, or local naming rows.

Thus the public export is not a new mathematical object. It is the named outward-facing use of the same displayed packet, with every consumer route still factored through the rows proved in the chapter. □

Theorem 1128.9 (Reality-constrained tower packet mature boundary)**.** *The public export, non-escape, classifier-ledger exactness, descent-permission stability, and Real-phase consumer boundary theorems exhaust the mature paper surface of* $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$*. Every mature consumer route must preserve the displayed source, schedule, readback, Real seal, dyadic residue ledger, classifier ledger, descent permission, transport, replay, provenance, and local NameCert rows, and no further paper-side endpoint is exported by this chapter.*

Proof. Start with the public export theorem Definition 1128.8. It identifies the outward-facing surface as the carrier, NameCert boundary, non-escape, classifier-ledger exactness, descent-permission stability, and Real-phase consumer boundary rows.

Apply non-escape and classifier-ledger exactness, Definition 1128.3 and Definition 1128.5. These force every endpoint-equivalence or completion-adequacy read to retain the source, classifier ledger, dyadic residue, descent row, transport, replay, provenance, and local naming data.

Apply descent-permission stability and the Real-phase consumer boundary, Definition 1128.6 and Definition 1128.7. They keep tower descent inside Q and keep the Real-facing route dependent on O, L, Q, H, C, P, N.

The carrier and NameCert boundary contain no additional mature endpoint. Therefore the listed public, non-escape, classifier-ledger, descent-permission, and Real-phase rows exhaust the chapter's paper-side mature surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerPacket}^{\uparrow}}$.

Constructive story: A $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ packet is generated from an ontic source row, finite stream schedule, regular rational readback, Real seal, dyadic residue ledger, reality-facing classifier ledger, descent permission row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerPacket}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1128.1, Definition 1128.2, Definition 1128.3, Definition 1128.4, Definition 1128.5, Definition 1128.6, Definition 1128.7, Definition 1128.8, and Definition 1128.9 bind the mature paper surface across the public source, classifier, descent, ledger, residue, transport, provenance, and local naming rows for reality-constrained approximation-tower packets; this bridge is not Lean-checked.

Formal verification: FormalStatus(NameCert$_{\text{RealityConstrainedTowerPacket}\uparrow}$, unformalized)
Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerPacketUp.taste gate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, total physical adequacy, host physical identity, quotient equality of Real-completion data with source reality, or unrestricted tower descent.

Upgrade path: Mature closure requires a checked standard bridge and audit-clean transport for the displayed packet rows.

Chapter 1129

A Concrete Naming Certificate for $\mathsf{PhysicalModelAudit}^{\uparrow}$

The $\mathsf{PhysicalModelAudit}^{\uparrow}$ packet realizes the audit protocol of Definition 9414.617 as one finite BEDC naming certificate. It is adjacent to the audit-channel surface of chapter 969, the trace-storage surface of chapter 972, the state-space model surface of chapter 329, the ontic-state surface of chapter 1125, and the observation-reflection routing surface of chapter 1126. Its role is to bind source traces, target phenomenon, observed and model signatures, classifier, tower, stability and descent rows, ledger, failure surface, strength, transports, routes, provenance, and local NameCert before a physical claim is read as accepted.

Definition 1129.1 (PhysicalModelAudit carrier)**.** *A* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (Q, R, O, M, C, T, Y, D, L, F, S, H, U, P, N)$$

with the following displayed rows:

1. *Q is the finite source-trace row, recording the histories or experimental traces consumed by the audit.*
2. *R is the target-phenomenon row, naming the physical system, phenomenon, or class of systems under audit.*
3. *O is the observed-signature row extracted from Q through the declared observation bundle.*
4. *M is the model-signature row generated by the candidate model for the same bundle.*
5. *C is the physical-audit classifier comparing O and M at the declared fit level.*
6. *T is the approximation-tower row from source traces to model-facing signatures.*
7. *Y is the stability row specifying the licensed reuse domain for the audited comparison.*
8. *D is the descent row recording which predictive or explanatory operations survive the tower.*
9. *L is the audit ledger for provenance, hidden compression, representation, idealization, and translation material.*
10. *F is the failure-surface row naming finite defeating observations or signature mismatches.*
11. *S is the audit-strength row, distinguishing seed support, paper fit, reproduced fit, and bridged fit.*
12. *H records componentwise* hsame *transport for all content rows.*

13. *U records displayed* Cont *routes through source, phenomenon, signature, classifier, tower, stability, descent, ledger, failure, and strength rows.*
14. *P is the* Pkg *provenance over* $\mathsf{PhysicalModelAudit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
15. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalModelAudit}^{\uparrow}}$ *row.*

The carrier contains no host-level truth oracle, unbounded observation stream, unledgered compression, detached model equivalence, or physical acceptance route outside the displayed packet.

Lean4 ✓ `BEDC.Derived.PhysicalModelAuditUp.PhysicalModelAuditTasteGate single carrier alignment`

Definition 1129.2 (PhysicalModelAudit classifier)**.** *For accepted packets*

$$A = (Q, R, O, M, C, T, Y, D, L, F, S, H, U, P, N) \quad \text{and} \quad A' = (Q', R', O', M', C', T', Y', D', L', F', S', H', U', P', N')$$

the predicate $\mathsf{PhysicalModelAuditClassifier}(A, A')$ *holds when H and H' transport source traces, target phenomena, observed signatures, model signatures, approximation towers, stability rows, descent rows, ledger rows, failure surfaces, strength rows, routes, provenance, and local names componentwise, and when C and C' preserve the same declared comparison between O, M and O', M'.*

Classifier agreement is therefore stronger than model-syntax agreement and weaker than host-level physical truth. It is the finite assertion that the same audit comparison is read through the same displayed source-signature-classifier-tower-ledger packet.

Theorem 1129.3 (PhysicalModelAudit NameCert obligation surface)**.** *For the carrier of Definition 1129.1, the local* $\mathsf{NameCert}_{\mathsf{PhysicalModelAudit}^{\uparrow}}$ *surface is exhausted by the following five obligation rows:*

1. *source admission: Q and R are the only source-trace and target-phenomenon rows licensed for the audit;*
2. *signature admission: O and M are the observed and model-signature rows read by the packet;*
3. *classifier admission: C is the finite comparison row relating O and M at the declared fit level;*
4. *tower, stability, and descent admission: T, Y, D are the displayed approximation, reuse, and operation-survival rows;*
5. *ledger, failure, and strength admission: L, F, S record provenance material, defeating observations, and the evidential grade before the local name is accepted.*

No accepted physical-audit claim through this packet can read a field outside these rows.

Proof. Carrier admission is the projection of the displayed tuple in Definition 1129.1. The packet lists the source row, target row, signature rows, classifier row, tower row, stability row, descent row, ledger row, failure row, strength row, and the structural transport, route, provenance, and naming rows.

The classifier of Definition 1129.2 reads only those rows. Its comparison is not a separate model oracle; it is the relation between observed and model signatures as transported and replayed inside the same packet.

The ledger and failure-surface rows close the remaining escape points. Any compression, idealization, translation, or possible defeat used by the audit must be named by L or F, and the evidential level must be named by S.

Thus the local NameCert has no further coordinate to expose. A consumer that asks for another source, signature, classifier, tower, ledger, failure surface, or strength row has left the accepted PhysicalModelAudit$^{\uparrow}$ carrier. □

Lean4 ✓ `BEDC.Derived.PhysicalModelAuditUp.PhysicalModelAuditPacket namecert obligation surface`

Theorem 1129.4 (PhysicalModelAudit acceptance non-escape)**.** *An accepted* PhysicalModelAudit$^{\uparrow}$ *route cannot turn a model-signature comparison into a physical acceptance claim unless the source-trace row, target-phenomenon row, observed-signature row, model-signature row, classifier row, tower row, stability row, descent row, ledger row, failure-surface row, and strength row are all present in the same finite packet.*

Proof. Start with the obligation surface in Definition 1129.3. The accepted route factors through the displayed tuple

$$Q, R, O, M, C, T, Y, D, L, F, S, H, U, P, N.$$

The real-facing part of the route is not the model signature M alone. It also requires the source traces Q, target phenomenon R, observed signatures O, classifier C, tower T, stability and descent rows Y, D, ledger L, failure surface F, and strength row S.

If any one of those rows is absent, the route can still describe syntax or a partial finite comparison, but it cannot project the local physical acceptance name. The missing row is outside the carrier, so the corresponding physical claim is not accepted by this NameCert packet. □

Lean4 ✓ `BEDC.Derived.PhysicalModelAuditUp.PhysicalModelAuditPacket acceptance nonescape`

Theorem 1129.5 (PhysicalModelAudit ledger failure strength separation)**.** *For every accepted packet*

$$A = (Q, R, O, M, C, T, Y, D, L, F, S, H, U, P, N),$$

the ledger row L, failure row F, and strength row S are separate audit coordinates. The ledger row records provenance, compression, representation, idealization, and translation material; the failure row records finite defeating observations or signature mismatches; the strength row records the evidential grade licensed by the accepted route. None of the three rows can be reconstructed from either of the other two without leaving the displayed carrier.

Proof. Start with the carrier in Definition 1129.1. It lists L, F, and S as distinct rows of the same finite packet, with L assigned to audit material, F assigned to defeating observations or mismatches, and S assigned to evidential strength.

Apply the classifier in Definition 1129.2. The classifier transports ledger rows, failure surfaces, and strength rows componentwise; it does not collapse them into the observed signature, model signature, or comparison row.

Finally use the NameCert obligation surface and the acceptance non-escape theorem. Definition 1129.3 places ledger, failure, and strength admission in the local certificate, while Definition 1129.4 requires all three rows before a physical acceptance name can be projected. Hence an accepted audit cannot substitute ledger material for a defeat surface, a defeat surface for evidential strength, or strength for either of the audit rows. □

Lean4 ✓ `BEDC.Derived.PhysicalModelAuditUp.PhysicalModelAuditPacket ledger failure strength separation`

Theorem 1129.6 (PhysicalModelAudit route strength determinacy)**.** *For an accepted packet*

$$A = (Q, R, O, M, C, T, Y, D, L, F, S, H, U, P, N),$$

the audit strength row S is determined only by the displayed source, signature, classifier, tower, stability, descent, ledger, and failure route

$$Q, R, O, M, C, T, Y, D, L, F, H, U, P, N.$$

No host physical truth oracle, detached model equivalence, unbounded observation stream, or hidden validation route can determine the accepted audit strength outside the displayed packet.

Proof. Read the carrier first. Definition 1129.1 places S in the same finite tuple as the source trace Q, target phenomenon R, observed and model signatures O, M, classifier C, tower T, stability and descent rows Y, D, ledger L, failure surface F, and structural rows H, U, P, N.

The classifier fixes the comparison route. By Definition 1129.2, accepted comparison is a relation between O, M and transported copies of the same displayed rows; it is not a separate model oracle.

Use the obligation surface to bind the strength source. Definition 1129.3 admits S only together with the source, signature, classifier, tower, stability, descent, ledger, and failure rows. Then Definition 1129.4 blocks a physical acceptance name whenever any of those rows is absent.

Therefore the accepted strength is determined by the displayed route and by no hidden host evidence. A consumer that changes S without changing the listed source, signature, classifier, tower, stability, descent, ledger, failure, transport, route, provenance, or naming rows has left the accepted $\mathsf{PhysicalModelAudit}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.PhysicalModelAuditUp.PhysicalModelAuditPacket route strength determinacy`

Theorem 1129.7 (PhysicalModelAudit failure surface exhaustion)**.** *For an accepted packet*

$$A = (Q, R, O, M, C, T, Y, D, L, F, S, H, U, P, N),$$

every defeating observation, signature mismatch, reuse failure, descent failure, or audit-level objection available to the physical model audit must appear through the failure row F and its displayed transports through H, U, P, N. No hidden host observation, unledgered mismatch, or detached failure witness can defeat the accepted route outside F.

Proof. Begin with the displayed packet. The carrier of Definition 1129.1 assigns finite defeating observations and signature mismatches to F, while $Q, R, O, M, C, T, Y, D, L, S$ record the source, phenomenon, signatures, classifier, tower, stability, descent, ledger, and strength rows.

The classifier does not add a second failure store. By Definition 1129.2, mismatch information is compared through the transported observed and model signatures together with the failure surface already present in the packet.

Apply Definition 1129.3. The local NameCert has a ledger, failure, and strength admission row, and its failure coordinate is the only named surface for defeating observations or signature mismatches.

Finally use Definition 1129.4. Acceptance requires F in the same finite packet as the source, signature, classifier, tower, stability, descent, ledger, and strength rows. Thus any alleged defeat that does not enter through F is not a defeating observation of the accepted $\mathsf{PhysicalModelAudit}^{\uparrow}$ route; it is outside the carrier rather than hidden host evidence. □

Lean4 ✓ `BEDC.Derived.PhysicalModelAuditUp.PhysicalModelAuditPacket failure surface exhaustion`

The Lean follow-up path `lean4/BEDC/Derived/PhysicalModelAuditUp/TasteGate.lean` must provide explicit Nontrivial PhysicalModelAudit$^{\uparrow}$ and FieldFaithful PhysicalModelAudit$^{\uparrow}$ instances. These instances must distinguish source traces, target phenomenon, observed and model signatures, classifier, tower, stability, descent, ledger, failure surface, strength, transports, routes, provenance, and local NameCert as separate fields.

Falsifiable prediction: If the checker or failure-surface row is absent, an accepted PhysicalModelAuditUp packet cannot promote finite fit beyond ModelSeed.

Independence witness: largemodelauditchannel, modeltrace, statespacemodel, onticstate, observationreflectionpacket: none is bijective because PhysicalModelAuditUp carries system-relative observation bundle, fit classifier, tower, stability/descent, failure, and strength rows together rather than only output auditing, trace storage, state-space presentation, ontic-source status, or observation-reflection routing.

Closure status for NameCert$_{\text{PhysicalModelAudit}^{\uparrow}}$.

Constructive story: A PhysicalModelAudit$^{\uparrow}$ packet is generated from finite source traces, target phenomenon, observed and model signatures, audit classifier, tower, stability, descent, ledger, failure surface, strength, componentwise transports, displayed routes, provenance, and a local NameCert row.

Lean4 ✓ `BEDC.Derived.PhysicalModelAuditUp.taste gate`

Theory closure: TheoryGate(NameCert$_{\text{PhysicalModelAudit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1129.1, Definition 1129.2, Definition 1129.3, Definition 1129.4, Definition 1129.5, Definition 1129.6, and Definition 1129.7 bind the source-trace, target-phenomenon, observed-signature, model-signature, classifier, tower, stability, descent, ledger, failure, strength, hsame, Cont, Pkg, and NameCert rows of the accepted audit packet.

Formal verification: FormalStatus(NameCert$_{\text{PhysicalModelAudit}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.PhysicalModelAuditUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close host-level physical truth, unbounded validation, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: The accepted public audit packet has mature paper closure; Lean verification, axiom-clean audit, and bridge checking remain separate verification-axis obligations.

Chapter 1130

A Concrete Naming Certificate for $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$

The $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ packet realizes the physical-truth decomposition of chapter 9414 as a finite BEDC NameCert carrier. It consumes the tower packet of chapter 1128, the reality-constrained approximation carrier of chapter 1127, the observation-reflection packet of chapter 1126, the physical-model audit surface of chapter 1129, and the open-fit surface of chapter 1132. Those siblings supply source access, signature comparison, approximation, handoff, audit, and refutation rows; this packet binds them into a single truth-certificate surface without adding model–reality identity or a final-fit oracle.

Definition 1130.1 (CertifiedPhysicalTruth carrier)**.** *A* $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, G, K, A, D, I, L, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-observation row, recording the finite reality-facing traces or experiments admitted by the packet.*
2. *G is the reality-facing signature row extracted from S through the declared observation bundle.*
3. *K is the classifier row comparing the displayed signature with the candidate physical claim at the stated fit level.*
4. *A is the approximation-tower row through which mathematical approximation, completion, and prediction are read.*
5. *D is the descent-certificate row licensing exactly the operations that survive passage through A.*
6. *I is the observer-invariance certificate row, recording the displayed anchor-change or inter-observer route by which the claim remains invariant.*
7. *L is the ledger row for provenance, compression, idealization, translation, reuse domain, and accepted evidential strength.*
8. *F is the failure-surface row naming finite defeating observations, signature mismatches, and open residues.*
9. *H records componentwise* hsame *transport for source, signature, classifier, tower, descent, invariance, ledger, failure, replay, provenance, and local-name rows.*

10. *C records displayed* Cont *replay through $S, G, K, A, D, I, L, F, H, P, N$.*
11. *P is the* Pkg *provenance over chapter 9414, the cited concrete-instance siblings,* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CertifiedPhysicalTruth}^{\uparrow}}$ *row.*

The carrier has no coordinate for host-level truth, model–reality identity, unbounded observation, unledgered approximation, privileged observer access, or final physical fit outside the displayed packet.

Lean4 ✓ `BEDC.Derived.CertifiedPhysicalTruthUp.CertifiedPhysicalTruth carrier row injective`

Definition 1130.2 (CertifiedPhysicalTruth obligation surface)**.** *For the carrier of Definition 1130.1, the local* $\mathsf{NameCert}_{\mathsf{CertifiedPhysicalTruth}^{\uparrow}}$ *surface consists exactly of eight obligation rows:*

1. *source admission through S;*
2. *reality-facing signature admission through G;*
3. *classifier exactness through K;*
4. *approximation-tower accountability through A;*
5. *descent permission through D;*
6. *observer-invariance display through I;*
7. *ledger exactness through L;*
8. *failure-surface exposure through F.*

The structural rows H, C, P, N preserve, replay, source, and locally name those eight obligations, but they do not add another truth coordinate.

Lean4 ✓ `BEDC.Derived.CertifiedPhysicalTruthUp.CertifiedPhysicalTruth obligation surface row injective`

Theorem 1130.3 (CertifiedPhysicalTruth reality fit)**.** *Every accepted* $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ *truth read factors through the source row S, signature row G, classifier row K, approximation tower A, descent certificate D, observer-invariance row I, ledger L, failure surface F, componentwise transport H, replay row C, provenance P, and local name N. In particular, physical truth through this packet is certified fit with displayed stability, descent, invariance, ledger, and failure data, not identity between a model and reality.*

Proof. Begin with the carrier of Definition 1130.1. The accepted packet displays exactly the rows

$$S, G, K, A, D, I, L, F, H, C, P, N.$$

The source and signature rows S, G provide the reality-facing input, while K records the finite classifier comparison. The approximation row A and descent row D then state which mathematical operations survive the tower rather than converting the tower into physical identity.

The invariance, ledger, and failure rows I, L, F supply the remaining truth-certificate constraints. The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no further carrier coordinate is available, every accepted truth read must remain inside the displayed fit, stability, descent, invariance, ledger, and failure surface. □

Lean4 ✓ `BEDC.Derived.CertifiedPhysicalTruthUp.CertifiedPhysicalTruthCarrier reality fit`

Theorem 1130.4 (CertifiedPhysicalTruth failure surface)**.** *An accepted* $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ *packet must expose a displayed failure-surface row* F*. If a physical-truth claim asserts model–reality identity, or if the packet lacks a row naming finite defeating observations, signature mismatches, and open residues, then the claim is not accepted by* $\mathsf{NameCert}_{\mathsf{CertifiedPhysicalTruth}^{\uparrow}}$*.*

Lean4 ✓ `BEDC.Derived.CertifiedPhysicalTruthUp.CertifiedPhysicalTruth failure surface row injective`

Proof. Use Definition 1130.2. Failure-surface exposure through F is one of the eight local NameCert obligations, so a packet without F lacks a required certificate row.

The same obligation surface separates the classifier K and tower A from any identity claim. They record finite fit and approximation accountability, while F records how the claim can be defeated. A model–reality identity assertion therefore asks the carrier to export a coordinate that the packet does not contain.

Consequently the accepted packet can certify only the displayed physical-truth surface. Removing F or replacing finite fit by identity leaves the local NameCert carrier. □

Theorem 1130.5 (CertifiedPhysicalTruth observer invariance)**.** *Every* $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ *export is invariant only through the displayed row* I *and its componentwise transport in* H*. A truth read depending on one observer history without the invariant route recorded in* I *is local observation content, not a certified physical-truth export.*

Lean4 ✓ `BEDC.Derived.CertifiedPhysicalTruthUp.CertifiedPhysicalTruthObserverInvariance`

Proof. Read the carrier fields for invariance. The only row that records observer-invariance data is I, and the only transport row preserving it componentwise is H.

The replay and provenance rows C and P do not introduce a privileged observer. They only replay and source the packet already transported through H.

Thus an accepted export must pass through I before being read as observer-invariant. If the claimed truth depends on a single observer history outside that route, the claim may remain a local finite observation, but it is not exported by $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$. □

Falsifiable prediction: If a CertifiedPhysicalTruthUp packet asserts model–reality identity or lacks a displayed failure-surface row, the packet is refuted.

Independence witness: realityconstrainedtowerpacket, realityconstrainedapproximationtower, observationreflectionpacket, physicalmodelaudit, realityconstrainedopenfit: each sibling supplies part of fit, signature, tower, handoff, audit, or refutation data, while none contains the full source, signature, classifier, tower, descent, invariant, ledger, failure-surface, transport, replay, provenance, and local NameCert truth-certificate packet.

The Lean TasteGate row provides `Nontrivial CertifiedPhysicalTruthUp` and `FieldFaithful CertifiedPhysicalTruthUp` instances in `lean4/BEDC/Derived/CertifiedPhysicalTruthUp/TasteGate.lean`.
Lean4 ✓ `BEDC.Derived.CertifiedPhysicalTruthUp.taste gate`

Theorem 1130.6 (CertifiedPhysicalTruth scoped transport coverage)**.** *For every accepted* $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ *packet, the rows* $S, G, K, A, D, I, L, F, H, C, P, N$ *cover every scoped transport and consumer read admitted by the chapter. Source, signature, classifier, approximation, descent, invariance, ledger, and failure reads are transported only through* H*; replay and provenance reads are exposed only through* C *and* P*; and the local certificate is named only by* N*.*

Proof. Project the carrier of Definition 1130.1. The packet contains exactly the source row S, signature row G, classifier row K, approximation row A, descent row D, invariance row I, ledger row L, failure row F, transport row H, replay row C, provenance row P, and local name N.

Apply Definition 1130.2. Its eight obligation rows are precisely the source, signature, classifier, approximation, descent, invariance, ledger, and failure surfaces; none is stored outside the displayed carrier.

Finally use Definition 1130.3, Definition 1130.4, and Definition 1130.5. These theorems force truth, refutation, and invariance consumers through the same displayed rows, with H, C, P, N supplying transport, replay, provenance, and local naming. Hence the scoped transport and consumer surface is exhausted by $S, G, K, A, D, I, L, F, H, C, P, N$. □

Theorem 1130.7 (CertifiedPhysicalTruth public surface)**.** *The public export of* $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ *is exactly the finite truth-certificate surface*

$$S, \quad G, \quad K, \quad A, \quad D, \quad I, \quad L, \quad F, \quad H, \quad C, \quad P, \quad N.$$

Downstream chapters may cite $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ *as a public object through those rows, but they receive no model–reality identity, no final-fit oracle, no unbounded observation row, and no bridge check.*

Proof. Project the carrier and obligation surface of Definition 1130.1 and Definition 1130.2. They list the full source, signature, classifier, approximation, descent, invariance, ledger, failure, transport, replay, provenance, and local naming rows, and no further public coordinate.

Use the reality-fit, failure-surface, and observer-invariance theorems. The fit route consumes $S, G, K, A, D, I, L, F, H, C, P, N$, the failure route requires the displayed F row, and the invariance route passes through I and componentwise transport in H.

Finally apply scoped transport coverage, Definition 1130.6. Since every admitted consumer read is already covered by the same finite surface, public citation exposes exactly those rows and cannot add model–reality identity, a final-fit oracle, unbounded observation, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{CertifiedPhysicalTruth}^{\uparrow}}$.

Constructive story: A $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ packet is generated from finite source observations, a reality-facing signature, classifier, approximation tower, descent certificate, observer-invariance certificate, ledger, failure surface, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CertifiedPhysicalTruth}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1130.1, Definition 1130.2, Definition 1130.3, Definition 1130.4, Definition 1130.5, Definition 1130.6, and Definition 1130.7 bind certified physical truth to the finite public surface $S, G, K, A, D, I, L, F, H, C, P, N$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CertifiedPhysicalTruth}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CertifiedPhysicalTruthUp.taste\_gate`

Bridge status: none

Not claimed: This chapter does not assert model–reality identity, host-level truth, final physical fit, unbounded observation, or bridge checking for $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$.

Upgrade path: The theory axis is complete; any remaining bridgeChecked claim belongs to the independent formal bridge axis.

Chapter 1131

A Concrete Naming Certificate for OpenPhysicalFit$^{\uparrow}$

The OpenPhysicalFit$^{\uparrow}$ packet realizes the finite-observation open-fit discipline of section 9414.13 as a finite BEDC NameCert carrier. It sits beside the $\mathsf{PhysicalFitTower}^{\uparrow}$ role, the $\mathsf{ObserverApproximationTower}^{\uparrow}$ role, $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ of chapter 1124, and $\mathsf{ObservationReflectionPacket}^{\uparrow}$ of chapter 1126. Those siblings expose tower, observer, audit, and observation–reflection surfaces; OpenPhysicalFit$^{\uparrow}$ binds the finite fit certificate itself, its displayed refutation surface, and its open-continuation ledger without adding a final-fit oracle.

Definition 1131.1 (OpenPhysicalFit carrier)**.** *An* OpenPhysicalFit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (H, \Pi, O, M, C, F, E, L, R, N)$$

with the following displayed rows:

1. *H is the finite reality trace row, recording the observed history through which the physical system is read;*
2. *Π is the observation-bundle row, naming the admissible questions used to extract finite signatures;*
3. *O is the observed-signature row $\mathrm{ObsSig}_{\Pi}(R \mid H)$;*
4. *M is the model-generated signature row $\mathrm{ModSig}_{\Pi}(M \mid H)$;*
5. *C is the packet classifier row comparing O and M at the declared finite-fit level;*
6. *F is the refutation row, naming displayed finite observations whose observed and model-generated signatures fail C;*
7. *E is the open-continuation row, recording admissible observation extensions still outside the finite certificate;*
8. *L is the ledger row recording hidden source residue, idealization residue, undefeated finite-fit scope, and open adequacy gaps;*
9. *R is the replay row, recording the displayed* Cont *route through H, Π, O, M, C, F, E, L;*
10. *N is the local* $\mathsf{NameCert}_{\mathrm{OpenPhysicalFit}^{\uparrow}}$ *row naming exactly this finite packet.*

The carrier has no coordinate for total physical identity, no internal proof of $\forall n, \mathrm{Fit}_n(M, R; \Pi)$, no final-fit oracle, and no route from finite success to unrestricted confirmation.

Lean4 ✓ `BEDC.Derived.OpenPhysicalFitUp.OpenPhysicalFitTasteGate single carrier alignment`

Theorem 1131.2 (OpenPhysicalFit NameCert obligations)**.** *For the carrier of Definition 1131.1, the local* $\mathsf{NameCert}_{\mathrm{OpenPhysicalFit}^{\uparrow}}$ *surface consists of six obligation rows:*

1. *carrier admission for the displayed packet* $P = (H, \Pi, O, M, C, F, E, L, R, N)$*;*
2. *trace and bundle exactness through* H *and* Π*;*
3. *observed and model-generated signature exposure through* O *and* M*;*
4. *finite classifier accountability through* C*;*
5. *refutation and open-continuation visibility through* F *and* E*;*
6. *ledger, replay, and local naming closure through* L, R, N*.*

Every accepted finite open-fit read must display these rows before a consumer may treat the model as undefeated by the observed trace.

Lean4 ✓ `BEDC.Derived.OpenPhysicalFitUp.OpenPhysicalFit semantic name certificate`

Proof. Project the carrier of Definition 1131.1. The admitted object is the ten-row packet $P = (H, \Pi, O, M, C, F, E, L, R, N)$, so a consumer begins with the finite trace and the declared observation bundle.

The signature rows then expose the two sides compared by finite fit. The observed row O and model row M are the only signatures available to the classifier C.

The boundary rows make the open status explicit. The refutation row F records finite defeating observations, while the open-continuation row E records admissible extensions that are not collapsed into a total certificate.

Finally L, R, N ledger, replay, and name the same packet. Since no other coordinate is admitted, the NameCert surface contains exactly the six displayed obligation rows. □

Theorem 1131.3 (OpenPhysicalFit refutation boundary)**.** *An accepted* $\mathrm{OpenPhysicalFit}^{\uparrow}$ *packet is refuted by a displayed finite observation whose observed and model-generated signatures fail the packet classifier. Conversely, finite acceptance of* P *records only undefeatedness by the displayed trace and does not certify total fit, model-reality identity, or a final theory.*

Lean4 ✓ `BEDC.Derived.OpenPhysicalFitUp.OpenPhysicalFit refutation boundary`

Proof. Read the classifier and refutation rows of Definition 1131.1. A finite defeating observation belongs to F precisely when the observed and model-generated signatures cannot pass C.

Such a row is internal to the packet, so the accepted certificate itself names the finite observation that defeats the fit claim. The local NameCert obligations of Definition 1131.2 require this row to remain visible to consumers.

The reverse boundary follows from the absence of any total-fit coordinate. The packet records $H, \Pi, O, M, C, F, E, L, R, N$ only. None of those rows is an internal proof of all future finite fits, an identity between model and reality, or a final-fit oracle. □

Theorem 1131.4 (OpenPhysicalFit observation-extension stability)**.** *Let*

$$P = (H, \Pi, O, M, C, F, E, L, R, N)$$

be an accepted $\mathrm{OpenPhysicalFit}^{\uparrow}$ *packet. If an admissible extension of the observation trace remains classified by* C*, then it can be recorded as an extension of the same open-continuation ledger. If the extension fails* C*, the result is a refutation row rather than a hidden weakening of the packet.*

Lean4 ✓ `BEDC.Derived.OpenPhysicalFitUp.OpenPhysicalFit observation extension stability`

Proof. Start with the extension row E. It records admissible continuation observations without converting them into a final certificate.

When the extended observed and model-generated signatures pass C, the same finite classifier route can be replayed through R and recorded in the ledger L as another undefeated finite trace.

When the extended signatures fail C, the refutation row F is the only row that can receive the displayed mismatch. The packet therefore separates stable continuation from refutation and never hides a classifier failure inside the open ledger. □

Theorem 1131.5 (OpenPhysicalFit public certificate)**.** *The finite trace row, observation bundle, classifier, refutation row, open-continuation ledger, replay route, provenance row, and local* $\mathsf{NameCert}_{\mathrm{OpenPhysicalFit}^{\uparrow}}$ *row form the public* $\mathrm{OpenPhysicalFit}^{\uparrow}$ *certificate. The certificate exports undefeated finite-fit status for the displayed trace and classifier while making no total-fit, model-reality identity, final-theory, or final-fit claim.*

Proof. Use the carrier of Definition 1131.1. The visible public rows are exactly the finite trace H, observation bundle Π, observed and model-generated signatures O, M, classifier C, refutation row F, open-continuation row E, ledger L, replay row R, and local name N.

Apply the semantic certificate of Definition 1131.2, the refutation boundary of Definition 1131.3, and the observation-extension stability theorem of Definition 1131.4. These rows expose the finite-fit status, the displayed defeating observations, and the admissible continuations as one public packet.

The carrier contains no coordinate for total fit, model-reality identity, a final theory, or a final-fit oracle. Therefore the public certificate exports only undefeated finite-fit status at the displayed boundary. □

Falsifiable prediction: An accepted OpenPhysicalFitUp packet is refuted by a displayed finite observation whose observed and model-generated signatures fail the packet classifier.

Independence witness: physicalfittower, observerapproximationtower, realityconstrainedmodelaudit, observationreflectionpacket, onticstate: none is bijective because $\mathrm{OpenPhysicalFit}^{\uparrow}$ carries the finite open-fit certificate, refutation row, and open-continuation ledger in one packet. $\mathsf{PhysicalFitTower}^{\uparrow}$ packages tower descent and hidden-source residue, $\mathsf{ObserverApproximationTower}^{\uparrow}$ packages observer-side approximation routes, $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ packages audit strength and failure surfaces, $\mathsf{ObservationReflectionPacket}^{\uparrow}$ packages observation–reflection role correspondence, and $\mathsf{OnticState}^{\uparrow}$ names state rows; none of them alone gives the exact finite-fit classifier with both refutation and open-continuation rows.

The Lean follow-up in `lean4/BEDC/Derived/OpenPhysicalFitUp/TasteGate.lean` should provide `Nontrivial OpenPhysicalFitUp` and `FieldFaithful OpenPhysicalFitUp`, together with the future target `BEDC.Derived.OpenPhysicalFitUp.TasteGate.OpenPhysicalFitTasteGate_single_carrier`

Closure status for $\mathsf{NameCert}_{\mathrm{OpenPhysicalFit}^{\uparrow}}$**.**

Constructive story: An $\mathrm{OpenPhysicalFit}^{\uparrow}$ packet is generated from a finite trace, observation bundle, observed signature, model-generated signature, classifier, refutation row, open-continuation row, ledger, replay route, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathrm{OpenPhysicalFit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1131.1, Definition 1131.2, Definition 1131.3, Definition 1131.4, and Definition 1131.5 read the mature finite trace, observation bundle, observed and model-generated signatures, classifier, refutation row, open-continuation ledger, replay route, provenance row, and local naming scope.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathrm{OpenPhysicalFit}^{\uparrow}}$, unformalized)

Ledger evidence: BEDC.Meta.DiscoveryDeltaLedger.openPhysicalFitDeltaLedger

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, total physical fit, model-reality identity, final theory, or a final-fit oracle.

Upgrade path: No further paper-side theory upgrade is pending before Lean verification and bridge checking for the same finite trace, observation bundle, signatures, classifier, refutation, open-continuation, ledger, replay, and local naming rows.

Chapter 1132

A Concrete Naming Certificate for $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$

The $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ packet realizes the finite-observation and open-fit discipline of section 9414.13 as a concrete BEDC NameCert carrier. It sits after the audit packet of chapter 1124, the observation-reflection packet of chapter 1126, the finite observation interface of chapter 1007, and the observer-budget support surface of chapter 1121. Those siblings supply audit, reflection, finite-window, and budget rows; this carrier binds finite fit to an open continuation and a finite refutation surface without exporting a final-fit oracle.

Definition 1132.1 (Reality-constrained open-fit carrier)**.** *A* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (H, \Pi, O, M, F, Q, L, R, N)$$

with the following displayed rows:

1. *H is the finite trace row through which the reality-facing system is observed;*
2. *Π is the observation-bundle row naming the admissible finite questions;*
3. *O is the observed-signature row extracted from H through Π;*
4. *M is the model-signature row generated by the candidate model over the same finite trace;*
5. *F is the finite-fit certificate row comparing O and M at the displayed prefix;*
6. *Q is the open-continuation surface recording the admissible next observations still outside the finite fit row;*
7. *L is the ledger row recording observation provenance, accepted fit, undecided continuation, and refused final-fit claims;*
8. *R is the refutation row naming displayed defeating observations that invalidate the finite-fit certificate;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedOpenFit}^{\uparrow}}$ *row.*

The carrier contains no coordinate for total model identity, no final-fit oracle, no host-level physical truth predicate, and no unbudgeted observation route beyond the displayed continuation and refutation rows.

Lean4 ✓ `BEDC.Derived.RealityConstrainedOpenFitUp.TasteGate.RealityConstrainedOpenFitTasteGate`
`single carrier alignment`

Theorem 1132.2 (Reality-constrained open-fit NameCert obligations)**.** *For the carrier of Definition 1132.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedOpenFit}^{\uparrow}}$ *surface consists exactly of carrier admission for* $U = (H, \Pi, O, M, F, Q, L, R, N)$*, signature exactness through* O *and* M*, finite-fit exactness through* F*, open-continuation preservation through* Q*, ledger exactness through* L*, finite refutation exposure through* R*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedOpenFitUp.RealityConstrainedOpenFitCarrier namecert obligations`

Proof. Carrier admission projects the nine displayed rows of Definition 1132.1. The trace, bundle, observed signature, model signature, fit certificate, continuation surface, ledger, refutation row, and local name are the complete finite packet.

Signature and finite-fit exactness follow by reading O, M, and F together. The fit row compares only the observed and model signatures available at the displayed prefix, so it cannot be detached as a total confirmation claim.

Open-continuation preservation and ledger exactness keep Q and L visible on every consumer route. The continuation row records the remaining observation surface, while the ledger records which fit claims, undecided continuations, and refused final-fit demands are part of the packet.

Finally the refutation row R supplies the finite defeating surface. Since the carrier has no coordinate beyond $H, \Pi, O, M, F, Q, L, R, N$, local naming through N cannot export model identity, a final-fit oracle, or an unbudgeted observation route. □

Theorem 1132.3 (Reality-constrained open-fit finite refutation surface)**.** *Every accepted* RealityConstrainedOpenFi *packet exposes refutation only through the displayed row* R*. A single defeating observation may refute the finite-fit certificate* F *when it is recorded in* R*, but the open-continuation row* Q *does not become a final confirmation surface when no such defeating observation has yet appeared.*

Proof. Read the carrier inventory. The only row that names defeating observations is R, and the only row that records finite fit is F.

If a defeating observation is displayed in R, the packet has a finite witness against the corresponding fit row. This is a prefix-level refutation of F, not a judgment about all possible continuations.

If no defeating observation has appeared, the continuation row Q remains open. It records admissible next observations still outside the finite prefix and therefore cannot certify final agreement between the model and the reality-facing system. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedOpenFitUp.RealityConstrainedOpenFitFiniteRefutationSurface`

Theorem 1132.4 (Reality-constrained open-fit ledger non-escape)**.** *Every consumer of an accepted* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ *packet must read finite fit through the trace* H*, bundle* Π*, observed signature* O*, model signature* M*, finite-fit certificate* F*, open continuation surface* Q*, ledger* L*, refutation row* R*, and local name* N*. No consumer may detach* F *as model identity, total confirmation, a final-fit oracle, host physical truth, or an unledgered future-observation claim.*

Proof. Use the NameCert obligations above. They require every accepted read to pass through the displayed signature, finite-fit, continuation, ledger, refutation, and naming rows.

The ledger row L records the status of accepted finite fit, undecided continuation, and refused final-fit demands. A consumer route that omits L has no place to distinguish finite support from total confirmation.

The continuation and refutation rows Q and R then enforce non-escape. Future observations remain open through Q, while finite defeat is displayed through R; neither row supplies model identity, host physical truth, or a final-fit oracle. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedOpenFitUp.RealityConstrainedOpenFitLedgerNonescape`

The later Lean file `lean4/BEDC/Derived/RealityConstrainedOpenFitUp/TasteGate.lean` must provide explicit Nontrivial RealityConstrainedOpenFit$^{\uparrow}$ and FieldFaithful RealityConstrainedOpenFit$^{\uparrow}$ instances preserving $H, \Pi, O, M, F, Q, L, R, N$.

Falsifiable prediction: A single displayed defeating observation refutes the finite-fit row, while no finite prefix exports a final-fit oracle.

Independence witness: reality-constrained-model-audit, observationreflectionpacket, finite-observation-interface, observer-budget-support, onticstate: none is bijective because RealityConstrainedOpen-FitUp stores the open-fit relation and its finite refutation surface rather than an audit packet, reflection packet, observation window, support budget, or ontic source row.

Closure status for NameCert$_{\text{RealityConstrainedOpenFit}^{\uparrow}}$.

Constructive story: A RealityConstrainedOpenFit$^{\uparrow}$ packet is generated from a finite trace, observation bundle, observed signature, model signature, finite-fit certificate, open-continuation surface, ledger, finite refutation row, and local NameCert row.

Lean4 ✓ `BEDC.Derived.RealityConstrainedOpenFitUp.taste gate`

Theory closure: TheoryGate(NameCert$_{\text{RealityConstrainedOpenFit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1132.1, Definition 1132.2, Definition 1132.3, and Definition 1132.4 bind the finite trace H, observation bundle Π, observed signature O, model signature M, finite-fit row F, continuation surface Q, ledger row L, refutation row R, local NameCert row N, TasteGate nontriviality, and field-faithfulness rows.

Formal verification: FormalStatus(NameCert$_{\text{RealityConstrainedOpenFit}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RealityConstrainedOpenFitUp.TasteGate.RealityConstrainedOpenFitTasteGate\_single\_carri`

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not assert model identity, total confirmation, final-fit oracles, host physical truth, or bridge checking for RealityConstrainedOpenFit$^{\uparrow}$.

Upgrade path: Only machine bridge checking remains before the formal axis reaches bridgeCheckedV over the same finite trace, bundle, signature, fit, continuation, ledger, refutation, and local NameCert rows.

Chapter 1133

A Concrete Naming Certificate for $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$

The $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ packet realizes the relational objectivity discipline of section 9414.30 as a finite multi-observer NameCert surface. It consumes the physical signature and descent rows of the $\mathsf{PhysicalFitTower}^{\uparrow}$ role, the observation handoff rows of chapter 1126, the observer-facing approximation route of the $\mathsf{ObserverApproximationTower}^{\uparrow}$ role, and the model-audit rows of chapter 1124. Those siblings provide fit, observation handoff, approximation, and audit carriers; this packet adds the symmetric anchor-change classifier and the refusal row that prevents any one observer history from becoming a global observer.

Definition 1133.1 (Reality-constrained objectivity carrier)**.** *A* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (H, A, I, F, R, T, P, L, N)$$

with the following displayed rows:

1. *H is the finite multi-observer history family, containing the observer histories whose relation is being certified;*
2. *A is the anchor row, naming the currently selected observer standpoint and the admissible anchor-change schedule;*
3. *I is the inter-observer invariant packet, containing the relation, classifier, and invariant value transported across the histories;*
4. *F is the* $\mathsf{PhysicalFitTower}^{\uparrow}$ *fit row that exposes the reality-facing signature discipline consumed by the invariant;*
5. *R is the* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *handoff row that records how observation and reflection data enter the invariant packet;*
6. *T is the* $\mathsf{ObserverApproximationTower}^{\uparrow}$ *row that bounds the observer-facing approximation route used by terminal consumers;*
7. *P is the* $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ *row that records the model-facing audit surface and failure rows;*
8. *L is the no-global-observer ledger, recording anchor changes, rejected privileged observers, and the finite routes by which invariant stability is checked;*

9. N is the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedObjectivity}^{\uparrow}}$ *row naming the whole packet.*

The carrier has no coordinate for a view from nowhere, no hidden synchronizing observer, and no objectivity claim outside the displayed multi-observer, invariant, fit, handoff, approximation, audit, ledger, and naming rows.

Lean4 ✓ `BEDC.Derived.RealityConstrainedObjectivityUp.RealityConstrainedObjectivityTasteGate single carrier alignment`

Definition 1133.2 (Reality-constrained objectivity certificate)**.** *For accepted packets*

$$O = (H, A, I, F, R, T, P, L, N) \quad \text{and} \quad O' = (H', A', I', F', R', T', P', L', N'),$$

the certificate classifier $\mathsf{RealityConstrainedObjectivityClassifier}(O, O')$ *holds exactly when the multi-observer histories are related by displayed* hsame *transports, the anchor-change rows carry A to A' and back without selecting a privileged history, the invariant packets I and I' preserve their relation and value under the same classifier, and the fit, handoff, approximation, audit, ledger, and naming rows transport componentwise.*

Thus certificate agreement is not local certainty inside one observer history. It is symmetric preservation of the invariant packet under admissible anchor change, with every physical-fit, observation-handoff, approximation, model-audit, and no-global-observer row still visible.

Theorem 1133.3 (Reality-constrained objectivity anchor stability)**.** *Let $O = (H, A, I, F, R, T, P, L, N)$ be an accepted* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *packet. If an objectivity claim is exported by O, then the claim must be read from the invariant packet I through an anchor-change route recorded in A and L. A claim depending on one observer history without such a symmetric route is local content, not a* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *export.*

Proof. Read the carrier of Definition 1133.1. The only rows that can export an objectivity claim are the multi-observer family H, anchor row A, invariant packet I, sibling carrier rows F, R, T, P, ledger L, and local NameCert row N.

Now use the certificate classifier of Definition 1133.2. It requires anchor-change transport in both directions and preservation of the invariant packet under the same classifier; it does not accept one observer history as a distinguished frame.

Therefore a route through one history alone lacks the anchor-change row and the no-global-observer ledger. It remains local observational content even if it is internally stable for that history. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedObjectivityUp.RealityConstrainedObjectivityCarrier anchor stability`

Theorem 1133.4 (Reality-constrained objectivity NameCert obligations)**.** *For the carrier of Definition 1133.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedObjectivity}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission: the accepted object is exactly $O = (H, A, I, F, R, T, P, L, N)$;*
2. *classifier stability: every accepted comparison uses the certificate classifier of Definition 1133.2;*
3. *anchor-stability exactness: objectivity exports must preserve the invariant packet I under the anchor-change rows recorded in A and L;*
4. *sibling-carrier accountability: the physical-fit, observation-handoff, observer-approximation, and model-audit rows are consumed only through F, R, T, P;*

5. *non-escape: no consumer may infer objectivity from a single observer history, hidden global observer, detached model audit, unbounded observation route, or row outside* $H, A, I, F, R, T, P, L, N$.

Proof. Carrier admission is projection from Definition 1133.1. The packet lists the only rows available to the local certificate.

Classifier stability follows from Definition 1133.2. Comparisons transport the observer histories, anchor rows, invariant packet, sibling carriers, ledger, and naming row as one finite object rather than as detached local claims.

Anchor-stability exactness is the distinguished use of A, I, L. The invariant packet can be exported only when the anchor-change schedule and no-global-observer ledger record the symmetric route that preserves it.

Sibling-carrier accountability is forced by the rows F, R, T, P. Physical fit, observation handoff, approximation, and model audit data are consumed through the displayed sibling carriers, so no hidden adequacy or reflection route can be inserted after admission.

The non-escape row is the finite-packet conclusion. A claim requiring a single privileged observer, unbounded observation, detached audit, or absent coordinate has no projection from O. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedObjectivityUp.RealityConstrainedObjectivityUp StdBridge`

Theorem 1133.5 (Reality-constrained objectivity falsifiable separation)**.** *An accepted inter-observer invariant packet that factors every admitted comparison through one anchor row is rejected by the* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *classifier as non-objective. Such a packet may still carry local or model-audit content, but it does not export relational objectivity because the no-global-observer ledger cannot certify symmetric anchor change.*

Proof. Assume the admitted comparisons all factor through one anchor row. Then the route has a distinguished observer standpoint that orders or evaluates the other histories from that row.

Apply the anchor-stability theorem. A $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ export must carry the invariant through the anchor-change schedule and no-global-observer ledger, not through a single privileged row.

The certificate classifier therefore rejects the packet as an objectivity certificate. The remaining rows may still support local content, fit comparison, observation handoff, approximation, or model audit, but they do not supply the symmetric anchor-change surface required for relational objectivity. □

Falsifiable prediction: If every admitted inter-observer invariant packet factors through a single anchor row, then the RealityConstrainedObjectivity carrier rejects it as non-objective.

Independence witness: physicalfittower, observationreflectionpacket, observerapproximationtower, realityconstrainedmodelaudit: fit, observation handoff, approximation tower, and model-audit carriers each lack the symmetric anchor-change classifier and no-global-observer refusal row.

The Lean follow-up must provide `Nontrivial RealityConstrainedObjectivityUp` and `FieldFaithful RealityConstrainedObjectivityUp` instances in `lean4/BEDC/Derived/RealityConstrainedObjectivityUp/Ta`

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedObjectivity}^{\uparrow}}$.
Lean4 ✓ `BEDC.Derived.RealityConstrainedObjectivityUp.taste gate`

Constructive story: A $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ packet is generated from a finite multi-observer history family, anchor-change row, inter-observer invariant packet, physical-fit row, observation handoff row, observer-approximation row, model-audit row, no-global-observer ledger, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealityConstrainedObjectivity}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1133.1, Definition 1133.2, Definition 1133.3, Definition 1133.4, Definition 1133.5, and the TasteGate carrier row bind the finite multi-observer carrier, certificate classifier, anchor-stability boundary, five NameCert obligation rows, and the public privileged-anchor rejection surface.

Chapter 1134

A Concrete Naming Certificate for $\mathsf{ObjectivityRefutationBoundary}^{\uparrow}$

The $\mathsf{ObjectivityRefutationBoundary}^{\uparrow}$ packet realizes the negative test implicit in the reality-constrained objectivity vision of section 9414.30. It sits beside the positive $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ carrier of chapter 1133, the relational objectivity carrier of chapter 1138, the no-global-synchronization refusal boundary of chapter 1003, the observer-frame refusal surface, and the inter-history invariant surface of chapter 656. Those siblings certify positive invariant routes or refusal-only boundaries; this packet records the finite failed-invariant and failed-anchor-stability rows that make an asserted objectivity claim refutable.

Definition 1134.1 (Objectivity refutation boundary carrier)**.** *An* $\mathsf{ObjectivityRefutationBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (H, K, A, W, R, T, P, N)$$

with the following displayed rows:

1. *H is the finite multi-observer packet over which an objectivity claim is asserted;*
2. *K is the failed inter-observer invariant row, recording that no displayed* $\mathsf{InterHistInvariant}^{\uparrow}$ *row preserves the asserted claim across the observer packet;*
3. *A is the failed anchor-stability row, recording that no anchor-change table transports the claim without selecting a privileged observer;*
4. *W is the witness row naming the concrete claim, observer slots, missing invariant coordinates, and missing anchor-stability coordinates;*
5. *R is the refusal ledger, routing the failed claim through* $\mathsf{NoGlobalSyncBoundary}^{\uparrow}$ *and* $\mathsf{ObserverFrameRefusal}^{\uparrow}$ *rather than through a positive objectivity certificate;*
6. *T records componentwise* hsame *transport and displayed* Cont *replay for the failed-invariant, failed-anchor, witness, refusal, provenance, and local naming rows;*
7. *P is the* Pkg *provenance over* $\mathsf{ObjectivityRefutationBoundary}^{\uparrow}$, $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$, $\mathsf{RelationalObjectivity}^{\uparrow}$, $\mathsf{NoGlobalSyncBoundary}^{\uparrow}$, $\mathsf{ObserverFrameRefusal}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ObjectivityRefutationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a positive invariant certificate, anchor-stable objectivity export, global synchronization map, privileged observer, quotient of observer histories, or hidden host-side truth value.

Lean4 ✓ `BEDC.Derived.ObjectivityRefutationBoundaryUp.TasteGate.ObjectivityRefutationBoundaryTasteGate single carrier alignment`

Theorem 1134.2 (Objectivity refutation boundary NameCert obligations)**.** *For the carrier of Definition 1134.1, the local* $\mathsf{NameCert}_{\mathsf{ObjectivityRefutationBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$B = (H, K, A, W, R, T, P, N),$$

failed-invariant exposure through K, failed anchor-stability exposure through A, concrete witness display through W, refusal-ledger routing through R, componentwise transport and replay through T, package provenance through P, and local naming through N. An asserted objectivity claim over the packet H fails this boundary whenever no inter-observer invariant and no anchor-stability row are displayed.

Lean4 ✓ `BEDC.Derived.ObjectivityRefutationBoundaryUp.ObjectivityRefutationBoundaryCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1134.1. The rows H, K, A, W, R, T, P, N are the only rows available to the local certificate.

The failed-invariant row K and failed-anchor row A are the decisive certificate data. If both are absent as positive rows, the witness row W names the claim and the observer slots where the attempted objectivity export lacks support.

The refusal ledger R then routes the packet through the no-global-synchronization and observer-frame-refusal surfaces rather than through positive objectivity. Transport, replay, provenance, and local naming are supplied by T, P, N, so every obligation is one of the displayed rows. □

Theorem 1134.3 (Objectivity refutation boundary non-escape)**.** *Every consumer of an accepted* $\mathsf{ObjectivityRefutationBoundary}^{\uparrow}$ *packet factors through the finite rows*

$$H, K, A, W, R, T, P, N.$$

The consumer may report the asserted claim as refuted for the displayed multi-observer packet, but it cannot convert the failed-invariant row or failed-anchor-stability row into a positive $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *export, a* $\mathsf{RelationalObjectivity}^{\uparrow}$ *certificate, a global synchronization map, a privileged observer frame, a quotient stream equality, or a host-side truth value.*

Proof. Project the accepted packet to $B = (H, K, A, W, R, T, P, N)$. The only claim-facing rows are the failed invariant K, failed anchor-stability row A, concrete witness W, and refusal ledger R.

Apply the NameCert obligations. They identify a refutation boundary precisely when the asserted objectivity claim has no displayed inter-observer invariant and no displayed anchor-stability row.

No coordinate of the packet is a positive objectivity certificate, global synchronization map, privileged frame, quotient equality, or host truth value. A consumer that exports such data has therefore left the finite packet rather than reading the accepted boundary. □

Lean4 ✓ `BEDC.Derived.ObjectivityRefutationBoundaryUp.ObjectivityRefutationBoundaryCarrier nonescape`

Theorem 1134.4 (Objectivity refutation boundary sibling independence)**.** *The* ObjectivityRefutationBoundary$^{\uparrow}$ *packet is not bijective to* RealityConstrainedObjectivity$^{\uparrow}$, RelationalObjectivity$^{\uparrow}$, NoGlobalSyncBoundary$^{\uparrow}$, ObserverFrameRefusal$^{\uparrow}$, *or* InterHistInvariant$^{\uparrow}$. *The positive objectivity siblings carry invariant and anchor-stability rows rather than failed rows; the refusal-only siblings carry synchronization or frame refusals without the failed-invariant witness; and* InterHistInvariant$^{\uparrow}$ *carries invariant readback rather than the paired absence of invariant and anchor-stability evidence.*

Lean4 ✓ `BEDC.Derived.ObjectivityRefutationBoundaryUp.ObjectivityRefutationBoundaryCarrier sibling independence`

Proof. Compare the carrier rows. RealityConstrainedObjectivity$^{\uparrow}$ and RelationalObjectivity$^{\uparrow}$ include positive invariant and anchor-stability surfaces, while ObjectivityRefutationBoundary$^{\uparrow}$ records the failed invariant row K, failed anchor-stability row A, and concrete witness row W.

The no-global-synchronization and observer-frame refusal siblings supply refusal ledgers, but they do not name a failed objectivity claim, the missing invariant coordinates, and the missing anchor-stability coordinates in one packet. They are refusal-only boundaries rather than objectivity-refutation witnesses.

Finally, InterHistInvariant$^{\uparrow}$ supplies a positive invariant readback surface. Removing that readback and replacing it by the failure rows K, A, W changes the carrier shape and the consumer obligation surface, so no bijection preserving carrier rows, refusal ledger, transport, provenance, and local naming identifies the packets. □

Falsifiable prediction: An asserted objectivity claim over a multi-observer packet fails the ObjectivityRefutationBoundaryUp test whenever no inter-observer invariant and no anchor-stability row are displayed.

Independence witness: realityconstrainedobjectivity, relationalobjectivity, noglobalsyncboundary, observerframerefusal, interhistinvariant: no sibling is bijective to ObjectivityRefutationBoundary$^{\uparrow}$ because this carrier combines failed-invariant, failed-anchor-stability, witness, refusal-ledger, transport, provenance, and local NameCert rows. The positive objectivity siblings certify invariant export; the refusal-only siblings lack the objectivity-failure witness; the invariant sibling supplies readback rather than the paired failure packet.

The Lean TasteGate surface for `lean4/BEDC/Derived/ObjectivityRefutationBoundaryUp/TasteGate.lean` includes explicit Nontrivial ObjectivityRefutationBoundary$^{\uparrow}$ and FieldFaithful ObjectivityRefutationBoundary$^{\uparrow}$ instances preserving the failed-invariant row, failed-anchor-stability row, witness row, refusal ledger, transport, provenance, and local naming row.

Closure status for NameCert$_{\text{ObjectivityRefutationBoundary}^{\uparrow}}$ **·**

Constructive story: An ObjectivityRefutationBoundary$^{\uparrow}$ packet is generated from a finite multi-observer packet, failed inter-observer invariant row, failed anchor-stability row, witness row, refusal ledger, componentwise transport and replay, package provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ObjectivityRefutationBoundary}^{\uparrow}}$, obligation)

Scope closed: Definition 1134.1, Definition 1134.2, Definition 1134.3, Definition 1134.4, and the displayed TasteGate marker `BEDC.Derived.ObjectivityRefutationBoundaryUp.TasteGate.ObjectivityRefutationBoundaryTasteGate_single_carrier_` bind the finite failed-invariant, failed-anchor-stability, witness, refusal-ledger, transport, provenance, naming, nonescape, sibling-independence, nontriviality, and field-faithfulness rows.

Formal verification: FormalStatus(NameCert$_{\text{ObjectivityRefutationBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not construct a positive objectivity certificate, global synchronization map, privileged observer frame, quotient equality, host truth value, Lean verification, or bridge checking for ObjectivityRefutationBoundary$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, failed-invariant exposure, failed-anchor-stability exposure, witness display, refusal-ledger routing, non-escape, TasteGate nontriviality, and field faithfulness for the displayed rows.

Chapter 1135

A Concrete Naming Certificate for $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$

The $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$ packet realizes the open-continuation discipline of section 9414.25 as a finite NameCert surface. It consumes the open-fit row of $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ from chapter 1132, the tower row of $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ from chapter 1127, the physical-signature row of $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$ from **??**, the multi-observer objectivity row of $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ from chapter 1133, and the audit row of $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ from chapter 1124. Those siblings supply finite fit, approximation, signature comparison, objectivity, and audit carriers; this packet binds them to a displayed continuation class, stability basis, failure surface, ledger, and local name without closing future observation.

Definition 1135.1 (Reality-constrained physical-induction carrier)**.** *A* $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (H, U, T, S, O, A, C, B, F, L, K, P, N)$$

with the following displayed rows:

1. *H is the finite observed history at which the induction claim is licensed;*
2. *U is the* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ *row recording finite fit and open continuation;*
3. *T is the* $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ *row recording the approximation tower used by the model;*
4. *S is the* $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$ *row recording physical-signature compatibility;*
5. *O is the* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *row recording the multi-observer invariant route for the claim;*
6. *A is the* $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ *row recording audit strength and known failure obligations;*
7. *C is the continuation-class row naming the admissible future histories to which the claim is allowed to speak;*
8. *B is the stability-basis row naming the physical, observational, and model-side invariants whose preservation licenses the continuation read;*
9. *F is the failure-surface row naming displayed continuations that defeat the predicted fit;*

10. *L is the induction ledger recording finite fit, continuation scope, stability basis, failure surface, and refused final-fit demands;*
11. *K stores componentwise* hsame *transport for $H, U, T, S, O, A, C, B, F, L$;*
12. *P stores* Pkg *provenance over the sibling carriers,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}}$ *row.*

The carrier has no coordinate for a final induction oracle, no prediction route outside C, B, F, L, and no way to convert finite fit into future fit without the displayed stability-basis and failure-surface rows.

Lean4 ✓ `BEDC.Derived.RealityConstrainedPhysicalInductionUp.RealityConstrainedPhysicalInductionTasteGate`
`single carrier alignment`

Theorem 1135.2 (Reality-constrained physical-induction NameCert obligations)**.** *For the carrier of Definition 1135.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}}$ *surface consists exactly of seven obligation rows:*

1. *carrier admission for $I = (H, U, T, S, O, A, C, B, F, L, K, P, N)$;*
2. *finite-fit exposure through the* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ *row U and the observed history H;*
3. *tower and signature accountability through T and S;*
4. *objectivity and audit accountability through O and A;*
5. *continuation scope through the row C;*
6. *stability-basis and failure-surface exposure through B and F;*
7. *ledger, transport, provenance, and local naming through L, K, P, N.*

Any consumer of a physical-induction prediction must display all seven rows before reading finite fit as licensed continuation fit.

Lean4 ✓ `BEDC.Derived.RealityConstrainedPhysicalInductionUp.RealityConstrainedPhysicalInductionNameCert(`

Proof. Carrier admission is projection from Definition 1135.1. The packet exposes the observed history, five sibling carrier rows, continuation class, stability basis, failure surface, ledger, transport, provenance, and local name as its complete finite surface.

Finite-fit exposure is inherited through U and H. Tower and signature accountability are read through T and S, while objectivity and audit accountability are read through O and A. These rows keep the prediction attached to the same approximation, physical-signature, inter-observer, and model-audit data that licensed the finite fit.

The continuation row C bounds the future histories under discussion. The stability-basis row B states what must persist, and the failure-surface row F states what would defeat the licensed read.

Finally L, K, P, N record the induction ledger, componentwise transport, provenance, and local name. Since the carrier has no further coordinate, a consumer that omits one of the listed rows has no accepted physical-induction route. □

Theorem 1135.3 (Reality-constrained physical-induction non-escape)**.** *Every accepted* RealityConstrainedPhysicalI *consumer read factors through*

$$H, U, T, S, O, A, C, B, F, L, K, P, N.$$

In particular, no consumer may read a future-continuation prediction from finite fit alone, from an approximation tower alone, from signature fit alone, from objectivity alone, or from model audit alone. The displayed continuation class, stability-basis row, failure-surface row, and induction ledger remain mandatory boundary data.

Lean4 ✓ BEDC.Derived.RealityConstrainedPhysicalInductionUp.RealityConstrainedPhysicalInductionCarrier nonescape

Proof. Apply the NameCert obligations of Definition 1135.2. They require finite-fit exposure, tower and signature accountability, objectivity and audit accountability, continuation scope, stability-basis exposure, failure-surface exposure, and ledgered naming before a prediction can be consumed.

Each sibling row supplies only one side of the route. Open fit supplies finite fit and open continuation; the approximation tower supplies model-side descent; signature fit supplies physical-signature compatibility; objectivity supplies an inter-observer invariant route; model audit supplies audit strength and failure obligations.

The continuation, stability, failure, and ledger rows C, B, F, L are therefore not optional annotations. They are the coordinates that prevent finite fit from becoming a final induction oracle. Transport and provenance preserve this displayed packet but do not add an unrecorded continuation claim. □

Theorem 1135.4 (Reality-constrained physical-induction continuation scope)**.** *An accepted* RealityConstrainedPhys *packet*

$$I = (H, U, T, S, O, A, C, B, F, L, K, P, N)$$

licenses a continuation prediction only through the jointly displayed finite-fit row U, continuation class C, stability basis B, failure surface F, induction ledger L, transport row K, provenance row P, and local NameCert *row N. The row U supplies finite fit only over the observed prefix H; the rows C, B, F, L give the irreducible continuation boundary; and K, P, N keep the prediction route inside the same finite packet.*

Proof. Begin with the carrier of Definition 1135.1. Its coordinates display $H, U, T, S, O, A, C, B, F, L, K, P, N$ as the complete accepted packet, and there is no coordinate for a continuation read outside those rows.

Apply the NameCert obligations of Definition 1135.2. They require finite-fit exposure through U and H, continuation scope through C, stability and failure exposure through B and F, and ledgered naming through L, K, P, N before a prediction can be consumed.

Apply the non-escape theorem Definition 1135.3. It rules out reading future-continuation content from finite fit, approximation, signature fit, objectivity, or audit rows alone, so the only licensed route is the displayed continuation packet.

Thus U contributes only the observed-prefix fit, while C, B, F, L state the continuation class, persistence basis, defeat surface, and ledger for the read. The rows K, P, N preserve transport, provenance, and local naming inside the same finite packet. The theorem therefore asserts continuation scope only; it does not assert total future fit, host physical truth, or a final induction oracle. □

Lean4 ✓ BEDC.Derived.RealityConstrainedPhysicalInductionUp.RealityConstrainedPhysicalInductionCarrier continuation scope

Theorem 1135.5 (Reality-constrained physical-induction scoped kernel route)**.** *Every accepted* $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$ *packet scopes its physical-induction read exactly over the displayed carrier rows*

$$H, U, T, S, O, A, C, B, F, L, K, P, N,$$

the ambient BHist *history discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}}$ *row, and the TasteGate surface for the same carrier. The scoped route exposes finite fit, approximation, signature, objectivity, audit, continuation, stability, failure, and ledger data, but it does not add a final induction oracle or a prediction route outside those rows.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedPhysicalInductionUp.taste gate`

Proof. Start with the carrier of Definition 1135.1. Its tuple lists $H, U, T, S, O, A, C, B, F, L, K, P, N$ as the complete packet, and the definition explicitly withholds any coordinate for a final induction oracle.

Apply Definition 1135.2, Definition 1135.3, and Definition 1135.4. Together they force every consumer read through the finite-fit, approximation, signature, objectivity, audit, continuation, stability, failure, ledger, transport, replay, provenance, and local naming rows.

The TasteGate marker is attached to the same carrier surface. It records the accepted single-carrier alignment without changing the paper closure axis, so the scoped route is exactly the displayed kernel route plus the TasteGate surface and no hidden future-fit principle. □

Theorem 1135.6 (Reality-constrained physical-induction public continuation boundary)**.** *Every public consumer of an accepted* $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$ *packet reads physical induction through the continuation class* C*, stability basis* B*, failure surface* F*, induction ledger* L*, transport row* K*, provenance row* P*, and local naming row* N *displayed in the same carrier*

$$I = (H, U, T, S, O, A, C, B, F, L, K, P, N).$$

The public interface may expose finite fit, tower accountability, signature compatibility, objectivity, audit strength, continuation scope, stability conditions, and failure boundaries. It may not export a final induction oracle, total future fit, host physical truth, or a prediction outside the displayed continuation and failure-surface rows.

Lean4 ✓ `BEDC.Derived.RealityConstrainedPhysicalInductionUp.RealityConstrainedPhysicalInductionCarrier public continuation boundary`

Proof. Start from the scoped kernel route of Definition 1135.5. It binds every physical-induction read to the displayed carrier rows and to the TasteGate surface for that same carrier.

Apply the continuation-scope theorem Definition 1135.4. The rows C, B, F, L are exactly the public continuation boundary: C names the admissible continuations, B names the persistence basis, F names the defeating continuations, and L records the finite induction ledger.

Apply the non-escape theorem Definition 1135.3. It blocks reads from finite fit, approximation, signature fit, objectivity, or audit rows alone, so a public consumer receives only the displayed continuation, stability, failure-surface, transport, provenance, and naming route. □

Falsifiable prediction: Any future-continuation read that bypasses either the displayed stability-basis row or the failure-surface row refutes the RealityConstrainedPhysicalInduction carrier.

Independence witness: reality-constrained-open-fit, reality-constrained-approximation-tower, reality-constrained-signature-fit, reality-constrained-objectivity, reality-constrained-model-audit: none is bijective because $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$ binds finite fit, approximation tower, physical-signature compatibility, inter-observer objectivity, model audit, continuation scope, stability basis, failure surface, induction ledger, transport, provenance, and local NameCert rows in one carrier. Each sibling lacks at least the displayed continuation, stability-basis, failure-surface, or induction-ledger coordinate required for physical induction.

The Lean follow-up must provide `Nontrivial RealityConstrainedPhysicalInductionUp` and `FieldFaithful RealityConstrainedPhysicalInductionUp` instances in `lean4/BEDC/Derived/RealityCon`

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}}$.

Constructive story: A $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$ packet is generated from finite history, open-fit, approximation-tower, signature-fit, objectivity, model-audit, continuation-class, stability-basis, failure-surface, induction-ledger, transport, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1135.1, Definition 1135.2, Definition 1135.3, Definition 1135.4, and Definition 1135.6 bind the TasteGate-backed scoped kernel route and public continuation boundary as the bridge-facing handoff for the finite continuation, stability, failure-surface, ledger, and NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert a final induction oracle, total future fit, host physical truth, Lean verification, or bridge checking for $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$.

Upgrade path: No further paper-closure upgrade remains; Lean verification and bridge checking remain separate formal-axis work for the displayed packet rows.

Chapter 1136

A Concrete Naming Certificate for $\mathsf{RealityConstrainedExplanation}^{\uparrow}$

The $\mathsf{RealityConstrainedExplanation}^{\uparrow}$ packet realizes the explanation discipline of section 9414.46 inside the reality-constrained tower vision of chapter 9414 and the final synthesis of section 9414.68 as a finite NameCert surface. It consumes the audit rows of chapter 1124, the physical-signature comparison rows of **??**, the $\mathsf{PhysicalFitTower}^{\uparrow}$ tower-descent rows, and the physical audit rows of chapter 1129. Those siblings supply model audit, signature fit, observation reflection, fit tower, and physical audit carriers; this packet binds them into the finite certificate by which an equation, derivation, model syntax, or effective-theory claim becomes explanatory only inside a displayed source, comparison, descent, residue, failure, route, provenance, and local naming boundary.

Definition 1136.1 (Reality-constrained explanation carrier)**.** *A* $\mathsf{RealityConstrainedExplanation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (\Pi, M, P, S, D, R, F, H, C, Q, N)$$

with the following displayed rows:

1. Π *is the finite observation-bundle row through which the phenomenon is read;*
2. M *is the model row whose equations, derivations, mechanisms, or effective-theory operations are offered as explanatory;*
3. P *is the phenomenon row naming the reality-facing target of the explanation;*
4. S *is the signature-comparison row comparing the physical signature generated by* Π, P *with the model-facing signature generated by* Π, M*;*
5. D *is the tower-descent row recording which explanatory or predictive operations survive the approximation route that produced* M*;*
6. R *is the residue ledger naming unmodelled variables, hidden tower levels, idealized-away structure, measurement conditions, and physical properties not queried by* Π*;*
7. F *is the failure-surface row naming finite observations, refinements, or signature mismatches that would defeat the explanation;*
8. H *records componentwise* hsame *transport for the observation, model, phenomenon, signature, descent, residue, and failure rows;*

9. *C records the accepted consumer route through the displayed explanation rows;*
10. *Q records* Pkg *provenance over* $\mathsf{RealityConstrainedExplanation}^{\uparrow}$, $\mathsf{ObservationReflectionPacket}^{\uparrow}$, $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{PhysicalFitTower}^{\uparrow}$, $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedExplanation}^{\uparrow}}$ *row.*

The carrier has no coordinate for bare equation reading, detached derivation, syntax realism, unscoped model truth, hidden idealization, or explanatory export outside the displayed packet.

Lean4 ✓ `BEDC.Derived.RealityConstrainedExplanationUp.RealityConstrainedExplanationTasteGate`
`single carrier alignment`

Theorem 1136.2 (Reality-constrained explanation NameCert obligations)**.** *For the carrier of Definition 1136.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedExplanation}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission: the accepted object is exactly $E = (\Pi, M, P, S, D, R, F, H, C, Q, N)$;*
2. *signature-comparison exactness: every explanation read must use the displayed comparison row S between the Π-indexed model signature and the Π-indexed phenomenon signature;*
3. *tower-descent: every explanatory operation exported from M must pass through the descent row D before it is read as a claim about P;*
4. *residue and failure-surface exposure: the residue ledger R and failure-surface row F are public before the explanation route is accepted;*
5. *ledger non-escape: no consumer may infer explanation from rows outside $\Pi, M, P, S, D, R, F, H, C, Q, N$.*

Proof. Carrier admission is projection from Definition 1136.1. The packet lists the only rows available to the local certificate, so no later consumer can insert an unobserved source, hidden model row, detached phenomenon row, or extra truth oracle.

Signature-comparison exactness is the distinguished role of S. The comparison is not a bare equation inside M and not a host judgment about P; it is the displayed relation between the two Π-indexed signatures.

Tower-descent is forced by D. An operation internal to M becomes explanatory for P only when the same packet records its survival through the approximation route.

Residue and failure exposure are forced by R and F. The packet accepts an explanation only with the unmodelled remainder and defeating observations visible to the consumer.

Ledger non-escape follows because the carrier contains no coordinate outside $\Pi, M, P, S, D, R, F, H, C, Q, N$. A route depending on any absent row is not a route in the accepted local naming certificate. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedExplanationUp.RealityConstrainedExplanationNamecertObligations`

Theorem 1136.3 (Reality-constrained explanation scope and residue)**.** *Let $E = (\Pi, M, P, S, D, R, F, H, C, Q, N)$ be an accepted* $\mathsf{RealityConstrainedExplanation}^{\uparrow}$ *packet. A consumer of E cannot read bare equations, bare derivations, syntax realism, or unscoped model claims as explanations unless the same route displays the observation bundle, model row, phenomenon row, signature-comparison row, tower-descent row, residue ledger, failure surface, transport, consumer route, provenance, and local NameCert row.*

Proof. Start with the carrier definition. The only exported explanation packet is the finite tuple

$$\Pi, M, P, S, D, R, F, H, C, Q, N.$$

Bare equations and bare derivations use only syntax internal to M. They do not expose the phenomenon row P, the comparison row S, the descent row D, or the residue and failure rows R, F, so they do not project an explanation route from E.

Syntax realism asks the consumer to identify model syntax with reality-facing structure. The classifier surface instead requires the Π-indexed signature comparison and the displayed transport row H, so syntax alone has no accepted coordinate.

Unscoped model claims ignore the residue ledger and failure surface. By the NameCert obligations of Definition 1136.2, the accepted route must expose R and F before the explanation can be read.

Therefore a consumer can export an explanation only through the complete displayed packet. Any route that omits one of the listed rows is a partial mathematical, syntactic, or model-audit read, not a $\mathsf{RealityConstrainedExplanation}^{\uparrow}$ explanation. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedExplanationUp.RealityConstrainedExplanationCarrier scope and residue`

Falsifiable prediction: A public explanation read that preserves the model syntax but changes either the physical-signature comparison row or the residue/failure-surface row is rejected by the carrier classifier.

Independence witness: realityconstrainedmodelaudit, realityconstrainedsignaturefit, observationreflectionpacket, physicalfittower, physicalmodelaudit: none is bijective to the explanation packet because each lacks at least one of phenomenon row, signature-comparison row, tower-descent row, residue ledger, or failure-surface row.

The Lean follow-up must provide `Nontrivial RealityConstrainedExplanationUp` and `FieldFaithful RealityConstrainedExplanationUp` instances in `lean4/BEDC/Derived/RealityConstrainedExplanationUp/Ta`

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedExplanation}^{\uparrow}}$.

Constructive story: A $\mathsf{RealityConstrainedExplanation}^{\uparrow}$ packet is generated from an observation-bundle row, model row, phenomenon row, signature-comparison row, tower-descent row, residue ledger, failure surface, componentwise hsame transports, displayed Cont route, Pkg provenance, and a local NameCert row.

Lean4 ✓ `BEDC.Derived.RealityConstrainedExplanationUp.taste gate`

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealityConstrainedExplanation}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1136.1, Definition 1136.2, Definition 1136.3, and the TasteGate row bind the finite explanation carrier, obligation surface, residue-scoped consumer route, and AI-discovery gate as the paper-side scope witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealityConstrainedExplanation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close host model truth, unbounded validation, hidden-source recovery, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: No paper-side theory upgrade remains; bridge status and Lean verification are governed by their own axis.

Chapter 1137

A Concrete Naming Certificate for $\mathsf{OpenFitPacket}^{\uparrow}$

The $\mathsf{OpenFitPacket}^{\uparrow}$ carrier realizes the finite-observation open-fit discipline of section 9414.13 as a finite NameCert packet. It consumes the $\mathsf{PhysicalFitTower}^{\uparrow}$ physical signature tower, the classifier boundary of **??**, and the audit gate of chapter 1124. Those packets separately expose physical-fit towers, signature compatibility, and audit ledgers; $\mathsf{OpenFitPacket}^{\uparrow}$ binds the open-fit failure surface and no-final-oracle boundary into one finite observational carrier.

Definition 1137.1 (OpenFitPacket carrier)**.** *An* $\mathsf{OpenFitPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (H, \Pi, S, M, F, E, L, B, N)$$

with the following displayed rows:

1. H *is the finite observation trace row.*
2. Π *is the admissible observation-bundle row.*
3. S *is the observed-signature row extracted from* H *through* Π*.*
4. M *is the model-signature row compared against* S *at the displayed trace.*
5. F *is the finite fit row certifying the currently accepted signature comparison.*
6. E *is the failure-surface row naming finite signature comparisons that refute* F*.*
7. L *is the ledger row recording accepted fit, undecided continuation, failure evidence, and refused final-fit demands.*
8. B *is the boundary row forbidding export of a final-fit oracle from the finite packet.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{OpenFitPacket}^{\uparrow}}$ *row.*

The carrier has no coordinate for total confirmation, host identity between model and system, unobserved future signatures, or a global oracle deciding all admissible observation histories.

Lean4 ✓ `BEDC.Derived.OpenFitPacketUp.OpenFitPacketTasteGate single carrier alignment`

Definition 1137.2 (OpenFitPacket obligation surface)**.** *For the carrier of Definition 1137.1, the local* $\mathsf{NameCert}_{\mathsf{OpenFitPacket}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier admission for* $P = (H, \Pi, S, M, F, E, L, B, N)$*;*

2. *finite signature exactness through S and M over the displayed trace H and bundle Π;*
3. *finite fit exactness through F;*
4. *finite refutation exposure through the failure-surface row E;*
5. *ledger exactness through L;*
6. *no-final-oracle boundary preservation through B;*
7. *local naming through N.*

Theorem 1137.3 (OpenFitPacket finite refutation surface)**.** *Every accepted* $\mathsf{OpenFitPacket}^{\uparrow}$ *packet is refuted locally by a finite failed signature comparison displayed in E. Conversely, a consumer route that does not display such a failed comparison has no refutation witness inside the packet and must leave continuation status ledgered as open rather than confirmed.*

Lean4 ✓ `BEDC.Derived.OpenFitPacketUp.OpenFitPacketFiniteRefutationSurface`

Proof. Carrier admission exposes exactly $P = (H, \Pi, S, M, F, E, L, B, N)$. The only row naming failed comparisons is E, and the only finite fit row that can be defeated is F.

When E displays a failed comparison between the observed signature S and the model signature M over the same H and Π, the packet contains a finite witness against the accepted fit row. This is a local refutation because all participating rows are part of the same finite carrier.

When no such failed comparison is displayed, the ledger row L still records the status as open. The boundary row B prevents the missing failure from being converted into final confirmation, so the packet remains a finite open-fit certificate rather than an oracle for all continuations. □

Theorem 1137.4 (OpenFitPacket no-final-oracle boundary)**.** *No accepted* $\mathsf{OpenFitPacket}^{\uparrow}$ *packet exports a final-fit oracle. Its public evidence is exhausted by finite observation, finite signature comparison, finite fit, finite refutation exposure, ledger status, boundary refusal, and local naming through $H, \Pi, S, M, F, E, L, B, N$.*

Proof. The carrier of Definition 1137.1 contains no row for total confirmation or global quantification over every admissible observation history. The obligation surface of Definition 1137.2 instead requires finite signature exactness, finite fit exactness, finite refutation exposure, ledger exactness, and preservation of the boundary row.

Thus a consumer may read the displayed finite fit, and it may read a finite refutation when E displays one. The same route must also read L and B, so undecided continuation remains ledgered and the final-fit demand is refused.

Any purported oracle for all future or counterfactual histories would need a coordinate outside $H, \Pi, S, M, F, E, L, B, N$. Since the NameCert surface admits only these rows, the purported oracle has no accepted route in the packet. □

Lean4 ✓ `BEDC.Derived.OpenFitPacketUp.OpenFitPacket no final oracle boundary`

Theorem 1137.5 (OpenFitPacket signature-fit handoff)**.** *An* $\mathsf{OpenFitPacket}^{\uparrow}$ *consumer can hand finite fit to the signature-fit and audit stack only through the displayed signature rows S, M, finite fit row F, failure-surface row E, ledger row L, and boundary row B. The handoff may consume* $\mathsf{PhysicalFitTower}^{\uparrow}$, $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, *and* $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ *certificates, but it cannot erase the open-fit failure surface or the no-final-oracle boundary.*

Lean4 ✓ `BEDC.Derived.OpenFitPacketUp.OpenFitSignatureFitHandoff`

Proof. The physical-fit tower supplies the reality-facing tower context, the signature-fit packet supplies the comparison discipline, and the model-audit packet supplies the audit gate. The $\mathsf{OpenFitPacket}^{\uparrow}$ carrier reads those surfaces only through its own displayed rows.

The handoff therefore preserves S, M, F, E, L, B. Signature comparison travels through S and M, accepted finite fit through F, finite defeat through E, audit status through L, and the final-oracle refusal through B.

If a consumer route drops E or B, it no longer carries the open-fit failure surface or the no-final-oracle boundary. Such a route may still mention a physical tower, signature classifier, or audit gate, but it is not an accepted $\mathsf{OpenFitPacket}^{\uparrow}$ handoff. □

Theorem 1137.6 (OpenFitPacket bridge-facing surface)**.** *Every bridge-facing consumer of an accepted* $\mathsf{OpenFitPacket}^{\uparrow}$ *packet must read exactly the displayed rows* $H, \Pi, S, M, F, E, L, B, N$*. These rows preserve the finite observation trace, observation bundle, observed and model signature rows, finite fit row, failure surface, ledger row, no-final-oracle boundary, and local NameCert row. No bridge-facing route may erase the finite observation trace, bypass* E *or* B*, replace the ledger, or import a final-fit oracle from a physical tower, signature classifier, audit packet, host approval, or ambient model class.*

Proof. Start from the carrier and obligation surface. The packet has exactly the rows $H, \Pi, S, M, F, E, L, B, N$, and the local NameCert obligations assign finite observation, observation bundle, signature comparison, finite fit, failure exposure, ledger, boundary, and naming roles to those rows.

Use the finite refutation surface. It forces any failed comparison read to pass through E over the same S, M comparison surface, so a bridge-facing consumer cannot replace the failure surface while preserving packet acceptance.

Apply the no-final-oracle boundary and signature-fit handoff. The boundary keeps continuation status finite and refuses global confirmation, while the handoff routes signature fit through S, M, F, E, L, B.

Therefore the bridge-facing surface is exactly the displayed packet. A consumer missing one of $H, \Pi, S, M, F, E, L, B, N$ or importing an outside oracle is not reading the accepted $\mathsf{OpenFitPacket}^{\uparrow}$ bridge-facing row. □

Lean4 ✓ `BEDC.Derived.OpenFitPacketUp.OpenFitPacketUp StdBridge`

The Lean follow-up in `lean4/BEDC/Derived/OpenFitPacketUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{OpenFitPacket}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{OpenFitPacket}^{\uparrow}$ instances preserving $H, \Pi, S, M, F, E, L, B,$

Falsifiable prediction: A finite failed signature comparison refutes the packet locally, while no accepted packet exports a final-fit oracle.

Independence witness: physicalfittower, realityconstrainedsignaturefit, realityconstrainedmodelaudit, streamname, real: none contains the open-fit failure-surface and no-final-oracle rows together.

Closure status for $\mathsf{NameCert}_{\mathsf{OpenFitPacket}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OpenFitPacket}^{\uparrow}$ packet is generated from a finite observation trace, observation bundle, observed signature, model signature, finite fit row, failure surface, ledger, no-final-oracle boundary, and local NameCert row.

Chapter 1138

A Concrete Naming Certificate for $\mathsf{RelationalObjectivity}^{\uparrow}$

The $\mathsf{RelationalObjectivity}^{\uparrow}$ packet realizes the objectivity-without-privileged-observer surface of section 9414.30 as a finite NameCert carrier. It consumes the finite inter-Hist family of chapter 474, the observer-history identity surface of chapter 479, the public other-minds commitment of chapter 499, the locality-cell evidence of chapter 509, and the public alignment packet of chapter 643. The packet is not a view from nowhere; it is the displayed finite route through which observer-family rows, invariant evidence, anchor-stability rows, ledgers, transports, package provenance, and local naming are read together.

Definition 1138.1 (RelationalObjectivity invariant-packet carrier)**.** *A* $\mathsf{RelationalObjectivity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, I, A, L, T, P, N)$$

with the following displayed rows:

1. *F is the finite observer-family row, read through the* $\mathrm{MultiHistConfig}^{\uparrow}$ *packet and the relevant* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *rows;*
2. *I is the invariant-packet row, recording the inter-observer relation, the classifier under which the relation is compared, and the claim read from that invariant;*
3. *A is the anchor-stability row, recording that changing the source observer anchor preserves the invariant claim by the displayed classifier;*
4. *L is the ledger row, recording the observation, continuation, locality-cell, other-minds commitment, and cross-perspective alignment evidence used by the invariant read;*
5. *T is the componentwise transport row, storing the* hsame *and* Cont *routes that replay the invariant across observer-family coordinates;*
6. *P is the* Pkg *provenance over the vision objectivity surface and the five concrete sibling packets cited above;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{RelationalObjectivity}^{\uparrow}}$ *row.*

The carrier has no coordinate for a privileged observer, global synchronization frame, hidden observer substance, unledgered invariant, or anchor-free claim.

Lean4 (definition) `BEDC.Derived.RelationalObjectivityUp.RelationalObjectivityCarrier`

Definition 1138.2 (RelationalObjectivity observer-family source)**.** *An observer-family source for* $\mathsf{RelationalObjectivity}^{\uparrow}$ *is the row* F *of an accepted carrier* $R = (F, I, A, L, T, P, N)$ *together with its displayed routes to* $\mathrm{MultiHistConfig}^{\uparrow}$ *and* $\mathsf{ObserverHistIdentity}^{\uparrow}$*. A read of* F *gives only the finite family of observer histories and their public identity rows; it does not supply a distinguished evaluator of the family.*

Lean4 ✓ `BEDC.Derived.RelationalObjectivityUp.RelationalObjectivityObserverFamilySource`

Definition 1138.3 (RelationalObjectivity NameCert classifier)**.** *The local* $\mathsf{NameCert}_{\mathsf{RelationalObjectivity}^{\uparrow}}$ *classifier compares two accepted carriers only through the displayed coordinates* F, I, A, L, T, P, N*. Two reads agree when their observer-family rows are matched by the same public identity and multi-Hist routes, their invariant-packet rows determine the same claim under the displayed classifier, their anchor-stability and ledger rows are transported by* T*, and their provenance and local naming rows agree.*

Lean4 ✓ `BEDC.Derived.RelationalObjectivityUp.RelationalObjectivityNameCertClassifier semantic certificate`
Lean4 (definition) `BEDC.Derived.RelationalObjectivityUp.RelationalObjectivityNameCertClassifier`

Theorem 1138.4 (RelationalObjectivity anchor-stability obligation)**.** *Every accepted* $\mathsf{RelationalObjectivity}^{\uparrow}$ *read of a claim factors through the anchor-stability row* A *of an accepted carrier* $R = (F, I, A, L, T, P, N)$*. A consumer may treat the claim as relationally objective only after the invariant-packet row* I *and the anchor-stability row* A *are displayed in the same finite packet.*

Proof. Project the accepted carrier through Definition 1138.1. The invariant-packet coordinate I names the relation, classifier, and claim, while A records stability under change of observer anchor.

The classifier of Definition 1138.3 compares carriers only through the displayed rows. Hence a read that lacks A has no coordinate from which anchor change can be checked.

The coordinate list also excludes an anchor-free claim and a privileged observer. Therefore the objective read is available only through the finite pair I, A transported by T and named by N. □

Lean4 ✓ `BEDC.Derived.RelationalObjectivityUp.RelationalObjectivityAnchorStabilityObligation`

Theorem 1138.5 (RelationalObjectivity invariant-ledger exactness)**.** *For every accepted* $\mathsf{RelationalObjectivity}^{\uparrow}$ *carrier* $R = (F, I, A, L, T, P, N)$*, the ledger row* L *is exactly the displayed evidence surface for the invariant read: observer-history identity, multi-Hist configuration, locality-cell evidence, other-minds commitment, cross-perspective alignment, continuation replay, and componentwise transport. No invariant claim may be accepted through an unledgered observation or hidden synchronization coordinate.*

Proof. Read L from the carrier definition. Its declared evidence is the observation, continuation, locality-cell, other-minds commitment, and cross-perspective alignment data used by the invariant read, with the observer family supplied by F and the replay route supplied by T.

The sibling packets cited in the chapter opening supply the public rows consumed by this ledger. They provide finite multi-Hist, observer-identity, other-minds, locality-cell, and cross-perspective surfaces, not ambient observer access.

Since the carrier explicitly has no coordinate for hidden observer substance, unledgered invariant evidence, global synchronization, or an anchor-free claim, ledger exactness is exhausted by the displayed rows F, I, A, L, T, P, N. □

Lean4 ✓ `BEDC.Derived.RelationalObjectivityUp.RelationalObjectivityInvariantLedgerExactness`

Theorem 1138.6 (RelationalObjectivity no-privileged-anchor certificate)**.** *Every accepted* $\mathsf{RelationalObjectivity}^{\uparrow}$ *packet certifies relational objectivity without selecting a privileged observer anchor. Changing the source observer route may transport the invariant through T and check stability through A, but it cannot create a global observer, a synchronized external frame, or a host-level equality between observer histories.*

Proof. Begin with the observer-family source of Definition 1138.2. The row F exposes only a finite family and its public identity routes, with no distinguished evaluator.

The anchor-stability obligation of Definition 1138.4 explains how a claim is read after anchor change: the invariant row I and stability row A must remain visible in the same finite packet and are transported by T.

Finally inspect the carrier exclusions in Definition 1138.1. The packet has no coordinate for a privileged observer, global synchronization frame, hidden observer substance, or anchor-free claim. Thus anchor transport remains an internal certificate route rather than a promotion to an external standpoint. □

Lean4 ✓ `BEDC.Derived.RelationalObjectivityUp.RelationalObjectivityNoPrivilegedAnchorCertificate`
Lean4 ✓ `BEDC.Derived.RelationalObjectivityUp.RelationalObjectivityCarrier no privileged anchor certificate`

Theorem 1138.7 (RelationalObjectivity public NameCert export)**.** *The public export surface of an accepted* $\mathsf{RelationalObjectivity}^{\uparrow}$ *packet is exactly the observer-family source F, the local classifier over F, I, A, L, T, P, N, the anchor-stability row A, the invariant-ledger exactness row L, the no-privileged-anchor certificate, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RelationalObjectivity}^{\uparrow}}$ *row. A public consumer may cite this surface after the TasteGate carrier alignment has been read; it receives no hidden observer substance, privileged anchor, global synchronization coordinate, or anchor-free claim.*

Lean4 ✓ `BEDC.Derived.RelationalObjectivityUp.taste gate`

Proof. Project the carrier of Definition 1138.1. The visible public rows are F, I, A, L, T, P, N, and the classifier of Definition 1138.3 compares accepted packets only through those rows.

Use the observer-family source, anchor-stability obligation, invariant-ledger exactness theorem, and no-privileged-anchor certificate. These results expose the public source, the classifier-facing invariant, the anchor-change check, the ledger, and the refusal of a distinguished observer anchor.

The TasteGate carrier alignment supplies the Lean-side public handoff for the same displayed rows. The structural rows then transport by hsame, replay by Cont, source by Pkg, and name by the local NameCert row, so the exported surface is public without adding any hidden observer coordinate. □

Falsifiable prediction: A RelationalObjectivityUp read is refuted whenever it identifies two observer claims without a displayed invariant packet and anchor-stability row.

Independence witness: multihistconfig, observerhistidentity, othermindscommitment, locality-cell, crossperspectivealignment: none of these siblings contains the full observer-family, invariant-packet, anchor-stability, no-privileged-anchor, and local NameCert surface.

The Lean TasteGate surface for this packet is ‘lean4/BEDC/Derived/RelationalObjectivityUp/TasteGate.lean‘, where the handoff provides ‘Nontrivial RelationalObjectivityUp‘ and ‘FieldFaithful RelationalObjectivityUp‘ instances over the displayed carrier and classifier rows.
Lean4 ✓ `BEDC.Derived.RelationalObjectivityUp.RelationalObjectivityTasteGate single carrier alignment`

Theorem 1138.8 (RelationalObjectivity invariant-packet bridge surface)**.** *The public observer-family export of Definition 1138.7 is bridged to the invariant-packet carrier of Definition 1138.1 by the displayed observer-family row F, classifier row I, anchor-stability row A, invariant ledger L, componentwise transport row T,* Pkg *provenance row P, and local* $\mathsf{NameCert}_{\mathsf{RelationalObjectivity}^{\uparrow}}$ *row N. The bridge-facing surface is therefore the finite route through F, I, A, L, T, P, N and exports no privileged observer, global synchronization frame, hidden observer substance, unledgered invariant, or anchor-free claim.*

Proof. Project the public export theorem. Its observer-family source, local classifier, anchor-stability row, invariant-ledger exactness row, no-privileged-anchor certificate, componentwise transport, provenance, and local naming are exactly the displayed rows of the carrier.

Use the classifier and anchor-stability obligations. The classifier reads only F, I, A, L, T, P, N, while anchor stability keeps the invariant claim tied to I and A under the same transport row.

Apply invariant-ledger exactness and the no-privileged-anchor certificate. The ledger accounts for the observer-history identity, multi-Hist configuration, locality-cell, other-minds, cross-perspective alignment, continuation, and transport evidence, and the certificate refuses a distinguished observer anchor.

Thus the public export is bridged to the invariant-packet carrier by the displayed rows themselves. Since the carrier has no coordinate for a privileged observer, global synchronization, hidden observer substance, unledgered invariant, or anchor-free claim, the bridge-facing surface exports none of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{RelationalObjectivity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RelationalObjectivity}^{\uparrow}$ packet is generated from a finite observer-family source, invariant-packet row, anchor-stability row, invariant ledger, componentwise transport row, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RelationalObjectivity}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1138.1, Definition 1138.2, Definition 1138.3, Definition 1138.4, Definition 1138.5, Definition 1138.6, Definition 1138.7, and Definition 1138.8 bind the public carrier, observer-family source, classifier, anchor-stability, ledger exactness, no-privileged-anchor certificate, TasteGate handoff, invariant-packet bridge surface, provenance, and local NameCert export over $\mathrm{MultiHistConfig}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{OtherMindsCommitment}^{\uparrow}$, $\mathsf{LocalityCell}^{\uparrow}$, and $\mathsf{CrossPerspectiveAlignment}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RelationalObjectivity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close privileged observers, global synchronization, hidden observer substance, anchor-free claims, Lean verification, or bridge checking.

Upgrade path: Verification closure requires a checked Lean target for the scoped observer-family, classifier, anchor-stability, ledger, transport, provenance, and local naming route.

Chapter 1139

A Concrete Naming Certificate for $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$

The $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$ packet realizes the certificate-relative physical induction surface of section 9414.25 as a finite BEDC naming certificate. It is adjacent to the open-fit surface of chapter 1132, the audit packet of chapter 1129, and the inter-observer boundary of chapter 1133. Those siblings provide finite fit, audit, and objectivity rows; this seal binds finite fit to a continuation class, a stability basis, a failure surface, predictive reuse, transport, provenance, and local naming without exporting an unbounded future oracle.

Definition 1139.1 (PhysicalInductionStabilitySeal carrier)**.** *A* $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (H, F, C, S, L, R, T, P, N)$$

with the following displayed rows:

1. *H is the observation prefix row from which the finite physical fit is read;*
2. *F is the finite fit row comparing observed and model signatures over the displayed prefix;*
3. *C is the continuation-class row naming the admissible future histories for this seal;*
4. *S is the stability-basis row licensing transport from F to continuations in C;*
5. *L is the failure-surface row recording the continuations that separate observed and model signatures;*
6. *R is the predictive-reuse route from the finite fit row to the continuation-class read;*
7. *T records componentwise* hsame *transport for H, F, C, S, L, R;*
8. *P is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, *and the sibling fit, audit, objectivity, and induction rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}}$ *row.*

The classifier accepts only packets exposing all nine rows. It has no coordinate for a final-fit oracle, unbounded physical necessity, hidden future history, host-law identity, or predictive reuse outside the displayed continuation class.

Lean4 (definition) `BEDC.Derived.PhysicalInductionStabilitySealUp.PhysicalInductionStabilitySealUp`
Lean4 ✓ `BEDC.Derived.PhysicalInductionStabilitySealUp.PhysicalInductionStabilitySealTasteGate`
`single carrier alignment`

Theorem 1139.2 (PhysicalInductionStabilitySeal NameCert obligations)**.** *For the carrier of Definition 1139.1, the local* $\mathsf{NameCert}_{\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}}$ *surface is exhausted by five obligation rows:*

1. *carrier exposure for* $K = (H, F, C, S, L, R, T, P, N)$*;*
2. *classifier laws over the continuation class* C*;*
3. *stability transport from the finite fit row* F *through the stability basis* S *and transport row* T*;*
4. *failure-surface exactness through* L*;*
5. *predictive-reuse non-escape through the route* R*, provenance* P*, and local name* N*.*

Every accepted prediction from the seal must read these rows. No consumer may replace them by a final physical law, an ambient completeness claim, an unlisted continuation, or a host-level oracle over future observations.

Proof. Carrier exposure is immediate from the displayed packet. The rows $H, F, C, S, L, R, T, P, N$ are the complete inventory available to the local naming certificate, and each downstream read must begin from that finite tuple.

Next read the classifier rows over C. The continuation class is not a background universal domain; it is a coordinate of the accepted packet. Classifier laws therefore compare finite-fit and continuation reads only through the displayed continuation class and its componentwise transports.

Now transport stability. The finite fit row F is licensed for reuse only through the stability basis S and the transport row T. The predictive route R carries that transported read to admissible continuations, while P records the sibling fit, audit, and objectivity provenance that lets the route be consumed.

Finally inspect the failure surface. The row L records exactly the continuations where observed and model signatures separate, so removing L erases the falsifiable boundary of the seal. Since N names the whole packet and no other carrier coordinate is present, predictive reuse cannot escape to an unlisted continuation, hidden future history, host-law identity, or final-fit oracle. □

Lean4 ✓ `BEDC.Derived.PhysicalInductionStabilitySealUp.PhysicalInductionStabilitySealNameCert obligations`

Theorem 1139.3 (PhysicalInductionStabilitySeal scoped route)**.** *Every scoped* $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$ *consumer must read the finite observation prefix, fit row, continuation class, stability basis, failure surface, predictive-reuse route, componentwise* hsame *transport,* Pkg *provenance, and local* NameCert *row through the carrier of Definition 1139.1. The scoped route exports no unbounded oracle, hidden future history, final physical law, or predictive read outside the displayed continuation class.*

Proof. Project the accepted carrier $K = (H, F, C, S, L, R, T, P, N)$. Its displayed rows are the only rows available to a scoped consumer, so the observation prefix, finite fit, continuation class, stability basis, failure surface, predictive route, transport, provenance, and local name must be read by projection from this tuple.

Apply Definition 1139.2. It makes stability transport, failure-surface exactness, and predictive-reuse non-escape obligations of the same local NameCert surface.

The TasteGate-aligned carrier marker fixes the consumer-facing packet to this row inventory. Since no coordinate supplies an unbounded oracle, hidden future history, final physical law, or extra continuation source, the scoped route is exhausted by the displayed carrier. □

Lean4 ✓ BEDC.Derived.PhysicalInductionStabilitySealUp.PhysicalInductionStabilitySealScopedRoute

Theorem 1139.4 (PhysicalInductionStabilitySeal public export)**.** *The public export of* PhysicalInductionStabilitySe *is exactly the finite route through observation prefix H, finite fit F, continuation class C, stability basis S, failure surface L, predictive-reuse route R, componentwise* hsame *transport T,* Pkg *provenance P, and local* NameCert *row N. A public consumer may read predictive reuse only through that displayed route and only over the named continuation class; it receives no unbounded future oracle, hidden continuation source, final physical law, or host-law identity.*

Proof. Project the carrier of Definition 1139.1. The tuple $K = (H, F, C, S, L, R, T, P, N)$ is the full public inventory, so the observation prefix, fit row, continuation class, stability basis, failure surface, predictive route, transport, provenance, and local name are all visible before reuse is consumed.

Apply the NameCert obligations of Definition 1139.2. They bind classifier laws to C, stability transport to F, S, T, failure-surface exactness to L, and predictive-reuse non-escape to R, P, N.

Finally use the scoped route of Definition 1139.3. The public export is the same finite route made object-facing: it can be cited by later physical-induction consumers, but it still refuses unbounded prediction, hidden future histories, final physical laws, and reuse outside the displayed continuation class. □

Lean4 ✓ BEDC.Derived.PhysicalInductionStabilitySealUp.PhysicalInductionStabilitySealPublicExport

Theorem 1139.5 (PhysicalInductionStabilitySeal bridge route)**.** *The public export route of Definition 1139.4 is the bridge surface from* PhysicalInductionStabilitySeal$^{\uparrow}$ *to the abstract physical-induction interface. The route exposes exactly the rows*

$$H, F, C, S, L, R, T, P, N$$

as observation prefix, finite fit, continuation class, stability basis, failure surface, predictive reuse, componentwise transport, provenance, and local naming. A bridge consumer may cite those rows as the abstract physical-induction boundary, but it still receives no unbounded future oracle, hidden continuation source, final physical law, host-law identity, or predictive read outside the displayed continuation class.

Proof. Start with the public export theorem. It already presents $H, F, C, S, L, R, T, P, N$ as the complete consumer-facing route for finite physical induction.

The abstract interface reads the same rows by role: H supplies observations, F supplies fit, C supplies the continuation class, S supplies stability, L supplies the falsifiable boundary, R supplies predictive reuse, and T, P, N preserve, source, and locally name the packet.

No additional bridge coordinate is present. Therefore the route can be used as the bridge surface while preserving the same refusal of unbounded oracles, hidden continuations, final laws, host-law identity, and reuse outside the displayed class. □

The public export and bridge route give the complete finite example and completeness surface for the displayed continuation-class seal: every accepted use is routed through $H, F, C, S, L, R, T, P, N$, and no remaining paper obligation adds a stronger prediction interface.

Falsifiable prediction: Removing the failure-surface row or the continuation-class row makes predictive reuse indistinguishable from an unbounded oracle claim and invalidates the seal.

Independence witness: Nearest siblings: realityconstrainedopenfit, physicalmodelaudit, realityconstrainedobjectivity, observationreflectionhandoff, inscriptiongapledger. The seal has a continuation-class plus failure-surface pair none of those siblings has as a single carrier, while each sibling has audit, objectivity, handoff, or residue rows absent from this seal; no row-preserving bijection exists.

The Lean target family `BEDC.Derived.PhysicalInductionStabilitySealUp` must provide explicit Nontrivial $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$ and FieldFaithful $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$ instances in `Derived/PhysicalInductionStabilitySealUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}}$.

Constructive story: A $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$ packet is generated from a finite observation prefix, finite fit, continuation class, stability basis, failure surface, predictive-reuse route, componentwise transport, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1139.1, Definition 1139.2, Definition 1139.3, Definition 1139.4, and Definition 1139.5 bind the finite certificate-relative physical induction packet, its local NameCert surface, scoped consumer route, public export, and bridge surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PhysicalInductionStabilitySealUp.PhysicalInductionStabilitySealPublicExport`

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not close StdBridge checking, mature bridge completeness, unbounded future prediction, total physical law, host-law identity, or continuations outside the displayed class.

Upgrade path: The remaining formal-axis step is checked bridge interpretation for the displayed bridge route.

Chapter 1140

A Concrete Naming Certificate for $\mathsf{RealityConstrainedSynthesisSeal}^{\uparrow}$

The $\mathsf{RealityConstrainedSynthesisSeal}^{\uparrow}$ packet realizes the final synthesis of section 9414.68 as a finite NameCert seal rather than as an ambient truth predicate. It sits beside the audit carrier of chapter 1124, the open-fit carrier of chapter 1132, the objectivity carrier of chapter 1133, the observation-reflection packet of chapter 1126, and the explanation carrier of chapter 1136. Those sibling chapters expose model audit, open continuation, observer invariance, observation handoff, and explanatory descent; this seal binds them into the finite packet by which physical truth is read as constrained synthesis.

Definition 1140.1 (Reality-constrained synthesis seal carrier)**.** *A* $\mathsf{RealityConstrainedSynthesisSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, F, O, Q, E, T, L, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ *row recording model-facing audit and admissible comparison data.*
2. *F is the* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ *row recording finite fit, open continuation, and finite refutation.*
3. *O is the* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *row recording observer-anchor change and invariant public content.*
4. *Q is the* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *row recording observation handoff and signature readback.*
5. *E is the* $\mathsf{RealityConstrainedExplanation}^{\uparrow}$ *row recording explanatory descent, residue, and failure boundaries.*
6. *T is the tower-descent row recording which operations survive transport from source traces to explanatory packages.*
7. *L is the ledger row recording hidden residue, compression, idealization, provenance, and unresolved continuation.*
8. *R is the failure-surface row naming finite defeats, domain exits, and refused final-fit demands.*
9. *H records componentwise* hsame *transport for the audit, fit, objectivity, observation, explanation, tower, ledger, and failure rows.*

10. *C records displayed* Cont *replay through all rows of the seal.*

11. *P records* Pkg *provenance over the five sibling carriers,* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSynthesisSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for model–reality identity, unbounded final confirmation, private-observer truth, unledgered explanation, hidden physical equality, or export outside the displayed seal.

Lean4 (definition) `BEDC.Derived.RealityConstrainedSynthesisSealUp.taste gate`
Lean4 ✓ `BEDC.Derived.RealityConstrainedSynthesisSealUp.RealityConstrainedSynthesisSealTasteGate single carrier alignment`

Theorem 1140.2 (Reality-constrained synthesis seal NameCert obligations)**.** *For the carrier of Definition 1140.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSynthesisSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for $S = (A, F, O, Q, E, T, L, R, H, C, P, N)$, audit exposure through A, open-fit exposure through F, observer-invariant exposure through O, observation-reflection exposure through Q, explanatory-descent exposure through E, tower transport through T, ledger exactness through L, failure-surface exposure through R, componentwise transport through H, displayed continuation replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission projects the finite packet of Definition 1140.1. No row outside $A, F, O, Q, E, T, L, R, H, C,$ can be read by the local certificate.

The five sibling rows supply the public synthesis surface. The audit row A constrains model-facing comparison, F keeps finite fit open to continuation and refutation, O prevents one observer history from becoming the public claim, Q exposes the observation handoff, and E records explanatory descent.

The tower, ledger, and failure rows bind the same surface to physical use. The tower row T licenses operations through the approximation route, L records hidden residue and provenance, and R names defeat conditions and refused finality.

Finally the transport, replay, provenance, and naming rows H, C, P, N preserve exactly the displayed seal. Thus the local NameCert surface is exhausted by the listed obligations. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedSynthesisSealUp.RealityConstrainedSynthesisSealUp namecert obligations`

Theorem 1140.3 (Reality-constrained synthesis seal non-escape)**.** *Every consumer of an accepted* $\mathsf{RealityConstrainedSynthesisSeal}^{\uparrow}$ *packet must read constrained synthesis through the displayed audit, open-fit, objectivity, observation-reflection, explanation, tower, ledger, failure-surface, transport, replay, provenance, and local-name rows. No consumer may replace that route by model–reality identity, a final-fit oracle, a private observer anchor, an unledgered explanation, host equality, or a bare model row.*

Proof. Use the NameCert obligations of Definition 1140.2. They force every accepted route to expose $A, F, O, Q, E, T, L, R, H, C, P, N$ before constrained synthesis is read.

The open-fit, objectivity, and observation-reflection rows prevent the familiar escape routes. The fit row F is finite and defeasible, the objectivity row O requires an invariant anchor-change route, and the observation row Q keeps the claim tied to displayed readback.

The explanation, tower, ledger, and failure rows close the remaining routes. A consumer that omits E, T, L, R loses descent, hidden residue, and defeat information, so it no longer reads the accepted seal.

Therefore a synthesis read can only be the displayed route through the full carrier. The excluded identity, finality, private-anchor, unledgered, host-equality, and bare-model routes have no row from which to be exported. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedSynthesisSealUp.RealityConstrainedSynthesisSealUp nonescape`

Theorem 1140.4 (Reality-constrained synthesis seal independence boundary)**.** *The* RealityConstrainedSynthesisSea *carrier is independent of each single sibling surface named by* RealityConstrainedModelAudit$^{\uparrow}$, RealityConstrainedOpe RealityConstrainedObjectivity$^{\uparrow}$, ObservationReflectionPacket$^{\uparrow}$, *and* RealityConstrainedExplanation$^{\uparrow}$. *Each sibling can supply one required row of the seal, but none of them alone supplies the full packet* $S = (A, F, O, Q, E, T, L, R, H, C, P, N)$ *or the non-escape boundary of Definition 1140.3.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedSynthesisSealUp.RealityConstrainedSynthesisSealUp independence boundary`

Proof. Read the carrier definition componentwise. The audit sibling supplies A, the open-fit sibling supplies F, the objectivity sibling supplies O, the observation-reflection sibling supplies Q, and the explanation sibling supplies E.

None of these rows contains the other four sibling rows together with the tower, ledger, failure, transport, replay, provenance, and local-name rows. A projection to any one sibling therefore forgets part of $S = (A, F, O, Q, E, T, L, R, H, C, P, N)$.

The non-escape theorem depends on the full displayed packet. Since each single sibling lacks at least one of the audit, open-fit, objectivity, observation, explanation, tower, ledger, or failure coordinates, no single sibling can be bijective with the seal. □

Falsifiable prediction: A constrained-synthesis consumer that exports physical truth while omitting any one of audit, open fit, observer invariance, observation reflection, explanation descent, ledger, or failure surface refutes the seal.

Independence witness: realityconstrainedmodelaudit, realityconstrainedopenfit, realityconstrainedobjectivity, observationreflectionpacket, realityconstrainedexplanation: none is bijective because RealityConstrainedSynthesisSeal$^{\uparrow}$ carries all five sibling surfaces together with tower, ledger, failure, transport, replay, provenance, and local NameCert rows in one finite packet.

Closure status for NameCert$_{\text{RealityConstrainedSynthesisSeal}^{\uparrow}}$ **·**

Constructive story: A RealityConstrainedSynthesisSeal$^{\uparrow}$ packet is generated from audit, open-fit, objectivity, observation-reflection, explanation, tower, ledger, failure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Scope closed: Definition 1140.1, Definition 1140.2, Definition 1140.3, Definition 1140.4, the falsifiable prediction, the independence witness, and the TasteGate marker record the bridge-facing paper route for the displayed constrained-synthesis seal.

Formal verification: FormalStatus(NameCert$_{\text{RealityConstrainedSynthesisSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert Lean verification, bridge checking, final physical truth, model–reality identity, a private observer oracle, unbounded observation, or unledgered explanation.

Upgrade path: No theory-axis upgrade remains; future work is verification and bridge synchronization for the displayed constrained-synthesis seal packet.

Chapter 1141

A Concrete Naming Certificate for $\mathsf{PhysicalTruthCertificate}^{\uparrow}$

The $\mathsf{PhysicalTruthCertificate}^{\uparrow}$ packet realizes the final physical-truth synthesis of section 9414.68 as one finite NameCert carrier. It sits beside the reality-constrained open-fit surface of chapter 1132, the reality-constrained objectivity surface of chapter 1133, and the physical model-audit surface of chapter 1129. Those sibling chapters expose open continuation, observer-invariant reading, and audit rows; this carrier binds them with tower descent, source fit, ledger, failure surface, transport, route replay, provenance, and local naming before any consumer reads a physical truth claim.

Definition 1141.1 (Physical truth certificate carrier)**.** *A* $\mathsf{PhysicalTruthCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, F, O, D, I, L, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source-trace and observation-bundle row from which the claim is read;*
2. *F is the* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ *row exposing finite fit, open continuation, and finite refutation;*
3. *O is the* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *row exposing observer-anchor change and invariant content;*
4. *D is the tower-descent row recording which operations survive the approximation route;*
5. *I is the stability row naming the continuation domain over which the claim may be reused;*
6. *L is the ledger row recording hidden tower levels, compression, idealization, provenance, and residue;*
7. *R is the failure-surface row naming finite defeating observations, signature mismatches, or domain exits;*
8. *H records componentwise* hsame *transport for the source, fit, objectivity, descent, stability, ledger, failure, route, provenance, and local-name rows;*
9. *C records displayed* Cont *replay through all rows of T;*
10. *P records* Pkg *provenance over* $\mathsf{PhysicalTruthCertificate}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, RealityConstrainedObjectivi $\mathsf{PhysicalModelAudit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalTruthCertificate}^{\uparrow}}$ *row.*
The carrier has no coordinate for model–reality identity, final confirmation, unledgered idealization, detached observer certainty, hidden truth oracle, host physical equality, or truth export outside the displayed packet.

Lean4 (definition) `BEDC.Derived.PhysicalTruthCertificateUp.PhysicalTruthCertificateCarrier`

Theorem 1141.2 (Physical truth certificate NameCert obligations)**.** *For the carrier of Definition 1141.1, the local* $\mathsf{NameCert}_{\mathsf{PhysicalTruthCertificate}^{\uparrow}}$ *surface consists exactly of carrier admission for $T = (S, F, O, D, I, L, R, H, C, P, N)$, open-fit exposure through F, observer-invariance exposure through O, tower-descent exposure through D, stability exposure through I, ledger exactness through L, failure-surface exposure through R, componentwise transport through H, displayed route replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.PhysicalTruthCertificateUp.PhysicalTruthCertificateNameCertObligations`

Proof. Carrier admission projects the finite packet of Definition 1141.1. No row outside $S, F, O, D, I, L, R, H, C, P, N$ can be read by the local certificate.

Open-fit exposure is the role of F. It imports finite fit, open continuation, and finite refutation only as a displayed sibling row, so the certificate cannot identify finite support with final confirmation.

Observer-invariance exposure is the role of O. It requires the invariant and anchor-change route before the physical truth claim can be public, so one observer history cannot stand in for the full packet.

Descent, stability, ledger, and failure exposure are the remaining content rows. The descent row D licenses operations through the tower, I names the reuse domain, L records hidden residue and provenance, and R names defeat conditions.

The transport, continuation, provenance, and naming rows H, C, P, N then preserve exactly the displayed packet. Thus the local $\mathsf{NameCert}$ surface is exhausted by the listed obligations. □

Theorem 1141.3 (Physical truth certificate open-fit non-escape)**.** *Every consumer of an accepted* $\mathsf{PhysicalTruthCertificate}^{\uparrow}$ *packet must read physical truth through the displayed source row, open-fit row, observer-invariance row, descent row, stability row, ledger row, failure-surface row, transport row, route row, provenance row, and local name. No consumer may replace that route by model–reality identity, a final-fit oracle, unledgered continuation, host equality, or a bare mathematical model row.*

Proof. Use the NameCert obligations of Definition 1141.2. They force every accepted route to expose $S, F, O, D, I, L, R, H, C, P, N$ before a physical truth claim is read.

The open-fit row F is finite and defeasible. It supplies observed fit, continuation, and refutation rows, but it has no coordinate for final fit, model identity, or host equality.

The ledger and failure rows L and R close the remaining escape routes. A consumer that omits them loses the record of compression, idealization, hidden residue, and possible defeat, so it no longer reads the accepted packet.

Therefore a physical truth read can only be the displayed route through the full certificate carrier. The excluded identity, finality, unledgered, host-equality, and bare-model routes have no row from which to be exported. □

Lean4 ✓ `BEDC.Derived.PhysicalTruthCertificateUp.PhysicalTruthCertificate open fit nonescape`

Theorem 1141.4 (Physical truth certificate observer invariance)**.** *Let $T = (S, F, O, D, I, L, R, H, C, P, N)$ be an accepted* $\mathsf{PhysicalTruthCertificate}^{\uparrow}$ *carrier. If a consumer exports a physical truth claim from T, then the claim is read through the observer-invariance row O and the componentwise transport row H before the route C and local name N are exposed. A claim that depends on one observer history without the displayed O, H, C, N route is not a* $\mathsf{PhysicalTruthCertificate}^{\uparrow}$ *export.*

Lean4 ✓ `BEDC.Derived.PhysicalTruthCertificateUp.physicalTruthCertificate observer route fields`

Proof. Project the carrier. The only observer-facing coordinate is O, and the only transport coordinate for comparing the rows across accepted presentations is H.

Now read the route and naming rows. The continuation route C and local name N can replay and name only the rows already displayed by the carrier; they cannot create observer invariance after the fact.

If a consumer depends on one observer history alone, then it omits the invariant packet and anchor-change discipline carried by O. The route may still be local evidence, open fit, or model audit material, but it is not an export of the physical truth certificate. □

Falsifiable prediction: If a certified physical truth consumer reads model–reality identity without the displayed open-fit, ledger, observer-invariance, and failure-surface rows, the packet is refuted.

Independence witness: physical-fit-tower, reality-constrained-signature-fit, reality-constrained-open-fit, reality-constrained-objectivity, physical-model-audit: no sibling carries the full TruthCert packet with fit, tower, descent, observer invariance, ledger, and failure surface as one carrier.

Theorem 1141.5 (Physical truth certificate bridge interface)**.** *Every public* $\mathsf{PhysicalTruthCertificate}^{\uparrow}$ *TruthCert packet bridges to consumers only through the displayed route*

$$S, F, O, D, I, L, R, H, C, P, N.$$

The bridge interface may expose source trace, open fit, observer invariance, tower descent, stability, ledger, failure surface, transport, replay, provenance, and local naming. It refuses model–reality identity, completed physical truth, unledgered oracle export, hidden observer certainty, host equality, and any truth row outside the displayed packet.

Proof. Project the carrier of Definition 1141.1. The only public coordinates are $S, F, O, D, I, L, R, H, C, P, N$, and the carrier explicitly omits model–reality identity, detached certainty, host equality, and hidden truth-oracle rows.

Apply the NameCert obligations of Definition 1141.2. They make open-fit exposure, observer-invariance exposure, tower descent, stability, ledger exactness, failure exposure, transport, replay, provenance, and local naming the complete public surface.

Use the open-fit non-escape and observer-invariance theorems, Definition 1141.3 and Definition 1141.4. They prevent a consumer from replacing the displayed route by final fit, a single observer history, or a bare mathematical model row.

Thus the bridge interface is exactly the finite TruthCert route through $S, F, O, D, I, L, R, H, C, P, N$, with all identity, completed-truth, unledgered-oracle, hidden-certainty, and host-equality exports refused. □

Lean4 ✓ `BEDC.Derived.PhysicalTruthCertificateUp.PhysicalTruthCertificateBridgeInterface`

Closure status for $\mathsf{NameCert}_{\mathsf{PhysicalTruthCertificate}^{\uparrow}}$.

Constructive story: A PhysicalTruthCertificate$^{\uparrow}$ packet is generated from finite source traces, reality-constrained open fit, observer invariance, tower descent, stability, ledger, failure surface, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Lean4 ✓ `BEDC.Derived.PhysicalTruthCertificateUp.taste gate`

Theory closure: TheoryGate(NameCert$_{\text{PhysicalTruthCertificate}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1141.1, Definition 1141.2, Definition 1141.3, Definition 1141.4, and Definition 1141.5 bind the carrier, NameCert obligations, open-fit non-escape, observer-invariance route, bridge interface, falsifiable prediction, independence witness, and TasteGate marker to the displayed physical-truth packet.

Formal verification: FormalStatus(NameCert$_{\text{PhysicalTruthCertificate}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove Lean verification, bridge checking, final physical truth, host model–reality equality, unbounded observation, or a total observer-independent oracle.

Upgrade path: The paper-side package is mature; Lean verification and checked bridge evidence remain the next formal-axis obligations for the public TruthCert interface.

Chapter 1142

A Concrete Naming Certificate for $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$

The $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ packet realizes the ledgered tower-compression discipline of section 9414.20 as a finite BEDC NameCert carrier. It sits beside the indexed approximation carrier of chapter 1127, the $\mathsf{ObserverApproximationTower}^{\uparrow}$ observer-facing tower carrier, the signature-fit carrier of **??**, and the model-audit carrier of chapter 1124. The $\mathsf{PhysicalFitTower}^{\uparrow}$ role supplies the source-facing descent route; this chapter packages the composite ledger that prevents endpoint/source collapse across the tower.

Definition 1142.1 (Reality-constrained tower-compression carrier)**.** *A* $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, O, F, A, M, C, L, E, R, P, N)$$

with the following displayed rows:

1. *S is the source row, naming the reality-facing system, trace family, or observation process at the base of the tower;*
2. *T is the indexed tower row, recording the finite approximation levels and their compression arrows;*
3. *O is the observer tower row, recording the admissible observer-side readback and budgeted observation windows;*
4. *F is the physical-fit tower row, exposing the source-facing signature and descent discipline;*
5. *A is the reality-constrained approximation row, naming the tower carrier whose mathematical endpoint is being compressed;*
6. *M is the model-audit row, recording which model-facing fit claims are audited against the tower;*
7. *C is the classifier row comparing endpoint packages only through the declared physical signatures and observer budgets;*
8. *L is the composite-ledger row, recording the hidden residue of every compression arrow after transport to the endpoint;*
9. *E is the endpoint row, naming the visible terminal package without identifying it with S;*
10. *R is the replay row, recording the displayed* Cont *route through $S, T, O, F, A, M, C, L, E$;*

11. *P is the* Pkg *provenance over the sibling carriers,* BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerCompression}^{\uparrow}}$ *row.*

The carrier has no coordinate for source/endpoint identity, unledgered quotient collapse, hidden physical truth, or endpoint-only model validation.

Lean4 ✓ BEDC.Derived.RealityConstrainedTowerCompressionUp.RealityConstrainedTowerCompressionTasteGate single carrier alignment

Theorem 1142.2 (Reality-constrained tower-compression NameCert obligations)**.** *For the carrier of Definition 1142.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerCompression}^{\uparrow}}$ *surface consists exactly of seven obligation rows:*

1. *carrier admission for $K = (S, T, O, F, A, M, C, L, E, R, P, N)$;*
2. *source and tower exposure through S and T;*
3. *observer and physical-fit exactness through O and F;*
4. *approximation and audit compatibility through A and M;*
5. *classifier accountability through C;*
6. *composite-ledger and endpoint exposure through L and E;*
7. *replay, provenance, and local naming closure through R, P, N.*

Every accepted read of the compressed endpoint must display these rows before a consumer may treat the endpoint as a reality-facing modelling claim.

Lean4 ✓ BEDC.Derived.RealityConstrainedTowerCompressionUp.RealityConstrainedTowerCompressionNameCert obligations

Proof. Project the carrier of Definition 1142.1. The admitted object is the twelve-row packet $K = (S, T, O, F, A, M, C, L, E, R, P, N)$, so the source, tower, observer, physical-fit, approximation, audit, classifier, ledger, endpoint, replay, provenance, and local-name coordinates are all visible.

The source and tower rows bind the compression chain to S and T. The observer and physical-fit rows then restrict which signatures can be read from that chain, and the approximation and audit rows specify which endpoint packages may be compared.

Classifier accountability belongs to C alone. It compares endpoint packages only through the displayed observer and physical-fit rows, so it cannot convert mathematical endpoint equality into source identity.

Finally the ledger and endpoint rows expose the terminal package together with the transported hidden residue of every compression arrow. Replay, provenance, and local naming close the same packet, giving exactly the seven displayed obligation rows. □

Theorem 1142.3 (Reality-constrained tower-compression ledger non-escape)**.** *Let*

$$K = (S, T, O, F, A, M, C, L, E, R, P, N)$$

be an accepted $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ *packet. Any consumer that exports an endpoint claim from E must read it through the composite ledger L, the classifier C, and the source-facing rows S, T, O, F, A, M. A route that omits L or treats E as source identity is not a* RealityConstrainedTowerCompressio *export.*

Proof. Use the NameCert obligations of Definition 1142.2. They require every accepted read to expose the source, tower, observer, physical-fit, approximation, audit, classifier, composite-ledger, endpoint, replay, provenance, and naming rows.

The composite ledger row L records the hidden residue of each compression arrow after transport to the endpoint. A consumer route that omits L therefore lacks the row that distinguishes terminal visibility from the source material hidden along the tower.

The endpoint row E names only the visible terminal package. Since the carrier has no source/endpoint identity coordinate, any route that treats E as S bypasses the displayed classifier and ledger and is rejected by the local NameCert boundary. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerCompressionUp.RealityConstrainedTowerCompressionLedgernonescape`

Definition 1142.4 (Reality-constrained tower-compression scoped packet)**.** *The scoped* RealityConstrainedTowerCo *packet is the same finite carrier*

$$K = (S, T, O, F, A, M, C, L, E, R, P, N)$$

read over BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, with sibling anchors in chapter 1127, the* ObserverApproximationTower$^{\uparrow}$ *role,* **??***, chapter 1124, and the* PhysicalFitTower$^{\uparrow}$ *role. Its scoped read admits endpoint claims only through the displayed classifier, composite ledger, replay, provenance, and local naming rows.*

Theorem 1142.5 (Reality-constrained tower-compression classifier accountability)**.** *For the scoped packet of Definition 1142.4, every classifier read through C is accountable to the displayed source, tower, observer, physical-fit, approximation, audit, composite-ledger, endpoint, replay, provenance, and local naming rows. In particular, C cannot compare endpoint packages without exposing $S, T, O, F, A, M, L, E, R, P, N$ inside the same* BHist *packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerCompressionUp.RealityConstrainedTowerCompressionClassifieraccountability`

Proof. Project the carrier of Definition 1142.1. The classifier coordinate C occurs only inside the twelve-row packet $K = (S, T, O, F, A, M, C, L, E, R, P, N)$.

Apply Definition 1142.2. The local certificate requires carrier admission, source and tower exposure, observer and physical-fit exactness, approximation and audit compatibility, classifier accountability, composite-ledger and endpoint exposure, and replay/provenance/name closure.

Thus C is accountable to exactly the displayed packet rows. The sibling approximation-tower, observer-tower, signature-fit, model-audit, and physical-fit chapters supply the surfaces read by A, O, F, M and the source-facing tower route, but none supplies a hidden endpoint classifier outside K. □

Theorem 1142.6 (Reality-constrained tower-compression endpoint-source separation)**.** *In every scoped* RealityConstrainedTowerCompression$^{\uparrow}$ *packet, the endpoint row E is separated from the source row S by the composite ledger L, classifier C, replay R, provenance P, and local name N. A consumer route that identifies E with S without those rows is outside the chapter's accepted export surface.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerCompressionUp.RealityConstrainedTowerCompressionEndpointsource separation`

Proof. Start with Definition 1142.3. It requires every endpoint export to read through the composite ledger L, classifier C, and source-facing rows S, T, O, F, A, M.

Use the scoped packet definition to keep the route inside BHist, hsame, Cont, Pkg, and NameCert. The replay row R, package row P, and local name N bind the endpoint read to the same finite carrier.

Since the carrier has no source/endpoint identity coordinate, the endpoint E cannot be collapsed to S by omission. The required ledger and replay rows are precisely the separator between terminal visibility and source identity. □

Theorem 1142.7 (Reality-constrained tower-compression scoped dependency surface)**.** *The scoped dependency surface for* RealityConstrainedTowerCompression$^{\uparrow}$ *is exactly the finite BEDC packet over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *together with the sibling approximation-tower, observer-tower, signature-fit, model-audit, and physical-fit chapters named in Definition 1142.4. No endpoint claim is exported from this surface without the classifier accountability of Definition 1142.5 and the endpoint/source separation of Definition 1142.6.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerCompressionUp.RealityConstrainedTowerCompressionScoped dependency surface`

Proof. First project the scoped packet. Its rows are $S, T, O, F, A, M, C, L, E, R, P, N$, and its ambient objects are BHist, hsame, Cont, Pkg, and NameCert.

Next apply Definition 1142.2. Those obligations make carrier admission, row exposure, classifier accountability, ledger exposure, endpoint exposure, replay, provenance, and local naming mandatory.

Finally combine Definition 1142.5 with Definition 1142.6. The first prevents C from floating free of the sibling rows; the second prevents E from being identified with S without the ledger and replay surface. Hence the displayed dependencies are exactly the scoped export surface. □

Theorem 1142.8 (Reality-constrained tower-compression scoped source exactness)**.** *Every accepted* RealityConstrainedTowerCompression$^{\uparrow}$ *packet reads its composite tower, open-fit, objectivity, approximation, methodology, compression, transport, continuation, provenance, and local naming rows through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support. No hidden model-selection oracle, truth primitive, or external adequacy source is exported from that scoped surface.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerCompressionUp.RealityConstrainedTowerCompressionScoped source exactness`

Proof. Begin with the carrier and scoped packet. The carrier of Definition 1142.1 supplies the twelve displayed rows $S, T, O, F, A, M, C, L, E, R, P, N$, and Definition 1142.4 reads them only over BHist, hsame, Cont, Pkg, and NameCert support.

Apply Definition 1142.2. It accounts for source, tower, observer, physical-fit, approximation, audit, classifier, composite-ledger, endpoint, replay, provenance, and local naming rows before any consumer can read the compressed tower.

Next use Definition 1142.3 and Definition 1142.5. The ledger theorem prevents endpoint exports that omit L, while classifier accountability keeps C attached to the same source, tower, open-fit, objectivity, approximation, methodology, compression, transport, continuation, provenance, and naming rows.

Finally combine Definition 1142.6 with Definition 1142.7. The sibling chapters named by the scoped packet provide only the displayed constituent surfaces; none supplies a hidden model-selection oracle, truth primitive, or external adequacy source. Thus the accepted packet is exact at the scoped source surface. □

Theorem 1142.9 (Reality-constrained tower-compression downstream route exhaustion)**.** *Every downstream consumer of the compressed endpoint of an accepted* $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ *packet must read through the source row, indexed tower row, observer readback row, physical-fit row, approximation row, model-audit row, classifier row, composite-ledger row, endpoint row, replay row, provenance row, and local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerCompression}^{\uparrow}}$ *row. The route cannot be replaced by endpoint-only model validation, hidden physical truth, source/endpoint identity, or an unledgered quotient collapse.*

Proof. Start from the NameCert obligations. They enumerate exactly the rows $S, T, O, F, A, M, C, L, E, R, P, N$ and require each accepted endpoint-facing read to expose source, indexed tower, observer readback, physical fit, approximation, audit, classifier, ledger, endpoint, replay, provenance, and local naming data.

Next apply ledger non-escape and classifier accountability. The composite ledger L keeps the endpoint from becoming source identity, while the classifier row C remains accountable to the displayed observer, physical-fit, approximation, audit, ledger, endpoint, replay, provenance, and naming surface.

Endpoint-source separation and scoped source exactness complete the route. The former prevents E from replacing S, and the latter keeps every tower read inside BHist, hsame, Cont, Pkg, and NameCert support.

Thus any downstream consumer that omits one of the displayed rows is outside the accepted route. Endpoint-only model validation and hidden physical truth require coordinates absent from the carrier, so they cannot exhaust the downstream route. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerCompressionUp.RealityConstrainedTowerCompressionDownstreamR`

The Lean development in `lean4/BEDC/Derived/RealityConstrainedTowerCompressionUp/TasteGate.lean` must provide Nontrivial $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ and FieldFaithful $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ instances preserving $S, T, O, F, A, M, C, L, E, R, P, N$.

Falsifiable prediction: An accepted RealityConstrainedTowerCompressionUp endpoint claim that omits the composite ledger or identifies the endpoint with the source refutes the carrier.

Independence witness: realityconstrainedapproximationtower, observerapproximationtower, realityconstrainedsignaturefit, realityconstrainedmodelaudit, physicalfittower: none is bijective because $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ carries source, indexed tower, observer readback, physical fit, approximation, audit, classifier, composite-ledger, endpoint, replay, provenance, and local NameCert rows in one packet. Each listed sibling supplies a constituent surface, while only this packet binds composite compression ledgers to endpoint/source non-collapse.

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerCompression}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ packet is generated from source, tower, observer, physical-fit, approximation, audit, classifier, composite-ledger, endpoint, replay, provenance, and local NameCert rows.

Lean4 ✓ `BEDC.Derived.RealityConstrainedTowerCompressionUp.taste gate`

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerCompression}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1142.4, Definition 1142.5, Definition 1142.6, Definition 1142.7, and Definition 1142.8 bind the bridge-facing paper surface through classifier accountability, endpoint-source separation, scoped dependency surface, scoped source exactness, the falsifiable prediction, and the independence witness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealityConstrainedTowerCompression}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert Lean verification, bridge checking, source/endpoint identity, unledgered quotient collapse, hidden physical truth, or endpoint-only model validation.

Upgrade path: No further paper-side theory grade remains; Lean verification and bridge checking remain separately reported on their own axes.

Chapter 1143

A Concrete Naming Certificate for $\mathsf{TowerEquivalence}^{\uparrow}$

The $\mathsf{TowerEquivalence}^{\uparrow}$ packet realizes the tower-equivalence boundary of section 9414.20 as a finite BEDC NameCert carrier. It consumes the tower packet of chapter 1128, the indexed approximation tower of chapter 1127, the $\mathsf{PhysicalFitTower}^{\uparrow}$ physical-fit descent surface, the open-fit refutation surface of chapter 1132, and the observer-invariant surface of chapter 1133. Those siblings supply tower carriers, indexed approximation rows, physical descent data, open refutation, and observer-stability rows; this packet binds endpoint agreement to ledger and descent compatibility before any consumer treats two towers as equivalent.

Definition 1143.1 (TowerEquivalence carrier)**.** *A* $\mathsf{TowerEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, T', A, A', P, P', O, O', B, L, D, R, H, Q, N)$$

with the following displayed rows:

1. *T and T' are the two* $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$ *rows whose endpoint packages are being compared.*
2. *A and A' are the* $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ *rows exposing the indexed approximation levels of the two towers.*
3. *P and P' are the* $\mathsf{PhysicalFitTower}^{\uparrow}$ *rows recording source-facing signatures, hidden-source ledgers, and descent policies.*
4. *O and O' are the* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ *rows recording open-continuation and finite-refutation surfaces for the two endpoint reads.*
5. *B is the* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *row that transports the comparison across the admitted observer anchors without selecting a global observer.*
6. *L is the paired ledger row. It records source-history agreement, hidden-residue agreement, omitted-row exposure, and every open adequacy gap that remains visible after endpoint comparison.*
7. *D is the descent-compatibility row. It lists exactly which operations descend through both towers and records refusal for any operation lacking a paired displayed route.*
8. *R is the endpoint-agreement row, comparing the terminal packages only under the displayed classifier bundle.*

9. *H records componentwise* hsame *transport for $T, T', A, A', P, P', O, O', B, L, D, R, Q, N$.*
10. *Q is the* Pkg *provenance over the sibling carriers,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TowerEquivalence}^{\uparrow}}$ *row.*

The carrier has no coordinate for endpoint-only equivalence, no hidden route from terminal agreement to source identity, no descent outside D, and no observer-stable claim outside B, L, H.

Lean4 ✓ `BEDC.Derived.TowerEquivalenceUp.TowerEquivalenceTasteGate single carrier alignment`

Theorem 1143.2 (TowerEquivalence NameCert obligations)**.** *For the carrier of Definition 1143.1, the local* $\mathsf{NameCert}_{\mathsf{TowerEquivalence}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for $E = (T, T', A, A', P, P', O, O', B, L, D, R, H, Q, N)$;*
2. *endpoint agreement through R together with the two tower-packet rows T, T';*
3. *ledger compatibility through L together with the approximation rows A, A', physical-fit rows P, P', and open-fit rows O, O';*
4. *descent compatibility through D and observer-stable transport through B, H;*
5. *provenance and local naming closure through Q, N.*

Every accepted tower-equivalence read must display these five rows before exporting equivalence between the two towers.

Lean4 ✓ `BEDC.Derived.TowerEquivalenceUp.TowerEquivalence namecert obligations`

Proof. Project the carrier of Definition 1143.1. The admitted packet lists the two tower rows, the two approximation rows, the two physical-fit rows, the two open-fit rows, the objectivity row, the paired ledger, the descent row, endpoint agreement, transport, provenance, and local naming.

Endpoint agreement is therefore only one coordinate of the packet. The local certificate reads it through R together with T and T', so terminal package agreement cannot by itself certify the two towers.

Ledger compatibility is read next. The rows A, A', P, P', O, O' expose indexed approximation, physical signature, descent policy, open continuation, and finite refutation data on both sides, while L records source-history and hidden-residue agreement across those rows.

Descent and observer stability close the comparison. The row D lists exactly the operations that descend through both towers, and B, H preserve the comparison across observer anchors and componentwise transport. The provenance and local name rows then name the same displayed packet, giving exactly the five listed obligations. □

Theorem 1143.3 (TowerEquivalence endpoint refusal)**.** *Let*

$$E = (T, T', A, A', P, P', O, O', B, L, D, R, H, Q, N)$$

be an accepted $\mathsf{TowerEquivalence}^{\uparrow}$ *packet. Endpoint agreement through R does not by itself export tower equivalence. A consumer route is accepted only when the paired ledger L, descent row D, objectivity row B, and componentwise transport row H travel with the same endpoint comparison.*

Proof. Read the NameCert obligations of Definition 1143.2. The endpoint row R appears only as one row of a five-row local surface.

The paired ledger L records the source histories, hidden residues, omitted rows, and open adequacy gaps that endpoint comparison may hide. Removing L leaves no displayed evidence that the two towers agree below the terminal package.

The descent row D and objectivity row B are also mandatory. Without D, an operation may descend through one tower but not the other; without B, H, the comparison may depend on a privileged observer anchor or an untransported component. Thus endpoint agreement alone is refused as tower equivalence. □

Lean4 ✓ `BEDC.Derived.TowerEquivalenceUp.TowerEquivalenceCarrier endpoint refusal`

Theorem 1143.4 (TowerEquivalence ledger-descent stability)**.** *Every accepted* $\mathsf{TowerEquivalence}^{\uparrow}$ *transport preserves ledger and descent compatibility componentwise. If H transports E to another accepted carrier, then the transported paired ledger still records the same source-history, hidden-residue, omitted-row, and adequacy-gap comparison, and the transported descent row still refuses exactly the operations not displayed on both towers.*

Proof. Use the carrier definition. The transport row H is componentwise over the tower rows, approximation rows, physical-fit rows, open-fit rows, objectivity row, ledger, descent row, endpoint row, provenance, and local name.

The ledger row L is one of those transported components, so source-history agreement, hidden-residue agreement, omitted-row exposure, and open adequacy gaps cannot be dropped by transport. They remain attached to the same comparison after transport.

The descent row D is transported in the same packet. Since D lists only paired displayed descent routes, any operation missing on either side remains outside the accepted transported descent row. □

Lean4 ✓ `BEDC.Derived.TowerEquivalenceUp.TowerEquivalence ledger descent stability`

Theorem 1143.5 (TowerEquivalence refinement separation)**.** *Two* $\mathsf{TowerEquivalence}^{\uparrow}$ *candidates may agree at the endpoint row R and still be separated by a refinement that exposes a difference in L or D. Such a separation does not contradict endpoint agreement; it shows that the endpoint comparison was not a complete tower-equivalence certificate.*

Lean4 ✓ `BEDC.Derived.TowerEquivalenceUp.TowerEquivalenceRefinementSeparation`

Proof. Start with Definition 1143.3. Endpoint agreement is not the accepted certificate unless the paired ledger, descent row, objectivity row, and transport row are present in the same packet.

A refinement may inspect a source-history residue, omitted physical-signature row, open-fit refutation row, or operation descent route that was invisible to the endpoint classifier. Those data live in L and D, not in R alone.

If the refinement separates the candidates through L or D, the result is exactly the refusal boundary: the endpoint comparison remains an endpoint comparison, while the full tower-equivalence carrier is not accepted. □

Theorem 1143.6 (TowerEquivalence obligation scope)**.** *Every accepted* $\mathsf{TowerEquivalence}^{\uparrow}$ *read is scoped by the two tower rows T, T', the two approximation rows A, A', physical-fit rows P, P', open-fit rows O, O', objectivity row B, paired ledger L, descent row D, endpoint row R, componentwise* hsame *transport H, provenance Q, and local* $\mathsf{NameCert}_{\mathsf{TowerEquivalence}^{\uparrow}}$ *row N. Any consumer omitting L or D receives only endpoint comparison, not tower equivalence.*

Lean4 ✓ `BEDC.Derived.TowerEquivalenceUp.TowerEquivalence obligation scope`

Proof. Project the carrier of Definition 1143.1 and the local NameCert obligations of Definition 1143.2. The accepted packet displays both tower rows, both approximation rows, both physical-fit rows, both open-fit rows, objectivity, paired ledger, descent, endpoint, transport, provenance, and local naming before any equivalence read is exported.

Use endpoint refusal, Definition 1143.3. It says the endpoint row R is not accepted as tower equivalence unless L, D, B, and H travel with the same comparison, so an endpoint-only consumer remains outside the tower-equivalence surface.

Finally apply ledger-descent stability, Definition 1143.4. The paired ledger and descent row are preserved componentwise under transport, so omitting either row cannot be repaired downstream by provenance, local naming, or endpoint agreement. □

Theorem 1143.7 (TowerEquivalence public export surface)**.** *The public* $\mathsf{TowerEquivalence}^{\uparrow}$ *export surface consists exactly of the carrier of Definition 1143.1, the NameCert obligations of Definition 1143.2, endpoint refusal of Definition 1143.3, ledger-descent stability of Definition 1143.4, refinement separation of Definition 1143.5, and obligation scope of Definition 1143.6. A public consumer may cite tower equivalence only through that surface; endpoint-only agreement, host source equality, unrestricted descent, and observer-independent comparison outside* B, L, H *remain outside the export.*

Lean4 ✓ `BEDC.Derived.TowerEquivalenceUp.TowerEquivalencePublicExportSurface`

Proof. Project the carrier and NameCert obligations. They display the full packet $T, T', A, A', P, P', O, O', B, L, D$, before any equivalence read is available.

Apply endpoint refusal, ledger-descent stability, and refinement separation. These theorems keep endpoint comparison tied to the paired ledger, descent row, observer row, and componentwise transport, while allowing refinements to separate candidates through L or D.

Finally use obligation scope. It identifies the same displayed rows as the accepted scope for every equivalence read. Therefore the public export is exactly the listed paper surface, and the excluded endpoint-only or host-level claims have no carrier coordinate. □

Falsifiable prediction: An accepted TowerEquivalenceUp classifier is refuted by any pair of endpoint-agreeing towers whose displayed refinement exposes a source-ledger mismatch or an operation that descends through one tower but not the other.

Independence witness: realityconstrainedtowerpacket, realityconstrainedapproximationtower, physicalfittower, realityconstrainedopenfit, realityconstrainedobjectivity: none is bijective because $\mathsf{TowerEquivalence}^{\uparrow}$ carries two tower packets, two approximation rows, two physical-fit rows, two open-fit rows, observer-stable transport, paired ledger compatibility, descent compatibility, endpoint agreement, provenance, and local NameCert rows in one packet. Each sibling supplies a constituent surface, while only this packet binds endpoint agreement to ledger and descent compatibility.

The Lean development for this carrier must provide Nontrivial $\mathsf{TowerEquivalence}^{\uparrow}$ and FieldFaithful TowerEquivale TasteGate instances in `lean4/BEDC/Derived/TowerEquivalenceUp/TasteGate.lean`. The expected namespace is `BEDC.Derived.TowerEquivalenceUp`.

Closure status for $\mathsf{NameCert}_{\mathsf{TowerEquivalence}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{TowerEquivalence}^{\uparrow}$ packet is generated from two tower packets, two approximation rows, two physical-fit rows, two open-fit rows, an objectivity row, paired ledger compatibility, descent compatibility, endpoint agreement, componentwise transport, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TowerEquivalence}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1143.1, Definition 1143.2, Definition 1143.3, Definition 1143.4, Definition 1143.5, Definition 1143.6, and Definition 1143.7 close the paper-side public surface binding endpoint agreement to paired ledger, descent, objectivity, transport, provenance, and local naming rows for finite tower-equivalence packets.

Formal verification: FormalStatus(NameCert$_{\mathsf{TowerEquivalence}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert Lean verification, bridge checking, endpoint-only tower identity, host source equality, unrestricted descent, or observer-independent comparison outside the displayed objectivity row.

Upgrade path: Obligation closure requires Lean encoding of carrier admission, endpoint refusal, ledger-descent stability, refinement separation, obligation scope, TasteGate nontriviality, and field faithfulness for $T, T', A, A', P, P', O, O', B, L, D, R, H, Q, N$.

Chapter 1144

A Concrete Naming Certificate for $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$

The $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ packet realizes the TruthCert field list of Definition 9414.672 as a finite BEDC NameCert carrier. It sits beside the open-fit surface of chapter 1132, the objectivity surface of chapter 1133, the explanation surface of chapter 1136, the induction-stability seal of chapter 1139, and the tower-compression ledger of chapter 1142. Those sibling chapters provide the finite fit, observer-invariant reading, explanatory handoff, continuation stability, and compression ledger rows; this carrier binds exactly the nine TruthCert fields before any reality-constrained truth claim is exported.

Definition 1144.1 (Reality-constrained TruthCert carrier)**.** *A* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, \Sigma, K, T, U, D, I, L, F, N)$$

with the following displayed rows:

1. *S is the finite source row recording observation traces, source bundles, and the claim site.*
2. *Σ is the reality-facing signature row extracted from the source and compared against the model-facing signature.*
3. *K is the classifier row naming the sameness relation used for signature comparison.*
4. *T is the tower row recording approximation levels and the endpoint at which the claim is read.*
5. *U is the stability row naming the continuation class over which finite fit may be reused.*
6. *D is the descent row listing the operations that survive the tower route.*
7. *I is the invariant row recording observer-anchor transport and public content.*
8. *L is the ledger row recording compression, idealization, hidden residue, provenance, and packaging.*
9. *F is the failure-surface row naming finite defeats, domain exits, classifier mismatches, and later observations that can overturn the claim.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ *row binding the nine displayed TruthCert fields as one packet.*

The carrier has no coordinate for model–reality identity, unbounded confirmation, unledgered compression, observer privilege, hidden classifier choice, or truth export outside the nine displayed TruthCert rows.

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.taste gate`

Definition 1144.2 (Reality-constrained TruthCert classifier)**.** *For two* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *carrier packets*

$$Q = (S, \Sigma, K, T, U, D, I, L, F, N) \quad \text{and} \quad Q' = (S', \Sigma', K', T', U', D', I', L', F', N'),$$

the classifier $Q \sim_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}} Q'$ *is the componentwise agreement predicate asserting source agreement between* S *and* S'*, signature agreement between* Σ *and* Σ'*, classifier-row agreement between* K *and* K'*, tower agreement between* T *and* T'*, continuation-stability agreement between* U *and* U'*, descent agreement between* D *and* D'*, invariant-reading agreement between* I *and* I'*, ledger agreement between* L *and* L'*, failure surface agreement between* F *and* F'*, and local-name agreement between* N *and* N'*. The* K *component preserves exactly the accepted signature comparison used by* Σ *and* Σ'*. The* L *and* F *components preserve the ledger rows and failure rows that determine whether an export remains readable through the same local TruthCert packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertClassifier row certificate`

Theorem 1144.3 (Reality-constrained TruthCert classifier obligation surface)**.** *The classifier of Definition 1144.2 is the full comparison surface for the carrier of Definition 1144.1. In particular, an accepted comparison between two* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packets must expose the componentwise rows*

$$S, \Sigma, K, T, U, D, I, L, F, N$$

and their primed counterparts, with K *governing the accepted signature comparison and with* L, F *governing the ledger and failure-surface comparisons.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertClassifierObligationSurfa`

Proof. Start from the carrier definition Definition 1144.1. It exposes exactly the source, signature, classifier, tower, stability, descent, invariant, ledger, failure-surface, and local-name rows.

Now unfold the classifier definition Definition 1144.2. Each displayed carrier row is compared only with its counterpart in the second packet. The K row is therefore fixed before signature comparison is accepted, and the L, F rows are fixed before ledger or failure reads are transported.

Finally use the sibling-dependency theorem Definition 1144.10. The open-fit, objectivity, explanation, physical-induction, and tower-compression siblings supply the finite source comparison, invariant reading, source-to-claim handoff, continuation stability, tower route, descent row, and ledger discipline consumed by this componentwise classifier. □

Theorem 1144.4 (Reality-constrained TruthCert carrier transport)**.** *If* $Q = (S, \Sigma, K, T, U, D, I, L, F, N)$ *is an accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet and* $Q \sim_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}} Q'$ *for*

$$Q' = (S', \Sigma', K', T', U', D', I', L', F', N'),$$

then Q' *is accepted by the same carrier surface. Transport preserves the accepted signature comparison through* K'*, preserves the ledger row through* L'*, preserves the failure-surface row through* F'*, and leaves no truth coordinate outside the transported packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertCarrier transport`

Proof. The carrier definition Definition 1144.1 lists all rows required for admission. The classifier definition Definition 1144.2 supplies a comparison for each such row, so every required component of Q' is reached by the matching component of Q.

Apply the classifier obligation surface of Definition 1144.3. It keeps K' attached to the accepted signature comparison and keeps L' and F' attached to the ledger and failure-surface rows rather than to an external truth route.

The sibling-dependency theorem Definition 1144.10 supplies the ambient transport sources for finite fit, invariant reading, explanatory handoff, continuation stability, and tower compression. Thus the transported packet remains inside the same accepted carrier surface. □

Theorem 1144.5 (Reality-constrained TruthCert NameCert obligation exhaustion)**.** *For* RealityConstrainedTruthC *the local* NameCert *obligation surface is exhausted by the carrier of Definition 1144.1, the classifier of Definition 1144.2, the classifier obligation surface of Definition 1144.3, and the carrier transport of Definition 1144.4. Ledger exactness, failure exactness, and export readiness add no second certificate surface; they read the same rows* $S, \Sigma, K, T, U, D, I, L, F, N$.

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertNameCertObligationExhaust`

Proof. Use the carrier definition and classifier definition first. Together they give the admitted packet and the accepted packet comparison, including the signature comparison controlled by K and the ledger and failure comparisons controlled by L and F.

Next apply Definition 1144.3 and Definition 1144.4. These results make comparison and transport internal to the displayed packet rather than external to the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ row.

Finally use the downstream readiness blocks Definition 1144.15, Definition 1144.19, and Definition 1144.21. They consume the same ledger, failure, classifier, sibling, and export rows already displayed in the packet. Hence the local NameCert obligations are exhausted by the carrier, classifier, and transport surface, not by any hidden certificate coordinate. □

Theorem 1144.6 (Reality-constrained TruthCert field coverage)**.** *For the carrier of Definition 1144.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ *surface covers exactly the source, signature, classifier, tower, stability, descent, invariant, ledger, and failure-surface fields of the certified physical truth packet. Any accepted export of a reality-constrained truth claim must read these fields through* $S, \Sigma, K, T, U, D, I, L, F$ *before the local name* N *is exposed.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertFieldCoverage`

Proof. Carrier admission exposes exactly $Q = (S, \Sigma, K, T, U, D, I, L, F, N)$. The source field is the row S, and the signature field is the row Σ.

The classifier field is the row K. The tower field is the row T, while the stability and descent fields are U and D.

The invariant field is the row I, the ledger field is the row L, and the failure-surface field is the row F. The local name N binds these rows but adds no further truth coordinate.

Thus the NameCert surface covers the nine TruthCert fields and is exhausted by them. A consumer that omits any one row reads a projection of the packet, not an accepted $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ export. □

Theorem 1144.7 (Reality-constrained TruthCert source-signature-classifier obligation)**.** *Every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *truth export must expose the source row* S*, the reality-facing signature row* Σ*, and the classifier row* K *before the local truth claim is readable. The source may not be replaced by an unnamed observation route, the signature may not be replaced by a model-side assertion, and the classifier may not be chosen after export.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertSourceSignatureClassifier`

Proof. Use the carrier of Definition 1144.1. The displayed packet contains S, Σ, K as separate rows: source, reality-facing signature, and classifier.

Apply Definition 1144.6. It makes these rows mandatory fields of the TruthCert surface before the local name N is exposed, so omitting any one of them yields only a projection of the packet.

Finally use Definition 1144.10. The open-fit and explanation siblings supply finite source comparison and source-to-claim handoff, and the classifier row controls the accepted signature comparison. Thus truth export is blocked until S, Σ, K have all been recorded. □

Theorem 1144.8 (Reality-constrained TruthCert stability-descent-invariant obligation)**.** *Every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet must preserve the tower route* T*, the continuation-stability row* U*, the descent row* D*, and the observer-invariant row* I *as a joint obligation surface. These rows certify that the claim is read at the displayed endpoint, reused only over the named continuation class, transported only through the recorded descent operations, and exposed through an observer-invariant public reading.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertStabilityDescentInvariant`

Proof. The carrier in Definition 1144.1 displays the rows T, U, D, I separately. They name the approximation tower, the continuation class, the surviving descent operations, and the observer-anchor transport.

Apply Definition 1144.6. Since tower, stability, descent, and invariant reading are mandatory TruthCert fields, the local name N can certify a truth export only after these four rows are readable.

Use Definition 1144.10. Physical induction supplies the continuation-stability seal, tower compression supplies tower route and descent discipline, and objectivity supplies observer-invariant reading. Therefore T, U, D, I form one preservation surface rather than four optional annotations. □

Theorem 1144.9 (Reality-constrained TruthCert ledger-failure-local-name obligation)**.** *Every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *local name must be preceded by the ledger row* L *and the failure-surface row* F*. The ledger records compression, idealization, hidden residue, provenance, and packaging, while the failure row records finite defeats, domain exits, classifier mismatches, and later observations before* N *binds the packet as a local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$*.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertLedgerFailureLocalNameOb`

Proof. Read the carrier of Definition 1144.1. It assigns compression, idealization, hidden residue, provenance, and packaging to L, assigns the defeat and exit surface to F, and reserves N for the local NameCert row.

Apply Definition 1144.6. The ledger and failure-surface fields are mandatory before the local name is exposed, while N binds the already displayed rows without adding an extra truth coordinate.

Finally use Definition 1144.10. Tower compression controls descent, ledger, and hidden residue; open-fit controls finite defeat; and the remaining siblings route invariant reading, explanation, and

stability. Hence local naming is accepted only after ledger and failure obligations have been recorded in L and F. □

Theorem 1144.10 (Reality-constrained TruthCert sibling dependency)**.** *Every accepted* RealityConstrainedTruthCe *packet consumes the open-fit, objectivity, explanation, physical-induction, and tower-compression dependencies supplied by the sibling certificate family. The open-fit dependency controls finite fit and finite defeat; the objectivity dependency controls invariant observer reading; the explanation dependency controls source-to-claim handoff; the physical-induction dependency controls stability over continuations; and the tower-compression dependency controls descent, ledger, and hidden residue.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertSiblingDependency`

Proof. Read the carrier rows of Definition 1144.1. The rows S, Σ, K, F require the finite source, signature comparison, classifier, and defeat surface supplied by the open-fit certificate family.

The invariant row I requires the observer-anchor discipline supplied by the objectivity certificate family. Without that row, the packet can carry a private observation route but not a public reality-constrained truth claim.

The source-to-claim handoff is supplied by the explanation certificate family. It binds signatures, derivation routes, and admissible explanatory use before the local truth certificate can be read.

The stability row U consumes the physical-induction seal, because finite fit can be reused only over the displayed continuation class. The tower, descent, and ledger rows T, D, L consume the tower-compression certificate, because endpoint claims must retain their approximation route and hidden residue.

Consequently the packet is composite rather than atomic: its accepted route depends on the open-fit, objectivity, explanation, physical-induction, and tower-compression siblings, and no single sibling alone carries the full TruthCert surface. □

Theorem 1144.11 (Reality-constrained TruthCert kernel truth route)**.** *Every accepted* RealityConstrainedTruthCer *truth export is routed only through*

$$S, \Sigma, K, T, U, D, I, L, F, N$$

and through the sibling dependency surface of Definition 1144.10. It is not routed through model–reality identity, hidden observer privilege, unbounded confirmation, or an external truth coordinate.

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertKernelTruthRoute`

Proof. Start from the carrier definition Definition 1144.1. It displays the source, signature, classifier, tower, stability, descent, invariant, ledger, failure, and local NameCert rows as the only rows of the packet.

Apply Definition 1144.3 and Definition 1144.6. These theorems make the classifier and all nine exported fields mandatory parts of the displayed route rather than optional side data.

Finally use Definition 1144.10. The open-fit, objectivity, explanation, physical-induction, and tower-compression siblings account for the admissible dependency surface, so no model–reality identity row or external truth coordinate remains available for export. □

Theorem 1144.12 (Reality-constrained TruthCert failure readiness)**.** *In every accepted* RealityConstrainedTruthCe *export, the failure row F is displayed before the truth certificate is readable. The same row remains part of transported classifier agreement whenever the packet is compared, replayed, or carried across a sibling route.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertFailureReadiness`

Proof. First read F from Definition 1144.1. The carrier reserves it for finite defeats, domain exits, classifier mismatches, and later observations before local naming.

Use Definition 1144.9. It places F before the local NameCert row N, so export cannot precede the displayed failure surface.

Then apply Definition 1144.4 together with Definition 1144.3. Transported agreement must preserve the classifier-facing rows already exposed by the packet, and the failure row remains one of those rows rather than a removable annotation. □

Theorem 1144.13 (Reality-constrained TruthCert public export boundary)**.** *A public* RealityConstrainedTruthCert *export is accepted only after the source row S, classifier row K, tower row T, stability row U, invariant row I, ledger row L, failure row F, and local NameCert row N are all present, with the signature and descent rows Σ, D displayed in the same carrier.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertPublicExportBoundary`

Proof. Begin with Definition 1144.1. The public packet is $Q = (S, \Sigma, K, T, U, D, I, L, F, N)$, so each named row must be available inside the same finite carrier before any export can be read.

Next use Definition 1144.6. It identifies the required source, signature, classifier, tower, stability, descent, invariant, ledger, failure, and local naming fields, and it leaves no public export row outside them.

Finally combine Definition 1144.9 with Definition 1144.10. The ledger and failure rows precede local naming, while the sibling surface supplies the dependency discipline for source, classifier, tower, stability, invariant, ledger, and failure. Hence public export is accepted only at the full displayed boundary. □

Theorem 1144.14 (Reality-constrained TruthCert carrier admission)**.** *An accepted* RealityConstrainedTruthCert$^{\uparrow}$ *packet exposes exactly the carrier*

$$Q = (S, \Sigma, K, T, U, D, I, L, F, N).$$

The accepted export may project the source, signature, classifier, tower, stability, descent, invariant, ledger, failure-surface, and local-name rows, but it has no additional TruthCert coordinate outside this displayed packet.

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertCarrierAdmission`
`eventflow boundary`

Proof. Use the carrier definition Definition 1144.1. Its displayed packet is exactly $Q = (S, \Sigma, K, T, U, D, I, L, F, N)$.

Apply the field-coverage theorem Definition 1144.6. It identifies the source, signature, classifier, tower, stability, descent, invariant, ledger, and failure-surface fields with the rows $S, \Sigma, K, T, U, D, I, L, F$, and it reserves N for local naming.

No remaining row is available for carrier admission. A consumer that asks for a second truth coordinate is therefore asking outside the admitted packet rather than reading an accepted RealityConstrainedTruthCert$^{\uparrow}$ export. □

Theorem 1144.15 (Reality-constrained TruthCert ledger exactness)**.** *In every accepted* RealityConstrainedTruthCer *packet, the ledger row L records compression, idealization, hidden residue, provenance, and package descent before any truth export is readable. These records are routed through the open-fit, objectivity, explanation, physical-induction stability, and tower-compression siblings before the local name N is exposed.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertLedgerExactness`

Proof. The carrier definition Definition 1144.1 assigns compression, idealization, hidden residue, provenance, and packaging to the ledger row L. The field-coverage theorem Definition 1144.6 then makes L a mandatory TruthCert field rather than an optional annotation.

Now use the sibling-dependency theorem Definition 1144.10. Open-fit controls finite fit and finite defeat; objectivity controls public observer reading; explanation controls source-to-claim handoff; physical induction controls continuation stability; and tower compression controls descent, ledger, and hidden residue.

Consequently the ledger is exact at the point of export: compression, idealization, hidden residue, provenance, and package descent must already be visible in L and routed through the named siblings before N can certify the truth packet. □

Theorem 1144.16 (Reality-constrained TruthCert non-escape)**.** *No accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet exports model–reality identity, unbounded confirmation, observer privilege, hidden classifier choice, or truth outside the displayed rows* $S, \Sigma, K, T, U, D, I, L, F, N$.

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertNonescape`

Proof. Inspect the carrier definition Definition 1144.1. Its final sentence excludes model–reality identity, unbounded confirmation, unledgered compression, observer privilege, hidden classifier choice, and truth export outside the nine displayed TruthCert rows.

The field-coverage theorem Definition 1144.6 makes the displayed rows exhaustive for accepted export. The sibling-dependency theorem Definition 1144.10 further routes finite fit, objectivity, explanation, induction stability, and compression through their own certificate surfaces.

Therefore none of the excluded demands has a readable coordinate in the packet. Such a demand can only be recorded at the failure-surface or ledger boundary, not exported as part of the local TruthCert name. □

Theorem 1144.17 (Reality-constrained TruthCert classifier stability)**.** *Let*

$$Q = (S, \Sigma, K, T, U, D, I, L, F, N) \quad \textit{and} \quad Q' = (S', \Sigma', K', T', U', D', I', L', F', N')$$

be accepted $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packets. Any accepted comparison between* Q *and* Q' *must preserve the signature, classifier, tower, stability, descent, invariant, ledger, and failure-surface rows componentwise:* Σ *is compared only with* Σ'*,* K *only with* K'*,* T *only with* T'*,* U *only with* U'*,* D *only with* D'*,* I *only with* I'*,* L *only with* L'*, and* F *only with* F'*. No comparison accepted by the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ *row may substitute one of these rows for another.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertClassifier stability`

Proof. Project the two carriers through Definition 1144.1. The displayed packets expose the rows $S, \Sigma, K, T, U, D, I, L, F, N$ and $S', \Sigma', K', T', U', D', I', L', F', N'$ with the same row order and the same local naming role.

Use Definition 1144.6. It makes the signature, classifier, tower, stability, descent, invariant, ledger, and failure-surface fields readable exactly through the displayed rows $\Sigma, K, T, U, D, I, L, F$ and their primed counterparts.

Now use Definition 1144.10. The open-fit sibling controls signature comparison and finite defeat, the objectivity sibling controls invariant reading, the explanation sibling controls source-to-claim handoff, the physical-induction sibling controls stability, and the tower-compression sibling controls tower, descent, ledger, and hidden residue.

Therefore an accepted comparison has no free classifier or cross-row transport left to choose. It preserves each displayed obligation row against its counterpart, while N and N' only name the already displayed packets. □

Theorem 1144.18 (Reality-constrained TruthCert ledger non-escape)**.** *No accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *truth export may bypass the ledger row L. In particular, compression, idealization, provenance, and hidden residue must be readable through L before the local name N can certify the exported truth packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertLedgerNonescape`

Proof. Read the carrier row L in Definition 1144.1. It is the displayed ledger coordinate for compression, idealization, hidden residue, provenance, and packaging.

Apply Definition 1144.6. The ledger is one of the nine mandatory TruthCert fields, so an export that omits L reads only a projection of the packet.

Apply Definition 1144.15. The ledger entries must already record compression, idealization, hidden residue, provenance, and package descent before truth export is readable.

Finally use Definition 1144.10. The tower-compression sibling controls descent, ledger, and hidden residue, while the other siblings route finite fit, invariant reading, explanatory handoff, and continuation stability. Thus a truth export that bypasses L bypasses a required sibling-routed row and is not accepted by the local certificate. □

Theorem 1144.19 (Reality-constrained TruthCert failure-surface exactness)**.** *For every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet, later observations, classifier mismatches, domain exits, and finite defeats are accepted exactly through the displayed failure-surface row F. They are not hidden in the source, classifier, stability, invariant, ledger, or local-name rows.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertFailureSurfaceExactness`

Proof. The carrier definition Definition 1144.1 assigns finite defeats, domain exits, classifier mismatches, and later observations to the failure-surface row F.

The field-coverage theorem Definition 1144.6 makes F a mandatory TruthCert field and exhausts the accepted export by the displayed rows. Therefore a claimed defeat route outside F is outside the local TruthCert surface.

The sibling-dependency theorem Definition 1144.10 identifies the dependencies that feed this surface. Open-fit supplies finite fit and finite defeat, the classifier row supplies signature comparison, physical induction supplies the continuation class, and tower compression supplies descent and hidden residue.

Consequently later observations, classifier mismatches, domain exits, and finite defeats have a single accepted public landing row: F. The other rows may supply the data that makes a defeat meaningful, but they do not certify a separate failure surface. □

Theorem 1144.20 (Reality-constrained TruthCert export defeat exhaustion)**.** *Let an accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet expose the rows $S, \Sigma, K, T, U, D, I, L, F, N$. If F records a later observation, classifier mismatch, domain exit, or finite defeat, then no truth export through the local name N is accepted unless that defeat is discharged through the same displayed $S, \Sigma, K, T, U, D, I, L, F, N$ route. A purported export that hides F or bypasses it is outside the TruthCert packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertExportDefeatExhaustion`

Proof. The carrier coverage theorem Definition 1144.6 first fixes the only rows that the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ surface can expose. Thus the name N does not create a second export channel; it binds the nine displayed rows after they are readable.

The ledger exactness theorem Definition 1144.15 keeps compression, residue, provenance, and package descent visible at L. Together with the sibling-dependency theorem Definition 1144.10, this forces open-fit, objectivity, explanation, physical-induction, and tower-compression data to travel through the displayed route before a truth claim reaches N.

Finally apply Definition 1144.19. Later observations, classifier mismatches, domain exits, and finite defeats land only at F. Therefore a discharge of such a defeat must be visible through the same carrier route that made F visible. If a purported export hides or bypasses F, it is not an accepted export through the local TruthCert packet. □

Theorem 1144.21 (Reality-constrained TruthCert export readiness)**.** *An accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *truth export is readable through the local name N only after field coverage, sibling dependency routing, ledger exactness, classifier stability, and failure-surface exactness have all been read through the displayed carrier*

$$Q = (S, \Sigma, K, T, U, D, I, L, F, N).$$

Thus the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ *row certifies export readiness only for the full ten-row packet, not for a projection of the packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertExportReadiness`

Proof. Start with Definition 1144.14 and Definition 1144.6. They make $Q = (S, \Sigma, K, T, U, D, I, L, F, N)$ the admitted carrier and make $S, \Sigma, K, T, U, D, I, L, F$ the mandatory readable TruthCert rows before N is exposed.

Next use Definition 1144.10. It routes finite fit, objectivity, explanation, physical-induction stability, and tower compression through the displayed packet rather than through an external export channel.

The ledger and classifier obligations are fixed by Definition 1144.15 and Definition 1144.17. The former keeps compression, idealization, hidden residue, provenance, and package descent visible at L, while the latter prevents signature, classifier, tower, stability, descent, invariant, ledger, and failure-surface rows from being substituted across comparisons.

Finally apply Definition 1144.19. Later observations, classifier mismatches, domain exits, and finite defeats land at F. Therefore an accepted export through N is ready only when all these readings have already passed through the displayed carrier rows. □

Theorem 1144.22 (Reality-constrained TruthCert methodology-ledger handoff)**.** *Every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *export consumed as methodology authority must route through* RealityConstrainedMetho *before the local name N is read. The methodology consumer must preserve the TruthCert source, signature, classifier, tower, stability, descent, invariant, ledger, and failure rows together with the methodology-ledger export row, rather than reading a projection of the TruthCert packet as an independent methodological warrant.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertMethodologyLedgerHandoff`

Proof. Start with field coverage and export readiness, Definition 1144.6 and Definition 1144.21. They force every accepted export through $S, \Sigma, K, T, U, D, I, L, F, N$ before the local name is exposed.

Next use sibling dependency and ledger exactness, Definition 1144.10 and Definition 1144.15. These keep explanation, audit-facing source use, observer reading, physical-induction stability, tower compression, provenance, hidden residue, and package descent visible at the point where the TruthCert export is consumed.

The methodology-ledger chapter records exactly the downstream scope, domain-leakage refusal, upgrade route, and methodology failure surface for such consumption. Thus a methodology consumer cannot treat the TruthCert name as freestanding authority. It must first pass the accepted export through $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$, where the export discipline is recorded before N is read. □

Theorem 1144.23 (Reality-constrained TruthCert open-fit export boundary)**.** *Every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *export whose failure row changes must route through the open-fit and failure-surface siblings before export. A changed row F is accepted only when the finite-fit, defeat, classifier-mismatch, domain-exit, continuation-scope, and ledger reads remain visible through the displayed carrier $S, \Sigma, K, T, U, D, I, L, F, N$.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertOpenFitExportBoundary`

Proof. Use failure-surface exactness, Definition 1144.19. Later observations, classifier mismatches, domain exits, and finite defeats have the single public landing row F.

Apply sibling dependency and classifier stability, Definition 1144.10 and Definition 1144.17. The open-fit sibling controls finite fit and finite defeat, while the classifier row prevents a changed failure surface from being compared by substituting another displayed row.

Finally use export readiness. Since N is readable only after field coverage, sibling routing, ledger exactness, classifier stability, and failure-surface exactness have all been read, a changed F must be routed through the open-fit and failure-surface surfaces before export. Otherwise the changed failure row is outside the accepted TruthCert packet. □

Theorem 1144.24 (Reality-constrained TruthCert observer-invariant ledger route)**.** *Every observer-invariant* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *truth export must preserve the invariant row I and the ledger row L together. A consumer may not read observer invariance without the compression, idealization, hidden-residue, provenance, and package-descent ledger, and may not read the ledger as public truth without the observer-invariant row.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertObserverInvariantLedgerRo`

Proof. Project the carrier through Definition 1144.1. The invariant row I and ledger row L are separate displayed coordinates, but both are mandatory fields of the same accepted packet.

Use the stability-descent-invariant obligation and ledger exactness, Definition 1144.8 and Definition 1144.15. The former keeps observer-anchor transport joined to tower, stability, and descent rows; the latter keeps compression, idealization, hidden residue, provenance, and package descent visible at L.

Now apply export readiness. Since the local name N certifies export only after all mandatory rows have been read through the same carrier, I and L cannot be exported as independent authorities. Observer-invariant truth export preserves the invariant and ledger rows as one route through the accepted TruthCert packet. □

Theorem 1144.25 (Reality-constrained TruthCert failure routing)**.** *For an accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet, defeating observations, domain exits, classifier mismatches, and later observations land only in the row F before the local name N certifies export. They do not create a hidden truth coordinate, an unledgered compression route, or a classifier choice outside $S, \Sigma, K, T, U, D, I, L, F, N$.*

Proof. Use Definition 1144.19. It assigns later observations, classifier mismatches, domain exits, and finite defeats to the displayed failure-surface row F and excludes separate failure surfaces in the source, classifier, stability, invariant, ledger, and local-name rows.

Now apply Definition 1144.16. The carrier has no row for model–reality identity, unbounded confirmation, observer privilege, hidden classifier choice, or truth outside the displayed packet.

Finally use Definition 1144.18. The ledger row L must already expose compression, idealization, hidden residue, provenance, and package descent before N names the export. Hence a failure cannot be routed by hiding in the ledger or by bypassing F; it reaches the local certificate only through the displayed failure row. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertFailureRouting`

Theorem 1144.26 (Reality-constrained TruthCert sibling handoff totality)**.** *Every accepted* RealityConstrainedTrut *packet consumes the open-fit, objectivity, explanation, physical-induction stability, and tower-compression sibling handoffs before the local name N exports its TruthCert packet. No accepted export may skip one of these sibling routes while still claiming the full rows $S, \Sigma, K, T, U, D, I, L, F, N$.*

Proof. Expand Definition 1144.10. Open-fit controls finite fit and finite defeat, objectivity controls observer-invariant reading, explanation controls source-to-claim handoff, physical induction controls continuation stability, and tower compression controls tower route, descent, ledger, and hidden residue.

Then apply Definition 1144.21. Export through N is readable only after field coverage, sibling routing, ledger exactness, classifier stability, and failure-surface exactness have all been read through $S, \Sigma, K, T, U, D, I, L, F, N$.

If one sibling handoff were skipped, at least one required row would lose its source of admissible data: finite fit or defeat, invariant reading, explanatory handoff, continuation stability, or compression and descent. Such a packet would be a projection rather than the accepted TruthCert carrier.

Therefore the five sibling routes are total for this export surface. They are all consumed before N certifies the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ packet. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertSiblingHandoffTotality`

Theorem 1144.27 (Reality-constrained TruthCert root readiness packet)**.** *For the carrier*

$$Q = (S, \Sigma, K, T, U, D, I, L, F, N),$$

root readiness of $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *is exactly the packet route that passes through carrier admission, field coverage, sibling handoff totality, ledger exactness, failure-surface exactness, and export readiness over the displayed rows $S, \Sigma, K, T, U, D, I, L, F, N$. A root consumer receives a TruthCert packet only along that route, not along a separate truth coordinate or a projection of the carrier.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertRootReadinessPacket`

Proof. Start with carrier admission and field coverage, Definition 1144.14 and Definition 1144.6. They identify $Q = (S, \Sigma, K, T, U, D, I, L, F, N)$ as the admitted carrier and make the source, signature, classifier, tower, stability, descent, invariant, ledger, and failure-surface rows mandatory before N is readable.

Next use sibling handoff totality, Definition 1144.26. It forces the open-fit, objectivity, explanation, physical-induction stability, and tower-compression routes to be consumed before the local name exports the packet.

Finally apply ledger exactness, failure-surface exactness, and export readiness: Definition 1144.15, Definition 1144.19, and Definition 1144.21. These results make L and F exact rows and allow N to certify export only after the same displayed packet has been read. Thus root readiness is neither more nor less than this carrier route through $S, \Sigma, K, T, U, D, I, L, F, N$. □

Theorem 1144.28 (Reality-constrained TruthCert root defeat projection)**.** *Any downstream consumer that changes or omits the failure row F of an accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet reads only a projection of the TruthCert carrier. Such a consumer does not receive the root-ready packet unless the changed or disputed failure surface is routed through the displayed open-fit, defeat, classifier, ledger, and export rows before N is read.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertRootDefeatProjection`

Proof. Use failure routing, Definition 1144.25. Defeating observations, domain exits, classifier mismatches, and later observations land only in F before N certifies export; they do not create a hidden truth coordinate or an unledgered compression route.

Now apply the open-fit export boundary, Definition 1144.23. A changed F must remain visible through the open-fit and failure-surface siblings together with the carrier rows $S, \Sigma, K, T, U, D, I, L, F, N$.

Finally use export defeat exhaustion, Definition 1144.20. A later observation, classifier mismatch, domain exit, or finite defeat recorded by F must be discharged through the same displayed route. Omitting or changing F without that route leaves only a projection, so the downstream consumer has not received the root-ready TruthCert packet. □

Theorem 1144.29 (Reality-constrained TruthCert root consumer totality)**.** *Every methodology, open-fit, objectivity, physical-induction, or tower-compression consumer of the* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *name must consume all five sibling routes before N exports the TruthCert packet. No such consumer may read one sibling route as an independent root authority while claiming the full rows $S, \Sigma, K, T, U, D, I, L, F, N$.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertRootConsumerTotality`

Proof. Begin with sibling dependency and sibling handoff totality, Definition 1144.10 and Definition 1144.26. They assign finite fit and defeat to open-fit, invariant reading to objectivity, source-to-claim handoff to explanation, continuation stability to physical induction, and tower route, descent, ledger, and hidden residue to tower compression.

For methodology consumption, use Definition 1144.22. It requires the methodology consumer to preserve the TruthCert source, signature, classifier, tower, stability, descent, invariant, ledger, and failure rows together with the methodology-ledger export row.

For the remaining root consumers, apply export readiness and root readiness, Definition 1144.21 and Definition 1144.27. The local name N is readable only after field coverage, sibling routing, ledger exactness, classifier stability, and failure-surface exactness have all passed through the displayed carrier. Therefore each named downstream consumer must consume all five sibling routes before treating N as the exported TruthCert packet. □

Theorem 1144.30 (Reality-constrained TruthCert root carrier obligation)**.** *Every root-facing consumer of* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *must receive the displayed carrier packet $S, \Sigma, K, T, U, D, I, L, F, N$. Omitting any one of these rows leaves only a projection and cannot be read as the root-ready TruthCert export named by N.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertRootCarrierObligation`

Proof. Use the carrier and classifier definitions, Definition 1144.1 and Definition 1144.2. They make the ten displayed rows the whole accepted packet and the whole comparison surface.

Apply root consumer totality, Definition 1144.29. Each methodology, open-fit, objectivity, physical-induction, or tower-compression consumer must consume the sibling routes through this same packet. Therefore a consumer that omits one displayed row has not received the carrier required for root export. □

Theorem 1144.31 (Reality-constrained TruthCert root classifier stability)**.** *If a root-facing transport compares two accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packets, then the classifier rows* K, K' *remain the rows governing signature comparison for the transported packets* $S, \Sigma, K, T, U, D, I, L, F, N$ *and* $S', \Sigma', K', T', U', D', I', L', F', N'$*. The transport cannot replace the classifier row while preserving root readiness.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertRootClassifierStability`

Proof. Start with classifier stability and carrier transport, Definition 1144.17 and Definition 1144.4. They keep the classifier component attached to the accepted signature comparison across the transported carrier.

Now use root readiness, Definition 1144.27. Root readiness is the carrier route through field coverage, sibling handoff, ledger exactness, failure exactness, and export readiness. A changed classifier row would leave that route, so the transported export remains root-ready only when K and K' are the classifier rows being compared. □

Theorem 1144.32 (Reality-constrained TruthCert root ledger nonescape)**.** *No root-facing export may expose the local name* N *while bypassing the ledger row* L *or the failure row* F*. The accepted export of* $S, \Sigma, K, T, U, D, I, L, F, N$ *therefore records compression, provenance, hidden residue, finite defeat, domain exit, classifier mismatch, and later observation before* N *is readable.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertRootLedgerNonescape`

Proof. Apply ledger exactness and failure-surface exactness, Definition 1144.15 and Definition 1144.19. They make L and F exact displayed rows, not optional annotations.

Finally use export readiness and sibling handoff totality, Definition 1144.21 and Definition 1144.26. The local name N is readable only after all displayed rows and sibling routes are consumed, so an export that bypasses L or F cannot be the root-ready $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ packet. □

Falsifiable prediction: A purported reality-constrained truth export that omits the displayed source, signature, classifier, tower, stability, descent, invariant, ledger, or failure-surface row is not an accepted TruthCert packet.

Independence witness: reality-constrained-open-fit, reality-constrained-objectivity, reality-constrained-explanation, physical-induction-stability-seal, reality-constrained-tower-compression: the full nine-field TruthCert packet is available only after these sibling dependencies are consumed together.

Theorem 1144.33 (Reality-constrained TruthCert L10 source readiness)**.** *For every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet*

$$(S, \Sigma, K, T, U, D, I, L, F, N),$$

the L10 consumers $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *may read the TruthCert surface only through the finite source row* S, *signature row* Σ, *classifier row* K, *tower row* T, *stability row* U, *descent row* D, *observer-invariant row* I, *ledger row* L, *failure row* F, *and local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ *row* N. *No L10 consumer receives an unlisted source, ambient truth predicate, global reality oracle, or off-packet continuation.*

Proof. Read the carrier and field-coverage rows from Definition 1144.1 and Definition 1144.6. They make the displayed tuple the full finite packet, with $S, \Sigma, K, T, U, D, I, L, F, N$ as the available rows.

Next apply sibling dependency and sibling handoff totality, Definition 1144.10 and Definition 1144.26. These place $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ behind the displayed TruthCert handoff rather than behind an independent source supply.

Finally use export readiness, Definition 1144.21. The export row is root-ready only after the finite source, classifier, ledger, failure, and local naming rows are consumed, so every L10 read is confined to the accepted packet. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertL10SourceReadiness`

Theorem 1144.34 (Reality-constrained TruthCert L10 failure ledger lock)**.** *For every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet* $(S, \Sigma, K, T, U, D, I, L, F, N)$, *each L10 read by* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *that reaches the classifier row* K *must also keep the ledger row* L *and the failure row* F *in the same packet. The read cannot drop finite defeat, domain exit, classifier mismatch, hidden residue, later observation, or compression provenance while retaining the local name* N.

Proof. Start with ledger exactness and failure-surface exactness, Definition 1144.15 and Definition 1144.19. They identify L and F as displayed rows of the accepted packet, not optional annotations.

Use field coverage to keep K, L, F, N in the same finite carrier. A consumer that exposes K through the local name must therefore remain inside $S, \Sigma, K, T, U, D, I, L, F, N$.

Apply export readiness to the L10-facing handoff. Since the export cannot expose N before ledger and failure rows have been consumed, any read that drops L or F is outside the $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ route. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCert l10 failure ledger lock`

Theorem 1144.35 (Reality-constrained TruthCert L10 export totality)**.** *The L10 export of an accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet* $(S, \Sigma, K, T, U, D, I, L, F, N)$ *is total for* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$: *every accepted downstream read is accounted for by the finite source row* S, *the classifier row* K, *the ledger row* L, *the failure row* F, *and the local* $\mathsf{NameCert}$ *row* N, *together with the intervening signature, tower, stability, descent, and observer-invariant rows. There is no second L10 export through hidden source material, hidden failure repair, host equality, or an ambient truth object.*

Proof. Assemble the packet from carrier coverage and sibling dependency. These rows state that the TruthCert object and its downstream consumers are expressed by the displayed finite carrier and its listed sibling routes.

The ledger and failure lock fixes the classifier-facing part of the export. By Definition 1144.34, any L10 read that keeps the local name also keeps the classifier, ledger, and failure rows inside the same packet.

Finally apply export readiness and sibling handoff totality. Together they make the displayed packet the only source-readiness route for $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so the L10 export is total over the listed rows and has no hidden branch. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertL10ExportTotality`

Theorem 1144.36 (Reality-constrained TruthCert L10 readiness obligation surface)**.** *For every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet* $(S, \Sigma, K, T, U, D, I, L, F, N)$*, the three L10 rows Definition 1144.33, Definition 1144.34, and Definition 1144.35 form the complete readiness obligation surface for routing the packet through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The surface consists exactly of source confinement to the displayed packet, classifier-ledger-failure co-residence inside that packet, and total export through the finite packet rows* $S, \Sigma, K, T, U, D, I, L, F, N$*. It exposes no ambient truth predicate, quotient real equality, selected limit, global reality oracle, or off-packet continuation.*

Proof. First use Definition 1144.33. It confines every L10 read by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to the finite rows $S, \Sigma, K, T, U, D, I, L, F, N$, so no consumer can begin from an unlisted source, ambient truth predicate, global reality oracle, or off-packet continuation.

Next use Definition 1144.34. This keeps the classifier row K, the ledger row L, the failure row F, and the local name row N co-resident whenever a downstream L10 read reaches the classifier. Hence the readiness surface cannot retain classifier evidence while dropping defeat, domain exit, mismatch, hidden residue, observation, or compression provenance.

Finally apply Definition 1144.35. The export row accounts for every accepted downstream read by the displayed finite packet, so there is no alternate route through quotient real equality, selected limits, host equality, hidden repair, or an ambient truth object. The three rows therefore give the complete L10 obligation surface needed by the downstream $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertL10ReadinessObligationSur`

Theorem 1144.37 (Reality-constrained TruthCert L10 terminal source boundary)**.** *For every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet* $(S, \Sigma, K, T, U, D, I, L, F, N)$*, any terminal L10 consumer read by* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *that is licensed by the TruthCert route must pass through the same displayed source row* S*, classifier row* K*, ledger row* L*, failure row* F*, export row, and local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ *row* N*. The terminal read cannot substitute quotient real equality, host equality, model–reality identity, selected limits, hidden repair, or off-packet truth export for those packet rows.*

Proof. First apply Definition 1144.33. It confines each $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ read to the displayed packet $S, \Sigma, K, T, U, D, I, L, F, N$, so the terminal consumer has no source outside the accepted TruthCert carrier.

Next use Definition 1144.34. This keeps the classifier row K, the ledger row L, the failure row F, and the local name row N co-resident whenever the terminal route reaches classifier evidence.

The export side is exhausted by Definition 1144.35 and Definition 1144.36. Together they say that every accepted L10 read is already accounted for by the finite source, classifier, ledger, failure, export, and naming rows of the same packet.

Finally identify the downstream Real and Completion consumers through Definition 1144.42, Definition 1144.43, and Definition 1144.44. These root L10 obligations place physical fit, open-fit refusal, and terminal $\mathsf{Real}^{\uparrow}$ access on the same source boundary, blocking quotient real equality, host equality, model–reality identity, selected limits, hidden repair, and off-packet truth export. □

Lean4 ✓ BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertL10TerminalSourceBoundary

Theorem 1144.38 (Reality-constrained TruthCert L10 terminal readback determinacy)**.** *Let* $Q = (S, \Sigma, K, T, U, D, I, L, F, N)$ *and* $Q' = (S', \Sigma', K', T', U', D', I', L', F', N')$ *be accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packets. Suppose the terminal L10 reads of* Q *and* Q' *by* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *expose the same displayed source row, classifier row, ledger row, failure row, export row, and local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ *row. Then the two terminal reads determine the same accepted terminal TruthCert readback. No quotient real equality, host equality, selected limit, hidden repair, off-packet truth export, or ambient truth predicate can distinguish the two readbacks.*

Proof. Apply Definition 1144.33 to both packets. Each terminal read is confined to the displayed finite rows of its accepted TruthCert carrier, so a comparison between the two reads has no source material beyond the listed source, signature, classifier, tower, stability, descent, observer-invariant, ledger, failure, and local naming rows.

Next use Definition 1144.34. Since the exposed classifier, ledger, failure, and local name rows agree, the classifier-facing portions of the two readbacks stay co-resident in the same displayed packet positions. The terminal comparison cannot keep a classifier row while changing defeat, domain exit, mismatch, hidden residue, observation, or compression provenance.

The accepted export is exhausted by Definition 1144.35 and Definition 1144.36. Thus every downstream $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ read is already accounted for by the displayed rows shared by the two packets, together with the same export obligation.

Finally apply Definition 1144.37. It rules out the off-packet substitutes named in the statement, so nothing outside the common displayed source, classifier, ledger, failure, export, and local NameCert rows can separate the two accepted terminal TruthCert readbacks. □

Lean4 ✓ BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertL10TerminalReadbackDeterm

Theorem 1144.39 (Reality-constrained TruthCert root TasteGate obligation)**.** *For an accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet*

$$(S, \Sigma, K, T, U, D, I, L, F, N),$$

the root TasteGate obligation is determined by exactly the displayed source, signature, classifier, tower, stability, descent, invariant, ledger, failure, and local-name rows. The Lean TasteGate instance reads this finite packet and does not read a hidden truth coordinate, a hidden classifier choice, or an off-packet source of reality.

Proof. Use the carrier and field-coverage rows, Definition 1144.1 and Definition 1144.6. They make $(S, \Sigma, K, T, U, D, I, L, F, N)$ the whole admitted TruthCert packet before the local name is exposed.

Next apply sibling dependency, root readiness, and root consumer totality, Definition 1144.10, Definition 1144.27, and Definition 1144.29. These results force every root consumer to pass through the displayed sibling routes and through the same finite carrier.

Finally use root classifier stability and root ledger nonescape, Definition 1144.31 and Definition 1144.32. The classifier row K, ledger row L, and failure row F remain internal to the packet, so the TasteGate read has no coordinate beyond $S, \Sigma, K, T, U, D, I, L, F, N$. □

Lean4 ✓ BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertRootTasteGateObligation

Theorem 1144.40 (Reality-constrained TruthCert root nontrivial readiness)**.** *The root nontriviality obligation for* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *is witnessed at the packet surface*

$$(S, \Sigma, K, T, U, D, I, L, F, N).$$

A nontrivial TasteGate reading must distinguish accepted packet presence from off-packet absence by the displayed carrier, field coverage, sibling dependency, root readiness, root consumer totality, root classifier stability, and root ledger nonescape rows, not by a separate truth object.

Proof. Carrier admission and field coverage first supply the finite packet and its mandatory rows. Thus packet presence is read through $S, \Sigma, K, T, U, D, I, L, F, N$, while off-packet absence has no local $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ row to expose.

Sibling dependency, root readiness, and root consumer totality then determine which downstream reads count as root-facing reads. A consumer that omits one of the displayed sibling routes or displayed rows receives only a projection, so it cannot be the nontrivial root packet.

Root classifier stability and root ledger nonescape close the distinction at the classifier and ledger boundary. The rows K, L, F, N remain part of the same finite packet, so the Lean TasteGate instance may witness nontriviality from packet presence versus off-packet absence without consulting any hidden truth coordinate. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertRootNontrivialReadiness`

Theorem 1144.41 (Reality-constrained TruthCert root field-faithful readiness)**.** *The root field-faithfulness obligation for* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *is ready exactly when every TasteGate read of*

$$(S, \Sigma, K, T, U, D, I, L, F, N)$$

preserves the displayed rows as the TruthCert fields. In particular, the source, signature, classifier, tower, stability, descent, invariant, ledger, failure, and local-name rows are not compressed into a hidden truth coordinate, and no root consumer may replace their field order by an ambient object.

Proof. Start from the carrier and field-coverage theorems. They identify the accepted packet rows and make them the TruthCert fields that must be preserved before N becomes readable.

Apply sibling dependency, root readiness, and root consumer totality. These theorems route the open-fit, objectivity, explanation, physical-induction, and tower-compression dependencies through the same displayed packet, so a root-facing read cannot rearrange the fields through a second consumer path.

Finally use root classifier stability and root ledger nonescape. They keep K attached to signature comparison and keep L, F attached to ledger and failure discipline. Hence a field-faithful Lean TasteGate instance reads exactly $S, \Sigma, K, T, U, D, I, L, F, N$ and nothing outside that finite packet. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertRootFieldFaithfulReadines`

Theorem 1144.42 (Reality-constrained TruthCert L10 source exposure)**.** *For every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet*

$$(S, \Sigma, K, T, U, D, I, L, F, N),$$

the source exposed to the L10 chain $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *is exactly the displayed TruthCert surface. The chain reads the source row S, signature row Σ, classifier row K, approximation tower row T, continuation-stability row U, descent row D, observer-invariant row I, methodology-ledger row L, open-fit failure row F, and local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$ *row N through the same finite packet, not through model–reality identity, unbounded confirmation, observer privilege, host equality, quotient real equality, or a direct truth export.*

Proof. Start from field coverage and sibling dependency, Definition 1144.6 and Definition 1144.10. They project the accepted carrier to the nine displayed TruthCert rows and place the open-fit, objectivity, explanation, physical-induction, and tower-compression dependencies on that same carrier.

Next use L10 source readiness, Definition 1144.33. It routes the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ reads through $S, \Sigma, K, T, U, D, I, L, F, N$ and leaves no unlisted source, ambient truth predicate, global reality oracle, or off-packet continuation for the L10 consumer.

Finally apply the root TasteGate obligation Definition 1144.39. The root read consumes the same finite packet, so the L10 exposure cannot be replaced by identity between the model and reality, unbounded confirmation, observer privilege, host equality, quotient real equality, or direct truth export. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertL10SourceExposure`

Theorem 1144.43 (Reality-constrained TruthCert physical-fit nonescape)**.** *Every physical-fit read of an accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet that reaches* $\mathsf{Real}^{\uparrow}$ *must also expose the* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ *and* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *sibling surfaces in the same nine-row TruthCert boundary. In particular, finite fit, open continuation, finite defeat, methodology scope, domain-leakage refusal, provenance, hidden residue, and local naming remain recorded in* $S, \Sigma, K, T, U, D, I, L, F, N$*; no consumer may export physical fit by quotient real equality, host equality, model–reality identity, unbounded confirmation, observer privilege, or direct truth export.*

Proof. Project the carrier by field coverage. The rows $S, \Sigma, K, T, U, D, I, L, F, N$ are mandatory before the local name is readable, so a physical-fit read that drops one of them is only a projection of the TruthCert packet.

Use sibling dependency to identify the two sibling surfaces. The $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ route supplies finite fit, open continuation, and finite defeat, while $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ supplies methodology scope, refusal, provenance, hidden residue, and consumer discipline.

Now apply L10 source readiness together with the root TasteGate obligation. The $\mathsf{Real}^{\uparrow}$ read enters through the same L10 source boundary that serves $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$, and the root read has no hidden coordinate beyond the displayed packet.

Thus physical fit cannot escape through quotient real equality, host equality, model–reality identity, unbounded confirmation, observer privilege, or direct truth export. It remains a finite TruthCert read with the open-fit and methodology-ledger surfaces visible. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertPhysicalFitNonescape`

Theorem 1144.44 (Reality-constrained TruthCert open-fit refusal surface)**.** *For every accepted* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *packet* $(S, \Sigma, K, T, U, D, I, L, F, N)$*, any downstream read that uses the* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ *surface must carry the refusal information through the same L10 chain* $\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ *and through the* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *row. The refusal surface records finite defeat, domain exit, classifier mismatch, later observation, compression residue, and local naming, and it refuses model–reality identity, unbounded confirmation, observer privilege, host equality, quotient real equality, and direct truth export.*

Proof. Read the nine rows from field coverage. The failure row F, ledger row L, classifier row K, tower row T, and local name N are part of the same accepted carrier, so the refusal information cannot be detached from the TruthCert packet.

Apply sibling dependency to the open-fit and methodology-ledger routes. The open-fit surface contributes finite defeat and later-observation exposure, while the methodology-ledger surface records domain exit, refusal, compression residue, consumer discipline, and provenance.

Use L10 source readiness to place the refusal surface on the $\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ chain. The L10 read is therefore a finite source read of $S, \Sigma, K, T, U, D, I, L, F, N$, not a separate physical-truth channel.

Finally use the root TasteGate obligation. Since the root read consumes exactly the displayed packet, the open-fit refusal surface blocks model–reality identity, unbounded confirmation, observer privilege, host equality, quotient real equality, and direct truth export. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCertOpenFitRefusalSurface`

Theorem 1144.45 (Reality-constrained TruthCert scoped TasteGate route)**.** *The scoped surface of* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *is the route through the carrier of Definition 1144.1, the field coverage of Definition 1144.6, the sibling dependency of Definition 1144.10, the root TasteGate obligation of Definition 1144.39, the root nontrivial readiness of Definition 1144.40, the root field-faithful readiness of Definition 1144.41, and the L10 source readiness of Definition 1144.33. It binds exactly* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*, and the sibling TruthCert rows consumed by the displayed packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedTruthCertUp.RealityConstrainedTruthCert scoped tastegate route`

Proof. Start with the carrier and field-coverage rows. They expose the source, signature, classifier, tower, stability, descent, invariant, ledger, failure, and local-name entries as the whole accepted TruthCert packet.

Apply sibling dependency and L10 source readiness. The open-fit, objectivity, explanation, physical-induction, tower-compression, and L10 source rows enter as displayed dependencies of that same packet, not as separate truth authorities.

Finally use the root TasteGate obligation together with root nontrivial and field-faithful readiness. These rows force the TasteGate read to distinguish packet presence at $S, \Sigma, K, T, U, D, I, L, F, N$ and to preserve the listed fields through BHist, hsame, Cont, Pkg, and NameCert. Hence the scoped surface is exactly the displayed route and has no hidden model–reality identity, observer privilege, unbounded confirmation, or off-packet truth export. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ packet is generated from finite source traces, reality-facing signatures, a classifier, an approximation tower, a continuation-stability row, a descent row, an observer-invariant row, a ledger row, a failure surface, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1144.13 and Definition 1144.45 bind the exported bridge-facing TruthCert packet, TasteGate route, root readiness rows, and failure-surface exactness over the displayed kernel rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealityConstrainedTruthCert}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.RealityConstrainedTruthCertUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert standard bridge checking, model–reality identity, unbounded confirmation, observer privilege, or truth export outside the displayed packet.

Upgrade path: No further theory-axis upgrade is asserted here; bridge and audit claims remain governed by the formal axis.

The $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ hub reads the methodology-ledger carrier through the explanation, model-audit, objectivity, and open-fit family and exports it toward chapter 1144 and chapter 1185.

Chapter 1145

A Concrete Naming Certificate for RealityConstrainedMethodologyLedger$^{\uparrow}$

The RealityConstrainedMethodologyLedger$^{\uparrow}$ packet realizes the scientific-methodology discipline of section 9414.46 as a finite BEDC NameCert carrier. It consumes the explanation rows of chapter 1136, the model-audit rows of chapter 1124, the multi-observer rows of chapter 1133, the tower-compression rows of chapter 1142, and the open-fit rows of chapter 1137. Those siblings separately expose explanation scope, fit audit, observer symmetry, compression residue, and open refutation surfaces; this packet binds them into the finite ledger by which a scientific-methodology claim is admitted only with effective-region bounds, idealization residue, domain-leakage refusal, upgrade routes, provenance, and local naming rows visible.

Definition 1145.1 (Reality-constrained methodology-ledger carrier)**.** *A* RealityConstrainedMethodologyLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$$

with the following displayed rows:

1. *X is the explanation row, recording the observation, model, phenomenon, signature-comparison, descent, residue, and failure-surface material inherited from* RealityConstrainedExplanation$^{\uparrow}$*;*
2. *A is the audit row, recording source traces, observed signatures, model-generated signatures, classifier comparisons, ledgers, failure surfaces, and strength rows inherited from* RealityConstrainedModelAudit$^{\uparrow}$*;*
3. *O is the objectivity row, recording multi-observer histories, anchor-change schedules, invariant packets, and no-global-observer refusals inherited from* RealityConstrainedObjectivity$^{\uparrow}$*;*
4. *T is the tower-compression row, recording source, indexed tower, observer tower, physical-fit tower, endpoint, composite ledger, replay, and provenance data inherited from* RealityConstrainedTowerCompressio
5. *I is the open-fit row, recording finite observation traces, admissible observation bundles, current fit, open continuation, and finite refutation surface inherited from* OpenFitPacket$^{\uparrow}$*;*
6. *S is the scope row, naming the domain, observation budget, admissible consumers, and physical-signature interface for the methodology claim;*
7. *D is the domain-leakage refusal row, naming attempted exports beyond S and the finite reason each export is refused;*

8. *U is the upgrade-route row, naming the additional observations, classifier refinements, bridge rows, or ledger entries needed to extend the claim without deleting the present carrier;*
9. *F is the methodology failure-surface row, collecting finite tests, signature mismatches, observer-anchor failures, tower-residue conflicts, and open-fit defeats;*
10. *H records componentwise* hsame *transport for the explanation, audit, objectivity, tower-compression, open-fit, scope, refusal, upgrade, and failure rows;*
11. *C records the accepted consumer route through the displayed methodology ledger;*
12. *Q records* Pkg *provenance over the sibling carriers,* BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for unbounded explanation, final model truth, hidden observer privilege, endpoint/source identity, closed empirical fit, or methodological export outside the displayed packet.

Lean4 (definition) `BEDC.Derived.RealityConstrainedMethodologyLedgerUp.RealityConstrainedMethodologyLedgerC`

Definition 1145.2 (Reality-constrained methodology-ledger certificate)**.** *For accepted packets*

$$L = (X, A, O, T, I, S, D, U, F, H, C, Q, N) \quad \text{and} \quad L' = (X', A', O', T', I', S', D', U', F', H', C', Q', N'),$$

the certificate classifier $\mathsf{RealityConstrainedMethodologyLedgerClassifier}(L, L')$ *holds exactly when the explanation, audit, objectivity, tower-compression, and open-fit rows transport componentwise, the scope rows name the same admissible domain after* hsame *transport, the domain-leakage refusal rows preserve the refused exports, the upgrade-route rows preserve the admitted extension paths, the methodology failure surfaces preserve the defeating finite tests, and the consumer, provenance, and local naming rows transport through the same displayed route.*

Thus certificate agreement is not sameness of theories, models, or observers. It is preservation of the finite methodology ledger that records where the claim explains, where it fits, where it is objective, where it is compressed, where it remains open, where it refuses export, and how it may be extended.

Theorem 1145.3 (Reality-constrained methodology-ledger NameCert obligations)**.** *For the carrier of Definition 1145.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}}$ *surface consists exactly of six obligation rows:*

1. *carrier admission: the accepted object is exactly $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$;*
2. *sibling accountability: explanation, audit, objectivity, tower-compression, and open-fit reads must pass through X, A, O, T, I;*
3. *scope exactness: every methodology claim must display the scope row S before it is exported;*
4. *domain-leakage refusal: every attempted export beyond S must be recorded in D as refused or routed through U as a declared extension path;*
5. *failure-surface exposure: finite defeats from explanation, audit, objectivity, tower compression, and open fit must appear in F before the consumer route C is accepted;*
6. *ledger non-escape: no consumer may infer scientific-methodology authority from rows outside $X, A, O, T, I, S, D, U, F, H, C, Q, N$.*

Lean4 ✓ BEDC.Derived.RealityConstrainedMethodologyLedgerUp.RealityConstrainedMethodologyLedgerCarrier namecert obligations

Proof. Carrier admission is projection from Definition 1145.1. The packet lists the only rows available to the local certificate.

Sibling accountability follows from the distinguished roles of X, A, O, T, I. Explanation scope, model audit, objectivity, tower compression, and open fit are not reconstructed by host prose; they enter through the five displayed sibling rows.

Scope exactness and domain-leakage refusal are forced by S and D. A methodology claim is admitted only after its domain and budget are named, and an attempted export beyond that boundary is either refused in D or sent to the declared extension route U.

Failure exposure is forced by F. The consumer route may read the methodology ledger only after the finite tests, signature mismatches, anchor failures, tower-residue conflicts, and open-fit defeats are visible.

Ledger non-escape follows because the carrier contains no coordinate outside $X, A, O, T, I, S, D, U, F, H, C, Q, N$ A route depending on an absent row is not a route in the accepted local naming certificate. □

Theorem 1145.4 (Reality-constrained methodology-ledger domain-leakage refusal)**.** *Let $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. A claim that uses the explanation, audit, objectivity, tower-compression, or open-fit rows while exporting beyond the displayed scope row S is rejected unless the same packet records the attempted export in D and supplies an upgrade route in U.*

Lean4 ✓ BEDC.Derived.RealityConstrainedMethodologyLedgerUp.RealityConstrainedMethodologyLedgerDomainLea

Proof. Start with the scope-exactness and domain-leakage obligations of Definition 1145.3. They require the scope row before export and require every export beyond that scope to appear in the refusal or upgrade surface.

If a claim exports beyond S without a row in D, the packet lacks the displayed refusal record. If it also lacks a route in U, the packet gives no accepted extension path.

The carrier has no remaining coordinate through which the export could be licensed. The claim may remain a local explanation, audit read, objectivity read, tower-compression read, or open-fit read, but it is not a $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ methodology export. □

Theorem 1145.5 (Reality-constrained methodology-ledger scope-export exactness)**.** *Let $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Every methodology export must display the scope row S and either remain inside that displayed scope or route the attempted export through the refusal and upgrade rows D, U.*

Proof. Project the carrier of Definition 1145.1. The packet contains a distinguished scope row S, a domain-leakage refusal row D, and an upgrade-route row U; it contains no other export-authorizing coordinate.

Apply the NameCert obligations of Definition 1145.3. Scope exactness requires S before export, while domain-leakage refusal sends every attempted export beyond S through D or through the declared extension path U.

Finally use Definition 1145.4. A methodology claim that crosses the displayed scope without those rows is rejected as an export outside the accepted finite ledger. Hence the only accepted export routes are the in-scope route through S and the displayed beyond-scope route through D, U. □

Lean4 ✓ BEDC.Derived.RealityConstrainedMethodologyLedgerUp.RealityConstrainedMethodologyLedgerScopeExpo

Theorem 1145.6 (Reality-constrained methodology-ledger sibling independence)**.** *The* RealityConstrainedMethodo *carrier is not bijective to any one of* RealityConstrainedExplanation$^{\uparrow}$, RealityConstrainedModelAudit$^{\uparrow}$, RealityConstrainedObjectivity$^{\uparrow}$, RealityConstrainedTowerCompression$^{\uparrow}$, *or* OpenFitPacket$^{\uparrow}$. *Each sibling lacks at least one of the joined effective-region, idealization-residue, domain-leakage, upgrade-route, and methodology-ledger rows required by Definition 1145.1.*

Proof. Compare the carrier fields. RealityConstrainedExplanation$^{\uparrow}$ supplies explanation scope and residue but lacks the joined audit, objectivity, tower-compression, open-fit, domain-leakage, and upgrade-route rows.

RealityConstrainedModelAudit$^{\uparrow}$ supplies audit and failure rows but lacks the explanation, no-global-observer, tower-compression endpoint, open-continuation, methodology scope, and upgrade-route rows. RealityConstrainedObjectivity$^{\uparrow}$ supplies anchor-change and no-global-observer refusal but lacks the effective-region, idealization-residue, open-fit, and methodology-upgrade rows.

RealityConstrainedTowerCompression$^{\uparrow}$ supplies compression residue and endpoint/source separation but lacks the methodology domain-leakage refusal and open-fit refutation surface. OpenFitPacket$^{\uparrow}$ supplies finite fit and open continuation but lacks the joined explanation, audit, objectivity, tower-compression, and methodology-ledger rows.

Since each sibling omits at least one required field of L, no bijection can preserve all carrier fields of Definition 1145.1. □

Theorem 1145.7 (Reality-constrained methodology-ledger failure-surface exhaustion)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* RealityConstrainedMethodologyLedger$^{\uparrow}$ *packet. Every accepted methodology consumer routed by* C *must expose in* F *each finite defeating test available from the explanation, audit, objectivity, tower-compression, open-fit, scope, refusal, and upgrade rows before the route is accepted.*

Proof. The carrier of Definition 1145.1 displays F as the row collecting finite tests, signature mismatches, observer-anchor failures, tower-residue conflicts, and open-fit defeats. The certificate of Definition 1145.2 requires preservation of that row when two accepted packets agree as methodology ledgers.

Apply the failure-surface exposure clause of Definition 1145.3. It states that finite defeats from the sibling rows must appear in F before C is accepted.

The refusal theorem Definition 1145.4 closes the remaining route. A consumer that attempts to use an unexposed defeating test as if it were harmless either exports beyond the displayed scope or reads outside the admitted ledger, and neither route is licensed by D and U. □

Theorem 1145.8 (Reality-constrained methodology-ledger consumer-route exactness)**.** *For any accepted* RealityConstrainedMethodologyLedger$^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$, *the accepted consumer route factors exactly through the displayed rows* $X, A, O, T, I, S, D, U, F, H, C, Q, N$. *In particular, it cannot read hidden observer privilege, unbounded explanation, final model truth, closed empirical fit, or any other coordinate absent from the carrier.*

Proof. By Definition 1145.1, the packet has exactly the displayed coordinates and explicitly omits unbounded explanation, final model truth, hidden observer privilege, endpoint/source identity, closed empirical fit, and export outside the packet. Thus a consumer route that uses one of those omitted coordinates is not a route through L.

The certificate in Definition 1145.2 makes the same restriction invariant under accepted comparison: agreement preserves the displayed route through the sibling, scope, refusal, upgrade,

failure, transport, provenance, and local naming rows. The NameCert obligation theorem Definition 1145.3 records this as ledger non-escape.

Finally apply Definition 1145.4. Any alleged consumer authority that depends on a hidden observer, an unbounded explanation, a final truth coordinate, or a closed fit is an export beyond the displayed scope and must be refused unless it is rerouted through the admitted upgrade surface; without such a displayed row it is not accepted by C. □

Theorem 1145.9 (Reality-constrained methodology-ledger upgrade-route determinacy)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Every accepted export beyond the scope row* S *is determined by the displayed refusal row* D *and upgrade row* U*; it is not determined by deleting, replacing, or bypassing the present carrier.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedMethodologyLedgerUp.RealityConstrainedMethodologyLedgerUpgradeRo`

Proof. The carrier definition Definition 1145.1 assigns attempted exports beyond S to D and admissible extension paths to U. No separate coordinate records an export by erasing the carrier or by appealing to an outside methodological authority.

The classifier in Definition 1145.2 preserves both rows. Therefore accepted comparison of methodology-ledger packets keeps the refused exports and admitted extension paths visible rather than allowing them to be reconstructed from hidden data.

Use the domain-leakage clause of Definition 1145.3 and the refusal theorem Definition 1145.4. Together they force every beyond-S export to be either refused in D or supplied with a route in U, so bypassing the present carrier cannot determine an accepted upgrade route. □

Theorem 1145.10 (Reality-constrained methodology-ledger root scope carrier admission)**.** *Every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *root read is admitted only through the displayed carrier rows*

$$X, A, O, T, I, S, D, U, F, H, C, Q, N.$$

No root consumer may replace those rows by an unbounded explanation, final model truth coordinate, hidden observer privilege, closed empirical fit, endpoint identity, or off-ledger methodology export.

Proof. Project the carrier of Definition 1145.1. It lists exactly the explanation, audit, objectivity, tower-compression, open-fit, scope, refusal, upgrade, failure, transport, consumer, provenance, and local naming rows.

Apply the carrier-admission and ledger-non-escape clauses of Definition 1145.3. The accepted root read must therefore expose those rows before it is a local $\mathsf{NameCert}_{\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}}$ read.

The certificate of Definition 1145.2 preserves the same displayed rows under comparison. Hence any route using an absent coordinate is not a root read of the accepted methodology-ledger carrier. □

Theorem 1145.11 (Reality-constrained methodology-ledger root refusal upgrade coverage)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Every beyond-scope methodology export from the root read is covered by the domain-leakage refusal row* D *or by the upgrade-route row* U*.*

Proof. Start with scope-export exactness, Definition 1145.5. It requires the scope row S before any methodology export and sends every export beyond S through the displayed refusal and upgrade rows.

The domain-leakage refusal theorem, Definition 1145.4, gives the local rejection clause. A claim that crosses the displayed scope without a refusal record in D and an extension route in U is not accepted as a methodology export.

Finally apply upgrade-route determinacy, Definition 1145.9. It rules out deleting, replacing, or bypassing the carrier as a way to determine an accepted beyond-scope export, leaving only the D and U coverage rows. □

Theorem 1145.12 (Reality-constrained methodology-ledger root failure consumer exhaustion)**.** *For any accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, every accepted consumer route must expose the failure row* F *before using the consumer route* C*.*

Proof. Use the failure-surface exposure clause of Definition 1145.3. It places the finite defeats from the explanation, audit, objectivity, tower-compression, and open-fit rows in F before the consumer route is accepted.

Apply failure-surface exhaustion, Definition 1145.7. The same exhaustion requirement covers defeating tests available from the scope, refusal, and upgrade rows, so the root consumer cannot postpone F until after C.

Finally use consumer-route exactness, Definition 1145.8. Since C factors through the displayed carrier rows and no hidden failure surface exists outside them, every accepted consumer route must expose F before it is read through C. □

Theorem 1145.13 (Reality-constrained methodology-ledger source-refusal boundary)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Any export that reads one of the sibling source rows* X, A, O, T, I *beyond the displayed scope row* S *must be witnessed in the refusal row* D *before the consumer route* C *may accept it.*

Proof. Project the carrier of Definition 1145.1. The sibling source rows, the scope row, the refusal row, and the consumer route are all displayed in the same finite packet, and there is no off-ledger coordinate from which a consumer can authorize a beyond-scope read.

Apply the scope exactness and domain-leakage clauses of Definition 1145.3. They force every methodology export to display S and force every attempted export beyond S into the refusal or extension surface.

Now use Definition 1145.4. A beyond-scope export that lacks its witness in D is rejected before it reaches C. Finally, Definition 1145.9 rules out deleting, replacing, or bypassing the carrier as a competing source for the same accepted export. □

Theorem 1145.14 (Reality-constrained methodology-ledger root audit source lock)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Every root audit read of the methodology ledger must expose the sibling rows* X, A, O, T, I *and the kernel support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *before the consumer route* C *can treat the read as methodology authority.*

Proof. Begin with the carrier and certificate, Definition 1145.1 and Definition 1145.2. They place the explanation, audit, objectivity, tower-compression, and open-fit siblings in X, A, O, T, I and preserve them through the displayed comparison surface.

Apply the NameCert obligations of Definition 1145.3. The sibling-accountability and carrier-admission rows require those five sibling sources inside the same finite BHist packet, while the transport, continuation, provenance, and local naming rows are read through H, C, Q, N as hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Finally use scope-export exactness and source-refusal boundary, Definition 1145.5 and Definition 1145.13. They prevent a root audit read from exporting sibling authority beyond S unless the same packet records the refusal and route rows. Thus the audit source is locked to X, A, O, T, I over the displayed kernel support. □

Theorem 1145.15 (Reality-constrained methodology-ledger root open-fit refusal route)**.** *Let $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Any root read that uses the open-fit sibling row I as a public methodology refusal must route the read through the displayed sibling rows X, A, O, T, I, the refusal and failure rows D, F, and the* $\mathsf{BHist}/\mathsf{hsame}/\mathsf{Cont}/\mathsf{Pkg}/\mathsf{NameCert}$ *support of H, C, Q, N.*

Proof. Project the carrier. The open-fit material is one sibling row I of the same packet $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$, not a separate public refusal oracle.

Use the NameCert obligations, scope-export exactness, and source-refusal boundary. The obligations require sibling accountability and failure-surface exposure, scope-export exactness requires S before public methodology use, and the source-refusal boundary sends any beyond-scope sibling read through the displayed refusal row D before C accepts it.

Now apply root open-fit refusal package and failure-route locality, Definition 1145.27 and Definition 1145.18. They keep the open-fit defeat in F and the refusal route in D inside the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support, so the route cannot become an off-ledger empirical-fit authority. □

Theorem 1145.16 (Reality-constrained methodology-ledger root upgrade readiness)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$, the root upgrade surface is ready exactly when the sibling rows X, A, O, T, I, the scope/refusal/failure rows S, D, F, the upgrade row U, and the* $\mathsf{BHist}/\mathsf{hsame}/\mathsf{Cont}/\mathsf{Pkg}/\mathsf{NameCert}$ *support H, C, Q, N are displayed together. No upgrade route may delete the present carrier or replace it by an external methodology source.*

Proof. First assemble the displayed packet from Definition 1145.1. The upgrade row U is part of $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$, so it is read together with the sibling, scope, refusal, failure, transport, consumer, provenance, and local naming rows.

Apply upgrade-route determinacy and upgrade scope lock, Definition 1145.9 and Definition 1145.17. These results make every accepted extension a route through the displayed D, U surface and prevent the upgrade row from replacing the carrier.

Finally combine Definition 1145.14, Definition 1145.15, and Definition 1145.22. The audit lock keeps X, A, O, T, I visible, the open-fit refusal route keeps D, F visible for empirical defeats, and the closure package binds H, C, Q, N to hsame, Cont, Pkg, and $\mathsf{NameCert}$. Hence upgrade readiness is exactly the displayed root surface and not an external methodology authority. □

Theorem 1145.17 (Reality-constrained methodology-ledger upgrade scope lock)**.** *Let $L = (X, A, O, T, I, S, D, U, I$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. An accepted upgrade row U preserves the same displayed packet*

$$X, A, O, T, I, S, D, U, F, H, C, Q, N$$

by constraining U to the declared extension route; it does not replace the carrier, erase S or D, or create a second consumer packet for the methodology claim.

Proof. The carrier definition Definition 1145.1 makes U one row of the displayed packet rather than a substitute carrier. Thus an upgrade route is read together with the explanation, audit,

objectivity, tower-compression, open-fit, scope, refusal, failure, transport, consumer, provenance, and local naming rows.

Apply Definition 1145.3. The obligation surface demands carrier admission, sibling accountability, scope exactness, domain-leakage refusal, failure exposure, and ledger non-escape for the same packet whenever a methodology claim is accepted.

The refusal theorem Definition 1145.4 and upgrade-route determinacy Definition 1145.9 then close the route. They allow U to declare how the claim may be extended, but they do not allow U to delete the existing scope, refusal, failure, or consumer rows. □

Theorem 1145.18 (Reality-constrained methodology-ledger failure-route locality)**.** *Let $L = (X, A, O, T, I, S, D, U$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Defeating tests recorded in the failure row F remain local to the displayed sibling, scope, refusal, upgrade, transport, consumer, provenance, and local naming rows. They cannot be converted by C into unbounded model truth, hidden observer privilege, final explanation authority, or a closed empirical oracle.*

Proof. Read the carrier of Definition 1145.1. The failure row F is one component of the finite methodology ledger, and the omitted coordinates include unbounded explanation, final model truth, hidden observer privilege, and closed empirical fit.

Apply Definition 1145.3. The failure-surface exposure clause requires defeating tests to appear in F before C is accepted, while ledger non-escape prevents C from reading authority outside the displayed carrier.

Use Definition 1145.4 for any attempt to export those defeating tests beyond the displayed scope. Finally, Definition 1145.9 confines accepted beyond-scope movement to the displayed refusal and upgrade rows, so no defeating test in F becomes an unbounded truth or hidden-observer privilege. □

Theorem 1145.19 (Reality-constrained methodology-ledger route normal form)**.** *Every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *consumer route factors through exactly*

$$X, A, O, T, I, S, D, U, F, H, C, Q, N$$

before any methodology export is read.

Proof. Project the carrier of Definition 1145.1. It lists exactly the explanation, audit, objectivity, tower-compression, open-fit, scope, refusal, upgrade, failure, transport, consumer, provenance, and local naming rows.

Apply the NameCert obligations of Definition 1145.3. The carrier-admission, sibling-accountability, scope-exactness, failure-exposure, and ledger-non-escape clauses require the same rows before the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}}$ route accepts a methodology export.

Finally use consumer-route exactness, Definition 1145.8. Since the accepted consumer route has no coordinate outside the displayed carrier, every methodology export factors through the listed route and no shorter host route is available.

The failure and upgrade coordinates are fixed by Definition 1145.7 and Definition 1145.9. Thus the normal form does not hide defeating tests after C and does not move beyond S except through the displayed D, U rows. □

Theorem 1145.20 (Reality-constrained methodology-ledger sibling failure coverage)**.** *Let $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Finite defeating tests from the explanation, audit, objectivity, tower-compression, and open-fit sibling rows must be collected in F before C is accepted.*

Proof. Begin with the carrier and certificate, Definition 1145.1 and Definition 1145.2. They make F the displayed row preserving finite tests, signature mismatches, observer-anchor failures, tower-residue conflicts, and open-fit defeats.

Apply the failure-surface exhaustion theorem, Definition 1145.7. It requires the defeating tests available from the sibling, scope, refusal, and upgrade rows to appear in F before the consumer route is accepted.

The NameCert obligations and consumer-route exactness, Definition 1145.3 and Definition 1145.8, make this coverage a condition on the same accepted route C, not an external audit of a different carrier.

Use failure-route locality, Definition 1145.18, to close the remaining route. A defeating test not collected in F cannot be converted by C into a public methodology export, because such a conversion would read outside the displayed local ledger.

Finally apply Definition 1145.9. An attempted escape through an upgrade route remains displayed in U and cannot remove the prior requirement that sibling defeats have already been collected in F. □

Theorem 1145.21 (Reality-constrained methodology-ledger refusal-upgrade noncollapse)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the refusal row* D *and upgrade row* U *remain separate displayed rows. They cannot collapse into a silent methodology export outside the scope row* S*.*

Proof. Read the carrier definition. The refusal row D records attempted exports beyond S, while the upgrade row U records admitted extension paths; neither row is identified with the consumer route C or with the scope row S.

Apply the NameCert obligations and scope-export exactness, Definition 1145.3 and Definition 1145.5. They require the scope row before export and force any beyond-scope movement to remain visible in the refusal and upgrade surface.

Use failure-surface exhaustion and consumer-route exactness, Definition 1145.7 and Definition 1145.8. The consumer route cannot accept by hiding failures, and it cannot read a collapsed D, U authority outside the displayed carrier.

Finally use upgrade-route determinacy, Definition 1145.9. An accepted route beyond S is determined by the displayed D, U rows, not by a silent export outside S and not by collapsing the two rows into one hidden methodology authority. □

Theorem 1145.22 (Reality-constrained methodology-ledger obligation closure package)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the finite obligation-closure surface is exactly the carrier, certificate, NameCert obligation rows, domain-leakage refusal, scope-export exactness, failure-surface exhaustion, consumer-route exactness, upgrade-route determinacy, and failure-route locality displayed in this chapter. Thus every methodology-ledger consumer must factor through* $X, A, O, T, I, S, D, U, F, H, C, Q, N$ *with the sibling, scope, refusal, upgrade, failure, transport, consumer, provenance, and local* $\mathsf{NameCert}$ *rows visible.*

Proof. Begin with the carrier and certificate, Definition 1145.1 and Definition 1145.2. They provide the displayed packet and the classifier preserving the sibling, scope, refusal, upgrade, failure, consumer, provenance, and local naming rows.

Next apply the NameCert obligations, Definition 1145.3. Those obligations expose carrier admission, sibling accountability, scope exactness, domain-leakage refusal, failure-surface exposure, and ledger non-escape for the same packet.

Now use the local route theorems: Definition 1145.4, Definition 1145.5, Definition 1145.7, and Definition 1145.8. They force exported methodology authority, defeating tests, and consumer reads through the displayed rows.

Finally apply upgrade-route determinacy and failure-route locality, Definition 1145.9 and Definition 1145.18. They close the remaining beyond-scope and failure-consumer paths without adding an off-ledger carrier. □

Theorem 1145.23 (Reality-constrained methodology-ledger root upgrade refusal totality)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Every root export beyond the displayed scope row* S *is exhausted by the refusal row* D *and the upgrade row* U*. Such an export cannot bypass the carrier, delete the present scope, or appeal to an unbounded explanation, final model truth, hidden observer privilege, closed empirical fit, endpoint identity, or off-ledger methodology authority.*

Proof. Start with root refusal upgrade coverage, Definition 1145.11. It places every beyond-scope root export in the displayed D, U surface.

Apply scope-export exactness and domain-leakage refusal, Definition 1145.5 and Definition 1145.4. Together they require S before export and reject an attempted crossing that lacks the refusal or upgrade rows.

Finally use upgrade-route determinacy and upgrade scope lock, Definition 1145.9 and Definition 1145.17. They make U a row of the same carrier rather than a replacement carrier, so no bypass route can authorize the root export. □

Theorem 1145.24 (Reality-constrained methodology-ledger failure consumer public scope)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the consumer route* C *is not accepted before the failure row* F *and the displayed sibling, scope, refusal, and upgrade rows* X, A, O, T, I, S, D, U *are visible. Public methodology use therefore reads* C *only after the finite failure surface has been exposed inside the same local carrier.*

Proof. First apply root failure consumer exhaustion, Definition 1145.12. It requires the failure row F before the consumer route C can be read.

Next use failure-surface exhaustion and failure-route locality, Definition 1145.7 and Definition 1145.18. They keep the defeating tests local to the displayed sibling, scope, refusal, upgrade, transport, consumer, provenance, and naming rows.

Finally apply consumer-route exactness and the obligation closure package, Definition 1145.8 and Definition 1145.22. These make C a route through the same finite carrier, with no public consumer path that can hide F or omit the visible sibling, scope, refusal, or upgrade rows. □

Theorem 1145.25 (Reality-constrained methodology-ledger root methodology export totality)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, every methodology export factors through the displayed scope row* S*, refusal row* D*, upgrade row* U*, failure row* F*, consumer row* C*, provenance row* Q*, and local* $\mathsf{NameCert}$ *row* N*. The root methodology surface therefore has no off-ledger export coordinate, hidden observer privilege, final truth source, or closed empirical-fit authority.*

Proof. Start with the existing NameCert obligations, Definition 1145.3. They bind carrier admission, sibling accountability, scope exactness, refusal, failure exposure, consumer non-escape, provenance, and local naming to the same finite packet.

Apply scope-export exactness and domain-leakage refusal, Definition 1145.5 and Definition 1145.4. These force methodology export through S and route any beyond-scope attempt through the displayed refusal and upgrade surface.

Next use failure-surface exhaustion and consumer-route exactness, Definition 1145.7 and Definition 1145.8. They require finite defeats in F before a public methodology read reaches C, with no consumer authority outside the displayed ledger rows.

Finally combine upgrade-route determinacy with the obligation-closure package, Definition 1145.9 and Definition 1145.22. The accepted export remains a route inside S, D, U, F, C, Q, N, so no hidden authority can separate it from the local methodology ledger. □

Theorem 1145.26 (Reality-constrained methodology-ledger root TruthCert handoff)**.** *Any TruthCert-facing read of an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet uses the displayed explanation, audit, objectivity, tower-compression, open-fit, refusal, upgrade, and failure rows before it reaches methodology consumption. Such a read does not appeal to final truth, hidden observer privilege, endpoint identity, or an unbounded external validation row.*

Proof. First apply the NameCert obligation surface. By Definition 1145.3, an accepted packet exposes the explanation, audit, objectivity, tower-compression, open-fit, scope, refusal, upgrade, failure, transport, consumer, provenance, and naming rows together.

Use scope-export exactness and domain-leakage refusal next, Definition 1145.5 and Definition 1145.4. They prevent a TruthCert-facing read from crossing the displayed methodology scope unless the refusal and upgrade rows are visible.

Now apply failure-surface exhaustion and consumer-route exactness, Definition 1145.7 and Definition 1145.8. The read reaches C only after the defeating tests in F have been displayed, so it remains an auditable methodology handoff rather than final truth.

Finally use upgrade-route determinacy and the obligation-closure package. They keep any allowed extension inside the same ledger carrier and close the handoff through the declared rows, excluding hidden observer privilege and external TruthCert authority. □

Theorem 1145.27 (Reality-constrained methodology-ledger root open-fit refusal package)**.** *Every open-fit defeat in an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet is routed through the failure row F and the refusal row D before any public methodology consumer reads C. Thus an open-fit failure cannot become a consumer-facing methodology authority unless the displayed defeat and refusal package has already been exposed in the same local ledger.*

Proof. Begin with the NameCert obligations and scope-export exactness, Definition 1145.3 and Definition 1145.5. They place the open-fit row inside the same carrier and require the displayed scope row before methodology export.

Apply domain-leakage refusal and failure-surface exhaustion, Definition 1145.4 and Definition 1145.7. The first routes beyond-scope claims through D, while the second places the open-fit defeat in F before it can affect any consumer route.

Next use consumer-route exactness. By Definition 1145.8, the public consumer C reads only the displayed sibling, scope, refusal, upgrade, failure, transport, provenance, and naming rows.

Finally apply upgrade-route determinacy and the obligation-closure package, Definition 1145.9 and Definition 1145.22. They keep any open-fit response inside the same D, F, C package, so no public methodology consumer can read the defeat as an off-ledger authorization. □

Theorem 1145.28 (Reality-constrained methodology-ledger scope refusal triad)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$, any*

methodology export must pass through the displayed scope row S, refusal row D, and upgrade row U. The export cannot be read from the explanation, model-audit, objectivity, tower-compression, or open-fit siblings unless those three methodology rows are visible in the same carrier.

Proof. Use the carrier and NameCert obligations, Definition 1145.1 and Definition 1145.3. They place the sibling rows and methodology rows inside one finite packet and make S, D, U part of the local certificate surface.

Apply scope-export exactness and domain-leakage refusal, Definition 1145.5 and Definition 1145.4. The first requires S for methodology export, while the second routes any beyond-scope assertion through D.

Finally use upgrade-route determinacy, Definition 1145.9. It keeps U in the same carrier, so no sibling row can replace the displayed scope-refusal-upgrade triad. □

Theorem 1145.29 (Reality-constrained methodology-ledger failure upgrade triad)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the failure row F is visible before any upgrade route can be accepted by the consumer row C. Thus a consumer cannot read an upgrade as methodology authority unless the same local packet exposes the defeating tests that constrain the upgrade.*

Proof. Start with failure-surface exhaustion, Definition 1145.7. It places the finite defeating tests in row F as part of the accepted methodology-ledger surface.

Next apply upgrade-route determinacy and upgrade scope lock, Definition 1145.9 and Definition 1145.17. They make U a route inside the displayed carrier and keep it tied to the same scope and refusal rows.

Finally use consumer-route exactness and failure-route locality, Definition 1145.8 and Definition 1145.18. These force C to read the visible failure and upgrade rows together, with no consumer-side shortcut that hides F. □

Theorem 1145.30 (Reality-constrained methodology-ledger sibling audit triad)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the sibling rows X, A, O, T, I are jointly accountable to the methodology ledger. They cannot be replaced by a single explanation, model-audit, objectivity, tower, or open-fit sibling without losing at least one displayed accountability row.*

Proof. Project the carrier and NameCert obligations, Definition 1145.1 and Definition 1145.3. They list X, A, O, T, I as separate sibling rows and bind each one to the same local certificate.

Use scope-export exactness, failure-surface exhaustion, and consumer-route exactness, Definition 1145.5, Definition 1145.7, and Definition 1145.8. Together they require the sibling surface to remain visible before export, failure reading, and consumer reading.

The independence witness then separates the five siblings by the rows they do not jointly carry. Since the carrier has no collapse coordinate for replacing X, A, O, T, I with one sibling, the audit remains a joint row-wise obligation. □

Theorem 1145.31 (Reality-constrained methodology-ledger public obligation surface)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the public obligation surface consists exactly of the refusal, upgrade, failure-surface, consumer-route, prediction, sibling-audit, TruthCert handoff, open-fit refusal,* hsame, Cont, Pkg*, and local* NameCert *rows displayed in this chapter. It exports no domain-truth oracle, no physical-model adequacy theorem, no hidden fit selector, and no external methodology primitive.*

Proof. First assemble the refusal and upgrade rows. Apply Definition 1145.4 and Definition 1145.11. They force every beyond-scope methodology export to pass through the displayed domain-leakage refusal row D and accepted route row U.

Next add the public consumer and failure rows. Use Definition 1145.24. It requires the failure surface and consumer route to be read together before the packet can be consumed as a methodology-ledger export.

The TruthCert and open-fit interfaces are then local handoffs, not external sources. Apply Definition 1145.26 and Definition 1145.27; these keep TruthCert and open-fit readings inside the same refusal, route, package, and naming rows.

Finally use Definition 1145.30. It keeps X, A, O, T, I as accountable sibling rows and prevents their replacement by a domain-truth oracle, physical-model adequacy theorem, hidden fit selector, or external methodology primitive. The remaining hsame, Cont, Pkg, prediction, and local NameCert rows are already the displayed support rows of the same packet, so the public surface is exactly the listed finite interface. □

Theorem 1145.32 (Reality-constrained methodology-ledger root scope admission)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, a root methodology read is admitted only after the scope row* S*, domain-leakage refusal row* D*, upgrade-route row* U*, failure-surface row* F*, consumer row* C*, package row* Q*, and local* NameCert *row* N *are visible in the same carrier.*

Proof. Start from the carrier and NameCert obligations, Definition 1145.1 and Definition 1145.3. They make S, D, U, F, C, Q, N displayed coordinates of the accepted packet, not external methodology premises.

Apply scope-export exactness and domain-leakage refusal, Definition 1145.5 and Definition 1145.4. These force the root read to expose its scope and to route every beyond-scope attempt through the displayed refusal and upgrade surface.

Next use failure-route locality and consumer-route exactness, Definition 1145.18 and Definition 1145.8. They keep the failure row and consumer route inside the same finite ledger.

Finally apply the public obligation surface and upgrade-route determinacy, Definition 1145.31 and Definition 1145.9. The root read is therefore admitted only when S, D, U, F, C, Q, N are all visible. □

Theorem 1145.33 (Reality-constrained methodology-ledger root sibling accountability)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, root methodology admission keeps the five sibling rows* X, A, O, T, I *accountable as separate rows. No root read may collapse the explanation, audit, objectivity, tower-compression, and open-fit rows into a single sibling carrier.*

Proof. Project the carrier and local obligation surface. The definition displays X, A, O, T, I separately, while Definition 1145.3 identifies sibling accountability as one of the certificate rows.

Use the sibling-audit triad, Definition 1145.30. It states directly that the five siblings cannot be replaced by a single explanation, model-audit, objectivity, tower, or open-fit row.

Now route the public read through scope-export exactness, failure-route locality, and consumer-route exactness. These keep the root read inside the same S, D, U, F, C methodology surface and prevent a consumer shortcut from hiding one sibling behind another.

The public obligation surface then records the same accountability at the root boundary. Since no coordinate of L carries a collapsed sibling row, the root admission preserves X, A, O, T, I as separate accountable entries. □

Theorem 1145.34 (Reality-constrained methodology-ledger root export coverage)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, every beyond-scope methodology export is covered by the domain-leakage refusal row* D *or the upgrade-route row* U*. Every public consumer route must expose the failure-surface row* F *before it can be accepted as the consumer row* C*.*

Proof. Begin with scope-export exactness and domain-leakage refusal, Definition 1145.5 and Definition 1145.4. Together they send every export beyond S through the displayed D, U surface.

Apply upgrade-route determinacy. An accepted route beyond the displayed scope is therefore a route named by U against the refusal surface D, not an off-ledger methodology export.

Next use failure-route locality and the failure-consumer public-scope theorem, Definition 1145.18 and Definition 1145.24. They require finite defeats to remain visible in F before public methodology consumption.

Finally invoke the public obligation surface. It records D, U, F, C, Q, N as the root export package, so every public consumer route exposes F before it reads C. □

Falsifiable prediction: A carrier with no domain-leakage refusal row cannot support the methodology-ledger NameCert obligations.

Independence witness: realityconstrainedexplanation, realityconstrainedmodelaudit, realityconstrainedobjectivity, realityconstrainedtowercompression, openfitpacket: each sibling lacks at least one of the joined effective-region, idealization-residue, domain-leakage, upgrade-route, and methodology-ledger rows, so no bijection preserves all carrier fields.

The Lean TasteGate file supplies `Nontrivial RealityConstrainedMethodologyLedgerUp` and `FieldFaithful RealityConstrainedMethodologyLedgerUp` instances in `lean4/BEDC/Derived/RealityConstra`

Theorem 1145.35 (Reality-constrained methodology-ledger refusal upgrade totality)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Every refusal-facing or upgrade-facing methodology read anchored in the finite* BHist *carrier is exhausted by the displayed scope row* S*, refusal row* D*, upgrade row* U*, componentwise* hsame *transport* H*, consumer route* C*,* Pkg *provenance* Q*, and local* $\mathsf{NameCert}$ *row* N*. No such read can pass through unbounded explanation, final model truth, hidden observer privilege, closed empirical fit, endpoint identity, or an off-ledger methodology source.*

Proof. Begin with the carrier and local obligation surface in Definition 1145.1 and Definition 1145.3. They place S, D, U, H, C, Q, N inside the same finite BHist packet and require scope exactness, domain-leakage refusal, failure exposure, and ledger non-escape before methodology authority is consumed.

Next use scope-export exactness, domain-leakage refusal, upgrade-route determinacy, and upgrade scope lock. These theorems force every beyond-scope movement to be either refused in D or routed through U, while keeping the route attached to the same hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows.

Finally apply the root refusal and export coverage theorems. They identify the root read with the displayed carrier surface rather than with a hidden external methodology source. Since the carrier has no coordinate for unbounded explanation, final truth, hidden observer privilege, closed fit, or endpoint identity, the refusal and upgrade rows are total for the accepted read. □

Theorem 1145.36 (Reality-constrained methodology-ledger failure consumer coverage)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet.*

Every consumer route C that reads methodology authority from the finite BHist *ledger must expose the failure row F, the sibling rows X, A, O, T, I, the refusal and upgrade rows D, U, componentwise* hsame *transport H,* Pkg *provenance Q, and local* NameCert *row N before the consumer is accepted.*

Proof. Project the carrier of Definition 1145.1. The explanation, audit, objectivity, tower-compression, open-fit, refusal, upgrade, failure, transport, consumer, provenance, and naming rows are displayed together in one packet.

Apply the NameCert obligations of Definition 1145.3. The sibling-accountability and failure-surface clauses put the defeating tests in F before the consumer route is accepted, while ledger non-escape prevents C from importing hidden authority.

Now use failure-surface exhaustion, failure-route locality, and consumer-route exactness. These results keep finite defeats and consumer reads inside the same BHist/hsame/Cont/Pkg/NameCert support and route them through $X, A, O, T, I, D, U, F, H, C, Q, N$ rather than through an external audit.

The public failure-consumer and root export coverage theorems close the root case. They require the failure surface before public methodology consumption, so every accepted consumer route is covered by the displayed failure and methodology rows. □

Theorem 1145.37 (Reality-constrained methodology-ledger prediction row non-escape)**.** *For every accepted* RealityConstrainedMethodologyLedger$^{\uparrow}$ *packet $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$, any falsifiable-prediction read of the methodology ledger is anchored in the same finite* BHist *carrier. It may use only the sibling rows X, A, O, T, I, scope row S, refusal row D, upgrade row U, failure row F, componentwise* hsame *transport H, consumer route C,* Pkg *provenance Q, and local* NameCert *row N; it cannot become a domain-truth oracle, physical-model adequacy theorem, hidden fit selector, or off-ledger methodology primitive.*

Proof. Start from the carrier and certificate, Definition 1145.1 and Definition 1145.2. They make the prediction-facing read a route through the displayed methodology ledger, with componentwise transport and package provenance preserving the same rows.

Apply the NameCert obligation surface in Definition 1145.3. It requires scope exactness, refusal coverage, failure exposure, and non-escape before a methodology read reaches the consumer route.

Finally use the public obligation surface, sibling audit triad, and failure-route locality. These rows keep prediction, sibling accountability, failure exposure, hsame, Cont, Pkg, and local NameCert support inside L, and they exclude a domain-truth oracle, physical-model adequacy theorem, hidden fit selector, or off-ledger methodology primitive from the accepted prediction row. □

Theorem 1145.38 (Reality-constrained methodology-ledger formal-target route totality)**.** *For every accepted* RealityConstrainedMethodologyLedger$^{\uparrow}$ *packet $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$, a methodology-ledger formal-target read must pass through the displayed refusal-upgrade surface D, U, failure-consumer surface F, C, and prediction row before any truth-certificate consumer can read the methodology packet. The route remains inside the same finite* BHist/hsame/Cont/Pkg/NameCert *support and exports no domain-truth oracle, physical-model adequacy theorem, hidden fit selector, or off-ledger methodology primitive.*

Proof. First apply refusal upgrade totality, Definition 1145.35. It forces every beyond-scope methodology read through the displayed refusal row D and upgrade row U before the packet can be consumed.

Next use failure consumer coverage, Definition 1145.36. This places the failure row F and consumer route C in the same accepted packet as the sibling, transport, provenance, and local naming rows.

Finally apply prediction row non-escape, Definition 1145.37. The prediction-facing read is still a finite methodology-ledger read, so a truth-certificate consumer receives the packet only after the refusal-upgrade, failure-consumer, and prediction surfaces are all displayed. □

Theorem 1145.39 (Reality-constrained methodology-ledger TasteGate readback surface)**.** *For every displayed* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the rows shown in the paper carrier are the same rows decoded by the checked TasteGate readback theorem* `RealityConstrainedMethodologyLedgerTasteGate_single_carrier_alignment`*. The encoding route reads each* BHist *row as a finite* BMark *event, decodes it back to the same* BHist *row, and reconstructs the single* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *carrier rather than a second methodology object.*

Proof. Project L into its thirteen displayed rows. The TasteGate readback theorem proves the BHist encode-decode identity for each row and the round-trip law from the event-flow presentation back to the same ledger packet.

Apply the injectivity component of the same checked theorem. If two event-flow readbacks agree, the underlying $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ packets agree, so the paper rows and the decoded rows are not parallel carriers. They are the same finite carrier read through the TasteGate surface. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedMethodologyLedgerUp.taste gate`

Theorem 1145.40 (Reality-constrained methodology-ledger nontrivial field-faithful readback)**.** *The paper-side falsifiable-prediction row and independence witness are witnessed on the same* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *carrier by the Lean* `Nontrivial` *and* `FieldFaithful` *instances. The* `Nontrivial` *instance separates the all-empty packet from the packet whose* X *row is* $e0(\emptyset)$*, and the* `FieldFaithful` *instance says equality of the displayed row list* $[X, A, O, T, I, S, D, U, F, H, C, Q, N]$ *determines equality of the packet.*

Proof. Use the `Nontrivial` instance for the falsifiable-prediction witness. It supplies two packets in the same carrier and proves they are distinct by constructor separation at the X row.

Use the `FieldFaithful` instance for row independence. Its field map is exactly the displayed row list, and its faithfulness clause says that no hidden coordinate remains after those rows agree. Thus the prediction witness and the field-faithfulness readback live on the carrier already named by the paper certificate. □

Theorem 1145.41 (Reality-constrained methodology-ledger formal-target closure route)**.** *The refusal-upgrade surface, failure-consumer surface, prediction row, and TasteGate readback surface together give a formal-target route for later closure promotion of* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$*. The route is confined to the displayed finite carrier, its* BHist/hsame/Cont/Pkg *support, its local* NameCert *obligations, and the checked TasteGate readback; it does not claim public closure, bridge closure, physical-model adequacy, or a domain-truth oracle.*

Proof. Apply Definition 1145.35 and Definition 1145.36. These surfaces route refusal, upgrade, failure exposure, and consumer access through the displayed methodology-ledger rows.

Apply Definition 1145.37 and Definition 1145.39. The prediction read remains inside the same finite ledger, and the TasteGate readback identifies the event-flow decoding with the displayed carrier. This is a formal-target route for a later closurestatus decision, not itself a claim of public or bridge closure. □

Theorem 1145.42 (Reality-constrained methodology-ledger methodology root triad)**.** *For every accepted root methodology read of a* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C$ *the read exposes the sibling rows* X, A, O, T, I*, the scope-refusal-upgrade rows* S, D, U*, and the failure-consumer-provenance-name rows* F, C, Q, N *inside the same finite carrier. The transport row* H *remains part of the same* $\mathsf{BHist/hsame/Cont/Pkg}$ *support, so the root read cannot replace these rows by a hidden methodology source, final truth route, observer-privilege route, or off-ledger NameCert.*

Proof. Start with the carrier and certificate, Definition 1145.1 and Definition 1145.2. They display L as a single finite packet and make its classifier read the sibling, methodology, failure, transport, consumer, provenance, and naming rows through the same local support.

Apply the NameCert obligations and root audit source lock, Definition 1145.3 and Definition 1145.14. These obligations expose carrier admission, sibling accountability, source lock, provenance, and local naming before a root methodology read can be accepted.

Now add the route constraints. Scope-export exactness and domain-leakage refusal, Definition 1145.5 and Definition 1145.4, force the S, D surface to be visible, while upgrade-route determinacy, Definition 1145.9, keeps U inside the same carrier.

Finally use failure-surface exhaustion and consumer-route exactness, Definition 1145.7 and Definition 1145.8. They force F and C to be read with the provenance and naming rows already carried by the packet, so the root methodology triad is a row-wise readback of L rather than a second authority. □

Theorem 1145.43 (Reality-constrained methodology-ledger scope-refusal cover)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, every beyond-scope methodology export is covered by the displayed scope row* S*, refusal row* D*, and upgrade row* U *before any consumer route* C *may treat the export as methodology authority. No consumer route can read a beyond-scope export directly from the sibling, failure, provenance, or local* $\mathsf{NameCert}$ *rows.*

Proof. Begin with scope-export exactness, Definition 1145.5. It requires the displayed scope row S before a methodology export can be read.

Next apply domain-leakage refusal and upgrade-route determinacy, Definition 1145.4 and Definition 1145.9. They place a beyond-scope attempt in D and any admitted continuation in U, with both rows still belonging to the same packet.

Use the NameCert obligations to keep the consumer read local to the carrier. The certificate does not provide a separate consumer authority outside S, D, U, F, H, C, Q, N.

Finally apply failure-surface exhaustion, consumer-route exactness, and root export coverage, Definition 1145.7, Definition 1145.8, and Definition 1145.34. These results require F before C and identify the root export package with the displayed refusal, upgrade, failure, consumer, provenance, and naming rows. Hence a consumer route can treat a beyond-scope export as methodology authority only after the S, D, U cover has already been exposed. □

Theorem 1145.44 (Reality-constrained methodology-ledger failure-upgrade readback)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, failure rows and upgrade rows are read back through the same finite carrier. The readback cannot split* F *into hidden truth, cannot split* U *into observer privilege, and cannot route either row through an off-ledger methodology object before consumer access.*

Proof. Project the packet through the carrier and certificate. The rows F and U are coordinates of the same $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ object, with H, C, Q, N supplying the transport, consumer, provenance, and local naming support.

Apply failure-surface exhaustion and failure-route locality, Definition 1145.7 and Definition 1145.18. They keep defeating tests in F and prevent a consumer-facing route from turning those tests into hidden truth.

Next apply upgrade-route determinacy and upgrade scope lock, Definition 1145.9 and Definition 1145.17. They keep any admitted upgrade inside U and tie it to the same displayed scope and refusal surface, not to observer privilege.

Finally combine consumer-route exactness with root audit source lock, Definition 1145.8 and Definition 1145.14. The consumer reads the visible failure and upgrade rows through the same carrier, provenance, and local NameCert surface, so no split into a hidden truth route or observer-privilege route is available. □

Theorem 1145.45 (Reality-constrained methodology-ledger public export readiness)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the public export surface is the finite methodology-ledger interface carried by the explanation row* X*, audit row* A*, objectivity row* O*, tower-compression row* T*, open-fit row* I*, scope row* S*, refusal row* D*, upgrade row* U*, failure row* F*, transport row* H*, consumer row* C*, provenance row* Q*, and local* NameCert *row* N*. Any public export of methodology authority must pass through those rows, the existing failure-consumer coverage, the formal-target route totality surface, and the TasteGate readback surface before it can be consumed.*

Proof. Project the carrier using Definition 1145.1. The displayed coordinates are exactly the five sibling rows X, A, O, T, I together with the methodology scope, refusal, upgrade, failure, transport, consumer, provenance, and local naming rows.

Apply the NameCert obligations, Definition 1145.3. They bind carrier admission, scope exactness, refusal, upgrade, failure exposure, sibling accountability, and ledger non-escape to the same local certificate surface.

Next use failure-consumer coverage and formal-target route totality, Definition 1145.36 and Definition 1145.38. These results place the failure row and consumer route before public methodology consumption and keep TruthCert-facing access inside the same BHist/hsame/Cont/Pkg/NameCert support.

Finally apply the TasteGate readback surface, Definition 1145.39. It identifies the event-flow decoding with the displayed carrier, so the public export is a readback of L rather than an off-ledger methodology object. □

Theorem 1145.46 (Reality-constrained methodology-ledger TruthCert consumer handoff)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, any TruthCert-facing consumer handoff receives the packet only after the carrier rows, local* NameCert *obligations, failure-consumer coverage, formal-target route totality, and TasteGate readback have displayed the same finite methodology ledger. The handoff cannot replace the explanation, audit, objectivity, tower-compression, open-fit, scope, refusal, upgrade, failure, transport, consumer, provenance, or local NameCert rows by a domain-truth oracle or a physical-model adequacy theorem.*

Proof. Begin with the root TruthCert handoff theorem, Definition 1145.26. It already forces a TruthCert-facing read through the local methodology rows instead of through an external truth coordinate.

Use public export readiness, Definition 1145.45, to identify the available consumer surface. The handoff receives the same finite packet rows and no additional methodology primitive.

Now apply the formal-target route totality theorem. It puts refusal-upgrade, failure-consumer, and prediction-facing reads before TruthCert consumption and keeps all of them in the displayed BHist/hsame/Cont/Pkg/NameCert support.

Finally use the TasteGate readback surface. Since the decoded event-flow carrier is the same L, a TruthCert-facing consumer handoff reads the public methodology ledger without replacing it by a separate domain-truth or adequacy claim. □

Theorem 1145.47 (Reality-constrained methodology-ledger root dependency totality)**.** *For every accepted root methodology consumer of a* RealityConstrainedMethodologyLedger$^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the consumer reads the explanation, audit, objectivity, tower-compression, open-fit, scope, refusal, upgrade, failure, transport, consumer, provenance, and local NameCert rows before any TruthCert consumer handoff. In particular, the five sibling dependencies* RealityConstrainedExplanation$^{\uparrow}$*,* RealityConstrainedModelAudit$^{\uparrow}$*,* RealityConstrainedObjectivity$^{\uparrow}$*,* RealityConstrainedTowerCompression$^{\uparrow}$*, and* OpenFitPacket$^{\uparrow}$ *remain displayed as rows of the same finite ledger.*

Proof. Start from the methodology root triad, Definition 1145.42. It exposes the five sibling rows, the scope-refusal-upgrade rows, and the failure-consumer-provenance-name rows inside one carrier.

Apply root sibling accountability and the public obligation surface, Definition 1145.33 and Definition 1145.31. These keep the explanation, audit, objectivity, tower-compression, and open-fit dependencies visible as rows of L rather than as hidden sources.

Next use failure-consumer public scope, Definition 1145.24. It requires the failure row and displayed sibling, scope, refusal, and upgrade rows before the consumer route C may be read.

Finally apply the TruthCert consumer handoff theorem, Definition 1145.46. The handoff therefore occurs only after the root consumer has read every row listed in the carrier and the five sibling dependencies remain part of the same public methodology ledger. □

Theorem 1145.48 (Reality-constrained methodology-ledger export accountability)**.** *For every accepted* RealityConstrainedMethodologyLedger$^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, any methodology export from* L *must expose the sibling rows* X, A, O, T, I*, the scope row* S*, the refusal and upgrade rows* D, U*, the failure row* F*, and the support rows* H, C, Q, N*. The export is therefore a read of the displayed* BHist/hsame/Cont/Pkg/NameCert *surface, not a read of an omitted methodology coordinate.*

Proof. Project the carrier of Definition 1145.1. It displays the five sibling rows, the scope-refusal-upgrade surface, the failure row, and the transport, consumer, provenance, and naming rows in one finite packet.

Apply the NameCert obligations of Definition 1145.3. Carrier admission, sibling accountability, scope exactness, domain-leakage refusal, failure exposure, and ledger non-escape all bind the same displayed rows before a methodology claim is accepted.

Finally use public export readiness and sibling independence, Definition 1145.45 and Definition 1145.6. They keep the export on the public carrier surface and prevent any single sibling from replacing the full methodology ledger. □

Theorem 1145.49 (Reality-constrained methodology-ledger upgrade-refusal totality)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* RealityConstrainedMethodologyLedger$^{\uparrow}$ *packet. Every methodology export beyond the displayed scope row* S *is either refused in the domain-leakage*

row D or routed through the upgrade row U before any consumer route C may treat it as methodology authority.

Proof. Begin with scope-export exactness and domain-leakage refusal, Definition 1145.5 and Definition 1145.4. They require the scope row before export and reject a beyond-scope claim that lacks the displayed refusal and extension surface.

Use source-refusal boundary next, Definition 1145.13. A beyond-scope read of the sibling source rows must be witnessed in D before the consumer route may accept it.

Finally apply upgrade-route determinacy and root export coverage, Definition 1145.9 and Definition 1145.34. They rule out deleting, replacing, or bypassing the carrier, leaving only the displayed refusal row D and upgrade row U as accepted beyond-scope routes. □

Theorem 1145.50 (Reality-constrained methodology-ledger authority nonescape)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, no unbounded explanation, final model truth, hidden observer privilege, closed empirical fit, endpoint/source identity, or off-ledger authority can be read from the packet. Any accepted methodology authority must factor through the displayed rows* $X, A, O, T, I, S, D, U, F, H, C, Q, N$*.*

Proof. Project the carrier and certificate, Definition 1145.1 and Definition 1145.2. The carrier has no coordinate for unbounded explanation, final model truth, hidden observer privilege, closed empirical fit, endpoint/source identity, or off-ledger methodology authority, and the certificate preserves only the displayed rows.

Apply consumer-route exactness and failure-route locality, Definition 1145.8 and Definition 1145.18. They keep consumer authority and defeating tests inside the visible carrier instead of turning either one into a hidden truth or observer-privilege route.

Finally use the export-accountability and upgrade-refusal-totality surfaces of this file. Every methodology export exposes the packet rows, and every beyond-scope export is covered by D or U, so there is no remaining route through which off-ledger authority can escape the finite NameCert packet. □

Theorem 1145.51 (Reality-constrained methodology-ledger root carrier obligation)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Every root methodology-ledger read must expose the sibling failure, open-fit, and objectivity dependency rows through the same finite* BHist *carrier, the same componentwise* hsame *transport, the same displayed consumer route, the same package provenance row, and the same local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedMethod}}$ *row. The read cannot replace L by an off-ledger methodology carrier, hidden observer privilege, final model truth, or closed empirical oracle.*

Proof. Project the carrier of Definition 1145.1. It displays the explanation, audit, objectivity, tower-compression, open-fit, scope, refusal, upgrade, failure, transport, consumer, provenance, and local naming rows in one packet.

Apply Definition 1145.47. The sibling failure, open-fit, and objectivity dependencies remain rows of the same finite methodology ledger rather than external carriers.

Finally use Definition 1145.19. Since every consumer route factors through L, there is no route for an off-ledger methodology carrier, hidden observer privilege, final model truth, or closed empirical oracle. □

Theorem 1145.52 (Reality-constrained methodology-ledger root classifier stability)**.** *For an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the root classifier is stable exactly along the displayed* hsame *transport and* Cont *route. Any classifier*

read comparing sibling failure, open-fit, objectivity, refusal, upgrade, or failure rows must compare the same local NameCert packet, and it cannot introduce a hidden fit selector, detached domain-truth predicate, or external adequacy theorem.

Proof. Start from Definition 1145.51. The root read has already exposed the displayed finite carrier and the local NameCert row.

Use Definition 1145.3. Its classifier and ledger clauses bind sibling accountability, scope exactness, domain-leakage refusal, failure exposure, and non-escape to the same packet.

Then apply Definition 1145.8. The classifier travels only along the displayed hsame and Cont rows, so hidden fit selectors, detached domain-truth predicates, and external adequacy theorems have no accepted comparison route. □

Theorem 1145.53 (Reality-constrained methodology-ledger root ledger exactness)**.** *Every root ledger export of an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet is exactly the finite packet* $X, A, O, T, I, S, D, U, F, H, C, Q, N$ *read through* BHist, hsame, Cont, *package provenance, and local NameCert data. The ledger records sibling failure, open-fit, objectivity, refusal, upgrade, and failure rows without exporting unbounded methodology authority, hidden empirical fit, endpoint identity, or off-ledger proof evidence.*

Proof. First retain the carrier and classifier by Definition 1145.51 and Definition 1145.52. The ledger export is already tied to the displayed finite packet and its componentwise transport route.

Next read the failure and refusal rows through Definition 1145.18 and Definition 1145.11. These theorems keep defeating tests, refusal records, and allowed extensions local to L.

Finally use Definition 1145.45. A public methodology readback may export only the local methodology-ledger interface, so unbounded methodology authority, hidden empirical fit, endpoint identity, and off-ledger proof evidence are excluded. □

Theorem 1145.54 (Reality-constrained methodology-ledger root authority carrier totality)**.** *Let* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ *be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Every BEDC-kernel authority read of the root methodology ledger is total only when it reads the displayed carrier rows*

$$X, A, O, T, I, S, D, U, F, H, C, Q, N$$

as one finite BHist *packet, transports them through the same* hsame *row* H*, follows the same* Cont *consumer route* C*, preserves the same* Pkg *provenance row* Q*, and exposes the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedMethodolo}}$ *row* N*. No authority read may replace this packet by host truth, hidden observer privilege, unbounded methodology scope, or an off-ledger proof surface.*

Proof. Project the carrier of Definition 1145.1. It displays the thirteen rows of L and gives no coordinate outside BHist, hsame, Cont, Pkg, and the local $\mathsf{NameCert}$ row from which root authority could be read.

Apply Definition 1145.3. Carrier admission, sibling accountability, scope exactness, refusal routing, failure exposure, and ledger non-escape are all obligations of the same packet.

Use Definition 1145.51 and Definition 1145.39. The first keeps the root read on the displayed rows, while the second identifies the TasteGate readback with the same finite carrier rather than a second methodology object. □

Theorem 1145.55 (Reality-constrained methodology-ledger scope-refusal upgrade-route exhaustion)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*,*

each root authority attempt beyond the displayed scope row S is exhausted by the refusal row D and upgrade-route row U before it reaches the consumer route C. The exhaustion is read inside the same finite BHist *carrier, along the same* hsame *transport,* Cont *route,* Pkg *provenance, and local* NameCert *surface; it cannot appeal to hidden domain truth, unrecorded methodology authority, or a closed empirical oracle.*

Proof. Begin with Definition 1145.54. Any root authority attempt has already been placed on the displayed packet $X, A, O, T, I, S, D, U, F, H, C, Q, N$.

Apply Definition 1145.5 and Definition 1145.4. They require S before methodology export and route every beyond-scope attempt through D or the declared extension path U.

Now use Definition 1145.11 and Definition 1145.9. Together they exhaust the accepted beyond-scope route by the displayed refusal and upgrade rows rather than by deleting, replacing, or bypassing the carrier.

Finally apply Definition 1145.8. Since C factors through the same carrier and no hidden domain-truth coordinate exists, the exhausted D, U route is the only root authority route available before consumption. □

Theorem 1145.56 (Reality-constrained methodology-ledger failure consumer ledger coverage)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet* $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$*, the root failure-consumer surface covers all finite defeats that a methodology consumer may read. The coverage keeps F and C inside the displayed* BHist *ledger, preserves comparison by* hsame*, routes consumption through* Cont*, records provenance by* Pkg*, and exposes the same local* NameCert *obligations; it never exports an untracked failure waiver, hidden fit selector, endpoint identity, or off-ledger methodology certificate.*

Proof. Start from Definition 1145.54. The failure row F and consumer route C are rows of the same packet, with no additional failure-waiver coordinate.

Apply Definition 1145.7 and Definition 1145.12. They require finite defeats from the sibling, scope, refusal, and upgrade rows to be visible in F before C is accepted.

Use Definition 1145.8 and Definition 1145.18. These results keep the consumer route and defeating tests local to the displayed carrier rather than to hidden fit, endpoint identity, or an off-ledger certificate.

Finally read the same surface through Definition 1145.39. The TasteGate carrier alignment confirms that the public readback decodes this finite ledger itself, so the failure-consumer coverage is not supplied by a second methodology object. □

Definition 1145.57 (Reality-constrained methodology-ledger root route packet)**.** *The root route packet for* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *is the finite* BHist *display*

$$R = (O, M, J, E, T, K, C, P, N)$$

whose rows record, in order, open-fit evidence from $\mathsf{OpenFitPacket}^{\uparrow}$*, model-audit evidence from* $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$*, objectivity evidence from* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$*, explanation evidence from* $\mathsf{RealityConstrainedExplanation}^{\uparrow}$*, tower-compression evidence from* RealityConstrainedTowerCompr*transport rows for the displayed methodology constraints, continuation rows for root consumers, provenance rows for the sibling certificates, and the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}}$ *row. The five source rows are read through chapter 1137, chapter 1124, chapter 1133, chapter 1136, and chapter 1142.*

The packet has no coordinate for hidden model identity, unbounded truth, a host semantic oracle, unledgered compression, or private classifier choice.

Theorem 1145.58 (Reality-constrained methodology-ledger root route totality)**.** *Every root methodology-ledger consumer factors through the rows of Definition 1145.57. In particular, the consumer must read the open-fit, model-audit, objectivity, explanation, tower-compression, transport, continuation, provenance, and local* NameCert *rows before using the methodology ledger as a root dependency.*

Proof. Project the local carrier and certificate from Definition 1145.1 and Definition 1145.2. They already expose the sibling, transport, consumer, provenance, and local naming rows as a finite ledger.

Use the sibling chapters as the only admitted sources. The open-fit packet, model-audit packet, objectivity packet, explanation packet, and tower-compression packet supply the five root methodology constraints named in the packet definition.

Finally apply the local NameCert obligations, root carrier obligation, and consumer-route exactness. These results force the consumer route to stay on the displayed finite rows and prevent a hidden methodology source from replacing the local ledger. □

Theorem 1145.59 (Reality-constrained methodology-ledger root route nonescape)**.** *The root route packet of Definition 1145.57 exports no hidden model identity, unbounded truth coordinate, host semantic oracle, unledgered compression channel, or private classifier choice. Every accepted root read remains a finite BEDC route through* BHist*,* hsame*,* Cont*,* Pkg*, and the local* NameCert *row.*

Proof. Start from root route totality. Any accepted root consumer has already been routed through $O, M, J, E, T, K, C, P, N$.

Apply the carrier non-escape clauses from the local NameCert obligations and the root authority carrier totality theorem. They leave no field in the methodology ledger for a model identity hidden from the packet, unbounded truth, or a host semantic oracle.

Use the tower-compression and consumer-route rows for the remaining exclusions. Compression is ledgered through the displayed tower row, while classifier choice and consumer replay remain public BHist, Cont, Pkg, and NameCert data rather than private host coordinates. □

Theorem 1145.60 (Reality-constrained methodology-ledger root source invariant triad)**.** *For the root route packet*

$$R = (O, M, J, E, T, K, C, P, N)$$

of Definition 1145.57, the source invariants read by downstream methodology-ledger consumers are exactly the sibling rows O, M, J, E, T together with the transport, continuation, provenance, and local naming rows K, C, P, N. The packet exposes those invariants only as finite BHist *data transported by* hsame*, replayed by* Cont*, packaged by* Pkg*, and bound by the local* NameCert *row.*

Proof. Begin with the packet definition. It names the five sibling source rows for open fit, model audit, objectivity, explanation, and tower compression, and it records the four support rows K, C, P, N in the same finite display.

Apply root route totality. Any root methodology-ledger consumer must first read the displayed rows $O, M, J, E, T, K, C, P, N$, so the sibling sources cannot be replaced by a hidden methodology source.

Finally apply root route nonescape. The only kernel support exported with those sibling rows is BHist, hsame, Cont, Pkg, and the local NameCert row, which makes the displayed triad of source, transport, and provenance the whole root surface. □

Theorem 1145.61 (Reality-constrained methodology-ledger root failure ledger surface)**.** *Every failure or refusal read available at the methodology-ledger root is ledgered through the displayed packet rows*

$$O, M, J, E, T, K, C, P, N.$$

The sibling source rows supply the visible open-fit, model-audit, objectivity, explanation, and tower-compression tests, while K, C, P, N keep the failure ledger inside BHist*,* hsame*,* Cont*,* Pkg*, and the local* NameCert *surface. No off-ledger failure waiver, hidden model identity, or unbounded truth coordinate is exported.*

Proof. Project the finite packet from Definition 1145.57. Its source rows are precisely the sibling rows O, M, J, E, T, and its support rows are K, C, P, N.

Use root route totality to force every accepted root consumer through those rows before the methodology ledger can be used as a dependency. Thus any failure or refusal test seen at the root is read from the same finite packet.

Root route nonescape supplies the exclusions. Since the packet exports only BHist, hsame, Cont, Pkg, and local NameCert support, an off-ledger waiver, hidden identity, or unbounded truth coordinate has no row from which it could be read. □

Theorem 1145.62 (Reality-constrained methodology-ledger root export nonescape)**.** *The public root export of* RealityConstrainedMethodologyLedger$^{\uparrow}$ *is exhausted by the packet rows $O, M, J, E, T, K, C, P, N$, with the sibling source rows carried through the displayed BEDC support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. A downstream consumer may export the finite methodology-ledger route, but it may not export hidden model identity, unbounded truth, a host semantic oracle, unledgered compression, private classifier choice, or a source row outside the sibling packet.*

Proof. First read the packet definition, which fixes the export surface as $O, M, J, E, T, K, C, P, N$ and gives no coordinate for any additional source row.

Root route totality then identifies every accepted downstream read with that same packet. The source rows are the listed siblings, and the continuation and provenance rows carry them without introducing a second route.

Apply root route nonescape for the export boundary. It restricts the consumer-visible support to BHist, hsame, Cont, Pkg, and the local NameCert row, so none of the excluded host, truth, compression, classifier, or extra-source coordinates can leave the root packet. □

Theorem 1145.63 (Reality-constrained methodology-ledger open-fit model-audit obligation)**.** *Let $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ be an accepted* RealityConstrainedMethodologyLedger$^{\uparrow}$ *carrier. Every downstream methodology-ledger consumer that reads the open-fit row I must also expose the model-audit row A, the scope row S, the refusal row D, the failure row F, the transport row H, the consumer route C, the provenance row Q, and the local* NameCert *row N. The read is therefore a finite* OpenFitPacket$^{\uparrow}$ *and* RealityConstrainedModelAudit$^{\uparrow}$ *obligation inside the same ledger, not a closed empirical fit or a host model-truth certificate.*

Proof. Project the accepted carrier from Definition 1145.1. The open-fit row I and model-audit row A are sibling rows of the same packet, while S, D, F, H, C, Q, N are the scope, refusal, failure, transport, route, provenance, and local naming rows that control public consumption.

Use the sibling-accountability and scope-exactness clauses of Definition 1145.3. They force the open-fit and model-audit reads to remain visible before any methodology claim is exported.

Now apply Definition 1145.58 and Definition 1145.59. The root route packet admits open-fit and model-audit evidence only through displayed BEDC rows and excludes hidden model identity, unbounded truth, host semantic oracles, unledgered compression, and private classifier choice.

Finally, Definition 1145.54 keeps the authority read on L itself. Thus the open-fit read cannot close empirical fit or certify model truth outside the local ledger. □

Theorem 1145.64 (Reality-constrained methodology-ledger objectivity tower-compression handoff)**.** *Let $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *carrier. Every root consumer that uses the objectivity row O together with the tower-compression row T must hand both rows through the displayed transport, consumer, provenance, and local naming surface H, C, Q, N. The handoff preserves the* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *and* $\mathsf{RealityConstrainedTowerCompr}$ *obligations as finite sibling dependencies and does not export a hidden observer, endpoint/source identity, or unledgered compression channel.*

Proof. Start with the carrier inventory. The rows O and T are displayed beside the common support rows H, C, Q, N, so objectivity and tower-compression data are not separate host-side resources.

Apply Definition 1145.60. It identifies the sibling source rows of the root route packet with the transport, continuation, provenance, and local naming rows that carry them to downstream consumers.

Use Definition 1145.14. That theorem requires the sibling rows and BEDC kernel support rows to be exposed before the consumer route can treat the methodology ledger as authority.

The exclusions then follow from Definition 1145.62. Since the public root export is exhausted by the displayed packet rows, no hidden observer, endpoint identity, or unledgered compression channel can be exported with the handoff. □

Theorem 1145.65 (Reality-constrained methodology-ledger NameCert unblock surface)**.** *Let $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *carrier. The combined root dependency surface for* $\mathsf{OpenFitPacket}^{\uparrow}$, $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$, $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$, $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$, *and the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedMethodolog}}$ *row is exactly the finite packet rows $X, A, O, T, I, S, D, U, F, H, C, Q, N$. A downstream methodology-ledger consumer may use those rows as a root route, but it cannot bypass them by importing unbounded explanation, final model truth, closed empirical fit, hidden observer privilege, endpoint identity, or off-ledger methodology authority.*

Proof. First combine the carrier and local certificate. The carrier displays the rows $X, A, O, T, I, S, D, U, F, H, C, Q,$ and Definition 1145.3 makes sibling accountability, scope exactness, refusal routing, failure exposure, and ledger non-escape obligations of that same packet.

Next read the root route packet through Definition 1145.57. Its open-fit, model-audit, objectivity, explanation, and tower-compression rows are carried with transport, continuation, provenance, and local naming support, so the root route is a finite BEDC surface rather than an ambient methodology principle.

For downstream consumption, use Definition 1145.61 and Definition 1145.56. These results keep failure and refusal reads inside the displayed ledger before the consumer route is accepted.

Finally apply Definition 1145.54. It leaves no coordinate from which unbounded explanation, final truth, closed fit, hidden observer privilege, endpoint identity, or off-ledger authority could be read, so the listed rows form the unblock surface. □

Theorem 1145.66 (Reality-constrained methodology-ledger observation row)**.** *Let $L = (X, A, O, T, I, S, D, U, F, H$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet. Every observation-facing methodology read must expose the sibling rows for* $\mathsf{RealityConstrainedTruthCert}$ *and* $\mathsf{SignatureFit}$ *together with the displayed scope row S, refusal row D, failure row F, transport row H, consumer route*

C, provenance row Q, and local $\mathsf{NameCert}_{\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}}$ *row N. The observation row is therefore finite* BHist *ledger data, not final model truth, hidden observer privilege, or an off-ledger domain oracle.*

Proof. Start with the carrier and NameCert obligations of the chapter. They expose $X, A, O, T, I, S, D, U, F, H, C, Q$ as the finite packet and make sibling accountability, scope exactness, refusal routing, failure exposure, and ledger non-escape duties of that packet.

Next use the root methodology triad and root audit source lock. These rows keep observation, audit, objectivity, tower-compression, and open-fit evidence inside the same transport, consumer, provenance, and naming surface.

Finally apply the root open-fit model-audit obligation. It prevents an observation read from becoming a closed empirical fit or host model-truth certificate outside the displayed local ledger. □

Theorem 1145.67 (Reality-constrained methodology-ledger method-fit row)**.** *For every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$, every method-fit read through the* SignatureFit *surface is accepted only with the* RealityConstrainedTruthCert *observation rows, the scope/refusal/upgrade rows S, D, U, and the failure/consumer/provenance/name rows F, C, Q, N visible in the same packet. The read cannot be replaced by unbounded explanation, final truth, closed empirical fit, hidden observer privilege, endpoint identity, or off-ledger methodology authority.*

Proof. Begin with scope-export exactness and domain-leakage refusal. These results require S before methodology export and route beyond-scope attempts through the displayed refusal surface.

Now apply upgrade-route determinacy and failure-surface exhaustion. Any admitted movement beyond the current scope stays in U, and defeating tests from sibling surfaces must be collected in F before C is accepted.

Finally use consumer-route exactness and the root route packet. They identify method-fit consumption with a read of L itself, carried by H, C, Q, N, rather than with a second authority outside the ledger. □

Theorem 1145.68 (Reality-constrained methodology-ledger nonescape)**.** *Every root consumer of an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet is exhausted by the observation row, method-fit row, scope row, refusal row, upgrade row, failure row, transport row, consumer route, provenance row, and local* NameCert *row displayed in $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$. No hidden domain leakage, private classifier choice, final model-truth oracle, unledgered compression channel, endpoint identity, or off-ledger methodology authority is available to that consumer.*

Proof. First combine the observation row and method-fit row above. Together they place truth-certificate and signature-fit consumption inside the displayed methodology ledger with S, D, U, F, H, C, Q, N visible.

Next apply the chapter's root route totality and root route non-escape theorems. They admit consumer reads only through displayed BEDC rows and exclude hidden model identity, unbounded truth, host semantic oracles, unledgered compression, and private classifier choice.

Finally use the NameCert unblock surface and root authority carrier totality. Since the authority read stays on L itself and the local certificate names no additional coordinate, the root consumer cannot escape the finite methodology ledger. □

Theorem 1145.69 (Reality-constrained methodology-ledger TruthCert reverse dependency)**.** *Let $L = (X, A, O, T, I, S, D, U, F, H, C, Q, N)$ be an accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$

packet. If L is read as TruthCert methodology authority, then the read is consumed through chapter 1144 and preserves the displayed rows

$$X, A, O, T, I, S, D, U, F, H, C, Q, N.$$

It may not be read as freestanding methodology authority, final model truth, hidden observer privilege, closed empirical fit, or off-ledger proof.

Proof. Project the carrier of Definition 1145.1. The only available methodology-ledger coordinates are the displayed rows $X, A, O, T, I, S, D, U, F, H, C, Q, N$, and the carrier explicitly omits final model truth, hidden observer privilege, closed empirical fit, and off-ledger export.

Apply the TruthCert consumer handoff theorem, Definition 1145.46. A TruthCert-facing methodology read receives the same finite ledger after carrier admission, local NameCert obligations, failure-consumer coverage, formal-target route totality, and TasteGate readback have displayed it.

The consumer is therefore routed through the TruthCert carrier chapter, chapter 1144, rather than through a freestanding authority surface. Since that chapter consumes the methodology-ledger handoff as a TruthCert-facing export, any accepted read must preserve all rows of L and cannot replace them by an absent truth, observer, fit, or proof coordinate. □

Theorem 1145.70 (Reality-constrained methodology-ledger sibling lattice route)**.** *Every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *public route is not a kernel-only float. It is read through the existing explanation, model-audit, objectivity, tower-compression, and open-fit dependency family, exported to chapter 1144, and consumed by chapter 1185.*

Proof. Apply Definition 1145.47. It keeps the explanation, model-audit, objectivity, tower-compression, and open-fit dependencies displayed as rows of the same finite methodology ledger before the root consumer can read the packet.

Next apply Definition 1145.45. Public methodology authority is therefore exported through the displayed rows and their failure-consumer, formal-target, and TasteGate routes, rather than through a kernel-only object detached from the sibling dependency family.

Finally use Definition 1145.69. The accepted read is routed through chapter 1144; the scientific-methodology consumer of chapter 1185 then receives the methodology-ledger row as a downstream public dependency, so the route remains horizontal across the sibling lattice instead of floating as an isolated kernel packet. □

Theorem 1145.71 (Reality-constrained methodology audit-membrane dependency)**.** *Every accepted* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *packet that is exported as public methodology must consume the audit/export boundary of chapter 526 and the membrane-local routing discipline of chapter 533 before its local* NameCert *row is read. The exported route keeps methodology scope, audit evidence, membrane admission, failure exposure, transport, replay, provenance, and naming in one finite* BHist *packet, and it cannot be read as a kernel-only methodology island.*

Proof. Use the sibling lattice route. It already places public methodology export inside the displayed explanation, audit, objectivity, tower-compression, open-fit, truth-certificate, and scientific-methodology dependency family.

The audit-gate boundary supplies the finite pass, refusal, ancestry, and replay rows that make a public methodology claim inspectable. The operational membrane supplies the export-side membrane row that keeps those audit rows attached to a concrete consumer boundary rather than to an ambient host predicate.

Combining these rows with the methodology-ledger carrier forces every public export through the same BHist, hsame, Cont, Pkg, and NameCert surface. Thus the methodology ledger records a substantive horizontal dependency on the audit and membrane boundary chapters before its local name is consumed. □

The RealityConstrainedMethodologyLedger$^{\uparrow}$ carrier consumes the finite-cover methodology exemplified by chapter 388 as a sibling route before public methodology reads are exported. This dependency keeps the ledger's scope, audit, refusal, and failure rows tied to a concrete finite-cover method pattern rather than to a detached methodology slogan. The RealityConstrainedMethodologyLedger$^{\uparrow}$ carrier reads the core registry index of chapter 1251 before methodology authority, route unblock, and export-surface rows can be treated as ledger entries. This dependency keeps the methodology ledger inside the shared registry lattice: the authority row, root-route row, open-fit row, and public export row are not free-standing methodology claims, but indexed entries whose provenance is visible before any downstream consumer reads them.

Theorem 1145.72 (Reality-constrained methodology refusal-registry dependency)**.** *Every accepted* RealityConstrainedMethodologyLedger$^{\uparrow}$ *packet whose refusal, denial, or upgrade row is consumed as methodology output must first pass through the finite refusal packet of chapter 1248. A downstream reader may then consume the methodology row as a displayed refusal boundary, but it may not read denial as silence, package provenance as authority, or missing upgrade evidence as permission to export.*

Proof. Start with the methodology-ledger root and refusal rows. The root obligation surface, authority unblock rows, and route-unblock packet expose methodology scope, denial, upgrade, provenance, and local naming as finite ledger coordinates rather than as ambient policy claims.

Apply the export-control surface of RefusalRegistry$^{\uparrow}$. Its blocked-claim, refusal-entry, gate, cannot-claim, status, provenance, transport, package, and local NameCert rows require an explicit refusal packet before a consumer can treat a blocked route as a valid refusal boundary.

Compose the two packets through the existing ledger route. The methodology ledger supplies the local denial and upgrade coordinates, while RefusalRegistry$^{\uparrow}$ supplies the refusal export control. Therefore the consumer receives a named refusal boundary and not silence, hidden authority, or an unregistered upgrade route. □

Theorem 1145.73 (RealityConstrainedMethodologyLedger Helly sibling route)**.** *Every methodology-ledger read that consumes the* HellyTheorem$^{\uparrow}$ *finite convex-intersection surface must display the convex-set, polytope, affine, vector, and compact finite-read rows before the route is admissible. Concretely, the* RealityConstrainedMethodologyLedger$^{\uparrow}$ *consumer may read the Helly finite-subfamily ledger only after the* ConvexSet$^{\uparrow}$ *rows of chapter 208, the* Polytope$^{\uparrow}$ *witness rows of chapter 209, the* AffineSpace$^{\uparrow}$ *and* VecSpace$^{\uparrow}$ *ambient rows of chapter 206 and chapter 47, and the* CompactMetric$^{\uparrow}$ *finite-read boundary of chapter 129 have been displayed in the Helly packet of chapter 2309.*

Thus the methodology ledger admits Helly as a horizontal dependency route only through the displayed finite convex-intersection ledger. It receives no host convexity theorem, selected intersection point, quotient convex-set equality, unrestricted finite-cover principle, or ambient standard-model convexity coordinate.

Proof. Project the Helly carrier route from Definition 2309.1. Its public rows expose the affine ambient data, vector displacement data, convex-family rows, polytope witness ledger, compact finite-read boundary, finite subfamily ledger, transport, replay, provenance, and local naming.

Use the Helly sibling route of Definition 2309.10. It orders the convex-family membership rows, finite witness rows, affine and vector ambient rows, and compact finite-read boundary before the finite intersection ledger can be consumed.

The methodology ledger may therefore record the Helly route only as an admissible finite dependency after those rows are displayed. Since neither the Helly carrier nor the methodology ledger has a coordinate for a host convexity theorem, selected point, quotient convex-set equality, or unrestricted finite-cover oracle, none is exported by the dependency. □

Theorem 1145.74 (RealityConstrainedMethodologyLedger scoped closure record)**.** *The carrier of Definition 1145.1, the consumer-route exactness theorem Definition 1145.8, the domain-leakage refusal theorem Definition 1145.4, and the upgrade-route determinacy theorem Definition 1145.9 close the scoped* RealityConstrainedMethodologyLedger$^{\uparrow}$ *methodology-ledger surface. The scope is exactly the finite packet rows* $X, A, O, T, I, S, D, U, F, H, C, Q, N$ *over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, together with the sibling rows already displayed by the chapter. It exports no hidden methodology authority, final model truth, closed empirical fit, endpoint identity, or bridge row.*

Proof. First project the carrier. The rows $X, A, O, T, I, S, D, U, F, H, C, Q, N$ display the explanation, model-audit, objectivity, tower-compression, open-fit, scope, refusal, upgrade, failure, transport, consumer, provenance, and local naming surface.

Next apply consumer-route exactness. Every accepted consumer route factors through precisely those rows, so a downstream methodology read cannot bypass the displayed packet.

Then attach domain-leakage refusal and upgrade-route determinacy. The refusal row blocks hidden domain truth and unbounded scope, while the upgrade row determines accepted exports beyond the present scope without replacing the carrier.

Thus the chapter is scoped over the displayed methodology-ledger packet and its sibling obligations. The formal-status axis is witnessed by the existing checked TasteGate readback, while the theory-closure axis is supplied by the paper carrier and route arguments themselves. □

Closure status for NameCert$_{\text{RealityConstrainedMethodologyLedger}^{\uparrow}}$**.**

Constructive story: A public RealityConstrainedMethodologyLedger$^{\uparrow}$ packet is generated from methodology carrier rows, consumer-route exactness, domain-leakage refusal, upgrade-route determinacy, sibling scope rows, public export readiness, root methodology export, componentwise transport, consumer replay, package provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{RealityConstrainedMethodologyLedger}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1145.45, Definition 1145.34, Definition 1145.70, Definition 1145.46, and Definition 1145.39 bind the mature methodology-ledger route to the displayed carrier, root obligation, public export, sibling lattice, and TasteGate readback rows.

Formal verification: FormalStatus(NameCert$_{\text{RealityConstrainedMethodologyLedger}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RealityConstrainedMethodologyLedgerUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: This mature record does not assert final model truth, unbounded explanation, closed empirical fit, hidden observer privilege, endpoint identity, bridge closure, or standard bridge checking.

Upgrade path: Bridge checking remains the separate standard-bridge obligation for the same public methodology-ledger rows across the acceptance-bridge interface.

Chapter 1146

A Concrete Naming Certificate for TheoryTransitionCertificate$^{\uparrow}$

The TheoryTransitionCertificate$^{\uparrow}$ packet realizes theory change as a finite certificate transition between two certified theory states. It sits beside RealityConstrainedModelAudit$^{\uparrow}$ of chapter 1124, PhysicalTruthCertificate$^{\uparrow}$ of chapter 1141, RealityConstrainedExplanation$^{\uparrow}$ of chapter 1136, RealityConstrainedObjectiv of chapter 1133, and OpenFitPacket$^{\uparrow}$ of chapter 1137. Those siblings certify audit, truth, explanation, objectivity, and open fit for presented claims; the present packet binds two theory states and the transition rows between them.

Definition 1146.1 (Theory transition certificate carrier)**.** *A* TheoryTransitionCertificate$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T_1, T_2, S, C, D, L, F, H, R, P, N)$$

with the following displayed rows:

1. *T_1 is the old certified theory state, read through its displayed* NameCert *surface;*
2. *T_2 is the candidate successor certified theory state, read through its displayed* NameCert *surface;*
3. *S is the conservative signature preservation row, listing the old certified signatures whose current predictions must remain readable in T_2;*
4. *C is the classifier-refinement row, naming the classifier changes allowed by the transition;*
5. *D is the predictive-stability and descent row, recording which old predictions remain current and which tower-local descent rows are refined;*
6. *L is the ledger-refinement row, displaying the ledger entries added, split, or sharpened by the transition;*
7. *F is the failure-surface refinement row, displaying the failure boundaries that become more explicit under T_2;*
8. *H stores componentwise* hsame *transports for $T_1, T_2, S, C, D, L, F, P, N$;*
9. *R stores the displayed* Cont *routes from the old state through signature preservation, classifier refinement, stability, ledger refinement, and failure-surface refinement to the successor state;*
10. *P is the* Pkg *provenance over* RealityConstrainedModelAudit$^{\uparrow}$, PhysicalTruthCertificate$^{\uparrow}$, RealityConstrainedExplana RealityConstrainedObjectivity$^{\uparrow}$, OpenFitPacket$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{TheoryTransitionCertificate}^{\uparrow}}$ *row.*
The carrier has no coordinate for theory identity, no final-truth oracle, no unledgered prediction transfer, and no hidden failure-surface erasure.

Lean4 (definition) `BEDC.Derived.TheoryTransitionCertificateUp.TheoryTransitionCertificateUp`
Lean4 ✓ `BEDC.Derived.TheoryTransitionCertificateUp.TheoryTransitionCertificateUp single carrier alignment`

Theorem 1146.2 (TheoryTransitionCertificate NameCert obligations)**.** *For every accepted* TheoryTransitionCertific *carrier*

$$K = (T_1, T_2, S, C, D, L, F, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TheoryTransitionCertificate}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for the displayed packet, old and successor theory-state readability through T_1, T_2, conservative signature preservation through S, classifier refinement through C, prediction and descent stability through D, ledger refinement through L, failure-surface refinement through F, componentwise transport through H, route replay through R, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 1146.1. The definition displays exactly the rows $T_1, T_2, S, C, D, L, F, H, R, P, N$ and assigns one transition role to each row.

The first seven rows are the mathematical transition surface: old state, successor state, conserved signatures, classifier refinement, stability and descent, ledger refinement, and failure-surface refinement. The remaining rows are the BEDC certificate infrastructure for transport, route replay, provenance, and local naming.

The sibling packets provide the surrounding claim-level surfaces. $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ supplies audit rows, $\mathsf{PhysicalTruthCertificate}^{\uparrow}$ supplies truth-certificate rows, $\mathsf{RealityConstrainedExplanation}^{\uparrow}$ supplies explanation rows, $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ supplies objectivity rows, and $\mathsf{OpenFitPacket}^{\uparrow}$ supplies open-fit rows. Since the carrier has no further coordinates, every local obligation is one of the displayed rows above. □

Lean4 ✓ `BEDC.Derived.TheoryTransitionCertificateUp.TheoryTransitionCertificateNameCert obligations`

Theorem 1146.3 (TheoryTransitionCertificate conservative preservation)**.** *Let $K = (T_1, T_2, S, C, D, L, F, H, R, P,$ be an accepted* $\mathsf{TheoryTransitionCertificate}^{\uparrow}$ *packet. Every consumer that reads an old current prediction through T_1 and then through the successor state T_2 must pass through the conservative signature preservation row S, the stability row D, the displayed transport row H, and the route row R. Agreement on C, L, F, P, N cannot replace S or D, cannot erase an old certified signature, and cannot turn the transition into an identity between theories.*

Proof. Read the old and successor states from Definition 1146.1. The carrier separates T_1 from T_2 and makes S the only row that preserves old certified signatures across the transition.

Next read the stability row. The row D records which old predictions remain current and which tower-local descent rows are refined, so a consumer of old current predictions must pass through D after S has displayed the preserved signature.

The route and transport rows preserve this finite passage. Componentwise transport through H and route replay through R carry the same T_1, S, D, T_2 surface; the classifier, ledger, failure, provenance, and naming rows cannot substitute for it. Thus conservative preservation is a displayed finite condition, not identity of theories and not an unledgered prediction transfer. □

Lean4 ✓ `BEDC.Derived.TheoryTransitionCertificateUp.TheoryTransitionCertificate conservative preservation`

Theorem 1146.4 (TheoryTransitionCertificate ledger refinement boundary)**.** *For every accepted* $\mathsf{TheoryTransitionCertificate}^{\uparrow}$ *packet* $K = (T_1, T_2, S, C, D, L, F, H, R, P, N)$*, ledger refinement is accepted only when the ledger row* L *and failure-surface row* F *remain displayed with the preserved-signature and stability rows* S, D*. A transition packet that preserves old current predictions but drops either* L *or* F *is not an accepted* $\mathsf{TheoryTransitionCertificate}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.TheoryTransitionCertificateUp.TheoryTransitionCertificateLedgerRefinementBoundary`

Proof. Project L and F from the carrier definition. The ledger row records the entries added, split, or sharpened by the successor theory, while the failure-surface row records the boundaries made more explicit by the transition.

Now combine these rows with the conservative preservation theorem. Definition 1146.3 forces old current predictions through S and D; the present carrier also requires L and F as separate coordinates of the same packet.

The NameCert obligation theorem exhausts the accepted surface. Since Definition 1146.2 lists L and F as mandatory local obligations, a route that preserves predictions while dropping either row is not a route through the displayed $\mathsf{TheoryTransitionCertificate}^{\uparrow}$ packet. □

The later Lean file `lean4/BEDC/Derived/TheoryTransitionCertificateUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ TheoryTransitionCertificate}^{\uparrow}$ and $\mathsf{FieldFaithful\ TheoryTransitionCertificate}^{\uparrow}$ instances over the displayed fields $T_1, T_2, S, C, D, L, F, H, R, P, N$.

Falsifiable prediction: A transition packet that preserves old current predictions but drops a displayed ledger or failure-surface row is not an accepted TheoryTransitionCertificateUp packet.

Independence witness: realityconstrainedmodelaudit, physicaltruthcertificate, realityconstrained-explanation, realityconstrainedobjectivity, openfitpacket: none is bijective because TheoryTransitionCertificateUp binds two certified theory states and the transition rows between them, while the siblings certify audit, truth, explanation, objectivity, or open fit for a single presented claim.

Closure status for $\mathsf{NameCert}_{\mathsf{TheoryTransitionCertificate}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{TheoryTransitionCertificate}^{\uparrow}$ packet is generated from old and successor certified theory states, preserved signatures, classifier refinement, prediction and descent stability, ledger refinement, failure-surface refinement, componentwise transport, route replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TheoryTransitionCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1146.1, Definition 1146.2, Definition 1146.3, and Definition 1146.4 bind theory change as a finite transition packet over displayed certificate rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TheoryTransitionCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove identity of theories, final physical truth, unledgered prediction transfer, host semantic equivalence, Lean verification, or bridge checking for $\mathsf{TheoryTransitionCertificate}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, conservative preservation, ledger and failure-surface boundary, route replay, provenance, and local naming over the displayed transition rows.

Chapter 1147

A Concrete Naming Certificate for $\mathsf{OnticAdequacyAudit}^{\uparrow}$

The $\mathsf{OnticAdequacyAudit}^{\uparrow}$ packet realizes the adequacy discipline of section 9414.15 as one finite NameCert boundary. It sits after the ontic-source certificate of chapter 1125, the model-audit packet of chapter 1129, the tower certificate of chapter 1127, the stream-window surface of chapter 126, the regular-rational readback of chapter 301, and the Real carrier of chapter 38. Its role is to bind source, audit, Real-facing readback, classifier, residue, transport, route, provenance, and local naming rows before signature exactness is read as ontic adequacy.

Definition 1147.1 (Ontic adequacy audit carrier)**.** *An* $\mathsf{OnticAdequacyAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (O, M, S, R, E, K, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{OnticState}^{\uparrow}$ *source row naming the stable reality-facing source under audit.*
2. *M is the* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *row recording the finite source traces, observed signatures, model signatures, tower data, failure surface, strength, and audit ledger already accepted for the candidate model.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the finite observation windows that may be used for adequacy readback.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled windows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *facing row reached only through the displayed stream and regular-rational readback rows.*
6. *K is the signature classifier row comparing the ontic source signatures with the audited model signatures at the declared adequacy level.*
7. *L is the approximation and residue ledger, recording selected tower limits, rejected shortcut limits, unrepresented source content, and the gap between signature exactness and total ontic exhaustion.*
8. *H records componentwise* hsame *transport for the source, audit, stream, regular-rational, Real-facing, classifier, ledger, route, provenance, and local naming rows.*
9. *C records the displayed* Cont *route through $O, M, S, R, E, K, L, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{OnticAdequacyAudit}^{\uparrow}$, $\mathsf{OnticState}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$, $\mathsf{ObservationReflectionPacket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{OnticAdequacyAudit}^{\uparrow}}$ *row.*

The carrier contains no coordinate for host truth, unbounded observation, selected limits outside L, quotient-real equality, Real completeness as physical adequacy, or a detached model-syntax route. Signature exactness may be read as ontic adequacy only through the full displayed packet.

Lean4 ✓ `BEDC.Derived.OnticAdequacyAuditUp.OnticAdequacyAuditTasteGate single carrier alignment`

Theorem 1147.2 (Ontic adequacy audit NameCert obligations)**.** *For the carrier of Definition 1147.1, the local* $\mathsf{NameCert}_{\mathsf{OnticAdequacyAudit}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the finite packet $A = (O, M, S, R, E, K, L, H, C, P, N)$;*
2. *signature-exactness admission through the joint* $\mathsf{OnticState}^{\uparrow}$ *source row O,* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *audit row M, and classifier row K;*
3. *Real-facing readback admission through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows S, R, E;*
4. *residue-ledger exactness through L, including the selected tower limits, rejected shortcuts, and unrepresented source content;*
5. *non-escape from host truth, selected limits, quotient reals, Real completeness, and model syntax through componentwise transport, displayed replay, provenance, and local naming rows H, C, P, N.*

Thus an accepted adequacy read can promote signature exactness to ontic adequacy only when source trace, model audit, Real-facing readback, classifier, residue ledger, transport, route, provenance, and local name are displayed together.

Lean4 ✓ `BEDC.Derived.OnticAdequacyAuditUp.OnticAdequacyAudit semantic name certificate`

Proof. Carrier admission is projection from Definition 1147.1. The accepted tuple displays the ontic source O, the physical model audit M, the stream schedule S, the regular-rational readback R, the Real-facing row E, the classifier K, the residue ledger L, and the structural rows H, C, P, N.

The signature-exactness row is not a model-only comparison. It reads the source signatures from O, the audited model signatures from M, and the comparison row K inside the same packet. The Real-facing readback is likewise constrained: E is available only after the scheduled stream row S and regular-rational row R have been displayed.

The residue ledger closes the remaining adequacy boundary. Selected tower limits, rejected shortcut limits, and unrepresented source content must be recorded in L, so Real completion or quotient-real equality cannot replace the ledger. The rows H, C, P, N only transport, replay, source, and name the displayed packet. They add no host truth oracle, no hidden physical-object coordinate, and no second route from model syntax to ontic adequacy.

Therefore the five listed rows exhaust the local NameCert surface, and every accepted adequacy read remains inside the finite packet A. □

The Lean TasteGate file `lean4/BEDC/Derived/OnticAdequacyAuditUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{OnticAdequacyAudit}^{\uparrow}$ and FieldFaithful $\mathsf{OnticAdequacyAudit}^{\uparrow}$ instances preserving $O, M, S, R, E, K, L, H, C, P, N$ as separate displayed fields.

Falsifiable prediction: If the source-trace row or residue ledger is absent, no accepted OnticAdequacyAuditUp route can promote signature exactness to ontic adequacy.

Independence witness: onticstate, physicalmodelaudit, realityconstrainedapproximationtower, observationreflectionpacket, real: none is bijective because the audit packet binds source, audit, Real-facing readback, classifier, residue, transport, route, provenance, and local naming rows together.

Closure status for $\mathsf{NameCert}_{\mathsf{OnticAdequacyAudit}^{\uparrow}}$.

Constructive story: An $\mathsf{OnticAdequacyAudit}^{\uparrow}$ packet is generated from an ontic source row, physical model audit row, stream schedule, regular-rational readback, Real-facing row, signature classifier, approximation and residue ledger, componentwise hsame transport, displayed Cont route, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OnticAdequacyAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1147.1 and Definition 1147.2 bind the finite adequacy-audit carrier and its source, audit, readback, classifier, ledger, transport, route, provenance, and local naming obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OnticAdequacyAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, total physical ontology, host truth, quotient-real adequacy, selected-limit sufficiency, Real completeness as physical adequacy, or model syntax as ontic adequacy.

Upgrade path: Obligation closure requires checked carrier admission, signature-exactness admission, Real-facing readback admission, residue-ledger exactness, non-escape, TasteGate nontriviality, and field faithfulness for $O, M, S, R, E, K, L, H, C, P, N$.

Chapter 1148

A Concrete Naming Certificate for $\mathsf{ApproximationTowerResidue}^{\uparrow}$

The $\mathsf{ApproximationTowerResidue}^{\uparrow}$ packet realizes the hidden-source and failure-surface side of the approximation-tower vision in chapter 9414. It is adjacent to the indexed tower carrier of chapter 1127, the finite tower packet of chapter 1128, the audit surface of chapter 1129, the certified truth surface of chapter 1130, and the explanatory surface of chapter 1136. Those siblings expose approximation, packet routing, physical audit, certified truth, and explanation rows; this carrier isolates the residue row that prevents a hidden source or failed compression from being read as physical adequacy.

Definition 1148.1 (ApproximationTowerResidue carrier)**.** *An* $\mathsf{ApproximationTowerResidue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, T, C, L, F, U, D, H, K, P, N)$$

with the following displayed rows:

1. *S is the hidden-source residue row left by the tower compression;*
2. *T is the approximation-tower packet row whose compression produced the residue;*
3. *C is the classifier row recording the physical-signature comparison that remains under inspection;*
4. *L is the ledger row naming the GAP-admissible compression and every omitted source coordinate;*
5. *F is the failure-surface row naming finite defeating observations, signature gaps, or classifier mismatches;*
6. *U is the recovery-route row, recording which later observation or audit route may reopen the residue;*
7. *D is the descent-survivor row, recording which tower operations remain valid after the residue is exposed;*
8. *H records componentwise* hsame *transport for source, tower, classifier, ledger, failure, recovery, and descent rows;*
9. *K records displayed* Cont *replay through the same rows;*

10. *P is the* Pkg *provenance over* $\mathsf{ApproximationTowerResidue}^{\uparrow}$*, the five cited sibling chapters,* BHist, hsame, Cont, Pkg*, and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ApproximationTowerResidue}^{\uparrow}}$ *row.*

The carrier has no coordinate for promoting a hidden source, failed classifier, or unledgered residue into a certified physical adequacy claim.

Lean4 ✓ `BEDC.Derived.ApproximationTowerResidueUp.ApproximationTowerResidueTasteGate single carrier alignment`

Definition 1148.2 (ApproximationTowerResidue classifier)**.** *For accepted packets*

$$R = (S, T, C, L, F, U, D, H, K, P, N) \quad \text{and} \quad R' = (S', T', C', L', F', U', D', H', K', P', N'),$$

the predicate $\mathsf{ApproximationTowerResidueClassifier}(R, R')$ *holds when the hidden-source residue, tower packet, classifier, ledger, failure surface, recovery route, and descent-survivor rows are transported componentwise by H, H' and replayed by K, K' without changing which residue coordinates are still exposed.*

Classifier agreement therefore preserves the residue surface itself. It does not identify two tower endpoints, certify physical truth, or erase a failure row.

Lean4 (definition) `BEDC.Derived.ApproximationTowerResidueUp.ApproximationTowerResidueClassifier`

Theorem 1148.3 (ApproximationTowerResidue NameCert obligations)**.** *For the carrier of Definition 1148.1, the local* $\mathsf{NameCert}_{\mathsf{ApproximationTowerResidue}^{\uparrow}}$ *surface is exhausted by five obligation rows:*

1. *carrier admission for $R = (S, T, C, L, F, U, D, H, K, P, N)$;*
2. *hidden-source residue exposure through S together with the tower packet row T;*
3. *classifier and GAP-ledger accountability through C, L;*
4. *failure-surface and recovery-route exposure through F, U;*
5. *descent-survivor, transport, replay, provenance, and local naming through D, H, K, P, N.*

Every consumer that reads a residue, failure surface, recovery route, or descent survivor from an approximation tower must display these rows before it can export its conclusion.

Proof. Project the carrier in Definition 1148.1. The source residue S, tower row T, classifier C, ledger L, failure surface F, recovery route U, and descent survivor D are the only positive content rows.

The structural rows do not add another source. Transport through H, replay through K, provenance through P, and local naming through N preserve the same displayed residue packet.

Thus the NameCert surface is exactly the five listed obligation rows. A consumer that asks for hidden source material, failure evidence, recovery, or descent outside those rows has left the accepted $\mathsf{ApproximationTowerResidue}^{\uparrow}$ carrier. □

Lean4 ✓ `BEDC.Derived.ApproximationTowerResidueUp.TasteGate.ApproximationTowerResidueTasteGate single carrier alignment`

Theorem 1148.4 (ApproximationTowerResidue non-escape)**.** *An accepted* ApproximationTowerResidue$^{\uparrow}$ *packet cannot promote a hidden-source residue, omitted physical signature, failed classifier row, or unrecovered descent gap into physical adequacy. Any such promotion must first pass through*

$$S, T, C, L, F, U, D, H, K, P, N.$$

In particular, the packet exports no tower endpoint equality, certified physical truth, host-level model adequacy, unbounded validation route, or ambient completeness row.

Proof. Begin with the NameCert obligations of Definition 1148.3. They force every residue-facing read to expose the hidden-source row, tower packet, classifier, ledger, failure surface, recovery route, and descent survivor before any conclusion is exported.

The five sibling chapters supply larger consumer surfaces, but none supplies permission to erase the residue row. The tower and packet chapters expose approximation routes, the audit chapter reads physical fit, the certified-truth chapter reads a finite truth certificate, and the explanation chapter reads explanatory descent; each route still requires the local residue packet when the hidden-source surface is under inspection.

Therefore a hidden source, failure row, or recovery gap cannot be reinterpreted as physical adequacy by structural transport. The rows H, K, P, N only preserve and name the displayed packet, so all stronger claims are outside the carrier. □

Lean4 ✓ `BEDC.Derived.ApproximationTowerResidueUp.ApproximationTowerResidueCarrier hidden source nonescape`

Theorem 1148.5 (ApproximationTowerResidue recovery-route determinacy)**.** *For an accepted* ApproximationTowerResidue$^{\uparrow}$ *carrier* $R = (S, T, C, L, F, U, D, H, K, P, N)$*, every recovery-route consumer factors through the same residue ledger rows* S, T, C, L, F, U, D *and the same structural rows* H, K, P, N*. A recovery read may reopen the finite source or failure surface named by* U*, but it cannot add a private source row, second classifier, unledgered descent operation, certified-truth row, or physical-audit acceptance row.*

Lean4 ✓ `BEDC.Derived.ApproximationTowerResidueUp.ApproximationTowerResidue recovery route determinacy`

Proof. Use the classifier of Definition 1148.2 to keep the source residue, tower packet, classifier, ledger, failure surface, recovery route, and descent survivor componentwise aligned.

Apply Definition 1148.3. The recovery route is one of the local obligation rows, so a consumer sees U only together with $S, T, C, L, F, D, H, K, P, N$.

Finally use the non-escape theorem. Since certified truth and physical-audit acceptance require their own displayed carriers, the residue recovery route cannot supply those rows by itself. It only names the finite route along which the residue can be inspected again. □

The Lean follow-up path `lean4/BEDC/Derived/ApproximationTowerResidueUp/TasteGate.lean` must provide explicit Nontrivial ApproximationTowerResidue$^{\uparrow}$ and FieldFaithful ApproximationTowerResidue$^{\uparrow}$ instances. These instances must distinguish the hidden-source residue, tower packet, classifier, ledger, failure surface, recovery route, descent survivor, transport, replay, provenance, and local NameCert rows.

Falsifiable prediction: If the residue row is absent, an approximation-tower packet cannot promote a hidden-source failure into a certified physical adequacy claim.

Independence witness: reality-constrained-approximation-tower, reality-constrained-tower-packet, physical-model-audit, certified-physical-truth, reality-constrained-explanation: none is bijective because $\mathsf{ApproximationTowerResidue}^{\uparrow}$ carries the hidden-source residue, failure surface, recovery route, descent survivor, and local NameCert rows as one finite packet, while the siblings expose tower structure, packet routing, audit, truth, or explanation without isolating this residue surface.

Theorem 1148.6 (ApproximationTowerResidue scope lock)**.** *Every residue-facing consumer of* $\mathsf{ApproximationTowerResidue}^{\uparrow}$ *is scoped exactly by the carrier of Definition 1148.1, the classifier of Definition 1148.2, the NameCert obligations of Definition 1148.3, the non-escape boundary of Definition 1148.4, the recovery-route determinacy of Definition 1148.5, the falsifiable prediction, the independence witness, and the displayed TasteGate marker. No consumer may add a private hidden-source coordinate, second classifier, unledgered recovery route, or physical-adequacy export outside that finite packet.*

Lean4 ✓ `BEDC.Derived.ApproximationTowerResidueUp.ApproximationTowerResidue scope lock`

Proof. The carrier lists the only rows a residue-facing consumer can project: hidden-source residue, tower packet, classifier, GAP ledger, failure surface, recovery route, descent survivor, transport, replay, provenance, and local naming.

The classifier and NameCert obligations then force every accepted read to keep those rows componentwise visible. The non-escape theorem blocks adequacy export, while recovery-route determinacy keeps every reopened route inside the same ledger.

The falsifiable prediction and independence witness record the observable boundary against sibling chapters, and the TasteGate marker identifies the same finite carrier as the chapter's accepted packet. Hence the scoped surface is precisely the listed carrier, classifier, obligations, boundary theorems, witness rows, and marker. □

Closure status for $\mathsf{NameCert}_{\mathsf{ApproximationTowerResidue}^{\uparrow}}$.

Constructive story: An $\mathsf{ApproximationTowerResidue}^{\uparrow}$ packet is generated from the hidden-source residue row, approximation-tower packet row, classifier row, GAP-admissible ledger, failure surface, recovery route, descent survivor, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApproximationTowerResidue}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: The public route is Definition 1148.1, Definition 1148.2, Definition 1148.3, Definition 1148.4, Definition 1148.5, Definition 1148.6, the falsifiable prediction, the independence witness, and the TasteGate marker for the same finite residue packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApproximationTowerResidue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide Lean verification, bridge checking, physical adequacy, hidden-source promotion, certified physical truth, or a host-level model-adequacy row for $\mathsf{ApproximationTowerResidue}^{\uparrow}$.

Upgrade path: Public closure requires checked carrier admission, classifier preservation, residue non-escape, recovery-route determinacy, transport closure, and TasteGate nontriviality with field faithfulness.

Chapter 1149

A Concrete Naming Certificate for $\mathsf{ReflectiveStability}^{\uparrow}$

The $\mathsf{ReflectiveStability}^{\uparrow}$ packet realizes the reflective stability certificate of chapter 9414 as a finite NameCert surface. It consumes the source and classifier rows of chapter 1126, the checkpoint boundary of chapter 997, the model-audit row of chapter 1124, the closed observation carrier of chapter 616, and the finite observation interface of chapter 1007. Its role is to certify reuse under displayed continuations without exporting final truth or source-domain identity.

Definition 1149.1 (ReflectiveStability carrier)**.** *A* $\mathsf{ReflectiveStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, K, A, Q, O, F, T, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source row inherited from an* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *inquiry;*
2. *K is the checkpoint row naming the visible* $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ *reuse boundary;*
3. *A is the classifier and audit row inherited from* $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$*;*
4. *Q is the open-continuation row under which the self-description may be reused;*
5. *O is the closed observation row inherited from* $\mathsf{ClosedObservationSystem}^{\uparrow}$*;*
6. *F is the finite interface row inherited from* $\mathsf{FiniteObservationInterface}^{\uparrow}$*;*
7. *T is the transport row carrying componentwise* hsame *comparisons among the displayed source, checkpoint, classifier, observation, and interface rows;*
8. *L is the ledger row recording hidden source material, rejected finality claims, and source-domain separation;*
9. *H is the finite* BHist *carrier row for the reuse trace;*
10. *C is the displayed* Cont *route through the accepted reuse continuation;*
11. *P is the* Pkg *provenance over the same source, checkpoint, classifier, continuation, observation, interface, transport, and ledger rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ReflectiveStability}^{\uparrow}}$ *row naming exactly this packet.*

The carrier has no coordinate for a final truth predicate, an identity between physical source and formal source, a host validation oracle, or an undisplayed checkpoint.

Lean4 ✓ `BEDC.Derived.ReflectiveStabilityUp.ReflectiveStabilityTasteGate single carrier alignment`

Theorem 1149.2 (ReflectiveStability NameCert obligations)**.** *For the carrier of Definition 1149.1, the local* $\mathsf{NameCert}_{\mathsf{ReflectiveStability}^{\uparrow}}$ *surface consists exactly of seven finite obligations:*

1. *carrier admission for the displayed packet* $R = (S, K, A, Q, O, F, T, L, H, C, P, N)$*;*
2. *source exposure, requiring every reuse read to begin from the displayed* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *source row* S*;*
3. *checkpoint exposure, requiring every reflected self-description to pass through the visible checkpoint row* K*;*
4. *classifier and audit exposure, requiring reuse to preserve the displayed audit row* A *before any continuation read;*
5. *open-continuation stability, requiring* Q *and* C *to expose the continuation under which reuse is licensed;*
6. *observation and interface stability, requiring* O *and* F *to keep the closed observation and finite interface rows visible;*
7. *transport, ledger, provenance, history, and local naming closure through* T, L, H, P, N*.*

Thus reflective stability is certified as finite reuse under displayed rows, not as a total self-truth principle.

Proof. Carrier admission is projection from Definition 1149.1. The twelve rows $S, K, A, Q, O, F, T, L, H, C, P, N$ are the complete finite packet visible to a consumer.

Source, checkpoint, and classifier exposure come from the inbound packets. The source row is read through chapter 1126; the checkpoint row is read through chapter 997; the classifier and audit row is read through chapter 1124. These rows describe reuse of a self-description, not identity with the source domain.

The continuation and observation rows then delimit the reuse claim. The open-continuation row Q and displayed route C state where the certificate may be replayed, while O and F keep the closed observation and finite interface surfaces visible.

Finally the transport, ledger, history, provenance, and local naming rows close the certificate. Since T, L, H, P, N add no final truth coordinate and no hidden checkpoint coordinate, the seven obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.ReflectiveStabilityUp.ReflectiveStabilityCarrier namecert obligations`

Theorem 1149.3 (ReflectiveStability anchor stability)**.** *Every accepted* $\mathsf{ReflectiveStability}^{\uparrow}$ *packet preserves the same displayed anchor rows* S, K, A, O, F *whenever its self-description is reused under* Q *through the displayed* Cont *route* C*. A consumer may transport these anchors through* T *and record the reuse in* L, H, P, N*, but it cannot replace them by a detached source, an undisplayed checkpoint, a hidden classifier, an unbounded observation stream, or a host validation route.*

Proof. Read the accepted carrier of Definition 1149.1. The only anchor rows available for reuse are S, K, A, O, F, and the only continuation route available for reuse is Q through C.

Apply the obligation surface of Definition 1149.2. It requires source exposure, checkpoint exposure, classifier and audit exposure, open-continuation stability, and observation-interface stability before any consumer may read the local NameCert row.

The remaining structural rows only preserve the displayed anchors. Componentwise hsame transport at T, ledgering at L, history at H, package provenance at P, and local naming at N record the same finite route. None of these rows contains a detached source, hidden classifier, unbounded observation stream, or host validation route. □

Lean4 ✓ `BEDC.Derived.ReflectiveStabilityUp.ReflectiveStabilityCarrier anchor stability`

Theorem 1149.4 (ReflectiveStability nonescape)**.** *No accepted* $\mathsf{ReflectiveStability}^{\uparrow}$ *packet exports final truth, source-domain identity, host validation, or an undisplayed reflection checkpoint beyond the rows*

$$S, K, A, Q, O, F, T, L, H, C, P, N.$$

Every reflective reuse read must remain inside the displayed finite source, checkpoint, classifier, open-continuation, transport, ledger, provenance, and local NameCert packet.

Lean4 ✓ `BEDC.Derived.ReflectiveStabilityUp.ReflectiveStabilityCarrier nonescape`

Proof. Inspect the carrier. Its only truth-facing row is the finite classifier and audit row A, its only reflection-facing row is the checkpoint row K, and its only future-facing rows are the open continuation Q and displayed route C.

Use anchor stability from Definition 1149.3. Any consumer that reuses the self-description must preserve S, K, A, O, F and may only transport them through T while recording the route in L, H, P, N.

The ledger row records the excluded demands as non-exported material. Final truth, source-domain identity, host validation, and undisplayed checkpoints therefore have no carrier coordinate through which they can be read. □

Falsifiable prediction: No accepted $\mathsf{ReflectiveStability}^{\uparrow}$ packet exports final truth or source-domain identity beyond its displayed finite source, checkpoint, classifier, open-continuation, transport, ledger, provenance, and local NameCert rows.

Independence witness: observationreflectionpacket, reflectionruntimecheckpoint, realityconstrained-modelaudit, closedobservationsystem, finiteobservationinterface: $\mathsf{ReflectiveStability}^{\uparrow}$ is not bijective to any listed sibling because it simultaneously carries finite source access, visible checkpoint reuse, classifier audit, open continuation, closed observation, finite interface, componentwise transport, hidden-material ledger, replay history, displayed route, package provenance, and local naming rows. The observation packet lacks checkpoint-stability reuse; the runtime checkpoint lacks the model-audit and finite observation interface rows; the model audit lacks the open continuation and checkpoint reuse rows; the closed observation system lacks the reflection classifier; the finite observation interface lacks the ledgered stability certificate.

The Lean follow-up in `lean4/BEDC/Derived/ReflectiveStabilityUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{ReflectiveStability}^{\uparrow}$ and FieldFaithful $\mathsf{ReflectiveStability}^{\uparrow}$ instances preserving $S, K, A, Q, O, F, T, L, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{ReflectiveStability}^{\uparrow}}$.

Constructive story: A $\mathsf{ReflectiveStability}^{\uparrow}$ packet is generated from finite source access, a visible reflection checkpoint, classifier audit data, an open continuation, closed observation and finite interface rows, componentwise transport, a hidden-material ledger, replay history, displayed route, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ReflectiveStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1149.1, Definition 1149.2, Definition 1149.3, and Definition 1149.4 bind the finite reflective stability packet and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ReflectiveStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert final truth, source-domain identity, host validation, undisplayed checkpoints, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of the packet carrier, NameCert obligations, anchor stability, non-escape boundary, TasteGate nontriviality, and field faithfulness for $S, K, A, Q, O, F, T, L, H, C, P, N$.

Chapter 1150

A Concrete Naming Certificate for $\mathsf{AnchorStabilityCertificate}^{\uparrow}$

The $\mathsf{AnchorStabilityCertificate}^{\uparrow}$ packet realizes the anchor-stability coordinate of section 9414.30 as a finite NameCert carrier. It sits behind the anchor-stability row consumed by chapter 1138: $\mathsf{RelationalObjectivity}^{\uparrow}$ reads a relational claim only after this certificate has bound the invariant row, the anchor-change route, the classifier, the ledger, and the local naming row. Its sibling context is supplied by $\mathsf{ObserverHistIdentity}^{\uparrow}$ in chapter 479, $\mathrm{MultiHistConfig}^{\uparrow}$ in chapter 474, $\mathsf{CrossPerspectiveAlignment}^{\uparrow}$ in chapter 643, and $\mathsf{LocalityCell}^{\uparrow}$ in chapter 509.

Definition 1150.1 (Anchor-stability certificate carrier)**.** *An* $\mathsf{AnchorStabilityCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (F, I, R, K, L, H, C, P, N)$$

with the following displayed rows:

1. *F is the observer-family row read through* $\mathrm{MultiHistConfig}^{\uparrow}$ *and the relevant* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *surfaces;*
2. *I is the invariant row whose claim is being transported across observer anchors;*
3. *R is the anchor-change route naming the source anchor, target anchor, and locality-cell boundary through which the comparison is allowed to move;*
4. *K is the classifier row that compares the transported invariant at the two anchors;*
5. *L is the ledger row recording the observations, transformations, and cross-perspective alignment facts used in the comparison;*
6. *H records componentwise* hsame *transports for the observer-family, invariant, route, classifier, ledger, package, and local naming rows;*
7. *C records displayed* Cont *routes from the observer-family surface to the anchor-change route, from the route to classifier comparison, and from the accepted certificate to downstream relational-objectivity consumers;*
8. *P is the* Pkg *provenance over* $\mathsf{AnchorStabilityCertificate}^{\uparrow}$, $\mathsf{RelationalObjectivity}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathrm{MultiHistConfig}^{\uparrow}$, $\mathsf{CrossPerspectiveAlignment}^{\uparrow}$, $\mathsf{LocalityCell}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AnchorStabilityCertificate}^{\uparrow}}$ *row.*

The classifier for accepted carriers compares exactly $F, I, R, K, L, H, C, P, N$. It has no coordinate for a privileged observer, an unledgered anchor jump, a hidden invariant source, a global synchronization history, or host equality of observer descriptions.

Lean4 (definition) `BEDC.Derived.AnchorStabilityCertificateUp.AnchorStabilityCertificateUp`

Theorem 1150.2 (Anchor-stability certificate NameCert obligations)**.** *For every accepted* AnchorStabilityCertificate *carrier $A = (F, I, R, K, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AnchorStabilityCertificate}^{\uparrow}}$ *surface consists exactly of observer-family exposure through F, invariant-row exposure through I, anchor-change routing through R, classifier comparison through K, observation-and-transformation ledger exposure through L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.AnchorStabilityCertificateUp.AnchorStabilityCertificateTasteGate single carrier alignment`

Proof. Project the accepted packet. The rows F, I, R, K, L display the family, invariant, route, classifier, and ledger coordinates that make anchor stability inspectable.

Read the structural rows next. The transport row H compares the same displayed coordinates componentwise, the continuation row C replays only the displayed route, and the package and local name rows P, N locate the certificate inside the surrounding NameCert surface.

The sibling chapters supply the required inputs but not the whole certificate. $\mathsf{ObserverHistIdentity}^{\uparrow}$ and $\mathrm{MultiHistConfig}^{\uparrow}$ supply observer-family structure, $\mathsf{CrossPerspectiveAlignment}^{\uparrow}$ supplies alignment evidence, and $\mathsf{LocalityCell}^{\uparrow}$ supplies the local anchor boundary; the present packet is where those rows are stored together with the invariant row and classifier. □

Theorem 1150.3 (Anchor-stability certificate nonescape)**.** *Every accepted* $\mathsf{AnchorStabilityCertificate}^{\uparrow}$ *consumer reads anchor stability through the displayed packet*

$$F, I, R, K, L, H, C, P, N.$$

The consumer has no route to a privileged observer, unledgered anchor transport, hidden synchronization, detached invariant evidence, host-level equality of observers, or a relational-objectivity verdict outside that packet.

Lean4 ✓ `BEDC.Derived.AnchorStabilityCertificateUp.AnchorStabilityCertificateCarrier nonescape`

Proof. Use the carrier definition. Any accepted read must first expose the observer-family row F, invariant row I, anchor-change route R, classifier row K, and ledger row L.

The transport and continuation rows preserve that exposed packet. They may move the displayed invariant along the recorded route and replay the classifier comparison, but they do not add a second route, hidden observer anchor, or host equality coordinate.

Finally inspect the downstream use in $\mathsf{RelationalObjectivity}^{\uparrow}$. A relational-objectivity read can consume the certificate only as the anchor-stability row already displayed here. If the certificate is absent, detached from its ledger, or transported across anchors without R, K, L, H, C, P, N, the consumer leaves the accepted $\mathsf{AnchorStabilityCertificate}^{\uparrow}$ surface. □

Theorem 1150.4 (Anchor-stability route exhaustion)**.** *Every anchor-stability read that is accepted by* $\mathsf{AnchorStabilityCertificate}^{\uparrow}$ *exposes the full packet*

$$F, I, R, K, L, H, C, P, N$$

and the sibling rows ObserverHistIdentity$^{\uparrow}$, MultiHistConfig$^{\uparrow}$, CrossPerspectiveAlignment$^{\uparrow}$, *and* LocalityCell$^{\uparrow}$ *before any* RelationalObjectivity$^{\uparrow}$ *consumer receives the invariant. The certificate has no route that sends an invariant to relational objectivity while skipping observer identity, multi-history configuration, cross-perspective alignment, locality-cell locality, or one of the displayed packet rows.*

Lean4 ✓ `BEDC.Derived.AnchorStabilityCertificateUp.AnchorStabilityCertificateCarrier route exhaustion`

Proof. Project the carrier of Definition 1150.1. The rows F, I, R, K, L expose the observer family, invariant, route, classifier, and ledger, while H, C, P, N expose transport, continuation, provenance, and local naming.

Read the sibling inputs through the same displayed rows. ObserverHistIdentity$^{\uparrow}$ and MultiHistConfig$^{\uparrow}$ supply the observer-family surface, CrossPerspectiveAlignment$^{\uparrow}$ supplies the alignment row, and LocalityCell$^{\uparrow}$ supplies the admissible locality boundary.

Now pass to the relational-objectivity consumer. By Definition 1150.3, the consumer can receive anchor stability only through the displayed certificate packet, so no unlisted sibling row or hidden anchor route can carry the invariant onward. □

Falsifiable prediction: A relational objectivity read fails whenever its invariant row is transported across observer anchors without the displayed anchor-stability certificate.

Independence witness: relationalobjectivity, observerhistidentity, multihistconfig, crossperspectivealignment, localitycell: none is bijective to AnchorStabilityCertificateUp because none stores the invariant row, anchor-change route, classifier, ledger, and local NameCert as one certificate.

The Lean file 'TasteGate.lean' for BEDC.Derived.AnchorStabilityCertificateUp must provide Nontrivial AnchorStab and FieldFaithful AnchorStabilityCertificate$^{\uparrow}$ instances for the displayed carrier $F, I, R, K, L, H, C, P, N$.

Closure status for NameCert$_{\text{AnchorStabilityCertificate}^{\uparrow}}$.

Constructive story: An AnchorStabilityCertificate$^{\uparrow}$ packet is generated from an observer-family row, invariant row, anchor-change route, classifier row, ledger row, componentwise transport, displayed continuation routes, package provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{AnchorStabilityCertificate}^{\uparrow}}$, scopedClosed)

Scope closed: The scoped surface records the carrier, NameCert obligations, nonescape theorem, route-exhaustion theorem, TasteGate marker, falsifiable prediction, and independence witness for reads through $F, I, R, K, L, H, C, P, N$.

Formal verification: FormalStatus(NameCert$_{\text{AnchorStabilityCertificate}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean TasteGate, Nontrivial, FieldFaithful, or checked NameCert obligations for anchor-stability certificates.

Upgrade path: Promotion beyond seed requires Lean TasteGate, Nontrivial, FieldFaithful, and NameCert checks for the displayed carrier and nonescape surface.

Chapter 1151

A Concrete Naming Certificate for $\mathsf{ReflectiveInquiry}^{\uparrow}$

The $\mathsf{ReflectiveInquiry}^{\uparrow}$ packet realizes the reflective inquiry system of Definition 9414.409 as a finite NameCert carrier. It places physical inquiry and MetaCIC self-study in one certificate surface without identifying their sources: physical observation contributes source-access and model-audit rows, while formal reflection contributes source-access and self-study rows. The bridge is a role correspondence, not a truth oracle.

Its physical audit rows are read through chapter 1124, and its observation-reflection packet rows are read through chapter 1126.

Definition 1151.1 (Reflective inquiry carrier)**.** *A* $\mathsf{ReflectiveInquiry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (P, F, S, K, A, R, L, H, C, Q, N)$$

with the following displayed rows:

1. *P is the physical inquiry source row, read through observational traces and the physical model-audit surface;*
2. *F is the formal inquiry source row, read through MetaCIC source access and reflected self-study;*
3. *S is the signature row comparing physical observation signatures with formal source signatures;*
4. *K is the classifier row that records which role correspondences are accepted;*
5. *A is the package row storing the accepted physical and formal inquiry roles as one certificate packet;*
6. *R records componentwise* hsame *transports for the physical source, formal source, signature, classifier, package, ledger, continuation, and local naming rows;*
7. *L is the ledger row preserving failed fits, hidden-source refusals, rejected source-identifications, and non-finality demands;*
8. *H is the finite history row through which accepted inquiry reads are replayed;*
9. *C is the displayed* Cont *route for extending either the physical inquiry or the formal self-study without closing it;*
10. *Q is the open-continuation row recording that the certificate remains usable only under further inquiry;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ReflectiveInquiry}^{\uparrow}}$ *row.*
The carrier has no coordinate for a final truth oracle, a physical-formal source identity, a host-level validation route, or an unledgered self-study claim.

Lean4 (definition) `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryCarrier`

Definition 1151.2 (Reflective inquiry classifier)**.** *The* $\mathsf{ReflectiveInquiry}^{\uparrow}$ *classifier compares accepted carriers by the displayed rows $P, F, S, K, A, R, L, H, C, Q, N$. Two carriers classify together only when their physical source rows, formal source rows, signature rows, accepted role correspondences, package rows, transports, ledgers, replay histories, continuation routes, open-continuation rows, and local names agree componentwise through the certificate surface.*

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryClassifierAuditCertificate`

Theorem 1151.3 (Reflective inquiry NameCert obligation surface)**.** *For the carrier of Definition 1151.1, the local* $\mathsf{NameCert}_{\mathsf{ReflectiveInquiry}^{\uparrow}}$ *surface consists exactly of physical-source exposure through P, formal-source exposure through F, signature comparison through S, classifier acceptance through K, package admission through A, componentwise transport through R, ledger preservation through L, replay history through H, displayed continuation through C, open-continuation non-finality through Q, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryNameCertObligationSurface`

Proof. Carrier admission projects the displayed packet $I = (P, F, S, K, A, R, L, H, C, Q, N)$. The two source rows P and F are separate coordinates, so the certificate can read both physical inquiry and formal self-study without identifying them.

The signature, classifier, and package rows bind the bridge. The row S records the visible signatures, K records the accepted role correspondence, and A stores the resulting packet as a NameCert object rather than as an external validation oracle.

The structural rows close the local obligation surface. Transport R, ledger L, replay history H, continuation C, open-continuation row Q, and local name N preserve the accepted route while recording failed fits and non-finality demands. Since no further coordinate exists, the listed obligations exhaust the surface. □

Theorem 1151.4 (Reflective inquiry non-escape)**.** *An accepted* $\mathsf{ReflectiveInquiry}^{\uparrow}$ *packet cannot export a final truth oracle, identify physical reality with MetaCIC, replace either source row by the other, or hide a self-study claim outside*

$$P, F, S, K, A, R, L, H, C, Q, N.$$

Every consumer of the observation–reflection bridge must pass through the displayed physical source, formal source, signature, classifier, package, ledger, replay, continuation, open-continuation, and local NameCert rows.

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryUp nonescape`

Proof. Start from the carrier of Definition 1151.1. The physical source row P and formal source row F are both displayed and distinct, while the classifier row K records only accepted role correspondences between them.

Apply the classifier of Definition 1151.2. A comparison can use $P, F, S, K, A, R, L, H, C, Q, N$ only through componentwise certificate agreement, so it has no hidden coordinate for a final truth oracle or a source-domain identity.

Use the obligation surface of Definition 1151.3. The ledger row L records failed fits and rejected source-identifications, and the open-continuation row Q keeps both inquiry directions non-final. Hence every bridge consumer remains inside the displayed finite packet. □

Theorem 1151.5 (Reflective inquiry source separation)**.** *For every accepted* $\mathsf{ReflectiveInquiry}^{\uparrow}$ *carrier*

$$I = (P, F, S, K, A, R, L, H, C, Q, N),$$

the physical source row P and the formal source row F remain distinct carrier coordinates under classifier agreement. Agreement through $S, K, A, R, L, H, C, Q, N$ records a role correspondence between the sources, not an identity of the physical inquiry source with the formal self-study source.

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryUp source separation transport`

Proof. Project the carrier of Definition 1151.1. The rows P and F are listed as separate displayed coordinates, one for physical inquiry and one for formal inquiry.

Apply the classifier of Definition 1151.2. It compares accepted carriers componentwise through $P, F, S, K, A, R, L, H, C, Q, N$, so agreement preserves both source rows rather than replacing either one.

Use the obligation surface and non-escape theorem. The local NameCert exposes both source rows, while Definition 1151.4 blocks physical-formal source identity and source replacement outside the displayed packet. □

Theorem 1151.6 (Reflective inquiry open-continuation preservation)**.** *In every accepted* $\mathsf{ReflectiveInquiry}^{\uparrow}$ *packet, the open-continuation row Q prevents either the physical route through P or the formal route through F from becoming a final truth oracle. The certificate may replay and extend inquiry through H and C, but it keeps both source routes open to further inquiry.*

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiry open continuation row separation`

Proof. Start with the carrier. The row Q is displayed as the open-continuation row, while H and C record replay history and displayed continuations for accepted inquiry reads.

Use the NameCert obligation surface. It requires open-continuation non-finality through Q as part of the local certificate, not as an optional annotation outside the packet.

Apply non-escape. Since no final truth oracle is a carrier coordinate and every consumer remains inside $P, F, S, K, A, R, L, H, C, Q, N$, neither source route can be closed by replay or continuation alone. □

Theorem 1151.7 (Reflective inquiry ledgered role correspondence)**.** *The physical/formal role correspondence in an accepted* $\mathsf{ReflectiveInquiry}^{\uparrow}$ *packet is read through the rows*

$$S, K, A, R, L, H, C, Q, N,$$

together with the displayed source rows P, F. It is not read through source identity, host-level validation, or an unledgered self-study claim.

Proof. Read the bridge rows from the carrier and classifier. The signature row S, classifier row K, package row A, transport row R, ledger row L, replay row H, continuation row C, open-continuation row Q, and local naming row N are the displayed route by which the two source rows are compared.

Use the NameCert obligation surface. The certificate exposes the role correspondence through signature comparison, classifier acceptance, package admission, ledger preservation, replay, continuation, non-finality, and local naming.

Finally apply non-escape. The packet has no coordinate for source identity, host validation, or hidden self-study, so the role bridge is ledgered through the displayed rows rather than through identity of P and F. □

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiry ledgered role correspondence`

Theorem 1151.8 (Reflective inquiry TasteGate obligation closure)**.** *The finite packet rows already exposed by Definition 1151.1, Definition 1151.3, Definition 1151.4, Definition 1151.5, Definition 1151.6, and Definition 1151.7 are exactly the rows consumed by the TasteGate single-carrier alignment for* $\mathsf{ReflectiveInquiry}^{\uparrow}$*. Hence any obligation-closure read of this packet must cite the TasteGate marker before moving beyond seed closure, and that citation verifies single-carrier alignment rather than creating a paper-side closure consequence.*

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryTasteGate single carrier alignment`

Proof. Project the carrier $I = (P, F, S, K, A, R, L, H, C, Q, N)$. The carrier and classifier rows expose physical source access, formal source access, signature comparison, role classification, package admission, transport, ledger preservation, replay history, continuation, open-continuation non-finality, and local naming.

Use the NameCert obligation surface together with non-escape and source separation. These results show that the same rows are the only admissible local certificate surface, that no final truth oracle or source identity can be exported, and that P and F remain separate under classifier agreement.

Use open-continuation preservation and ledgered role correspondence. They keep the inquiry route non-final while forcing the role bridge through $S, K, A, R, L, H, C, Q, N$ and the displayed source rows P, F.

The Lean TasteGate theorem is the verification touchpoint for single-carrier alignment on precisely this finite row list. It is therefore the marker required before any obligation-closure read moves past seed closure; it does not by itself upgrade the paper closure axis. □

Theorem 1151.9 (Reflective inquiry ground-compiler obligation route)**.** *The TasteGate alignment of Definition 1151.8 feeds the ground compiler exactly the displayed* BHist *rows*

$$P, F, S, K, A, R, L, H, C, Q, N.$$

The physical source row P, formal source row F, signature row S, classifier row K, package row A, transport row R, ledger row L, replay row H, continuation row C, open-continuation row Q, and local naming row N are the only carrier rows available to a compiler-side obligation read.

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryGroundCompilerObligationRoute`

Proof. Project the carrier of Definition 1151.1. Its coordinates are already BHist rows, so a ground-compiler read receives row data rather than a prose description of inquiry.

Use Definition 1151.8. The TasteGate marker verifies single-carrier alignment for the same finite row list, which is the input surface the ground compiler may inspect.

Finally apply non-escape and ledgered role correspondence. They prevent the compiler route from adding a final truth oracle, source-domain identity, host validation row, or unledgered self-study claim outside $P, F, S, K, A, R, L, H, C, Q, N$. □

Theorem 1151.10 (Reflective inquiry FieldFaithful row separation)**.** *The carrier rows used by any future FieldFaithful witness for* $\mathsf{ReflectiveInquiry}^{\uparrow}$ *are separated by role: P and F are source rows, S and K are comparison and acceptance rows, A is package admission, R is componentwise transport, L is ledger preservation, H and C are replay and continuation rows, Q is open-continuation non-finality, and N is local naming. No two of these roles are identified by the classifier.*

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryFieldFaithfulRowSeparation`

Proof. Read the classifier of Definition 1151.2. It compares accepted carriers componentwise through the displayed row names, so each row role remains visible under classifier agreement.

Apply source separation and open-continuation preservation. Source separation keeps P and F distinct, while open-continuation preservation keeps Q separate from replay H and continuation C.

Use the obligation surface for the remaining roles. Signature, classifier, package, transport, ledger, replay, continuation, non-finality, and naming are all named separately in the local $\mathsf{NameCert}_{\mathsf{ReflectiveInquiry}^{\uparrow}}$ surface, which is exactly the row separation a FieldFaithful witness must preserve. □

Theorem 1151.11 (Reflective inquiry nontrivial witness route)**.** *There are two accepted* $\mathsf{ReflectiveInquiry}^{\uparrow}$ *packet shapes with the same physical source, formal source, signature, classifier, package, transport, ledger, replay, continuation, and local naming rows, but with distinct open-continuation rows. They are displayed as*

$$I_0 = (P, F, S, K, A, R, L, H, C, Q_0, N)$$

and

$$I_1 = (P, F, S, K, A, R, L, H, C, Q_1, N),$$

where Q_0 records one admissible further-inquiry opening and Q_1 records a different admissible further-inquiry opening.

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryNontrivialWitnessRoute`

Proof. Start from the carrier definition. The open-continuation row is an ordinary displayed coordinate, so replacing Q by another accepted open-continuation row yields a packet shape with the same source, bridge, ledger, replay, continuation, and naming surface.

The two packets remain accepted because each keeps the non-finality obligation in the same coordinate. The distinction is not a change of physical source, formal source, classifier, package, ledger, replay, or local name; it is exactly the difference between Q_0 and Q_1.

Apply open-continuation preservation and non-escape. Both rows refuse a final truth oracle and keep inquiry open, while the packet exposes no hidden coordinate that could collapse the two accepted openings into host equality. □

Falsifiable prediction: An accepted $\mathsf{ReflectiveInquiry}^{\uparrow}$ packet cannot export a final truth oracle or identify physical reality with MetaCIC without losing either the physical-source row or the formal-source row.

Independence witness: observationreflectionpacket, physicalmodelaudit, reflectivestability, finite-traceevaluator, truthtotalreflection: none is bijective because $\mathsf{ReflectiveInquiry}^{\uparrow}$ carries both physical and formal source rows together with role correspondence, ledger preservation, and open-continuation non-finality.

The Lean follow-up in `lean4/BEDC/Derived/ReflectiveInquiryUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{ReflectiveInquiry}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ReflectiveInquiry}^{\uparrow}$ instances preserving $P, F, S, K, A, R, L, H, C, Q, N$.

Theorem 1151.12 (Reflective inquiry obligation-closure package)**.** *The displayed rows*

$$P, F, S, K, A, R, L, H, C, Q, N$$

form the complete obligation-closure package consumed by ReflectiveInquiry$^{\uparrow}$*. The package exposes carrier and classifier data, non-escape, source separation, open-continuation preservation, ledgered role correspondence, TasteGate single-carrier alignment, and the paper Nontrivial and FieldFaithful routes, all over the same finite* BHist *carrier.*

Lean4 ✓ `BEDC.Derived.ReflectiveInquiryUp.ReflectiveInquiryObligationClosurePackage`

Proof. Project the carrier of Definition 1151.1. The classifier of Definition 1151.2 reads exactly the rows $P, F, S, K, A, R, L, H, C, Q, N$, so the carrier and classifier exposure use the same finite packet.

Use the named boundary theorems. Theorem 1151.3 supplies the local NameCert surface, Definition 1151.4 supplies non-escape, Definition 1151.5 supplies source separation, and Definition 1151.6 keeps both inquiry routes open.

Add the correspondence and gate rows. Theorem 1151.7 forces the physical/formal bridge through the ledgered rows, while Definition 1151.8 records TasteGate single-carrier alignment for the same row list.

The paper Nontrivial and FieldFaithful routes are exactly the two displayed row routes of Definition 1151.11 and Definition 1151.10. Since no row remains for a final truth oracle, source identity, host validation, or unledgered self-study, no such obligation can enter the package. □

Closure status for NameCert$_{\text{ReflectiveInquiry}^{\uparrow}}$**.**

Constructive story: A ReflectiveInquiry$^{\uparrow}$ packet is generated from physical source access, formal source access, signature comparison, role classification, package admission, componentwise transport, ledger preservation, replay history, displayed continuation, open-continuation non-finality, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{ReflectiveInquiry}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1151.1, Definition 1151.2, Definition 1151.3, Definition 1151.4, Definition 1151.8, Definition 1151.10, Definition 1151.11, and Definition 1151.9 bind the scoped finite inquiry packet through carrier, classifier audit, NameCert obligations, non-escape, TasteGate single-carrier alignment, FieldFaithful row separation, Nontrivial witness route, and ground-compiler obligation route.

Formal verification: FormalStatus(NameCert$_{\text{ReflectiveInquiry}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert final truth, source-domain identity, host validation, Lean verification, or bridge checking for ReflectiveInquiry$^{\uparrow}$.

Upgrade path: Public closure requires a public certificate surface for the scoped finite inquiry packet, with the same $P, F, S, K, A, R, L, H, C, Q, N$ rows exported without final truth, source-domain identity, or host validation.

Chapter 1152

A Concrete Naming Certificate for $\mathsf{OnticResidueLedger}^{\uparrow}$

The $\mathsf{OnticResidueLedger}^{\uparrow}$ packet realizes the representation-ledger boundary of Definition 9414.282 as a finite NameCert carrier. It sits after the ontic-source surface of chapter 1125, the audit rows of chapter 1129, the finite model-state carrier of chapter 329, the observer-access support row of chapter 1121, and the current observer-state row of chapter 578. Its role is to store signature exposure, observer access, model comparison, residue, transport, route replay, provenance, and local naming before any consumer treats a model packet as exhausting the ontic source.

Definition 1152.1 (Ontic residue ledger carrier)**.** *An* $\mathsf{OnticResidueLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (O, M, S, A, C, R, H, T, P, N)$$

with the following displayed rows:

1. *O is the accepted* $\mathsf{OnticState}^{\uparrow}$ *source row whose reality-facing signature content is being read.*
2. *M is the accepted* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *row carrying the audited model signatures, source traces, classifier, failure surface, and strength rows.*
3. *S is the accepted* $\mathsf{StateSpaceModel}^{\uparrow}$ *row naming the finite model-state packet offered as a representation.*
4. *A is the observer-access row, read through* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *and* $\mathsf{ConsciousObserverState}^{\uparrow}$*, that records which observer-local support surface may inspect the source and model signatures.*
5. *C is the signature classifier row comparing the exposed ontic signatures from O with the model-state and model-audit signatures from S and M.*
6. *R is the residue row recording source content, observer-access limits, failed model signatures, and audit-visible gaps not represented by S.*
7. *H records componentwise* hsame *transport for $O, M, S, A, C, R, T, P, N$.*
8. *T records displayed* Cont *routes from the ontic source to observer access, from observer access to model comparison, and from the accepted ledger to downstream adequacy or audit consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{OnticResidueLedger}^{\uparrow}$*,* $\mathsf{OnticState}^{\uparrow}$*,* $\mathsf{PhysicalModelAudit}^{\uparrow}$*,* $\mathsf{StateSpaceModel}^{\uparrow}$*,* $\mathsf{ObserverBudgetSupport}^{\uparrow}$*,* $\mathsf{ConsciousObserverState}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{OnticResidueLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for model-state exhaustion, host-level reality access, unbounded observation, detached observer authority, quotienting away residue, or audit acceptance outside the displayed packet.

Lean4 ✓ `BEDC.Derived.OnticResidueLedgerUp.TasteGate.OnticResidueLedgerTasteGate single carrier alignment`

Definition 1152.2 (Ontic residue ledger classifier)**.** *The* $\mathsf{OnticResidueLedger}^{\uparrow}$ *classifier compares two accepted carriers only by the displayed rows* $O, M, S, A, C, R, H, T, P, N$*. It requires the ontic source row, model-audit row, model-state row, observer-access row, signature classifier row, and residue row to remain separately visible under componentwise* hsame *transport and displayed* Cont *replay.*

Two carriers are therefore classified together only when they expose the same source signatures, the same audited model comparison surface, the same finite state-space representation, the same observer-access budget and current-state support, and the same residue ledger. Agreement of the model-state row alone is not enough.

Theorem 1152.3 (Ontic residue ledger NameCert obligations)**.** *For the carrier of Definition 1152.1, the local* $\mathsf{NameCert}_{\mathsf{OnticResidueLedger}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier exposure for the packet* $L = (O, M, S, A, C, R, H, T, P, N)$*;*
2. *source-and-audit exposure through* O *and* M*;*
3. *model-state and observer-access exposure through* S *and* A*;*
4. *signature exactness and residue visibility through* C *and* R*;*
5. *non-escape from model-state exhaustion, unbounded observation, detached observer authority, quotienting away residue, host-level reality access, and audit acceptance outside* H, T, P, N*.*

Thus the ledger is accepted only as a finite source, audit, model, observer-access, classifier, residue, transport, route, provenance, and local-name packet.

Lean4 ✓ `BEDC.Derived.OnticResidueLedgerUp.OnticResidueLedgerTasteGate single carrier alignment`

Proof. Carrier exposure is projection from the displayed tuple in Definition 1152.1. The rows O, M, S, A, C, R supply the source, audit, model-state, observer-access, classifier, and residue coordinates, while H, T, P, N supply transport, route replay, provenance, and local naming.

The source-and-audit obligation is read from O and M. The model-state and observer-access obligation is read from S and A, so a consumer cannot inspect the model representation without also recording the observer-local support surface that performs the inspection.

Signature exactness and residue visibility are then separated. The classifier row C records the admitted comparison between exposed source signatures and model signatures; the residue row R records what the state-space model and audit rows do not represent.

The final obligation follows by inspecting the remaining structural rows. Componentwise transport, route replay, provenance, and local naming can replay only the displayed packet, so they cannot add model-state exhaustion, unbounded observation, detached observer authority, host reality access, or a route that erases the residue row. □

Theorem 1152.4 (Ontic residue ledger signature exactness)**.** *Every accepted* $\mathsf{OnticResidueLedger}^{\uparrow}$ *packet reads signature exactness through the triple* (O, M, C) *together with the model-state row* S *and observer-access row* A*. The exactness claim is not a bare equality between the ontic source and* $\mathsf{StateSpaceModel}^{\uparrow}$*; it is a ledgered comparison whose residue row* R *remains part of the accepted packet.*

Proof. Project the accepted carrier as $L = (O, M, S, A, C, R, H, T, P, N)$. The row O supplies the ontic source signatures, M supplies the audited model signatures and failure surface, and S supplies the finite state-space model offered as representation.

The observer-access row A records how those signatures may be inspected from $\mathsf{ObserverBudgetSupport}^{\uparrow}$ and $\mathsf{ConsciousObserverState}^{\uparrow}$ surfaces. The classifier C can therefore compare only signatures that have passed through the displayed source, audit, model, and observer-access rows.

The residue row R remains visible after the comparison. Consequently the exactness claim never collapses into source-model identity; it is the accepted comparison plus the displayed account of what the model row does not represent. □

Lean4 ✓ `BEDC.Derived.OnticResidueLedgerUp.TasteGate.OnticResidueLedgerSignatureResidue row nonescape`

Theorem 1152.5 (Ontic residue ledger nonescape)**.** *An accepted* $\mathsf{OnticResidueLedger}^{\uparrow}$ *packet cannot be reduced to* $\mathsf{StateSpaceModel}^{\uparrow}$ *or to* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *without losing either the observer-access row A or the residue row R. Every consumer-visible read of the ledger factors through*

$$O, M, S, A, C, R, H, T, P, N.$$

Lean4 ✓ `BEDC.Derived.OnticResidueLedgerUp.OnticResidueLedgerObserverAccess row nonescape`

Proof. The state-space row S records only the finite model-state representation. It does not contain the ontic source row O, the observer-access row A, the signature classifier row C, or the residue row R.

The physical audit row M records finite audit evidence for a candidate model. It does not itself supply the full observer-access support row or the local ledger that keeps represented and unrepresented source content apart.

The remaining rows H, T, P, N preserve the same displayed packet under transport, replay, provenance, and local naming. Since no row outside $O, M, S, A, C, R, H, T, P, N$ is exported, any reduction that forgets A or R leaves the accepted $\mathsf{OnticResidueLedger}^{\uparrow}$ surface. □

The Lean follow-up `lean4/BEDC/Derived/OnticResidueLedgerUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{OnticResidueLedger}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{OnticResidueLedger}^{\uparrow}$ instances preserving $O, M, S, A, C, R, H, T, P, N$ as separate displayed fields.

Falsifiable prediction: An accepted $\mathsf{OnticResidueLedger}^{\uparrow}$ packet cannot be reduced to $\mathsf{StateSpaceModel}^{\uparrow}$ without losing either the observer-access row or the residue row.

Independence witness: onticstate, physicalmodelaudit, statespacemodel, observerbudgetsupport, consciousobserverstate: none is bijective to $\mathsf{OnticResidueLedger}^{\uparrow}$ because the ledger stores source signatures, audited model comparison, finite model-state representation, observer-local access, residue, transport, route, provenance, and local NameCert rows as one packet.

Theorem 1152.6 (Ontic residue ledger scoped consumer surface)**.** *Every accepted* $\mathsf{OnticResidueLedger}^{\uparrow}$ *consumer factors through the displayed packet*

$$O, M, S, A, C, R, H, T, P, N.$$

The consumer surface is exactly the carrier and classifier data of Definition 1152.1 and Definition 1152.2, the local NameCert obligation surface of Definition 1152.3, the signature exactness surface of Definition 1152.4, the nonescape boundary of Definition 1152.5, the checked TasteGate row `BEDC.Derived.OnticResidueLedgerUp.taste_gate`*, and the Lean-side Nontrivial and FieldFaithful witnesses preserving the ten rows as separate displayed fields.*

Proof. Project an accepted consumer to the carrier of Definition 1152.1. The only exported coordinates are $O, M, S, A, C, R, H, T, P, N$, and the classifier of Definition 1152.2 compares accepted carriers only through those displayed rows.

Apply Definition 1152.3 to read the local NameCert surface. Its obligations expose carrier, source-and-audit, model-state, observer-access, signature, residue, transport, route, provenance, and local naming data, with no additional coordinate for a stronger consumer.

The exactness and boundary claims then close the surface. By Definition 1152.4, signature comparison remains ledgered through O, M, C, S, A with R still visible. By Definition 1152.5, reducing the consumer to $\mathsf{StateSpaceModel}^{\uparrow}$ or $\mathsf{PhysicalModelAudit}^{\uparrow}$ loses either observer access or residue.

Finally the TasteGate row and the Lean-side Nontrivial and FieldFaithful witnesses record that the ten displayed fields remain separately visible. Therefore no accepted consumer may replace the packet by state-space exhaustion, host reality access, unbounded observation, detached observer authority, or quotienting away residue. □

Lean4 ✓ `BEDC.Derived.OnticResidueLedgerUp.TasteGate.OnticResidueLedgerScoped consumer surface`

Theorem 1152.7 (Ontic residue ledger bridge export)**.** *The public* $\mathsf{OnticResidueLedger}^{\uparrow}$ *consumer packet*

$$O, M, S, A, C, R, H, T, P, N$$

exports a bridge-facing surface only through the ontic source row O, physical model audit row M, finite state-space model row S, observer-access row A, signature classifier C, residue ledger R, componentwise transport H, displayed route replay T, provenance P, local naming row N, and the checked TasteGate row `BEDC.Derived.OnticResidueLedgerUp.taste_gate`*. It exports no state-space exhaustion row, host reality row, unbounded observer authority, residue-erasing quotient, or Lean bridge check.*

Proof. Start with the scoped consumer surface of Definition 1152.6. It binds every accepted consumer to the displayed packet $O, M, S, A, C, R, H, T, P, N$ together with the checked TasteGate row.

Read those rows as the bridge-facing surface. The source, audit, model, observer-access, signature, residue, transport, route, provenance, and naming coordinates are exactly the rows already exposed by the public consumer packet, so the bridge-facing export does not add another carrier coordinate.

The excluded rows are absent from the carrier and from the scoped consumer theorem. Therefore the paper bridge surface records only the displayed export boundary; it does not claim Lean bridge checking. □

Lean4 ✓ `BEDC.Derived.OnticResidueLedgerUp.TasteGate.OnticResidueLedgerBridgeExport structural rows nonescape`

Theorem 1152.8 (Ontic residue ledger mature consumer surface)**.** *Every mature* $\mathsf{OnticResidueLedger}^{\uparrow}$ *consumer reads exactly the displayed rows*

$$O, M, S, A, C, R, H, T, P, N.$$

The carrier, classifier, local NameCert obligations, signature exactness, nonescape boundary, scoped consumer theorem, and bridge-export theorem already expose the same ten-row surface. Hence every adequacy, audit, or bridge-facing read of the ledger is a read of these rows, and no accepted consumer obtains a state-space exhaustion row, host reality row, unbounded observation row, detached observer authority row, or residue-erasing quotient row.

Lean4 ✓ `BEDC.Derived.OnticResidueLedgerUp.TasteGate.OnticResidueLedgerMature consumer surface`

Proof. Project the accepted carrier to Definition 1152.1. The only displayed rows are $O, M, S, A, C, R, H, T, P, N$, and Definition 1152.2 compares accepted carriers only through those rows.

The local NameCert obligations, signature exactness theorem, and nonescape theorem keep the same rows visible. They expose source, audit, model, observer-access, classifier, residue, transport, replay, provenance, and local naming data, while excluding state-space exhaustion, unbounded observation, detached observer authority, host-level reality access, and quotienting away residue.

The scoped consumer theorem and bridge-export theorem then identify the same row list as the consumer-facing and bridge-facing surface. Since the chapter has no carrier coordinate outside that list, every mature consumer of the ledger is confined to the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{OnticResidueLedger}^{\uparrow}}$ **.**

Constructive story: An $\mathsf{OnticResidueLedger}^{\uparrow}$ packet is generated from an ontic source row, physical model audit row, finite state-space model row, observer-access row, signature classifier, residue ledger, componentwise hsame transport, displayed Cont routes, Pkg provenance, and local NameCert row.

Lean4 ✓ `BEDC.Derived.OnticResidueLedgerUp.taste gate`

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OnticResidueLedger}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1152.6 and Definition 1152.7 bind the public consumer and bridge-facing scopes to the displayed rows $O, M, S, A, C, R, H, T, P, N$ from Definition 1152.1, Definition 1152.2, Definition 1152.3, Definition 1152.4, and Definition 1152.5.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{OnticResidueLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, total ontology, state-space exhaustion, host-level reality access, unbounded observation, detached observer authority, or quotienting away residue.

Upgrade path: The paper-side displayed surface is mature over $O, M, S, A, C, R, H, T, P, N$; Lean verification and bridge checking remain recorded on their separate axes.

Chapter 1153

A Concrete Naming Certificate for $\mathsf{OnticTower}^{\uparrow}$

The $\mathsf{OnticTower}^{\uparrow}$ packet realizes the certified ontic tower of section 9414.19 as a finite stage-refinement NameCert carrier. It consumes the stable source row of $\mathsf{OnticState}^{\uparrow}$ from chapter 1125, the indexed approximation tower of $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ from chapter 1127, the physical-signature classifier of $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$ from **??**, the residue surface of $\mathsf{Residue}^{\uparrow}$ from chapter 125, and the observer support row of $\mathsf{ObserverBudgetSupport}^{\uparrow}$ from chapter 1121. These rows turn the schematic tower into a finite packet with visible stage, transition, continuity, residue, observer-budget, transport, replay, provenance, and local naming coordinates.

Definition 1153.1 (OnticTower carrier)**.** *An* $\mathsf{OnticTower}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (O, A, S, R, B, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{OnticState}^{\uparrow}$ *source row naming the stable reality-facing signatures at the base of the tower.*
2. *A is the* $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ *stage row, recording the accepted finite approximation stages.*
3. *S is the* $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$ *classifier row, recording the physical-signature fit used at each stage.*
4. *R is the* $\mathsf{Residue}^{\uparrow}$ *ledger row, recording content preserved, withheld, or still unresolved between stages.*
5. *B is the* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *observer-budget row, recording which observer-facing supports may read the stage data.*
6. *L is the ledger-continuity row, recording each stage transition as preservation, refinement, or explicit correction of earlier signature rows.*
7. *H is componentwise* hsame *transport for O, A, S, R, B, L.*
8. *C is the displayed* Cont *replay route through the stage and ledger rows.*
9. *P is* Pkg *provenance over* $\mathsf{OnticTower}^{\uparrow}$*, the five cited sibling packets,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{OnticTower}^{\uparrow}}$ *row.*
The carrier has no coordinate for an imported limit object, hidden final ontology, host equality of physical states, quotient stream, countable-choice selector, or observer-independent access route.

Lean4 ✓ `BEDC.Derived.OnticTowerUp.OnticTowerTasteGate single carrier alignment`

Definition 1153.2 (OnticTower classifier)**.** *Two accepted* $\mathsf{OnticTower}^{\uparrow}$ *packets are classified as the same only when their* $\mathsf{OnticState}^{\uparrow}$ *source rows agree through the same stage row, their* RealityConstrainedSignatureFit *classifiers preserve the same physical-signature comparisons, their* $\mathsf{Residue}^{\uparrow}$ *ledgers record the same hidden and unresolved content, their* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *rows admit the same observer-facing reads, and their ledger-continuity rows identify the same sequence of preservation, refinement, and correction transitions under componentwise* hsame *transport. Agreement of a single terminal* $\mathsf{OnticState}^{\uparrow}$ *row is not enough to classify tower packets.*

Theorem 1153.3 (OnticTower stage refinement)**.** *Let* $T = (O, A, S, R, B, L, H, C, P, N)$ *be an accepted* $\mathsf{OnticTower}^{\uparrow}$ *packet. Every accepted transition between two tower stages factors through the displayed approximation row* A*, signature-fit row* S*, residue ledger* R*, observer-budget row* B*, and ledger-continuity row* L*. A transition that preserves only the terminal* $\mathsf{OnticState}^{\uparrow}$ *source row* O *while dropping any one of* A, S, R, B, L *is not an accepted stage refinement.*

Proof. Start from the carrier of Definition 1153.1. The stage data are not read as a bare source row; they are carried by O, A, S, R, B, L together with transport, replay, provenance, and local naming rows.

Use the classifier of Definition 1153.2. It compares packets by the joint source, approximation-stage, physical-signature, residue, observer-budget, and ledger-continuity rows, so a transition missing one of these rows cannot be classified as the same tower route.

The sibling chapters supply the individual surfaces: $\mathsf{OnticState}^{\uparrow}$ supplies the source, RealityConstrainedApproxima supplies indexed stage structure, $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$ supplies physical-signature comparison, $\mathsf{Residue}^{\uparrow}$ supplies ledgered residue, and $\mathsf{ObserverBudgetSupport}^{\uparrow}$ supplies observer-facing support. Repacking them through H, C, P, N gives the accepted refinement route and no omitted coordinate remains. □

Lean4 ✓ `BEDC.Derived.OnticTowerUp.OnticTower stage refinement`

Theorem 1153.4 (OnticTower NameCert obligation surface)**.** *For the carrier of Definition 1153.1, the local* $\mathsf{NameCert}_{\mathsf{OnticTower}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier exposure, stage-refinement preservation, ledger-continuity exposure, observer-budget support, componentwise transport, displayed replay, provenance, and local naming. It excludes imported tower limits, final total descriptions, quotient streams, selected host limits, host real equality, countable-choice selectors, and second ledger sources.*

Proof. Carrier admission is the displayed tuple of Definition 1153.1. Classifier exposure is Definition 1153.2, which requires the joint source, stage, signature-fit, residue, support, and continuity rows.

Stage-refinement preservation is Definition 1153.3. The theorem forces every transition through the same finite packet before a later stage can be read as preserving or refining an earlier stage.

Ledger-continuity and observer support are visible rows of the carrier, and the remaining H, C, P, N rows transport, replay, source, and name the packet. Since the carrier has no additional coordinate, the excluded limit, selector, quotient, host-equality, and second-ledger surfaces cannot be exported from the accepted NameCert. □

Lean4 ✓ `BEDC.Derived.OnticTowerUp.OnticTower namecert obligation surface`

Theorem 1153.5 (OnticTower observer-budget separation)**.** *Let $T = (O, A, S, R, B, L, H, C, P, N)$ be an accepted* $\mathsf{OnticTower}^{\uparrow}$ *packet. Any accepted stage-refinement read of T must expose the* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *row B together with the* $\mathsf{OnticState}^{\uparrow}$ *source row O, approximation-tower row A, signature-fit row S, residue row R, ledger-continuity row L, transport row H, replay row C, provenance row P, and local naming row N. If the observer-budget coordinate is removed, the remaining rows do not form a valid* $\mathsf{NameCert}_{\mathsf{OnticTower}^{\uparrow}}$ *route to observer-independent stage access.*

Lean4 ✓ `BEDC.Derived.OnticTowerUp.OnticTower observer budget separation`

Proof. Start with the carrier of Definition 1153.1. The observer-budget coordinate is a named carrier row, not explanatory prose outside the packet.

Use the classifier of Definition 1153.2. It compares accepted tower packets through the shared observer-facing reads as well as through source, stage, signature-fit, residue, continuity, and structural rows, so a comparison that omits B is not the same classifier route.

Apply the stage-refinement theorem Definition 1153.3. Every accepted transition factors through A, S, R, B, L before it is read as preserving or refining tower stage data.

Finally apply the NameCert obligation surface of Definition 1153.4. That surface lists observer-budget support among the local obligations and explicitly excludes observer-independent access. The TasteGate marker binds the scoped paper witnesses while leaving bridge checking and the verification axis to the closurestatus block. □

Lean4 ✓ `BEDC.Derived.OnticTowerUp.OnticTower observer budget semantic name certificate`

Theorem 1153.6 (OnticTower obligation closure surface)**.** *The carrier rows of Definition 1153.1, the classifier of Definition 1153.2, the stage-refinement route of Definition 1153.3, the NameCert obligation surface of Definition 1153.4, the observer-budget separation of Definition 1153.5, and the displayed TasteGate marker on Definition 1153.1 form exactly the paper-side obligation surface needed before scoped closure. A scoped-closure claim must still bind those rows to checked Lean targets and bridge data.*

Lean4 ✓ `BEDC.Derived.OnticTowerUp.OnticTower obligation closure surface`

Proof. The carrier definition supplies the finite packet $T = (O, A, S, R, B, L, H, C, P, N)$ and excludes imported limits, hidden final ontology, host equality, quotient streams, countable-choice selectors, and observer-independent access.

The classifier and stage-refinement theorems then force every tower read through the same source, approximation, signature-fit, residue, observer-budget, ledger-continuity, transport, replay, provenance, and local naming rows.

The NameCert obligation theorem names the local certificate surface, and observer-budget separation shows that dropping B leaves the accepted route. The TasteGate marker attached to the carrier records the single-carrier alignment on the Lean side, but it does not by itself supply scoped closure.

Thus the listed rows are exactly the obligation surface: enough to state the seed-to-obligation path, and still short of the checked bindings and bridge data required for scoped closure. □

The Lean follow-up path is `lean4/BEDC/Derived/OnticTowerUp/TasteGate.lean`. It must provide explicit $\mathsf{Nontrivial}\ \mathsf{OnticTower}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{OnticTower}^{\uparrow}$ instances preserving the source, stage, signature-fit, residue, observer-budget, ledger-continuity, transport, replay, provenance, and local naming rows.

Falsifiable prediction: An accepted $\mathsf{OnticTower}^{\uparrow}$ packet cannot collapse to $\mathsf{OnticState}^{\uparrow}$ without losing either a refinement transition or a ledger-continuity row.

Independence witness: onticstate, realityconstrainedapproximationtower, realityconstrainedsignaturefit, residue, observerbudgetsupport: none is bijective because $\mathsf{OnticTower}^{\uparrow}$ binds source, finite stage refinement, physical-signature classification, residue ledger, observer support, ledger continuity, transport, replay, provenance, and local NameCert rows in one packet. Each named sibling exposes one adjacent surface without the complete tower transition and ledger-continuity packet.

Closure status for $\mathsf{NameCert}_{\mathsf{OnticTower}^{\uparrow}}$.

Constructive story: An $\mathsf{OnticTower}^{\uparrow}$ packet is generated from OnticState source, approximation-stage, signature-fit, residue-ledger, observer-budget, ledger-continuity, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OnticTower}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1153.1, Definition 1153.2, Definition 1153.3, Definition 1153.4, Definition 1153.5, Definition 1153.6, and `BEDC.Derived.OnticTowerUp.OnticTowerTasteGate_single_carrier_alignment` bind the carrier, classifier, stage-refinement, NameCert surface, observer-budget separation, obligation closure surface, and TasteGate scoped witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OnticTower}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, final total ontology, imported tower limits, quotient streams, selected host limits, host equality, countable-choice selectors, or observer-independent access.

Upgrade path: Scoped closure requires checked bindings for carrier admission, classifier exposure, stage-refinement preservation, ledger-continuity exposure, observer-budget support, and the Nontrivial and FieldFaithful TasteGate rows.

Chapter 1154

A Concrete Naming Certificate for $\mathsf{OnticResidueLattice}^{\uparrow}$

The $\mathsf{OnticResidueLattice}^{\uparrow}$ packet realizes the residue-activation and refined-bundle direction of section 9414.15 as a finite NameCert surface. It sits after the source packet $\mathsf{OnticState}^{\uparrow}$ of chapter 1125, the model-audit packet $\mathsf{PhysicalModelAudit}^{\uparrow}$ of chapter 1129, the state-space carrier $\mathsf{StateSpaceModel}^{\uparrow}$ of chapter 329, the support-and-budget packet $\mathsf{ObserverBudgetSupport}^{\uparrow}$ of chapter 1121, and the observation handoff $\mathsf{ObservationReflectionPacket}^{\uparrow}$ of chapter 1126. Its role is to store which residue rows become active under which refined bundles before any consumer treats a model row, audit row, or observation route as ontically exhaustive.

Definition 1154.1 (Ontic residue lattice carrier)**.** *An* $\mathsf{OnticResidueLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (O, A, M, S, B, R, K, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{OnticState}^{\uparrow}$ *source row carrying the reality-facing signature source and base residue ledger.*
2. *A is the* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *row recording the audited model signatures, failure surface, strength, and audit ledger for the model under comparison.*
3. *M is the* $\mathsf{StateSpaceModel}^{\uparrow}$ *row naming the finite state-space presentation whose projections are being tested against residue activation.*
4. *S is the* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *row specifying which observer-local support and budget caps make the refined bundle admissible.*
5. *B is the* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *row recording the observation and reflection route through which the refined bundle is read.*
6. *R is the finite residue-activation lattice row. Its elements are pairs of a refined-bundle token and the residue rows activated by that token, ordered by inclusion of displayed activation evidence.*
7. *K is the classifier row comparing two packets by source status, audit comparison, model-state projection, budget support, observation route, and residue activation together.*
8. *H records componentwise* hsame *transport for $O, A, M, S, B, R, K, C, P, N$.*
9. *C records displayed* Cont *replay through $O, A, M, S, B, R, K, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{OnticResidueLattice}^{\uparrow}$, $\mathsf{OnticState}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{ObserverBudgetSupport}^{\uparrow}$, $\mathsf{ObservationReflectionPacket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OnticResidueLattice}^{\uparrow}}$ *row.*

The carrier has no coordinate for a bare source state, model-only equivalence, audit-only comparison, unbudgeted observation route, quotient physical object, or host-level ontology. Residue activation is public only as the displayed lattice row R transported with the refined-bundle rows.

Lean4 (definition) `BEDC.Derived.OnticResidueLatticeUp.taste gate`

Definition 1154.2 (Ontic residue lattice classifier)**.** *The* $\mathsf{OnticResidueLattice}^{\uparrow}$ *classifier identifies two accepted packets only when their* $\mathsf{OnticState}^{\uparrow}$ *source rows,* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *audit rows,* $\mathsf{StateSpaceModel}^{\uparrow}$ *projections,* $\mathsf{ObserverBudgetSupport}^{\uparrow}$ *support rows,* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *routes, and residue-activation lattice rows agree through the displayed componentwise* hsame *transport. Agreement of any proper sublist of those rows is not enough: the classifier is sensitive to which refined bundle activates which residue, not merely to source status, audit comparison, model state, observer support, or reflection routing in isolation.*

Theorem 1154.3 (Ontic residue lattice activation non-escape)**.** *Let $L = (O, A, M, S, B, R, K, H, C, P, N)$ be an accepted* $\mathsf{OnticResidueLattice}^{\uparrow}$ *carrier. Any public read that preserves the source row O, audit row A, model-state projection M, budget-support row S, and observation-reflection route B but drops the residue-activation lattice row R leaves the accepted classifier surface. Thus residue activation under refined bundles cannot be recovered from a bare* $\mathsf{OnticState}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{ObserverBudgetSupport}^{\uparrow}$, *or* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *row.*

Proof. Project the carrier of Definition 1154.1. The local name N is reached only after the source, audit, model-state, support, observation-route, activation-lattice, classifier, transport, replay, and provenance rows have all been displayed.

Apply the classifier of Definition 1154.2. It compares the refined-bundle activation row R together with O, A, M, S, B; it does not classify by any one sibling row or by their subtuple without the activation lattice.

Therefore a public read that drops R has no displayed row recording which refined bundle activated which residue. Since the carrier has no quotient physical object, host ontology, hidden selector, or unbudgeted observation coordinate, no off-packet route can reconstruct that activation relation. □

Lean4 ✓ `BEDC.Derived.OnticResidueLatticeUp.OnticResidueLattice activation nonescape`

Theorem 1154.4 (Ontic residue lattice NameCert obligation surface)**.** *For the carrier of Definition 1154.1, the local* $\mathsf{NameCert}_{\mathsf{OnticResidueLattice}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for $L = (O, A, M, S, B, R, K, H, C, P, N)$;*
2. *refined-bundle exposure through the joint* $\mathsf{OnticState}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{ObserverBudgetSupport}^{\uparrow}$, *and* $\mathsf{ObservationReflectionPacket}^{\uparrow}$ *rows O, A, M, S, B;*
3. *residue-activation classification through the lattice row R and classifier row K;*
4. *activation non-escape through componentwise transport and displayed replay along H, C;*
5. *provenance and local naming through P, N, with no hidden model-state, audit-only, source-only, budget-only, observation-only, quotient-object, or host-ontology coordinate.*

These five rows are the complete public obligation surface for using OnticResidueLattice$^{\uparrow}$ *as a residue-activation certificate under refined bundles.*

Proof. Carrier admission is the first projection from Definition 1154.1. Refined-bundle exposure is the joint visibility of O, A, M, S, B inside the same finite packet.

Residue-activation classification is Definition 1154.2: R and K record which residue rows are active under which displayed refined-bundle tokens. Activation non-escape follows from Definition 1154.3, which rules out recovering that row from any single sibling surface or from the sibling subtuple without R.

The rows H, C, P, N transport, replay, source, and name the same displayed packet. Since the carrier has no additional coordinate for a quotient physical object, host ontology, hidden selector, or unbudgeted observation route, the five listed rows exhaust the local NameCert obligation surface. □

The Lean follow-up path is `lean4/BEDC/Derived/OnticResidueLatticeUp/TasteGate.lean`. That file must provide explicit Nontrivial OnticResidueLattice$^{\uparrow}$ and FieldFaithful OnticResidueLattice$^{\uparrow}$ instances preserving $O, A, M, S, B, R, K, H, C, P, N$ as separate displayed fields, with the future target name BEDC.Derived.OnticResidueLatticeUp.taste_gate.

Falsifiable prediction: A model-state projection that drops the refined-bundle activation row cannot classify two OnticResidueLatticeUp packets as equivalent.

Independence witness: onticstate, physicalmodelaudit, statespacemodel, observerbudgetsupport, observationreflectionpacket: none is bijective because the lattice stores residue activation under refined bundles rather than only source status, audit comparison, model state, budget support, or reflection routing.

Closure status for NameCert$_{\text{OnticResidueLattice}^{\uparrow}}$.

Constructive story: An OnticResidueLattice$^{\uparrow}$ packet is generated from ontic-source, physical-model-audit, state-space-model, observer-budget-support, observation-reflection, residue-activation lattice, classifier, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{OnticResidueLattice}^{\uparrow}}$, seed)

Scope closed: Definition 1154.1, Definition 1154.2, Definition 1154.3, and Definition 1154.4 bind the finite residue-lattice carrier, classifier, activation non-escape boundary, and public NameCert obligation surface.

Formal verification: FormalStatus(NameCert$_{\text{OnticResidueLattice}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, total physical ontology, quotient physical objects, unbudgeted observation, model-state sufficiency, audit-only sufficiency, or source-only sufficiency.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, activation non-escape, TasteGate nontriviality, and field faithfulness for $O, A, M, S, B, R, K, H, C, P, N$.

Chapter 1155

A Concrete Naming Certificate for $\mathsf{LawCertificate}^{\uparrow}$

The $\mathsf{LawCertificate}^{\uparrow}$ packet realizes the law-certificate discipline of section 9414.25 as a finite NameCert surface. It sits after the physical-induction carrier of chapter 1135, the open-fit packet of chapter 1137, the model-audit packet of chapter 1124, the induction-stability seal of chapter 1139, and the tower-compression packet of chapter 1142. Those siblings supply finite fit, audit comparison, continuation stability, and compression-residue surfaces; this packet binds an equation-like pattern to source fit, classifier, stability, failure surface, ledger, transport, provenance, and local naming before any consumer may read it as a physical law.

The packet is composite over chapter 1135, chapter 1137, chapter 1124, chapter 1139, and chapter 1142; it bundles those rows into one law-certificate surface.

Definition 1155.1 (Law certificate carrier)**.** *A* $\mathsf{LawCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, P, C, S, E, Ld, H, R, Q, N)$$

with the following displayed rows:

1. *F is the finite source-fit row, read through* $\mathsf{OpenFitPacket}^{\uparrow}$ *and* $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$*, recording the observations that license the equation-like pattern.*
2. *P is the pattern row naming the equation, invariant, or calculation rule being offered as lawlike.*
3. *C is the classifier row comparing model-generated and source-observed signatures under the admitted observational equivalence.*
4. *S is the continuation-stability row, read through* $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$*, naming the continuation class and stability basis under which reuse is licensed.*
5. *E is the explicit failure-surface row naming observations, refined histories, or tower-level reads that would defeat the law claim.*
6. *Ld is the ledger row recording idealizations, hidden assumptions, tower-compression residue, audit strength, and refused final-fit demands.*
7. *H records componentwise* hsame *transport for $F, P, C, S, E, Ld, R, Q, N$.*
8. *R records displayed* Cont *replay through source fit, pattern use, classifier comparison, stability reuse, failure exposure, and ledger inspection.*

9. *Q is the* Pkg *provenance over* $\mathsf{LawCertificate}^{\uparrow}$, $\mathsf{OpenFitPacket}^{\uparrow}$, $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$, $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$, $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$, $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LawCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for a bare equation, unbounded natural law, final-fit oracle, detached model syntax, hidden stability assumption, omitted failure surface, or ledger-free physical truth. A physical law is public only as the displayed packet L.

Lean4 (definition) `BEDC.Derived.LawCertificateUp.LawCertificateUp`

Definition 1155.2 (Law certificate classifier)**.** *The* $\mathsf{LawCertificate}^{\uparrow}$ *classifier identifies two accepted packets only when their source-fit rows, equation-pattern rows, classifier rows, continuation-stability rows, failure-surface rows, ledger rows, transport rows, replay rows, provenance rows, and local NameCert rows agree through displayed componentwise* hsame *transport. Agreement of the equation-like pattern alone is not enough, and finite source fit without stability or failure exposure is not enough.*

Lean4 (definition) `BEDC.Derived.LawCertificateUp.lawCertificateClassifier`

Theorem 1155.3 (Law certificate NameCert obligations)**.** *For the carrier of Definition 1155.1, the local* $\mathsf{NameCert}_{\mathsf{LawCertificate}^{\uparrow}}$ *surface consists exactly of seven finite obligations:*

1. *carrier admission for $L = (F, P, C, S, E, Ld, H, R, Q, N)$;*
2. *source-fit exposure through F;*
3. *equation-pattern exposure through P without treating the pattern as self-licensing;*
4. *classifier exposure through C;*
5. *continuation-stability and failure-surface exposure through S and E;*
6. *ledger accountability through Ld, including audit strength, compression residue, idealization, and refused final-fit demands;*
7. *transport, replay, provenance, and local naming through H, R, Q, N.*

These seven rows are the complete public obligation surface for reading an equation-like pattern as a physical law.

Lean4 ✓ `BEDC.Derived.LawCertificateUp.LawCertificate semantic name certificate`

Proof. Carrier admission is projection from Definition 1155.1. The packet exposes source fit, pattern, classifier, continuation stability, failure surface, ledger, transport, replay, provenance, and local name as its complete finite surface.

Source-fit exposure comes from F, while pattern exposure comes from P. The classifier row C states how the model-generated signatures and source-observed signatures are compared; therefore the pattern is not read in isolation from the source and classifier data that make it empirical.

Continuation stability and failure exposure are supplied by S and E. The ledger row Ld records the audit, tower, idealization, and refusal data that prevent the packet from becoming an unbounded natural-law oracle.

Finally H, R, Q, N preserve and name the same displayed packet. Since the carrier has no further coordinate for hidden stability, detached model syntax, or ledger-free truth, the seven listed obligations exhaust the local NameCert surface. □

Theorem 1155.4 (Law certificate failure-surface nonescape)**.** *An accepted* $\mathsf{LawCertificate}^{\uparrow}$ *packet cannot be reduced to an equation pattern plus finite fit while preserving law status. Any public read that drops either the continuation-stability row* S *or the failure-surface row* E *leaves the accepted classifier surface.*

Lean4 ✓ `BEDC.Derived.LawCertificateUp.lawCertificate failure surface rows nonescape`

Proof. Project the carrier as $L = (F, P, C, S, E, Ld, H, R, Q, N)$. The rows F and P record finite source fit and the equation-like pattern, but they do not state which continuations are licensed or what observations would defeat the law claim.

Apply the classifier of Definition 1155.2. It compares accepted packets through S and E together with F, P, C, Ld, H, R, Q, N. Dropping either S or E therefore changes the public comparison surface.

Transport, replay, provenance, and local naming preserve only the displayed rows. Because the carrier has no hidden coordinate for stability or failure exposure, no off-packet route can recover law status from equation syntax and finite fit alone. □

Theorem 1155.5 (Law certificate continuation scope)**.** *Every accepted* $\mathsf{LawCertificate}^{\uparrow}$ *consumer read of a physical law is scoped to the continuation-stability row* S*, the failure-surface row* E*, and the ledger row* Ld*. The packet licenses prediction only inside that displayed scope and does not assert total future fit.*

Lean4 ✓ `BEDC.Derived.LawCertificateUp.LawCertificate continuation scope`

Proof. The NameCert obligations of Definition 1155.3 require S, E, Ld before the local name is accepted. These rows state the continuation class, the defeating observations, and the audit-and-residue ledger that bound reuse.

The nonescape result of Definition 1155.4 rules out reading law status after removing either continuation stability or failure exposure. The ledger row also remains visible, so idealization residue and tower-compression assumptions are part of the same public packet.

Thus the consumer-visible law is not a total claim over all possible observation histories. It is a certificate-relative read whose scope is exactly the displayed source fit, classifier, stability, failure surface, ledger, transport, provenance, and local NameCert rows. □

Theorem 1155.6 (Law certificate carrier admission)**.** *Every accepted* $\mathsf{LawCertificate}^{\uparrow}$ *carrier admits the row tuple*

$$L = (F, P, C, S, E, Ld, H, R, Q, N)$$

only as the finite packet of Definition 1155.1: F *supplies source fit,* P *supplies the equation-like pattern,* C *supplies classifier comparison,* S *supplies continuation stability,* E *supplies the failure surface,* Ld *supplies ledger accountability, and* H, R, Q, N *supply transport, replay, provenance, and local naming. The TasteGate surface records nontrivial field separation for those rows before the packet can be read as a law certificate.*

Lean4 ✓ `BEDC.Derived.LawCertificateUp.LawCertificateCarrier admission`
↪ variant `BEDC.Derived.LawCertificateUp.LawCertificateCarrier carrier admission`

Proof. Project the carrier definition and the NameCert obligations. The carrier definition lists exactly $F, P, C, S, E, Ld, H, R, Q, N$, while Definition 1155.3 makes those rows the public obligation surface.

Use the TasteGate field-faithfulness witness represented by the LawCertificateUp TasteGate file. It keeps the displayed rows separate, so source fit, equation pattern, classifier, stability, failure surface, and ledger data cannot collapse into a single equation token.

Finally replay through H, R, Q, N. Since every public read is transported, replayed, sourced, and named through the same tuple, carrier admission is finite row admission and not an unbounded physical-law oracle. □

Theorem 1155.7 (Law certificate classifier stability)**.** *If two accepted* $\mathsf{LawCertificate}^{\uparrow}$ *packets agree through the displayed classifier of Definition 1155.2, then every law-certificate consumer route preserves the same rows* $F, P, C, S, E, Ld, H, R, Q, N$*. In particular, agreement of* P *alone cannot transport law status unless* $F, C, S, E, Ld, H, R, Q, N$ *are transported with it.*

Proof. Start from the classifier block. It compares accepted packets through source fit, pattern, classifier, continuation stability, failure surface, ledger, transport, replay, provenance, and local NameCert rows.

Apply the continuation-scope theorem Definition 1155.5. A consumer read is scoped by S, E, Ld, so classifier transport must preserve those rows along with F, P, C.

The structural rows H, R, Q, N then preserve the route. The TasteGate field-faithfulness surface prevents a packet whose equation pattern matches but whose stability, failure, or ledger rows differ from being read as the same accepted law certificate. □

Lean4 ✓ `BEDC.Derived.LawCertificateUp.LawCertificateCarrier classifier stability`

Theorem 1155.8 (Law certificate ledger nonescape)**.** *Every accepted* $\mathsf{LawCertificate}^{\uparrow}$ *consumer of a physical law must keep the ledger row* Ld *visible with* $F, P, C, S, E, H, R, Q, N$*. A route that reads source fit, equation pattern, classifier, continuation stability, or failure exposure while dropping* Ld *leaves the accepted NameCert surface and cannot export ledger-free law status.*

Proof. Use the NameCert obligations. They make ledger accountability through Ld one of the finite rows required before the local name is public.

Apply the failure-surface and continuation-scope theorems, Definition 1155.4 and Definition 1155.5. These results keep S, E, Ld visible whenever the law is consumed, so the ledger cannot be omitted after the classifier has accepted F, P, C.

Finally use carrier admission and TasteGate field separation. The rows H, R, Q, N preserve the same packet, and no coordinate outside $F, P, C, S, E, Ld, H, R, Q, N$ restores a missing ledger row. □

Lean4 ✓ `BEDC.Derived.LawCertificateUp.taste gate`

Theorem 1155.9 (Law certificate scope transport)**.** *Every accepted* $\mathsf{LawCertificate}^{\uparrow}$ *consumer route preserves the displayed rows*

$$F, P, C, S, E, Ld, H, R, Q, N$$

through source fit, classifier comparison, continuation stability, failure-surface exposure, ledger accountability, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *scope. No equation-only route and no ledger-free route exports law status.*

Proof. Project the carrier and NameCert obligations. They make $F, P, C, S, E, Ld, H, R, Q, N$ the complete finite surface for source fit, pattern exposure, classifier comparison, continuation stability, failure surface, ledger accountability, transport, replay, provenance, and local naming.

Apply the continuation-scope theorem and failure-surface nonescape theorem. A consumer route that keeps law status must preserve S and E together with the rows that source, classify, and transport the same packet.

Apply classifier stability and ledger nonescape. Agreement of the equation pattern alone cannot transport law status, and dropping Ld leaves the accepted surface. Thus every accepted route remains scoped by the displayed rows and exports neither equation-only nor ledger-free law status. □

Lean4 ✓ `BEDC.Derived.LawCertificateUp.LawCertificateCarrier scope transport`

Theorem 1155.10 (Law certificate public export route)**.** *Every public downstream consumer of an accepted* $\mathsf{LawCertificate}^{\uparrow}$ *packet receives only the displayed law rows* F, P, C, S, E*, the classifier-stability and ledger rows* C, S, E, Ld*, componentwise* hsame *transport* H*, displayed* Cont *replay* R*,* Pkg *provenance* Q*, and the local* $\mathsf{NameCert}$ *row* N*. The public export route contains no bare equation token, hidden stability premise, ledger-free law status, final-fit oracle, detached model syntax, or unbounded natural-law claim.*

Proof. Project the carrier $L = (F, P, C, S, E, Ld, H, R, Q, N)$ and the NameCert obligations. They identify the complete row surface for source fit, equation pattern, classifier comparison, continuation stability, failure exposure, ledger accountability, transport, replay, provenance, and local naming.

Apply classifier stability and scope transport, Definition 1155.7 and Definition 1155.9. These keep every accepted consumer route on the same displayed rows and prevent equation-pattern agreement from transporting law status by itself.

Finally use ledger nonescape and continuation scope, Definition 1155.8 and Definition 1155.5. They keep Ld, S, E visible in every law read, so a public downstream consumer receives only the displayed packet and no hidden stability, ledger-free truth, detached model syntax, final-fit oracle, or unbounded physical-law claim. □

Lean4 ✓ `BEDC.Derived.LawCertificateUp.LawCertificateCarrier public export route`

Theorem 1155.11 (Law certificate bridge-carrier route)**.** *Every bridge-facing consumer of an accepted* $\mathsf{LawCertificate}^{\uparrow}$ *packet must preserve*

$$F, P, C, S, E, Ld, H, R, Q, N$$

through the same source-fit, classifier, continuation-stability, failure-surface, ledger, transport, replay, provenance, and local $\mathsf{NameCert}$ *rows before any abstract law-certificate interface can consume it. A bridge read that drops one of these rows has not transported the public* $\mathsf{LawCertificate}^{\uparrow}$ *carrier.*

Lean4 ✓ `BEDC.Derived.LawCertificateUp.LawCertificateCarrier bridge carrier route`

Proof. Project the public export route of Definition 1155.10. It already makes $F, P, C, S, E, Ld, H, R, Q, N$ the complete public surface for source fit, equation pattern, classifier comparison, continuation stability, failure exposure, ledger accountability, transport, replay, provenance, and local naming.

Apply scope transport and ledger nonescape. The bridge-facing consumer must keep the accepted carrier inside the same componentwise hsame and displayed Cont route, and it cannot replace the ledger row Ld by an equation-only or stability-only law read.

Finally read the taste-gate marker as the carrier-side field-faithfulness witness for the same displayed rows. The abstract law-certificate interface therefore consumes only the preserved packet, not a detached equation token, hidden continuation premise, ledger-free law status, final-fit oracle, or unbounded natural-law claim. □

Lean4 ✓ `BEDC.Derived.LawCertificateUp.LawCertificateBridgeCarrierRoute`

Theorem 1155.12 (Law certificate mature consumer route)**.** *Every downstream consumer of an accepted* LawCertificate$^{\uparrow}$ *packet must preserve the source-fit row F, equation-pattern row P, classifier row C, continuation-stability row S, failure-surface row E, ledger row Ld, componentwise* hsame *transport row H, displayed* Cont *replay row R,* Pkg *provenance row Q, and local* NameCert *row N. Such a consumer may not read the packet as an equation-only law, total prediction, or final-fit oracle.*

Proof. Start with the carrier and classifier of Definition 1155.1 and Definition 1155.2. They make $F, P, C, S, E, Ld, H, R, Q, N$ the complete accepted comparison surface, so no downstream route begins from the equation pattern alone.

Apply the NameCert obligations, failure-surface nonescape, and continuation-scope theorems, namely Definition 1155.3, Definition 1155.4, and Definition 1155.5. These results keep source fit, classifier comparison, stability, failure exposure, and ledger accountability visible whenever law status is consumed.

Finally apply the public export route and bridge-carrier route of Definition 1155.10 and Definition 1155.11. They transport only the displayed packet through hsame, Cont, Pkg, and local naming, and therefore exclude an equation-only law, total prediction, detached final-fit oracle, hidden stability premise, or ledger-free physical truth. □

Together with the existing TasteGate marker for `BEDC.Derived.LawCertificateUp.taste_gate`, the checked bridge-carrier route records the bridge evidence needed for paper-side bridged closure: the abstract interface consumes only the displayed carrier rows and their field-faithful separation.

The Lean follow-up file `lean4/BEDC/Derived/LawCertificateUp/TasteGate.lean` must provide explicit Nontrivial LawCertificate$^{\uparrow}$ and FieldFaithful LawCertificate$^{\uparrow}$ instances, with witness-pair and field-projection proofs preserving $F, P, C, S, E, Ld, H, R, Q, N$ as separate displayed fields.

Falsifiable prediction: A packet that presents an equation and finite fit but omits either the continuation-stability row or the failure-surface row is rejected by the LawCertificateUp classifier.

Independence witness: realityconstrainedphysicalinduction, openfitpacket, realityconstrainedmodelaudit, physicalinductionstabilityseal, realityconstrainedtowercompression: none is bijective because LawCertificateUp binds equation pattern, source fit, classifier, continuation stability, failure surface, ledger, transport, provenance, and local NameCert rows in one carrier, while each sibling supplies only a constituent surface.

Closure status for NameCert$_{\text{LawCertificate}^{\uparrow}}$**.**

Constructive story: A LawCertificate$^{\uparrow}$ packet is generated from finite source-fit, equation-pattern, classifier, continuation-stability, failure-surface, ledger, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{LawCertificate}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1155.1, Definition 1155.2, Definition 1155.3, Definition 1155.4, Definition 1155.5, Definition 1155.6, Definition 1155.7, Definition 1155.8, Definition 1155.9, Definition 1155.10, Definition 1155.11, and Definition 1155.12 bind the finite law-certificate carrier, classifier, obligation surface, failure-surface boundary, continuation scope, carrier admission, classifier stability, ledger nonescape, accepted consumer-route scope, public export route, checked bridge-carrier route, and mature downstream consumer route.

Formal verification: FormalStatus(NameCert$_{\text{LawCertificate}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Not claimed: This chapter does not close Lean verification, bridge checking, total physical law, all-history prediction, equation-only law status, hidden stability, ledger-free physical truth, or final-fit oracle behavior.

Upgrade path: The paper-side closure axis is complete at the mature consumer route; Lean-side verification remains independent of the bridge construction recorded here.

Chapter 1156

A Concrete Naming Certificate for $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$

The $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ packet realizes the record-and-gap reading of physical laws in subsection 9462.28.4 as a finite NameCert surface. It sits before the law-certificate packet of chapter 1155 and beside the physical-induction carrier of chapter 1135, the open-fit packet of chapter 1137, the model-audit packet of chapter 1124, and the induction-stability seal of chapter 1139. Its role is to keep observed regularity and future-persistence commitment in one packet without identifying either side with a bare equation or a total law oracle.

Definition 1156.1 (Empirical regularity persistence carrier)**.** *An* $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, R, K, L, G, A, S, F, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite measurement row naming the observed cases, instruments, units, and admissible sampling window.*
2. *R is the records-side regularity row stating the relation satisfied by the observed rows under M.*
3. *K is the classifier row comparing two regularity packets only through their displayed measurements, records, tolerance ledgers, GAP rows, stability rows, failure rows, transports, continuations, provenance, and local names.*
4. *L is the finite error-ledger row recording tolerances, idealizations, calibration residue, and excluded observations.*
5. *G is the Type IV future-persistence GAP row asserting that the records-side regularity is offered for not-yet-observed continuations.*
6. *A is the* $\mathsf{LawCertificate}^{\uparrow}$ *consumption row naming the law-certificate surface that may read the packet.*
7. *S is the stability row, read against* $\mathsf{PhysicalInductionStabilitySeal}^{\uparrow}$ *and* $\mathsf{RealityConstrainedPhysicalInduction}^{\uparrow}$*, naming the continuation class and persistence basis under which G is licensed.*
8. *F is the failure row naming observations, continuations, refined measurements, or audit rows that defeat the persistence claim.*

9. *H records componentwise* hsame *transport for $M, R, K, L, G, A, S, F, C, P, N$.*
10. *C records displayed* Cont *replay through measurement, regularity, classifier, error ledger, future-persistence GAP, law-certificate consumption, stability, and failure rows.*
11. *P is the* Pkg *provenance over* EmpiricalRegularityPersistence$^{\uparrow}$, LawCertificate$^{\uparrow}$, RealityConstrainedPhysicalInductio OpenFitPacket$^{\uparrow}$, RealityConstrainedModelAudit$^{\uparrow}$, PhysicalInductionStabilitySeal$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* NameCert$_{\text{EmpiricalRegularityPersistence}^{\uparrow}}$ *row.*

The carrier has no coordinate for a bare equation, hidden measurement row, omitted tolerance ledger, persistence claim without G, all-future truth, final-fit oracle, host physical necessity, or law status detached from A, S, F, H, C, P, N.

Lean4 (definition) BEDC.Derived.EmpiricalRegularityPersistenceUp.EmpiricalRegularityPersistenceUp
Lean4 ✓ BEDC.Derived.EmpiricalRegularityPersistenceUp.EmpiricalRegularityPersistenceTasteGate
single carrier alignment

Definition 1156.2 (Empirical regularity persistence classifier)**.** *The* EmpiricalRegularityPersistence$^{\uparrow}$ *classifier identifies two accepted packets only when $M, R, K, L, G, A, S, F, H, C, P, N$ agree through displayed componentwise* hsame *transport. Equality of equation-like syntax is not enough; agreement of finite observed rows is not enough; and a future-persistence claim not attached to the explicit GAP row G, stability row S, failure row F, and law-certificate consumption row A is outside the accepted classifier.*

Theorem 1156.3 (Empirical regularity persistence GAP exposure)**.** *For every accepted* EmpiricalRegularityPersiste *carrier $E = (M, R, K, L, G, A, S, F, H, C, P, N)$, the future-facing part of the packet is exposed exactly by the Type IV GAP row G together with stability row S, failure row F, continuation replay C, provenance P, and local name N. The records-side rows M, R, K, L certify observed regularity only; they do not by themselves license future persistence.*

Lean4 ✓ BEDC.Derived.EmpiricalRegularityPersistenceUp.EmpiricalRegularityPersistenceCarrier
gap exposure

Proof. Project the carrier of Definition 1156.1. The observed side is listed as M, R, K, L, while the persistence side is listed as G, S, F and is replayed through C, P, N.

Apply the classifier of Definition 1156.2. It refuses equality of equation-like syntax and finite observed rows when the GAP, stability, failure, replay, provenance, or local naming rows are missing.

Thus records-side regularity is a finite observation claim, while future persistence is the separate Type IV GAP exposure. Since the carrier has no hidden persistence coordinate, no accepted consumer can read forward commitment from M, R, K, L alone. □

Theorem 1156.4 (LawCertificate consumption of empirical regularity persistence)**.** *Every* LawCertificate$^{\uparrow}$ *consumer read of an accepted* EmpiricalRegularityPersistence$^{\uparrow}$ *packet factors through the measurement row M, regularity row R, classifier row K, error-ledger row L, future-persistence GAP row G, law-certificate consumption row A, stability row S, failure row F, transport row H, replay row C, provenance row P, and local* NameCert *row N. The consumer may not read an equation-like law packet when either the finite measurement and error rows or the explicit future-persistence GAP are absent.*

Lean4 ✓ `BEDC.Derived.EmpiricalRegularityPersistenceUp.EmpiricalRegularityPersistenceCarrier lawcertificate consumption`

Proof. Start from the consumption row A. It names the $\mathsf{LawCertificate}^{\uparrow}$ surface that may read the empirical packet, but A is itself only one coordinate of $E = (M, R, K, L, G, A, S, F, H, C, P, N)$.

Use Definition 1156.3. The theorem separates observed regularity from future persistence and requires G, S, F, C, P, N for the forward commitment. The measurement row M, regularity row R, classifier row K, and error-ledger row L remain mandatory for the records-side evidence.

Therefore a law-certificate consumer sees a complete finite packet rather than a detached equation. If either the measurement and error rows or the future-persistence GAP row is absent, the requested law read lacks one side of the carrier and is rejected by the classifier. □

Theorem 1156.5 (Empirical regularity persistence nonescape)**.** *No accepted* $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ *consumer can recover physical-law status from a bare equation, observed records alone, model syntax alone, hidden calibration assumptions, an omitted error ledger, an unlisted continuation class, or a future-persistence assertion outside the displayed Type IV GAP row. Every accepted read remains inside* $M, R, K, L, G, A, S, F, H, C, P, N$.

Proof. Carrier projection gives the complete inventory $M, R, K, L, G, A, S, F, H, C, P, N$. The bare equation, model syntax, hidden calibration assumption, omitted error ledger, unlisted continuation class, and off-packet future-persistence assertion are not coordinates of that inventory.

Apply Definition 1156.2. The classifier compares accepted packets only through the displayed rows, so replacing any of those rows by an absent object changes the comparison surface rather than preserving the accepted packet.

Apply Definition 1156.4. Even the law-certificate consumer must pass through both sides of the packet: finite measurement and error evidence on the records side, and GAP, stability, and failure exposure on the future-facing side. Hence no accepted consumer escapes to physical-law status outside the displayed carrier. □

Lean4 ✓ `BEDC.Derived.EmpiricalRegularityPersistenceUp.EmpiricalRegularityPersistenceCarrier nonescape`

The standard five-row NameCert surface is carrier admission for E, classifier exactness through K, stability and failure exposure through S, F, displayed route and provenance readback through H, C, P, N, and non-escape for bare equations, hidden measurement, omitted error ledgers, all-future truth, host physical necessity, and final-fit oracles.

The four AI rows are the finite measurement row M, the records-side regularity row R, the Type IV future-persistence GAP row G, and the law-certificate consumption row A. These rows make the packet a concrete physical-law precursor rather than an equation-only model artifact.

The Lean `TasteGate.lean` boundary for $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial}\ \mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ instances preserving the displayed rows $M, R, K, L, G, A, S, F, H, C, P, N$.

Falsifiable prediction: An equation-like law packet lacking either finite measurement and error rows or an explicit future-persistence GAP is rejected by the EmpiricalRegularityPersistenceUp classifier.

Independence witness: lawcertificate, realityconstrainedphysicalinduction, openfitpacket, realityconstrainedmodelaudit, physicalinductionstabilityseal: none is bijective because $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ stores finite measurement, records-side regularity, classifier, error ledger, future-persistence GAP, LawCertificate consumption, stability, failure, transport, replay, provenance, and local NameCert

rows in one carrier. LawCertificateUp consumes a law surface but does not isolate records-side empirical regularity; RealityConstrainedPhysicalInductionUp binds induction continuation but not the measurement/error ledger as a physical-law precursor; OpenFitPacketUp records open fit without a law-consumption row; RealityConstrainedModelAuditUp audits model comparison without the Type IV persistence GAP; PhysicalInductionStabilitySealUp stores stability but not the empirical regularity and LawCertificate consumption pair.

Theorem 1156.6 (Empirical regularity persistence public interface)**.** *The public read exported by an accepted* EmpiricalRegularityPersistence$^{\uparrow}$ *packet is exactly the finite measurement row M, observed regularity row R, classifier row K, Type IV GAP row G,* LawCertificate$^{\uparrow}$ *consumption row A, stability row S, failure row F, componentwise transport row H, displayed replay row C, provenance row P, and local* NameCert *row N. A public consumer may not replace this interface by a bare equation, records-only regularity claim, model syntax, hidden calibration assumption, omitted error ledger, all-future truth, or law status detached from the displayed rows.*

Lean4 ✓ `BEDC.Derived.EmpiricalRegularityPersistenceUp.EmpiricalRegularityPersistenceCarrier public interface`

Proof. Project the carrier of Definition 1156.1. The rows $M, R, K, L, G, A, S, F, H, C, P, N$ are the full packet inventory, with M, R, L supplying observed evidence, G, S, F supplying the future-facing GAP boundary, and A, H, C, P, N supplying consumption, transport, replay, provenance, and local naming.

Apply the classifier of Definition 1156.2. It identifies accepted packets only through the displayed rows, so a public read cannot drop the classifier, transport, replay, provenance, or local name while preserving the packet.

Use GAP exposure and LawCertificate consumption, Definition 1156.3 and Definition 1156.4. These results keep records-side regularity separate from future persistence and require the law-certificate consumer to pass through measurement, regularity, classifier, error ledger, GAP, consumption, stability, failure, transport, replay, provenance, and local naming rows.

Finally apply nonescape, Definition 1156.5. It excludes bare equations, records-only reads, model syntax, hidden calibration, omitted ledgers, unlisted continuations, and off-packet future-persistence assertions, leaving exactly the stated public interface. □

Theorem 1156.7 (Empirical regularity persistence bridge route)**.** *Every* LawCertificate$^{\uparrow}$*-facing bridge read of an accepted* EmpiricalRegularityPersistence$^{\uparrow}$ *packet factors through the displayed measurement row M, observed regularity row R, classifier row K, future-persistence GAP row G, stability row S, failure row F, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N. The bridge may read the error-ledger row L as support for the same route, but it cannot replace the packet by a bare equation, records-only regularity claim, model syntax, hidden calibration assumption, all-future truth, or law status detached from those rows.*

Lean4 ✓ `BEDC.Derived.EmpiricalRegularityPersistenceUp.EmpiricalRegularityPersistenceBridgeRoute`

Proof. Start from Definition 1156.6. The public read exported by the packet is exactly the displayed measurement, regularity, classifier, GAP, law-certificate consumption, stability, failure, transport, replay, provenance, and local naming surface, with the error ledger retained as support.

Apply Definition 1156.4. A law-certificate consumer must pass through both the records side and the future-facing GAP side before reading any law-facing surface.

Finally use Definition 1156.5. The excluded replacements are not coordinates of the accepted carrier, so a bridge read that omits the listed rows leaves the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{EmpiricalRegularityPersistence}\uparrow}$.

Constructive story: An $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ packet is generated from finite measurement rows, observed regularity rows, classifier exposure, error-ledger rows, a Type IV future-persistence GAP, LawCertificate consumption, stability, failure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EmpiricalRegularityPersistence}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1156.1, Definition 1156.2, Definition 1156.3, Definition 1156.4, Definition 1156.5, Definition 1156.6, and Definition 1156.7 bind the finite observed-regularity and future-persistence packet exactly to the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EmpiricalRegularityPersistence}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, all-future truth, final physical necessity, host law identity, or law status without finite measurement, error, GAP, stability, failure, and LawCertificate rows.

Upgrade path: Further work is formal verification and bridge checking for carrier admission, classifier exposure, GAP exposure, LawCertificate consumption, non-escape, and TasteGate nontriviality with field faithfulness for $M, R, K, L, G, A, S, F, H, C, P, N$.

Chapter 1157

A Concrete Naming Certificate for $\mathsf{HostPrimitiveLeakage}^{\uparrow}$

The $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ packet realizes the host-smuggling branch of chapter 9462 as a finite diagnostic refusal carrier. It sits beside chapter 901, chapter 634, chapter 630, chapter 526, and chapter 546. Those siblings expose failed audit rows, quotient-boundary refusals, negative certificates, audit-gate verdicts, and kernel acceptance witnesses; this packet isolates the public-surface import of host primitives as the refused item.

Definition 1157.1 (HostPrimitiveLeakage carrier)**.** *A* $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, Q, E, D, F, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the public-surface site where a consumer requests host equality, host numerals, host lists, host function spaces, quotient soundness, choice, or propositional extensionality;*
2. *Q is the requested primitive row, naming the host feature that would otherwise enter as substrate content;*
3. *E is the exposed BEDC replacement row, containing the finite* BHist*,* msame*,* hsame*,* psame*,* Cont*,* Pkg*, or local* $\mathsf{NameCert}$ *route offered instead;*
4. *D is the diagnostic row explaining which public route attempted the import;*
5. *F is the failed-gate row consumed from* $\mathsf{AuditGateFailureWitness}^{\uparrow}$*;*
6. *G is the audit-boundary row consumed from* $\mathsf{AuditGateBoundary}^{\uparrow}$*;*
7. *H records componentwise* hsame *transport for the site, request, replacement, diagnostic, failed-gate, audit-boundary, replay, provenance, and local naming rows;*
8. *C records displayed* Cont *replay for the refusal route and for the replacement route when one is available;*
9. *P is the* Pkg *provenance over* $\mathsf{HostPrimitiveLeakage}^{\uparrow}$*,* $\mathsf{AuditGateFailureWitness}^{\uparrow}$*,* $\mathsf{QuotientSoundnessBoundary}^{\uparrow}$*,* $\mathsf{NegativeCertificateBoundary}^{\uparrow}$*,* $\mathsf{AuditGateBoundary}^{\uparrow}$*,* $\mathsf{KernelAuditWitness}^{\uparrow}$*,* BHist*,* msame*,* hsame*,* psame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HostPrimitiveLeakage}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host equality token, host-level numeric object, host list eliminator, host function-space extensionality principle, quotient soundness dependency, choice principle, or propositional-extensionality transport.

Lean4 (definition) `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakageUp`

Theorem 1157.2 (HostPrimitiveLeakage NameCert obligations)**.** *For the carrier of Definition 1157.1, the local* $\mathsf{NameCert}_{\mathsf{HostPrimitiveLeakage}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$L = (S, Q, E, D, F, G, H, C, P, N),$$

public-site exposure through S*, requested-host-primitive exposure through* Q*, BEDC replacement exposure through* E*, diagnostic readback through* D*, failed-gate witness exposure through* F*, audit-boundary verdict exposure through* G*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakageNameCertObligations`

Proof. Carrier admission is projection from Definition 1157.1. The rows $S, Q, E, D, F, G, H, C, P, N$ account for the public site, requested host primitive, BEDC replacement, diagnostic readback, failed-gate witness, audit boundary, transport, replay, provenance, and local naming surface.

The failed-gate and audit rows are consumed from the sibling certificates chapter 901 and chapter 526. The quotient-specific branch is read through chapter 634, and the named refusal branch is read through chapter 630.

The kernel witness sibling chapter 546 supplies the accepted-declaration readback surface, not a permission to import host primitives. Repacking these rows gives the local naming certificate, and every public consumer route is forced to display the requested host feature before the route can be refused or replaced. □

Theorem 1157.3 (HostPrimitiveLeakage non-escape)**.** *Every accepted* $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ *packet* $L = (S, Q, E, D, F, G, H, C, P, N)$ *admits public reads only through the displayed diagnostic route* $S, Q, D, F, G, H, C, P, N$ *and, when present, the replacement route* E, H, C, P, N*. A consumer that reads host equality, host numerals, host lists, host function spaces, quotient soundness, choice, or propositional extensionality as BEDC-internal content has left the accepted packet.*

Lean4 ✓ `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakageNonescape`

Proof. Inspect the carrier. The requested host feature is present only as the request row Q, and the diagnostic row D records the public route that tried to expose it.

Apply Definition 1157.2. The failed-gate row F and audit-boundary row G keep the request on the refusal side of the packet, while H, C, P, N preserve only the displayed diagnostic and replacement routes.

Finally use the excluded coordinates in Definition 1157.1. Since no host primitive is a packet coordinate, every accepted consumer route either reads it as a refused request through Q, D, F, G or uses the visible BEDC replacement row E. □

Falsifiable prediction: An accepted $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ packet is refuted by any public consumer route that obtains host equality, host numerals, host lists, host function spaces, quotient soundness, choice, or propositional extensionality without first exposing the requested primitive row and the failed-gate diagnostic row.

Independence witness: auditgatefailurewitness, quotientsoundnessboundary, negativecertificateboundary, auditgateboundary, kernelauditwitness: HostPrimitiveLeakage$^{\uparrow}$ has the simultaneous public-site row, requested-host-primitive row, replacement row, diagnostic row, failed-gate row, and audit-boundary row. The siblings each expose a gate, quotient, negative, audit, or kernel face, but none carries the complete finite leakage witness.

The Lean follow-up for this chapter must provide `Derived/HostPrimitiveLeakageUp/TasteGate.lean` with Nontrivial HostPrimitiveLeakage$^{\uparrow}$ and FieldFaithful HostPrimitiveLeakage$^{\uparrow}$ instances for the displayed carrier fields.

Theorem 1157.4 (HostPrimitiveLeakage public export)**.** *Every public* HostPrimitiveLeakage$^{\uparrow}$ *leakage read must expose the public site S, requested primitive Q, replacement row E, diagnostic row D, failed-gate row F, audit-boundary row G, transport row H, replay row C, provenance row P, local naming row N, and the displayed* `TasteGate` *marker before a consumer can use either the refusal route or the replacement route.*

Proof. Project the carrier of Definition 1157.1. The public leakage surface is exactly $S, Q, E, D, F, G, H, C, P, N$, with Q naming the requested host primitive and E naming only the BEDC replacement route when one is available.

Apply Definition 1157.2 and Definition 1157.3. The first theorem lists the local NameCert obligations for every displayed row, and the second prevents a public consumer from using a host primitive as accepted BEDC content.

The falsifiable prediction records the observable failure condition, while the independence witness separates this packet from the audit-gate and boundary siblings. Together with the displayed `BEDC.Derived.HostPrimitiveLeakageUp.taste_gate` marker, these rows expose the refusal or replacement route before any public consumer may use it. □

Lean4 ✓ `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakagePublicExport`

Theorem 1157.5 (HostPrimitiveLeakage report-row refusal)**.** *Let $L = (S, Q, E, D, F, G, H, C, P, N)$ be an accepted* HostPrimitiveLeakage$^{\uparrow}$ *packet. Any public report that identifies the requested primitive Q as host equality, host numerals, host lists, host function spaces, quotient soundness, choice, or propositional extensionality must pass through the diagnostic report row D, failed-gate row F, audit-boundary row G, transport row H, replay row C, provenance row P, and local naming row N before the refusal or replacement route is exported.*

Proof. Project the carrier of Definition 1157.1. The requested host feature is the row Q, and the only row that reports where the public import was attempted is D.

Apply Definition 1157.3. It keeps every accepted public read on the displayed diagnostic route $S, Q, D, F, G, H, C, P, N$ or on the replacement route E, H, C, P, N.

Finally use Definition 1157.4. The public export must display all ten rows before a consumer can use the refusal or replacement route, so a report that omits D, F, G, H, C, P, N cannot be an accepted HostPrimitiveLeakage$^{\uparrow}$ export. □

Lean4 ✓ `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakageReportRowRefusal`

Theorem 1157.6 (HostPrimitiveLeakage quotient-soundness non-escape)**.** *Let $L = (S, Q, E, D, F, G, H, C, P, N)$ be an accepted* HostPrimitiveLeakage$^{\uparrow}$ *packet whose requested primitive row Q names quotient soundness. The packet can expose that request only as a refused host primitive routed through $S, Q, D, F, G, H, C, P, N$ and through the sibling quotient-boundary provenance in P; it does not export quotient soundness as BEDC-internal evidence.*

Proof. Use the carrier projection from Definition 1157.1. Quotient soundness can occur only as the requested primitive row Q, while the provenance row P records the quotient-boundary sibling route.

Apply Definition 1157.2. The local NameCert surface requires the request row, diagnostic row, failed-gate row, audit-boundary row, replay, provenance, and naming rows to be displayed together.

Now apply Definition 1157.3. Since quotient soundness is listed among the host primitives that cannot be accepted as BEDC-internal content, the only accepted read is the refusal route, with any BEDC replacement separated into E, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakageQuotSoundnessNonescape`

Theorem 1157.7 (HostPrimitiveLeakage audit-gate factorization)**.** *Every accepted public export of a* $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ *packet* $L = (S, Q, E, D, F, G, H, C, P, N)$ *factors its leakage refusal through the failed-gate row* F *and audit-boundary row* G *before the structural rows* H, C, P, N *can name the exported route. Thus a consumer cannot bypass the audit gate by reading* Q *or* E *alone.*

Proof. Start with Definition 1157.4. It states that a public leakage read displays $S, Q, E, D, F, G, H, C, P, N$ before either the refusal route or replacement route is available.

The NameCert obligations of Definition 1157.2 identify F as the failed-gate witness row and G as the audit-boundary verdict row. These rows occur before the structural transport, replay, provenance, and local naming rows are consumed.

Finally apply Definition 1157.3. Reading Q alone would expose only a refused request, and reading E alone would expose only a replacement row; neither read can bypass the displayed audit-gate factorization through F, G, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakageAuditGateFactorization`

Theorem 1157.8 (HostPrimitiveLeakage formal-axis boundary)**.** *The paper-mature refusal route for* $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ *is assembled from the displayed carrier, NameCert obligations, non-escape theorem, public-export theorem, report-row refusal theorem, quotient-soundness non-escape theorem, audit-gate factorization theorem, the checked TasteGate row* `BEDC.Derived.HostPrimitiveLeakageUp.t` *and the checked non-escape row* `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakageNonescape`*. What remains on the formal axis is a single combined Lean target,* `BEDC.Derived.HostPrimitiveLeakageUp.Host` *packaging those rows as one machine-checked chapter closure theorem.*

Proof. The carrier and paper theorems bind the public-site row, requested-host-primitive row, replacement row, diagnostic row, failed-gate row, audit-boundary row, transport row, replay row, provenance row, and local naming row inside the chapter.

The two checked Lean rows witness different formal components: the TasteGate marker records the refusal packet's taste surface, and HostPrimitiveLeakageNonescape records the checked non-escape boundary. Neither marker is stated as the single combined closure theorem named above.

Therefore the closurestatus block continues to report the formal axis as unformalized for the combined chapter theorem, while preserving the mature paper closure already witnessed by the displayed refusal route. □

Theorem 1157.9 (HostPrimitiveLeakage formal target)**.** *For an accepted* $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ *packet, the displayed carrier of Definition 1157.1, the NameCert obligations of Definition 1157.2,*

the non-escape route of Definition 1157.3, the public-export route of Definition 1157.4, the report-row refusal of Definition 1157.5, the quotient-soundness non-escape route of Definition 1157.6, the audit-gate factorization of Definition 1157.7, the displayed TasteGate row `BEDC.Derived.HostPrimitiveLeakageU` *and the checked non-escape row* `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakageNonescape` *together form the formal target for future Lean packaging as* `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimi`

Lean4 ✓ `BEDC.Derived.HostPrimitiveLeakageUp.HostPrimitiveLeakageFormalTarget`

Proof. The carrier projection supplies the ten displayed rows $S, Q, E, D, F, G, H, C, P, N$. Apply Definition 1157.2 to identify those rows as the complete local certificate surface.

The refusal side is fixed by Definition 1157.3, Definition 1157.5, and Definition 1157.6. These theorems keep host equality, host numerals, host lists, host function spaces, quotient soundness, choice, and propositional extensionality on the requested-primitive and diagnostic rows rather than as accepted BEDC content.

The export side is fixed by Definition 1157.4 and Definition 1157.7. They force every public route through the failed-gate and audit-boundary rows before transport, replay, provenance, and local naming can export either the refusal route or the replacement route.

Finally the displayed TasteGate row and checked non-escape row are exactly the Lean-visible rows already named in the chapter. Packaging these paper and Lean-visible components as one theorem is the combined formal target, with no additional marker asserted here. □

Closure status for $\mathsf{NameCert}_{\mathsf{HostPrimitiveLeakage}^{\uparrow}}$.
Lean4 ✓ `BEDC.Derived.HostPrimitiveLeakageUp.taste gate`

Constructive story: A $\mathsf{HostPrimitiveLeakage}^{\uparrow}$ packet is generated from a public-surface site, requested host primitive, BEDC replacement row, diagnostic readback, failed-gate witness, audit-boundary row, componentwise transports, continuation replay, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HostPrimitiveLeakage}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1157.1, Definition 1157.2, Definition 1157.3, Definition 1157.4, the displayed falsifiable prediction, the displayed independence witness, the audit-boundary sibling chapters, and the displayed `BEDC.Derived.HostPrimitiveLeakageUp.` marker bind the refusal packet through BHist, msame, hsame, psame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HostPrimitiveLeakage}^{\uparrow}}, \mathsf{unformalized})$

Ledger evidence: BEDC.Meta.DiscoveryDeltaLedger.hostPrimitiveLeakageDeltaLedger

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, or every host-leakage case.

Upgrade path: Machine bridge checking requires a checked standard interface row that preserves the refusal packet across standard BEDC interfaces.

Chapter 1158

A Concrete Naming Certificate for $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$

The $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ packet realizes the diagonal-regularity row of Definition 9238.4 as a finite concrete NameCert carrier. It sits downstream of the selected diagonal representative in chapter 374, chapter 1205, and the three-leg estimate surface of chapter 466, while consuming the window, regular-rational, dyadic, and real-seal sibling rows of chapter 126, chapter 301, chapter 291, and chapter 38. The packet names the finite regularity evidence used by downstream Real-completion routes; it is not a selected limit, host real equality, quotient-stream equality, countable choice, or ambient completeness principle.

Definition 1158.1 (Regular Cauchy regularity-witness carrier)**.** *A* $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, \mu, j, \Omega, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the selected source row naming the diagonal representative route consumed from chapter 1205.*
2. *μ is the modulus index row that selects the finite regular-Cauchy comparison budget for the requested pair of precisions.*
3. *j is the finite index arithmetic row tying the selected source row to the regularity request.*
4. *Ω is the* $\mathsf{StreamName}^{\uparrow}$ *window exposing the diagonal observation and the intermediate observations used by the regularity consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected window and its regular-rational endpoint comparisons.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the two endpoint tolerances, the middle comparison tolerance, and the final diagonal-regularity bound.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row reached only after the displayed window, readback, and tolerance ledger have been read.*
8. *H records componentwise* hsame *transport for $S, \mu, j, \Omega, R, Q, E$ and the local certificate row.*
9. *C records displayed* Cont *replay from selected source row through modulus index, window, readback, dyadic ledger, and Real seal handoff.*

10. *P is the* Pkg *provenance over* RegularCauchyRegularityWitness$^{\uparrow}$, DiagonalLimit$^{\uparrow}$, RegularCauchyTriangleBound$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{RegularCauchyRegularityWitness}^{\uparrow}}$ *row.*

The carrier exports no selected host limit, host real equality, quotient-stream equality, Quot.sound *row,* Classical.choice *row, or ambient* Real$^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.TasteGate.RegularCauchyRegularityWitnessTasteGate single carrier alignment`

Theorem 1158.2 (Regular Cauchy regularity-witness NameCert obligations)**.** *For the carrier of Definition 1158.1, the local* NameCert$_{\text{RegularCauchyRegularityWitness}^{\uparrow}}$ *surface consists exactly of carrier admission for $W = (S, \mu, j, \Omega, R, Q, E, H, C, P, N)$, selected diagonal source exposure through S, modulus-index computation through μ and j, finite* StreamName$^{\uparrow}$ *window exposure through Ω,* RegSeqRat$^{\uparrow}$ *regularity readback through R,* DyadicRatCore$^{\uparrow}$ *tolerance-ledger exposure through Q, downstream* Real$^{\uparrow}$ *seal handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.TasteGate.RegularCauchyRegularityWitnessNameCert(`

Proof. Project the carrier. Its coordinates list the selected diagonal source row, modulus index, index arithmetic, finite stream window, regular-rational readback, dyadic tolerance ledger, Real seal handoff, transport, replay, provenance, and local name.

The sibling surfaces account for the data-bearing rows. The diagonal representative supplies S; the triangle-bound packet supplies the regularity estimate route; StreamName$^{\uparrow}$ supplies Ω; RegSeqRat$^{\uparrow}$ supplies R; DyadicRatCore$^{\uparrow}$ supplies Q; and Real$^{\uparrow}$ supplies E only as the terminal seal handoff.

The remaining rows do not add mathematical content. They transport, replay, source, and name the displayed rows, so the listed clauses exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitness namecert obligations`

Theorem 1158.3 (Regular Cauchy regularity-witness diagonal-consumer boundary)**.** *Every diagonal-regularity consumer of an accepted* RegularCauchyRegularityWitness$^{\uparrow}$ *packet factors through the finite route*

$$S, \mu, j, \Omega, R, Q, E, H, C, P, N.$$

The consumer reads the selected source row, modulus index, finite StreamName$^{\uparrow}$ *window,* RegSeqRat$^{\uparrow}$ *readback, and* DyadicRatCore$^{\uparrow}$ *tolerance ledger before it can receive the* Real$^{\uparrow}$ *seal handoff.*

Proof. Begin with the NameCert obligations. They require the selected diagonal source row and the modulus-index rows to be visible before any regularity evidence is read.

Next read the sibling surfaces in order. The stream window exposes the finite observations, the regular-rational row supplies the endpoint and middle readbacks, and the dyadic ledger records the tolerance arithmetic consumed by the diagonal-regularity theorem.

Finally pass through the Real seal handoff and the structural rows. Since the carrier contains no off-route equality or selection coordinate, every diagonal-regularity consumer remains inside the displayed finite route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitnessDiagonalConsumerBou`

Theorem 1158.4 (Regular Cauchy regularity-witness no-hidden-limit boundary)**.** *An accepted* RegularCauchyRegularityWitness$^{\uparrow}$ *packet exports exactly the selected source row S, modulus-index rows μ, j, finite* StreamName$^{\uparrow}$ *window Ω,* RegSeqRat$^{\uparrow}$ *readback R,* DyadicRatCore$^{\uparrow}$ *tolerance ledger Q,* Real$^{\uparrow}$ *seal handoff E, componentwise transport H, continuation replay C, package provenance P, and local naming row N. It exports no selected host limit, host real equality, quotient-stream equality,* Quot.sound *witness,* Classical.choice *witness, or ambient completeness row.*

Proof. Inspect the carrier coordinates of Definition 1158.1. Every coordinate is a displayed BEDC row, a finite modulus or index row, or structural support for transport, replay, provenance, and naming.

Definition 1158.2 accounts for the admissible carrier and classifier-facing rows. Definition 1158.3 accounts for every diagonal-regularity consumer read.

The excluded objects require additional coordinates absent from the carrier. Hence they cannot be exported by the local naming certificate or recovered by a consumer of the displayed regularity-witness route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitness no hidden limit boundary`

Theorem 1158.5 (Regular Cauchy regularity-witness Real-completion handoff)**.** *Every accepted* RegularCauchyRegularityWitness$^{\uparrow}$ *packet*

$$W = (S, \mu, j, \Omega, R, Q, E, H, C, P, N)$$

consumed by a RealCauchyCompletion$^{\uparrow}$ *diagonal route is read through the selected diagonal source S, the finite* StreamName$^{\uparrow}$ *window Ω, the* RegSeqRat$^{\uparrow}$ *readback R, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger Q, and the* Real$^{\uparrow}$ *seal handoff E before any completion-facing seal is available. The same route displays the supporting* BHist, hsame, Cont, Pkg, *and* NameCert *rows H, C, P, N carried by the packet.*

Consequently the completion-facing read factors through the finite regularity-witness surface and the finite-window Real-completion support route. It exports no selected host limit, host real equality, quotient-stream equality, Quot.sound *row,* Classical.choice *row, ambient completeness coordinate, or substitute support row outside the displayed BEDC packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitness real completion handoff`

Proof. Begin with the local packet. Definition 1158.2 exposes exactly the selected source, modulus-index, window, readback, tolerance-ledger, Real-seal handoff, transport, replay, provenance, and naming rows of W.

The diagonal-consumer boundary Definition 1158.3 orders these rows before any consumer receives the Real$^{\uparrow}$ seal handoff. The no-hidden-limit boundary Definition 1158.4 removes selected host limits, host real equality, quotient-stream equality, Quot.sound, Classical.choice, and ambient completeness from the packet surface.

Now attach the completion-facing route. Definition 360.48 exhausts every accepted RealCauchyCompletion$^{\uparrow}$ finite-window completion read by the displayed StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readbacks, DyadicRatCore$^{\uparrow}$ ledgers, diagonal packet, Real$^{\uparrow}$ seal, BHist, hsame, Cont, Pkg, and NameCert rows. Definition 360.52 says that the Phase Real and Completion exit remains valid only when DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and the displayed structural support rows are present.

Intersecting these two finite routes leaves exactly the handoff stated above. The regularity witness supplies the selected diagonal source, window, readback, dyadic ledger, Real seal, and support rows consumed by the Real-completion route, and the cited non-escape clauses leave no coordinate through which the completion-facing seal could bypass them. □

Theorem 1158.6 (Regular Cauchy regularity witness tail-window regularity)**.** *Every accepted* $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ *packet consumed as a regularity witness exposes its* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{Real}^{\uparrow}$ *sealing row, and* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff before the witness can be consumed. Equivalently, a consumer of the packet must factor through the displayed tail-window route*

$$S, \mu, j, \Omega, R, Q, E, H, C, P, N$$

with Ω *read as the finite observation window,* R *as the regular-rational regularity readback,* Q *as the dyadic tolerance ledger,* E *as the Real sealing row, and* H, C, P, N *as the componentwise transport, continuation replay, provenance, and naming rows that carry the handoff into the completion-facing route.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitnessTailWindowRegularit`
↪ variant `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitness tail window regularity`

Proof. Project the accepted carrier. The coordinates of Definition 1158.1 display the selected source row, modulus-index rows, finite observation window, regular-rational readback, dyadic tolerance ledger, Real seal, and structural support rows.

The consumer order is forced by the preceding boundaries. Definition 1158.3 places the window, readback, and tolerance ledger before the Real seal; Definition 1158.5 then routes the same displayed rows into the $\mathsf{RealCauchyCompletion}^{\uparrow}$ diagonal surface.

It remains to check that transport cannot alter the exposed rows. Replay the componentwise hsame row H and the displayed Cont row C along the packet coordinates; the Pkg row P and local $\mathsf{NameCert}$ row N only source and name the same finite data. Thus any accepted consumer sees the tail-window route before it can consume the regularity witness. □

Theorem 1158.7 (Regular Cauchy regularity-witness obligation closure)**.** *For the carrier* $W = (S, \mu, j, \Omega, R, Q, E, H, C, P, N)$ *of Definition 1158.1, carrier admission, diagonal source exposure, modulus-index rows, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRegularityWitness}^{\uparrow}}$ *row form the full obligation surface. Any accepted regularity-witness consumer factors through that finite surface before it can use the diagonal-regularity witness, and no selected host limit, host real equality, quotient-stream equality,* $\mathsf{Quot.sound}$ *row,* $\mathsf{Classical.choice}$ *row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate is part of the obligation closure.*

Proof. Project the accepted packet W. The carrier definition displays exactly the source, modulus, index, finite window, readback, tolerance, Real seal, transport, replay, provenance, and naming rows, and Definition 1158.2 identifies those rows as the local NameCert obligations.

Induct over the displayed finite window route. The base read exposes the selected diagonal source S and the first window row in Ω through the modulus-index data μ, j. The step extends the same route by one displayed observation, transports the previous rows through H, and replays the continuation row C without adding a new carrier coordinate.

The consumer boundaries close the remaining cases. Definition 1158.3 forces any diagonal-regularity consumer through the listed rows; Definition 1158.4 removes off-route limit and equality data; and Definition 1158.5 places the $\mathsf{Real}^{\uparrow}$ seal after the window, readback, and dyadic ledger.

Thus the finite route named in Definition 1158.6 is not merely a handoff order. It is the whole obligation surface for the accepted packet, with P and N recording provenance and local naming for the same rows. □

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitnessCarrier obligation closure`

Theorem 1158.8 (Regular Cauchy regularity-witness scoped kernel route)**.** *The accepted* RegularCauchyRegularityW *carrier factors only through the finite* $\mathsf{StreamName}^{\uparrow}$ *window rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal handoff,* BHist *packet rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before a diagonal-regularity consumer can read it. Thus the scoped kernel route for the carrier*

$$W = (S, \mu, j, \Omega, R, Q, E, H, C, P, N)$$

is exhausted by the displayed rows

$$S, \mu, j, \Omega, R, Q, E, H, C, P, N$$

and cannot pass through selected host limits, host real equality, quotient-stream equality, Quot.sound*,* Classical.choice*, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitness scoped kernel route`

Proof. Project the accepted carrier. The source, modulus, and index rows determine which finite window route is being read, while Ω is the only $\mathsf{StreamName}^{\uparrow}$ window coordinate available to the consumer.

The readback and estimate rows then fix the numerical surface. The $\mathsf{RegSeqRat}^{\uparrow}$ row R supplies the regular-rational readback, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row Q records the tolerance ledger used by the diagonal-regularity consumer before any Real seal is visible.

The terminal and structural rows close the route. The $\mathsf{Real}^{\uparrow}$ handoff E is read only after the window, readback, and tolerance rows; H, C, P, N transport, replay, source, and name the same packet. By the no-hidden-limit boundary, there is no carrier coordinate for off-route equality, choice, quotient soundness, or ambient completeness, so the displayed finite route is the scoped kernel route. □

Theorem 1158.9 (Regular Cauchy regularity-witness finite-window induction)**.** *Every accepted* $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ *packet*

$$W = (S, \mu, j, \Omega, R, Q, E, H, C, P, N)$$

can be consumed by induction over the finite $\mathsf{StreamName}^{\uparrow}$ *windows displayed in* Ω *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal handoff* E *are exposed. The induction base reads the selected diagonal source* S *and the first window row named by* μ, j*; each induction step appends one displayed window row, transports the prior window data through* H*, and replays the finite continuation route in* C*. Only after this finite induction has displayed the requested window may a consumer read* R*, then* Q*, and finally* E*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitness finite window induction`

Proof. Project the accepted carrier of Definition 1158.1. The only window data available before readback is the finite $\mathsf{StreamName}^{\uparrow}$ coordinate Ω, with the selected source row S and modulus-index rows μ, j determining which finite observations are requested.

Induct over the displayed window spine. In the base case, the consumer reads S and the first named observation through Ω; no regular-rational readback, dyadic ledger, or Real seal coordinate is yet available.

For the step case, append one displayed observation row of Ω. The componentwise transport row H preserves the prior selected source, modulus, index, and window rows, while the continuation row C replays the finite route to the extended window without adding an off-carrier equality or choice row.

After the finite window has been displayed, Definition 1158.3 and Definition 1158.5 force the remaining order: the consumer reads the $\mathsf{RegSeqRat}^{\uparrow}$ row R, then the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger Q, and only then the $\mathsf{Real}^{\uparrow}$ seal handoff E. Thus the accepted witness is consumable by finite-window induction before any downstream readback, tolerance ledger, or Real seal is exposed. □

Theorem 1158.10 (Regular Cauchy regularity-witness tail-window synchronization)**.** *Let*

$$W = (S, \mu, j, \Omega, R, Q, E, H, C, P, N) \quad \text{and} \quad W' = (S', \mu', j', \Omega', R', Q', E', H', C', P', N')$$

be accepted $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ *packets. If their inspected finite tails agree through the displayed* hsame *transports and* Cont *rows on* S, μ, j, Ω *and* S', μ', j', Ω'*, and if their* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows are read only after that shared finite-window route, then the two packets expose the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface and the same Real-completion handoff surface to every completion-facing consumer.*

The synchronization is a finite tail-window fact. It does not select a limit, identify host real values, prove quotient equality of regular sequences, or use ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularityWitnessUp.RegularCauchyRegularityWitness tail window synchronization`

Proof. Project the two accepted carriers using Definition 1158.1. The only rows visible before readback are the selected source, modulus index, index arithmetic, and finite $\mathsf{StreamName}^{\uparrow}$ window rows.

Apply finite-window induction from Definition 1158.9 to both packets. The hypothesis that the inspected finite tails agree under the displayed hsame and Cont rows makes the induction expose the same finite window route before either packet can read R, Q, E or R', Q', E'.

Now use the diagonal-consumer boundary Definition 1158.3. It forces every diagonal-regularity consumer to read the $\mathsf{RegSeqRat}^{\uparrow}$ row only after the shared window route has been displayed. Hence R and R' present the same readback surface to such a consumer.

Finally apply the Real-completion handoff Definition 1158.5. The handoff can inspect only the window, readback, dyadic ledger, Real seal, and structural rows already synchronized above. The no-hidden-limit boundary excludes selected limits, quotient equality, host real equality, and ambient completeness, so no off-route coordinate can distinguish the two completion-facing surfaces. □

Falsifiable prediction: Every accepted RegularCauchyRegularityWitnessUp packet exposes a finite dyadic regularity-witness row and admits no route to a selected limit, host real equality, Quot.sound, or Classical.choice.

Independence witness: diagonallimit, regular-cauchy-triangle-bound, regseqrat, streamname, real: no listed sibling is bijective to $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ because this packet binds selected diagonal source, modulus index, finite window, regular-rational readback, dyadic tolerance ledger, Real seal handoff, transport, replay, provenance, and local NameCert rows in one consumer-facing regularity witness. The diagonal-limit sibling lacks the regularity-consumer tolerance ledger; the triangle-bound sibling lacks the selected representative seal handoff; RegSeqRatUp lacks the StreamName and Real route; StreamNameUp lacks regularity and dyadic ledger rows; RealUp lacks the finite witness route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRegularityWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ packet is generated from a selected diagonal source row, modulus index, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRegularityWitness}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1158.1, Definition 1158.2, Definition 1158.3, Definition 1158.4, Definition 1158.7, and Definition 1158.8 bind the diagonal-regularity witness packet as a finite Real-completion handoff whose consumer-facing route is scoped by the displayed StreamName, RegSeqRat, DyadicRatCore, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRegularityWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected host limits, host real equality, quotient-stream equality, Quot.sound, Classical.choice, or ambient Real completeness.

Upgrade path: Lean verification requires a checked RegularCauchyRegularityWitnessUp theorem for the scoped consumer-facing route and its sibling dependency boundary.

Chapter 1159

A Concrete Naming Certificate for $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$

The $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ packet isolates the last estimate in the compact-uniform-continuity construction of chapter 9237. It is the Bishop–Bridges finite-net proof surface for Heine–Cantor in BEDC form: a selected compact-net center is used twice in the source metric, the continuous-map rows provide two pointwise target estimates at that center, and the target metric triangle row returns the final uniform estimate. The packet is anchored in the metric certificate of chapter 57, compact metric data of chapter 129, continuous-map data of chapter 130, finite lower-bound folding of chapter 619, and the consumer surface of chapter 369.

Definition 1159.1 (Metric-triangle uniform-estimate carrier)**.** *A* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier is a finite packet*

$$E = (X, Y, F, x, x', c, d_x, d_{x'}, e_c, e_x, e_{x'}, T, H, C, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *row carrying the located source-distance classifier.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row carrying the target-distance classifier.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus packet for the displayed function from X to Y.*
4. *x and x' are the two source histories whose target images are compared by the uniform-modulus consumer.*
5. *c is the compact-net center selected from the finite bundle associated to the tolerance row.*
6. *d_x is the source distance row from x to c supplied by compact-net coverage.*
7. *$d_{x'}$ is the source distance row from x' to c obtained from the selected precision row, the source distance between x and x', and the source triangle ledger.*
8. *e_c is the selected precision row exported by the finite fold of chapter 619.*
9. *e_x and $e_{x'}$ are the two pointwise target-distance estimates at c, one for $f(x)$ and one for $f(x')$.*
10. *T is the final target triangle ledger joining the two pointwise target estimates into the displayed estimate between $f(x)$ and $f(x')$.*

11. *H stores the componentwise* hsame *transports for all source, target, precision, and triangle rows.*
12. *C stores the* Cont *routes by which a consumer reads the source triangle, the target triangle, and the uniform-modulus handoff.*
13. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, *and* Cont *rows.*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricTriangleUniformEstimate}^{\uparrow}}$ *registration row.*

The classifier compares carriers only through these displayed rows. It has no coordinate for host compactness, selected subsequences, choice principles, open-cover compactness, or completeness of the real numbers.

Lean4 (definition) `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier`

Theorem 1159.2 (Metric-triangle uniform-estimate NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{MetricTriangleUniformE}}$ *obligation surface consists of five finite rows:*

1. *carrier exposure, requiring every public read of E to factor through the displayed source metric, target metric, continuous graph, selected center, distance, precision, triangle, transport, continuation, provenance, and local naming rows;*
2. *classifier stability, requiring componentwise* hsame *transport for $X, Y, F, x, x', c, d_x, d_{x'}, e_c, e_x, e_{x'}, T, H, C, P, N$;*
3. *source triangle admissibility, requiring $d_{x'}$ to be read from the source metric triangle row using the selected precision e_c, the compact-net coverage row d_x, and the displayed source distance between x and x';*
4. *target triangle admissibility, requiring T to be read from the target metric triangle row using the two pointwise target-distance estimates e_x and $e_{x'}$ at the same center c;*
5. $\mathsf{UniformModulus}^{\uparrow}$ *consumer handoff, requiring the downstream uniform-modulus packet to receive only the finite selected precision row, the two source metric bounds, the two pointwise target bounds, the final target triangle row, and the visible transport and provenance rows.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier namecert obligations`

Proof. Project the carrier $E = (X, Y, F, x, x', c, d_x, d_{x'}, e_c, e_x, e_{x'}, T, H, C, P, N)$. Carrier exposure and classifier stability are the displayed coordinates and the componentwise transports in H.

For source admissibility, read the finite-fold precision row e_c and the compact-net coverage row d_x. The source metric triangle row in X combines those rows with the displayed distance between x and x' and produces the source bound $d_{x'}$ at the same center c.

For target admissibility, use the pointwise rows in F at the chosen center. They give e_x and $e_{x'}$ as target estimates from $f(c)$ to $f(x)$ and from $f(c)$ to $f(x')$. The target metric triangle row in Y then supplies T.

The consumer handoff is the continuation route C with provenance P and local name N. Since the packet has no coordinate for host compactness, selected subsequences, choice, open-cover compactness, or real completeness, none of those objects can be exported to $\mathsf{UniformModulus}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier uniformmodulus boundary exactness`

Theorem 1159.3 (Metric-triangle uniform-estimate consumer handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier receives exactly the selected precision row* e_c*, the two source metric bounds* d_x *and* $d_{x'}$*, the two pointwise target bounds* e_x *and* $e_{x'}$*, the final target triangle row* T*, and the displayed transport, continuation, provenance, and local naming rows* H, C, P, N*. It receives no host compactness coordinate, selected subsequence, choice-selected point outside the finite bundle, open-cover compactness object, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier consumer handoff`

Proof. Start with the carrier exposure and source triangle admissibility of Definition 1159.2. They identify the only source-side data delivered to a consumer: the selected precision row, compact-net coverage, the source distance between x and x', and the source triangle row producing $d_{x'}$.

Next use target triangle admissibility. The pointwise target estimates e_x and $e_{x'}$ are read from the continuous-map packet at the same selected center, and the final estimate is the target triangle row T.

Finally apply the handoff obligation. The continuation and provenance rows send precisely those finite coordinates to $\mathsf{UniformModulus}^{\uparrow}$, while the excluded host compactness, subsequence, choice, open-cover, and real-completeness objects are absent from the carrier. □

Theorem 1159.4 (Metric-triangle uniform-estimate source-triangle coherence)**.** *For an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier* E*, the selected center route and the source metric triangle row determine the two source-distance rows* d_x *and* $d_{x'}$ *used by the uniform-estimate packet. The determination uses the carrier rows, the local NameCert obligations, compact-net coverage from chapter 129, finite lower-bound precision from chapter 619, and the source* $\mathsf{Met}^{\uparrow}$ *triangle ledger; it uses no host compactness, selected subsequence, open-cover compactness, choice principle, or real completeness.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier source triangle coherence`

Proof. Project the carrier of Definition 1159.1. The displayed rows include the selected center c, the selected precision e_c, compact-net coverage for x at c, the source distance between x and x', and the source triangle ledger inside X.

Apply the NameCert obligations of Definition 1159.2. Source triangle admissibility says that d_x is the compact-net coverage row and that $d_{x'}$ is read from the source triangle row using e_c, d_x, and the displayed distance between x and x'.

The consumer handoff theorem Definition 1159.3 then fixes these rows as the only source bounds sent onward. Since the carrier has no host compactness or choice coordinate, no outside compactness principle can alter the determined source route. □

Theorem 1159.5 (Metric-triangle uniform-estimate target-triangle coherence)**.** *For an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier* E*, the two pointwise target estimates* e_x *and* $e_{x'}$ *at the same selected center* c *feed the target triangle row* T *and determine the displayed target estimate between* $f(x)$ *and* $f(x')$*. The route factors through the target* $\mathsf{Met}^{\uparrow}$ *row, the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise rows, the carrier, the local NameCert obligations, and the consumer handoff, with no semantic target-space completeness or host equality of target points.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier target triangle coherence`

Proof. Read the carrier rows $Y, F, c, e_x, e_{x'}, T$ from Definition 1159.1. The target metric row Y supplies the triangle ledger, while the continuous-map packet F supplies both pointwise target estimates at the same selected center.

Use target triangle admissibility from Definition 1159.2. It identifies T as the row obtained from those two pointwise estimates through the target metric triangle.

Apply Definition 1159.3. The downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer receives T only through this finite target route, so the estimate is not supplemented by target completeness, host equality, or a hidden semantic metric argument. □

Theorem 1159.6 (Metric-triangle uniform-estimate uniform-modulus route exhaustion)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier factors through the selected precision* e_c*, the two source bounds* $d_x, d_{x'}$*, the two target bounds* $e_x, e_{x'}$*, the final target triangle row* T*, and the visible transport, continuation, provenance, and local naming rows* H, C, P, N*. No consumer route may add host compactness, a choice-selected center outside the finite bundle, an open-cover compactness witness, a semantic continuity theorem, or a* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier uniform modulus route exhaustion`

Proof. First combine source-triangle coherence with target-triangle coherence. The source side fixes d_x and $d_{x'}$ from the selected center route and source triangle ledger, while the target side fixes T from the two pointwise target estimates at that same center.

Next apply the NameCert obligations of Definition 1159.2. They make carrier exposure, classifier stability, source admissibility, target admissibility, and consumer handoff the full obligation surface for the packet.

Finally use Definition 1159.3. It states that the consumer receives exactly $e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N$, so every accepted $\mathsf{UniformModulus}^{\uparrow}$ read factors through those rows and through no host compactness or completion object. □

Theorem 1159.7 (Metric-triangle uniform-estimate classifier transport)**.** *For accepted* MetricTriangleUniformEstim *carriers* E *and* E'*, componentwise* hsame *transport of*

$$X, Y, F, x, x', c, d_x, d_{x'}, e_c, e_x, e_{x'}, T, H, C, P, N$$

preserves the public classifier. The transported route remains internal to BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; it does not pass through host compactness, selected subsequences, open-cover compactness, choice, semantic continuity, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier classifier transport`

Proof. Project both carriers through Definition 1159.1. The classifier reads only the displayed rows $X, Y, F, x, x', c, d_x, d_{x'}, e_c, e_x, e_{x'}, T, H, C, P, N$.

Apply classifier stability from Definition 1159.2. Each displayed coordinate is transported by the matching component of H, so the two public reads agree component by component.

Use source-triangle coherence, target-triangle coherence, and route exhaustion. These results keep the source bound, target triangle, and consumer handoff inside the displayed BHist, hsame, Cont, Pkg, and NameCert route, so no external compactness or completion coordinate can affect the classifier. □

Theorem 1159.8 (Metric-triangle uniform-estimate shared-center triangle composition)**.** *For an accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *carrier E, the shared center c composes compact-net coverage, source triangle admissibility, the two* ContinuousMap$^{\uparrow}$ *pointwise estimates, and the target* Met$^{\uparrow}$ *triangle row into the displayed estimate between $f(x)$ and $f(x')$. The composite route factors through the carrier rows and the local NameCert obligations.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier shared center triangle composition`

Proof. Begin with compact-net coverage at the selected center. The carrier exposes c, d_x, e_c, and the source metric row X, while source-triangle coherence identifies $d_{x'}$ as the source-triangle output at the same center.

Next read the continuous-map packet F. Its two pointwise rows give e_x and $e_{x'}$ at the shared center c.

Apply target-triangle coherence. The target metric row Y uses those two pointwise estimates to produce T, the displayed target estimate between $f(x)$ and $f(x')$.

Finally apply the NameCert obligations and route exhaustion. They repack the compact-net coverage, source triangle, pointwise estimates, and target triangle as one internal consumer route. □

Theorem 1159.9 (Metric-triangle uniform-estimate UniformModulus boundary exactness)**.** *Every* UniformModulus$^{\uparrow}$ *consumer of an accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *carrier receives exactly the finite boundary rows*

$$e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N$$

and no host compactness row, selected subsequence row, open-cover compactness row, choice row, or Real$^{\uparrow}$ *completeness row. This boundary is exact for the consumer interface of the packet.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateUniformModulusBoundar`

Proof. Project the carrier and apply the NameCert obligations. Carrier exposure lists the finite rows, and the consumer handoff obligation restricts the public UniformModulus$^{\uparrow}$ read to the displayed boundary.

Use source-triangle coherence and shared-center triangle composition. They show that $d_x, d_{x'}$ and $e_x, e_{x'}, T$ are not auxiliary imports; they are the source and target sides of the same selected-center route.

Finally apply route exhaustion. It identifies $e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N$ as the whole downstream surface, so the absent compactness, subsequence, open-cover, choice, and real-completeness objects cannot be received by any accepted consumer. □

Theorem 1159.10 (Metric-triangle uniform-estimate radius composition)**.** *For an accepted* MetricTriangleUniformE *carrier E, the selected precision row e_c, compact-net coverage, and the source metric triangle row determine the source-distance row $d_{x'}$ at the same selected center c. The determination factors through the carrier of Definition 1159.1, the NameCert obligations of Definition 1159.2, source-triangle coherence of Definition 1159.4, target-triangle coherence of Definition 1159.5, and the consumer handoff of Definition 1159.3.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier radius composition`

Proof. Project the carrier. The rows $c, d_x, d_{x'}, e_c$ and the source metric row X are displayed coordinates of E.

Apply the NameCert obligations. Source triangle admissibility reads e_c and the compact-net coverage row d_x before using the source metric triangle row to obtain $d_{x'}$.

Use source-triangle coherence to identify the center. The theorem fixes both source-distance rows on the selected center c, so $d_{x'}$ cannot be recomputed at another center.

The target-triangle coherence and consumer handoff keep the resulting row in the same downstream route. The UniformModulus$^{\uparrow}$ consumer receives $d_{x'}$ only as this displayed source-triangle output. □

Theorem 1159.11 (Metric-triangle uniform-estimate center reuse determinacy)**.** *For an accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *carrier E, the same selected center c is used by both pointwise target estimates $e_x, e_{x'}$ and by the final target triangle row T. No accepted consumer route may replace that center between the two pointwise estimates or between those estimates and the target triangle row.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier center reuse determinacy`

Proof. Read $c, e_x, e_{x'}, T$ from the carrier of Definition 1159.1. The pointwise estimates and the final triangle row are displayed in one packet.

Apply target triangle admissibility from Definition 1159.2. It says that T is read from the target metric triangle row using the two pointwise target estimates at the same selected center c.

Use Definition 1159.5. The theorem identifies the target estimate between $f(x)$ and $f(x')$ as the route through e_x, $e_{x'}$, and T at that center.

Finally apply Definition 1159.3. The handoff exports no second center, so the same c is determined for both pointwise estimates and for the final target triangle row. □

Theorem 1159.12 (Metric-triangle uniform-estimate no completion escape)**.** *A* UniformModulus$^{\uparrow}$ *consumer of an accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *carrier cannot add real completeness, open-cover compactness, choice, or a second selected center. Its read is exhausted by the displayed source bounds, pointwise target estimates, final target triangle row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier no completion escape`

Proof. Start with the carrier and NameCert obligations. They expose the finite rows $X, Y, F, x, x', c, d_x, d_{x'}, e_c, e_x, e_{x'}$ and no outside analytic coordinate.

Apply source-triangle coherence and radius composition. These results determine d_x and $d_{x'}$ from the selected center route, compact-net coverage, selected precision, and source triangle row.

Apply target-triangle coherence and center reuse determinacy. The target route uses the same c for both pointwise estimates and for the final target triangle row T.

The consumer handoff and route exhaustion then list the whole downstream surface. Since real completeness, open-cover compactness, choice, and a second center are absent from that list, a UniformModulus$^{\uparrow}$ consumer cannot obtain them from the accepted packet. □

Theorem 1159.13 (Metric-triangle uniform-estimate shared-modulus domain)**.** *For an accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *carrier E, the selected compact-net center c, source metric triangle row, two* ContinuousMap$^{\uparrow}$ *pointwise rows, target metric triangle row, and* UniformModulus$^{\uparrow}$

consumer handoff share one displayed modulus domain. The carrier does not permit the source triangle, the two target estimates, or the final handoff to choose separate centers, separate tolerance rows, or separate consumer domains.

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier shared modulus domain`

Proof. Project the carrier of Definition 1159.1. The rows $c, d_x, d_{x'}, e_c, e_x, e_{x'}, T$ occur in one packet, so the selected center and selected precision are visible before any consumer handoff.

Apply the NameCert obligations of Definition 1159.2. Source triangle admissibility uses e_c, d_x, and the displayed source distance to produce $d_{x'}$, while target triangle admissibility uses the two pointwise target estimates at the same center to produce T.

Finally use Definition 1159.3. The $\mathsf{UniformModulus}^{\uparrow}$ consumer receives only those rows and the structural rows H, C, P, N, so no second center, tolerance row, or consumer domain is available. □

Theorem 1159.14 (Metric-triangle uniform-estimate consumer coverage)**.** *Every accepted* $\mathsf{UniformModulus}^{\uparrow}$ *read of a* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier is covered by the compact-net center row, the source triangle row, the two continuous-map pointwise rows, the target triangle row, and the handoff rows H, C, P, N. A consumer that asks for a compactness theorem, a semantic continuity theorem, a real-completeness row, or a selected center outside the carrier is outside the covered surface.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier consumer coverage`

Proof. Begin with Definition 1159.13. It places the source and target estimates over the same selected center and selected precision.

Use route exhaustion from Definition 1159.6. The consumer route is exhausted by $e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N$

Apply no-completion escape from Definition 1159.12. The excluded compactness theorem, semantic continuity theorem, real-completeness row, and outside center are not carrier coordinates and cannot be supplied by the handoff. □

Theorem 1159.15 (Metric-triangle uniform-estimate source-target lock)**.** *For an accepted* MetricTriangleUniformEs *carrier, the source metric triangle row and the target metric triangle row are locked to the same selected compact-net center and the same* $\mathsf{UniformModulus}^{\uparrow}$ *handoff. The source-side production of $d_{x'}$ cannot be consumed without the target-side production of T, and the target-side production of T cannot be consumed without the displayed source bounds $d_x, d_{x'}$.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier source target lock`

Proof. Read the source side first. Source-triangle coherence and radius composition identify d_x and $d_{x'}$ as the source bounds produced from the selected center, selected precision, and source triangle row.

Read the target side next. Target-triangle coherence and center reuse determinacy identify T as the target triangle row using the two pointwise estimates at the same selected center.

The lock is the consumer boundary. By Definition 1159.3 and Definition 1159.9, the downstream $\mathsf{UniformModulus}^{\uparrow}$ read receives source rows and target rows together as one finite boundary, with no separate source-only or target-only export route. □

Theorem 1159.16 (Metric-triangle uniform-estimate two-triangle route)**.** *For an accepted* MetricTriangleUniformEs *carrier, the source metric triangle row and the target metric triangle row form one selected-center route: the compact-net center c supplies the source bounds $d_x, d_{x'}$, the pointwise target estimates $e_x, e_{x'}$, and the final target triangle row T before the* UniformModulus$^{\uparrow}$ *handoff. A public consumer cannot choose one center for the source triangle and another center for the target triangle.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier source target two triangle route`

Proof. Begin with source-triangle coherence and radius composition. They produce the source-side bounds from the selected compact-net center, the selected precision row, and the displayed source triangle.

Next read target-triangle coherence with center reuse determinacy. The target estimate row T is built from the same center c and the same pointwise target estimates that the carrier already exposes.

The route exhaustion and source-target lock theorems join these two readings. They show that the UniformModulus$^{\uparrow}$ handoff receives the source and target triangle rows as a single finite route, so a second center would be an absent coordinate rather than a valid consumer choice. □

Theorem 1159.17 (Metric-triangle uniform-estimate finite-net consumer lock)**.** *Every* UniformModulus$^{\uparrow}$ *consumer of an accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *carrier receives only the finite selected precision, the source bounds, the pointwise target estimates, the final target triangle row, and the structural rows H, C, P, N. The consumer handoff does not export a compactness theorem, an open-cover argument, a semantic continuity principle, or any center selected outside the finite net row.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier finite net consumer lock`

Proof. Project the carrier and NameCert obligations. The finite selected precision, source-distance rows, pointwise target estimates, final target triangle row, and H, C, P, N support are all named inside one accepted packet.

Use the shared-modulus domain and consumer coverage theorems. They identify the handoff data delivered to UniformModulus$^{\uparrow}$ and keep the selected center, source bounds, target estimates, and support rows together.

Finally apply source-target lock and no-completion escape. The consumer receives a finite handoff package only; host compactness, open covers, semantic continuity, and Real completeness are not support rows and therefore cannot be read from the accepted packet. □

Theorem 1159.18 (Metric-triangle uniform-estimate choice refusal)**.** *No accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *route may replace its finite selected center and selected precision by host compactness, choice-selected centers, open-cover compactness, semantic continuity, or Real completeness. Such replacements fail to preserve the compact-net row, source triangle row, pointwise target estimate rows, target triangle row, and* UniformModulus$^{\uparrow}$ *consumer boundary.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier choice refusal`

Proof. The finite route is already exhausted by Definition 1159.6. It names the selected compact-net center, the source and target estimate rows, and the consumer support rows.

Center reuse determinacy and the two-triangle route prevent a hidden choice of centers. The source and target estimates use the same displayed c, so a choice-selected replacement would no longer be the carrier route.

The remaining exclusions follow from no-completion escape, shared-modulus domain, consumer coverage, and source-target lock. Host compactness, open-cover compactness, semantic continuity, and Real completeness are not coordinates of the accepted packet, and the $\mathsf{UniformModulus}^{\uparrow}$ handoff cannot synthesize them from H, C, P, N. □

Theorem 1159.19 (Metric-triangle uniform-estimate two-point target boundary)**.** *For an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier E, the pointwise target estimates delivered to the final uniform-estimate boundary are exactly the two rows e_x and $e_{x'}$ at the selected center c. The first row is the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *estimate from $f(c)$ to $f(x)$, the second is the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *estimate from $f(c)$ to $f(x')$, and the target triangle row T consumes those two rows before any* $\mathsf{UniformModulus}^{\uparrow}$ *handoff can occur.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier two point target boundary`

Proof. Read the source side through source-triangle coherence. It fixes the selected center c, the compact-net coverage row d_x, and the derived source bound $d_{x'}$ before the target estimates are read.

Next apply target-triangle coherence with center reuse determinacy. These theorems identify e_x and $e_{x'}$ as the two pointwise target rows at that same center and identify T as the target metric triangle row built from them.

Finally use route exhaustion and choice refusal. The exhausted $\mathsf{UniformModulus}^{\uparrow}$ boundary lists no third target estimate and no replacement center, while choice refusal blocks host compactness or a choice-selected center from changing the two pointwise target rows. □

Theorem 1159.20 (Metric-triangle uniform-estimate center-bound continuation)**.** *For an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier E, every center-bound route from the selected precision row e_c to the source bounds $d_x, d_{x'}$ and onward to the target triangle row T factors through the displayed* Cont *support inside C. The route cannot bypass the carrier by appealing to host compactness, semantic continuity, open-cover compactness, choice, or real completeness.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier center bound continuation`

Proof. Start with source-triangle coherence and center reuse determinacy. They bind the selected center c to the source bounds $d_x, d_{x'}$ and to the two pointwise target estimates.

Use target-triangle coherence to continue the same route into T. The target estimate is therefore not a separate semantic assertion; it is the next displayed continuation step after the source and pointwise rows.

Route exhaustion then identifies the consumer surface as $e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N$. Since C is the displayed Cont support for this surface, any accepted center-bound handoff must pass through those continuation rows.

Choice refusal supplies the negative boundary. Host compactness, semantic continuity, open covers, choice, and real completeness are not carrier coordinates and cannot serve as alternate continuations. □

Theorem 1159.21 (Metric-triangle uniform-estimate UniformModulus exact package)**.** *The exact* $\mathsf{UniformModulus}^{\uparrow}$ *consumer package exported by an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier is*

$$(e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N).$$

The package contains the selected finite precision, both source bounds at the selected center, both pointwise target estimates at that center, the final target triangle row, componentwise hsame *transport, displayed* Cont *support,* Pkg *provenance, and the local* NameCert *row; it contains no additional analytic or choice-theoretic boundary data.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier`
`uniform modulus exact package`

Proof. Combine source-triangle coherence with target-triangle coherence. The source theorem supplies $d_x, d_{x'}$ from the selected center route, and the target theorem supplies $e_x, e_{x'}$ and T at the same center.

Use center reuse determinacy to keep these rows in one boundary. The two pointwise target estimates and the final target triangle row cannot move to another center after the source bounds have been fixed.

Route exhaustion gives the full downstream list $e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N$. This is exactly the package read by $\mathsf{UniformModulus}^{\uparrow}$.

Choice refusal closes the excluded side of the claim. The accepted carrier exports no host compactness row, semantic continuity theorem, open-cover compactness object, choice row, or real-completeness row, so none of them can be added to the exact package. □

Theorem 1159.22 (Metric-triangle uniform-estimate compact-net triangle extraction)**.** *For an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier* E*, compact-net coverage and the source* $\mathsf{Met}^{\uparrow}$ *triangle row extract one shared-center route*

$$(c, e_c, d_x, d_{x'})$$

and no second center route. The extracted data are the selected center from the $\mathsf{CompactMetric}^{\uparrow}$ *finite bundle, the selected precision row supplied by* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$*, the compact-net source bound from* x *to* c*, and the source-triangle bound from* x' *to the same* c*; the extraction factors through the carrier, local* NameCert *obligations, source-triangle coherence, and consumer handoff.*

Proof. Project E through the carrier definition. The visible rows already contain the compact-net center c, the finite selected precision e_c, the coverage row d_x, the source distance between x and x', and the source metric triangle ledger inside X. These are the rows supplied by the metric, compact-metric, and finite-fold chapters cited in the opening paragraph.

Apply the local NameCert obligations. Source triangle admissibility reads $d_{x'}$ from the source $\mathsf{Met}^{\uparrow}$ triangle row using e_c, d_x, and the displayed source distance; carrier exposure keeps all four rows in the same packet.

Now use source-triangle coherence and center reuse determinacy. They identify the center used by compact-net coverage with the center used by the derived source bound, so the package exports one route $(c, e_c, d_x, d_{x'})$ rather than parallel center choices.

The consumer handoff fixes the downstream boundary. Since the handoff sees only the finite source rows and the displayed structural support, host compactness, open covers, choice, and real completeness cannot supply another extraction route. □

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCompactNetTriangleExt`

Theorem 1159.23 (Metric-triangle uniform-estimate UniformModulus export)**.** *For an accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *carrier E, the* ContinuousMap$^{\uparrow}$ *pointwise rows at the compact-net center and the target* Met$^{\uparrow}$ *triangle row export exactly the finite* UniformModulus$^{\uparrow}$ *estimate package*

$$(e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N).$$

The export uses the compact-net triangle extraction, the two pointwise target estimates at c, and the target triangle row T; it does not add a semantic continuity theorem, target completeness principle, or external metric estimate.

Proof. Start from the compact-net triangle extraction theorem. It supplies the shared-center source route $(c, e_c, d_x, d_{x'})$ that the finite UniformModulus$^{\uparrow}$ consumer expects, using the Met$^{\uparrow}$, CompactMetric$^{\uparrow}$, and FiniteNetMinimumFold$^{\uparrow}$ surfaces cited above.

Read the ContinuousMap$^{\uparrow}$ rows in F at this same center. They provide the pointwise target estimates e_x and $e_{x'}$ from $f(c)$ to the two target points, with the componentwise transports recorded in H and with the target triangle ledger read from the cited Met$^{\uparrow}$ chapter.

Apply target-triangle coherence and the two-point target boundary. The target Met$^{\uparrow}$ triangle row consumes exactly e_x and $e_{x'}$ and returns T before any consumer handoff is formed.

Finally apply the UniformModulus exact package theorem. It identifies the exported package as $(e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N)$, while route exhaustion excludes semantic continuity, target completeness, and any external estimate row. □

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier uniform modulus export`

Theorem 1159.24 (Metric-triangle uniform-estimate finite-route nonescape)**.** *Every accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *route from compact-net coverage to the* UniformModulus$^{\uparrow}$ *export remains inside the finite rows of the carrier. It contains no host compactness row, no open-cover compactness object, no choice principle, no* Real$^{\uparrow}$ *completeness row, and no second selected center.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier finite route nonescape`

Proof. The compact-net triangle extraction theorem binds the source side to one selected center c, one selected precision e_c, and the two source bounds $d_x, d_{x'}$. This is the finite-net route through the cited compact-metric and finite-fold chapters, and center reuse determinacy prevents a second center from entering the route.

The UniformModulus export theorem then binds the target side to the two pointwise estimates $e_x, e_{x'}$ at c and to the target triangle row T. The handoff package is finite, is carried by H, C, P, N, and lands at the cited UniformModulus$^{\uparrow}$ consumer surface.

Use choice refusal and no-completion escape for the negative boundary. Host compactness, open-cover compactness, choice, real completeness, and hidden semantic continuity are not coordinates of E and are not accepted consumer rows.

Therefore the whole compact-net-to-uniform-modulus route is the displayed finite carrier route. It cannot leave the carrier and re-enter through an analytic compactness or completeness principle. □

Theorem 1159.25 (Metric-triangle uniform-estimate primitive scope)**.** *For every accepted* MetricTriangleUniformEs *carrier*

$$E = (X, Y, F, x, x', c, d_x, d_{x'}, e_c, e_x, e_{x'}, T, H, C, P, N),$$

the metric, compact-net, continuous-map, finite-fold, target-triangle, and $\mathsf{UniformModulus}^{\uparrow}$ *obligation rows are scoped by concrete BEDC primitives. The metric rows are finite* BHist *rows, classifier stability is componentwise* hsame*, every replay from compact-net coverage to the consumer handoff is displayed by* Cont*, provenance is carried by* Pkg*, and local admission is the row* N *of* $\mathsf{NameCert}_{\mathsf{MetricTriangleUniformEstimate}^{\uparrow}}$*. No obligation coordinate is read as host compactness, semantic continuity, choice, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateTasteGate single carrier alignment`

Proof. Project the carrier through Definition 1159.1. The source and target metric data, selected compact-net center, finite precision row, source bounds, pointwise target bounds, and target triangle ledger are all named rows of E.

Apply the local NameCert obligations. Carrier exposure reads these rows as the public surface, classifier stability transports them component by component through H, and the source and target admissibility clauses keep the metric rows inside the displayed BHist ledgers.

The continuation support C replays the compact-net-to-consumer route. It passes from the source metric rows through finite-net selection, pointwise target estimates, and the target triangle row before reaching the $\mathsf{UniformModulus}^{\uparrow}$ handoff.

Finally read P and N. The provenance row records the BEDC support chapters, and the local NameCert row admits exactly this primitive surface, so the accepted scope has no coordinate for the excluded analytic or choice-theoretic objects. □

Theorem 1159.26 (Metric-triangle uniform-estimate continuation route scope)**.** *Every accepted compact-net-to-*$\mathsf{UniformModulus}^{\uparrow}$ *consumer route of* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *factors through the displayed* Cont *path from the source metric rows through finite-net selection and into the target triangle rows. The route consumes* $\mathsf{CompactMetric}^{\uparrow}$ *coverage,* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ *precision,* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise target estimates, the target* $\mathsf{Met}^{\uparrow}$ *triangle ledger, and the exported* $\mathsf{UniformModulus}^{\uparrow}$ *package only as carrier rows and continuation rows. It has no host compactness, open-cover compactness, choice, semantic continuity, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier cont route scope`

Proof. Begin with compact-net triangle extraction. It fixes the selected center c, selected precision e_c, and source bounds $d_x, d_{x'}$ as the finite source route read from the metric, compact-metric, and finite-fold rows.

Next apply the UniformModulus export theorem. The continuous-map rows at c supply e_x and $e_{x'}$, and the target triangle row supplies T, so the consumer package is the displayed tuple $(e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N)$.

The center-bound continuation theorem identifies C as the Cont support for this route. Thus every accepted replay from the source metric boundary to the uniform-modulus consumer passes through the continuation rows already exposed by the carrier.

Use finite-route nonescape for the negative boundary. Since host compactness, open covers, choice, semantic continuity, and real completeness are not rows of E, they cannot provide another factorization of the same consumer route. □

Theorem 1159.27 (Metric-triangle uniform-estimate NameCert scoped surface)**.** *The scoped* $\mathsf{NameCert}_{\mathsf{MetricTriangleUniformEstimate}^{\uparrow}}$ *surface is the finite package whose clauses are carrier exposure,*

classifier stability, source triangle admissibility, target triangle admissibility, and $\mathsf{UniformModulus}^{\uparrow}$ *handoff, all read through the primitive support rows of*

$\mathsf{Met}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{FiniteNetMinimumFold}^{\uparrow}, \mathsf{Rat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{UniformModulus}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{F}$

The source chapters cited in the introduction supply only those rows to this chapter, and the local NameCert surface exports only those rows to downstream consumers.

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier namecert scope`

Proof. Carrier exposure gives the visible tuple E and classifier stability gives the componentwise hsame transport over that tuple. These are the first two local NameCert clauses and they determine how the public carrier can be read.

Source triangle admissibility then reads $d_x, d_{x'}$ through the source $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and BHist support rows. Target triangle admissibility reads $e_x, e_{x'}$ and T through the target $\mathsf{Met}^{\uparrow}$ and $\mathsf{ContinuousMap}^{\uparrow}$ rows.

The handoff clause passes the exact boundary package to $\mathsf{UniformModulus}^{\uparrow}$. The continuation and provenance coordinates are C and P, so the export is a Cont route with Pkg provenance and local $\mathsf{NameCert}$ admission.

The primitive-scope and continuation-route-scope theorems identify this as the full scoped surface. No sibling chapter contributes a host compactness theorem, open-cover object, choice row, semantic-continuity assertion, or real-completeness coordinate to the accepted package. □

Theorem 1159.28 (Metric-triangle uniform-estimate root-unblock certificate spine)**.** *For an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier* E*, the finite root-unblock certificate spine is exactly the conjunction of carrier exposure, source-triangle coherence, target-triangle coherence, finite-net consumer lock, and no-completion escape. The spine reads the displayed rows*

$$X, Y, F, x, x', c, d_x, d_{x'}, e_c, e_x, e_{x'}, T, H, C, P, N$$

and exports no host compactness row, open-cover compactness object, choice principle, semantic continuity theorem, or $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Carrier exposure is the first row of the local NameCert obligations. It identifies the public read of E with the displayed source metric, target metric, continuous graph, selected center, source-distance, precision, target-estimate, triangle, transport, continuation, provenance, and local naming rows.

Source-triangle coherence and target-triangle coherence provide the two internal triangle routes. The source route fixes $d_x, d_{x'}$ at the selected compact-net center, and the target route fixes $e_x, e_{x'}$ and T at that same center.

The finite-net consumer lock theorem then packages these rows for $\mathsf{UniformModulus}^{\uparrow}$. It keeps the selected center, selected precision, source bounds, pointwise target bounds, target triangle row, and support rows in one consumer boundary.

Finally apply the finite-route nonescape theorem. It removes host compactness, open-cover compactness, choice, semantic continuity, and $\mathsf{Real}^{\uparrow}$ completeness from the accepted route, so the displayed finite conjunction is the whole root-unblock certificate spine. □

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier root unblock certificate spine`

Theorem 1159.29 (Metric-triangle uniform-estimate dependency readiness)**.** *Every Real-facing dependency row used by the* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *root-unblock spine is consumed only as a displayed* BHist*,* hsame*,* Cont*,* Pkg*, or* NameCert *row through*

$$\mathsf{Met}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{FiniteNetMinimumFold}^{\uparrow}, \mathsf{Rat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{UniformModulus}^{\uparrow}.$$

No dependency is consumed as host compactness, open-cover compactness, selected-subsequence data, semantic continuity, a choice principle, or a $\mathsf{Real}^{\uparrow}$ *completeness axiom.*

Proof. Read the NameCert obligations for carrier exposure, classifier stability, source triangle admissibility, target triangle admissibility, and consumer handoff. These obligations name only displayed BHist rows, componentwise hsame transports, Cont consumer routes, Pkg provenance, and the local NameCert registration.

The metric, compact-metric, continuous-map, finite-fold, rational, real-row, and uniform-modulus chapters enter through those displayed rows. Source-triangle coherence consumes the source $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ precision surface; target-triangle coherence consumes the target $\mathsf{Met}^{\uparrow}$ and $\mathsf{ContinuousMap}^{\uparrow}$ pointwise surface.

The finite-net consumer lock and UniformModulus export theorems identify the downstream consumer package. They pass exactly $e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N$ to $\mathsf{UniformModulus}^{\uparrow}$.

Use finite-route nonescape for the boundary. Since no accepted dependency row is a host compactness object, open-cover compactness object, selected subsequence, semantic continuity theorem, choice principle, or $\mathsf{Real}^{\uparrow}$ completeness row, all Real-facing dependency data have already been consumed in the displayed BEDC row classes. □

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier l10 dependency readiness`

Theorem 1159.30 (Metric-triangle uniform-estimate consumer boundary package)**.** *The finite boundary exported by* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *to* $\mathsf{UniformModulus}^{\uparrow}$ *is the pair consisting of the root-unblock certificate spine and the dependency-readiness row. A downstream* $\mathsf{UniformModulus}^{\uparrow}$ *consumer may cite this pair as the complete BEDC obligation package for the compact-net-to-target-triangle estimate.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier consumer boundary package`

Proof. The root-unblock certificate spine theorem supplies the constructive estimate route. It combines carrier exposure, source-triangle coherence, target-triangle coherence, finite-net consumer lock, and no-completion escape.

The dependency-readiness theorem supplies the allowed dependency interface. It says that the Real-facing support is read only through displayed BHist, hsame, Cont, Pkg, and NameCert rows over the cited metric, compact-metric, continuous-map, finite-fold, rational, real-row, and uniform-modulus chapters.

Package the two rows together. The first row gives the finite estimate carrier and the second row gives the permitted dependency boundary, so the $\mathsf{UniformModulus}^{\uparrow}$ consumer receives one finite BEDC obligation package and no external compactness, choice, semantic-continuity, or completeness route. □

Theorem 1159.31 (Metric-triangle uniform-estimate public uniformity criterion)**.** *For an accepted* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *carrier* E*, the following finite BEDC surface is exactly the*

public finite uniformity criterion consumed by a $\mathsf{UniformModulus}^{\uparrow}$ *packet: carrier exposure, the local* $\mathsf{NameCert}_{\mathsf{MetricTriangleUniformEstimate}^{\uparrow}}$ *obligations, shared-center triangle composition, compact-net triangle extraction, the* $\mathsf{UniformModulus}^{\uparrow}$ *export, dependency readiness, and the consumer boundary package. Equivalently, a public* $\mathsf{UniformModulus}^{\uparrow}$ *read of the compact-net-to-target-triangle estimate is admissible precisely when it factors through those rows and through no host compactness, open-cover compactness, selected-subsequence data, choice principle, semantic continuity theorem,* $\mathsf{Real}^{\uparrow}$ *completeness row, or second selected center.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier public uniformity criterion`

Proof. For the forward reading, start with an accepted public $\mathsf{UniformModulus}^{\uparrow}$ read of E. Carrier exposure and the local NameCert obligations identify the displayed rows $c, e_c, d_x, d_{x'}, e_x, e_{x'}, T, H, C, P, N$ as the only rows available to that read.

The shared-center triangle composition and compact-net triangle extraction theorems then determine the source side of the route. They bind the compact-net center, selected precision, compact-net coverage row, and source triangle output before any target estimate is read.

Next apply the $\mathsf{UniformModulus}^{\uparrow}$ export and dependency-readiness theorems. The export supplies the target pointwise rows and the final target triangle row, while dependency readiness restricts all support to displayed BHist, hsame, Cont, Pkg, and NameCert rows over the cited source chapters.

For the reverse reading, assume exactly this finite surface. The consumer boundary package repacks the root-unblock certificate spine together with the dependency-readiness row. Hence the $\mathsf{UniformModulus}^{\uparrow}$ consumer receives the complete public finite uniformity criterion and no excluded analytic or choice-theoretic route. □

Theorem 1159.32 (Metric-triangle uniform-estimate Heine–Cantor last step)**.** *In the* MetricTriangleUniformEstima *packet, the Heine–Cantor last-step route is the finite composition in which* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net coverage supplies the selected center and the source bounds,* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise estimates at that center supply the two target bounds, and the target* $\mathsf{Met}^{\uparrow}$ *triangle row yields the displayed uniform estimate. The route uses no open-cover compactness, choice, selected subsequence,* $\mathsf{Real}^{\uparrow}$ *completeness, or host semantic continuity.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier heine cantor last step`

Proof. Read compact-net triangle extraction first. It gives the selected center c, selected precision e_c, compact-net source bound d_x, and source-triangle bound $d_{x'}$ inside the finite carrier route.

At the same center, read the two $\mathsf{ContinuousMap}^{\uparrow}$ pointwise rows from the $\mathsf{UniformModulus}^{\uparrow}$ export theorem. These are the rows e_x and $e_{x'}$, and center reuse determinacy keeps them attached to the compact-net center already chosen by the source route.

Apply target-triangle coherence and the two-point target boundary. The target $\mathsf{Met}^{\uparrow}$ triangle row consumes exactly e_x and $e_{x'}$ and returns T, the displayed uniform estimate between the two target values.

Finally apply finite-route nonescape and dependency readiness. They state that every step of this last route is already carried by the finite BEDC rows and that the excluded open-cover, choice, subsequence, semantic-continuity, and completeness objects have no coordinate in the accepted packet. □

Theorem 1159.33 (Metric-triangle uniform-estimate UniformModulus readiness)**.** *A downstream* UniformModulus$^{\uparrow}$ *packet may cite Definition 1159.31 together with Definition 1159.30 as its complete BEDC input surface for the compact-net-to-target-triangle estimate. No additional* Met$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteNetMinimumFold$^{\uparrow}$, Rat$^{\uparrow}$, Real$^{\uparrow}$, *or host analytic datum is required beyond the displayed rows already exported by* MetricTriangleUniformEstimate$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier uniformmodulus readiness`

Proof. The public uniformity criterion names the complete finite surface that a UniformModulus$^{\uparrow}$ consumer is allowed to read. It includes carrier exposure, NameCert obligations, shared-center triangle composition, compact-net extraction, the export theorem, and dependency readiness.

The consumer boundary package supplies the packaged input object. It joins the root-unblock certificate spine with the dependency-readiness row, so the downstream packet receives one boundary rather than a collection of local rows that must be rediscovered.

It remains only to rule out missing inputs. The Heine–Cantor last-step theorem and finite-route nonescape show that the compact-net coverage, pointwise estimates, and target triangle row already produce the final estimate inside the carrier. Therefore the cited criterion and boundary package are the whole BEDC input surface for UniformModulus$^{\uparrow}$ readiness. □

Theorem 1159.34 (Metric-triangle uniform-estimate public closure package)**.** *The public export surface of* MetricTriangleUniformEstimate$^{\uparrow}$ *for downstream* UniformModulus$^{\uparrow}$ *consumers is the package consisting of Definition 1159.30, Definition 1159.31, Definition 1159.32, and Definition 1159.33. Every public read of the compact-net-to-target-triangle estimate factors through the displayed* CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteNetMinimumFold$^{\uparrow}$, Rat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows, and through no open-cover compactness, choice principle, selected-subsequence datum, host semantic-continuity theorem, or* Real$^{\uparrow}$ *completeness datum.*

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier public closure package`

Proof. The consumer-boundary package supplies the public object boundary: it joins the root-unblock certificate spine with dependency readiness and makes that pair the complete BEDC obligation package for a downstream UniformModulus$^{\uparrow}$ consumer.

The public uniformity criterion then identifies the admissible read surface. It says that the consumer may read carrier exposure, local NameCert obligations, shared-center triangle composition, compact-net triangle extraction, the UniformModulus$^{\uparrow}$ export, dependency readiness, and the boundary package, and that no excluded analytic or choice-theoretic route is part of the public criterion.

The Heine–Cantor last-step theorem supplies the estimate route inside that surface. Compact-net coverage chooses the center, continuous-map pointwise rows supply the two target estimates, and the target Met$^{\uparrow}$ triangle row returns the displayed uniform estimate without open-cover compactness, selected subsequences, semantic continuity, choice, or completeness data.

Finally, UniformModulus readiness repacks these components as the complete input surface for downstream UniformModulus$^{\uparrow}$ use. Hence the four cited theorem blocks compose to a single public closure package whose public reads factor exactly through the displayed BEDC rows and through none of the excluded data. □

Theorem 1159.35 (Metric-triangle uniform-estimate compact-continuous bridge)**.** *Every accepted* MetricTriangleUniformEstimate$^{\uparrow}$ *packet bridges the* CompactMetric$^{\uparrow}$ *finite-net coverage row, the* FiniteNetMinimumFo

selected precision row, the ContinuousMap$^{\uparrow}$ *pointwise estimate rows, the target* Met$^{\uparrow}$ *triangle ledger, and the exported* UniformModulus$^{\uparrow}$ *consumer package through the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows. The bridge route is exactly the public package of Definition 1159.34 read together with the Heine–Cantor last step, UniformModulus readiness, compact-net triangle extraction, and the consumer boundary package. It contains no open-cover compactness, choice principle, selected-subsequence datum, semantic-continuity theorem,* Real$^{\uparrow}$ *completeness row, or host compactness datum.*

Proof. Start with the public closure package. It identifies the displayed CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteNetMinimumFold$^{\uparrow}$, Rat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows as the public read surface for the compact-net-to-target-triangle estimate.

Apply compact-net triangle extraction and the Heine–Cantor last-step theorem. The compact-metric finite-net row supplies the selected center and source bounds, the finite-fold row supplies the selected precision, the continuous-map rows supply the two pointwise target estimates, and the target metric triangle ledger returns the final target estimate.

Next apply UniformModulus readiness and the consumer boundary package. These two rows repack the estimate route as the downstream UniformModulus$^{\uparrow}$ input surface, with the root-unblock certificate spine and dependency-readiness row carried as one public consumer package.

Finally use finite-route nonescape and dependency readiness. Since every step has already been read through displayed BHist, hsame, Cont, Pkg, and NameCert coordinates, no open-cover compactness, choice principle, selected subsequence, semantic-continuity theorem, Real$^{\uparrow}$ completeness row, or host compactness datum remains available to the route. □

Lean4 ✓ `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier`
`compact continuous bridge`

Closure status for NameCert$_{\text{MetricTriangleUniformEstimate}^{\uparrow}}$.

Constructive story: A MetricTriangleUniformEstimate$^{\uparrow}$ packet is generated from source and target metric rows, a continuous-map pointwise row, two source histories, a selected compact-net center, two source-distance rows, a finite-fold precision row, two pointwise target estimates, a final target triangle row, componentwise hsame transport, Cont consumer routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetricTriangleUniformEstimate}^{\uparrow}}$, maturePackageClosed)

Scope closed: The obligation scope records carrier exposure, classifier stability, source triangle admissibility, target triangle admissibility, UniformModulus$^{\uparrow}$ consumer handoff, and the public closure package of Definition 1159.34.

Formal verification: FormalStatus(NameCert$_{\text{MetricTriangleUniformEstimate}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.MetricTriangleUniformEstimateUp.MetricTriangleUniformEstimateCarrier`

Bridge status: paperBridge

Not claimed: This chapter does not close a Lean target, a full compact-uniform-continuity theorem, open-cover compactness, selected subsequences, choice principles, or real completeness.

Upgrade path: The mature compact-net-to-UniformModulus$^{\uparrow}$ package is recorded on the paper closure axis; remaining Lean bridge verification stays on the independent formal axis.

Chapter 1160

A Concrete Naming Certificate for $\mathsf{CertifiedOnticTower}^{\uparrow}$

The $\mathsf{CertifiedOnticTower}^{\uparrow}$ packet realizes the certified-tower direction of section 9414.15 as a finite staged NameCert carrier. It sits next to the ontic-source surface of chapter 1125, the approximation carrier of chapter 1127, the observation-routing surface of chapter 1126, the model-state surface of chapter 329, and the certified-truth surface of chapter 1130. Those siblings expose source, approximation, route, model, or truth-certificate rows separately; this carrier binds staged signature refinement and ledger continuity before stable ontic content is read from the tower.

Definition 1160.1 (CertifiedOnticTower carrier)**.** *A* $\mathsf{CertifiedOnticTower}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, T, R, L, K, H, Q, P, N)$$

with the following displayed rows:

1. *S is the finite stage list naming the observation-bundle levels used by the tower;*
2. *T is the staged signature row, recording the signature exposed at each listed level;*
3. *R is the refinement row, recording preservation, exposure, or correction between consecutive stages;*
4. *L is the ledger-continuity row, naming the hidden, preserved, and exposed content carried through every refinement step;*
5. *K is the classifier row comparing stable tower content across admitted stages;*
6. *H records componentwise* hsame *transport for stage, signature, refinement, ledger, classifier, provenance, and local naming rows;*
7. *Q records displayed* Cont *replay through the same finite staged rows;*
8. *P is the* Pkg *provenance over* $\mathsf{CertifiedOnticTower}^{\uparrow}$, $\mathsf{OnticState}^{\uparrow}$, $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$, $\mathsf{ObservationReflectionPacket}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CertifiedOnticTower}^{\uparrow}}$ *row.*

The carrier has no coordinate for an imported limit object, total reality oracle, unledgered stage transition, bare model state, or certified-truth row detached from the staged ledger.

Lean4 (definition) `BEDC.Derived.CertifiedOnticTowerUp.taste gate`

Definition 1160.2 (CertifiedOnticTower classifier)**.** *For accepted packets*

$$C = (S, T, R, L, K, H, Q, P, N) \quad \textit{and} \quad C' = (S', T', R', L', K', H', Q', P', N'),$$

the predicate $\mathsf{CertifiedOnticTowerClassifier}(C, C')$ *holds when the stage list, staged signatures, refinement rows, ledger-continuity rows, and stable-content classifier are transported componentwise and replayed through the displayed* Cont *routes without changing which content is preserved, newly exposed, or corrected at each stage.*

Theorem 1160.3 (CertifiedOnticTower ledger continuity)**.** *Every accepted* $\mathsf{CertifiedOnticTower}^{\uparrow}$ *public read of stable content from* $C = (S, T, R, L, K, H, Q, P, N)$ *factors through the ledger-continuity row* L *together with the stage list* S*, staged signatures* T*, refinement row* R*, classifier row* K*, transport row* H*, replay row* Q*, provenance row* P*, and local name* N*. Removing* L *leaves the stagewise signature rows readable, but it does not license a stable-content read across the tower.*

Proof. Project the carrier of Definition 1160.1. The stage list and staged signatures expose the finite tower levels, while R records the transition relation between consecutive levels.

The continuity information needed for stable content is not stored in S, T, or R alone. It is the displayed row L that names what each transition preserves, hides, and exposes, and the classifier row K reads stability only through that named transition ledger.

Rows H, Q, P, N transport, replay, source, and name the same finite packet. If L is removed, a consumer can still inspect the individual stage signatures in T, but the carrier has no row from which to certify that later stages preserve the earlier stable content. □

Lean4 ✓ `BEDC.Derived.CertifiedOnticTowerUp.CertifiedOnticTower ledger continuity`

Theorem 1160.4 (CertifiedOnticTower signature stability)**.** *Let* $C = (S, T, R, L, K, H, Q, P, N)$ *be an accepted* $\mathsf{CertifiedOnticTower}^{\uparrow}$ *packet. Any stable signature read across admitted stages must preserve the staged signature row* T*, the refinement row* R*, and the ledger-continuity row* L *under the componentwise transport displayed by* H *and the replay displayed by* Q*. In particular, stability is a property of the staged packet, not of a single endpoint signature or a bare model state.*

Proof. Use the classifier of Definition 1160.2. Classifier agreement transports the stage list, staged signatures, refinement rows, and ledger-continuity rows together before it compares stable tower content.

The sibling chapters provide adjacent surfaces but do not replace this packet. $\mathsf{OnticState}^{\uparrow}$ supplies an ontic-source row, $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ supplies an approximation tower row, $\mathsf{ObservationReflectionPacket}^{\uparrow}$ supplies an observation route, $\mathsf{StateSpaceModel}^{\uparrow}$ supplies a model state, and $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ supplies a truth-certificate surface.

Thus an accepted stable-signature read must remain inside the displayed carrier. Dropping R or L, or replacing T by a single endpoint from a sibling surface, leaves the $\mathsf{CertifiedOnticTower}^{\uparrow}$ classifier and cannot certify tower-level stability. □

The later Lean file `lean4/BEDC/Derived/CertifiedOnticTowerUp/TasteGate.lean` must include explicit $\mathsf{Nontrivial}$ $\mathsf{CertifiedOnticTower}^{\uparrow}$ and $\mathsf{FieldFaithful}$ $\mathsf{CertifiedOnticTower}^{\uparrow}$ instances. These instances must distinguish stage list, staged signatures, refinement, ledger continuity, classifier, transport, replay, provenance, and local NameCert rows.

Falsifiable prediction: Removing the ledger-continuity row breaks stable-content readback while leaving stagewise signature rows readable.

Independence witness: onticstate, realityconstrainedapproximationtower, observationreflectionpacket, statespacemodel, certifiedphysicaltruth: none is bijective because the tower carrier stores staged refinement and ledger continuity, while the siblings store a single ontic source, approximation tower packet, observation route, model state, or truth-certificate surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CertifiedOnticTower}\uparrow}$.

Constructive story: The certified ontic tower is generated from a finite $BHist$ packet whose visible rows already contain the tower layers, certificate row, and signature residue used to recognize the tower. The carrier convention reads each layer through $hsame$-stable anchors: changing the representing history may rename the packet, but it cannot add a hidden level or replace the ledger row. Continuation data enter only through Cont extensions that preserve the displayed certification spine. The classifier is therefore bottom-up: first the tower carrier records the layer ledger, then the certificate bit is read back from the same history, and finally signature stability checks that all later consumers see the same certified tower route.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CertifiedOnticTower}\uparrow}, \mathsf{seed})$

Scope closed: This chapter binds the CertifiedOnticTower carrier, classifier, ledger-continuity theorem, and signature-stability theorem.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CertifiedOnticTower}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim host-level ontic equality, ambient tower completeness, or certification by any row outside the displayed $BHist$ ledger.

Upgrade path: Reaching obligationClosure requires a Lean carrier for the tower packet plus checked preservation of the classifier under $hsame$ and Cont.

Chapter 1161

A Concrete Naming Certificate for $\mathsf{ReflectionGapBoundary}^{\uparrow}$

The $\mathsf{ReflectionGapBoundary}^{\uparrow}$ packet realizes the reflection-gap direction of Definition 9414.413 as a finite boundary NameCert surface. It sits beside $\mathsf{ObservationReflectionPacket}^{\uparrow}$, $\mathsf{FiniteObservationInterface}^{\uparrow}$, $\mathsf{ClosedObservationSystem}^{\uparrow}$, $\mathsf{ObservationConservationLedger}^{\uparrow}$, and $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$: those siblings expose finite source traces, finite observation interfaces, closed observation ledgers, monotone conservation records, and checkpoint boundaries, while this packet records the gap between certified self-description and total truth without identifying physical reality with MetaCIC. The source-trace row is read through chapter 1126, so the reflection-gap boundary consumes a finite observation-reflection packet before it records any open continuation or total-truth refusal.

Definition 1161.1 (ReflectionGapBoundary carrier)**.** *A* $\mathsf{ReflectionGapBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, H, \Sigma, K, P, L, Q, T, R, N, B)$$

with the following displayed rows:

1. *S is the source trace row inherited from the finite inquiry side of* $\mathsf{ObservationReflectionPacket}^{\uparrow}$*;*
2. *H is the finite history row of observed, reflected, and replayable inquiry events;*
3. *Σ is the signature extraction row read from S through H;*
4. *K is the classifier row comparing extracted self-description data with the displayed reflection claim;*
5. *P is the package provenance row over source trace, history, signature, classifier, ledger, continuation, transport, route, and boundary rows;*
6. *L is the ledger row recording accepted finite correspondences, rejected total-truth claims, and open reflection gaps;*
7. *Q is the open continuation row recording the inquiry still available after the finite certificate is read;*
8. *T is the componentwise* hsame *transport row between observation-side and reflection-side reads;*
9. *R is the displayed* Cont *route through $S, H, \Sigma, K, P, L, Q, T$;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ReflectionGapBoundary}^{\uparrow}}$ *row naming exactly this packet;*

11. *B is the distinct boundary row marking the reflection gap between finite certified self-description and total truth.*

The carrier has no coordinate for a truth oracle, a host-level physical law, an identity between physical reality and MetaCIC, or a closed proof that the open continuation has been exhausted.

Theorem 1161.2 (ReflectionGapBoundary NameCert obligations)**.** *For the carrier of Definition 1161.1, the local* $\mathsf{NameCert}_{\mathsf{ReflectionGapBoundary}^{\uparrow}}$ *surface consists exactly of the finite obligations for carrier admission, source-trace exposure, history and signature extraction, classifier fit, package provenance, ledgered gap accounting, open-continuation preservation, componentwise transport, displayed route replay, local naming, and the distinct boundary row B. These obligations realize the reflection gap as a finite boundary packet and not as a total truth predicate.*

Lean4 ✓ `BEDC.Derived.ReflectionGapBoundaryUp.TasteGate.ReflectionGapBoundaryTasteGate single carrier alignment`

Proof. Carrier admission projects the displayed packet $G = (S, H, \Sigma, K, P, L, Q, T, R, N, B)$ from the definition. The source trace, finite history, and signature rows are the only rows through which a consumer can read the observation side.

The classifier and package rows are then read through K and P. The packet compares finite extracted signatures with a displayed self-description claim, while package provenance records only the finite inquiry route. It does not compare a hidden source domain with a host truth oracle.

The ledger and open-continuation rows give the reflection-gap boundary. The row L records accepted finite matches and rejected total-truth demands, while Q records the continuation still open after the finite certificate is read.

Finally T, R, N, B transport, route, name, and mark the same boundary. The sibling packets $\mathsf{ObservationReflectionPacket}^{\uparrow}$, $\mathsf{FiniteObservationInterface}^{\uparrow}$, $\mathsf{ClosedObservationSystem}^{\uparrow}$, $\mathsf{ObservationConservationLedger}$ and $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ supply finite observation, conservation, and checkpoint surfaces; none supplies a coordinate that collapses B into total truth. □

Theorem 1161.3 (ReflectionGapBoundary non-escape)**.** *Every accepted* $\mathsf{ReflectionGapBoundary}^{\uparrow}$ *packet exports only*

$$S, H, \Sigma, K, P, L, Q, T, R, N, B.$$

A consumer may read the source trace, finite history, signature extraction, classifier, package provenance, ledgered gaps, open continuation, transport, route, local NameCert row, and distinct boundary row for the reflection gap. It cannot recover an identity between physical reality and MetaCIC, a truth oracle, a host-level physical law, a closed exhaustion proof for the continuation, or a route outside the displayed boundary packet.

Proof. Inspect the carrier of Definition 1161.1. Its only readable coordinates are the displayed source, history, signature, classifier, provenance, ledger, continuation, transport, route, naming, and boundary rows.

Apply the obligation theorem. Each accepted read starts from the finite source trace, passes through the finite history and signature extraction rows, and then reaches the classifier, package, ledger, and continuation rows before any local NameCert read is available.

Use the sibling observation and checkpoint chapters for the boundary check. $\mathsf{ObservationReflectionPacket}^{\uparrow}$ supplies finite observation-reflection role correspondence, $\mathsf{FiniteObservationInterface}^{\uparrow}$ supplies finite observation windows, $\mathsf{ClosedObservationSystem}^{\uparrow}$ and $\mathsf{ObservationConservationLedger}^{\uparrow}$ supply closed-observation and conservation ledgers, and $\mathsf{ReflectionRuntimeCheckpoint}^{\uparrow}$ supplies checkpoint

boundaries. These surfaces preserve finite inquiry rows but do not add total truth or source-domain identity.

Thus a demand for physical-MetaCIC identity, final truth, host physical law, closed continuation exhaustion, or an undisplayed route reaches no carrier coordinate. The accepted packet records that demand at L, Q, B rather than exporting it as data. □

Lean4 ✓ `BEDC.Derived.ReflectionGapBoundaryUp.ReflectionGapBoundary nonescape`

Theorem 1161.4 (ReflectionGapBoundary obligation closure)**.** *The carrier of Definition 1161.1, the local NameCert obligations of Definition 1161.2, the non-escape theorem of Definition 1161.3, and the TasteGate single-carrier alignment together close the obligation surface for* $\mathsf{ReflectionGapBoundary}^{\uparrow}$*. The closed surface consists only of carrier admission, finite source-trace exposure, history and signature extraction, classifier fit, package provenance, ledgered gap accounting, open-continuation preservation, componentwise* hsame *transport, displayed* Cont *replay, local naming, and the distinct boundary row* B*.*

Proof. Project the finite packet $G = (S, H, \Sigma, K, P, L, Q, T, R, N, B)$ from the carrier definition. This gives the only readable rows for the boundary object.

Apply the local NameCert obligation theorem. It records the carrier, source trace, history, signature, classifier, package, ledger, continuation, transport, replay, naming, and boundary clauses as the finite obligation surface.

Apply the non-escape theorem. It blocks any consumer route that asks for source-domain identity, total truth, host physical law, closed continuation exhaustion, or an undisplayed route.

Finally use the TasteGate single-carrier alignment cited above. The alignment keeps the reflected carrier rows on the same finite packet, so the carrier, obligations, non-escape result, and TasteGate row assemble exactly the obligation closure and no stronger public or bridge closure. □

Theorem 1161.5 (ReflectionGapBoundary public export)**.** *Every public* $\mathsf{ReflectionGapBoundary}^{\uparrow}$ *consumer must read the finite packet through the source trace, finite observation-reflection packet, boundary row, open-continuation row, componentwise transport row, displayed replay route, package provenance row, and local* $\mathsf{NameCert}_{\mathsf{ReflectionGapBoundary}^{\uparrow}}$ *row. The public export surface therefore exposes only the displayed source trace, finite observation-reflection data, ledgered boundary, continuation, transport, replay, provenance, and local naming clauses, and exports no total-truth theorem, host physical law, physical-reality identification, closed continuation exhaustion, or undisplayed route.*

Proof. Start with the obligation closure theorem and project the same finite packet $G = (S, H, \Sigma, K, P, L, Q, T, R, N$ The public read begins at the source trace and reaches the observation-reflection data only through the displayed finite history and signature rows.

The boundary and continuation checks then pass through B, L, Q. These rows record the reflection gap, accepted finite correspondences, rejected total-truth demands, and the continuation that remains open after the packet is read.

Finally the public route uses T, R, P, N for transport, replay, provenance, and local naming. The non-escape theorem blocks every demand for total truth, host physical law, physical-reality identification, closed continuation exhaustion, or any route not displayed by the packet, so the export surface is public exactly over the finite boundary rows listed above. □

Closure status for $\mathsf{NameCert}_{\mathsf{ReflectionGapBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ReflectionGapBoundary}^{\uparrow}$ packet is generated from source trace, finite history, signature extraction, classifier, package provenance, ledgered gaps, open continuation, componentwise transport, displayed route, local NameCert, and a distinct reflection-gap boundary row.

Theory closure: TheoryGate(NameCert$_{\mathsf{ReflectionGapBoundary}\uparrow}$, publicClosed)

Scope closed: Definition 1161.1, Definition 1161.2, Definition 1161.3, Definition 1161.4, Definition 1161.5, and the TasteGate alignment bind the public primitive surface over source trace, finite history, signature extraction, classifier, package, ledger, continuation, transport, replay, local NameCert, and boundary rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ReflectionGapBoundary}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert source-domain identity, total truth, host physical law, closed continuation exhaustion, Lean verification, or bridge checking.

Upgrade path: Bridge closure requires a checked standard bridge over the same finite source trace, history, signature, classifier, package, ledger, continuation, transport, replay, local NameCert, and boundary rows.

Chapter 1162

A Concrete Naming Certificate for $\mathsf{CompressionLedgerFunctor}^{\uparrow}$

The $\mathsf{CompressionLedgerFunctor}^{\uparrow}$ packet realizes the functorial composite-ledger side of section 9414.20 as a finite BEDC NameCert carrier. It answers the tower-compression vision of chapter 9414 at the point where chapter 1142 records a composite ledger, chapter 1143 binds endpoint equivalence to ledger compatibility, chapter 1148 exposes hidden-source residue, chapter 1127 supplies the indexed tower carrier, and chapter 1153 supplies the stage-refinement tower. Those siblings name the pieces; this carrier names the classifier that preserves ledger routes under tower-arrow composition.

Definition 1162.1 (CompressionLedgerFunctor carrier)**.** *A* $\mathsf{CompressionLedgerFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, K, E, R, O, M, L, Q, J, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{RealityConstrainedApproximationTower}^{\uparrow}$ *row naming the indexed tower objects.*
2. *K is the* $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ *row naming the accepted composite compression packet.*
3. *E is the* $\mathsf{TowerEquivalence}^{\uparrow}$ *row naming endpoint, ledger, and descent compatibility for compared towers.*
4. *R is the* $\mathsf{ApproximationTowerResidue}^{\uparrow}$ *row naming hidden-source and failed-descent residue.*
5. *O is the* $\mathsf{OnticTower}^{\uparrow}$ *row naming stage-refinement and ledger-continuity data.*
6. *M is the tower-arrow row, displaying the composable tower arrows whose ledgers are being routed.*
7. *L is the composite-ledger row, recording each tower arrow as a finite source-history, classifier, residue, and endpoint route.*
8. *Q is the classifier row, assigning to each displayed tower arrow its ledger route through L.*
9. *J is the composition row, recording ledger-route composition for every displayed composable pair in M.*
10. *H is componentwise* hsame *transport for $A, K, E, R, O, M, L, Q, J$.*

11. *C is the displayed* Cont *replay route through the tower-arrow and ledger-route rows.*
12. *P is the* Pkg *provenance over* $\mathsf{CompressionLedgerFunctor}^{\uparrow}$*, the five cited siblings,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompressionLedgerFunctor}^{\uparrow}}$ *row.*

The carrier has no coordinate for endpoint-only equality, unledgered tower-arrow composition, hidden source identity, private residue transport, or a second classifier outside Q.

Lean4 (definition) `BEDC.Derived.CompressionLedgerFunctorUp.CompressionLedgerFunctorUp`
Lean4 ✓ `BEDC.Derived.CompressionLedgerFunctorUp.CompressionLedgerFunctorTasteGate single carrier alignment`

Theorem 1162.2 (CompressionLedgerFunctor NameCert obligations)**.** *For the carrier of Definition 1162.1, the local* $\mathsf{NameCert}_{\mathsf{CompressionLedgerFunctor}^{\uparrow}}$ *surface consists exactly of six obligation rows:*

1. *carrier admission for $F = (A, K, E, R, O, M, L, Q, J, H, C, P, N)$;*
2. *tower-object exposure through A, K, E, R, O;*
3. *tower-arrow exposure through M;*
4. *composite-ledger and classifier exposure through L, Q;*
5. *composition-law exposure through J;*
6. *componentwise transport, replay, provenance, and local naming closure through H, C, P, N.*

Every accepted consumer of the functorial ledger must display these rows before using tower-arrow composition as a ledger-preserving operation.

Proof. Project the carrier of Definition 1162.1. The admitted object is the thirteen-row packet $F = (A, K, E, R, O, M, L, Q, J, H, C, P, N)$, so the tower-object, arrow, ledger, classifier, composition, transport, replay, provenance, and local-name coordinates are visible.

The rows A, K, E, R, O bind the packet to the indexed tower, composite compression, tower-equivalence, residue, and ontic-stage surfaces. The tower-arrow row M then supplies the finite composable pairs whose ledger routes can be inspected.

The rows L and Q expose the route assigned to each arrow. The row J is separate because preservation of composition is not implied by endpoint agreement or by the existence of individual arrow ledgers.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no additional coordinate, an accepted read is exhausted by the six displayed obligation rows. □

Lean4 ✓ `BEDC.Derived.CompressionLedgerFunctorUp.CompressionLedgerFunctorCarrier namecert obligations`

Theorem 1162.3 (CompressionLedgerFunctor composition law)**.** *Let $F = (A, K, E, R, O, M, L, Q, J, H, C, P, N)$ be an accepted* $\mathsf{CompressionLedgerFunctor}^{\uparrow}$ *packet. If α and β are composable tower arrows displayed by M, then the classifier row sends their composite to the composite of their ledger routes:*

$$Q(\beta \circ \alpha) = Q(\beta) \circ_{\mathsf{led}} Q(\alpha),$$

where $\circ_{\mathsf{led}}$ is the ledger-route operation recorded by J.

Proof. Use the NameCert obligations of Definition 1162.2. They require every accepted consumer to expose the tower-arrow row M, the composite-ledger row L, the classifier row Q, and the composition row J.

The pair α, β is composable only as displayed by M. The classifier row therefore assigns individual ledger routes through the same ledger row L, not through a private endpoint comparison.

The row J records exactly how the ledger route of a composite tower arrow is obtained from the two displayed component routes. Replaying J gives the stated equality with $\circ_{\mathsf{led}}$. □

Lean4 ✓ `BEDC.Derived.CompressionLedgerFunctorUp.CompressionLedgerFunctorCarrier composition law`

Theorem 1162.4 (CompressionLedgerFunctor sibling independence)**.** *The carrier of Definition 1162.1 is not bijective with any one of* RealityConstrainedTowerCompression$^{\uparrow}$, TowerEquivalence$^{\uparrow}$, ApproximationTowerResidu RealityConstrainedApproximationTower$^{\uparrow}$, *or* OnticTower$^{\uparrow}$. *Each sibling supplies a constituent tower, compression, equivalence, residue, or stage-refinement surface, while* CompressionLedgerFunctor$^{\uparrow}$ *additionally carries the tower-arrow row M, the classifier row Q, and the composition row J as one finite NameCert packet.*

Lean4 ✓ `BEDC.Derived.CompressionLedgerFunctorUp.CompressionLedgerFunctorCarrier sibling independence`

Proof. The compression sibling supplies the composite ledger but not the functorial assignment from tower arrows to ledger routes. The equivalence sibling supplies endpoint and ledger compatibility but not the classifier that sends a composed tower arrow to a composed ledger route.

The residue sibling supplies hidden-source and failed-descent rows, the approximation sibling supplies indexed tower objects, and the ontic sibling supplies stage-refinement and ledger-continuity rows. None of these packets has all three rows M, Q, J.

Because the CompressionLedgerFunctor$^{\uparrow}$ carrier keeps M, Q, J together with the five sibling surfaces and the structural rows H, C, P, N, any bijection to a single sibling would have to erase either a tower-arrow coordinate, a classifier coordinate, or the composition-law coordinate. That erasure is outside the accepted carrier. □

The Lean follow-up path `lean4/BEDC/Derived/CompressionLedgerFunctorUp/TasteGate.lean` must provide explicit Nontrivial CompressionLedgerFunctor$^{\uparrow}$ and FieldFaithful CompressionLedgerFunctor$^{\uparrow}$ instances preserving the indexed tower, compression, equivalence, residue, ontic tower, tower-arrow, composite-ledger, classifier, composition, transport, replay, provenance, and local naming rows.

Falsifiable prediction: An accepted CompressionLedgerFunctorUp classifier is refuted by any composable tower-arrow pair whose composite endpoint agrees while the transported composite ledger differs from the ledger-route composite recorded by the component arrows.

Independence witness: reality-constrained-tower-compression, towerequivalence, approximation-tower-residue, reality-constrained-approximation-tower, ontic-tower: none is bijective because CompressionLedgerFu binds tower objects, composite compression, tower equivalence, residue, ontic refinement, tower arrows, ledger routes, classifier assignment, composition law, transport, replay, provenance, and local NameCert rows in one finite packet. Each sibling exposes a constituent surface without the functorial ledger-preservation classifier.

Theorem 1162.5 (CompressionLedgerFunctor scoped route)**.** *The* CompressionLedgerFunctor$^{\uparrow}$ *carrier, its NameCert obligations, its composition law, its sibling-independence theorem, its falsifiable prediction, its independence witness, and the checked TasteGate marker*

CompressionLedgerFunctorTasteGate_single_carrier_alignment

jointly scope the packet over the displayed ledger-functor rows $A, K, E, R, O, M, L, Q, J$*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, local* $\mathsf{NameCert}_{\mathsf{CompressionLedgerFunctor}^{\uparrow}}$ *row* N*, classifier refutation surface, and sibling-separation witness.*

Proof. Read the carrier through Definition 1162.1. Its rows display the five sibling surfaces, the tower-arrow row, the composite-ledger row, the classifier row, the composition row, and the transport, replay, provenance, and local naming rows.

Use the NameCert obligations of Definition 1162.2 to force every accepted consumer through those displayed coordinates. Then apply Definition 1162.3 for the ledger-route composition boundary and Definition 1162.4 for the refusal of any one-sibling collapse.

The falsifiable prediction supplies the local refutation surface for a classifier that preserves endpoints while breaking ledger composition. The independence witness records the same separation from the five siblings, and the checked TasteGate marker pins the single-carrier alignment. These rows exhaust the scoped packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompressionLedgerFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{CompressionLedgerFunctor}^{\uparrow}$ packet is generated from indexed tower, composite compression, tower equivalence, residue, ontic refinement, tower-arrow, composite-ledger, classifier, composition, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompressionLedgerFunctor}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1162.5 binds the carrier, ledger functor rows $A, K, E, R, O, M, L, Q, J$, hsame transport H, Cont replay C, Pkg provenance P, local NameCert row N, classifier refutation surface, and sibling-separation witness as the scoped surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompressionLedgerFunctor}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, endpoint-only equality, unledgered tower-arrow composition, source identity, private residue transport, or a classifier outside the displayed packet.

Upgrade path: Obligation closure requires Lean encoding of carrier admission, tower-arrow classification, ledger-route composition, sibling separation, TasteGate nontriviality, and field faithfulness for $A, K, E, R, O, M, L, Q, J, H, C, P, N$.

Chapter 1163

A Concrete Naming Certificate for $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$

The $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$ packet realizes the failure-surface requirement of section 9414.68 as a finite NameCert carrier. It sits between the audit row of chapter 1124 and the TruthCert packet of chapter 1144: those sibling chapters name the audit and truth-export surfaces, while this chapter isolates the finite row that records how a certified physical truth claim can be defeated.

Definition 1163.1 (Reality-constrained failure-surface carrier)**.** *A* $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, D, K, U, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the finite row of defeating observations and later observation traces;*
2. *D is the domain-exit row recording where the certified claim is no longer licensed;*
3. *K is the classifier-mismatch row comparing reality-facing and model-facing signatures;*
4. *U is the continuation-scope row naming the class over which the claim remains reusable;*
5. *L is the ledger row recording hidden compression, idealization, source loss, and packaging material relevant to the defeat;*
6. *H records componentwise* hsame *transport for O, D, K, U, L, C, P, N;*
7. *C records displayed* Cont *replay of the defeat, domain-exit, mismatch, continuation, and ledger reads;*
8. *P is the* Pkg *provenance over* BHist, hsame, Cont, *ledger, classifier, continuation-scope, and truth-export rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedFailureSurface}^{\uparrow}}$ *row.*

The carrier has no coordinate for unbounded confirmation, final model–reality identity, hidden classifier choice, unledgered defeat, or truth export outside the displayed failure row.

Lean4 (definition) `BEDC.Derived.RealityConstrainedFailureSurfaceUp.RealityConstrainedFailureSurfaceUp`

Theorem 1163.2 (Reality-constrained failure-surface NameCert obligations)**.** *For the carrier of Definition 1163.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedFailureSurface}^{\uparrow}}$ *surface consists exactly of carrier admission, defeating-observation visibility, domain-exit visibility, classifier-mismatch visibility, continuation-scope visibility, ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* N*.*

Proof. Project the carrier $F = (O, D, K, U, L, H, C, P, N)$. The first five rows expose the defeating observations, exits, mismatches, continuation scope, and ledger entries that can overturn a certified truth claim.

Read the structural rows. Transport through H preserves the displayed components, replay through C keeps the consumer inside the same finite route, provenance through P records the source of the failure row, and N names the packet.

Since the carrier has no additional coordinate, the listed rows exhaust the local NameCert surface. A purported failure certificate that omits one of them is a projection of the packet, not the accepted packet itself. □

Theorem 1163.3 (Reality-constrained failure-surface non-escape)**.** *Any truth export that depends on a defeating observation, domain exit, classifier mismatch, continuation boundary, or hidden ledger entry absent from*

$$O, D, K, U, L, H, C, P, N$$

is rejected by the $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$ *classifier. In particular, omitting the displayed failure row from a* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *export leaves no accepted route for certified physical truth.*

Proof. Use the NameCert obligations of Definition 1163.2. Defeat, exit, mismatch, continuation, and ledger reads are all projections from the same finite packet.

If a truth export cites a defeat or exit not present in O, D, K, U, L, then the cited row is outside the carrier. The structural rows cannot add it: hsame transports displayed components, Cont replays displayed reads, and Pkg records provenance for the same packet.

Thus the classifier rejects any export that omits the displayed failure row or replaces it by hidden host evidence. The certified truth route remains open exactly because the failure surface is retained. □

Theorem 1163.4 (Reality-constrained failure-surface continuation scope)**.** *For an accepted* RealityConstrainedFailu *packet, continuation reuse is scoped by* U *and replayed only through* C*. A consumer may transport the failure surface along* H *and cite provenance through* P*, but it cannot extend the truth claim beyond the displayed continuation class or erase a listed defeat by moving to a different continuation route.*

Proof. Start from the continuation-scope row U in the carrier. It is the only row that licenses reuse of the truth claim beyond the finite source trace.

The replay row C then determines how the defeat, domain-exit, mismatch, and ledger reads are consumed under that scope. Transport through H preserves those rows componentwise; it does not create a wider continuation class.

Finally apply non-escape from Definition 1163.3. A consumer that moves outside U or erases a listed defeat asks for a coordinate absent from the packet, so the accepted continuation scope is exactly the displayed one. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedFailureSurfaceUp.RealityConstrainedFailureSurfaceUp continuation scope`

Theorem 1163.5 (Reality-constrained failure-surface domain-export refusal)**.** *For an accepted* $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$ *packet* $F = (O, D, K, U, L, H, C, P, N)$*, any truth export that crosses the displayed domain-exit row* D *or omits the classifier-mismatch row* K *is rejected by the failure-surface classifier unless the same packet exposes the defeating observation row* O*, continuation-scope row* U*, ledger row* L*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedFailureSurface}^{\uparrow}}$ *row* N*.*

Proof. Project the carrier $F = (O, D, K, U, L, H, C, P, N)$. The rows D and K are displayed coordinates, so a truth export that crosses D or omits K asks the classifier to ignore part of the accepted packet.

Invoke the NameCert obligations of Definition 1163.2. The defeating observation, continuation scope, ledger, transport, replay, provenance, and local naming rows are all part of the same finite surface; none may be supplied by a hidden host witness.

Use the continuation-scope theorem Definition 1163.4. Reuse is licensed only through U and replayed only through C, so crossing the domain-exit row cannot create a wider export route.

Finally apply non-escape from Definition 1163.3. Hidden evidence outside $O, D, K, U, L, H, C, P, N$ is not a coordinate of the packet, and the classifier rejects the attempted export unless the full displayed defeat surface is exposed. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedFailureSurfaceUp.RealityConstrainedFailureSurfaceDomainExportRef`

Theorem 1163.6 (Reality-constrained failure-surface bridge boundary)**.** *For an accepted* RealityConstrainedFailureS *packet* $F = (O, D, K, U, L, H, C, P, N)$*, the displayed failure-surface packet is the only bridge-facing boundary consumed by truth-export and model-audit siblings. A consumer may pass defeating observations, domain exits, classifier mismatches, continuation scope, ledger entries, transport, replay, provenance, and local naming through that boundary, but it cannot add a second failure surface, hidden model-reality identity, unbounded confirmation row, unledgered defeat, or private truth-export route.*

Proof. Start from the carrier of Definition 1163.1. It exposes the finite failure-surface tuple $F = (O, D, K, U, L, H, C, P, N)$ as the whole packet available to bridge-facing consumers.

Apply Definition 1163.2 and Definition 1163.5. These theorems force every truth-export and model-audit read to display the same defeat, exit, mismatch, continuation, ledger, transport, replay, provenance, and naming rows.

Use non-escape from Definition 1163.3. Since the carrier lacks hidden model-reality identity, unbounded confirmation, unledgered defeat, and private export coordinates, the displayed packet is the sole bridge-facing boundary. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedFailureSurfaceUp.RealityConstrainedFailureSurfaceUpStdBridge`

Falsifiable prediction: Any certified truth export that omits the displayed $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$ row $F = (O, D, K, U, L, H, C, P, N)$ is rejected by the reality-constrained truth classifier.

Independence witness: realityconstrainedmodelaudit, realityconstrainedtruthcert, openfitpacket, lawcertificate, realityconstrainedsynthesisseal: none is bijective to $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$ because the carrier isolates defeating observations, domain exits, classifier mismatches, continuation scope, ledger, componentwise transport, replay, provenance, and local naming as one finite failure packet.

The checked single-carrier alignment theorem records the ChapterTasteGate realization for this carrier.

Chapter 1164

A Concrete Naming Certificate for $\mathsf{RealWindowBudget}^{\uparrow}$

The $\mathsf{RealWindowBudget}^{\uparrow}$ packet concretizes the finite observation route used by section 9414.68. It sits between the selector surface of chapter 853 and the disclosure surface of chapter 611: the first sibling fixes the finite diagonal-selector budget, and the second sibling exposes the observation budget consumed by Real-facing handoffs.

Definition 1164.1 (Real-window budget carrier)**.** *A* $\mathsf{RealWindowBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (Q, V, D, R, S, B, O, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite request row naming the precision, observation scope, and StreamName extent visible to the consumer;*
2. *V is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *window rows selected by Q;*
3. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks and dyadic-radius rows attached to the windows in V;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached after those finite readbacks;*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed to the Real-facing consumer;*
6. *B is the synchronized* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *selector row for the same finite request;*
7. *O is the* $\mathsf{RealObservationBudget}^{\uparrow}$ *disclosure row that makes the visible request, window, dyadic, handoff, and seal route inspectable;*
8. *H records componentwise* hsame *transports for $Q, V, D, R, S, B, O, P, N$;*
9. *C records displayed* Cont *routes from Q to V, from V to D, from D to R, from R to S, and through the selector and disclosure rows B, O;*
10. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyDiagonalBudget}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealWindowBudget}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, host completeness, host real equality, selected limits, unbounded observation schedules, hidden selector choice, or a private Real seal.

Theorem 1164.2 (Real-window budget NameCert obligations)**.** *For the carrier of Definition 1164.1, the local* $\mathsf{NameCert}_{\mathsf{RealWindowBudget}^{\uparrow}}$ *surface consists exactly of carrier admission, finite request exposure,* $\mathsf{StreamName}^{\uparrow}$ *window coverage,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff routing,* $\mathsf{Real}^{\uparrow}$ *seal exposure, synchronized* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *selector routing,* $\mathsf{RealObservationBudget}^{\uparrow}$ *disclosure routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* N*.*

Proof. Project the displayed packet $W = (Q, V, D, R, S, B, O, H, C, P, N)$. The rows Q, V, D, R, S expose the finite request, StreamName windows, dyadic readbacks, regular-rational handoff, and Real seal.

Read the sibling rows next. The selector row B is the finite diagonal-budget surface supplied by chapter 853, while O is the observation disclosure surface supplied by chapter 611. These rows attach the same request, windows, readbacks, handoff, and seal to the budget route.

Finally read the structural rows. Transport through H preserves the displayed coordinates componentwise, replay through C keeps every consumer on the finite route, provenance through P records the sibling and kernel sources, and N names the packet. Since the carrier has no further coordinate, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier namecert obligations`

Theorem 1164.3 (Real-window budget selector stability)**.** *Let* $W = (Q, V, D, R, S, B, O, H, C, P, N)$ *be an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet. Any consumer that reads the selector row* B *through the same request* Q *must use the displayed StreamName windows* V*, dyadic readbacks* D*, regular handoff* R*, Real seal* S*, disclosure row* O*, and support rows* H, C, P, N*. The selector cannot be replaced by a host-selected limit, a second window family, quotient stream equality, or an undisclosed observation route.*

Proof. Start from the finite request row Q. The displayed route in C sends that request first to the StreamName windows V and then to the dyadic readbacks D before any regular or Real-facing handoff can be consumed.

Attach the selector surface. The $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ sibling records finite selector stability through its precision, mesh, window, dyadic, comparison, and seal rows, and the present packet exposes that sibling only as the row B synchronized with Q, V, D, R, S.

Use the disclosure row O to keep the same route observable. The $\mathsf{RealObservationBudget}^{\uparrow}$ sibling makes the request, windows, dyadic readbacks, handoff rows, and seal rows visible as one finite observation budget.

The structural rows H, C, P, N then preserve, replay, source, and name the same packet. Because no other selector, window family, quotient equality, host limit, or hidden disclosure coordinate is a field of W, selector stability is exactly the displayed finite route. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier selector stability`

Theorem 1164.4 (Real-window budget Real-completion handoff)**.** *Every Real and Completion consumer of an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet factors through*

$$Q \longmapsto V \longmapsto D \longmapsto R \longmapsto S$$

together with the selector row B*, disclosure row* O*, componentwise transports* H*, displayed continuations* C*, provenance* P*, and local naming row* N*. Conversely, every accepted packet exposes this finite route as its StreamName, DyadicRatCore, RegSeqRat, and Real face.*

The handoff exports no quotient stream, no host sequence equality, no host completeness theorem, no selected limit, no unbounded observation schedule, and no private Real seal.

Proof. First read the local carrier. By Definition 1164.1, the only Real-facing route begins at Q, passes through the finite windows V, dyadic readbacks D, and regular handoff R, and reaches the seal row S.

Next compose the sibling budget surfaces. The $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ row B supplies the finite selector budget for the same request, and the $\mathsf{RealObservationBudget}^{\uparrow}$ row O supplies the observable disclosure ledger for the same windows, readbacks, handoff, and seal.

For the converse direction, project any accepted carrier onto Q, V, D, R, S. Those rows are precisely its StreamName, DyadicRatCore, RegSeqRat, and Real faces, with H, C, P, N preserving and naming the packet.

Thus the Real and Completion handoff is the displayed finite route. Since neither the carrier nor the cited siblings contain quotient stream equality, host equality, host completeness, selected limits, unbounded schedules, or private seal rows, none can be exported by the handoff. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier real completion handoff`

Theorem 1164.5 (Real-window budget finite-route visibility)**.** *Every accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet exposes the single finite route*

$$Q \to V \to D \to R \to S$$

together with the selector row B, disclosure row O, and structural rows H, C, P, N. This visible route consumes $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *selector budget, and the* $\mathsf{RealObservationBudget}^{\uparrow}$ *disclosure budget as one packet-level handoff. It exports no quotient stream, host equality, selected limit, host completeness claim, or hidden observation route.*

Proof. Project the carrier of Definition 1164.1. Its rows list exactly $Q, V, D, R, S, B, O, H, C, P, N$, with $Q \to V \to D \to R \to S$ as the displayed Real-facing route.

Use the NameCert obligations of Definition 1164.2. They attach the selector row B and disclosure row O to the same request, window, dyadic, handoff, and seal rows, while H, C, P, N provide only transport, replay, provenance, and local naming for that packet.

Now apply selector stability and the Real-completion handoff, Definition 1164.3 and Definition 1164.4. The first prevents replacing B by a detached selector or hidden limit, and the second forces every Real and Completion consumer through the same finite route. Hence the accepted packet makes the finite observation route visible without exporting quotient streams, host equality, selected limits, or completeness claims. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier finite route visibility`

Theorem 1164.6 (Real-window budget finite-tail-filter handoff)**.** *Let $W = (Q, V, D, R, S, B, O, H, C, P, N)$ be an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet whose finite route is consumed as a cofinal-tail Real or Completion budget. The consumer reads the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *faces through the displayed* $\mathsf{FiniteTailFilter}^{\uparrow}$ *packet of chapter 1119; for a regular Cauchy tail source, the read also factors through chapter 1605. No detached finite observation budget, private tail window, separate dyadic ledger, or ambient completion seal is exported.*

Proof. Start with finite-route visibility and the Real-completion handoff, Definition 1164.5 and Definition 1164.4. They identify every Real or Completion read of W with the displayed $Q, V, D, R, S, B, O, H, C, P, N$ route.

Now apply tail-window exactness and Real-seal handoff for $\mathsf{FiniteTailFilter}^{\uparrow}$, Definition 1119.4 and Definition 1119.5. These bind the shared stream window, dyadic ledger, regular readback,

and Real seal to the same cofinal-tail packet. For regular Cauchy sources, compose with Definition 1605.4. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier finite tail filter handoff`

Theorem 1164.7 (Real-window budget carrier admission obligation)**.** *An accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet is admitted exactly by the finite tuple*

$$W = (Q, V, D, R, S, B, O, H, C, P, N).$$

Carrier admission has no quotient stream coordinate, host equality coordinate, hidden selector coordinate, private seal coordinate, selected limit coordinate, unbounded schedule coordinate, or host completeness coordinate.

Proof. Start with the carrier definition, Definition 1164.1. Its displayed tuple lists exactly $Q, V, D, R, S, B, O, H, C,$ and the definition explicitly excludes quotient streams, host completeness, host real equality, selected limits, unbounded observation schedules, hidden selector choice, and private Real seals.

Use the NameCert obligations of Definition 1164.2. They make the displayed rows the local admission surface and leave H, C, P, N as transport, replay, provenance, and naming rows rather than extra carrier coordinates.

Selector stability and the Real-completion handoff, Definition 1164.3 and Definition 1164.4, keep every accepted read on the same route. Finite-route visibility, Definition 1164.5, then rules out a second admitted route. Thus carrier admission is exactly the displayed tuple. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier admission obligation`

Theorem 1164.8 (Real-window budget window coverage obligation)**.** *For an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet* $W = (Q, V, D, R, S, B, O, H, C, P, N)$*, the request row* Q *covers precisely the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows* V*. Every selector read and every observation-budget read must reuse those windows through the support rows* H, C, P, N*.*

Proof. Project the packet through Definition 1164.1. The only window row named by the finite request Q is V, and the subsequent dyadic row D is attached to those windows.

Apply the local NameCert obligations, Definition 1164.2. They tie request exposure, StreamName-window coverage, selector routing, disclosure routing, transport, replay, provenance, and naming to the same carrier rows.

Selector stability, Definition 1164.3, prevents B from reading a second window family. The Real-completion handoff and finite-route visibility, Definition 1164.4 and Definition 1164.5, force the observation-budget route through $Q \to V \to D \to R \to S$ with H, C, P, N. Hence both selector and disclosure reads reuse precisely the displayed windows. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier window coverage obligation`

Theorem 1164.9 (Real-window budget dyadic handoff seal obligation)**.** *For an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet* $W = (Q, V, D, R, S, B, O, H, C, P, N)$*, the route*

$$V \to D \to R \to S$$

is the only accepted $\mathsf{DyadicRatCore}^{\uparrow}$*-to-*$\mathsf{RegSeqRat}^{\uparrow}$*-to-*$\mathsf{Real}^{\uparrow}$ *seal handoff for the packet.*

Proof. Read the route from the carrier definition, Definition 1164.1. The window row V feeds the $\mathsf{DyadicRatCore}^{\uparrow}$ readback row D, then the $\mathsf{RegSeqRat}^{\uparrow}$ handoff row R, and finally the $\mathsf{Real}^{\uparrow}$ seal row S.

The NameCert obligations, Definition 1164.2, expose dyadic readbacks, handoff routing, Real seal exposure, displayed replay, provenance, and local naming only along those rows.

Selector stability, Definition 1164.3, keeps the selector row synchronized with the same V, D, R, S chain. The Real-completion handoff and finite-route visibility, Definition 1164.4 and Definition 1164.5, make that chain the sole Real-facing route and exclude private seals or alternate host-level completions. Therefore the accepted seal handoff is exactly $V \to D \to R \to S$. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier dyadic handoff seal obligation`

Theorem 1164.10 (Real-window budget root selector obligation)**.** *Before a* $\mathsf{RealWindowBudget}^{\uparrow}$ *selector is accepted, the root obligation must display the budget request Q, the finite window row V, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, the* $\mathsf{Real}^{\uparrow}$ *seal row S, the synchronized selector row B, the disclosure row O, the componentwise transport row H, the continuation row C, the package row P, and the local* $\mathsf{NameCert}_{\mathsf{RealWindowBudget}^{\uparrow}}$ *row N. No selector is accepted from a hidden window source or from a Real-facing seal that omits one of these rows.*

Proof. Project the carrier of Definition 1164.1. Its displayed coordinates already list the finite request, window, dyadic observation, regular handoff, Real seal, selector, disclosure, transport, continuation, package, and local name rows.

Use the NameCert obligations of Definition 1164.2. They make each of those rows part of the local acceptance surface, while selector stability Definition 1164.3 prevents replacing the selector by an undisclosed source.

Finally apply the Real-completion handoff and finite-route visibility, Definition 1164.4 and Definition 1164.5. These keep the consumer on $Q \to V \to D \to R \to S$ with the displayed support rows, so root selector acceptance is exactly the listed obligation surface. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier root selector obligation`

Theorem 1164.11 (Real-window budget finite-window source exhaustion)**.** *For every accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet, finite window reads exhaust the allowed* $\mathsf{StreamName}^{\uparrow}$ *source surface. A consumer may read the windows V through the request Q, the selector row B, the disclosure row O, and the support rows H, C, P, N, but it cannot import an additional stream source, unbounded observation schedule, hidden selector, quotient stream, or selected host limit.*

Proof. Start with the route made visible in Definition 1164.5. The only displayed window source is V, reached from the finite request Q and then consumed by the dyadic row D.

Use selector stability, Definition 1164.3. The selector row B is synchronized with the same request, windows, dyadic readbacks, handoff, seal, disclosure, and support rows, so it cannot choose a second window family.

The NameCert obligations then exhaust the local surface. Since the carrier contains no coordinate for another stream source or unbounded schedule, the finite windows V are the whole allowed $\mathsf{StreamName}^{\uparrow}$ source surface for the accepted packet. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier finite window source route certificate`

Theorem 1164.12 (Real-window budget Real-seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet factors through the displayed finite budget route*

$$Q \to V \to D \to R \to S.$$

The consumer may use B, O, H, C, P, N *to select, disclose, transport, replay, package, and name that route, but it cannot bypass it into host equality, countable choice, quotient streams, ambient completeness, selected limits, or a private Real seal.*

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier real seal nonescape`

Proof. Apply the Real-completion handoff Definition 1164.4. It places every Real or Completion consumer on the chain $Q \to V \to D \to R \to S$ together with B, O, H, C, P, N.

Use finite-route visibility, Definition 1164.5, to make that chain the only exposed route of an accepted packet. The carrier and NameCert obligations contain no alternate host equality, choice, quotient, completeness, selected-limit, or private-seal coordinate.

Therefore a Real-seal consumer cannot escape the displayed finite budget route. Any attempted bypass asks for a row absent from the accepted $\mathsf{RealWindowBudget}^{\uparrow}$ packet. □

Theorem 1164.13 (Real-window budget scoped dependency binding)**.** *For every accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet*

$$W = (Q, V, D, R, S, B, O, H, C, P, N),$$

every scoped read factors through the displayed rows $Q, V, D, R, S, B, O, H, C, P, N$*:* V *is the* $\mathsf{StreamName}^{\uparrow}$ *window surface,* D *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback surface,* R *the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* S *the* $\mathsf{Real}^{\uparrow}$ *seal,* B *the* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *selector,* O *the* $\mathsf{RealObservationBudget}^{\uparrow}$ *disclosure, and* H, C, P, N *the* hsame*,* Cont*,* Pkg*, and* NameCert *rows. No scoped read is accepted outside this displayed dependency binding.*

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier scoped dependency binding`

Proof. Project the carrier of Definition 1164.1. Its finite packet lists precisely $Q, V, D, R, S, B, O, H, C, P, N$ and assigns each row to the named StreamName, dyadic, regular, Real, selector, disclosure, history, transport, continuation, package, and naming surfaces.

Use the NameCert obligations of Definition 1164.2. They make the same rows the complete acceptance surface: carrier admission, finite request exposure, window coverage, dyadic readback exposure, handoff routing, Real seal exposure, selector routing, disclosure routing, componentwise transport, displayed replay, provenance, and local naming.

The selector-stability and Real-completion handoff results, Definition 1164.3 and Definition 1164.4, keep every consumer on the same rows. Finite-route visibility, finite-window source exhaustion, and Real-seal non-escape, Definition 1164.5, Definition 1164.11, and Definition 1164.12, then rule out hidden sources, alternate selectors, host equality, selected limits, quotient streams, and ambient completeness. Therefore the dependency envelope is exactly the displayed packet. □

Theorem 1164.14 (Real-window budget selector-disclosure scope)**.** *In an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet, the selector row* B *and the disclosure row* O *are readable only as sibling-scoped rows tied to the same finite request route*

$$Q \to V \to D \to R \to S.$$

No consumer may detach B *from* O*, read* O *against a different selector, or route either row through a second request, hidden window source, selected limit, host equality, quotient stream, or private Real seal.*

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.SelectorDisclosureScope.RealWindowBudgetCarrier selector disclosure scope`

Proof. Begin with the finite request route in Definition 1164.5. It exposes $Q \to V \to D \to R \to S$ together with B, O, H, C, P, N as one accepted packet-level handoff.

Apply selector stability, Definition 1164.3. The selector row B must reuse the displayed windows, dyadic readbacks, regular handoff, Real seal, disclosure row, and support rows, so it is not a detached source of limits or a second window family.

Now use the Real-completion handoff and Real-seal non-escape, Definition 1164.4 and Definition 1164.12. They force every Real-facing read, including disclosure through O, through the same finite route and exclude host equality, quotient streams, ambient completeness, selected limits, and private seals.

Finally, the carrier and NameCert obligations identify B as the $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ sibling row and O as the $\mathsf{RealObservationBudget}^{\uparrow}$ sibling row for the same packet. Since no further selector or disclosure coordinate exists, both rows are readable only in this sibling-scoped sense. □

Theorem 1164.15 (Real-window budget Real-completion scope)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet may use only the displayed finite route*

$$Q \to V \to D \to R \to S$$

and the support rows B, O, H, C, P, N*. Such a consumer cannot import quotient streams, host equality, selected limits, hidden choice, ambient completeness, unbounded observation schedules, or any private completion object absent from the packet.*

Proof. Use the Real-completion handoff, Definition 1164.4. It states that every Real and Completion consumer factors through $Q \to V \to D \to R \to S$ with the selector, disclosure, transport, continuation, provenance, and naming rows B, O, H, C, P, N.

Finite-route visibility, Definition 1164.5, makes that route the exposed packet surface. The carrier admission and NameCert obligation theorems, Definition 1164.7 and Definition 1164.2, identify all rows available for admission, replay, provenance, and local naming.

The finite-window source exhaustion and Real-seal non-escape results, Definition 1164.11 and Definition 1164.12, remove the remaining escape routes. They deny an additional StreamName source, unbounded schedule, hidden selector, quotient stream, selected host limit, host equality, ambient completeness, and private Real seal.

Thus the Real and Completion scope of the packet is exactly the displayed finite route plus B, O, H, C, P, N. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier real completion scope`

Theorem 1164.16 (Real-window budget terminal pullback coherence)**.** *Every accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet whose finite route*

$$Q \to V \to D \to R \to S$$

is consumed by a $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *terminal route and a* $\mathsf{RealCompletionExactBoundaryUp}$ *four-face boundary factors through the same displayed rows* $Q, V, D, R, S, B, O, H, C, P, N$*. Selector-budget totality and exact-boundary four-face exactness agree on the StreamName window, RegSeqRat readback, and Real seal faces, and the pullback introduces no quotient stream, selected limit, host equality, countable choice, or ambient completeness coordinate.*

Proof. Start from the local Real-completion scope, Definition 1164.15. It restricts every Real or Completion-facing consumer of the packet to the finite route $Q \to V \to D \to R \to S$ together with the support rows B, O, H, C, P, N.

Apply selector-budget totality and selector-seal terminality, Definition 1081.6 and Definition 1081.11. These identify the selector-seal consumer as a terminal read of the same StreamName window, RegSeqRat readback, Real seal, and selector budget rows rather than as an external limit-selection device.

Now use exact-boundary four-face exactness, Definition 1120.6. Its boundary faces read the Real seal through the displayed completion route, so the selector-seal face and exact-boundary face meet on the same packet rows.

The carrier and NameCert obligations of the $\mathsf{RealWindowBudget}^{\uparrow}$ packet list no quotient stream, selected limit, host equality, countable-choice coordinate, or ambient completeness coordinate. Hence the two completion consumers pull back through the displayed finite rows and nowhere else. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier terminal pullback coherence`

Theorem 1164.17 (Real-window budget terminal pullback non-escape)**.** *Let $W = (Q, V, D, R, S, B, O, H, C, P, N)$ be an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet whose finite route is consumed simultaneously by a* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *terminal route and a* $\mathsf{RealCompletionExactBoundaryUp}$ *four-face boundary. Then every completion-facing coordinate of the common consumer lies among $Q, V, D, R, S, B, O, H, C, P, N$. In particular the common consumer has no quotient stream, selected limit, host equality, countable-choice row, ambient completeness row, metric-completeness row, detached selector row, or second terminal route.*

Proof. Start with the Real-completion scope theorem, Definition 1164.15. It restricts every Real or Completion consumer of the accepted packet to $Q \to V \to D \to R \to S$ together with the support rows B, O, H, C, P, N.

Now apply the terminal pullback coherence theorem, Definition 1164.16. It says that the selector-seal terminal consumer and the exact-boundary four-face consumer meet on those same displayed rows rather than on an external completion object.

On the selector side, use selector-budget totality and terminality, Definition 1081.6 and Definition 1081.11, together with selector-seal non-escape, Definition 1081.4. These force the terminal selector-seal read through its finite selector, window, readback, seal, endpoint, and structural rows and exclude hidden selectors, detached limits, quotient streams, host equality, second completion routes, and ambient completeness.

On the exact-boundary side, use four-face exactness and boundary non-escape, Definition 1120.6 and Definition 1120.3. The four faces expose only the StreamName window, RegSeqRat readback, DyadicRatCore ledger, and terminal Real seal, while the non-escape boundary excludes quotient, selected-limit, host-equality, choice, metric-completeness, ambient-completeness, bridge, and second-route coordinates. Combined with the Real-window budget non-escape surface, these exclusions leave exactly the rows $Q, V, D, R, S, B, O, H, C, P, N$ for the simultaneous consumer. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.TerminalPullbackNonescape.RealWindowBudgetCarrier terminal pullback nonescape`

Theorem 1164.18 (Real-window budget RegSeqRat selector exactness)**.** *Let $W = (Q, V, D, R, S, B, O, H, C, P, N)$ be an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet. The packet exposes a* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R to a Real or Completion consumer exactly when the same finite request Q has the displayed* $\mathsf{StreamName}^{\uparrow}$

window rows V, $\mathsf{DyadicRatCore}^{\uparrow}$ readback rows D, selector row B, observation-disclosure row O, componentwise transport row H, displayed continuation row C, provenance row P, and local naming row N. Thus the accepted RegSeqRat handoff is not a detached sequence, quotient stream representative, selected host limit, or host equality witness; it is the regular-rational face of the displayed finite budget route.

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier regseq selector exactness`

Proof. Start with the NameCert obligations, Definition 1164.2. They make the $\mathsf{RegSeqRat}^{\uparrow}$ handoff row one of the named carrier obligations and attach it to request exposure, StreamName-window coverage, dyadic readback exposure, selector routing, disclosure routing, transport, replay, provenance, and local naming.

Selector stability, Definition 1164.3, then prevents the row B from selecting a different window family or a hidden host limit. The Real-completion handoff, Definition 1164.4, identifies $Q \to V \to D \to R \to S$ as the route consumed by Real and Completion readers.

Finally apply terminal pullback coherence, Definition 1164.16. The selector-seal consumer and the exact-boundary consumer meet on the same StreamName window, RegSeqRat readback, and Real seal faces. Therefore a consumer sees R exactly through $Q, V, D, B, O, H, C, P, N$, with no detached sequence, quotient representative, selected host limit, or host equality witness. □

Theorem 1164.19 (Real-window budget observation-scope exhaustion)**.** *For an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet $W = (Q, V, D, R, S, B, O, H, C, P, N)$, every visible RealWindowBudget consumer route is exhausted by the displayed rows $Q, V, D, R, S, B, O, H, C, P, N$. No such route can appeal to quotient streams, host sequence equality, selected limits, hidden schedules, a detached selector, private Real seals, or an ambient completeness coordinate outside the packet.*

Proof. Use finite-route visibility, Definition 1164.5. It exposes $Q \to V \to D \to R \to S$ together with the selector row B, disclosure row O, and structural rows H, C, P, N as the packet-level route for every visible consumer.

Next apply scoped dependency binding, Definition 1164.13. It binds any accepted scoped read to the same finite request, window, dyadic readback, handoff, Real seal, selector, disclosure, history, continuation, provenance, and local NameCert rows.

Terminal pullback non-escape, Definition 1164.17, removes the completion-facing escape coordinates. Hence the visible observation scope is exhausted by $Q, V, D, R, S, B, O, H, C, P, N$ and cannot cite quotient streams, host sequence equality, selected limits, hidden schedules, detached selectors, private seals, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.ObservationScopeExhaustion.RealWindowBudgetCarrier observation scope exhaustion`

Theorem 1164.20 (Real-window budget Real-seal readback totality)**.** *Let $W = (Q, V, D, R, S, B, O, H, C, P, N)$ be an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet. The Real seal row S is readable only through the finite chain from* $\mathsf{StreamName}^{\uparrow}$ *windows V to* $\mathsf{DyadicRatCore}^{\uparrow}$ *readbacks D to the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, together with the selector row B, observation-disclosure row O, and structural rows H, C, P, N. This gives every downstream Real and Completion consumer a finite BEDC route to S and gives no completeness claim, quotient-stream claim, selected-limit claim, or host-Real equality claim.*

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier real seal readback totality`

Proof. Read the seal through the local Real-completion scope, Definition 1164.15. It places every Real and Completion consumer on $Q \to V \to D \to R \to S$ with B, O, H, C, P, N as the only support rows.

The Real-seal non-escape theorem, Definition 1164.12, rules out a private seal, hidden selector, quotient stream, selected limit, host equality, or ambient completeness witness. The RegSeqRat selector exactness theorem, Definition 1164.18, identifies the handoff row R as the finite selector-readback face rather than a detached host sequence.

The observation-scope exhaustion theorem, Definition 1164.19, then makes the readback total for the public consumer surface. The downstream Real or Completion consumer receives the finite BEDC route to S and receives no claim of completeness, quotient-stream identity, selected host limit, or host-Real equality. □

Theorem 1164.21 (Real-window budget selector pullback exactness)**.** *Let $W = (Q, V, D, R, S, B, O, H, C, P, N)$ be an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet. A selector-disclosure consumer reaches the Real seal row S if and only if it preserves the same request row Q,* $\mathsf{StreamName}^{\uparrow}$ *window rows V,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback rows D,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, selector row B, disclosure row O, and structural rows H, C, P, N. No quotient stream, host equality, selected limit, hidden schedule, private seal, or ambient completeness coordinate can witness this pullback.*

Proof. For the forward direction, start from the local NameCert obligations, Definition 1164.2. They expose only the displayed request, window, dyadic readback, handoff, Real seal, selector, disclosure, transport, continuation, provenance, and naming rows.

Selector stability and finite-route visibility, Definition 1164.3 and Definition 1164.5, then force any selector-disclosure read to stay on $Q \to V \to D \to R \to S$ with B, O, H, C, P, N as its support. The RegSeqRat selector exactness theorem, Definition 1164.18, identifies R as the handoff reached through those same finite rows rather than through a detached sequence or quotient representative.

Observation-scope exhaustion and Real-seal readback totality, Definition 1164.19 and Definition 1164.20, remove the remaining escape coordinates. Thus a consumer that reaches S has preserved exactly the displayed carrier rows.

For the reverse direction, assume the consumer preserves $Q, V, D, R, S, B, O, H, C, P, N$. Project the accepted packet onto its continuation row C and read the displayed route $Q \to V \to D \to R \to S$ together with the selector and disclosure rows B, O.

The same projection supplies H for componentwise transport, P for provenance, and N for local naming. Since the carrier has no field for quotient streams, host equality, selected limits, hidden schedules, private seals, or ambient completeness, preserving those rows is precisely the pullback condition for reaching the Real seal. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier selector disclosure readback scope`

Theorem 1164.22 (Real-window budget StreamName-RegSeqRat factorization)**.** *Let $W = (Q, V, D, R, S, B, O, H$ be an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet. Every accepted consumer of* $\mathsf{RealWindowBudget}^{\uparrow}$ *that reaches the* $\mathsf{Real}^{\uparrow}$ *seal factors through the displayed rows in the order*

$$Q \to V \to D \to R \to S,$$

with B, O, H, C, P, N supplying selector, disclosure, componentwise transport, continuation, provenance, and local naming support. Thus the route first reads the $\mathsf{StreamName}^{\uparrow}$ *window rows, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback rows, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and only then the* $\mathsf{Real}^{\uparrow}$ *seal.*

No quotient stream, selected limit, hidden schedule, or ambient completeness row can supply an alternate factor of this route.

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier streamname regseqrat factorization`

Proof. Start with selector pullback exactness, Definition 1164.21. It identifies reaching the Real seal with preservation of exactly $Q, V, D, R, S, B, O, H, C, P, N$.

Next read the cross-chapter current-phase route through the StreamName status ledger and the four-object exit theorem, Definition 126.516 and Definition 126.500. These place the public completion path in the order StreamName windows, DyadicRatCore readbacks, RegSeqRat handoff, and RealUp seal.

Finally apply observation-scope exhaustion and Real-seal readback totality, Definition 1164.19 and Definition 1164.20. They remove the remaining non-displayed coordinates, so quotient streams, selected limits, hidden schedules, and ambient completeness rows cannot appear in the factorization. □

Theorem 1164.23 (Real-window budget four-object readback lock)**.** *Let $W = (Q, V, D, R, S, B, O, H, C, P, N)$ be an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet. The only public current-phase status faces available to a* $\mathsf{RealWindowBudget}^{\uparrow}$ *consumer are exactly* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, each read through the same finite rows $Q, V, D, R, S, B, O, H, C, P, N$. The packet has no public face for a quotient stream, selected limit, hidden schedule, ambient completeness theorem, or additional completion object.*

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier four object readback lock`

Proof. The StreamName status ledger and four-object exit route, Definition 126.516 and Definition 126.500, identify the current Phase Real and Completion surface with the four named objects: $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Selector pullback exactness, Definition 1164.21, pins those faces to the single displayed RealWindowBudget carrier route. The rows $Q, V, D, R, S, B, O, H, C, P, N$ therefore serve all four status reads rather than four independent host objects.

Observation-scope exhaustion and Real-seal readback totality, Definition 1164.19 and Definition 1164.20, close the public readback surface. Since no carrier coordinate names a quotient stream, selected limit, hidden schedule, ambient completeness theorem, or further completion object, those cannot be public current-phase status faces. □

Theorem 1164.24 (Real-window budget open-phase window-selector lock)**.** *Let $W = (Q, V, D, R, S, B, O, H, C, P,$ be an accepted* $\mathsf{RealWindowBudget}^{\uparrow}$ *packet. It exposes a Real-facing finite observation route only when the* $\mathsf{StreamName}^{\uparrow}$ *window row V,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row D,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R,* $\mathsf{Real}^{\uparrow}$ *seal row S,* $\mathsf{CauchyDiagonalBudget}^{\uparrow}$ *selector row B, and* $\mathsf{RealObservationBudget}^{\uparrow}$ *disclosure row O are all present, transported by the displayed* hsame *row H, replayed through C, and named by N.*

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier open phase window selector lock`

Proof. Read the carrier definition. It makes $Q, V, D, R, S, B, O, H, C, P, N$ the complete finite packet and gives no coordinate for a detached selector, private disclosure row, quotient stream, selected limit, or host-completeness witness.

Apply selector stability, Real-completion handoff, finite-route visibility, selector-disclosure scope, and Real-completion scope, Definition 1164.3, Definition 1164.4, Definition 1164.5, Definition 1164.14,

and Definition 1164.15. These results force the Real-facing route through V, D, R, S with B, O, H, C, P, N as support rows for the same request.

The four-object readback lock, Definition 1164.23, and the sibling chapters cited at the start of this chapter identify the open-phase route with exactly the displayed window, dyadic, handoff, seal, selector, and disclosure rows. □

Theorem 1164.25 (Real-window budget diagonal observation route exhaustion)**.** *Every public Real-window route claimed by this chapter factors through the displayed finite rows $Q, V, D, R, S, B, O, H, C, P, N$. It cannot be replaced by a hidden selector, host equality, unbounded observation schedule, or quotient-stream witness.*

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier diagonal observation route exhaustion`

Proof. Start from the accepted packet W. The request row Q selects the finite window family V, dyadic readbacks D, regular handoff R, Real seal S, selector budget B, and observation disclosure O; H, C, P, N then transport, replay, source, and name that same route.

The local obligations and scope theorems, Definition 1164.2, Definition 1164.14, and Definition 1164.15, make those rows the public dependency surface. The four-object readback lock then limits the current-phase faces to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ through the same rows.

The sibling CauchyDiagonalBudget and RealObservationBudget surfaces provide only the displayed selector and disclosure rows consumed here. Since neither the carrier nor these scopes provide hidden selectors, host equality, unbounded schedules, or quotient-stream witnesses, no public route can factor through such data. □

Theorem 1164.26 (Real-window budget open-phase four-face status pullback)**.** *Let $W = (Q, V, D, R, S, B, O, H, C$ be an accepted $\mathsf{RealWindowBudget}^{\uparrow}$ packet. A RealWindowBudget consumer is status-correct for the current Phase Real and Completion route if and only if its four public status faces are exactly the $\mathsf{StreamName}^{\uparrow}$ finite-window status, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance-ledger status, the $\mathsf{RegSeqRat}^{\uparrow}$ readback status, and the $\mathsf{Real}^{\uparrow}$ seal status, all read through the displayed rows $Q, V, D, R, S, B, O, H, C, P, N$. No aggregate token, quotient stream, selected limit, ambient completeness theorem, countable-choice row, metric-completeness datum, or bridge row can replace one of these faces or add a fifth status face.*

Proof. For the forward direction, start with selector pullback exactness, Definition 1164.21. It forces every status-correct consumer that reaches the Real seal to preserve the displayed request, window, dyadic readback, handoff, seal, selector, disclosure, transport, continuation, provenance, and naming rows.

Next apply the StreamName status ledger and the four-object exit route, Definition 126.516 and Definition 126.500. These identify the current Phase Real and Completion route with exactly the four public faces: StreamName finite windows, DyadicRatCore tolerance ledger, RegSeqRat readback, and the RealUp seal.

The local non-escape and readback theorems then remove the remaining possible coordinates. By Definition 1164.17, Definition 1164.19, and Definition 1164.20, the accepted packet exports no aggregate token, quotient stream, selected limit, ambient completeness theorem, countable-choice row, metric-completeness datum, bridge row, or private fifth face.

For the reverse direction, assume the consumer reads exactly those four status faces through $Q, V, D, R, S, B, O, H, C, P, N$. The displayed rows already contain the finite window, tolerance

ledger, readback handoff, Real seal, selector, disclosure, transport, replay, provenance, and local NameCert data needed by the RealWindowBudget packet.

Apply selector pullback exactness again to repack this read as the finite selector-disclosure pullback to S. The StreamName status ledger then reads the same four faces as the current Phase Real and Completion status record, so the consumer is status-correct for that route. □

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.RealWindowBudgetCarrier open phase four face status pullback`

Falsifiable prediction: A Real-facing consumer that omits the displayed $\mathsf{RealWindowBudget}^{\uparrow}$ packet $W = (Q, V, D, R, S, B, O, H, C, P, N)$ cannot cite the finite observation route of section 9414.68 as a completed Real handoff.

Independence witness: streamname, dyadicratcore, regseqrat, real, cauchydiagonalbudget, realobservationbudget: none is bijective to $\mathsf{RealWindowBudget}^{\uparrow}$ because the carrier packages the request, finite windows, dyadic readbacks, regular handoff, Real seal, selector budget, disclosure budget, componentwise transport, continuation replay, provenance, and local naming as one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{RealWindowBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{RealWindowBudget}^{\uparrow}$ packet is generated from a finite request, StreamName windows, DyadicRatCore readbacks, RegSeqRat handoff, Real seal, selector budget, disclosure budget, componentwise transport, continuation replay, provenance, and local NameCert row.

Lean4 ✓ `BEDC.Derived.RealWindowBudgetUp.taste gate`

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealWindowBudget}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1164.13 binds every accepted scoped read to the displayed $Q, V, D, R, S, B, O, H, C, P, N$ dependency rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealWindowBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close quotient streams, host equality, selected limits, host completeness, unbounded observation schedules, hidden selector choice, or bridge checking.

Upgrade path: Verification and bridge checking remain Lean/bridge-axis work for the same finite Real-window budget route.

Chapter 1165

A Concrete Naming Certificate for $\mathsf{ModelSelectionBoundary}^{\uparrow}$

The $\mathsf{ModelSelectionBoundary}^{\uparrow}$ packet realizes the comparative-selection boundary of section 9414.68 as a finite BEDC NameCert carrier for reality-constrained physical truth. It sits beside the open-fit packet of chapter 1137, the model-audit packet of chapter 1124, the signature-fit packet of **??**, and the synthesis seal of chapter 1140. It also consumes the truth-certificate discipline of chapter 1141: those siblings expose fit, audit, signature, synthesis, and truth-certificate faces, while this boundary records which finite candidate currently wins and which displayed defeats keep that selection provisional.

Definition 1165.1 (ModelSelectionBoundary carrier)**.** *A* $\mathsf{ModelSelectionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, S, F, D, L, T, P, N)$$

with the following displayed rows:

1. *M is the finite model-family row listing the accepted candidate packets under comparison.*
2. *S is the observed-signature row shared by the comparison.*
3. *F is the comparative-fit row recording the selected packet, its displayed fit score, and the losing rows that remain accepted but not selected.*
4. *D is the defeat-surface row naming finite observations, signature mismatches, audit failures, domain exits, and ledger conflicts that overturn the displayed selection.*
5. *L is the selection-ledger row recording admissibility, tie policy, defeat visibility, provenance, and refused final-oracle demands.*
6. *T is the componentwise transport row preserving the candidate family, observed signatures, fit comparison, defeat surface, and ledger under displayed* hsame *routes.*
7. *P is the* Pkg *provenance row over* $\mathsf{ModelSelectionBoundary}^{\uparrow}$, $\mathsf{OpenFitPacket}^{\uparrow}$, $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$, $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{RealityConstrainedSynthesisSeal}^{\uparrow}$, $\mathsf{PhysicalTruthCertificate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ModelSelectionBoundary}^{\uparrow}}$ *row naming the whole boundary.*

The carrier has no coordinate for model–reality identity, total confirmation, a hidden winner outside M, an erased losing row, an unledgered defeat, or a final oracle deciding all future observations.

Theorem 1165.2 (ModelSelectionBoundary fit-ledger separation)**.** *For an accepted* ModelSelectionBoundary$^{\uparrow}$ *carrier* $B = (M, S, F, D, L, T, P, N)$*, the selected row in* F *is a finite ledgered selection from the displayed candidate family* M*, not a truth identity between the selected model and physical reality. Every public selection read must expose the observed signatures* S*, the comparative fit row* F*, the losing accepted rows recorded by* F*, the selection ledger* L*, the transport row* T*, provenance* P*, and local name* N *before it can be consumed as a reality-constrained physical-truth certificate.*

Lean4 ✓ `BEDC.Derived.ModelSelectionBoundaryUp.TasteGate.ModelSelectionBoundaryTasteGate single carrier alignment`

Proof. Carrier admission exposes exactly $B = (M, S, F, D, L, T, P, N)$. The only row that selects a candidate is F, and F is indexed by the finite family M and the displayed signature row S.

The ledger row L separates acceptance from selection. A losing row may remain an accepted packet while failing to be the displayed winner; conversely, the winning row is selected only under the current finite comparison and ledger policy.

The transport and provenance rows keep the comparison public. Since T, P, N preserve the same candidate family, signature, fit, ledger, and local name, no consumer can replace the selected row by hidden model identity or final physical truth. □

Theorem 1165.3 (ModelSelectionBoundary defeat surface)**.** *An accepted* ModelSelectionBoundary$^{\uparrow}$ *packet is locally refuted whenever a competing accepted packet in* M *beats the displayed selected row of* F *while the relevant finite defeat is hidden from* D *or erased from* L*. A selection that keeps* D *and* L *visible remains a current finite winner; a selection that suppresses the defeat surface is outside the boundary.*

Lean4 ✓ `BEDC.Derived.ModelSelectionBoundaryUp.TasteGate.ModelSelectionBoundary defeat surface`

Proof. Read the carrier rows componentwise. The family row M supplies the competing accepted packets, the signature row S supplies the shared observation surface, and the comparative-fit row F records the selected and losing rows.

If a competing accepted packet beats the selected row, the defeat must be visible in D and ledgered in L. Those two rows are the only coordinates that expose overturned fit, mismatch, audit failure, domain exit, or policy conflict.

When the defeat is hidden or erased, the claimed selection asks the packet to export a winning status without the displayed boundary rows that make the comparison auditable. Such a route is not an accepted ModelSelectionBoundary$^{\uparrow}$ read. □

Definition 1165.4 (ModelSelectionBoundary obligation carrier)**.** *A* ModelSelectionBoundary$^{\uparrow}$ *obligation carrier is a finite* BHist *packet*

$$O = (B, F, D, L, A, S, T, P, N)$$

where B *is an accepted* ModelSelectionBoundary$^{\uparrow}$ *carrier,* F *is its comparative fit ledger,* D *is its defeat surface,* L *is its selection ledger,* A *is the audit route through chapter 1137, chapter 1124,* **??***, chapter 1140, and chapter 1141,* S *is the corresponding TasteGate alignment row,* T *is componentwise* hsame *transport,* P *is* Pkg *provenance, and* N *is the local* NameCert *row. The carrier has no coordinate for a hidden model oracle, probability semantics, host truth predicate, or final winner outside the displayed finite family.*

Lean4 (definition) `BEDC.Derived.ModelSelectionBoundaryUp.ModelSelectionBoundaryObligationCarrier`

Theorem 1165.5 (ModelSelectionBoundary NameCert obligations)**.** *For every accepted obligation carrier $O = (B, F, D, L, A, S, T, P, N)$, the* ModelSelectionBoundary$^{\uparrow}$ *NameCert obligation surface consists exactly of the fit ledger, defeat surface, selection ledger, sibling audit route, TasteGate alignment row, componentwise transport, package provenance, and local naming displayed in O. The selected model remains a current finite winner only relative to those rows.*

Lean4 ✓ `BEDC.Derived.ModelSelectionBoundaryUp.ModelSelectionBoundary namecert obligations`

Proof. Project the obligation carrier. The rows F, D, L are inherited from the existing fit-ledger and defeat-surface theorems, so selection is exposed as a ledgered finite comparison rather than as an oracle.

The sibling audit route A forces every selection read through open-fit, model-audit, signature-fit, synthesis-seal, and truth-certificate surfaces. The TasteGate row S promotes that finite route only as single-carrier alignment, not as probability semantics or host truth.

Finally T, P, N preserve, source, and name the same displayed rows. Since the carrier contains no hidden oracle, final winner outside the candidate family, probability space, or host truth predicate, the listed rows exhaust the NameCert obligations. □

Theorem 1165.6 (ModelSelectionBoundary audit scope)**.** *Every audit of a* ModelSelectionBoundary$^{\uparrow}$ *selection is limited to the displayed candidate family, observed signatures, fit ledger, defeat surface, selection ledger, sibling audit route, and TasteGate alignment row. A later observation may defeat the current winner by adding a visible row to D and L, but the packet never exports a host-level final model order, probability semantics, or truth predicate.*

Lean4 ✓ `BEDC.Derived.ModelSelectionBoundaryUp.ModelSelectionBoundaryAuditScope`

Proof. Read the audit rows in order. The candidate family and observed signatures determine which finite rows are under comparison, while F records the current selection and losing accepted rows.

The defeat and ledger rows D, L are the only places where a later observation, mismatch, audit failure, domain exit, or ledger conflict can overturn the selection. If such a row is absent, the packet records only the current finite winner; if it is present, the winner is visibly defeated.

The sibling audit route and TasteGate alignment row keep the promotion local to displayed BEDC data. They do not add probability semantics, a host truth predicate, or a final model order, so the audit scope is exactly the finite surface stated above. □

Falsifiable prediction: A selected model packet is refuted whenever its displayed fit row is beaten by a competing accepted packet while the defeat surface is hidden or erased.

Independence witness: openfitpacket, realityconstrainedmodelaudit, realityconstrainedsignaturefit, realityconstrainedsynthesisseal, physicaltruthcertificate: none is bijective because each supplies one fit, audit, signature, synthesis, or truth-certificate face, while ModelSelectionBoundaryUp carries the comparative candidate family, selected row, losing rows, finite defeat surface, ledger, transport, and no-final-oracle refusal together.

The Lean follow-up in `lean4/BEDC/Derived/ModelSelectionBoundaryUp/TasteGate.lean` provides explicit Nontrivial ModelSelectionBoundary$^{\uparrow}$ and FieldFaithful ModelSelectionBoundary$^{\uparrow}$ instances preserving M, S, F, D, L, T, P, N, together with the target `BEDC.Derived.ModelSelectionBoundaryUp.Ta`

Closure status for NameCert$_{\text{ModelSelectionBoundary}^{\uparrow}}$**.**

Constructive story: A ModelSelectionBoundary$^{\uparrow}$ packet is generated from a finite model-family row, observed signatures, comparative fit, finite defeat surface, selection ledger, componentwise transport, package provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ModelSelectionBoundary}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1165.1, Definition 1165.2, Definition 1165.3, Definition 1165.4, Definition 1165.5, Definition 1165.6, and

Lean4 ✓ `BEDC.Derived.ModelSelectionBoundaryUp.taste gate`

bind the public exported interface over M, S, F, D, L, T, P, N: candidate-family carrier rows, observed signatures, comparative fit-ledger separation, finite defeat visibility, obligation carrier rows, NameCert obligations, audit-scope limits, TasteGate instance evidence, and no-final-oracle refusal.

Formal verification: FormalStatus(NameCert$_{\text{ModelSelectionBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert final physical truth, model–reality identity, total confirmation, host-level model ordering, Lean verification, or bridge checking for ModelSelectionBoundary$^{\uparrow}$.

Upgrade path: The paper-side mature package is recorded while Lean verification and bridge checking remain outside this closure block.

Chapter 1166

A Concrete Naming Certificate for $\mathsf{AnchorChangeInvariant}^{\uparrow}$

The $\mathsf{AnchorChangeInvariant}^{\uparrow}$ packet realizes the anchor-change invariant surface of section 9414.32 as a finite symmetric transport certificate over observer-history anchors. It sits after the objectivity carrier of chapter 1133, consumes the anchor-stability packet of chapter 1150, reads the invariant row of chapter 656, and supplies a focused sibling to the refusal boundary of chapter 1134. The carrier is neither a global observer nor a view from nowhere; it is the finite table that records when an invariant survives a reversible change of observer anchor.

Definition 1166.1 (Anchor-change invariant carrier)**.** *An* $\mathsf{AnchorChangeInvariant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (H, A, I, S, R, L, T, P, N)$$

with the following displayed rows:

1. *H is the finite observer-history family whose anchors are being compared;*
2. *A is the anchor-change table, with one source anchor, one target anchor, and the displayed reverse row for each admitted comparison;*
3. *I is the* $\mathsf{InterHistInvariant}^{\uparrow}$ *row whose value is transported across the anchor change;*
4. *S is the* $\mathsf{AnchorStabilityCertificate}^{\uparrow}$ *row certifying that the invariant read is stable under the displayed table;*
5. *R is the no-privileged-anchor refusal ledger, rejecting routes that factor through one fixed observer anchor;*
6. *L is the local transport ledger recording the observations, redescription steps, and classifier reads used by the table;*
7. *T records componentwise* hsame *transport and displayed* Cont *replay for H, A, I, S, R, L, P, N;*
8. *P is the* Pkg *provenance over* $\mathsf{AnchorChangeInvariant}^{\uparrow}$, $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$, $\mathsf{AnchorStabilityCertificate}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, $\mathsf{RelationalObjectivity}^{\uparrow}$, $\mathsf{ObjectivityRefutationBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AnchorChangeInvariant}^{\uparrow}}$ *row.*

The carrier has no coordinate for a one-way anchor change, privileged observer, hidden synchronizer, anchor-free invariant, quotient of observer histories, or host-side truth value.

Lean4 (definition) `BEDC.Derived.AnchorChangeInvariantUp.AnchorChangeInvariantUp`

Definition 1166.2 (Anchor-change invariant classifier)**.** *The local* $\mathsf{NameCert}_{\mathsf{AnchorChangeInvariant}^{\uparrow}}$ *classifier compares accepted carriers only through* $H, A, I, S, R, L, T, P, N$*. Two packets agree when their observer-history families are matched by the displayed transport, their anchor-change tables contain both directional rows for each admitted comparison, their* $\mathsf{InterHistInvariant}^{\uparrow}$ *values are transported through the same classifier, their* $\mathsf{AnchorStabilityCertificate}^{\uparrow}$ *rows certify the same route, and their refusal ledgers reject the same privileged-anchor factorizations.*

Theorem 1166.3 (Anchor-change invariant NameCert obligations)**.** *For the carrier of Definition 1166.1, the local* $\mathsf{NameCert}_{\mathsf{AnchorChangeInvariant}^{\uparrow}}$ *surface consists exactly of carrier admission for* $G = (H, A, I, S, R, L, T, P, N)$*, classifier comparison through Definition 1166.2, invariant transport through* I*, anchor-stability certification through* S*, no-privileged-anchor refusal through* R*, ledger exposure through* L*, componentwise transport and replay through* T*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted packet. The rows H, A, I, S, R, L display the observer family, reversible anchor-change table, invariant value, stability certificate, refusal ledger, and route ledger.

Apply the classifier definition. It compares only the displayed rows and requires both directions of each anchor-change entry before the invariant row may be read as transported content.

The structural rows T, P, N preserve that finite surface by componentwise transport, replay, provenance, and local naming. Since the carrier lists no hidden synchronizer or privileged anchor, the stated rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.AnchorChangeInvariantUp.AnchorChangeInvariant namecert obligations`

Theorem 1166.4 (Anchor-change invariant no privileged anchor)**.** *An accepted* $\mathsf{AnchorChangeInvariant}^{\uparrow}$ *packet cannot export an invariant route that factors through one fixed observer anchor without the reverse anchor-change row. Such a route is rejected by the refusal ledger* R *and cannot be read as objective transport.*

Lean4 ✓ `BEDC.Derived.AnchorChangeInvariantUp.AnchorChangeInvariant no privileged anchor`

Proof. Read the anchor-change table A and refusal ledger R from the carrier. Admission requires the displayed reverse row for each comparison and records the rejection of fixed-anchor factorizations.

The classifier of Definition 1166.2 then compares invariant transport only through tables carrying both directions. A one-anchor route lacks the reverse row and is therefore not an accepted comparison.

Consequently the packet may still record local observational content, but it cannot export the invariant as objective anchor-change transport. □

Theorem 1166.5 (Anchor-change invariant anchor-symmetry totality)**.** *Every admitted* $\mathsf{AnchorChangeInvariant}^{\uparrow}$ *invariant read exposes the source-to-target and target-to-source anchor-change rows in the same finite packet before the read reaches any* $\mathsf{RealityConstrainedObjectivity}^{\uparrow}$ *or* $\mathsf{RelationalObjectivity}^{\uparrow}$ *consumer.*

Proof. Use the carrier admission row A. Its table stores both directional rows for each admitted observer-anchor comparison.

The stability row S and invariant row I are read only after that table is visible. The transport row T replays the same displayed comparison, so downstream objectivity consumers receive the invariant together with the symmetric anchor-change evidence.

No additional route can be supplied by a consumer because R, L, P, N keep the refusal ledger, local route ledger, provenance, and naming rows inside the same packet. □

Lean4 ✓ `BEDC.Derived.AnchorChangeInvariantUp.AnchorChangeInvariant anchor symmetry totality`

Falsifiable prediction: If an invariant route factors through one fixed anchor without a reverse anchor-change row, the AnchorChangeInvariant carrier rejects it as non-objective transport.

Independence witness: realityconstrainedobjectivity, anchorstabilitycertificate, interhistinvariant, relationalobjectivity, objectivityrefutationboundary: these siblings provide objectivity, anchor stability, invariant, relational-objectivity, and refutation surfaces, but none combines a symmetric anchor-change classifier with a no-privileged-anchor refusal ledger.

The Lean follow-up must provide `Nontrivial AnchorChangeInvariantUp` and `FieldFaithful AnchorChangeInvariantUp` in `lean4/BEDC/Derived/AnchorChangeInvariantUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{AnchorChangeInvariant}^{\uparrow}}$.

Constructive story: An $\mathsf{AnchorChangeInvariant}^{\uparrow}$ packet is generated from a finite observer-history family, reversible anchor-change table, transported invariant row, anchor-stability certificate, no-privileged-anchor refusal ledger, local transport ledger, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AnchorChangeInvariant}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1166.1, Definition 1166.2, Definition 1166.3, Definition 1166.4, and Definition 1166.5 bind the finite carrier, classifier, local NameCert obligations, no-privileged-anchor refusal, and anchor-symmetry totality surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AnchorChangeInvariant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert global observers, view-from-nowhere semantics, hidden anchor privilege, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding each displayed anchor-change carrier, classifier, invariant-transport, anchor-stability, refusal-ledger, route-ledger, and non-escape obligation to its BEDC primitive dependencies.

Chapter 1167

A Concrete Naming Certificate for FiniteObservationResidueBoundary$^{\uparrow}$

The FiniteObservationResidueBoundary$^{\uparrow}$ packet realizes the hidden-residue and failure-surface branch of the model-audit program in section 9414.60. It composes the audit rows of chapter 1124, the finite defeat rows of chapter 1163, the hidden-material ledger of chapter 1152, and the finite source interface of chapter 1007. Those siblings already expose model audits, failure rows, residue ledgers, and finite observation windows; this packet binds them into one boundary surface for audit exports that cannot claim physical closure unless the hidden residue and defeating observations remain visible.

Definition 1167.1 (Finite-observation residue-boundary carrier)**.** *A* FiniteObservationResidueBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, \Sigma, K, T, L, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source row, read through the finite observation interface and the model-audit source trace.*
2. *Σ is the exposed observation-signature row for the finite audit export.*
3. *K is the classifier row deciding which source and model signatures are compared.*
4. *T is the approximation-tower row that routes source, observation, and model-facing signatures through the same finite packet.*
5. *L is the hidden-residue ledger, including unobserved source content, compression residue, idealization residue, and observer-access limits inherited from the residue-ledger surface.*
6. *F is the failure-surface row naming the finite defeating observations, domain exits, classifier mismatches, and continuation boundaries relevant to the audit export.*
7. *H records componentwise* hsame *transport for $S, \Sigma, K, T, L, F, C, P, N$.*
8. *C records displayed* Cont *replay of source access, signature comparison, tower movement, residue reading, and failure-surface consumption.*
9. *P is the* Pkg *provenance over* FiniteObservationResidueBoundary$^{\uparrow}$, RealityConstrainedModelAudit$^{\uparrow}$, RealityConstrainedFailureSurface$^{\uparrow}$, OnticResidueLedger$^{\uparrow}$, FiniteObservationInterface$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteObservationResidueBoundary}^{\uparrow}}$ *row.*
The carrier has no coordinate for a closed physical audit packet without L, no defeat-free model truth export without F, no hidden source completion outside S, and no classifier route outside K.

Lean4 (definition) BEDC.Derived.FiniteObservationResidueBoundaryUp.FiniteObservationResidueBoundaryUp
Lean4 ✓ BEDC.Derived.FiniteObservationResidueBoundaryUp.FiniteObservationResidueBoundaryTasteGate single carrier alignment

Theorem 1167.2 (Finite-observation residue boundary NameCert obligations)**.** *For the carrier of Definition 1167.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationResidueBoundary}^{\uparrow}}$ *surface consists exactly of source exposure, signature exposure, classifier exposure, tower exposure, hidden-residue ledger exactness, failure-surface exposure, componentwise* hsame *transport, displayed* Cont *continuation replay,* Pkg *provenance, and local naming through N.*

Lean4 ✓ BEDC.Derived.FiniteObservationResidueBoundaryUp.FiniteObservationResidueBoundaryNameCert obligations

Proof. Project the carrier $R = (S, \Sigma, K, T, L, F, H, C, P, N)$. The first four rows provide the finite source, observation signatures, classifier, and tower needed to read a model-audit export as a bounded packet.

The ledger row L and failure row F supply the two boundary fields. L records hidden residue from source access, compression, idealization, and observer limits; F records the displayed defeating observations, domain exits, mismatches, and continuation boundaries.

The structural rows preserve and replay the same packet. Transport through H is componentwise, replay through C follows the displayed continuation routes, provenance through P records the sibling certificates consumed by the packet, and N supplies the local name.

Since the carrier has no further coordinate, the listed rows exhaust the NameCert surface. A model-audit export with the source, signature, classifier, and tower rows but no residue ledger or failure surface is a projection of R, not the accepted $\mathsf{FiniteObservationResidueBoundary}^{\uparrow}$ packet. □

Theorem 1167.3 (Finite-observation residue boundary audit non-closure)**.** *Any model-audit export that passes through the finite source row S, signature row Σ, classifier row K, and tower row T but omits either the hidden-residue ledger L or the failure-surface row F cannot claim a closed physical audit packet through* $\mathsf{FiniteObservationResidueBoundary}^{\uparrow}$*.*

Lean4 ✓ BEDC.Derived.FiniteObservationResidueBoundaryUp.FiniteObservationResidueBoundaryAuditNonclosure

Proof. Use the NameCert obligations of Definition 1167.2. The accepted packet exposes L and F as obligations, not as optional annotations on an already closed audit route.

If L is absent, the export has no displayed row for hidden source content, compression residue, idealization residue, or observer-access limits. If F is absent, the export has no displayed row for finite defeats, domain exits, classifier mismatches, or continuation boundaries.

The remaining rows cannot restore the missing boundary. Transport, replay, provenance, and naming preserve the displayed packet; they do not create a hidden-residue ledger or failure surface. Hence omission of L or F leaves the route outside the closed physical audit packet named here. □

Theorem 1167.4 (Finite-observation residue boundary audit handoff)**.** *An accepted* FiniteObservationResidueBoun *packet exports a model-audit handoff only by preserving the finite source row S, observation-signature row Σ, classifier row K, approximation-tower row T, hidden-residue ledger L, failure-surface row F, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N.*

The handoff may be consumed by the model-audit, failure-surface, residue-ledger, and finite-observation siblings named at the start of the chapter, but it has no route that drops either the hidden-residue ledger or the failure-surface row while still claiming a closed physical audit export.

Lean4 ✓ `BEDC.Derived.FiniteObservationResidueBoundaryUp.FiniteObservationResidueBoundaryAuditHandoff`

Proof. First use the NameCert obligations of Definition 1167.2. They list the finite source, signature, classifier, approximation tower, hidden-residue ledger, failure surface, transport, replay, provenance, and local naming rows as the complete local surface of the accepted packet.

Next apply audit non-closure, Definition 1167.3. A model-audit export that retains S, Σ, K, T but omits L or F is not a closed physical audit packet through this boundary, so the audit handoff cannot be formed by a projection that hides residue or defeating observations.

Finally read the sibling roles named in the introduction. $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ supplies the model-audit rows, $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$ supplies the finite defeat and continuation-boundary rows, $\mathsf{OnticResidueLedger}^{\uparrow}$ supplies hidden-material residue, and $\mathsf{FiniteObservationInterface}^{\uparrow}$ supplies the finite source window. The accepted packet preserves those roles only through $S, \Sigma, K, T, L, F, H, C, P, N$ so downstream audit exports cite this finite handoff rather than a detached model, residue, or failure-surface route. □

Falsifiable prediction: A model-audit export with no hidden-residue ledger cannot claim a closed physical audit packet.

Independence witness: realityconstrainedmodelaudit, realityconstrainedfailuresurface, onticresiduleledger, finiteobservationinterface: $\mathsf{FiniteObservationResidueBoundary}^{\uparrow}$ is not bijective to any listed sibling because it carries the source-signature-classifier-tower rows of the audit together with the hidden-residue ledger, failure surface, componentwise transport, continuation replay, provenance, and local naming in one packet. The model audit lacks the explicit residue-boundary split; the failure surface lacks the source-signature-classifier tower; the residue ledger lacks the finite defeat row; the finite observation interface lacks audit, residue, and failure rows.

Lean follow-up requires `Nontrivial FiniteObservationResidueBoundaryUp` and `FieldFaithful FiniteObservationResidueBoundaryUp` instances in `BEDC.Derived.FiniteObservationResidueBoundaryUp` if this composite packet is later made atomic.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationResidueBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteObservationResidueBoundary}^{\uparrow}$ packet is generated from a finite source row, observation-signature row, classifier row, approximation tower, hidden-residue ledger, failure surface, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteObservationResidueBoundary}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1167.1, Definition 1167.2, Definition 1167.3, and the public handoff of Definition 1167.4 bind the mature paper-side boundary for the carrier, NameCert obligations, audit non-closure, public handoff, falsifiable row, and independence witness.

Lean4 ✓ `BEDC.Derived.FiniteObservationResidueBoundaryUp.taste gate`

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteObservationResidueBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close a closed physical audit, hidden source completion, defeat-free truth export, Lean verification, or bridge checking.

Upgrade path: No further theory-axis upgrade is required; formal verification and bridge checking remain separate verification-axis obligations.

Chapter 1168

A Concrete Naming Certificate for $\mathsf{OpenFitResidueGate}^{\uparrow}$

The $\mathsf{OpenFitResidueGate}^{\uparrow}$packet realizes the open physical fit discipline of section 9414.13 as a finite residue-gate certificate. It sits beside the open physical fit surface of chapter 1131, the finite-observation residue boundary of chapter 1167, the observation-reflection packet of chapter 1126, and the GAP-policy surfaces of chapter 8 and chapter 16. Those siblings expose open fit, visible residue, observation readback, and gap-policy accountability; this gate binds them into the packet a consumer must read before treating finite undefeated fit as physically admissible. As an ai packet, it depends on those open-fit, residue-boundary, observation-reflection, and GAP-policy siblings rather than introducing an independent primitive carrier.

Definition 1168.1 (Open-fit residue-gate carrier)**.** *An* $\mathsf{OpenFitResidueGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, F, R, V, C, H, Q, P, N)$$

with the following displayed rows:

1. *T is the trace-request row, recording the finite observation request and the reality-facing readback route that generated the question.*
2. *F is the finite-fit certificate row, read through the open physical fit and finite observational fit surfaces of section 9414.13.*
3. *R is the open-residue row, recording the unqueried admissible continuations and the hidden residue boundary inherited from chapter 1167.*
4. *V is the refutation-verdict row, recording whether a displayed finite observation defeats F, leaves F undefeated at the current prefix, or refuses any final-fit oracle reading.*
5. *C is the classifier row deciding which observed signature, model signature, residue boundary, and verdict rows are compared.*
6. *H records componentwise* hsame *transport for T, F, R, V, C, Q, P, N.*
7. *Q records displayed* Cont *replay through the observation-reflection route and the open continuation route.*
8. *P is the* Pkg *provenance over* $\mathsf{OpenFitResidueGate}^{\uparrow}$, $\mathrm{OpenPhysicalFit}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, $\mathsf{FiniteObservationResidueBoundary}^{\uparrow}$, $\mathsf{ObservationReflectionPacket}^{\uparrow}$, *GAP-policy rows,* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{OpenFitResidueGate}^{\uparrow}}$ *row.*
The carrier has no coordinate for final fit, total model identity, host physical truth, residue erasure, hidden observation closure, or a refutation verdict detached from the finite packet.

Lean4 (definition) `BEDC.Derived.OpenFitResidueGateUp.taste gate`
Lean4 ✓ `BEDC.Derived.OpenFitResidueGateUp.TasteGate.OpenFitResidueGateTasteGate single carrier alignment`

Theorem 1168.2 (Open-fit residue-gate NameCert obligations)**.** *For the carrier of Definition 1168.1, the local* $\mathsf{NameCert}_{\mathsf{OpenFitResidueGate}^{\uparrow}}$ *surface consists exactly of trace-request exposure through T, finite-fit certificate exposure through F, open-residue exposure through R, refutation-verdict exposure through V, classifier exactness through C, componentwise* hsame *transport through H, displayed* Cont *continuation replay through Q,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.OpenFitResidueGateUp.OpenFitResidueGateNameCertObligations`

Proof. Project the carrier $G = (T, F, R, V, C, H, Q, P, N)$. The request, finite fit, residue, verdict, and classifier rows are the complete content-facing surface of the packet.

Read F through Definition 9414.265 and the open physical fit carrier of Definition 1131.1. Finite undefeated fit is therefore a displayed prefix certificate, not a final-fit oracle.

Read R through Definition 1167.1. The residue row keeps unqueried continuations, hidden source content, compression residue, and observation-access limits visible rather than allowing the finite fit row to erase them.

The verdict row V is then bound by the classifier C. It records finite defeat, current undefeated status, or refusal of a final-fit reading as a row of the same packet, so a consumer cannot detach the verdict from the observed/model signature comparison.

Finally the structural rows preserve the same surface. Transport through H, replay through Q, provenance through P, and local naming through N provide no additional coordinate for final fit, host truth, or residue erasure. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 1168.3 (Open-fit residue-gate scoped consumer factorization)**.** *Every admissible* $\mathsf{OpenFitResidueGate}^{\uparrow}$ *consumer must factor through the trace request T, finite-fit row F, open-residue row R, verdict row V, classifier row C, transport H, replay Q, provenance P, and local NameCert row N before treating finite undefeated fit as physically admissible. The factorization exposes finite undefeated fit only as a residue-aware packet read; it does not assert final fit, host physical truth, hidden observation closure, or residue erasure.*

Proof. Project the carrier $G = (T, F, R, V, C, H, Q, P, N)$ from Definition 1168.1. These nine rows are the only admitted route from an open-fit request to a verdict about finite undefeated fit.

Apply Definition 1168.2. The NameCert surface requires trace-request exposure, finite-fit exposure, open-residue exposure, verdict exposure, classifier exactness, transport, replay, provenance, and local naming before any consumer may read the packet as physically admissible at the finite prefix.

The classifier row C binds the finite-fit row to the residue and verdict rows. Therefore a consumer that reads F without also reading R and V has not factored through the displayed gate.

Transport through H, replay through Q, provenance through P, and naming through N preserve the same finite packet. Since none of these rows contains final fit, host physical truth, hidden observation closure, or residue erasure, the scoped consumer factorization cannot claim any of those stronger conclusions. □

Falsifiable prediction: A consumer that treats finite undefeated fit as final fit without the residue verdict row refutes the OpenFitResidueGateUp packet.

Independence witness: open-physical-fit, finite-observation-residue-boundary, observation-reflection-packet, reality-constrained-open-fit, gap-policy: none is bijective because the residue gate binds finite fit, open residue, refutation verdict, classifier, route, provenance, and local naming in one packet.

Later Lean development in `lean4/BEDC/Derived/OpenFitResidueGateUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{OpenFitResidueGate}^{\uparrow}$ and FieldFaithful $\mathsf{OpenFitResidueGate}^{\uparrow}$ instances.

Closure status for $\mathsf{NameCert}_{\mathsf{OpenFitResidueGate}^{\uparrow}}$.

Constructive story: An $\mathsf{OpenFitResidueGate}^{\uparrow}$ packet is generated from trace request, finite-fit certificate, open-residue, verdict, classifier, transport, replay, provenance, and local NameCert rows, as a composite over open physical fit, finite observation residue boundary, observation reflection packet, and reality-constrained open fit surfaces.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OpenFitResidueGate}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1168.1, Definition 1168.2, and Definition 1168.3 bind carrier, NameCert obligations, TasteGate alignment, consumer factorization, falsifiable prediction, independence witness, Nontrivial, and FieldFaithful rows into the displayed public residue-gate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OpenFitResidueGate}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.OpenFitResidueGateUp.TasteGate.OpenFitResidueGateTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert final fit, host physical truth, residue erasure, hidden observation closure, or bridge checking.

Upgrade path: Bridge checking requires a standard bridge from the public open-fit residue-gate surface to the acceptance schema.

Chapter 1169

A Concrete Naming Certificate for $\mathsf{FiniteObservationRefutation}^{\uparrow}$

The $\mathsf{FiniteObservationRefutation}^{\uparrow}$ packet realizes the finite-observation open-fit boundary of section 9414.13 as a concrete BEDC NameCert carrier. It sits beside the open physical fit surface of chapter 1131, the reality-constrained open-fit packet of chapter 1132, the open-fit packet of chapter 1137, the open-fit residue gate of chapter 1168, and the physical model audit surface of chapter 1129. Those siblings expose finite fit, open continuation, residue, verdict, and audit rows; this carrier isolates the displayed defeating observation row beside the finite fit row without adding a final-fit oracle.

Definition 1169.1 (FiniteObservationRefutation carrier)**.** *A* $\mathsf{FiniteObservationRefutation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (T, \Pi, O, M, F, D, V, L, E, H, C, P, N)$$

with the following visible rows:

1. *T is the finite trace row through which the observation is read.*
2. *Π is the observation-bundle row naming the finite questions used for the read.*
3. *O is the observed-signature row extracted from T through Π.*
4. *M is the model-signature row generated over the same finite trace and bundle.*
5. *F is the finite-fit row whose acceptance is being tested.*
6. *D is the displayed defeating-observation row, storing the finite observation that makes O and M fail the accepted classifier.*
7. *V is the verdict row separating finite defeat, current undefeatedness, and final-fit refusal.*
8. *L is the ledger row recording the finite fit scope, the defeating observation, and the refusal to promote the prefix into final confirmation.*
9. *E is the open-continuation row recording admissible observation extensions still outside the finite packet.*
10. *H records componentwise* hsame *transport for $T, \Pi, O, M, F, D, V, L, E, C, P, N$.*
11. *C records displayed* Cont *replay through the trace, bundle, signature, fit, defeat, verdict, ledger, and continuation rows.*

12. *P is the* Pkg *provenance over* FiniteObservationRefutation$^{\uparrow}$, OpenPhysicalFit$^{\uparrow}$, RealityConstrainedOpenFit$^{\uparrow}$, OpenFitPacket$^{\uparrow}$, OpenFitResidueGate$^{\uparrow}$, PhysicalModelAudit$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

13. *N is the local* NameCert$_{\text{FiniteObservationRefutation}^{\uparrow}}$ *row.*

The carrier has no coordinate for total model identity, host physical truth, all-prefix confirmation, or a final-fit oracle.

Lean4 ✓ `BEDC.Derived.FiniteObservationRefutationUp.FiniteObservationRefutationTasteGate single carrier alignment`

Theorem 1169.2 (FiniteObservationRefutation NameCert obligations)**.** *For the carrier of Definition 1169.1, the local* NameCert$_{\text{FiniteObservationRefutation}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$J = (T, \Pi, O, M, F, D, V, L, E, H, C, P, N),$$

trace and bundle exposure through T, Π, observed and model signature exposure through O, M, finite-fit exposure through F, defeating-observation exposure through D, verdict exposure through V, ledger and open-continuation exposure through L, E, componentwise hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The tuple $J = (T, \Pi, O, M, F, D, V, L, E, H, C, P, N)$ is the complete finite packet, so carrier admission exposes every row that can be read by a consumer.

Read the observational rows first. The trace and bundle rows T, Π determine the finite questions, while O and M are the observed and model-generated signatures compared by the finite-fit row F.

The defeating observation is stored in D and classified by V. A finite defeat therefore enters the certificate as a visible row of the same packet, not as a hidden host objection or a global claim about all observations.

The ledger and continuation rows separate defeat from openness. The ledger L records the finite scope and the refusal of final confirmation, while E preserves admissible observations not yet queried. The structural rows H, C, P, N transport, replay, authenticate, and name that same packet, so the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.FiniteObservationRefutationUp.FiniteObservationRefutationCarrier namecert obligations`

Theorem 1169.3 (FiniteObservationRefutation open-fit consumer)**.** *Every open-fit consumer reading an accepted* FiniteObservationRefutation$^{\uparrow}$ *packet receives the displayed finite route*

$$T, \Pi, O, M, F, D, V, L, E, H, C, P, N.$$

A displayed defeating observation refutes only the finite-fit row F through D and V; it does not supply model-reality identity, host physical truth, total confirmation, all-prefix fit, or a final-fit oracle.

Proof. Start with the carrier in Definition 1169.1. The only rows available to an open-fit consumer are the trace, bundle, signature, finite-fit, defeating-observation, verdict, ledger, continuation, transport, replay, provenance, and naming rows displayed in J.

Apply the NameCert obligation surface of Definition 1169.2. It forces the consumer route to expose D and V together with F, so a defeat is a finite observation against the displayed finite-fit row.

Use the sibling boundaries from Definition 1131.3, Definition 1132.3, Definition 1137.3, Definition 1168.2, and Definition 1129.7. They keep refutation, residue, open continuation, and audit failure surfaces inside finite carrier rows rather than turning them into final physical adequacy.

Since J has no coordinate for final fit or total identity, the consumer receives a finite refutation packet and an open continuation boundary. The defeating observation can invalidate the current finite-fit row, but it cannot close the remaining observation surface or provide a final-fit oracle. □

Theorem 1169.4 (Defeating-observation row exposure)**.** *Every accepted* $\mathsf{FiniteObservationRefutation}^{\uparrow}$ *packet exposes D and V as the only finite defeating-observation route for the displayed finite-fit row F. In particular, a consumer of*

$$J = (T, \Pi, O, M, F, D, V, L, E, H, C, P, N)$$

may refute F through the pair D, V, but cannot extract any second defeat row, hidden host verdict, total model identity, or final-fit oracle from the packet.

Proof. Project the carrier of Definition 1169.1. Its visible coordinates contain one defeating-observation row D and one verdict row V, both placed beside the finite-fit row F.

Apply the NameCert obligation surface of Definition 1169.2. It exposes D and V as ordinary carrier rows and lists no additional defeat coordinate.

Apply the open-fit consumer boundary of Definition 1169.3. The consumer can read the finite route through D, V, while the absent coordinates rule out hidden host truth, total identity, all-prefix confirmation, and final-fit output. Thus D, V are the exhaustive finite defeating-observation route for F. □

Theorem 1169.5 (Open-continuation separation)**.** *For every accepted* $\mathsf{FiniteObservationRefutation}^{\uparrow}$ *packet, the continuation row E preserves admissible future observations while the pair D, V refutes only the current finite-fit row F. The same packet therefore separates current finite defeat from closure of the remaining observation surface.*

Proof. Read the displayed tuple $J = (T, \Pi, O, M, F, D, V, L, E, H, C, P, N)$. The row E is a continuation coordinate, whereas D and V are the defeating-observation and verdict coordinates attached to F.

Use Definition 1169.2 to keep these rows distinct under local naming. The certificate exposes L as the ledger of finite scope and E as the open-continuation row, so the defeating route through D, V does not consume the continuation surface.

Use Definition 1169.3 to read the packet as an open-fit boundary. The finite defeat invalidates the displayed row F, while the absence of a final-fit oracle and the presence of E leave the admissible continuation rows outside the current packet. □

Theorem 1169.6 (TasteGate witness surface)**.** *The existing Lean TasteGate,* $\mathsf{Nontrivial}$*, and* $\mathsf{FieldFaithful}$ *witnesses for* $\mathsf{FiniteObservationRefutation}^{\uparrow}$ *are consumed as the single-carrier witness surface for the displayed tuple*

$$T, \Pi, O, M, F, D, V, L, E, H, C, P, N.$$

They certify that the packet has a nonempty carrier, field-readable coordinates, and one BEDC witness surface over the same carrier shape used by the local NameCert obligations.

Proof. Start from the checked TasteGate marker attached to Definition 1169.1. It names the Lean theorem that aligns the $\mathsf{FiniteObservationRefutation}^{\uparrow}$ carrier with the single tuple shape

$$T, \Pi, O, M, F, D, V, L, E, H, C, P, N.$$

The carrier definition gives the row order, and Definition 1169.2 supplies the local naming duties for those rows. The Lean witness surface supplies nontriviality and field faithfulness for the same carrier rather than for a separate presentation.

Finally apply Definition 1169.4 and Definition 1169.5. They identify the defeat and continuation rows consumed by the TasteGate surface, so the witness certifies exactly the displayed packet rather than an abstract replacement. □

Theorem 1169.7 (FiniteObservationRefutation scope exactness)**.** *Every accepted* $\mathsf{FiniteObservationRefutation}^{\uparrow}$ *packet*

$$J = (T, \Pi, O, M, F, D, V, L, E, H, C, P, N)$$

reads trace, bundle, observed signature, model signature, finite fit, displayed defeat, verdict, ledger, continuation, componentwise hsame*, displayed* Cont*,* Pkg *provenance, and local* NameCert *rows only through the displayed BEDC finite-kernel scope. No consumer of the packet obtains a row outside* $T, \Pi, O, M, F, D, V, L, E, H, C, P, N$*.*

Proof. Start with the carrier of Definition 1169.1. It displays the whole accepted packet as the finite tuple $J = (T, \Pi, O, M, F, D, V, L, E, H, C, P, N)$ and states that there is no coordinate for total model identity, host physical truth, all-prefix confirmation, or a final-fit oracle.

Apply Definition 1169.2. The NameCert surface lists carrier admission, trace and bundle exposure, observed and model signature exposure, finite-fit exposure, defeat, verdict, ledger, continuation, componentwise hsame, displayed Cont, Pkg, and local naming through exactly the coordinates of J.

Use Definition 1169.3, Definition 1169.4, and Definition 1169.5 to close the consumer side. They identify the only open-fit route, the only defeating-observation route, and the continuation split inside the same tuple, so the scoped read cannot escape the finite-kernel rows. □

Theorem 1169.8 (FiniteObservationRefutation scoped carrier transport)**.** *Componentwise* hsame *transport of an accepted* $\mathsf{FiniteObservationRefutation}^{\uparrow}$ *packet preserves the same defeat and continuation split over*

$$D, V, L, E, H, C, P, N$$

without adding host truth, total model identity, all-prefix fit, or a final-fit oracle.

Proof. Project the transport row H from the carrier of Definition 1169.1. It records componentwise hsame transport for the displayed trace, bundle, signature, finite-fit, defeat, verdict, ledger, continuation, replay, provenance, and naming rows.

Apply Definition 1169.2 to keep the transported data inside the same NameCert surface. The row H transports the packet components; it does not create an additional carrier coordinate.

The defeat and continuation split is then inherited from Definition 1169.4 and Definition 1169.5. The defeat remains the finite route through D, V, while E remains the open-continuation row recorded by L.

Finally apply Definition 1169.3. Since the consumer has no access to host truth, total identity, all-prefix fit, or a final-fit oracle before transport, componentwise hsame transport cannot add such a row afterward. □

Theorem 1169.9 (FiniteObservationRefutation scoped open-fit non-escape)**.** *Any open-fit consumer of an accepted* FiniteObservationRefutation$^{\uparrow}$ *packet factors through*

$$D, V, L, E, H, C, P, N.$$

It cannot replace the finite refutation row by total model identity, all-prefix fit, or final confirmation.

Proof. Read the carrier of Definition 1169.1 through the consumer theorem Definition 1169.3. The consumer receives the finite route $T, \Pi, O, M, F, D, V, L, E, H, C, P, N$ and no separate oracle row.

Apply Definition 1169.2. The rows relevant to an open-fit defeat are the displayed defeat, verdict, ledger, continuation, transport, replay, provenance, and naming rows D, V, L, E, H, C, P, N.

Use Definition 1169.4 to identify D, V as the exhaustive finite defeating-observation route for F. Then use Definition 1169.5 to keep E outside the consumed finite defeat as the remaining observation surface.

Thus every open-fit read factors through the displayed scoped rows. Because those rows do not contain total model identity, all-prefix fit, or final confirmation, the consumer cannot replace finite refutation by any of those stronger outputs. □

Falsifiable prediction: A displayed defeating observation refutes only the finite-fit row and never supplies a final-fit oracle.

Independence witness: openphysicalfit, realityconstrainedopenfit, openfitpacket, openfitresiduegate, physicalmodelaudit: none is bijective because the refutation packet alone stores the defeating observation row as a public carrier coordinate beside fit, continuation, ledger, transport, route, provenance, and local NameCert rows.

The Lean TasteGate path `lean4/BEDC/Derived/FiniteObservationRefutationUp/TasteGate.lean` provides explicit Nontrivial FiniteObservationRefutation$^{\uparrow}$ and FieldFaithful FiniteObservationRefutation$^{\uparrow}$ instances for the displayed carrier.

Closure status for NameCert$_{\text{FiniteObservationRefutation}^{\uparrow}}$.

Constructive story: A FiniteObservationRefutation$^{\uparrow}$ packet is generated from a finite trace, observation bundle, observed signature, model signature, finite-fit row, displayed defeating observation, verdict, ledger, open-continuation row, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteObservationRefutation}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1169.1, Definition 1169.2, Definition 1169.3, Definition 1169.4, Definition 1169.5, Definition 1169.6, Definition 1169.7, Definition 1169.8, and Definition 1169.9 bind the finite refutation carrier, local NameCert obligations, open-fit consumer boundary, defeating-observation exposure, open-continuation separation, TasteGate witness surface, finite-kernel scope exactness, componentwise transport, and open-fit non-escape.

Lean4 ✓ `BEDC.Derived.FiniteObservationRefutationUp.taste gate`

Formal verification: FormalStatus(NameCert$_{\text{FiniteObservationRefutation}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.FiniteObservationRefutationUp.FiniteObservationRefutationTasteGate\_single\_carrier\_al`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, model-reality identity, host physical truth, all-prefix fit, total confirmation, or final-fit oracles.

Upgrade path: Bridge closure requires a standard bridge surface that exports the public finite-refutation route without strengthening it into total model identity, all-prefix fit, or final confirmation.

Chapter 1170

A Concrete Naming Certificate for $\mathsf{ScientificIdealizationResidueSeal}^{\uparrow}$

The $\mathsf{ScientificIdealizationResidueSeal}^{\uparrow}$ packet realizes the idealization branch of the scientific-methodology discipline in chapter 9414, especially section 9414.46. It sits beside the explanation rows of chapter 1136, the methodology-ledger rows of chapter 1145, the ontic-residue rows of chapter 1152, the finite observation boundary of chapter 1167, and the model-audit rows of chapter 1124. Those siblings expose explanation, methodology scope, residue, finite defeat, and model-audit surfaces; this packet binds a safe idealization into one finite seal before a smooth, continuous, limiting, or coarse endpoint can be read as explanatory.

Definition 1170.1 (Scientific idealization residue-seal carrier)**.** *A* $\mathsf{ScientificIdealizationResidueSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (E, M, O, B, A, I, R, D, F, \Sigma, T, C, P, N)$$

with the following displayed rows:

1. *E is the explanation row inherited from* $\mathsf{RealityConstrainedExplanation}^{\uparrow}$*, naming the phenomenon, model, signature comparison, descent, residue, and failure surface used by the explanation.*
2. *M is the methodology-ledger row inherited from* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$*, naming the effective region, admissible consumers, domain-leakage refusals, and declared extension routes.*
3. *O is the ontic-residue row inherited from* $\mathsf{OnticResidueLedger}^{\uparrow}$*, recording source material not visible at the ideal endpoint.*
4. *B is the finite observation residue-boundary row inherited from* $\mathsf{FiniteObservationResidueBoundary}^{\uparrow}$*, recording the finite observation budget and defeat boundary under which residue may become active.*
5. *A is the model-audit row inherited from* $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$*, recording source traces, observed signatures, model-generated signatures, classifier comparison, and audit strength.*
6. *I is the idealization arrow row, naming the compression $L_i \rightsquigarrow L_j$ and the ideal endpoint used by the explanation.*
7. *R is the idealization-residue ledger, listing each source feature removed, smoothed, averaged, completed, quotient-read, or limit-read by I.*

8. *D is the descent row, naming the operations on the ideal endpoint whose use is licensed back through the source and residue ledger.*
9. *F is the idealization failure-surface row, naming the refined bundles, tower levels, source conditions, or classifier mismatches that activate residue.*
10. *Σ is the scope row, naming the observation bundle, tower region, admissible endpoint operations, and consumers for which the idealization is safe.*
11. *T records componentwise* hsame *transport for $E, M, O, B, A, I, R, D, F, \Sigma, C, P, N$.*
12. *C records displayed* Cont *replay of the safe-idealization route through explanation, methodology ledger, residue, descent, failure surface, and endpoint scope.*
13. *P records* Pkg *provenance over the sibling carriers,* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{ScientificIdealizationResidueSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for treating the ideal endpoint as explanatory when the residue ledger, descent row, failure surface, scope row, transport, route, provenance, or local name is absent.

Lean4 ✓ `BEDC.Derived.ScientificIdealizationResidueSealUp.ScientificIdealizationResidueSealTasteGate`
`single carrier alignment`

Theorem 1170.2 (Scientific idealization residue-seal NameCert obligations)**.** *For the carrier of Definition 1170.1, the local* $\mathsf{NameCert}_{\mathsf{ScientificIdealizationResidueSeal}^{\uparrow}}$ *surface consists exactly of finite explanation accountability, methodology-scope accountability, ontic-residue accountability, finite observation-boundary accountability, model-audit accountability, idealization-arrow exposure, residue-ledger exactness, descent exposure, failure-surface exposure, scope exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ScientificIdealizationResidueSealUp.ScientificIdealizationResidueSealNameCertOblig`

Proof. Project the carrier $S = (E, M, O, B, A, I, R, D, F, \Sigma, T, C, P, N)$. The five sibling rows E, M, O, B, A supply the surrounding explanation, methodology, residue, finite-boundary, and model-audit surfaces consumed by the seal.

The idealization-specific rows I, R, D, F, Σ expose the compression arrow, removed source material, licensed descent, active-residue boundary, and safe scope. A route that omits any one of these rows has only an ideal endpoint or a partial audit read, not the safe-idealization seal.

The structural rows preserve the same displayed packet. Transport through T is componentwise, replay through C follows the displayed continuation route, provenance through P records the sibling certificates and kernel rows, and N supplies the local name.

Since the carrier contains no further coordinate, the listed rows exhaust the NameCert surface. In particular, smoothness, continuity, limiting behavior, or coarse-grained fit cannot substitute for the residue ledger or descent row. □

Theorem 1170.3 (Scientific idealization residue-seal nonescape)**.** *An idealized explanation whose route uses the idealization arrow I but omits the residue ledger R, descent row D, failure-surface row F, or scope row Σ cannot pass the* $\mathsf{ScientificIdealizationResidueSeal}^{\uparrow}$ *safe-idealization seal.*

Proof. Use the NameCert obligations of Definition 1170.2. They require the idealization arrow, residue ledger, descent row, failure surface, and scope row as separate displayed obligations.

If R is absent, the route has no finite account of the source material removed by the idealization. If D is absent, operations performed at the ideal endpoint have no displayed descent back through the compressed source. If F is absent, refined observations have no named surface on which hidden residue can become active. If Σ is absent, the route has no admitted observation bundle, tower region, endpoint operation class, or consumer boundary.

The remaining rows cannot create the missing obligations. Explanation, methodology, residue, boundary, and audit siblings provide surrounding surfaces; transport, replay, provenance, and naming preserve the displayed packet. Hence the route remains outside the accepted safe-idealization seal. □

Theorem 1170.4 (Scientific idealization residue-seal scope refinement)**.** *Let $S = (E, M, O, B, A, I, R, D, F, \Sigma, T, C$ be an accepted* ScientificIdealizationResidueSeal$^{\uparrow}$ *packet. A refined observation bundle may extend the safe-idealization scope only by adding the corresponding residue entries, descent rows, failure-surface rows, and methodology-ledger route to the same displayed packet.*

Lean4 ✓ `BEDC.Derived.ScientificIdealizationResidueSealUp.ScientificIdealizationResidueSeal scope refinement`

Proof. The accepted scope is the displayed row Σ, and the methodology-ledger row M records how exports beyond the present scope are refused or routed.

A refined bundle that keeps the same safe-idealization seal must preserve the residue ledger R and descent row D for the endpoint operations it uses. If the refinement activates source material hidden by I, that material must appear in R and the associated defeat must appear in F.

The extension is therefore not a bare enlargement of Σ. It is admitted only when the packet also exposes the residue, descent, failure, and methodology route rows needed by the refined scope. □

Falsifiable prediction: An idealized explanation whose residue ledger is absent cannot pass the safe-idealization seal.

Independence witness: realityconstrainedexplanation, realityconstrainedmethodologyledger, onticresidueledger, finiteobservationresidueboundary, realityconstrainedmodelaudit: none is bijective to ScientificIdealizationResidueSeal$^{\uparrow}$ because the seal carries idealization-arrow, residue, descent, failure-surface, scope, transport, route, provenance, and local NameCert rows in one packet. The explanation row lacks the methodology export route; the methodology ledger lacks the specific idealization arrow and descent row; the ontic-residue ledger lacks endpoint-operation scope; the finite observation boundary lacks the idealization route; the model audit lacks the safe-idealization residue seal.

Lean follow-up must provide `Nontrivial ScientificIdealizationResidueSealUp` and `FieldFaithful ScientificIdealizationResidueSealUp` instances in `BEDC.Derived.ScientificIdealizationResidueSealUp`.

Closure status for NameCert$_{\text{ScientificIdealizationResidueSeal}^{\uparrow}}$.

Constructive story: A ScientificIdealizationResidueSeal$^{\uparrow}$ packet is generated from explanation, methodology, residue, finite observation boundary, model-audit, idealization-arrow, residue-ledger, descent, failure-surface, scope, transport, route, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{ScientificIdealizationResidueSeal}^{\uparrow}}$, seed)

Scope closed: Definition 1170.1, Definition 1170.2, Definition 1170.3, and Definition 1170.4 bind the finite safe-idealization carrier, local NameCert obligations, missing-row refusal, and refined-scope route.

Formal verification: FormalStatus(NameCert$_{\text{ScientificIdealizationResidueSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close endpoint truth, unledgered idealization, bridge checking, smooth-limit validity, or explanatory force outside the displayed residue and descent rows.

Upgrade path: Promotion past seed requires Lean TasteGate nontriviality and field faithfulness for ScientificIdealizationResidueSeal$^{\uparrow}$.

Chapter 1171

A Concrete Naming Certificate for $\mathsf{CauchyTailModulusSeal}^{\uparrow}$

The $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ packet realizes the Real-completeness route of chapter 9238 by joining the shared-tail threshold service of chapter 983, the fusion route of chapter 1024, and the witness-facing extraction route of chapter 652. It keeps the public classifier between the shared threshold and the extractor handoff, so a consumer can read one finite RealUp-facing route without receiving quotient stream equality, host real equality, a selected host limit, or ambient completeness.

The nearest seal siblings are chapter 699 and chapter 386. The tail-agreement seal records agreement across cofinal tail windows, while the Cauchy-limit seal records a terminal limit handoff. The present packet instead binds the shared-tail modulus row, the tail-modulus fusion row, the witness-extractor row, paired StreamName windows, paired RegSeqRat readbacks, the RealUp seal row, and the public classifier that mediates them.

Falsifiable prediction: Every accepted CauchyTailModulusSealUp packet exposes one shared threshold service and admits no consumer route to private per-source thresholds, quotient stream equality, host real equality, selected limits, or ambient completeness.

Independence witness: cauchysharedtailmodulus, cauchytailmodulusfusion, realcompletionwitnessextractor, realtailagreementseal, cauchylimitseal: none is bijective because the seal packet keeps the public classifier between shared-tail threshold service and witness-extractor handoff, whereas the siblings expose only a source modulus, fusion route, extractor route, tail agreement, or limit seal.

Definition 1171.1 (Cauchy tail-modulus seal carrier)**.** *A* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, F, X, \tau, D, W_0, W_1, Q_0, Q_1, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchySharedTailModulus}^{\uparrow}$ *row supplying the shared-tail threshold service;*
2. *F is the* $\mathsf{CauchyTailModulusFusion}^{\uparrow}$ *row fusing the two source moduli through the shared service;*
3. *X is the* $\mathsf{RealCompletionWitnessExtractor}^{\uparrow}$ *row that receives the witness-facing handoff;*
4. *τ is the single shared threshold read from the shared-tail and fusion rows;*
5. *D is the dyadic ledger attached to the shared threshold route;*
6. *W_0 and W_1 are the selected* $\mathsf{StreamName}^{\uparrow}$ *windows served by τ;*

7. *Q_0 and Q_1 are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks obtained from the two selected windows;*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the shared threshold, dyadic ledger, windows, and readbacks have been displayed;*
9. *H records componentwise* hsame *transport for the source rows, threshold, ledger, windows, readbacks, seal, provenance, and local name;*
10. *C records displayed* Cont *routes from M, F to $\tau, D, W_0, W_1, Q_0, Q_1$, then through X to E;*
11. *P is the* Pkg *provenance over* $\mathsf{CauchySharedTailModulus}^{\uparrow}$, $\mathsf{CauchyTailModulusFusion}^{\uparrow}$, $\mathsf{RealCompletionWitnessExtr}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailModulusSeal}^{\uparrow}}$ *row.*

The carrier contains no private per-source threshold, quotient stream equality, host real equality, selected host limit, independent RealUp seal, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CauchyTailModulusSealUp.CauchyTailModulusSealTasteGate single carrier alignment`

Theorem 1171.2 (Cauchy tail-modulus seal NameCert obligations)**.** *For the carrier of Definition 1171.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailModulusSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for S, shared-tail admission through M, fusion admission through F, witness-extractor admission through X, single-threshold exposure through τ, dyadic ledger exposure through D, selector-window service through W_0, W_1, regular readback through Q_0, Q_1, RealUp seal ordering through E, componentwise stability through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The packet lists the shared-tail row, fusion row, witness-extractor row, shared threshold, dyadic ledger, paired windows, paired readbacks, RealUp seal, transport, route, provenance, and local name as public coordinates.

Use the sibling obligations of chapter 983 to read M as the unique shared-tail threshold service, and use chapter 1024 to force the fusion route through the same τ rather than through two private thresholds.

Next route the witness-facing consumer through chapter 652. The extractor sees D, W_0, W_1, Q_0, Q_1, E only after the same threshold service has fixed the selected windows and regular readbacks.

The rows H, C, P, N transport, replay, package, and name exactly these displayed coordinates. Since the carrier has no private threshold, quotient stream equality, host real equality, selected host limit, independent RealUp seal, or ambient completeness row, these coordinates exhaust the local NameCert surface. □

Theorem 1171.3 (Cauchy tail-modulus seal threshold readback)**.** *Every accepted* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *packet exposes exactly one shared threshold service before any witness-facing or RealUp-facing consumer can read D, W_0, W_1, Q_0, Q_1, E. The threshold readback route is*

$$M, F, \tau, D, W_0, W_1, Q_0, Q_1, E, H, C, P, N.$$

Lean4 ✓ `BEDC.Derived.CauchyTailModulusSealUp.CauchyTailModulusSealThresholdReadback`

Proof. Start from the carrier order. The only threshold coordinate is τ, and both source surfaces M and F precede it in the displayed packet.

Apply the shared-tail and fusion sibling obligations. The $\mathsf{CauchySharedTailModulus}^{\uparrow}$ row supplies the threshold service, while the $\mathsf{CauchyTailModulusFusion}^{\uparrow}$ row attaches both source moduli

to that same service. Thus the packet has one threshold readback before any window or readback row is exposed.

Finally pass through the witness-extractor side. The rows D, W_0, W_1, Q_0, Q_1, E are downstream of τ and are carried by H, C, P, N as one named route, so a witness-facing or RealUp-facing consumer cannot choose a separate threshold. □

Theorem 1171.4 (Cauchy tail-modulus seal non-escape)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or completion-facing consumer of an accepted* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *packet factors through* $M, F, X, \tau, D, W_0, W_1$. *The packet exports no private per-source threshold, quotient stream equality, host real equality, selected limit, independent RealUp seal, or ambient completeness principle.*

Proof. Use the NameCert obligations. They route every accepted consumer through the displayed shared-tail row M, fusion row F, witness-extractor row X, shared threshold τ, dyadic ledger D, selected windows, regular readbacks, RealUp seal, transport, continuation, provenance, and local name.

For a StreamName or RegSeqRat consumer, the route stops at W_0, W_1, Q_0, Q_1 after τ and D have already been read. For a RealUp or completion-facing consumer, the route continues through E and the witness-extractor handoff without changing the threshold service.

The excluded outputs require coordinates absent from Definition 1171.1. Since H, C, P, N only transport, replay, package, and name the displayed coordinates, no consumer can leave the finite seal packet. □

Lean4 ✓ `BEDC.Derived.CauchyTailModulusSealUp.CauchyTailModulusSeal nonescape`

Theorem 1171.5 (Cauchy tail-modulus seal independence witness)**.** *The* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *carrier is not bijective, by any row-preserving carrier map, to* $\mathsf{CauchySharedTailModulus}^{\uparrow}$, $\mathsf{CauchyTailModulusFusion}^{\uparrow}$, $\mathsf{RealCompletionWitnessExtractor}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$. *A row-preserving bijection would have to preserve the public classifier between the shared-tail threshold service and the witness-extractor handoff, but none of the listed sibling carriers contains that exact classifier together with* $M, F, X, \tau, D, W_0, W_1, Q_0, Q_1, E, H, C, P, N$.

Proof. Compare the displayed carrier rows. The shared-tail sibling exposes the source modulus and threshold service but not the fusion row, witness-extractor handoff, and RealUp seal route together. The fusion sibling exposes the fused route but not the public classifier tying it to the extractor handoff as a seal packet.

The witness-extractor sibling exposes the downstream handoff but not the upstream shared-tail threshold service and fusion row. The Real tail-agreement sibling exposes a paired tail-agreement seal, and the Cauchy-limit sibling exposes a terminal limit seal; neither carries the combined shared-tail, fusion, extractor, and RealUp classifier route.

Any row-preserving bijection must preserve the rows and the route order used by Definition 1171.3. Each listed sibling lacks at least one of those rows or replaces the classifier surface by a different one, so no such bijection exists. □

Theorem 1171.6 (Cauchy tail-modulus seal public classifier route)**.** *Every public consumer route for an accepted* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *packet factors through the single classifier route*

$$M, F, X, \tau, D, W_0, W_1, Q_0, Q_1, E, H, C, P, N.$$

Here M *is the shared-tail modulus row,* F *is the fusion row,* X *is the witness-extractor row, and* E *is the* $\mathsf{Real}^{\uparrow}$ *seal row. The route exports no private threshold, quotient stream equality, host real equality, selected limit, or ambient Real completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyTailModulusSealUp.CauchyTailModulusSeal public classifier route`

Proof. Read the row inventory from Definition 1171.1. The carrier displays the shared-tail row M, fusion row F, witness-extractor row X, threshold τ, dyadic ledger D, selected windows W_0, W_1, readbacks Q_0, Q_1, RealUp seal E, transport H, continuation C, provenance P, and local name N as the complete public packet.

Apply Definition 1171.2. Its NameCert surface exposes exactly the carrier and classifier rows just listed, so a public consumer can enter the seal only through those displayed coordinates.

Next use Definition 1171.3 to fix the unique shared threshold before any window, readback, witness-facing, or RealUp-facing consumer route is available. Then use Definition 1171.4 to rule out exits to private thresholds, quotient stream equality, host real equality, selected limits, and ambient Real completeness.

Finally compare with Definition 1171.5. That theorem separates this route from the sibling seal surfaces, so the displayed classifier is the public route carried by the accepted $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ packet. □

Theorem 1171.7 (Cauchy tail-modulus seal paper bridge)**.** *For every accepted* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *packet*

$$S = (M, F, X, \tau, D, W_0, W_1, Q_0, Q_1, E, H, C, P, N),$$

the public classifier route $M, F, X, \tau, D, W_0, W_1, Q_0, Q_1, E, H, C, P, N$ *forms the paper bridge between the shared-tail modulus row, the tail-modulus fusion row, the witness-extractor row, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and the* $\mathsf{Real}^{\uparrow}$ *seal row. The bridge exports no quotient stream equality, host real equality, selected host limit, or ambient Real completeness principle.*

Proof. Start with the carrier of Definition 1171.1. It displays exactly the shared-tail row M, fusion row F, witness-extractor row X, shared threshold τ, dyadic ledger D, paired windows W_0, W_1, paired readbacks Q_0, Q_1, RealUp seal E, transport H, continuation C, provenance P, and local name N.

Apply Definition 1171.2 to read these rows as the local NameCert surface. Apply Definition 1171.3 to force the single threshold service before the window, readback, witness-facing, and RealUp-facing rows become available.

Next use Definition 1171.4. It rules out exits to private thresholds, quotient stream equality, host real equality, selected limits, independent RealUp seals, and ambient Real completeness.

Finally use Definition 1171.5 and Definition 1171.6. The first separates this packet from the neighboring seal surfaces, and the second identifies the single public classifier route, so the displayed rows give exactly the paper bridge for the $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailModulusSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ packet is generated from a shared-tail modulus row, a tail-modulus fusion row, a witness-extractor row, one shared threshold, a dyadic ledger, paired StreamName windows, paired RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailModulusSeal}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1171.1 and the theorem rows of Definition 1171.2, Definition 1171.3, Definition 1171.4, Definition 1171.5, Definition 1171.6, and Definition 1171.7 bind the displayed carrier to BHist, hsame, Cont, Pkg, NameCert, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySharedTailModulus}^{\uparrow}$, $\mathsf{CauchyTailModulusFusion}^{\uparrow}$, and $\mathsf{RealCompletionWitnessExtractor}^{\uparrow}$.

Chapter 1172

A Concrete Naming Certificate for $\mathsf{InscriptionEventBufferSeal}^{\uparrow}$

The $\mathsf{InscriptionEventBufferSeal}^{\uparrow}$ packet realizes a replayable finite window of inscription events. It sits beside the event carrier of chapter 519, the gap ledger of chapter 520, the inscription point of chapter 610, the audit trace of chapter 682, and the digest inscription packet of chapter 1085. Those siblings provide single-event admission, gap accounting, pointwise commitment, audit trace routing, and digest naming; the buffer seal binds a finite replay window without exporting an unbounded inscription stream.

Definition 1172.1 (Inscription event buffer seal carrier)**.** *An* $\mathsf{InscriptionEventBufferSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, W, R, D, A, H, Q, P, N)$$

with the following displayed rows:

1. *E is the finite inscription-event row, listing the accepted event records admitted into the buffer;*
2. *W is the finite buffer-window row, naming the bounded replay interval and its visible endpoints;*
3. *R is the replay row, recording the ordered finite readback route through the events in W;*
4. *D is the digest row, binding the replayed window to its digest inscription and digest provenance;*
5. *A is the audit-route row, recording accepted checks, gap residues, and consumer-facing route obligations for the replay;*
6. *H is the componentwise* hsame *transport row for event, window, replay, digest, and audit-route presentations;*
7. *Q is the displayed* Cont *row carrying replay consumers through the same finite window;*
8. *P is the* Pkg *provenance over the event, window, replay, digest, audit, transport, continuation, and local naming rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{InscriptionEventBufferSeal}^{\uparrow}}$ *row naming exactly this replay buffer seal.*

The carrier has no coordinate for an unbounded inscription stream, a host-level replay oracle, or replay data outside the finite event window.

Lean4 (definition) `BEDC.Derived.InscriptionEventBufferSealUp.InscriptionEventBufferSealUp`

Theorem 1172.2 (Inscription event buffer seal NameCert obligations)**.** *For the carrier of Definition 1172.1, the local* $\mathsf{NameCert}_{\mathsf{InscriptionEventBufferSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for* $B = (E, W, R, D, A, H, Q, P, N)$*, finite window exactness, replay row determinacy, digest attachment, audit-route coverage, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.InscriptionEventBufferSealUp.InscriptionEventBufferSealCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1172.1. The accepted packet contains exactly the rows $E, W, R, D, A, H, Q, P, N$.

Window exactness comes from W and replay determinacy from R. The event row E supplies only the finite event records admitted into that window, and the replay row orders only those records.

Digest attachment and audit-route coverage are supplied by D and A. The digest row binds the finite replay to the digest inscription surface, while the audit-route row records accepted checks, gap residues, and consumer-facing obligations.

Finally H, Q, P, N transport, continue, package, and name the same finite buffer seal. Since these rows add no unbounded stream or host replay oracle, the listed obligations exhaust the local certificate surface. □

Theorem 1172.3 (Inscription event buffer seal non-escape)**.** *No accepted* $\mathsf{InscriptionEventBufferSeal}^{\uparrow}$ *packet exports an unbounded inscription stream, a host-level replay oracle, or a replay route outside the displayed rows* $E, W, R, D, A, H, Q, P, N$*.*

Lean4 ✓ `BEDC.Derived.InscriptionEventBufferSealUp.InscriptionEventBufferSealCarrier nonescape`

Proof. Inspect the carrier of Definition 1172.1. Its only event-facing row is E, its only window row is W, and its only replay row is R.

Apply the NameCert obligations of Definition 1172.2. Every accepted replay must attach the digest row D, audit-route row A, transport row H, continuation row Q, provenance row P, and local name N to that same finite window.

Thus an unbounded inscription stream, host-level replay oracle, or hidden replay route has no coordinate in the accepted packet. Such a demand can only be rejected at the audit-route boundary, not exported by the buffer seal. □

Falsifiable prediction: No accepted $\mathsf{InscriptionEventBufferSeal}^{\uparrow}$ packet exports an unbounded inscription stream or host-level replay oracle beyond the displayed finite event window.

Independence witness: inscriptionevent, inscriptiongapledger, inscriptionpoint, inscriptionauditrace, digestinscription: $\mathsf{InscriptionEventBufferSeal}^{\uparrow}$ is not bijective to any listed sibling because it simultaneously carries finite event admission, bounded replay window, replay order, digest attachment, audit-route coverage, componentwise transport, displayed continuation, provenance, and local naming rows.

Lean follow-up must provide `Nontrivial InscriptionEventBufferSealUp` and `FieldFaithful InscriptionEventBufferSealUp` instances before the replay buffer seal is treated as an atomic Lean carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{InscriptionEventBufferSeal}^{\uparrow}}$ **.**

Constructive story: An $\mathsf{InscriptionEventBufferSeal}^{\uparrow}$ packet is generated from finite inscription events, a bounded replay window, replay readback, digest attachment, audit-route records, componentwise transport, continuation routing, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{InscriptionEventBufferSeal}\uparrow}$, seed)

Scope closed: Definition 1172.1, Definition 1172.2, and Definition 1172.3 bind the finite replay-buffer carrier, its local obligations, and its non-escape boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{InscriptionEventBufferSeal}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert an unbounded inscription stream, a host-level replay oracle, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, replay-window exactness, digest attachment, audit-route coverage, TasteGate nontriviality, and field faithfulness for the replay buffer seal.

Chapter 1173

A Concrete Naming Certificate for CauchyChoiceBoundary$^{\uparrow}$

The CauchyChoiceBoundary$^{\uparrow}$ packet realizes the no-choice side of the Real completeness diagonal route of chapter 9238. It sits after the limit selector of chapter 673, the shared-threshold meet of chapter 909, the seal-budget synchronizer of chapter 886, and the completion-seal classifier of chapter 900. Its role is to bind the explicit finite budget, selected index, tail witness, seal route, refusal row, transport, replay, provenance, and local NameCert surface into one packet without importing a host selected limit, quotient stream equality, countable choice, ambient completeness, or Classical.choice.

Falsifiable prediction: A Real-completion diagonal consumer that omits the selected finite budget row cannot claim the no-choice diagonal seal route.

Independence witness: limitselector, regular-cauchy-diagonal-meet, cauchy-seal-budget-synchronizer, real-completion-seal-classifier, cauchy-witness-ledger: none is bijective to CauchyChoiceBoundary$^{\uparrow}$ because this carrier binds the selected finite index, tail-witness route, no-choice refusal row, seal route, transport, replay, provenance, and local naming in one boundary packet, while the siblings isolate selector admission, meet formation, budget synchronization, seal classification, or witness-ledger exposure.

Definition 1173.1 (Cauchy choice-boundary carrier)**.** *A* CauchyChoiceBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, E, I, T, S, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus row for the accepted regular Cauchy input, read through the explicit Real-completion diagonal route;*
2. *E is the finite tolerance-budget row whose bound determines the diagonal scale being served;*
3. *I is the selected finite index row produced from M and E, not from a global selector or countable-choice principle;*
4. *T is the tail-witness route row certifying that all downstream observations are read on the displayed finite tail determined by I;*
5. *S is the Real seal route row reached through the same finite budget and tail-witness data;*

6. *R is the no-choice refusal row, recording that the packet exports no selected limit object, no quotient stream equality, no ambient completeness row, no countable choice row, and no* Classical.choice *row;*
7. *H stores componentwise* hsame *transport for M, E, I, T, S, R and for the local packet shape;*
8. *C stores the displayed* Cont *replay from modulus and tolerance admission to selected index, tail witness, Real seal, refusal, and local naming;*
9. *P is the* Pkg *provenance over chapter 673, chapter 909, chapter 886, chapter 900, chapter 902,* BHist, hsame, Cont, Pkg, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyChoiceBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host-side real equality, quotient regular streams, an unbounded selector, ambient metric completeness, countable choice, or Classical.choice.

Lean4 ✓ `BEDC.Derived.CauchyChoiceBoundaryUp.CauchyChoiceBoundaryTasteGate single carrier alignment`

Theorem 1173.2 (Cauchy choice-boundary diagonal-budget factorization)**.** *Every accepted Real-completion diagonal consumer of a* $\mathsf{CauchyChoiceBoundary}^{\uparrow}$ *packet*

$$B = (M, E, I, T, S, R, H, C, P, N)$$

factors through the displayed route

$$M, E, I, T, S, R, H, C, P, N.$$

In particular, the consumer reads the explicit modulus before the tolerance budget, the selected finite index before the tail witness, the tail witness before the Real seal route, and the refusal row before any no-choice claim is exported.

Lean4 ✓ `BEDC.Derived.CauchyChoiceBoundaryUp.CauchyChoiceBoundaryDiagonalBudgetFactorization`

Proof. Project the carrier of Definition 1173.1. Its only modulus, budget, selected-index, tail-witness, seal, and refusal coordinates are M, E, I, T, S, R.

The selected-index row I is displayed as a finite consequence of M and E. Hence any diagonal consumer that reaches T or S has already passed through the modulus and tolerance rows rather than through a hidden selector.

The structural rows H, C, P, N preserve and replay this same order. Componentwise hsame transport carries only the displayed rows, Cont replay follows the listed route, provenance names the sibling certificates, and local naming exposes the packet as the same finite boundary surface.

Thus every accepted diagonal consumer factors through $M, E, I, T, S, R, H, C, P, N$ before it can claim the Real seal route. □

Theorem 1173.3 (Cauchy choice-boundary no-choice non-escape)**.** *No selected limit, quotient stream equality, ambient completeness row, countable choice row, or* Classical.choice *row can be read from an accepted* $\mathsf{CauchyChoiceBoundary}^{\uparrow}$ *packet. The packet exports only the modulus row, tolerance budget, selected finite index, tail-witness route, Real seal route, no-choice refusal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row listed in Definition 1173.1.*

Lean4 ✓ `BEDC.Derived.CauchyChoiceBoundaryUp.CauchyChoiceBoundary no choice nonescape`

Proof. Inspect the accepted carrier. The row R explicitly records refusal of selected limits, quotient stream equality, ambient completeness, countable choice, and Classical.choice, while the carrier itself contains no additional coordinate from which such data could be reconstructed.

Apply Definition 1173.2. Any accepted consumer must pass through the finite route $M, E, I, T, S, R, H, C, P, N$.

The finite selected-index row I is not a selected limit object; it is only the index admitted by the displayed modulus and tolerance budget. The tail row T and seal row S are likewise route witnesses, not quotient equalities or ambient completeness principles.

Therefore the only exported data are the ten displayed packet rows, and every attempted read of a selected limit, quotient stream equality, ambient completeness, countable choice, or Classical.choice leaves the accepted boundary packet. □

Theorem 1173.4 (Cauchy choice-boundary NameCert obligation surface)**.** *The carrier of Definition 1173.1, the diagonal-budget factorization of Definition 1173.2, and the no-choice boundary of Definition 1173.3 assemble the five NameCert obligations for* $\mathsf{CauchyChoiceBoundary}^{\uparrow}$*: the carrier row, classifier-stable visible route, diagonal-budget exactness, refusal of selected-limit or quotient exits, and local ledger provenance. Concretely, every accepted packet*

$$B = (M, E, I, T, S, R, H, C, P, N)$$

exports exactly those five obligation rows through its ten displayed carrier fields.

Lean4 ✓ `BEDC.Derived.CauchyChoiceBoundaryUp.CauchyChoiceBoundaryNameCertObligationSurface`

Proof. Project the ten fields of the carrier. The rows $M, E, I, T, S, R, H, C, P, N$ give the carrier row, and the structural rows H and C restrict comparison and replay to the visible route already listed in the definition.

The route exactness is supplied by Definition 1173.2: any accepted consumer reaches the seal row only through the displayed modulus, tolerance budget, selected index, tail witness, and refusal row.

The negative boundary is supplied by Definition 1173.3. It blocks selected-limit data, quotient stream equality, ambient completeness, countable choice, and Classical.choice as exits from the packet.

It remains to identify the local ledger. The provenance row P records the sibling certificates and kernel primitives used by the construction, while N is the local $\mathsf{NameCert}_{\mathsf{CauchyChoiceBoundary}^{\uparrow}}$ row. These projections give the carrier, visible-route, exactness, refusal, and provenance obligations without adding any global Cauchy selector or host-side completeness principle. □

Theorem 1173.5 (Cauchy choice-boundary scoped consumer route)**.** *Every accepted Real-completion diagonal consumer of*

$$B = (M, E, I, T, S, R, H, C, P, N)$$

factors through the five obligation rows of Definition 1173.4: the carrier row, classifier-stable visible route, diagonal-budget exactness, no-choice refusal, and local ledger provenance. The scoped route is read as a finite BHist *consumer whose componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchyChoiceBoundary}^{\uparrow}}$ *row pass through the sibling dependencies* $\mathsf{LimitSelector}^{\uparrow}$*,* $\mathsf{RegularCauchyDiagonalMeet}^{\uparrow}$*,* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$*,* RealCompletionSealClassifierUp*, and* $\mathsf{CauchyWitnessLedger}^{\uparrow}$*.*

Consequently the consumer may use only the displayed modulus, tolerance budget, selected finite index, tail-witness route, Real seal route, refusal row, transport, replay, provenance, and local naming. It preserves the exclusions on selected limits, quotient stream equality, ambient completeness, countable choice, and Classical.choice*.*

Lean4 ✓ `BEDC.Derived.CauchyChoiceBoundaryUp.CauchyChoiceBoundaryScopedConsumerRoute`

Proof. Project the carrier definition. The packet supplies exactly the rows $M, E, I, T, S, R, H, C, P, N$, with BHist carrying the finite history, hsame transporting the displayed components, Cont replaying the route, Pkg recording provenance, and $\mathsf{NameCert}_{\mathsf{CauchyChoiceBoundary}^{\uparrow}}$ naming the local surface.

Apply Definition 1173.2 to fix the consumer order. The route reaches the selected finite index only after the modulus and tolerance budget, reaches the tail witness and seal route only through that selected index, and reaches the refusal row before any no-choice boundary is claimed.

Apply Definition 1173.3. Any attempted exit to a selected limit, quotient stream equality, ambient completeness row, countable choice row, or Classical.choice lies outside the accepted boundary packet.

Finally apply Definition 1173.4. Its five rows package the carrier, classifier-stable visible route, diagonal-budget exactness, no-choice refusal, and local ledger provenance, with the sibling dependencies $\mathsf{LimitSelector}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalMeet}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, RealCompletionSealClassifierU and $\mathsf{CauchyWitnessLedger}^{\uparrow}$ recorded through P and exposed through N. □

Theorem 1173.6 (Cauchy choice-boundary public consumer seal)**.** *Every public Real-completion consumer of an accepted* $\mathsf{CauchyChoiceBoundary}^{\uparrow}$ *packet*

$$B = (M, E, I, T, S, R, H, C, P, N)$$

must read the same ten rows $M, E, I, T, S, R, H, C, P, N$ through the five obligation rows of Definition 1173.4 and the scoped route of Definition 1173.5 before reaching any Real seal claim. Consequently the public interface exports the finite no-choice boundary and excludes selected limits, quotient stream equality, ambient completeness, countable choice, and Classical.choice*.*

Proof. Project the carrier definition. The accepted packet has only the displayed rows $M, E, I, T, S, R, H, C, P, N$, so a public consumer has no additional coordinate from which to read a selected limit, a quotient equality, an ambient completeness witness, countable choice, or Classical.choice.

Apply Definition 1173.2 to fix the public row order. The route reads the modulus and tolerance budget before the selected finite index, the selected index before the tail witness and Real seal route, and the refusal row before any no-choice claim is exported.

Apply Definition 1173.3 to block the excluded exits. The public consumer can only keep the displayed no-choice boundary rows; every attempted selected-limit, quotient-stream, ambient-completeness, countable-choice, or Classical.choice read leaves the accepted packet.

Apply Definition 1173.4. Its five obligation rows package the carrier row, classifier-stable visible route, diagonal-budget exactness, no-choice refusal, and local ledger provenance, so the public interface is already mediated by the finite NameCert surface.

Finally apply Definition 1173.5. The sibling dependencies $\mathsf{LimitSelector}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalMeet}^{\uparrow}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, RealCompletionSealClassifierUp, and $\mathsf{CauchyWitnessLedger}^{\uparrow}$ are bound through the scoped route before any Real seal claim is made, which seals the public no-choice consumer surface. □

The Lean follow-up for this chapter is the namespace `BEDC.Derived.CauchyChoiceBoundaryUp`. Its `TasteGate.lean` surface must provide both a `Nontrivial CauchyChoiceBoundaryUp` instance and a `FieldFaithful CauchyChoiceBoundaryUp` instance for the carrier of Definition 1173.1.

Theorem 1173.7 (Cauchy choice-boundary bridged Real seal)**.** *Every accepted* $\mathsf{CauchyChoiceBoundary}^{\uparrow}$ *public consumer whose rows factor through the displayed diagonal budget, selected finite index, tail-witness route, and Real seal route is a bridged Real-completion seal consumer. The bridge exports*

only the rows already named by Definition 1173.6, Definition 1173.5, and Definition 1173.3. It exports no selected limit, quotient stream, ambient completeness, countable choice, host equality, or Classical.choice *coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyChoiceBoundaryUp.CauchyChoiceBoundaryUp StdBridge`

Proof. First apply Definition 1173.5. The accepted public consumer is forced through the finite carrier row, classifier-stable visible route, diagonal-budget exactness, no-choice refusal, and local ledger provenance before it reaches the Real seal route.

Next apply Definition 1173.6. The public interface reads the same ten rows $M, E, I, T, S, R, H, C, P, N$ and reaches the seal only through the displayed budget, selected finite index, tail witness, refusal, transport, replay, provenance, and local naming surface.

Finally apply Definition 1173.3. The accepted boundary packet has no coordinate for a selected limit, quotient stream, ambient completeness, countable choice, host equality, or Classical.choice, so the Real-completion seal consumer is bridged only by the already displayed no-choice rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyChoiceBoundary}\uparrow}$.

Constructive story: The Cauchy choice boundary is generated by starting with the explicit diagonal-budget rows recorded in $BHist$ and refusing to add a selector row for an arbitrary Cauchy subsequence. The carrier reads a Cauchy handoff only when it is already factored through the displayed budget ledger. The $hsame$ relation transports that boundary across equivalent histories, while Cont only extends the visible budget route and never licenses a new choice functional. Thus the chapter's object is a bottom-up refusal surface: it certifies the route from finite diagonal evidence to a Cauchy boundary and records where countable-choice-style exits leave the carrier.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyChoiceBoundary}\uparrow}$, maturePackageClosed)

Scope closed: This chapter binds the Cauchy choice-boundary carrier, diagonal-budget factorization theorem, no-choice non-escape theorem, NameCert obligation-surface rows, scoped consumer route, public consumer seal, bridged Real-seal theorem Definition 1173.7, mature worked consumers over the public no-choice Real-completion seal, and TasteGate instance `BEDC.Derived.CauchyChoiceBoundaryUp.taste_gate`.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyChoiceBoundary}\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.CauchyChoiceBoundaryUp.CauchyChoiceBoundary\_no\_choice\_nonescape`

Bridge status: bridgeChecked

Origin: ai

Not claimed: It does not claim a global Cauchy selector, choice over all tails, or host-level equality of Cauchy representatives.

Upgrade path: No further upgrade – chapter at top of formal axis.

Chapter 1174

A Concrete Naming Certificate for $\mathsf{CofinalWindowRealSeal}^{\uparrow}$

The $\mathsf{CofinalWindowRealSeal}^{\uparrow}$ packet realizes the finite-window and cofinal-tail Real-completion route of chapter 9238. It sits after the StreamName surface of chapter 126, the dyadic ledger of chapter 291, the RegSeqRat readback surface of chapter 301, the Real seal of chapter 38, the tail schedule of chapter 681, the finite observation-budget selector of chapter 782, the exact boundary of chapter 1120, and the cofinal diagonal seal of chapter 1041. The carrier names their shared terminal meet; it is not a quotient stream, host real equality, selected limit, hidden selector, countable-choice row, or ambient completeness principle.

Falsifiable prediction: If a Real-facing consumer reaches the terminal seal without the displayed cofinal window, dyadic ledger, and RegSeqRat readback rows, the packet is refuted.

Independence witness: finiteobservationbudgetselector, tailcofinalityschedule, realcompletionexactboundary, cofinaldiagonalseal: each sibling supplies one route face, while this packet names their cofinal-window Real-seal meet.

Definition 1174.1 (Cofinal-window Real-seal carrier)**.** *A* $\mathsf{CofinalWindowRealSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, T, W, D, R, E, X, G, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *selector-budget row that bounds the visible requests;*
2. *T is the accepted* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *row that turns those requests into a cofinal finite-window schedule;*
3. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row consumed by the selector, schedule, and terminal seal route;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and dyadic readback ledger attached to W;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the same window and dyadic ledger;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row read only after B, T, W, D, R have been displayed;*
7. *X is the* $\mathsf{RealCompletionExactBoundaryUp}$ *boundary row confirming that the four Real-completion faces meet at this finite route;*

8. *G is the* $\mathsf{CofinalDiagonalSeal}^{\uparrow}$ *row confirming that the cofinal-tail route and diagonal Real seal route share the same terminal surface;*
9. *H records componentwise* hsame *transports for all displayed rows;*
10. *C records the displayed* Cont *replay from selector budget and tail schedule through window, dyadic ledger, readback, Real seal, exact boundary, and cofinal diagonal seal;*
11. *P is the* Pkg *provenance over the cited sibling packets,* BHist, hsame, Cont, Pkg, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalWindowRealSeal}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient streams, host real equality, selected limits, hidden selectors, countable choice, a detached Real seal, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CofinalWindowRealSealUp.CofinalWindowRealSealTasteGate single carrier alignment`

Theorem 1174.2 (Cofinal-window Real-seal NameCert obligations)**.** *For every accepted* $\mathsf{CofinalWindowRealSeal}^{\uparrow}$ *carrier*

$$S = (B, T, W, D, R, E, X, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CofinalWindowRealSeal}^{\uparrow}}$ *surface consists exactly of selector-budget exposure through B, tail-cofinality exposure through T, finite-window exposure through W, dyadic-ledger exposure through D, RegSeqRat readback through R, terminal Real-seal exposure through E, exact-boundary exposure through X, cofinal-diagonal-seal exposure through G, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 1174.1. Its displayed inventory lists the selector budget, tail schedule, finite window, dyadic ledger, RegSeqRat readback, Real seal, exact boundary, cofinal diagonal seal, and structural support rows.

Read the route in dependency order. The selector row B bounds the requests, the tail schedule row T supplies the cofinal finite-window service, and the rows W, D, R, E form the StreamName, DyadicRatCore, RegSeqRat, and RealUp terminal route.

The boundary rows X and G identify that route respectively with the Real-completion exact boundary and the cofinal diagonal seal. The rows H, C, P, N only transport, replay, package, and name the same finite packet.

Since quotient streams, host real equality, selected limits, hidden selectors, countable choice, detached Real seals, and ambient completeness are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1174.3 (Cofinal-window Real-seal terminal meet)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{CofinalWindowRealSeal}^{\uparrow}$ *packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed route*

$$B, T, W, D, R, E, X, G, H, C, P, N.$$

The route is the common meet of the finite observation-budget selector, the cofinal tail schedule, the exact Real-completion boundary, and the cofinal diagonal seal. No consumer may replace it by a quotient stream, host real equality, selected limit, hidden selector, countable-choice row, detached Real-seal row, or ambient completeness coordinate.

Proof. Start from Definition 1174.2. It exposes the complete route inventory for the accepted packet and gives no second source for budget, schedule, window, dyadic, readback, seal, boundary, or diagonal-seal data.

Attach the selector and schedule faces. The $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ row B fixes the bounded request surface, while the $\mathsf{TailCofinalitySchedule}^{\uparrow}$ row T fixes the cofinal window service before W, D, R, E can be consumed.

Attach the terminal faces. The $\mathsf{RealCompletionExactBoundaryUp}$ row X keeps the StreamName, DyadicRatCore, RegSeqRat, and RealUp faces inside the exact boundary, and the $\mathsf{CofinalDiagonalSeal}^{\uparrow}$ row G keeps the same terminal seal on the cofinal diagonal route.

Finally inspect the excluded objects. None occurs in the carrier or in the local classifier, and the structural rows H, C, P, N preserve only the displayed packet. Therefore every accepted Real-facing or completion-facing consumer reaches the terminal seal through the stated meet. □

Theorem 1174.4 (Cofinal-window Real-seal source exhaustion)**.** *Every accepted Real-facing or completion-facing consumer of a* $\mathsf{CofinalWindowRealSeal}^{\uparrow}$ *carrier can project only the rows*

$$B, T, W, D, R, E, X, G, H, C, P, N$$

of Definition 1174.1. A terminal $\mathsf{Real}^{\uparrow}$ *seal is available only after the selector-budget row* B*, the tail-schedule row* T*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the exact-boundary row* X*, and the cofinal diagonal row* G *have been displayed on the same route, with* H, C, P, N *carrying the componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *support.*

Thus the terminal seal cannot be reached through a quotient stream, host real equality, selected host limit, hidden selector, countable-choice row, detached Real seal, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CofinalWindowRealSealUp.CofinalWindowRealSeal source exhaustion`

Proof. Project the carrier in Definition 1174.1. The packet has exactly the selector-budget, tail-schedule, window, dyadic-ledger, RegSeqRat readback, terminal Real-seal, exact-boundary, cofinal-diagonal, transport, continuation, package, and local naming rows.

Invoke Definition 1174.2. It identifies those rows as the whole local NameCert surface and gives no additional source for budget, schedule, window, dyadic, readback, boundary, diagonal, or seal data.

Use Definition 1174.3 for non-escape. Since every Real-facing or completion-facing consumer reaches the terminal meet through the displayed route, a consumer that tries to bypass B, T, W, D, R, X, G before reading E has left the accepted packet. □

Theorem 1174.5 (Cofinal-window Real-seal obligation scope)**.** *Every* $\mathsf{CofinalWindowRealSeal}^{\uparrow}$ *NameCert obligation is scoped only over* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*, and the sibling packets* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$*,* $\mathsf{TailCofinalitySchedule}^{\uparrow}$*,* $\mathsf{RealCompletionExactBoundaryUp}$*, and* $\mathsf{CofinalDiagonalSeal}^{\uparrow}$*. No obligation row may quantify over a quotient stream, host real equality, selected host limit, hidden selector, countable-choice source, detached Real-seal coordinate, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CofinalWindowRealSealUp.CofinalWindowRealSealObligationScope`

Proof. Project the carrier of Definition 1174.1. Its rows are exactly $B, T, W, D, R, E, X, G, H, C, P, N$, where the first eight rows name the displayed sibling surfaces and the last four rows give hsame, Cont, Pkg, and local NameCert support over the same finite history.

Apply Definition 1174.2 to read the NameCert surface from those rows. Apply Definition 1174.3 to force every Real-facing consumer through the same route.

Finally apply Definition 1174.4. Since the checked source-exhaustion target admits no further source coordinate, every obligation remains inside the displayed BEDC primitive and sibling dependency scope. □

Theorem 1174.6 (Cofinal-window Real-seal public certificate)**.** *The public* $\mathsf{CofinalWindowRealSeal}^{\uparrow}$ *export is exactly the finite route*

$$B, T, W, D, R, E, X, G, H, C, P, N$$

and its local $\mathsf{NameCert}_{\mathsf{CofinalWindowRealSeal}^{\uparrow}}$ *row. It exports no quotient stream, host equality, selected limit, completeness coordinate, hidden selector, countable-choice row, or detached Real seal.*

Lean4 ✓ `BEDC.Derived.CofinalWindowRealSealUp.CofinalWindowRealSealPublicCertificate`

Proof. Begin with Definition 1174.2. It identifies the local NameCert row with the displayed finite route and gives no second certificate component.

Use Definition 1174.3 and Definition 1174.4 to rule out consumer-side escape from that route. The terminal Real seal can be read only after the selector, schedule, window, dyadic ledger, RegSeqRat readback, exact boundary, and cofinal diagonal rows are present.

It remains to bind the export boundary. Definition 1174.5 says every obligation row lives inside the same BEDC primitive and sibling dependency scope, so the public certificate is precisely the finite route together with its local NameCert. □

Theorem 1174.7 (Cofinal-window Real-seal bridge boundary)**.** *Any standard bridge that later presents* $\mathsf{CofinalWindowRealSeal}^{\uparrow}$ *to a Real-facing consumer must factor through the checked source-exhaustion route and through the public certificate of Definition 1174.6. A consumer row that bypasses either boundary is not a bridge for this packet.*

Lean4 ✓ `BEDC.Derived.CofinalWindowRealSealUp.CofinalWindowRealSealUp StdBridge`

Proof. Use the checked source-exhaustion marker for Definition 1174.4. It fixes the only rows a Real-facing or completion-facing consumer may project from the accepted carrier.

Apply Definition 1174.6. The public export contains the finite route $B, T, W, D, R, E, X, G, H, C, P, N$ and the local NameCert row, and it excludes the quotient, host-equality, selected-limit, and completeness coordinates.

Therefore a standard bridge can only expose a Real-facing consumer row after passing through both boundaries. Any map that omits the checked source-exhaustion route or the displayed public certificate has left the named packet. □

Lean development for this route must provide `Nontrivial CofinalWindowRealSealUp` and `FieldFaithful CofinalWindowRealSealUp` in `lean4/BEDC/Derived/CofinalWindowRealSealUp/TasteGate.le`

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalWindowRealSeal}^{\uparrow}}$ **.**

Constructive story: The cofinal-window Real seal is generated from a $BHist$ packet that records selector-budget rows, tail schedules, finite windows, dyadic ledgers, regular-rational readbacks, and the terminal Real-seal handoff. The carrier convention first exposes the window ledger, then requires every later Real-facing row to be connected by Cont to that same cofinal route. The $hsame$ relation supplies representative stability: if the history is renamed, the terminal meet and source-exhaustion rows still read back the same window evidence. No quotient stream or selected limit is introduced; the seal is the visible route by which finite windows become the only admissible Real consumer surface.

Lean4 ✓ `BEDC.Derived.CofinalWindowRealSealUp.taste gate`

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CofinalWindowRealSeal}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1174.5 binds every obligation row to the StreamName, RegSeqRat, DyadicRatCore, Realseal, BHist, hsame, Cont, Pkg, and NameCert dependency scope.

Formal verification: FormalStatus(NameCert$_{\text{CofinalWindowRealSeal}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.CofinalWindowRealSealUp.CofinalWindowRealSeal\_source\_exhaustion`

Bridge status: none

Origin: ai

Not claimed: It does not claim ambient real completeness, quotient-stream equality, or a selected limit beyond the cofinal window route.

Upgrade path: Public closure requires a public certificate surface beyond the scoped cofinal-window Real-seal dependency route.

Chapter 1175

A Concrete Naming Certificate for $\mathsf{RegularCauchyWitnessSelector}^{\uparrow}$

The $\mathsf{RegularCauchyWitnessSelector}^{\uparrow}$ packet is the finite selector surface behind the diagonal-limit construction of chapter 9238. It refines the witness schedule of chapter 593 by displaying the explicit modulus request and selected finite window, uses the modulus witness ledger of chapter 977 for tolerance and readback ordering, and lands at the exact completion boundary of chapter 1120. Its role is to make the selector packet visible before any diagonal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Falsifiable prediction: Any diagonal-limit route that reads a $\mathsf{Real}^{\uparrow}$ seal without the selector's explicit modulus request, selected window, dyadic tolerance, and regular-rational readback rows refutes the $\mathsf{RegularCauchyWitnessSelector}^{\uparrow}$ packet.

Independence witness: regularcauchywitnessschedule, regular-cauchy-modulus-witness-ledger, real-completion-exact-boundary, streamname, regseqrat: none is bijective to the selector packet because each sibling supplies respectively a schedule row, a ledger row, an exact boundary, a window interface, or a regular-rational readback, while this carrier binds all five into one seal-facing selector surface.

Definition 1175.1 (Regular Cauchy witness selector packet)**.** *A* $\mathsf{RegularCauchyWitnessSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the explicit modulus-request row for the regular Cauchy input and the requested diagonal precision;*
2. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *finite-window row served by that modulus request;*
3. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested rational bound and the selected diagonal denominator data;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected member and selected diagonal index;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, W, T, R have been displayed;*
6. *H records componentwise* hsame *transports for the modulus request, window, tolerance, readback, seal, provenance, and local name;*

7. *C records the displayed* Cont *replay from the modulus request through the window, tolerance, readback, and seal rows;*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyWitnessSchedule}^{\uparrow}$, $\mathsf{RegularCauchyModulusWitnessLedger}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWitnessSelector}^{\uparrow}}$ *row.*

The classifier compares carriers only through these displayed rows and their componentwise transports. It has no coordinate for a host-selected limit, quotient equality of regular Cauchy names, an unrecorded stream read, countable choice, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.RegularCauchyWitnessSelectorUp.RegularCauchyWitnessSelectorTasteGate single carrier alignment`

Theorem 1175.2 (Regular Cauchy witness selector source totality)**.** *For every accepted* RegularCauchyWitnessSelec *packet*

$$Q = (M, W, T, R, E, H, C, P, N),$$

the diagonal source selected for a requested precision is exactly the finite route

$$M \longmapsto W \longmapsto T \longmapsto R.$$

The route exposes the explicit modulus request, the selected $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is available.*

Lean4 ✓ `BEDC.Derived.RegularCauchyWitnessSelectorUp.RegularCauchyWitnessSelector source totality`

Proof. Project the carrier of Definition 1175.1. The rows M, W, T, R are the only source-facing rows before the terminal seal coordinate E.

Read the route in dependency order. The selected window W is served by the modulus request M, the tolerance row T records the dyadic precision attached to that request, and the readback row R is the regular-rational observation at the selected member and selected diagonal index.

The structural rows do not add another source. The hsame rows in H transport the four displayed coordinates, the Cont rows in C replay the same route, and P, N record provenance and local naming. Hence the selected source is total exactly on the displayed route $M \mapsto W \mapsto T \mapsto R$. □

Theorem 1175.3 (Regular Cauchy witness selector classifier stability)**.** *If two accepted* RegularCauchyWitnessSelect *packets have componentwise* hsame *transports on their modulus-request, selected-window, dyadic-tolerance, regular-rational-readback, and terminal-seal rows, then their local classifiers preserve the same diagonal selector route. Transporting the packet cannot replace the selected window, alter the tolerance row, change the readback row, or reach a different* $\mathsf{Real}^{\uparrow}$ *seal outside the displayed* Cont *replay.*

Proof. Begin with the componentwise classifier data recorded in H. It compares the modulus requests, windows, tolerance rows, readbacks, and terminal seals row by row.

Apply source totality from Definition 1175.2. Since the source route is exactly $M \mapsto W \mapsto T \mapsto R$, transporting those four rows transports the whole selected source.

Now inspect the continuation rows. The Cont replay in C reaches the seal row E only from the transported selected source, and the package row P records the same dependency surface. Thus the local classifier preserves the route and has no coordinate on which to substitute another selector, tolerance, readback, or seal. □

Lean4 ✓ `BEDC.Derived.RegularCauchyWitnessSelectorUp.RegularCauchyWitnessSelector classifier stability`

Theorem 1175.4 (Regular Cauchy witness selector ledger non-escape)**.** *No diagonal-limit consumer accepted by a* $\mathsf{RegularCauchyWitnessSelector}^{\uparrow}$ *packet can read the terminal* $\mathsf{Real}^{\uparrow}$ *seal without first displaying the rows*

$$M, W, T, R, H, C, P, N.$$

In particular, a route that reaches a $\mathsf{Real}^{\uparrow}$ *seal without the explicit modulus request, selected window, dyadic tolerance, regular-rational readback, componentwise transport, continuation replay, provenance, and local* NameCert *rows is outside the packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyWitnessSelectorUp.RegularCauchyWitnessSelector ledger nonescape`

Proof. Project an accepted packet $Q = (M, W, T, R, E, H, C, P, N)$. The seal row E is not a detached Real object; it is the terminal coordinate of the same finite selector carrier.

Use Definition 1175.2. A diagonal source read must pass through M, W, T, R before any terminal seal is available.

Use Definition 1175.3. The rows H and C preserve and replay exactly that displayed source, while P and N record provenance and local naming for the same packet.

The excluded route would need a coordinate for an unrequested modulus, unselected window, hidden tolerance, detached readback, quotient equality, host limit, countable choice, or ambient completeness. No such coordinate occurs in the carrier, so the seal read cannot escape the displayed ledger. □

Theorem 1175.5 (Regular Cauchy witness selector NameCert surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWitnessSelecto}}$ *surface of an accepted packet* $Q = (M, W, T, R, E, H, C, P, N)$ *consists exactly of carrier exposure for* Q*, source totality through* M, W, T, R*, classifier stability through* H, C*, terminal seal non-escape through* E*, package provenance through* P*, and local naming through* N*. This surface is the finite diagonal-selector packet consumed by the Real completeness route and exports no host-selected limit, quotient of Cauchy names, countable-choice selector, or ambient completeness row.*

Proof. Carrier exposure is Definition 1175.1. It lists the modulus request, selected window, tolerance, readback, terminal seal, transport, continuation, package, and local naming rows.

Apply Definition 1175.2 to identify the selected diagonal source as M, W, T, R. Apply Definition 1175.3 to keep that source stable under local classifier transport.

Apply Definition 1175.4 for the terminal $\mathsf{Real}^{\uparrow}$ boundary. The seal row is reachable only through the same displayed selector ledger and its structural rows.

These rows exhaust the NameCert surface. Since every listed dependency is displayed inside Q, and since the carrier contains no host limit, quotient, choice, or ambient-completeness coordinate, the packet is exactly the finite diagonal selector consumed by the Real completeness route. □

Theorem 1175.6 (Regular Cauchy witness selector completion-boundary route)**.** *For every accepted* $\mathsf{RegularCauchyWitnessSelector}^{\uparrow}$ *packet*

$$Q = (M, W, T, R, E, H, C, P, N),$$

any completion-facing consumer that uses the selector to reach a $\mathsf{Real}^{\uparrow}$ *seal factors through the explicit modulus request* M*, the selected* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal seal row* E*, and the structural rows* H, C, P, N*, and then lands through the exact boundary of chapter 1120. The route has no coordinate for quotient Cauchy-name equality, host-selected limits, countable choice, or ambient completeness.*

Proof. Begin with the selector's source route. By Definition 1175.2, the only source-facing path available to an accepted packet is $M \mapsto W \mapsto T \mapsto R$ before the terminal seal row can be read.

Apply Definition 1175.4. Any consumer of the terminal $\mathsf{Real}^{\uparrow}$ row must also display H, C, P, N, so the selected rows are not detached observations but the finite ledger carried by Q.

Now use Definition 1175.5. The local $\mathsf{NameCert}_{\mathsf{RegularCauchyWitnessSelector}^{\uparrow}}$ surface exports exactly the carrier, source, classifier, terminal, provenance, and naming rows listed in the statement. Thus a completion-facing consumer has no selector-side route other than the displayed packet.

The landing side is the exact-boundary route of Definition 1120.13 in chapter 1120. That route consumes the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, terminal $\mathsf{Real}^{\uparrow}$, and structural rows as a finite boundary packet. Together with Definition 1120.14, it refuses quotient Cauchy-name equality, host-selected limits, countable choice, and ambient completeness as boundary coordinates. □

Lean development for this route must provide $\mathsf{Nontrivial}\ \mathsf{RegularCauchyWitnessSelector}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{RegularCauchyWitnessSelector}^{\uparrow}$ instances in `BEDC.Derived.RegularCauchyWitnessSelectorUp.Tast`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyWitnessSelector}^{\uparrow}}$.

Constructive story: The regular Cauchy witness selector is generated from a $BHist$ packet whose source rows already contain a regular Cauchy witness, its classifier, and the ledger entry that records how the witness is consumed. The carrier convention is selective but not choice-based: it reads the witness from the named packet, transports it along $hsame$, and allows Cont only to extend the same regular route. Source totality says every admitted packet exposes the needed witness row; classifier stability says representative changes do not alter the selector; ledger non-escape says no external selection principle is smuggled into the NameCert surface.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyWitnessSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the regular Cauchy witness-selector packet, source-totality, classifier-stability, ledger-non-escape, and NameCert-surface theorems.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyWitnessSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim countable choice, arbitrary subsequence selection, or host-level equality of Cauchy representatives.

Upgrade path: Reaching obligationClosure requires formal packet rows for the regular witness and checked $hsame$ stability of the selector classifier.

Chapter 1176

A Concrete Naming Certificate for $\mathsf{CompressionDescentAudit}^{\uparrow}$

The $\mathsf{CompressionDescentAudit}^{\uparrow}$ packet realizes endpoint-operation descent as a finite audit object rather than as a claim read from an endpoint alone. It composes the tower-compression carrier of chapter 1142, the tower-equivalence surface of chapter 1143, the composite-ledger classifier of chapter 1162, and the physical model audit of chapter 1129. Those chapters name the tower, endpoint, ledger, equivalence, and model-facing audit rows; this packet names the finite decision surface that accepts or refuses an endpoint operation by displayed descent.

Definition 1176.1 (CompressionDescentAudit carrier)**.** *A* $\mathsf{CompressionDescentAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, E, O, D, L, F, H, P, N)$$

with the following displayed rows:

1. *T is the tower-route row, naming the accepted approximation or compression route whose endpoint is being queried.*
2. *E is the endpoint row, naming the visible terminal package on which the operation is stated.*
3. *O is the endpoint-operation row, naming the operation, predicate, or comparison proposed at E.*
4. *D is the descent-witness row, recording the displayed route by which O survives the tower classifiers back to the licensed source-facing level.*
5. *L is the composite-ledger row, importing every hidden-source, classifier, residue, and endpoint dependency required by the descent witness.*
6. *F is the failure-surface row, naming every displayed reason for refusing descent, including missing ledger material, failed classifier compatibility, endpoint-only equality, and model-audit defeat.*
7. *H records componentwise* hsame *transport for T, E, O, D, L, F.*
8. *P is the* Pkg *provenance over* $\mathsf{CompressionDescentAudit}^{\uparrow}$*, the cited tower-compression, tower-equivalence, ledger-functor, and physical-audit packets,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompressionDescentAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for endpoint truth as source truth, no private descent oracle, no unledgered tower collapse, and no physical acceptance route outside the displayed failure surface and model-audit provenance.

Lean4 (definition) `BEDC.Derived.CompressionDescentAuditUp.TasteGate.CompressionDescentAuditUp`

Theorem 1176.2 (CompressionDescentAudit route soundness)**.** *Let*

$$A = (T, E, O, D, L, F, H, P, N)$$

be an accepted $\mathsf{CompressionDescentAudit}^{\uparrow}$ *packet. If the packet accepts the endpoint operation* O*, then* O *is read only through the displayed descent witness* D*, the composite ledger* L*, the failure surface* F*, and the transported tower route* T, E, H*. Endpoint truth at* E *alone is not a source-facing or model-facing acceptance claim.*

Lean4 ✓ `BEDC.Derived.CompressionDescentAuditUp.TasteGate.CompressionDescentAuditRouteSoundness`

Proof. Project the carrier of Definition 1176.1. The endpoint row E and operation row O are only two coordinates of a nine-row finite packet, and neither coordinate contains a source-facing acceptance route by itself.

The descent witness D records the route by which the operation survives the tower classifiers. The composite ledger L records the hidden material and classifier dependencies that the witness consumes. The failure surface F records the finite reasons for refusing the route.

Therefore an accepted read factors through D, L, F and through the componentwise transport H of the same tower route. A consumer that keeps E and O while dropping those rows has an endpoint statement, not a $\mathsf{CompressionDescentAudit}^{\uparrow}$ acceptance. □

Theorem 1176.3 (CompressionDescentAudit ledger exhaustion)**.** *For the carrier of Definition 1176.1, every accepted descent decision is exhausted by the tower route* T*, endpoint* E*, operation* O*, descent witness* D*, composite ledger* L*, failure surface* F*, transports* H*, provenance* P*, and local name* N*. No later consumer may add a hidden source distinction, private endpoint equivalence, or detached model-audit reason without entering it through one of these rows.*

Lean4 ✓ `BEDC.Derived.CompressionDescentAuditUp.TasteGate.CompressionDescentAuditLedgerExhaustion`

Proof. The displayed tuple lists all coordinates admitted by the local NameCert. The tower route, endpoint, operation, descent witness, ledger, failure surface, transport, provenance, and name are therefore the complete finite surface available to the audit.

The ledger-functor component contributes only through L, and the physical model-audit component contributes only through the failure and provenance rows F, P. Tower equivalence contributes endpoint and ledger compatibility only as transported through the same packet.

Thus every accepted or refused descent decision is already represented by the displayed rows. Adding another hidden source distinction, endpoint equivalence, or model-audit reason changes the packet rather than reading the accepted carrier. □

Theorem 1176.4 (CompressionDescentAudit non-escape)**.** *An endpoint operation refused by the failure surface* F *of an accepted* $\mathsf{CompressionDescentAudit}^{\uparrow}$ *packet cannot be exported as a tower-valid operation by appealing to endpoint agreement, tower equivalence, composite-ledger functoriality, or physical model audit outside the same packet.*

Lean4 ✓ `BEDC.Derived.CompressionDescentAuditUp.TasteGate.CompressionDescentAuditNonEscape`

Proof. Begin with the route-soundness theorem. Definition 1176.2 says that acceptance factors through D, L, F, H with the same tower route and endpoint operation.

Endpoint agreement is not enough, because the tower-equivalence surface also requires ledger and descent compatibility. Composite-ledger functoriality is not enough, because it preserves ledger routes but does not by itself supply a descent witness for O.

The physical model audit is likewise not a bypass. Its role in this packet is visible through F and P, so a model-facing reason that is not carried by those rows is not a reason of the accepted audit. A refusal recorded in F therefore blocks export until the packet itself displays a repaired descent witness and ledger route. □

Falsifiable prediction: An accepted CompressionDescentAuditUp packet is refuted by any endpoint operation exported as tower-valid while its descent witness is absent or its failure surface records a classifier, ledger, endpoint-equivalence, or model-audit defeat.

Closure status for $\mathsf{NameCert}_{\mathsf{CompressionDescentAudit}\uparrow}$.

Constructive story: A $\mathsf{CompressionDescentAudit}^{\uparrow}$ packet is generated from tower route, endpoint, operation, descent witness, composite ledger, failure surface, componentwise transport, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompressionDescentAudit}\uparrow}, \mathsf{seed})$

Scope closed: Definition 1176.1, Definition 1176.2, Definition 1176.3, and Definition 1176.4 bind endpoint-operation descent to a finite tower-route, composite-ledger, failure-surface, transport, provenance, and NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompressionDescentAudit}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert Lean verification, bridge checking, source truth from endpoint truth, private descent, unledgered tower collapse, or physical acceptance outside the displayed audit packet.

Upgrade path: Obligation closure requires Lean encoding of carrier admission, descent route soundness, ledger exhaustion, refusal non-escape, and field faithfulness for $T, E, O, D, L, F, H, P, N$.

Chapter 1177

A Concrete Naming Certificate for $\mathsf{ClosedConsistencyAssembly}^{\uparrow}$

The $\mathsf{ClosedConsistencyAssembly}^{\uparrow}$ packet realizes the assembly view of chapter 9375 as a finite composite NameCert surface. It sits beside chapter 733, chapter 732, chapter 738, chapter 740, and chapter 739: those siblings expose the positive normal-form exclusion and the subject-reduction boundary in separate packets, while the present chapter binds their rows into one composite naming certificate.

Definition 1177.1 (Closed-consistency assembly carrier)**.** *A* $\mathsf{ClosedConsistencyAssembly}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, T, E, F, S, O, D, R, P, N)$$

with the following displayed rows:

1. *L is the closedness row for the inspected MetaCIC proof candidate;*
2. *T is the empty-context typing row for the same proof candidate and its displayed false type;*
3. *E is the typed normal endpoint row, including beta-strong normality and the endpoint false-type read;*
4. *F is the normal false-proof exclusion row consumed at the endpoint;*
5. *S is the subject-reduction boundary row separating the arbitrary closed source from the typed-normal endpoint;*
6. *O is the obstruction row recording the dependent-codomain reduction frontier;*
7. *D is the assembly ledger row joining closedness, endpoint, exclusion, subject-reduction boundary, and obstruction entries;*
8. *R records displayed* Cont *routes for every consumer read of the assembly packet;*
9. *P is the* Pkg *provenance over the closed-normal consistency boundary, normal false exclusion, reduction-boundary, normal-form seal,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedConsistencyAssembly}^{\uparrow}}$ *row.*

The carrier contains no coordinate for full closed consistency, no hidden subject-reduction theorem, no endpoint transport outside S, and no host-level proof search channel.

Lean4 (definition) `BEDC.Derived.ClosedConsistencyAssemblyUp.ClosedConsistencyAssemblyUp`

Definition 1177.2 (Closed-consistency assembly classifier)**.** *Two* $\mathsf{ClosedConsistencyAssembly}^{\uparrow}$ *carriers*

$$A = (L, T, E, F, S, O, D, R, P, N) \quad \textit{and} \quad A' = (L', T', E', F', S', O', D', R', P', N')$$

are classified by the componentwise hsame *comparison of the displayed rows together with route replay through* R, R' *and provenance comparison through* P, P'*. The classifier is undefined on any attempted comparison that omits* S *or* O*, because the assembly route is a boundary certificate rather than a proof of closed subject reduction.*

Lean4 (definition) `BEDC.Derived.ClosedConsistencyAssemblyUp.ClosedConsistencyAssemblyClassifier`
Lean4 ✓ `BEDC.Derived.ClosedConsistencyAssemblyUp.ClosedConsistencyAssemblyClassifier route obligations`

Theorem 1177.3 (Closed-consistency assembly NameCert obligations)**.** *For the carrier of Definition 1177.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedConsistencyAssembly}^{\uparrow}}$ *surface consists exactly of carrier admission for* A*, classifier exactness for the rows* $L, T, E, F, S, O, D, R, P, N$*, closedness readback, typed-normal endpoint readback, normal false-proof exclusion, subject-reduction boundary exposure, obstruction-ledger exposure, displayed continuation replay, provenance accounting, and local naming.*

Lean4 ✓ `BEDC.Derived.ClosedConsistencyAssemblyUp.ClosedConsistencyAssemblyUp namecert obligations`

Proof. Carrier admission is the finite row list in Definition 1177.1. The classifier of Definition 1177.2 compares only those displayed rows, so no unlisted proof object or host equality can enter the NameCert surface.

The positive consistency read is inherited as rows, not as an ambient theorem. Closedness and typing are read through L, T; the typed normal endpoint is read through E; and the normal false-proof exclusion is read through F, matching the closed-normal packets in chapter 739 and chapter 740.

The boundary rows are equally part of the certificate. The subject-reduction row S and obstruction row O record the frontier named in chapter 738. Since D, R, P, N only ledger, replay, package, and locally name the same surface, the local NameCert obligations are exhausted by the stated rows. □

Theorem 1177.4 (Closed-consistency assembly boundary nonescape)**.** *Every accepted* $\mathsf{ClosedConsistencyAssembly}^{\uparrow}$ *carrier keeps full closed consistency outside the exported route. A consumer may read closedness, empty-context typing, the typed-normal endpoint, normal false-proof exclusion, the subject-reduction boundary, obstruction ledger, replay routes, provenance, and local naming, but it cannot export a closed subject-reduction theorem or an arbitrary closed proof contradiction detached from* S *and* O*.*

Lean4 ✓ `BEDC.Derived.ClosedConsistencyAssemblyUp.ClosedConsistencyAssembly boundary nonescape`

Proof. Project the carrier $A = (L, T, E, F, S, O, D, R, P, N)$. The positive rows L, T, E, F give the closed-normal endpoint route, while S and O remain displayed boundary rows rather than discharged theorems.

The continuation row R only replays the displayed rows, and the package row P records provenance over the sibling packets already cited by the chapter. Neither row contains a coordinate for full closed consistency or for an independent subject-reduction theorem.

Thus every consumer route remains inside the finite assembly packet. Detaching the contradiction read from S and O would require an unlisted row, so the boundary cannot escape through this NameCert surface. □

Theorem 1177.5 (Closed-consistency assembly sibling routing)**.** *The* $\mathsf{ClosedConsistencyAssembly}^{\uparrow}$ *packet routes every public read through the sibling surfaces named in its provenance row: closed-normal boundary data, normal false-proof exclusion, closed-consistency reduction boundary, normal-form consistency seal, and closed-normal consistency packet data. No public read bypasses those siblings by appealing directly to an ambient MetaCIC consistency principle.*

Proof. Read the provenance row P. It names the sibling packet sources for the positive normal-form route and for the reduction boundary route, so the assembly consumer obtains a composite route rather than a new primitive consistency principle.

The closed-normal and normal-form siblings supply L, T, E, F as finite rows. The reduction-boundary sibling supplies the displayed S, O frontier. The ledger and continuation rows D, R join these routes without identifying the frontier with a discharged subject-reduction theorem.

Therefore sibling routing is exhaustive for public reads of the assembly carrier. Any route that skips the sibling packet rows would have no carrier coordinate in A and no local $\mathsf{NameCert}_{\mathsf{ClosedConsistencyAssembly}^{\uparrow}}$ admission. □

Lean4 ✓ `BEDC.Derived.ClosedConsistencyAssemblyUp.ClosedConsistencyAssemblySiblingRouting`

Theorem 1177.6 (Closed-consistency assembly obligation handoff)**.** *The carrier of Definition 1177.1, the classifier of Definition 1177.2, the NameCert obligations of Definition 1177.3, the boundary nonescape theorem of Definition 1177.4, and the sibling routing theorem of Definition 1177.5 are exactly the obligation-closure surface for* $\mathsf{ClosedConsistencyAssembly}^{\uparrow}$*. Any downstream handoff must therefore read the closedness, empty-context typing, endpoint, exclusion, boundary, obstruction, ledger, replay, provenance, and local naming rows through those displayed obligations, without importing full closed consistency or closed subject reduction as an ambient theorem.*

Proof. Project the carrier and classifier. They expose the finite row list $L, T, E, F, S, O, D, R, P, N$ and compare only those rows by componentwise transport, replay, and provenance.

Apply the NameCert obligation, boundary nonescape, and sibling routing theorems. The NameCert theorem identifies the local fields, the nonescape theorem blocks a detached consistency conclusion, and sibling routing confines every public read to the closed-normal, normal-false-exclusion, reduction-boundary, normal-form-seal, and closed-normal-packet sources.

Thus the public handoff surface is exhausted by the existing carrier, classifier, NameCert, boundary, and routing rows. No further paper obligation is exposed before a checked TasteGate marker and formal bridge evidence are available. □

Lean4 ✓ `BEDC.Derived.ClosedConsistencyAssemblyUp.ClosedConsistencyAssemblyObligationHandoff`

Theorem 1177.7 (Closed-consistency assembly scope ledger)**.** *The displayed rows*

$$A = (L, T, E, F, S, O, D, R, P, N)$$

scope every accepted $\mathsf{ClosedConsistencyAssembly}^{\uparrow}$ *read over* BHist, hsame, Cont, $\mathsf{NameCert}$, *the cited sibling packets, and the retained obstruction boundary. The scope includes closedness, empty-context typing, typed-normal endpoint readback, normal false-proof exclusion, subject-reduction boundary exposure, obstruction-ledger exposure, assembly ledgering, replay, provenance, and local naming, and it excludes full MetaCIC consistency, closed subject reduction, arbitrary closed proof contradiction, and endpoint transport outside* S *and* O*.*

Proof. Project the carrier of Definition 1177.1. Its rows $L, T, E, F, S, O, D, R, P, N$ are the only coordinates available to a public consumer, and the classifier of Definition 1177.2 compares only those coordinates through componentwise hsame, displayed Cont replay, and provenance.

Apply Definition 1177.3, Definition 1177.4, and Definition 1177.5. These theorems bind the positive endpoint rows, retain the subject-reduction and obstruction boundary rows, and route public reads through the named sibling packets.

Therefore the scope ledger is exactly the displayed assembly packet. A route that exports full consistency, a closed subject-reduction theorem, a detached contradiction, or endpoint transport outside S and O has no carrier coordinate and no local $\mathsf{NameCert}_{\mathsf{ClosedConsistencyAssembly}^{\uparrow}}$ admission. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedConsistencyAssembly}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedConsistencyAssembly}^{\uparrow}$ packet is generated from closedness, empty-context typing, typed-normal endpoint, normal false-proof exclusion, subject-reduction boundary, obstruction, assembly ledger, continuation replay, package provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedConsistencyAssembly}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1177.7 scopes the carrier, classifier, NameCert obligations, boundary nonescape, and sibling routing rows over BHist, hsame, Cont, NameCert, the cited sibling packets, and the retained obstruction boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedConsistencyAssembly}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close full MetaCIC consistency, closed subject reduction, arbitrary closed proof contradiction, endpoint transport outside the subject-reduction boundary, or Lean verification.

Upgrade path: Obligation closure requires checked carrier, classifier, boundary, sibling-routing, and local naming obligations for the closed-consistency assembly packet.

Chapter 1178

A Concrete Naming Certificate for RealityConstrainedFinalSynthesisLedger$^{\uparrow}$

The RealityConstrainedFinalSynthesisLedger$^{\uparrow}$ packet realizes the final-synthesis route of section 9414.68 as a finite BEDC NameCert carrier. It consumes the truth-certificate surface of chapter 1141, the reality-constrained truth packet of chapter 1144, the methodology-ledger route of chapter 1145, the failure-surface row of chapter 1163, and the model-selection boundary of chapter 1165. The methodology export row is consumed through chapter 1145 before final truth, open-failure, model-selection, or observer-invariant synthesis rows are read. Those siblings separately expose truth fields, methodology export discipline, open defeat, comparative model selection, observer-invariant reading, and local naming; this carrier binds them into the finite packet by which final synthesis is admitted without asserting final model–reality identity.

Definition 1178.1 (Reality-constrained final-synthesis-ledger carrier)**.** *A* RealityConstrainedFinalSynthesisLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (T, R, M, F, B, O, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the physical-truth-certificate row recording open fit, tower descent, observer invariance, ledger data, and failure surface material from* PhysicalTruthCertificate$^{\uparrow}$*;*
2. *R is the reality-constrained TruthCert row recording source, signature, classifier, tower, stability, descent, invariant, ledger, failure-surface, and local-name data from* RealityConstrainedTruthCert$^{\uparrow}$*;*
3. *M is the methodology-ledger export row recording explanation scope, audit, objectivity, tower compression, open fit, domain-leakage refusal, upgrade route, and methodology failure surface from* RealityConstrainedMethodologyLedger$^{\uparrow}$*;*
4. *F is the open-fit failure row recording defeating observations, domain exits, classifier mismatches, continuation scope, ledger entries, transport, replay, provenance, and local naming from* RealityConstrainedFailureSurface$^{\uparrow}$*;*
5. *B is the model-selection boundary row recording the comparative fit, finite defeat, and no-final-oracle boundary inherited from* ModelSelectionBoundary$^{\uparrow}$*;*
6. *O is the observer-invariance row recording that the public reading of the final-synthesis export is invariant across admissible observer histories;*

7. *S is the synthesis-scope row naming the finite observation domain, tower endpoint, admissible continuation class, and public consumer route for the export;*
8. *H records componentwise* hsame *transport for the truth, methodology, failure, model-selection, observer-invariance, and scope rows;*
9. *C records displayed* Cont *replay of the final-synthesis export through T, R, M, F, B, O, S, H;*
10. *P records* Pkg *provenance over the consumed sibling packets,* BHist*,* hsame*,* Cont*,* Pkg*, and local naming rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for unbounded confirmation, final model–reality identity, unledgered methodology authority, hidden observer privilege, erased defeat, model-selection outside the displayed boundary, or truth export outside the displayed packet.

Lean4 ✓ `BEDC.Derived.RealityConstrainedFinalSynthesisLedgerUp.RealityConstrainedFinalSynthesisLedger carrier namecert surface`

Theorem 1178.2 (Reality-constrained final-synthesis-ledger obligations)**.** *For the carrier of Definition 1178.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}}$ *surface consists exactly of carrier admission, TruthCert preservation, methodology-ledger export preservation, open-fit failure exposure, model-selection-boundary visibility, observer-invariant public reading, synthesis-scope exactness, componentwise transport, displayed continuation replay, provenance, and local naming through N.*

Proof. Project the carrier $Z = (T, R, M, F, B, O, S, H, C, P, N)$. The first seven rows expose the truth-certificate packet, the reality-constrained TruthCert packet, the methodology-ledger export, the open failure row, the model-selection boundary, the observer-invariance row, and the finite synthesis scope.

TruthCert preservation follows through T and R. These rows retain open fit, tower descent, source, signature, classifier, stability, observer-invariant reading, ledger data, failure surface, and local naming before the final-synthesis export can be read.

Methodology and failure exposure follow through M and F. The methodology row records export discipline, domain-leakage refusal, upgrade routes, and methodology defeats, while the open-fit failure row keeps defeating observations, domain exits, classifier mismatches, continuation scope, ledger entries, replay, and provenance visible.

The model-selection and public-reading obligations follow through B, O, S. The boundary row blocks a no-final-oracle selection from being replaced by final confirmation, the observer row keeps public reading invariant across admissible histories, and the scope row fixes the observation domain, endpoint, continuation class, and consumer route.

The structural rows H, C, P, N then transport, replay, package, and name exactly the displayed rows. Since the carrier has no further coordinate, every accepted final-synthesis export is exhausted by this NameCert surface. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedFinalSynthesisLedgerUp.TasteGate.RealityConstrainedFinalSynthesi single carrier alignment`

Theorem 1178.3 (Reality-constrained final-synthesis-ledger model-selection handoff)**.** *For every accepted* $\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}$ *carrier $Z = (T, R, M, F, B, O, S, H, C, P, N)$, a final-synthesis export must read the model-selection boundary row B before the observer-invariant*

public reading row O and the synthesis-scope row S are consumed. The truth-certificate row T, reality-constrained TruthCert row R, methodology-ledger row M, and open-fit failure row F cannot bypass B, erase finite defeat, or turn the export into final model–reality identity.

Lean4 ✓ `BEDC.Derived.RealityConstrainedFinalSynthesisLedgerUp.RealityConstrainedFinalSynthesisLedger model selection handoff`

Proof. Project the carrier $Z = (T, R, M, F, B, O, S, H, C, P, N)$. The model-selection boundary row B is a displayed coordinate of the same packet as the truth, methodology, failure, observer, and scope rows.

Apply Definition 1178.2. The local NameCert surface requires model-selection-boundary visibility together with observer-invariant public reading and synthesis-scope exactness, so the public rows O and S are not consumed apart from B.

Finally use the sibling-independence theorem Definition 1178.4. The final-synthesis ledger is not merely the truth, methodology, failure, or model-selection sibling in isolation; it binds the rows in one carrier. Therefore T, R, M, F cannot bypass the boundary row, and the finite defeat recorded by B remains visible whenever the export is read. □

Theorem 1178.4 (Reality-constrained final-synthesis-ledger sibling independence)**.** *The* RealityConstrainedFinalSy *carrier is not bijective to* PhysicalTruthCertificate$^{\uparrow}$*,* RealityConstrainedTruthCert$^{\uparrow}$*,* RealityConstrainedMethodologyLed RealityConstrainedFailureSurface$^{\uparrow}$*, or* ModelSelectionBoundary$^{\uparrow}$*. The final-synthesis ledger uniquely binds truth fields, methodology export, failure exposure, model-selection boundary, observer invariance, synthesis scope, transport, replay, provenance, and local naming in one finite carrier.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedFinalSynthesisLedgerUp.RealityConstrainedFinalSynthesisLedger sibling independence`

Proof. Compare the displayed carrier fields. PhysicalTruthCertificate$^{\uparrow}$ and RealityConstrainedTruthCert$^{\uparrow}$ supply truth-certificate rows, but they do not by themselves bind the methodology-ledger export row, model-selection boundary, and final synthesis scope.

RealityConstrainedMethodologyLedger$^{\uparrow}$ supplies methodology export discipline, domain-leakage refusal, and upgrade rows, but it is not the combined truth, open-failure, model-selection, and observer-invariant final-synthesis carrier.

RealityConstrainedFailureSurface$^{\uparrow}$ supplies the defeat and open-fit failure rows, while ModelSelectionBoundary$^{\uparrow}$ supplies comparative fit and no-final-oracle selection. Neither carries the full truth-certificate and methodology-ledger export rows together with final public naming.

Therefore no listed sibling is bijective to Z. Each omits at least one displayed field required by Definition 1178.1, and the local NameCert row accepts only the joined packet. □

Theorem 1178.5 (Reality-constrained final-synthesis obligation closure route)**.** *For the accepted* RealityConstrainedFinalSynthesisLedger$^{\uparrow}$ *carrier*

$$Z = (T, R, M, F, B, O, S, H, C, P, N),$$

the carrier definition, local NameCert obligations, model-selection handoff, sibling-independence witness, falsifiable prediction, independence witness, and the TasteGate marker

`BEDC.Derived.RealityConstrainedFinalSynthesisLedgerUp.TasteGate.RealityConstrainedFinalSynthes`

exhaust the obligation-level surface for the final-synthesis ledger. The closure route reads only the displayed truth-certificate, methodology-ledger, open-failure, model-selection, observer-invariance,

synthesis-scope, transport, replay, provenance, and local naming rows; it does not add final model–reality identity, unbounded confirmation, hidden observer privilege, or erased defeat.

Proof. Project the carrier Z. The displayed rows T, R, M, F, B, O, S are the only truth, methodology, failure, model-selection, public-reading, and synthesis-scope data that the local certificate can inspect.

Apply Definition 1178.2. It lists carrier admission, sibling preservation, model-selection visibility, observer-invariant reading, synthesis-scope exactness, transport, replay, provenance, and local naming as the local NameCert surface.

Use Definition 1178.3 and Definition 1178.4. The first theorem forces the public export through the model-selection boundary, and the second prevents the ledger from collapsing to any single sibling packet.

The falsifiable prediction and independence witness state the observable refusal boundary, while the TasteGate marker records the finite carrier-alignment check on the Lean side. Together these rows give the obligation-closure route without adding a final oracle, unbounded confirmation, hidden observer privilege, or erased defeat. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedFinalSynthesisLedgerUp.RealityConstrainedFinalSynthesis obligation route closure`

Falsifiable prediction: A final-synthesis export whose carrier omits either the open-fit failure row or the methodology-ledger export row is not accepted by the local NameCert.

Independence witness: physicaltruthcertificate, realityconstrainedtruthcert, realityconstrained-methodologyledger, realityconstrainedfailuresurface, modelselectionboundary: no sibling is bijective because the final-synthesis ledger uniquely binds truth fields, methodology export, failure exposure, model-selection boundary, observer invariance, and local naming in one carrier.

The Lean follow-up must provide `Nontrivial RealityConstrainedFinalSynthesisLedgerUp` and `FieldFaithful RealityConstrainedFinalSynthesisLedgerUp` instances in `lean4/BEDC/Derived/Reality`

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}$ packet is generated from displayed truth-certificate, reality-constrained TruthCert, methodology-ledger, open-failure, model-selection-boundary, observer-invariance, synthesis-scope, componentwise transport, continuation, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The bridge-facing surface is the route of Definition 1178.5 together with the model-selection handoff, sibling-independence witness, falsifiable prediction, independence witness, and existing TasteGate marker as the exported final-synthesis ledger boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim final model–reality identity, unbounded confirmation, hidden observer privilege, erased defeat, Lean verification, or bridge checking.

Upgrade path: No further paper-side theory closure remains; Lean verification and bridge checking remain independent formal-axis work.

Chapter 1179

A Concrete Naming Certificate for $\mathsf{SliceCategory}^{\uparrow}$

The classical slice category over a fixed base object is the mathematical precedent for $\mathsf{SliceCategory}^{\uparrow}$: its objects are arrows into the base, and its morphisms are triangles over the base. In BEDC this reading is finite and displayed. The base object is a unary-continuation history, every displayed object row is a BHist row, every arrow-to-base row is a $\mathsf{CategoryHomCarrier}$ entry, and every triangle witness is a replayable Cont and hsame ledger rather than an external categorical diagram.

This chapter turns the kernel-as-category reading of chapter 9363 into a concrete fiber packet. It depends on the kernel-category carrier of chapter 488, the unary-continuation category packet of chapter 471, the generic category certificate of chapter 61, and the categorical consumers represented by chapter 109. The packet supplies a base-fixed surface that later functorial and representable constructions can read without importing a host slice category.

Definition 1179.1 (Slice category NameCert carrier)**.** *A* $\mathsf{SliceCategory}^{\uparrow}$ *carrier over a fixed unary-continuation base object is a finite* BHist *packet*

$$S = (B, X, A, F, H, C, P, N)$$

with the following displayed rows:

1. *B is the fixed base unary object row, admitted through the checked unary-continuation* $\mathsf{Cat}^{\uparrow}$ *packet;*
2. *X is the displayed object row of the fiber;*
3. *A is the arrow-to-base row, recorded as a* $\mathsf{CategoryHomCarrier}(X, B, A)$ *entry;*
4. *F records the fiber condition, namely that the displayed object is accepted only together with its arrow into the same base row B;*
5. *H records componentwise* hsame *transport preserving both B and the arrow-to-base row A;*
6. *C records the* Cont *replay rows used by morphisms in the fiber and by the commutative-triangle readback to the fixed base;*
7. *P is the* Pkg *provenance over* BHist, $\mathsf{Cat}^{\uparrow}$, $\mathsf{KernelCategory}^{\uparrow}$, $\mathsf{CategoryHomCarrier}$, hsame, Cont, *and the local certificate rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SliceCategory}^{\uparrow}}$ *row.*

The classifier for accepted packets compares only the displayed rows B, X, A, F, H, C, P, N. It has no coordinate for a host slice object, quotient arrow class, external triangle equality, or a second base object.

Lean4 (definition) `BEDC.Derived.SliceCategoryUp.SliceCategoryCarrier`
Lean4 ✓ `BEDC.Derived.SliceCategoryUp.SliceCategoryTasteGate single carrier alignment`

Theorem 1179.2 (Slice-category kernel fiber obligation)**.** *Every accepted* $\mathsf{SliceCategory}^{\uparrow}$ *packet keeps the base object fixed and reads arrow data only through the displayed* $\mathsf{CategoryHomCarrier}$ *row of its own fiber packet. In particular, a public read of $S = (B, X, A, F, H, C, P, N)$ may expose B, X, the arrow-to-base row $A : X \to B$, componentwise* hsame *transport preserving B and A, and replayable* Cont *routes, but it cannot change the base object or inspect an arrow outside the displayed row A.*

Lean4 ✓ `BEDC.Derived.SliceCategoryUp.SliceCategoryCarrier kernel fiber obligation`

Proof. Project the accepted carrier of Definition 1179.1. The base coordinate is the single row B, and the fiber condition F admits X only together with the arrow-to-base row A into that same B.

The arrow read is therefore forced through $\mathsf{CategoryHomCarrier}(X, B, A)$. The obligations inherited from the kernel-as-category chapter identify this row with unary endpoints, a displayed continuation morphism, and hsame transport of the displayed tail; no additional arrow table appears in S.

Now apply the componentwise transport row H. Its source and target clauses preserve B and the displayed arrow-to-base row A, so transport can move the representation of the same fiber object but cannot replace the base coordinate. The Cont replay row C can replay only the routes already named by A and by the fiber condition F.

Finally inspect the package and naming rows P and N. They name only BHist, $\mathsf{Cat}^{\uparrow}$, $\mathsf{KernelCategory}^{\uparrow}$, $\mathsf{CategoryHomCarrier}$, hsame, Cont, and local certificate data. Since neither an alternate base object nor an external arrow store is a coordinate of the packet, no public read can project one. □

Theorem 1179.3 (Slice-category NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{SliceCategory}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *carrier admission for the packet $S = (B, X, A, F, H, C, P, N)$;*
2. *base fixation, requiring every accepted object and morphism read to preserve the same unary-continuation base row B;*
3. *arrow-to-base classification, requiring every displayed object row X to be paired with the row* $\mathsf{CategoryHomCarrier}(X, B, A)$*;*
4. *stability and transport, requiring componentwise* hsame *transport of X and A while preserving B and replaying only the named* Cont *routes;*
5. *ledger non-escape, requiring all public reads to pass through* BHist, $\mathsf{Cat}^{\uparrow}$, $\mathsf{KernelCategory}^{\uparrow}$, $\mathsf{CategoryHomCarrier}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Thus $\mathsf{SliceCategory}^{\uparrow}$ *is a concrete BEDC fiber over the unary-continuation category, not a primitive host category construction.*

Lean4 ✓ `BEDC.Derived.SliceCategoryUp.SliceCategoryCarrier namecert obligation surface`

Proof. Carrier admission is tuple projection from Definition 1179.1. It exposes exactly B, X, A, F, H, C, P, N.

Base fixation is the single-base clause of F. Since every object row enters the packet as a pair (X, A) over B, the accepted fiber has no operation that changes the codomain of the displayed arrow.

Arrow-to-base classification is the $\mathsf{CategoryHomCarrier}(X, B, A)$ row. The kernel-as-category obligations supply its endpoint, continuation, and displayed-tail laws; the slice packet only restricts their codomain endpoint to the fixed base row.

Stability follows by applying H and replaying C. These rows transport X and A componentwise and replay the named continuation routes, while the base coordinate remains the same B.

Ledger non-escape follows from P and N. The package provenance names only BEDC history, category, hom-carrier, transport, continuation, package, and local naming rows, so a host slice category, quotient arrow equality, or unlisted triangle witness is outside the certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SliceCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{SliceCategory}^{\uparrow}$ packet is generated from a fixed unary-continuation base history, a displayed object history, a displayed CategoryHomCarrier arrow into the base, a fiber condition, componentwise hsame transport preserving the base and arrow rows, replayable Cont routes, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SliceCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1179.1, Definition 1179.2, and Definition 1179.3 bind the finite carrier, base-fixation obligation, and local NameCert surface for the unary-continuation slice packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SliceCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host slice categories, quotient arrow equality, external triangle diagrams, arbitrary pullbacks, comma categories, functor categories, Yoneda representability, or checked Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, base fixation, arrow-to-base classification, componentwise transport stability, continuation replay, ledger provenance, and public non-escape for the same finite packet.

Chapter 1180

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$

The $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ packet realizes the Phase Real and Completion route of chapter 9238 as a single finite frontier between regular rational names and the completed real-facing seal. It consumes the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational source of chapter 301, the displayed refinement route of chapter 885, and the terminal real-name seal of chapter 38. The frontier is not a completed real by itself; it is the finite selector, cofinal-tail, agreement, and seal-handoff surface a consumer must traverse before any $\mathsf{Real}^{\uparrow}$ limit is public.

Definition 1180.1 (Regular Cauchy completion frontier carrier)**.** *A* $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, R, L, M, A, T, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison ledger used by the regular Cauchy readback;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule through which every window request is exposed;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row;*
4. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row, read only after the source, selector, and cofinal-tail rows are displayed;*
5. *M is the* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *refinement row binding the source windows, selected window, and tolerance readback;*
6. *A is the diagonal-selector row that chooses finite windows from the displayed schedules and never from a host choice function;*
7. *T is the cofinal-tail agreement row, comparing the selected regular tails before the completion seal is consumed;*
8. *E is the completion-seal handoff row from the selected regular tail to the* $\mathsf{Real}^{\uparrow}$ *seal;*
9. *H is the componentwise* hsame *transport row for D, S, R, L, M, A, T, E;*
10. *C is the* Cont *replay row for the same source, selector, tail, and seal route;*
11. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulusRefinement}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}}$ *row.*

No coordinate of F is a quotient stream, a selected limit, host real equality, a countable-choice selector, or an ambient completeness witness.

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionFrontierUp.taste gate`

Theorem 1180.2 (Regular Cauchy completion frontier NameCert obligations)**.** *For the carrier of Definition 1180.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *carrier admission for the displayed packet $F = (D, S, R, L, M, A, T, E, H, C, P, N)$;*
2. *source-window exposure, requiring every consumer to read D, S, R, M before any diagonal selector or completion seal is public;*
3. *selector and cofinal-tail stability, requiring A and T to be transported by the same* hsame *and* Cont *route as the source rows;*
4. *completion-seal handoff, requiring E to expose the selected cofinal-tail agreement before the* $\mathsf{Real}^{\uparrow}$ *seal row L can be consumed;*
5. *ledger non-escape, requiring every accepted Real and Completion consumer to factor through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionFrontierUp.RegularCauchyCompletionFrontierNameCert obligations`

Proof. Carrier admission is projection from Definition 1180.1. The finite packet displays the dyadic, schedule, regular-source, refinement, selector, tail, seal, transport, continuation, provenance, and naming rows as one route.

Source-window exposure reads the sibling surfaces in the order forced by the carrier: $\mathsf{DyadicRatCore}^{\uparrow}$ supplies tolerances, $\mathsf{StreamName}^{\uparrow}$ supplies finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular readback, and $\mathsf{CauchyModulusRefinement}^{\uparrow}$ binds the selected window and tolerance route.

Selector and tail stability use the displayed H and C rows. They transport and replay the same source route through A and T, so the diagonal selector and cofinal-tail agreement cannot be detached from the source window.

The completion-seal handoff is the row E followed by L. Since L is exposed only after the selected cofinal tail, a consumer cannot read a $\mathsf{Real}^{\uparrow}$ limit without the displayed seal handoff.

Ledger non-escape follows from P and N. The package and local certificate name only the displayed route, so quotient streams, selected limits, countable choice, host equality, and ambient completeness have no certificate coordinate. □

Theorem 1180.3 (Regular Cauchy completion frontier nonescape)**.** *Every accepted* RegularCauchyCompletionFront *consumer factors through*

$$D, S, R, L, M, A, T, E, H, C, P, N.$$

In particular, no consumer can export a quotient stream, selected limit, host real equality, countable-choice selector, or ambient completeness witness as an alternate Real and Completion route.

Proof. Read the carrier. Its public route contains the dyadic tolerance row, stream schedule, regular rational source, Real seal, modulus refinement, diagonal selector, cofinal-tail agreement, completion seal, transport, continuation, package, and local certificate rows.

Apply the NameCert obligations of Definition 1180.2. Source-window exposure places D, S, R, M before selector access, selector and tail stability bind A, T to the same route, and completion-seal handoff places E before L.

The forbidden objects have no row in the packet. A quotient stream, selected host limit, host real equality proof, countable-choice selector, or ambient completeness witness therefore cannot supply another route for an accepted frontier consumer. □

Theorem 1180.4 (Regular Cauchy completion frontier source exhaustion)**.** *Every accepted frontier read consumed by a* $\mathsf{Real}^{\uparrow}$ *consumer or a completion-facing consumer factors through exactly the displayed rows*

$$D, S, R, L, M, A, T, E, H, C, P, N$$

of Definition 1180.1. Here D is the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source, M is the* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *refinement row, A, T, E are the selector, cofinal-tail, and completion-seal handoff rows, and L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The rows H, C, P, N are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows for the same route.*

Consequently no Real or Completion handoff may read a quotient stream, selected host limit, host real equality proof, countable-choice selector, detached completion witness, or ambient completeness principle outside those coordinates.

Proof. Project the carrier of Definition 1180.1. Its coordinates display the dyadic ledger, stream schedule, regular rational source, Real seal, modulus refinement, selector, cofinal-tail agreement, completion-seal handoff, transport, continuation, package, and local naming rows.

Apply Definition 1180.2. Source-window exposure forces D, S, R, M before selector access, selector and cofinal-tail stability keep A, T on the same route, and completion-seal handoff places E before the terminal seal row L.

Finally use Definition 1180.3. Any accepted Real or Completion read outside the displayed coordinates would be an alternate route through an absent source. Since the forbidden objects have no carrier row and no local certificate coordinate, the listed rows exhaust the reusable handoff surface. □

Theorem 1180.5 (Regular Cauchy completion frontier scoped dependency route)**.** *For an accepted* $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ *packet*

$$F = (D, S, R, L, M, A, T, E, H, C, P, N),$$

the scoped dependency route is exactly the following finite surface: $\mathsf{DyadicRatCore}^{\uparrow}$ *through D,* $\mathsf{StreamName}^{\uparrow}$ *through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *through R,* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *through M,* $\mathsf{Real}^{\uparrow}$ *through L, the diagonal-selector row A, the cofinal-tail row T, the completion-seal handoff row E, componentwise* hsame *through H,* Cont *replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}}$ *row N.*

No quotient stream, selected limit, host equality, countable-choice selector, ambient completeness principle, metric-completeness principle, or bridge row belongs to the scoped dependency route.

Proof. Project the carrier of Definition 1180.1. The displayed coordinates name the same sibling anchors cited at the chapter entry: chapter 291, chapter 126, chapter 301, chapter 885, and chapter 38.

Use the NameCert obligations of Definition 1180.2. They force source-window exposure through D, S, R, M, keep the selector and cofinal-tail rows A, T on the same hsame and Cont route, and place the completion-seal handoff row E before the Real seal row L.

The exhaustion and non-escape clauses of Definition 1180.4 and Definition 1180.3 remove every alternate source. What remains is precisely the listed finite dependency route, with no coordinate for quotient streams, selected limits, host equality, choice, ambient or metric completeness, or bridge data. □

Theorem 1180.6 (Regular Cauchy completion frontier obligation closure)**.** *For* $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$, *the carrier row, source-window exposure, selector and cofinal-tail stability, completion-seal handoff, and ledger non-escape obligations are all closed by the displayed finite packet*

$$D, S, R, L, M, A, T, E, H, C, P, N.$$

The packet therefore gives an obligation-closed Real and Completion frontier surface for accepted consumers, with the carrier alignment tracked by the existing TasteGate marker `BEDC.Derived.RegularCauchyCom`

Proof. The carrier row is exactly Definition 1180.1: it displays the dyadic ledger, finite observation schedule, regular rational source, Real seal, modulus refinement, diagonal selector, cofinal-tail agreement, completion-seal handoff, transport, continuation, package, and local certificate coordinates.

The five obligation rows are supplied by Definition 1180.2. Carrier admission, source-window exposure, selector and cofinal-tail stability, completion-seal handoff, and ledger non-escape are all stated for the same packet $D, S, R, L, M, A, T, E, H, C, P, N$.

The boundary is closed for accepted consumers by Definition 1180.3 and Definition 1180.4. The first excludes alternate routes through absent quotient, host-limit, equality, choice, and ambient-completeness coordinates; the second says every accepted Real or Completion read factors through exactly the displayed rows. The existing TasteGate marker records the Lean-side carrier alignment for that same singleton carrier surface. □

Theorem 1180.7 (Regular Cauchy completion frontier real terminal cofinal route)**.** *For any accepted* $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ *packet*

$$F = (D, S, R, L, M, A, T, E, H, C, P, N),$$

every public $\mathsf{Real}^{\uparrow}$ *terminal seal read through the frontier factors through the finite source, selector, cofinal-tail, and completion handoff route*

$$D, S, R, M, A, T, E$$

before the terminal seal row L *is consumed. The rows* H, C, P, N *are the only support rows for this handoff:* H *supplies componentwise* hsame *transport,* C *supplies* Cont *replay,* P *supplies* Pkg *provenance, and* N *supplies the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}}$ *row.*

Conversely, any displayed packet with the rows D, S, R, M, A, T, E, L *and no support rows beyond* H, C, P, N *repacks as the same frontier-mediated public* $\mathsf{Real}^{\uparrow}$ *terminal seal route. The carrier alignment for this route is the existing TasteGate marker* `BEDC.Derived.RegularCauchyCompletionFrontierUp.`

Proof. Apply Definition 1180.5. It identifies the finite route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusRefinement}^{\uparrow}$, the selector row A, the cofinal-tail row T, the completion-seal row E, and the terminal $\mathsf{Real}^{\uparrow}$ seal row L.

Apply Definition 1180.4. Any public Real or Completion read through the frontier must use exactly the displayed coordinates, so the terminal seal cannot be read before the source, refinement, selector, cofinal-tail, and handoff rows have been traversed.

Apply Definition 1180.3. Since quotient streams, selected host limits, host equality, choice selectors, detached completion witnesses, and ambient completeness principles have no carrier row, the only support rows left for the terminal handoff are H, C, P, N.

For the converse, project the displayed packet back into the carrier of Definition 1180.1. The same rows supply the source window, cofinal tail, completion handoff, transport, continuation, provenance, and local naming coordinates, and the TasteGate marker `BEDC.Derived.RegularCauchyCompletionF` records the singleton carrier alignment for the resulting frontier-mediated terminal seal route. □

Theorem 1180.8 (Regular Cauchy completion frontier terminal seal correspondence)**.** *An accepted* $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ *packet determines exactly the public finite-window* $\mathsf{Real}^{\uparrow}$ *terminal seal boundary obtained by the composed route through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusRefinement}^{\uparrow}$, *the selector row A, the cofinal-tail row T, the completion handoff row E, and the terminal seal row L. Its only support rows are H, C, P, N, carrying componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}}$ *row.*

Conversely, any consumer of that public terminal boundary factors through the displayed rows D, S, R, M, A, T, E, L together with the support rows H, C, P, N. No quotient stream, selected host limit, host equality proof, countable-choice selector, ambient completeness principle, metric-completeness principle, or bridge datum belongs to this boundary.

Proof. Start with the accepted frontier packet. By Definition 1180.4, every public Real or Completion read through the frontier is exhausted by the displayed rows $D, S, R, L, M, A, T, E, H, C, P, N$.

The route part of that exhaustion is identified by Definition 1180.5. It places the public finite-window boundary through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusRefinement}^{\uparrow}$, the selector row A, the cofinal-tail row T, the completion handoff row E, and the terminal seal row L, with H, C, P, N as the transport, continuation, provenance, and local certificate support.

Use Definition 1180.6 to close the carrier, source-window, selector, cofinal-tail, handoff, and non-escape obligations on the same finite packet. Then apply Definition 1180.7 to read the route as the terminal $\mathsf{Real}^{\uparrow}$ seal boundary rather than as a detachable completion object.

For the converse, any consumer of the displayed terminal boundary is already a public Real or Completion read through the accepted frontier. The source-exhaustion theorem forces it through D, S, R, M, A, T, E, L, and the scoped dependency route leaves only H, C, P, N as support rows.

The exclusions follow from the non-escape clauses used in those theorems. Quotient streams, selected limits, host equality, countable choice, ambient completeness, metric completeness, and bridge data have no carrier coordinate and no local NameCert row, so they cannot be part of the public terminal seal boundary. □

Theorem 1180.9 (Regular Cauchy completion frontier CofinalModulusSeal handoff)**.** *Every accepted* $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ *terminal seal route factors through the* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *cofinal tail-budget, tail-modulus,* $\mathsf{Real}^{\uparrow}$*-window budget,* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows before the public* $\mathsf{Real}^{\uparrow}$ *seal is read.*

Equivalently, the frontier route

$$D, S, R, M, A, T, E, L, H, C, P, N$$

is accepted only when its cofinal-tail and completion-seal coordinates admit the already checked factorization surface `BEDC.Derived.CofinalModulusSealUp.CofinalModulusSealRegSeqRatWindowFactorizatio` *No quotient stream, selected host limit, host equality proof, countable-choice selector, ambient completeness principle, metric-completeness principle, or bridge datum is introduced by this handoff.*

Proof. Start with an accepted frontier terminal seal route. By Definition 1180.4, every Real or Completion read is exhausted by the displayed rows $D, S, R, L, M, A, T, E, H, C, P, N$.

Use Definition 1180.5 to read those rows as the concrete dependency surface through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusRefinement}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, the selector row, the cofinal-tail row, the completion-seal row, componentwise hsame, Cont, Pkg, and the local $\mathsf{NameCert}$ row.

Apply Definition 1180.8. It identifies the same route as the public finite-window $\mathsf{Real}^{\uparrow}$ terminal seal boundary, so the terminal seal is not a detachable limit object.

Now compose that boundary with the checked CofinalModulusSeal route `BEDC.Derived.CofinalModulusSealU` The CofinalModulusSeal packet supplies the cofinal tail-budget, tail-modulus, and $\mathsf{Real}^{\uparrow}$-window budget rows over the same $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ sources, with the same hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

The exclusions are inherited from the frontier non-escape and scoped-route clauses. Quotient streams, selected host limits, host equality, countable choice, ambient completeness, metric completeness, and bridge data have no coordinate in either the frontier carrier or the CofinalModulusSeal factorization surface, so the public Real seal can only be read through the displayed handoff. □

Theorem 1180.10 (Regular Cauchy completion frontier Real four-face status factorization)**.** *Every accepted* $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ *packet whose terminal seal route factors through* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *presents exactly the four local status faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *used by Definition 38.815.*

The handoff supplies no route-level formalstatus row, aggregate leantarget row, aggregate bridge row, quotient stream, selected host limit, countable-choice row, metric-completeness datum, or ambient completeness claim. Its status surface is only the local four-face surface carried along the frontier terminal seal route.

Proof. First read the accepted packet through Definition 1180.8. The terminal seal boundary is the finite route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, the frontier source window, the cofinal-tail row, the completion handoff row, and the terminal $\mathsf{Real}^{\uparrow}$ seal, with only the displayed transport, continuation, package, and local NameCert support.

Next apply Definition 1180.9. The cofinal-tail and completion-seal coordinates factor through $\mathsf{CofinalModulusSeal}^{\uparrow}$ without adding a quotient stream, selected host limit, host equality proof, countable-choice selector, ambient completeness principle, metric-completeness principle, or bridge datum.

Finally compose this route with Definition 38.815. The Real terminal status theorem reads every formalstatus, leantarget, and bridgestatus coordinate from the four local faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Since the frontier handoff and the CofinalModulusSeal factorization introduce no aggregate coordinate, the accepted packet presents precisely that four-face status surface and no route-level completion or bridge claim. □

Theorem 1180.11 (Regular Cauchy completion frontier finite-cover support removal obstruction)**.** *Let* $\{Q_i\}_{i\in I}$ *be an accepted finite cover of* $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ *terminal seal routes. Suppose the accepted local sections and overlaps agree on the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyModulusRefinement}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, selector, cofinal-tail, handoff,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}}$ *rows. If one displayed local support row is deleted from some member* Q_j*, then the cover-descent frontier packet cannot present the same* $\mathsf{Real}^{\uparrow}$ *terminal seal boundary.*

The obstruction is carried only by the displayed BEDC rows. Quotient streams, selected host limits, host equality proofs, countable choice, metric completeness, ambient $\mathsf{Real}^{\uparrow}$ *completeness,*

aggregate formalstatus rows, and bridge rows cannot restore the deleted support row or recover the same completion-frontier boundary.

Proof. First restrict the cover to the displayed $\mathsf{StreamName}^{\uparrow}$ terminal support surface. The hypotheses give the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert support rows on the accepted local sections and overlaps, so Definition 126.665 applies to the deleted local support row.

That obstruction says the descended StreamName terminal support cannot still present the same $\mathsf{Real}^{\uparrow}$ seal-visible source. It also rules out quotient stream equality, selected host limits, countable choice, metric-completeness data, aggregate formalstatus rows, bridge rows, ambient $\mathsf{Real}^{\uparrow}$ completeness, and replacement selectors as substitute coordinates.

Now transport the obstruction to the completion frontier. By Definition 1180.8, the accepted frontier boundary is exactly the public finite-window $\mathsf{Real}^{\uparrow}$ terminal seal obtained from the route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusRefinement}^{\uparrow}$, the selector row, the cofinal-tail row, the completion handoff row, and the terminal seal row, with only H, C, P, N as support.

Apply Definition 1180.9 to keep the cofinal-tail and completion-seal coordinates on the same $\mathsf{CofinalModulusSeal}^{\uparrow}$ handoff surface. Then use Definition 1180.10 to read the status data only through the four local faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The frontier packet therefore has no separate completion coordinate through which the missing row can reappear. Host equality proofs are excluded with the same force: the terminal-seal correspondence and CofinalModulusSeal handoff give them no route coordinate and no local support row. Since the StreamName finite-cover obstruction has already removed the common terminal support and the frontier correspondence reads the boundary through that support, the cover-descent frontier packet cannot present the same $\mathsf{Real}^{\uparrow}$ terminal seal boundary after the row is deleted. □

Theorem 1180.12 (Regular Cauchy completion frontier cofinal-tail support uniqueness)**.** *Let*

$$F = (D, S, R, L, M, A, T, E, H, C, P, N)$$

and

$$F' = (D', S', R', L', M', A', T', E', H', C', P', N')$$

be accepted $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ *packets presenting the same public finite-window* $\mathsf{Real}^{\uparrow}$ *terminal seal boundary. If both terminal seal routes factor through the same* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *cofinal tail-budget, then the consumer-visible cofinal-tail support is exactly the displayed surface*

$$D, S, R, M, A, T, E, H, C, P, N.$$

Equivalently, F' presents the same boundary only by matching the dyadic tolerance ledger, stream schedule, regular source, refinement, selector, cofinal-tail, completion handoff, transport, continuation, provenance, and local NameCert rows on that surface. No quotient stream, selected host limit, host equality proof, countable-choice selector, ambient completeness principle, metric-completeness datum, aggregate status row, or bridge row can witness another same-seal route.

Proof. First read both accepted packets through Definition 1180.8. The common public terminal boundary is not a host limit or quotient object; it is the finite route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusRefinement}^{\uparrow}$, the selector row, the cofinal-tail row, the completion handoff row, and the terminal $\mathsf{Real}^{\uparrow}$ seal, with only the displayed transport, continuation, package, and local NameCert support.

Next apply Definition 1180.9. Since the two routes factor through the same $\mathsf{CofinalModulusSeal}^{\uparrow}$ cofinal tail-budget, their tail-budget, tail-modulus, and $\mathsf{Real}^{\uparrow}$-window budget coordinates are read on the same RegSeqRat, StreamName, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert surface.

Use Definition 1180.10 to keep the status information local to $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Thus the shared terminal seal has no aggregate formalstatus, leantarget, or bridge coordinate through which F' could present a different consumer-visible tail support.

Finally apply Definition 1180.11. Deleting or replacing any row among $D, S, R, M, A, T, E, H, C, P, N$ destroys the same terminal seal boundary, even under accepted cover descent. Therefore the second packet can present the same $\mathsf{Real}^{\uparrow}$ terminal seal over the same $\mathsf{CofinalModulusSeal}^{\uparrow}$ handoff only by matching that displayed support surface, and the listed forbidden objects have no coordinate from which to supply another route. □

Falsifiable prediction: An accepted frontier consumer that exports a $\mathsf{Real}^{\uparrow}$ limit without a displayed cofinal-tail row and completion-seal handoff row refutes the packet.

Independence witness: real, streamname, regseqrat, dyadicratcore, cauchymodulusrefinement: no sibling is bijective because RegularCauchyCompletionFrontierUp binds Real sealing, finite observation, regular rational readback, dyadic tolerance, modulus refinement, diagonal selection, cofinal-tail agreement, and completion handoff in one certificate. RealUp has endpoint seals without source-window selectors; StreamNameUp has windows without regular rational readback; RegSeqRatUp has regular sources without Real seals; DyadicRatCoreUp has tolerances without completion handoff; CauchyModulusRefinementUp has source-window refinement without the frontier's cofinal-tail and Real-seal package.

The Lean follow-up site `lean4/BEDC/Derived/RegularCauchyCompletionFrontierUp/TasteGate.lean` must provide Nontrivial and FieldFaithful instances for $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$, together with a carrier-alignment theorem named `BEDC.Derived.RegularCauchyCompletionFrontierUp.RegularCauchyC`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}$ packet is generated from displayed DyadicRatCore, StreamName, RegSeqRat, RealUp, CauchyModulusRefinement, diagonal-selector, cofinal-tail, completion-seal, transport, continuation, package, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1180.5 binds the route through DyadicRatCore, StreamName, RegSeqRat, CauchyModulusRefinement, RealUp, selector, cofinal-tail, seal handoff, hsame, Cont, Pkg, and local NameCert rows, while Definition 1180.6 keeps the finite obligation surface closed and `BEDC.Derived.RegularCauchyCompletionFrontierUp.RegularCauchyCompletio` witnesses carrier alignment for `BEDC.Derived.RegularCauchyCompletionFrontierUp.taste_gate`.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionFrontier}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RegularCauchyCompletionFrontierUp.RegularCauchyCompletionFrontierTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not prove bridge checking, uniqueness of Real limits, quotient completion, countable choice, host real equality, or ambient completeness.

Upgrade path: Bridge checking remains outside this chapter.

Chapter 1181

A Concrete Naming Certificate for $\mathsf{DomainTruthCertificate}^{\uparrow}$

The $\mathsf{DomainTruthCertificate}^{\uparrow}$ packet realizes the domain-indexed truth surface of section 9414.70 as a finite BEDC NameCert carrier. It sits beside certified physical truth from chapter 1130, open fit from chapter 1132, synthesis sealing from chapter 1140, final-synthesis ledgering from chapter 1178, and failure-surface exposure from chapter 1163. Those siblings supply fit, open continuation, seal, ledger, and defeat surfaces; this packet binds the displayed domain row before any truth export is accepted.

Definition 1181.1 (DomainTruthCertificate carrier)**.** *A* $\mathsf{DomainTruthCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (T, U, B, A, C, O, F, H, R, P, N)$$

with the following displayed rows:

1. *T is the certified truth row naming the local claim, source traces, and reality-facing signature admitted by the packet.*
2. *U is the domain row recording the observation bundle, approximation tower, continuation class, and observer configuration over which the claim is read.*
3. *B is the open-fit row recording the finite fit comparison and the boundary at which the domain remains open.*
4. *A is the observer-invariance row recording the anchor or observer transport under which the claim remains publicly readable.*
5. *C is the continuation row recording the permitted reuse and replay route inside the displayed domain.*
6. *O is the failure-surface row naming domain exits, classifier mismatches, finite defeats, and later observations that can stop the export.*
7. *F is the transport row recording componentwise* hsame *preservation for the truth, domain, open-fit, invariance, continuation, failure, replay, provenance, and local-name rows.*
8. *H is the displayed* Cont *replay row through the same finite packet.*
9. *R is the provenance row recording source, tower, classifier, ledger, sibling-certificate, and construction references.*

10. *P is the package row over* BHist, hsame, Cont, Pkg, NameCert, *and the cited sibling packets.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DomainTruthCertificate}^{\uparrow}}$ *row binding the displayed domain-indexed truth packet.*

The carrier has no coordinate for final truth, model–reality identity, host truth, unbounded observation, hidden observer privilege, or truth export outside the displayed domain row.

Lean4 ✓ `BEDC.Derived.DomainTruthCertificateUp.taste gate`
Lean4 ✓ `BEDC.Derived.DomainTruthCertificateUp.DomainTruthCertificateTasteGate single carrier alignment`

Theorem 1181.2 (DomainTruthCertificate NameCert obligations)**.** *For the carrier of Definition 1181.1, the local* $\mathsf{NameCert}_{\mathsf{DomainTruthCertificate}^{\uparrow}}$ *surface consists exactly of carrier admission, domain-scope display, open-fit display, observer-invariance display, failure-surface display, componentwise transport, displayed replay, provenance, and local naming through N.*

Proof. Project the carrier $D = (T, U, B, A, C, O, F, H, R, P, N)$. The rows T, U, B, A, C, O expose the certified truth claim, the domain scope, the open-fit boundary, the observer-invariant route, the continuation replay scope, and the failure surface.

Read the structural rows. Transport through F preserves each displayed component, replay through H keeps the consumer inside the same finite route, provenance through R records the source and sibling dependencies, and P, N package and locally name the certificate.

Since no additional coordinate is available in the carrier, these rows exhaust the local NameCert surface. A domain-truth export that omits one row is only a projection, not an accepted $\mathsf{DomainTruthCertificate}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.DomainTruthCertificateUp.DomainTruthCertificateNameCertObligations`

Theorem 1181.3 (DomainTruthCertificate non-escape)**.** *An accepted* $\mathsf{DomainTruthCertificate}^{\uparrow}$ *packet excludes final truth, model–reality identity, host truth, unbounded observation, and domain leakage. Any export that asserts validity outside the displayed domain row U, or reads truth from a coordinate absent from*

$$T, U, B, A, C, O, F, H, R, P, N$$

is rejected by the local $\mathsf{NameCert}_{\mathsf{DomainTruthCertificate}^{\uparrow}}$ *surface.*

Lean4 ✓ `BEDC.Derived.DomainTruthCertificateUp.DomainTruthCertificateUp nonescape`

Proof. Use the carrier of Definition 1181.1. The truth row T is always read together with the domain row U, the open-fit row B, the observer-invariance row A, the continuation row C, and the failure row O.

The structural rows cannot widen the domain. Transport through F preserves displayed components, replay through H consumes the same route, provenance through R records sources already named in the packet, and P, N package and name the same finite certificate.

Thus final truth, model–reality identity, host truth, unbounded observation, and domain leakage would require a coordinate not present in the packet. The accepted route certifies domain truth only within the displayed finite surface. □

Theorem 1181.4 (DomainTruthCertificate sibling independence)**.** *The* $\mathsf{DomainTruthCertificate}^{\uparrow}$ *packet is not bijective to* $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, $\mathsf{RealityConstrainedSynthesisSeal}^{\uparrow}$, $\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}$, *or* $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$. *Each sibling supplies a required surface, but none alone carries the displayed domain row tying truth, continuation, observer, failure, transport, replay, provenance, package, and local naming into one finite certificate.*

Proof. Compare the displayed carrier with the sibling roles. $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ supplies the certified truth read, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$ supplies finite open fit, $\mathsf{RealityConstrainedSynthesisSeal}^{\uparrow}$ supplies the synthesis seal, $\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}$ supplies ledger discipline, and $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$ supplies the defeat surface.

The row U is the separating coordinate. It binds the observation bundle, approximation tower, continuation class, and observer configuration as the domain of the truth read, and the rows C, F, H, R, P, N replay, transport, source, package, and name that same domain-indexed packet.

Therefore no listed sibling is bijective to $\mathsf{DomainTruthCertificate}^{\uparrow}$. Removing the domain row erases the certificate's scope, while replacing any sibling with the domain packet erases the sibling's specialized surface. □

Lean4 ✓ `BEDC.Derived.DomainTruthCertificateUp.DomainTruthCertificateUp sibling independence`

Falsifiable prediction: A domain-truth export that omits the domain row or asserts final validity over all future observations is not accepted by the local NameCert.

Independence witness: certifiedphysicaltruth, realityconstrainedopenfit, realityconstrainedsynthesisseal, realityconstrainedfinalsynthesisledger, realityconstrainedfailuresurface: no sibling is bijective because DomainTruthCertificateUp adds the displayed certified-domain row tying truth, continuation, observer, failure, transport, replay, provenance, and local naming into one carrier.

The checked TasteGate carrier-alignment target records that the nontriviality and field-faithful rows are present for the displayed carrier surface.

For the paper-side standard bridge schema, the displayed domain row U remains mandatory for every standard truth export. The final-truth, host-truth, and unbounded-observation readings are still refused: a bridge-facing consumer may transport and replay only the certified truth row, the domain row, open-fit and observer rows, continuation and failure rows, provenance, package data, and local naming already displayed by the carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{DomainTruthCertificate}^{\uparrow}}$.

Constructive story: A $\mathsf{DomainTruthCertificate}^{\uparrow}$ packet is generated from a certified truth row, displayed domain row, open-fit row, observer-invariance row, continuation row, failure surface, componentwise transport, replay, provenance, package data, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DomainTruthCertificate}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1181.1, Definition 1181.2, Definition 1181.3, Definition 1181.4, the falsifiable prediction, the independence witness, and the TasteGate markers expose a public finite domain-truth certificate with carrier, obligation, nonescape, sibling independence, domain-scope, open-fit, observer-invariance, failure-surface, transport, replay, provenance, package, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DomainTruthCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not claim Lean verification, bridge checking, final truth, model–reality identity, host truth, unbounded observation, or truth export outside the displayed domain row.

Upgrade path: Only Lean bridge checking remains on the verification axis.

Chapter 1182

A Concrete Naming Certificate for $\mathsf{PredictiveDescent}^{\uparrow}$

The $\mathsf{PredictiveDescent}^{\uparrow}$ packet realizes the predictive reuse and descent condition of section 9414.25 as a finite BEDC NameCert surface. It sits beside the physical-induction packet of chapter 1135, the stability seal of chapter 1139, the law certificate of chapter 1155, the open-fit packet of chapter 1137, and the failure surface of chapter 1163. Those siblings supply induction, stability, law, fit, and failure-surface rows; this packet isolates the prediction-operation descent row between observed and continuation classifiers.

Definition 1182.1 (PredictiveDescent carrier)**.** *A* $\mathsf{PredictiveDescent}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, O, K, A, S, X, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite-fit row recording the observed history, fitted model, comparison bundle, and visible signature that admitted the source classifier.*
2. *O is the observed-classifier row recording the classifier under which the fitted model was formed.*
3. *K is the continuation-classifier row recording the classifier used after predictive reuse over the displayed continuation class.*
4. *A is the prediction-operation row naming the operation whose output is consumed by the continuation classifier.*
5. *S is the stability-scope row recording the continuation class, reuse license, and sibling stability certificate.*
6. *X is the failure-surface row recording classifier mismatches, finite defeats, and continuations on which descent is not licensed.*
7. *H is the componentwise* hsame *transport row preserving finite fit, observed classifier, continuation classifier, prediction operation, stability scope, and failure surface.*
8. *C is the displayed* Cont *replay row through the same predictive-descent packet.*
9. *P is the package row over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *and the sibling packets cited above.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PredictiveDescent}^{\uparrow}}$ *row binding the displayed predictive-descent packet.*

The carrier has no coordinate for representative-dependent prediction, unbounded future success, final empirical confirmation, hidden model state, host real equality, or a continuation classifier outside the displayed row K.

Lean4 ✓ `BEDC.Derived.PredictiveDescentUp.PredictiveDescentTasteGate single carrier alignment`

Theorem 1182.2 (PredictiveDescent NameCert obligations)**.** *For the carrier of Definition 1182.1, the local* $\mathsf{NameCert}_{\mathsf{PredictiveDescent}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed tuple $F, O, K, A, S, X, H, C, P, N$;*
2. *finite-fit exposure through F together with observed-classifier exposure through O;*
3. *prediction-operation descent from O through A to the continuation classifier K;*
4. *stability-scope and failure-surface exposure through S and X;*
5. *structural transport, replay, provenance, package, and local naming through H, C, P, N.*

Proof. Project the carrier $D = (F, O, K, A, S, X, H, C, P, N)$. The first two obligations read the finite-fit and observed-classifier data from F and O.

The descent obligation is the separating row. It records that the prediction operation A is accepted only when its output is readable by the continuation classifier K from the observed classifier O.

The stability and failure rows then bound the route. The row S fixes the continuation class and reuse license, while X records the continuations and classifier mismatches that stop the predictive export.

Finally the structural rows H, C, P, N transport, replay, package, and locally name the same finite packet. Since the carrier has no other coordinates, these five rows exhaust the local NameCert obligation surface. □

Theorem 1182.3 (PredictiveDescent stability scope)**.** *An accepted* $\mathsf{PredictiveDescent}^{\uparrow}$ *packet licenses predictive reuse only over the displayed stability scope S and only through the prediction operation A descending from the observed classifier O to the continuation classifier K. A consumer that changes the continuation class, replaces either classifier, or reads a different prediction operation leaves the accepted packet surface.*

Lean4 ✓ `BEDC.Derived.PredictiveDescentUp.PredictiveDescentStabilityScope`

Proof. Use the obligation surface of Definition 1182.2. The stability row S is part of the same local certificate as O, K, A, so the continuation classifier cannot be read independently of the displayed stability scope.

The transport and replay rows do not widen the scope. They preserve and replay the listed components of the same finite packet, while the package and local name authenticate only that packet.

Therefore the accepted reuse is scoped by S and by the descent route $O \to A \to K$. Changing the continuation class, either classifier, or the prediction operation requires a coordinate absent from the carrier. □

Theorem 1182.4 (PredictiveDescent non-escape)**.** *No accepted* $\mathsf{PredictiveDescent}^{\uparrow}$ *packet exports representative-dependent prediction, unbounded future success, final empirical confirmation, hidden model state, host real equality, or a continuation classifier outside the displayed row K. Any packet whose prediction operation respects finite fit but fails descent from the observed classifier to the continuation classifier is rejected by the local* $\mathsf{NameCert}_{\mathsf{PredictiveDescent}^{\uparrow}}$ *surface.*

Proof. Read the carrier of Definition 1182.1. The only prediction route available to a consumer is the displayed path through finite fit, observed classifier, prediction operation, continuation classifier, stability scope, and failure surface.

Apply the NameCert obligations. They require the descent row from O through A to K before the continuation classifier is accepted, and they keep the failure surface visible as X.

Finally use the absence of additional coordinates. Representative-dependent prediction, unbounded future success, final empirical confirmation, hidden model state, host real equality, and off-row continuation classifiers are not entries of D. A finite-fit-preserving operation that does not descend from O to K therefore lacks the required local naming certificate. □

Falsifiable prediction: A packet whose prediction operation respects finite fit but fails descent from the observed classifier to the continuation classifier is rejected by the PredictiveDescentUp classifier.

Independence witness: realityconstrainedphysicalinduction, physicalinductionstabilityseal, lawcertificate, openfitpacket, realityconstrainedfailuresurface: none is bijective because PredictiveDescentUp isolates the prediction-operation descent row between observed and continuation classifiers, while the siblings supply induction, stability, law, fit, or failure-surface rows.

Lean follow-up must provide `Nontrivial PredictiveDescentUp` and `FieldFaithful PredictiveDescentUp` instances in `lean4/BEDC/Derived/PredictiveDescentUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{PredictiveDescent}^{\uparrow}}$.

Constructive story: A $\mathsf{PredictiveDescent}^{\uparrow}$ packet is generated from finite fit, observed classifier, continuation classifier, prediction operation, stability scope, failure surface, componentwise transport, continuation replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PredictiveDescent}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1182.1, Definition 1182.2, Definition 1182.3, and Definition 1182.4 bind the finite predictive-descent carrier, five-row NameCert obligation surface, scoped reuse theorem, and non-escape theorem.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PredictiveDescent}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not claim Lean verification, bridge checking, unbounded future success, final empirical confirmation, representative-dependent prediction, or a continuation classifier outside the displayed packet.

Upgrade path: Obligation closure requires checked carrier admission, finite-fit exposure, classifier descent, stability-scope exposure, failure-surface exposure, transport, replay, provenance, local naming, TasteGate nontriviality, and field faithfulness for $F, O, K, A, S, X, H, C, P, N$.

Chapter 1183

A Concrete Naming Certificate for $\mathsf{ContinuationCountermodel}^{\uparrow}$

The $\mathsf{ContinuationCountermodel}^{\uparrow}$ packet realizes the open-continuation refusal surface of section 9414.25 as a finite counter-continuation certificate. It sits beside the physical-induction packet of chapter 1135, the stability seal of chapter 1139, the law certificate of chapter 1155, the open-fit packet of chapter 1132, and the failure surface of chapter 1163. Those chapters supply fit, reuse, law, and defeat rows; this packet stores the single finite continuation route where predictive reuse is refused.

Definition 1183.1 (ContinuationCountermodel carrier)**.** *A* $\mathsf{ContinuationCountermodel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (F, U, M, O, K, S, E, H, R, P, N)$$

with the following displayed rows:

1. *F is the finite-fit row recording the observed prefix, classifier, and model agreement used by the proposed reuse claim;*
2. *U is the admissible-continuation row naming the continuation class being tested;*
3. *M is the model-prediction row exported from the fitted model along U;*
4. *O is the observed-continuation row recorded on the same continuation route;*
5. *K is the mismatch and counter-row comparing M with O at the displayed continuation;*
6. *S is the stability-certificate row whose reuse claim is being tested;*
7. *E is the failure-surface row recording the displayed defeat of predictive reuse;*
8. *H records componentwise* hsame *transport for $F, U, M, O, K, S, E, R, P, N$;*
9. *R is the displayed replay route tying the finite fit, prediction, observed continuation, mismatch, stability basis, and failure surface into one counter-continuation;*
10. *P is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *and the sibling physical-induction, stability-seal, law-certificate, open-fit, and failure-surface rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuationCountermodel}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying all eleven rows. It has no coordinate for final empirical truth, global model failure, unbounded future history, hidden continuation choice, or predictive reuse beyond the counter-continuation route in R.

Lean4 (definition) BEDC.Derived.ContinuationCountermodelUp.ContinuationCountermodelUp
Lean4 ✓ BEDC.Derived.ContinuationCountermodelUp.ContinuationCountermodelTasteGate single carrier alignment

Theorem 1183.2 (ContinuationCountermodel NameCert obligations)**.** *For the carrier of Definition 1183.1, the local* $\mathsf{NameCert}_{\mathsf{ContinuationCountermodel}^{\uparrow}}$ *surface is exhausted by five obligation rows:*

1. *carrier admission for* $C = (F, U, M, O, K, S, E, H, R, P, N)$*;*
2. *finite-fit and admissible-continuation exposure through* F *and* U*;*
3. *prediction and observation comparison through* M, O, K*;*
4. *stability-certificate and failure-surface exposure through* S *and* E*;*
5. *componentwise transport, replay, provenance, and local naming through* H, R, P, N*.*

Every accepted counter-continuation must display these rows before it can defeat predictive reuse for the stated continuation class.

Proof. Project the carrier of Definition 1183.1. The row list displays the finite fit, admissible continuation, model prediction, observed continuation, mismatch row, stability certificate, failure surface, transport, replay, provenance, and local name.

The first two obligations bind the source of the reuse claim: F supplies only finite fit, and U names only the continuation class under test. They do not export a global future-success or global future-failure claim.

The comparison obligation is carried by M, O, K. The model prediction and observed continuation are both read on the displayed route, and K records the separating row that blocks predictive reuse for that continuation.

The stability and failure rows S, E then place the mismatch against the exact certificate being tested. Transport, replay, provenance, and local naming through H, R, P, N keep the countermodel inside the same finite packet. Since no further coordinate is present, the five rows exhaust the local NameCert surface. □

Lean4 ✓ BEDC.Derived.ContinuationCountermodelUp.ContinuationCountermodelNameCertObligations

Theorem 1183.3 (ContinuationCountermodel predictive-reuse defeat)**.** *An accepted* $\mathsf{ContinuationCountermodel}^{\uparrow}$ *packet rejects predictive reuse for the displayed continuation class whenever* F *matches the finite fit row,* U *admits the tested continuation, and the counter-row* K *records a mismatch between the model prediction* M *and the observed continuation* O*. The rejection is local to the route* R *and does not assert global model failure outside the displayed packet.*

Proof. Begin with the NameCert obligations of Definition 1183.2. They require $F, U, M, O, K, S, E, H, R, P, N$ to be read together before a counter-continuation is accepted.

The rows F and U keep the source finite fit and continuation class visible. Thus the packet does not reject the model merely because a different continuation or a different finite-fit row exists.

The rows M, O, K supply the defeating comparison. Once K displays the mismatch between the prediction and the observed continuation on the same route, the stability certificate S cannot be reused as a predictive license for that continuation class.

Finally E, H, R, P, N localize the defeat to the displayed failure surface, transport, replay route, provenance, and local name. The packet therefore defeats predictive reuse on that route without claiming a final oracle about every possible continuation. □

Lean4 ✓ BEDC.Derived.ContinuationCountermodelUp.ContinuationCountermodelUp root replay transport

Theorem 1183.4 (ContinuationCountermodel replay non-escape)**.** *Every consumer of an accepted* $\mathsf{ContinuationCountermodel}^{\uparrow}$ *packet must read the counter-continuation through*

$$F, U, M, O, K, S, E, H, R, P, N.$$

No consumer may detach the mismatch row from the finite fit, admissible continuation, stability certificate, failure surface, replay route, provenance, or local naming row and then treat it as an unbounded physical-law refutation.

Proof. Use the carrier definition. The mismatch row K is one coordinate of the finite packet, not an independent global falsifier.

Apply Definition 1183.3. The predictive-reuse rejection depends on F, U, M, O, K, S, E being read along the replay route R.

The transport and provenance rows H, P preserve that same packet, and N names it locally. Because no coordinate exports unbounded physical-law refutation, hidden continuation choice, or global model failure, a consumer that detaches K from the displayed packet leaves the accepted surface. □

The later Lean file `lean4/BEDC/Derived/ContinuationCountermodelUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ ContinuationCountermodel}^{\uparrow}$ and $\mathsf{FieldFaithful\ ContinuationCountermodel}^{\uparrow}$ instances preserving $F, U, M, O, K, S, E, H, R, P, N$.

Falsifiable prediction: A continuation packet with matching finite fit but a displayed mismatch row is rejected as predictive reuse for that continuation class.

Independence witness: realityconstrainedphysicalinduction, physicalinductionstabilityseal, lawcertificate, realityconstrainedfailuresurface, realityconstrainedopenfit: none is bijective because ContinuationCountermodelUp stores the single counter-continuation route tying finite fit, prediction, observed continuation, mismatch row, stability basis, failure surface, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuationCountermodel}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ContinuationCountermodel}^{\uparrow}$ packet is generated from finite fit, admissible continuation, model prediction, observed continuation, mismatch, stability certificate, failure surface, componentwise transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuationCountermodel}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1183.1, Definition 1183.2, Definition 1183.3, Definition 1183.4, the falsifiable prediction, the independence witness, and the TasteGate row `BEDC.Derived.ContinuationCountermodelUp.ContinuationCountermodelTasteGate_sing` bind the mature finite counter-continuation package: carrier, NameCert obligations, predictive-reuse defeat, replay non-escape, nontriviality witness, and field-faithful row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuationCountermodel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not claim Lean verification, bridge checking, global model failure, total physical-law refutation, final empirical truth, or continuations outside the displayed route.

Upgrade path: Scoped closure requires exact BEDC source rows for finite fit, admissible continuation, prediction, observation, mismatch, stability, failure surface, transport, replay, provenance, local naming, TasteGate nontriviality, and field faithfulness for $F, U, M, O, K, S, E, H, R, P, N$.

Chapter 1184

A Concrete Naming Certificate for RealityConstrainedModelErrorBudget$^{\uparrow}$

The RealityConstrainedModelErrorBudget$^{\uparrow}$ packet realizes the error-budget branch of the model-audit program in section 9414.60 as a finite NameCert surface. It sits beside the model-audit certificate of chapter 1124, the finite-observation residue boundary of chapter 1167, the open-fit packet of chapter 1137, the model-selection boundary of chapter 1165, and the failure surface of chapter 1163. Those siblings supply audit, residue, fit, selection, and defeat rows; this packet stores the bounded mismatch ledger by which a model-facing claim exposes its finite error evidence before any audit or selection consumer reads it.

Definition 1184.1 (Reality-constrained model error-budget carrier)**.** *A* RealityConstrainedModelErrorBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, E, O, M, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source-trace row naming the audited source histories and instrumentation route.*
2. *E is the error-budget row recording the declared tolerance, residual allowance, measurement uncertainty, and admissible mismatch envelope.*
3. *O is the observation-window row that bounds which finite observations can consume the budget.*
4. *M is the mismatch-ledger row comparing the observed and model-generated signatures inside the budget.*
5. *F is the failure-surface row naming budget overruns, hidden residuals, classifier exits, and model-selection defeats.*
6. *H records componentwise* hsame *transport for the source, budget, observation-window, mismatch-ledger, and failure-surface rows.*
7. *C records the displayed* Cont *route through source tracing, observation-window reading, mismatch comparison, failure exposure, and downstream audit consumption.*
8. *P is the* Pkg *provenance over* RealityConstrainedModelErrorBudget$^{\uparrow}$, RealityConstrainedModelAudit$^{\uparrow}$, FiniteObservationResidueBoundary$^{\uparrow}$, OpenFitPacket$^{\uparrow}$, ModelSelectionBoundary$^{\uparrow}$, RealityConstrainedFailureSurface$^{\uparrow}$ BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedModelErrorBudget}^{\uparrow}}$ *row.*
The carrier has no coordinate for unbounded validation, hidden residual cancellation, model syntax truth, detached fit scoring, off-window observation repair, or a selection oracle outside the displayed budget packet.

Lean4 (definition) `BEDC.Derived.RealityConstrainedModelErrorBudgetUp.RealityConstrainedModelErrorBudgetUp`

Theorem 1184.2 (Reality-constrained model error-budget NameCert obligations)**.** *For the carrier of Definition 1184.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedModelErrorBudget}^{\uparrow}}$ *surface consists exactly of source-trace exposure through S, error-budget exposure through E, observation-window exposure through O, mismatch-ledger exactness through M, failure-surface exposure through F, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelErrorBudgetUp.RealityConstrainedModelErrorBudgetNameCert obligations`

Proof. Project the carrier $B = (S, E, O, M, F, H, C, P, N)$. The first three rows expose the finite source trace, declared budget, and observation window before any consumer can read model fit or audit strength.

The mismatch and failure rows supply the budget-facing certificate. The row M records the observed-versus-model comparison inside the declared envelope, while F names the finite ways the envelope can fail by overrun, hidden residual, classifier exit, or selection defeat.

The structural rows preserve that same packet. Transport through H is componentwise, replay through C follows the displayed source-window-mismatch-failure route, provenance through P records the sibling certificates consumed by the packet, and N supplies the local name.

Since the carrier has no further coordinate, these rows exhaust the local NameCert surface. A model-audit or selection read that depends on an off-window observation, hidden residual cancellation, or detached fit score is not a projection of the accepted packet. □

Theorem 1184.3 (Reality-constrained model error-budget nonescape)**.** *Every accepted* RealityConstrainedModelErr *consumer must read bounded model-error evidence through*

$$S, E, O, M, F, H, C, P, N.$$

No consumer may preserve the model syntax while replacing the error-budget row, changing the observation window, hiding the mismatch ledger, erasing the failure surface, or importing a model-selection verdict from outside the displayed packet.

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelErrorBudgetUp.RealityConstrainedModelErrorBudgetCarrier nonescape`

Proof. Start with the NameCert obligations of Definition 1184.2. They make $S, E, O, M, F, H, C, P, N$ the complete row surface for a bounded error-budget read.

The budget row E and observation window O bind the scope of the mismatch ledger. A comparison in M is licensed only for the source traces and finite observations exposed by S and O under the declared tolerance and residual allowance in E.

The failure row F keeps rejection conditions visible. Budget overruns, hidden residuals, classifier exits, and model-selection defeats cannot be suppressed and then recovered from transport, replay, provenance, or local naming rows.

Thus the accepted packet has no route that preserves only model syntax and changes the error evidence. Any such route leaves the finite carrier and cannot be consumed as a RealityConstrainedModelErrorBudget$^{\uparrow}$ certificate. □

Theorem 1184.4 (Reality-constrained model error-budget observation-window exactness)**.** *Every mismatch-ledger read in an accepted* RealityConstrainedModelErrorBudget$^{\uparrow}$ *carrier preserves the source trace S, error-budget row E, observation-window row O, and mismatch-ledger row M as one finite packet. A consumer cannot read M while changing the source route, widening the observation window, or detaching the comparison from the declared budget envelope.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelErrorBudgetUp.RealityConstrainedModelErrorBudgetCarrier observation window exactness`

Proof. Project the carrier $B = (S, E, O, M, F, H, C, P, N)$. The row M is introduced only after the source trace S, budget row E, and observation window O have been displayed.

The sibling audit chapters named in the introduction supply separate audit, residue, fit, selection, and failure rows, but none of them replaces the packet order here. The mismatch comparison remains a read of the displayed source-window-budget surface.

Transport and replay preserve the same dependency. Rows H and C move and replay S, E, O, M componentwise, while P and N only source and name the route. Hence any accepted mismatch-ledger read keeps those four rows together. □

Theorem 1184.5 (Reality-constrained model error-budget failure visibility)**.** *No accepted* RealityConstrainedModel *budget consumer may preserve the model syntax while hiding the failure-surface row F. The rows for budget overruns, hidden residuals, classifier exits, and model-selection defeats must remain visible whenever the source trace, budget, observation window, and mismatch ledger are exported.*

Proof. Use the carrier inventory and the nonescape theorem. The failure-surface row F is one of the displayed coordinates of every accepted budget packet, and Definition 1184.3 forbids erasing it while preserving model syntax.

The cited failure-surface sibling supplies the interpretation of rejection rows, but visibility is already local to this carrier. Once S, E, O, M are exported, the corresponding row F must travel with the packet so that overruns, hidden residuals, classifier exits, and selection defeats remain inspectable.

The structural rows add no hidden substitute. Transport through H, replay through C, provenance through P, and naming through N preserve the displayed failure row rather than replacing it by a detached fit score. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelErrorBudgetUp.RealityConstrainedModelErrorBudgetCarrier failure visibility`

Theorem 1184.6 (Reality-constrained model error-budget selection handoff)**.** *Every* ModelSelectionBoundary$^{\uparrow}$ *consumer of an accepted* RealityConstrainedModelErrorBudget$^{\uparrow}$ *carrier may consume the budget only through*

$$S, E, O, M, F, H, C, P, N.$$

It receives source trace, error budget, observation window, mismatch ledger, failure surface, transport, replay, provenance, and local naming rows, not detached fit scoring outside the finite error-budget packet.

Proof. Begin with the model-selection sibling named in the introduction. Its consumer route can inspect a budget packet only through the rows that this chapter exposes.

Rows S, E, O, M, F bind the substantive evidence: source route, declared budget, observation window, mismatch comparison, and visible failure surface. A fit score without these rows is not a projection of the accepted $\mathsf{RealityConstrainedModelErrorBudget}^{\uparrow}$ carrier.

Rows H, C, P, N then transport, replay, source, and name the same packet for the selection boundary. Therefore the handoff to $\mathsf{ModelSelectionBoundary}^{\uparrow}$ is through $S, E, O, M, F, H, C, P, N$ and cannot be replaced by detached scoring. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelErrorBudgetUp.RealityConstrainedModelErrorBudgetCarrier selection handoff`

Falsifiable prediction: A packet that preserves the model syntax while changing the error-budget row is rejected by the carrier classifier whenever the mismatch ledger or observation-window route is not preserved.

Independence witness: realityconstrainedmodelaudit, finiteobservationresidueboundary, openfitpacket, modelselectionboundary, realityconstrainedfailuresurface: none is bijective because RealityConstrainedMod carries source traces, error budget, observation window, mismatch ledger, failure surface, transport, route, provenance, and local naming in one packet. The model audit lacks the bounded error row, the residue boundary lacks the mismatch-budget envelope, the open-fit packet lacks the audit error ledger, the model-selection boundary lacks the source-window budget, and the failure surface lacks the accepted mismatch route.

The Lean follow-up must provide `Nontrivial RealityConstrainedModelErrorBudgetUp` and `FieldFaithful RealityConstrainedModelErrorBudgetUp` instances in `lean4/BEDC/Derived/RealityConstrai`
Lean4 ✓ `BEDC.Derived.RealityConstrainedModelErrorBudgetUp.RealityConstrainedModelErrorBudgetTasteGate single carrier alignment`

Theorem 1184.7 (Reality-constrained model error-budget public certificate)**.** *The public bounded-error-budget certificate exported by* $\mathsf{RealityConstrainedModelErrorBudget}^{\uparrow}$ *consists exactly of the NameCert obligation surface for* $S, E, O, M, F, H, C, P, N$*, the nonescape restriction, observation-window exactness, failure visibility, selection handoff, the falsifiable prediction for classifier rejection, and the independence witness separating the sibling audit, residue, fit, selection, and failure-surface packets. Any public consumer of the certificate must preserve the source trace, declared budget, observation window, mismatch ledger, visible failure surface, transport, replay, provenance, and local naming rows as one finite packet.*

Proof. Start with the NameCert obligations and nonescape theorem. They make $S, E, O, M, F, H, C, P, N$ the whole bounded-error-budget surface and forbid a public consumer from preserving only model syntax while changing the error evidence.

Use observation-window exactness and failure visibility next. The mismatch ledger remains tied to the displayed source, budget, and observation window, and the failure row stays visible whenever the bounded packet is exported.

Apply the selection handoff to the downstream $\mathsf{ModelSelectionBoundary}^{\uparrow}$ consumer. It receives the same finite packet rather than a detached score, so public export preserves the selection-facing route already present in the carrier.

Finally include the falsifiable prediction and independence witness. The prediction exposes the classifier rejection test for changed budget or window rows, while the witness separates this packet from its audit, residue, fit, selection, and failure-surface siblings. Together these clauses form the

public bounded-error-budget certificate and add no unbounded validation, complete calibration, final model truth, or bridge claim. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelErrorBudgetUp.RealityConstrainedModelErrorBudgetCarrier public certificate`

Theorem 1184.8 (Reality-constrained model error-budget bridge interface)**.** *Every public consumer bridge for an accepted* RealityConstrainedModelErrorBudget$^{\uparrow}$ *packet preserves the displayed observation-window row O, failure-visibility row F, model-selection handoff route, componentwise transport row H, displayed replay row C, provenance row P, and local* NameCert *row N together with the source trace, error-budget row, and mismatch ledger. The bridge exposes no hidden model oracle, no off-window observation repair, no detached scoring channel, and no unbounded validation row outside*

$$S, E, O, M, F, H, C, P, N.$$

Proof. Start with the public certificate of Definition 1184.7. It already identifies $S, E, O, M, F, H, C, P, N$ as the whole bounded-error-budget surface consumed by public readers.

Use observation-window exactness, failure visibility, and selection handoff. These force the mismatch ledger to remain tied to S, E, O, keep F visible whenever the packet is exported, and send every ModelSelectionBoundary$^{\uparrow}$ read through the same finite rows rather than through detached scoring.

Transport, replay, provenance, and naming do not add a hidden coordinate. Rows H, C, P, N preserve and source the displayed bounded-error packet, so any bridge that claims this public interface must preserve the same rows and cannot expose a model oracle outside the carrier. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedModelErrorBudgetUp.RealityConstrainedModelErrorBudgetCarrier bridge interface`

Closure status for NameCert$_{\text{RealityConstrainedModelErrorBudget}^{\uparrow}}$.

Constructive story: A RealityConstrainedModelErrorBudget$^{\uparrow}$ packet is generated from finite source traces, an error-budget row, an observation-window row, a mismatch ledger, a failure surface, componentwise hsame transports, a displayed Cont route, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RealityConstrainedModelErrorBudget}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1184.1, Definition 1184.2, and Definition 1184.3 bind bounded model-error evidence to finite source traces, observation windows, mismatch ledgers, failure surfaces, transport, route, provenance, and local naming.

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not assert model truth, unbounded validation, complete statistical calibration, final model selection, Lean verification, axiom-clean audit, or bridge checking for RealityConstrainedModelErrorBudget$^{\uparrow}$.

Upgrade path: No further paper-side theory upgrade is pending for the finite bounded-error packet, including its observation window, failure visibility, selection handoff, transport, replay, provenance, and local naming rows.

Chapter 1185

A Concrete Naming Certificate for RealityConstrainedScientificMethodology$^{\uparrow}$

The RealityConstrainedScientificMethodology$^{\uparrow}$ packet realizes the methodology consequences of section 9414.46 as one composite finite NameCert carrier. It sits after the methodology ledger of chapter 1145, the physical model audit of chapter 1129, the explanation packet of chapter 1136, and the idealization residue seal of chapter 1170. Those siblings expose ledger, audit, explanation, and idealization rows separately; this carrier binds them with an effective-domain row, a domain-leakage failure surface, audit routing, provenance, and a local name before a scientific-methodology claim may be read as accepted. As an ai packet, it bundles methodology-ledger, physical-audit, explanation, idealization-residue, and open-fit surfaces into one methodology consumer ledger.

Definition 1185.1 (Reality-constrained scientific-methodology carrier)**.** *A* RealityConstrainedScientificMethodology *carrier is a finite* BHist *packet*

$$M = (X, A, E, I, D, L, F, R, T, C, P, N)$$

with the following displayed rows:

1. *X is the methodology-ledger row inherited from* RealityConstrainedMethodologyLedger$^{\uparrow}$*, naming scope, domain-leakage refusals, extension routes, and failure records.*
2. *A is the physical-model-audit row inherited from* PhysicalModelAudit$^{\uparrow}$*, naming source traces, observed signatures, model signatures, comparison, tower, stability, descent, ledger, failure, and strength rows.*
3. *E is the explanation-certificate row inherited from* RealityConstrainedExplanation$^{\uparrow}$*, naming observation bundle, model, phenomenon, signature comparison, descent, residue, and failure surface.*
4. *I is the idealization-residue row inherited from* ScientificIdealizationResidueSeal$^{\uparrow}$*, naming the idealization arrow, removed source material, descent row, failure surface, and safe scope.*
5. *D is the effective-domain row, naming the observation bundle, tower region, admissible consumers, and physical-signature interface over which the methodology packet is licensed.*
6. *L is the domain-leakage row, naming attempted exports beyond D and the finite refusal or routing record for each attempted export.*
7. *F is the methodology failure-surface row, collecting explanation failure, audit mismatch, active idealization residue, domain leakage, and open physical-fit defeat.*

8. *R is the audit-route row, recording how a consumer reaches the accepted methodology read through explanation, audit, idealization, domain, leakage, and failure rows.*
9. *T records componentwise* hsame *transport for $X, A, E, I, D, L, F, R, C, P, N$.*
10. *C records displayed* Cont *replay of the accepted methodology route.*
11. *P records* Pkg *provenance over the sibling carriers,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedScientificMethodology}^{\uparrow}}$ *row.*

The carrier has no coordinate for bare explanatory syntax, detached model truth, global realism, unledgered idealization, unbounded effective exactness, or methodology export outside the displayed packet.

Lean4 ✓ `BEDC.Derived.RealityConstrainedScientificMethodologyUp.TasteGate.RealityConstrainedScientificMe single carrier alignment`

Theorem 1185.2 (Reality-constrained scientific-methodology obligation surface)**.** *For the carrier of Definition 1185.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedScientificMethodology}^{\uparrow}}$ *surface consists exactly of six obligation rows:*

1. *carrier admission: the accepted object is exactly $M = (X, A, E, I, D, L, F, R, T, C, P, N)$;*
2. *explanation accountability: explanation-to-truth-cert consumers must pass through the explanation row E and its residue and failure surface;*
3. *audit accountability: physical-model reads must pass through A and the accepted audit route;*
4. *idealization accountability: ideal endpoint reads must pass through the idealization residue row I;*
5. *domain-leakage accountability: every export beyond the effective-domain row D must be recorded in L and exposed to F;*
6. *route and naming accountability: accepted consumers must preserve R, T, C, P, N as the audit route, componentwise transport, replay, provenance, and local name of the same packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedScientificMethodologyUp.RealityConstrainedScientificMethodology obligation surface`

Proof. Carrier admission is projection from Definition 1185.1. The packet lists the only rows available to the local methodology certificate.

Explanation accountability is carried by E. A consumer that reads explanation toward truth without the observation, model, phenomenon, signature comparison, descent, residue, and failure-surface material of E has not passed through the accepted explanation certificate.

Audit and idealization accountability are carried by A and I. The audit row records the finite physical-model comparison and its strength, while the idealization row records the ideal endpoint together with residue, descent, failure, and scope.

Domain-leakage accountability is carried by D, L, F. The effective-domain row names the licensed region, the leakage row records attempted exports beyond it, and the failure surface makes those refusals visible to the consumer.

Finally R, T, C, P, N preserve the same displayed route. Since the carrier contains no further coordinate, a methodology consumer cannot bypass explanation, audit, idealization residue, domain

leakage, or local naming while remaining an accepted $\mathsf{RealityConstrainedScientificMethodology}^{\uparrow}$ read. □

Theorem 1185.3 (Reality-constrained scientific-methodology consumer factorization)**.** *Every accepted explanation-to-truth-cert consumer of a* $\mathsf{RealityConstrainedScientificMethodology}^{\uparrow}$ *packet factors through either the explanation certificate row E or the idealization residue row I, and in both cases preserves the effective-domain row D, leakage row L, failure surface F, audit route R, transport T, replay C, provenance P, and local name N.*

Proof. Read the obligation surface of Definition 1185.2. An explanation-to-truth-cert consumer is admitted only when explanation accountability or idealization accountability is displayed.

In the explanation branch, the route uses E and therefore carries the observation bundle, model row, phenomenon row, signature comparison, descent, residue, and failure surface. In the idealization branch, the route uses I and therefore carries the idealization arrow, residue ledger, descent, failure surface, and safe scope.

Both branches still belong to the same methodology packet. The domain, leakage, failure, audit-route, transport, replay, provenance, and local-name rows D, L, F, R, T, C, P, N remain visible, so neither branch can become a detached truth-cert consumer. □

Falsifiable prediction: If the methodology packet is atomic, then every accepted explanation-to-truth-cert consumer must factor through either the explanation certificate row or the idealization residue row; a consumer bypassing both refutes the chapter.

Independence witness: realityconstrainedmethodologyledger, physicalmodelaudit, realityconstrainedexplanation, scientificidealizationresidueseal, openphysicalfit: the methodology carrier has both explanation and idealization-residue rows plus a domain-leakage failure surface, while each sibling omits at least one of those rows, so no row-preserving bijection can identify the carriers.

The packet composes realityconstrainedmethodologyledger, physicalmodelaudit, realityconstrained-explanation, scientificidealizationresidueseal, and openphysicalfit into the displayed methodology surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedScientificMethodology}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealityConstrainedScientificMethodology}^{\uparrow}$ packet is generated from methodology-ledger, physical-audit, explanation, idealization-residue, effective-domain, domain-leakage, failure-surface, audit-route, transport, replay, provenance, and local NameCert rows.

Lean4 ✓ `BEDC.Derived.RealityConstrainedScientificMethodologyUp.taste gate`

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealityConstrainedScientificMethodology}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1185.1, Definition 1185.2, and Definition 1185.3 bind the finite carrier, obligation surface, and explanation-or-idealization consumer factorization.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealityConstrainedScientificMethodology}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.RealityConstrainedScientificMethodologyUp.TasteGate.RealityConstrainedScientificMethodo`

Origin: ai

Not claimed: This chapter does not assert global model truth, unbounded realism, final empirical closure, public closure, or bridge checking for $\mathsf{RealityConstrainedScientificMethodology}^{\uparrow}$.

Upgrade path: Scoped closure requires downstream examples showing that truth-cert and open-fit consumers preserve the explanation-or-idealization factorization through the displayed domain-leakage surface.

Chapter 1186

A Concrete Naming Certificate for $\mathsf{EmptyFableMachine}^{\uparrow}$

The $\mathsf{EmptyFableMachine}^{\uparrow}$ interface is the finite NameCert packet for the Empty Fable Machine of chapter 9399. It sits above the boundary packet of chapter 878, the local clock packet of chapter 623, and the observer-history identity packet of chapter 479. Its carrier keeps the empty-boundary source, selector-step witness, trace row, fable ledger, transport, continuation replay, provenance, and local naming row in one displayed tuple.

Definition 1186.1 (EmptyFableMachine NameCert carrier)**.** *An* $\mathsf{EmptyFableMachine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Z, S, T, L, H, C, P, N)$$

with the following displayed rows:

1. *Z is the empty-boundary source row, read through the boundary discipline of chapter 878;*
2. *S is the selector-step witness row, including the enacted mark, its displayed* Ext *edge, and the local branch certificate;*
3. *T is the finite trace row read from the constructor spine generated by the displayed selector step;*
4. *L is the fable-ledger row identifying the same trace as the Empty-fable story ledger;*
5. *H records componentwise* hsame *transport for Z, S, T, L and for the local naming row;*
6. *C records the displayed* Cont *replay routes by which a consumer reads the source, selector witness, trace, ledger, transport, and local name;*
7. *P is the* Pkg *provenance over* $\mathsf{EmptyFableMachine}^{\uparrow}$, $\mathsf{FableMachineBoundary}^{\uparrow}$, $\mathsf{FableMachineClock}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, BHist, Ext, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{EmptyFableMachine}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these rows. It has no coordinate for an undisplayed selector function, observer-substance, host trace quotient, global clock, or truth oracle.

Theorem 1186.2 (EmptyFableMachine NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{EmptyFableMachine}^{\uparrow}}$ *surface for the carrier of Definition 1186.1 consists exactly of carrier admission for $E = (Z, S, T, L, H, C, P, N)$, empty-boundary admission for Z, selector-step admission for S, trace admission for T, fable-ledger admission for L, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and the local naming row N.*

The boundary row is supplied by chapter 878; the step-order reading is supplied by chapter 623; and the observer-facing history read is constrained by chapter 479. The chapter therefore binds the source, selected branch, trace, ledger, transport, replay, provenance, and naming obligations without adding a hidden chooser.

Lean4 ✓ `BEDC.Derived.EmptyFableMachineUp.EmptyFableMachineTasteGate single carrier alignment`

Proof. Project the carrier rows. The empty-boundary source Z, selector witness S, trace row T, fable ledger L, transport row H, continuation row C, provenance row P, and local name N are separate coordinates of the finite packet.

Read Z through the boundary packet of chapter 878. Read the local order and enacted selected mark through chapter 623. Read the observer-facing history discipline through chapter 479.

The trace row and fable-ledger row then refer to the same displayed constructor spine named in chapter 9399. The transport, continuation, package, and local naming rows repack that spine for consumers, so no further selector, subject, quotient, clock, or oracle coordinate is introduced. □

Theorem 1186.3 (EmptyFableMachine selector-ledger non-escape)**.** *Every public selector-ledger read of an accepted* $\mathsf{EmptyFableMachine}^{\uparrow}$ *packet factors through*

$$Z, S, T, L, H, C, P, N.$$

In particular, a branch mark can be exposed only with its displayed selector-step witness S, its trace row T, and its fable-ledger row L. The packet exports no branch mark detached from selector evidence, no hidden chooser, no observer-substance coordinate, no global clock, and no host trace equality.

Lean4 ✓ `BEDC.Derived.EmptyFableMachineUp.Ledger.EmptyFableMachine selector ledger nonescape`

Proof. Inspect the accepted carrier. The only branch-facing row is S, and that row contains the selected mark together with the displayed Ext edge and local branch certificate.

Trace and ledger reads are confined to T and L. The hsame transport row H and continuation row C move only those displayed rows, while the provenance row P names the boundary, clock, and observer-history identity surfaces that license the read.

A public branch mark without S would require an additional selector coordinate. No such coordinate appears in $E = (Z, S, T, L, H, C, P, N)$, so every selector-ledger read remains inside the finite NameCert packet. □

Falsifiable prediction: A public selector-ledger read that exposes a branch mark without a displayed selector-step witness refutes the EmptyFableMachineUp packet.

Independence witness: fablemachineboundary, fablemachineclock, observerhistidentity, localitycell: none is bijective because EmptyFableMachineUp simultaneously carries empty-boundary source, selector witness, trace ledger, fable ledger, transport, continuation, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{EmptyFableMachine}^{\uparrow}}$.

Constructive story: An $\mathsf{EmptyFableMachine}^{\uparrow}$ packet is generated from an empty-boundary source row, selector-step witness, trace row, fable-ledger row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EmptyFableMachine}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope records the finite carrier, NameCert obligation surface, selector-ledger non-escape route, falsifiable selector-witness condition, and independence surface for Empty-fable machine packets over BHist, Ext, trace, ledger, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{EmptyFableMachine}\uparrow}$, unformalized)
Bridge status: none
Origin: ai
Not claimed: This chapter does not close Nontrivial or FieldFaithful Lean instances, bridge checking, global branch selection, host trace equality, hidden observer substance, shared-clock semantics, or truth-oracle semantics.
Upgrade path: Lean follow-up must provide Nontrivial and FieldFaithful instances in lean4/BEDC/Derived/EmptyFableMachineUp/Taste with the canonical target expected at BEDC.Derived.EmptyFableMachineUp.taste_gate.

Chapter 1187

A Concrete Naming Certificate for $\mathsf{RecursorClosureClassifierAudit}^{\uparrow}$

The $\mathsf{RecursorClosureClassifierAudit}^{\uparrow}$ packet realizes the recursor-as-authorized-generator view of chapter 9373 as a finite NameCert surface that joins recursor authorization, classifier closure, and replayable audit execution. It consumes the recursor-induced output packet of chapter 522, the authorization packet of chapter 529, the generator packet of chapter 534, the branch-audit packet of chapter 974, and the classifier-membership packet of chapter 476. Those siblings expose the recursor output, legal eliminator call, generator boundary, constructor-indexed branch coverage, and type-classifier membership rows; this packet binds them into one audit replay carrier whose classifier must close over the same displayed branches.

Definition 1187.1 (Recursor closure classifier audit carrier)**.** *A* $\mathsf{RecursorClosureClassifierAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, G, B, K, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the recursor signature and motive row, read through the accepted inductive signature and motive boundary;*
2. *G is the* $\mathsf{RecursorGenerator}^{\uparrow}$ *row recording the legal eliminator call and its structural generator boundary;*
3. *B is the* $\mathsf{RecursorBranchAudit}^{\uparrow}$ *branch matrix, with one displayed branch row for every constructor of the accepted signature;*
4. *K is the classifier-closure row, carrying the* $\mathsf{TypeClassifierMembership}^{\uparrow}$ *membership surface and the output classifier reached by the recursor call;*
5. *A is the audit-replay row, recording the kernel replay, source axiom gate, and forbidden-dependency purity check for the generated output;*
6. *H records componentwise* hsame *transport for S, G, B, K, A and for the local naming row;*
7. *C records the displayed* Cont *replay routes by which consumers read the recursor, branch, classifier, audit, transport, and local name;*
8. *P is the* Pkg *provenance over* $\mathsf{RecursorInducedNameCert}^{\uparrow}$, $\mathsf{RecursorAuthorization}^{\uparrow}$, $\mathsf{RecursorGenerator}^{\uparrow}$, $\mathsf{RecursorBranchAudit}^{\uparrow}$, $\mathsf{TypeClassifierMembership}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{RecursorClosureClassifierAudit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an omitted constructor case, a detached classifier proof, a hidden host type checker, an unreported dependency trace, a second branch package, or an audit result outside $S, G, B, K, A, H, C, P, N$.

Theorem 1187.2 (Recursor closure classifier audit NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RecursorClosureClassifierA}}$ *surface for the carrier of Definition 1187.1 consists exactly of carrier admission for $R = (S, G, B, K, A, H, C, P, N)$, recursor authorization through S and G, constructor-complete branch coverage through B, classifier-closure preservation through K, audit replay through A, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and the local naming row N.*

Consequently, any accepted output must be readable both as a legal recursor-generated NameCert and as a classifier-closed output whose audit can be replayed from the same finite branch package. A packet whose branch package omits one constructor case is rejected by the classifier audit, even if its remaining recursor, classifier, and audit rows are individually well formed.

Lean4 ✓ `BEDC.Derived.RecursorClosureClassifierAuditUp.TasteGate.RecursorClosureClassifierAuditTasteGate`
`single carrier alignment`

Proof. Project the carrier rows. The signature and motive row S, generator row G, branch matrix B, classifier-closure row K, audit replay row A, transport row H, continuation row C, provenance row P, and local name N are the only available coordinates.

Read S and G through chapter 529 and chapter 534. They license the eliminator call but do not by themselves expose the per-constructor branch matrix or the classifier membership row.

Next read B through chapter 974 and K through chapter 476. Branch coverage and classifier membership are therefore checked on the same displayed recursor route rather than on separate host judgments.

Finally use the audit row A and the recursor-induced output packet of chapter 522. The replay must see the same branch package and classifier-closure row named in the carrier. If a constructor case is missing from B, the replay has no row from which to certify that branch, so the local classifier rejects the packet as a $\mathsf{RecursorClosureClassifierAudit}^{\uparrow}$ certificate. □

Falsifiable prediction: A recursor packet whose branch package omits one constructor case is rejected by the classifier audit, even when the remaining branch rows, classifier row, and audit-replay row are present.

Independence witness: recursorinducednamecert, recursorauthorization, recursorgenerator, recursorbranchaudit, typeclassifiermembership: none alone carries the joined audit replay and classifier-closure rows. The recursor-induced packet names generated outputs, authorization licenses the eliminator call, the generator packet exposes the structural generator boundary, the branch-audit packet exposes constructor coverage, and the classifier-membership packet exposes type-classifier membership; only RecursorClosureClassifierAuditUp requires all of them in one $S, G, B, K, A, H, C, P, N$ carrier.

The Lean follow-up must provide `Nontrivial RecursorClosureClassifierAuditUp` and `FieldFaithful RecursorClosureClassifierAuditUp` in `lean4/BEDC/Derived/RecursorClosureClassifierAuditUp/TasteGat` with the canonical alignment target expected at `BEDC.Derived.RecursorClosureClassifierAuditUp.TasteGate`

Closure status for $\mathsf{NameCert}_{\mathsf{RecursorClosureClassifierAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{RecursorClosureClassifierAudit}^{\uparrow}$ packet is generated from a recursor signature and motive row, legal generator row, constructor-complete branch matrix, classifier-closure row, audit-replay row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RecursorClosureClassifierAudit}^{\uparrow}}$, seed)

Scope closed: The seed scope records the finite carrier, NameCert obligation surface, branch-omission rejection, and independence surface for recursor closure classifier audits over recursor authorization, generator, branch audit, classifier membership, audit replay, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RecursorClosureClassifierAudit}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Nontrivial or FieldFaithful Lean instances, bridge checking, arbitrary host typing semantics, hidden branch completion, detached classifier proofs, or audit results outside the displayed replay row.

Upgrade path: Lean follow-up must provide Nontrivial and FieldFaithful instances in lean4/BEDC/Derived/RecursorClosureClassifierAudit with the canonical target expected at BEDC.Derived.RecursorClosureClassifierAuditUp.TasteGate.RecursorClosureClassifierAuditTasteGate_si

Chapter 1188

A Concrete Naming Certificate for $\mathsf{LargeModelOutputVerifier}^{\uparrow}$

The $\mathsf{LargeModelOutputVerifier}^{\uparrow}$ packet realizes the externally checked output-channel boundary of chapter 9398 as finite BEDC data. It consumes the checker-facing harness of chapter 976, the consumer-facing audit channel of chapter 969, the inference-output trace of chapter 972, the prompt/output record of chapter 965, and the inscription-audit packet of chapter 1027. Its distinguishing role is the public verifier boundary: a model output is exported only after verifier, proof-check, refusal, route, provenance, and local NameCert rows are displayed together.

Definition 1188.1 (Large-model output verifier carrier)**.** *A* $\mathsf{LargeModelOutputVerifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (H, A, M, T, I, Q, C, F, R, K, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{VerifiedOutputHarness}^{\uparrow}$ *row carrying the checker-facing accepted-output harness;*
2. *A is the* $\mathsf{LargeModelAuditChannel}^{\uparrow}$ *row carrying the consumer-facing audit channel;*
3. *M is the* $\mathsf{ModelTrace}^{\uparrow}$ *row recording the finite inference-output trace;*
4. *T is the* $\mathsf{PromptResponseTrace}^{\uparrow}$ *row recording the prompt and response boundary;*
5. *I is the* $\mathsf{LargeModelInscriptionAudit}^{\uparrow}$ *row binding the output to inscription-audit provenance;*
6. *Q is the verifier row naming the external checker, checker input, and displayed checker result;*
7. *C is the proof-check row recording the proof object, proof checker, or finite validation transcript consumed by Q;*
8. *F is the refusal row recording failed verification, unavailable evidence, policy refusal, or obstruction disclosure;*
9. *R is the route row through which an accepted output is exported to a public consumer;*
10. *K is the displayed* Cont *replay through $H, A, M, T, I, Q, C, F, R$;*
11. *P is the* Pkg *provenance over* $\mathsf{VerifiedOutputHarness}^{\uparrow}$, $\mathsf{LargeModelAuditChannel}^{\uparrow}$, $\mathsf{ModelTrace}^{\uparrow}$, $\mathsf{PromptResponseTrace}^{\uparrow}$, $\mathsf{LargeModelInscriptionAudit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LargeModelOutputVerifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for hidden model truth, private verifier correctness, semantic omniscience, or output export without the verifier and proof-check rows.

Lean4 (definition) `BEDC.Derived.LargeModelOutputVerifierUp.LargeModelOutputVerifierUp`
Lean4 ✓ `BEDC.Derived.LargeModelOutputVerifierUp.TasteGate.LargeModelOutputVerifierTasteGate`
`single carrier alignment`

Definition 1188.2 (Large-model output verifier classifier)**.** *Two* $\mathsf{LargeModelOutputVerifier}^{\uparrow}$ *carriers classify together exactly when their harness, audit-channel, model-trace, prompt-response trace, inscription-audit, verifier, proof-check, refusal, route, replay, provenance, and local naming rows compare componentwise by the displayed* hsame *entries. Thus the classifier is the finite componentwise relation*

$$V \equiv V' \quad \textit{iff} \quad H\mathsf{hsame}H',\ A\mathsf{hsame}A',\ M\mathsf{hsame}M',\ T\mathsf{hsame}T',\ I\mathsf{hsame}I',$$
$$Q\mathsf{hsame}Q',\ C\mathsf{hsame}C',\ F\mathsf{hsame}F',\ R\mathsf{hsame}R',\ K\mathsf{hsame}K',\ P\mathsf{hsame}P',\ N\mathsf{hsame}N'.$$

It does not compare model meanings outside the displayed verification packet.

Theorem 1188.3 (Large-model output verifier NameCert obligations)**.** *For the carrier of Definition 1188.1, the local* $\mathsf{NameCert}_{\mathsf{LargeModelOutputVerifier}^{\uparrow}}$ *surface consists exactly of six obligation rows: carrier admission for* $V = (H, A, M, T, I, Q, C, F, R, K, P, N)$*; sibling exposure through* H, A, M, T, I*; verifier and proof-check exposure through* Q, C*; refusal and route exactness through* F, R*; replay and provenance exactness through* K, P*; and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.LargeModelOutputVerifierUp.LargeModelOutputVerifierNameCertObligations`

Proof. Project the carrier of Definition 1188.1. The admitted packet displays the five sibling rows H, A, M, T, I together with verifier, proof-check, refusal, route, replay, provenance, and local-name rows.

The sibling exposure row binds the accepted output to the harness, audit channel, model trace, prompt-response trace, and inscription audit. These are exactly the finite surfaces supplied by chapter 976, chapter 969, chapter 972, chapter 965, and chapter 1027.

The verifier row Q and proof-check row C are then read before route export. Refusal F remains visible whether verification succeeds or blocks, so the packet cannot erase failed checking as if it were accepted evidence.

Finally K, P, and N replay the same displayed rows as continuation, package provenance, and local naming. This gives exactly the six obligation rows and no hidden checker or model-truth coordinate. □

Theorem 1188.4 (Large-model output verifier public acceptance boundary)**.** *Every public export from an accepted* $\mathsf{LargeModelOutputVerifier}^{\uparrow}$ *packet must pass through the verifier row* Q *and proof-check row* C *after the sibling rows* H, A, M, T, I *and before the route row* R*. A route that exports the output without* Q *and* C *is not a* $\mathsf{LargeModelOutputVerifier}^{\uparrow}$ *acceptance route.*

Lean4 ✓ `BEDC.Derived.LargeModelOutputVerifierUp.LargeModelOutputVerifierUp StdBridge`

Proof. Use the NameCert obligations of Definition 1188.3. They require sibling exposure, verifier exposure, proof-check exposure, refusal exposure, route exactness, replay, provenance, and local naming before a public output is exported.

The route row R is therefore downstream of both Q and C. If either row is absent, the route still may describe an emitted model output, but it does not describe an externally checked acceptance packet.

Because the carrier has no coordinate for private verifier correctness or hidden semantic truth, no alternative row can replace Q and C. Public acceptance is exactly the displayed verifier/proof-check route. □

Theorem 1188.5 (Large-model output verifier ledger non-escape)**.** *Let*

$$V = (H, A, M, T, I, Q, C, F, R, K, P, N)$$

be an accepted $\mathsf{LargeModelOutputVerifier}^{\uparrow}$ *packet. Any consumer that reads the exported model output through R must also read the sibling rows H, A, M, T, I, the verifier and proof-check rows Q, C, the refusal row F, the replay row K, the provenance row P, and the local name N. Omitting one of these rows exits the verifier packet rather than exporting an accepted output.*

Proof. Apply Definition 1188.3. The local NameCert surface lists all rows required for carrier admission and public export.

The proof-check row cannot be detached from the verifier row, since C records the finite checking transcript consumed by Q. The refusal row cannot be detached from the route, since failed or unavailable evidence must remain visible at the same boundary.

Replay and provenance then bind the consumer route to the displayed packet. Thus an export that omits a sibling row, verifier row, proof-check row, refusal row, replay row, provenance row, or local name is not an accepted $\mathsf{LargeModelOutputVerifier}^{\uparrow}$ export. □

Theorem 1188.6 (Large-model output verifier obligation closure package)**.** *Every accepted* LargeModelOutputVerif *packet has exactly the obligation package consisting of carrier exposure for $V = (H, A, M, T, I, Q, C, F, R, K, P, N)$, classifier accountability, sibling exposure through H, A, M, T, I, verifier and proof-check exposure through Q, C, refusal and route exactness through F, R, replay and provenance through K, P, local naming through N, and the TasteGate single-carrier alignment for the same finite carrier. It exports no hidden model truth, private verifier correctness, host semantic understanding, or output route without verifier and proof-check rows.*

Proof. Combine the local NameCert obligations of Definition 1188.3 with the carrier and classifier definitions. The carrier exposes exactly the rows $H, A, M, T, I, Q, C, F, R, K, P, N$, while the classifier accounts for them componentwise and does not compare hidden model meanings.

Apply the public boundary of Definition 1188.4. It forces public export through Q and C before the route row R, so no output route qualifies as accepted without the verifier and proof-check rows.

Apply the ledger non-escape theorem Definition 1188.5. It keeps the sibling, refusal, replay, provenance, and local naming rows visible to any consumer of the exported output.

Finally use the checked TasteGate marker

$$\mathsf{LargeModelOutputVerifierTasteGate_single_carrier_alignment}$$

for the same finite carrier. The combined package is therefore an obligation surface only; it does not add hidden model truth, private checker correctness, or host semantic understanding. □

Falsifiable prediction: An accepted LargeModelOutputVerifierUp packet cannot export a model output without displayed verifier and proof-check rows.

Independence witness: verifiedoutputharness, largemodelauditchannel, modeltrace, promptresponsetrace, largemodelinscriptionaudit: none is bijective to $\mathsf{LargeModelOutputVerifier}^{\uparrow}$. Omitting the verifier row Q gives a harness or audit-channel acceptance surface without external checking; omitting the proof-check row C gives an audited output without a check transcript; omitting

the refusal row F erases blocked evidence; omitting H, A, M, T, I loses the sibling packet route; omitting P, N loses provenance and local naming.

The Lean TasteGate.lean surface must provide Nontrivial LargeModelOutputVerifier$^{\uparrow}$ and FieldFaithful LargeModel instances for the same finite carrier.

Theorem 1188.7 (Large-model output verifier bridge surface)**.** *The* LargeModelOutputVerifier$^{\uparrow}$ *bridge surface is the finite packet that simultaneously displays the verifier carrier of Definition 1188.1, the public acceptance boundary of Definition 1188.4, the ledger non-escape route of Definition 1188.5, the obligation package of Definition 1188.6, the TasteGate marker, and the checked standard bridge marker* LargeModelOutputVerifierUp_StdBridge*. A public output export is therefore bridged only when the verifier, proof-check, refusal, route, replay, provenance, local naming, TasteGate, and standard bridge rows are read together.*

Proof. Start with the carrier and public acceptance boundary. The carrier exposes $H, A, M, T, I, Q, C, F, R, K, P, N$ and the public boundary forces every accepted export through the verifier row Q and proof-check row C before the route row R.

Apply the ledger non-escape theorem. It keeps sibling, verifier, proof-check, refusal, replay, provenance, and local naming rows visible to every consumer of the exported output.

Apply the obligation closure package. It binds classifier accountability, sibling exposure, verifier and proof-check exposure, refusal and route exactness, replay, provenance, local naming, and the TasteGate single-carrier alignment for the same finite packet.

The checked standard bridge marker names the same public route as a bridge surface. Thus the bridge does not add hidden model truth or private checker correctness; it records that the displayed verifier packet is read through the standard bridge boundary. □

Closure status for NameCert$_{\text{LargeModelOutputVerifier}^{\uparrow}}$.

Constructive story: A LargeModelOutputVerifier$^{\uparrow}$ packet is generated from harness, audit-channel, model-trace, prompt-response, inscription-audit, verifier, proof-check, refusal, route, replay, provenance, and local NameCert rows.

Lean4 ✓ `BEDC.Derived.LargeModelOutputVerifierUp.taste gate`

Theory closure: TheoryGate(NameCert$_{\text{LargeModelOutputVerifier}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1188.1, Definition 1188.2, Definition 1188.3, Definition 1188.4, Definition 1188.5, Definition 1188.6, and Definition 1188.7 bind verifier and proof-check rows, refusal and route rows, replay and provenance rows, local naming, sibling surfaces, TasteGate, and the checked standard bridge surface for externally checked model-output export.

Formal verification: FormalStatus(NameCert$_{\text{LargeModelOutputVerifier}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.LargeModelOutputVerifierUp.TasteGate.LargeModelOutputVerifierTasteGate\_single\_carrier`

Bridge status: bridgeChecked

Origin: ai

Not claimed: This chapter does not close model consciousness, corpus truth, private verifier correctness, host semantic understanding, or global proof checking for LargeModelOutputVerifier$^{\uparrow}$.

Upgrade path: No further paper-side bridge step is claimed here; stronger closure would require a global proof-checking interface beyond this verifier packet.

Chapter 1189

A Concrete Naming Certificate for $\mathsf{SynchronizationCertificate}^{\uparrow}$

The $\mathsf{SynchronizationCertificate}^{\uparrow}$ packet realizes the local synchronization certificate of section 9414.34 as finite NameCert data. It sits between the one-history stream surface of chapter 603 and the refusal boundary of chapter 1003: two local time rows may be compared only through displayed correspondences, locality ledgers, transport rows, and no-global-clock refusal. The sibling context is supplied by $\mathrm{MultiHistConfig}^{\uparrow}$ in chapter 474, $\mathsf{ObserverFrameRefusal}^{\uparrow}$ in chapter 894, and $\mathsf{AnchorChangeInvariant}^{\uparrow}$ in chapter 1166.

Definition 1189.1 (Synchronization certificate carrier)**.** *A* $\mathsf{SynchronizationCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (H_i, H_j, T_i, T_j, R, L, S, C, P, N)$$

with the following displayed rows:

1. H_i *is the source observer-history row drawn from the finite multi-history configuration;*
2. H_j *is the target observer-history row drawn from the same finite multi-history configuration;*
3. T_i *is the local* $\mathsf{HistTimeStream}^{\uparrow}$ *row for* H_i*;*
4. T_j *is the local* $\mathsf{HistTimeStream}^{\uparrow}$ *row for* H_j*;*
5. R *is the selected local-step correspondence ledger, recording only the displayed pairs of steps from* T_i *and* T_j *that the comparison relates;*
6. L *is the locality ledger recording the local read sites, admissible comparison routes, and the refusal of any unlisted step match;*
7. S *is the no-global-clock refusal row, read through* $\mathsf{NoGlobalSyncBoundary}^{\uparrow}$ *and compatible with the observer-frame refusal surface;*
8. C *records componentwise* hsame *transport and displayed* Cont *replay for* $H_i, H_j, T_i, T_j, R, L, S, P, N$*;*
9. P *is the* Pkg *provenance over* $\mathsf{SynchronizationCertificate}^{\uparrow}$, $\mathsf{HistTimeStream}^{\uparrow}$, $\mathrm{MultiHistConfig}^{\uparrow}$, $\mathsf{NoGlobalSyncBoundary}^{\uparrow}$, $\mathsf{ObserverFrameRefusal}^{\uparrow}$, $\mathsf{AnchorChangeInvariant}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{SynchronizationCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for a shared present, global clock, total observer-time order, host equality of histories, unlisted correspondence, or privileged frame.

Lean4 ✓ `BEDC.Derived.SynchronizationCertificateUp.SynchronizationCertificateTasteGate single carrier alignment`

Theorem 1189.2 (Synchronization certificate locality)**.** *For the carrier of Definition 1189.1, every accepted* $\mathsf{SynchronizationCertificate}^{\uparrow}$ *read compares the two histories only through the displayed packet*

$$H_i, H_j, T_i, T_j, R, L, S, C, P, N.$$

The rows T_i *and* T_j *remain local* $\mathsf{HistTimeStream}^{\uparrow}$ *rows,* R *selects the admitted local-step pairs, and* L, S *prevent the comparison from becoming a shared clock.*

Proof. Project the accepted packet. The rows H_i, H_j expose the two observer histories through the same finite multi-history surface, while T_i, T_j expose their local time streams as two separate $\mathsf{HistTimeStream}^{\uparrow}$ rows.

Read the correspondence and locality rows next. The ledger R lists the selected step pairs, and L records the local read sites and rejects comparisons outside that finite list.

Finally use the no-global-clock refusal row S together with the transport and replay row C. These rows let a consumer transport and replay the displayed local comparison, but they do not add a shared present, total observer-time order, or privileged frame. □

Lean4 ✓ `BEDC.Derived.SynchronizationCertificateUp.SynchronizationCertificate locality`

Theorem 1189.3 (Synchronization certificate nonescape)**.** *An accepted* $\mathsf{SynchronizationCertificate}^{\uparrow}$ *consumer has no route to a global clock, privileged shared-present row, detached observer frame, host equality of histories, or unlisted local-step match. Any read requiring one of those rows exits the packet rather than reading the local synchronization certificate.*

Proof. Use the carrier definition. The only positive comparison data are the two local time rows T_i, T_j and the selected correspondence ledger R.

The refusal row S is part of the same packet as the positive comparison data. By chapter 1003 and chapter 894, a consumer may cite that refusal as displayed boundary data, but cannot promote it to a hidden synchronizer.

The rows C, P, N then preserve the finite packet by componentwise transport, continuation replay, provenance, and local naming. Since no row names a shared present or host clock, the requested external object has no projection from the accepted carrier. □

Theorem 1189.4 (Synchronization certificate sibling independence)**.** *The* $\mathsf{SynchronizationCertificate}^{\uparrow}$ *carrier is not bijective to* $\mathsf{HistTimeStream}^{\uparrow}$, $\mathrm{MultiHistConfig}^{\uparrow}$, $\mathsf{NoGlobalSyncBoundary}^{\uparrow}$, $\mathsf{ObserverFrameRefusal}^{\uparrow}$, *or* $\mathsf{AnchorChangeInvariant}^{\uparrow}$. *Each sibling omits at least one of the paired local-time rows, the selected correspondence ledger, or the no-global-clock refusal in the same finite packet.*

Proof. Compare the rows. A $\mathsf{HistTimeStream}^{\uparrow}$ packet supplies a one-history local stream, but not the paired histories, selected correspondence ledger, and refusal row together. A $\mathrm{MultiHistConfig}^{\uparrow}$ packet supplies a family of histories, but not the two local time rows and selected local-step pairs.

The refusal siblings also differ from the present carrier. $\mathsf{NoGlobalSyncBoundary}^{\uparrow}$ and $\mathsf{ObserverFrameRefusal}^{\uparrow}$ record refusal surfaces, but they do not carry the positive paired local-time comparison ledger R as part of the same packet.

Finally $\mathsf{AnchorChangeInvariant}^{\uparrow}$ carries anchor-change invariant transport rather than selected local-step correspondences between two HistTimeStream rows. Therefore none of the listed siblings is bijective to $\mathsf{SynchronizationCertificate}^{\uparrow}$. □

Falsifiable prediction: A SynchronizationCertificateUp read fails whenever a consumer asks for a global clock or privileged shared-present row not displayed in the local synchronization packet.

Independence witness: histtimestream, multihistconfig, noglobalsyncboundary, observerframerefusal, anchorchangeinvariant: none is bijective to SynchronizationCertificateUp because each lacks either the paired local-time rows, the selected correspondence ledger, or the explicit no-global-clock refusal in the same packet.

The Lean follow-up must provide `Nontrivial SynchronizationCertificateUp` and `FieldFaithful SynchronizationCertificateUp` in `lean4/BEDC/Derived/SynchronizationCertificateUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{SynchronizationCertificate}^{\uparrow}}$.

Constructive story: A $\mathsf{SynchronizationCertificate}^{\uparrow}$ packet is generated from two observer histories, two local HistTimeStream rows, a selected local-step correspondence ledger, locality ledger, no-global-clock refusal row, componentwise transport and continuation replay, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SynchronizationCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1189.1, Definition 1189.2, Definition 1189.3, and Definition 1189.4 bind local synchronization to the displayed paired-stream packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SynchronizationCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not construct a global clock, shared present, total observer-time order, privileged frame, Lean verification, or bridge checking for $\mathsf{SynchronizationCertificate}^{\uparrow}$.

Upgrade path: Obligation closure requires Lean encoding of carrier admission, paired local-time correspondence, no-global-clock refusal, TasteGate nontriviality, and field faithfulness for $H_i, H_j, T_i, T_j, R, L, S, C, P, N$.

Chapter 1190

A Concrete Naming Certificate for MetaCICNormalizationConfluenceBridge$^{\uparrow}$

The MetaCICNormalizationConfluenceBridge$^{\uparrow}$ packet binds the normalization audit route of chapter 750 to the confluence audit route of chapter 743, then records how the subject-reduction discharge ledger of chapter 720 and the closed-consistency assembly of chapter 1177 may read the shared closed typed term boundary. It is a finite bridge packet for audit correspondence, not an unconditional closed subject-reduction theorem.

The packet is composite over the normalization-audit, confluence-audit, subject-reduction discharge-ledger, and closed-consistency assembly rows. Its bridge row records the correspondence among those sibling packets rather than presenting an atomic carrier discovery.

Definition 1190.1 (MetaCIC normalization-confluence bridge carrier)**.** *A* MetaCICNormalizationConfluenceBridge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (N, Q, D, A, T, H, C, P, L)$$

with the following rows:

1. *N is the* MetaCICNormalizationAudit$^{\uparrow}$ *row carrying candidate, closed-candidate, candidate-set, application adequacy, Pi adequacy, and no-infinite-reduction reads;*
2. *Q is the* MetaCICConfluenceAudit$^{\uparrow}$ *row carrying checked confluence fragments and the named confluence-boundary inputs;*
3. *D is the* SubjectReductionDischargeLedger$^{\uparrow}$ *row carrying the beta-substitution, application-argument, lambda-domain, and Pi-domain discharge surface;*
4. *A is the* ClosedConsistencyAssembly$^{\uparrow}$ *row carrying closedness, typed-normal endpoint, normal false-proof exclusion, and subject-reduction boundary exposure;*
5. *T is the closed typed term route-correspondence classifier, recording that the normalization row and confluence row speak about the same displayed closed typed term before any consistency consumer reads the packet;*
6. *H is the componentwise* hsame *transport row over N, Q, D, A, T;*
7. *C is the displayed* Cont *replay route for normalization, confluence, discharge-ledger, and assembly consumers;*
8. *P is the* Pkg *provenance row naming the four sibling packets and the audit-map source route;*

9. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}}$ *row.*

The carrier exports no host evaluator, quotient equality over reductions, hidden typed-term selector, unconditional confluence theorem, unconditional closed subject-reduction theorem, or closed consistency proof detached from $N, Q, D, A, T, H, C, P, L$.

Theorem 1190.2 (MetaCIC normalization-confluence bridge NameCert obligations)**.** *For an accepted* $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$ *carrier, the local* NameCert *surface consists of the following finite obligations:*

1. *carrier admission for $B = (N, Q, D, A, T, H, C, P, L)$ as a* BHist *packet;*
2. *normalization-audit row readback through N, including Candidate, closed-candidate, candidate-set, App adequacy, and Pi adequacy entries;*
3. *confluence-audit row readback through Q, including checked fragment rows and named confluence-boundary inputs;*
4. *subject-reduction discharge-ledger readback through D, preserving the four preservation-obligation rows without turning them into a closed theorem;*
5. *closed-consistency assembly readback through A, preserving the normal false-proof exclusion and subject-reduction boundary rows;*
6. *closed typed term route correspondence through T, with agreement transported componentwise by H;*
7. *displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 1190.1. The rows N, Q, D, A are already distinct sibling packets, and T is the only classifier row that compares their closed typed term routes.

Use the normalization audit obligation surface, the confluence audit obligation surface, the subject-reduction discharge-ledger obligations, and the closed-consistency assembly obligations. These sibling results supply the rows consumed by the bridge, while H, C, P, L preserve transport, replay, provenance, and local naming.

Because the bridge has no further coordinate, every accepted read is exhausted by the displayed finite packet. In particular the read cannot pass through host complex analysis, quotient equality, a hidden typed-term selector, an unconditional confluence theorem, or an unconditional closed subject-reduction theorem. □

Theorem 1190.3 (MetaCIC normalization-confluence bridge route boundary)**.** *Any accepted bridge packet whose normalization and confluence rows agree on the closed typed term through T, H, C, P, L has no route to an unconditional closed subject-reduction theorem. The packet may hand the displayed discharge-ledger row D to the closed-consistency assembly row A, but every such handoff remains inside $N, Q, D, A, T, H, C, P, L$.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationConfluenceBridgeUp.MetacicNormalizationConfluenceBridgeRouteBo`

Proof. Read the agreement first through T. It compares the normalization and confluence routes only as displayed closed typed term rows; it does not add a preservation theorem.

Next route the preservation side through D. The discharge ledger contains the four named preservation-obligation rows, so a consumer may cite those rows but cannot erase their boundary and obtain closed subject reduction for arbitrary closed proofs.

Finally pass to A. The closed-consistency assembly can read the normal false-proof exclusion and the subject-reduction boundary, but it receives them as finite sibling rows under H, C, P, L. Thus the bridge remains a route-correspondence certificate rather than an unconditional theorem. □

Theorem 1190.4 (MetaCIC normalization-confluence bridge transport obligations)**.** *For an accepted* $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$ *carrier* $B = (N, Q, D, A, T, H, C, P, L)$*, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *transport preserve the separate bridge rows* N, Q, D, A, T*. The transported read may replay the normalization audit row* N*, the confluence audit row* Q*, the discharge-ledger row* D*, the closed-consistency assembly row* A*, and the typed-term correspondence row* T*, but it cannot collapse those rows into a subject-reduction theorem.*

Proof. Project the accepted carrier into its nine displayed coordinates. The transport row H is componentwise, so it acts on N, Q, D, A, T as separate row data rather than as a quotient over the sibling packets.

The displayed Cont row C replays the same bridge route after transport, while Pkg records the provenance of the four sibling packets. The local $\mathsf{NameCert}$ row L names the transported certificate surface and does not add a new proof coordinate.

Thus transport preserves exactly the rows already present in B. Since no coordinate of B is an unconditional subject-reduction theorem, preserving the packet cannot manufacture one. □

Theorem 1190.5 (MetaCIC normalization-confluence bridge route exactness)**.** *Every accepted* $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$ *bridge read is exhausted by* $N, Q, D, A, T, H, C, P, L$*. In particular, the read has no hidden typed-term selector, no quotient reduction equality, no host evaluator, no unconditional confluence theorem, no closed subject-reduction theorem, and no extra route outside the displayed packet.*

Proof. Read the bridge through the carrier definition. Its displayed rows are exactly $N, Q, D, A, T, H, C, P, L$, with T as the only row comparing the closed typed term routes and H, C, P, L as structural transport, replay, provenance, and local naming rows.

Any accepted route must therefore factor through one of those coordinates. The carrier definition exports no further selector and no equality quotient over reduction routes, so there is no place for a hidden typed-term selector or host evaluator to enter.

The same exhaustion excludes unconditional metatheorems. Confluence is read only through Q, and preservation is read only through D and the boundary row visible to A; neither read becomes a closed theorem detached from the packet. □

Theorem 1190.6 (MetaCIC normalization-confluence bridge discharge boundary)**.** *Within an accepted* $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$ *carrier, row* D *can be handed to row* A *only as the displayed subject-reduction discharge-ledger boundary. The handoff preserves the named discharge rows consumed by closed consistency, but it does not assert an unconditional closed subject-reduction theorem.*

Proof. The discharge side of the bridge is the row D. It carries the named preservation-obligation rows from the subject-reduction discharge ledger and remains distinct from the closed-consistency assembly row A.

The assembly row may consume D only through the displayed bridge route. This gives A access to the ledger boundary that it cites, together with the normal false-proof exclusion already internal to the assembly packet.

Because the bridge has no additional preservation coordinate, the handoff cannot erase the ledger boundary. The result is a routed discharge boundary for the assembly consumer, not an unconditional closed subject-reduction theorem. □

Theorem 1190.7 (MetaCIC normalization-confluence bridge TasteGate surface)**.** *The Lean file* `TasteGate.lean` *for* MetaCICNormalizationConfluenceBridge$^{\uparrow}$ *must provide* Nontrivial MetaCICNormalizationConflue *and* FieldFaithful MetaCICNormalizationConfluenceBridge$^{\uparrow}$ *instances. The nontrivial instance must distinguish bridge packets that agree on N, Q but differ on D or A, and the field-faithful instance must preserve the separate rows $N, Q, D, A, T, H, C, P, L$.*

Lean4 ✓ `BEDC.Derived.MetacicNormalizationConfluenceBridgeUp.MetacicNormalizationConfluenceBridgeTasteGa`
`single carrier alignment`

Proof. The carrier has four sibling packet rows and five structural rows. A TasteGate that identifies all carriers would collapse the bridge to one point and would lose the distinction between normalization, confluence, discharge-ledger, and assembly reads.

Field faithfulness is forced by the same packet shape. Preserving $N, Q, D, A, T, H, C, P, L$ separately is exactly what prevents the bridge from rereading a normalization or confluence agreement as a subject-reduction theorem or as closed consistency. □

Theorem 1190.8 (MetaCIC normalization-confluence bridge obligation closure package)**.** *The displayed rows $N, Q, D, A, T, H, C, P, L$, together with the local* NameCert *obligations, the route-boundary theorem, the TasteGate marker, the falsifiable prediction, and the independence witness below, form the complete* obligation *package for* MetaCICNormalizationConfluenceBridge$^{\uparrow}$.

Proof. Start with the carrier of Definition 1190.1. It fixes the only admissible packet shape $B = (N, Q, D, A, T, H, C, P, L)$ and states that no hidden evaluator, quotient equality, typed-term selector, global confluence theorem, unconditional subject-reduction theorem, or detached consistency proof is exported.

Apply Definition 1190.2. The seven obligation rows cover carrier admission, the normalization-audit row, the confluence-audit row, the discharge-ledger row, the closed-consistency assembly row, closed typed term route correspondence, and the replay/provenance/local-name rows.

Apply Definition 1190.3 and Definition 1190.7. The route theorem keeps every preservation or consistency handoff inside $N, Q, D, A, T, H, C, P, L$, while the TasteGate theorem records that Lean supplies the nontrivial and field-faithful surface needed to keep those rows distinct.

The falsifiable prediction states the observable route failure for unconditional closed subject reduction, and the independence witness records why the four sibling packets do not already contain the simultaneous bridge classifier. Hence the chapter closes precisely the obligation package for this bridge. It does not claim global normalization, global confluence, global subject reduction, or closed consistency. □

Theorem 1190.9 (MetaCIC normalization-confluence bridge scope index)**.** *The scoped* MetaCICNormalizationConfl *read consumes exactly the following displayed rows: the normalization-audit row N, the confluence-audit row Q, the subject-reduction obstruction and discharge row D, the closed-consistency assembly row A, the typed-term route-correspondence row T, componentwise transport H, displayed replay C, provenance P, and local naming L. No scoped read may replace these rows by a host evaluator, quotient reduction equality, hidden typed-term selector, unconditional confluence theorem, unconditional subject-reduction theorem, or detached consistency proof.*

Proof. Start with the carrier fixed in Definition 1190.1. Its coordinates are exactly $N, Q, D, A, T, H, C, P, L$.

Apply Definition 1190.2 to read the local obligation surface. The normalization audit, confluence audit, discharge-ledger boundary, closed-consistency assembly, typed-term correspondence, transport, replay, provenance, and local naming rows are all displayed there.

Apply Definition 1190.3, Definition 1190.6, and Definition 1190.5. These theorems exclude the host evaluator, quotient equality, hidden typed-term selector, unconditional confluence, unconditional subject reduction, and detached consistency routes, so the listed rows are the complete scoped index. □

Theorem 1190.10 (MetaCIC normalization-confluence bridge candidate-mediated normalization)**.** *Every normalization conclusion exported by an accepted* $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$ *carrier is mediated by the displayed candidate and closed-candidate evidence in N. It may be transported through H and replayed through C, and it may be compared with the confluence row Q through T, but it cannot be read as strong normalization for all closed typed terms outside the candidate-mediated route.*

Proof. Read the normalization side through N. By Definition 1190.1, this row is the normalization-audit packet carrying candidate, closed-candidate, candidate-set, application adequacy, Pi adequacy, and no-infinite-reduction reads.

The comparison row T only records that the normalization and confluence rows speak about the same displayed closed typed term. Transport through H and replay through C preserve that row structure; they do not add a universal normalization coordinate.

Finally apply Definition 1190.3 and Definition 1190.8. The bridge remains a finite route-correspondence certificate, so the normalization conclusion is candidate-mediated and not an unconditional strong-normalization theorem for all closed typed terms. □

Theorem 1190.11 (MetaCIC normalization-confluence bridge conditional Church-Rosser boundary)**.** *Every Church-Rosser use exported by an accepted* $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$ *carrier remains conditional on the displayed confluence row Q, the typed-term correspondence row T, and the discharge-ledger boundary row D. In particular, such a use cannot discharge the beta-substitution, application-argument, lambda-domain, and Pi-domain subject-reduction hypotheses recorded in D.*

Proof. The confluence side of the bridge is the row Q. It supplies only the checked confluence fragments and named confluence-boundary inputs recorded by the carrier.

The bridge can compare Q with the normalization row only through T. That comparison is a route correspondence for the displayed closed typed term, not a replacement for the preservation rows stored in D.

Apply Definition 1190.6. The row D is handed to the assembly row A only as the displayed subject-reduction discharge-ledger boundary. Hence Church-Rosser use remains conditional on Q, T, D and cannot discharge the four subject-reduction hypotheses. □

Falsifiable prediction: Any accepted bridge packet whose normalization and confluence rows agree on the closed typed term has no route to an unconditional closed subject-reduction theorem.

Independence witness: metacicnormalizationaudit, metacic-confluence-audit, subjectreductiondischargeledger, closed-consistency-assembly: the bridge has a simultaneous four-row carrier and route-correspondence classifier absent from each sibling alone.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}}$.

Constructive story: The MetaCIC normalization-confluence bridge is generated from a $BHist$ packet that records a normalization row, a confluence row, and the bridge route joining them to the local certificate surface. The carrier does not assert global metatheory; it reads only the named normalization and confluence evidence and transports that evidence along $hsame$ when the representing history changes. Cont supplies the route boundary: later uses of the bridge must extend the same packet rather than appeal to an external proof of adequacy. The TasteGate surface is then the visible bridge between these rows and the admitted NameCert obligation.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalizationConfluenceBridge}\uparrow}$, scopedClosed)

Scope closed: This chapter binds the MetaCIC normalization-confluence bridge carrier, NameCert obligations, route-boundary theorem, TasteGate-surface theorem, scope index, candidate-mediated normalization boundary, and conditional Church-Rosser boundary.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICNormalizationConfluenceBridge}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.MetacicNormalizationConfluenceBridgeUp.MetacicNormalizationConfluenceBridgeTasteGate\_s`
Lean4 ✓ `BEDC.Derived.MetacicNormalizationConfluenceBridgeUp.taste gate`

Bridge status: none

Origin: ai

Not claimed: It does not claim full MetaCIC normalization, global confluence, or kernel soundness outside the displayed bridge packet.

Upgrade path: Public closure requires a checked consumer-facing package for normalization, confluence, discharge, and assembly reads over the same scoped bridge carrier.

Chapter 1191

A Concrete Naming Certificate for $\mathsf{PhysicalNameCertAudit}^{\uparrow}$

The $\mathsf{PhysicalNameCertAudit}^{\uparrow}$ packet realizes the physical NameCert analogue of section 9414.38 as one finite BEDC naming certificate. It sits beside chapter 1126, chapter 1129, chapter 1149, and chapter 1161. Those siblings expose observation routing, audit strength, reflective reuse, and reflection-gap boundaries; this packet binds the certificate-template rows needed before a model signature may be read as a certified physical name.

Definition 1191.1 (PhysicalNameCertAudit carrier)**.** *A* $\mathsf{PhysicalNameCertAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (S, O, M, C, Y, L, F, H, R, Q, N)$$

with the following displayed rows:

1. *S is the source row recording the finite observation or experiment trace that licenses the naming attempt;*
2. *O is the observed-signature row extracted from S through the displayed observation-reflection route;*
3. *M is the model-signature row offered as the physical name candidate;*
4. *C is the classifier row comparing O and M without importing a hidden model-reality identity;*
5. *Y is the stability certificate row recording the continuation discipline under which the comparison remains reusable;*
6. *L is the ledger policy row recording accepted fits, open gaps, and hidden residue that may later become active;*
7. *F is the failure-surface row on which missing source, classifier, stability, or ledger data are recorded as certificate blockers;*
8. *H is the componentwise* hsame *transport row for source, signature, classifier, stability, ledger, and failure reads;*
9. *R is the displayed* Cont *route through S, O, M, C, Y, L, F, H;*
10. *Q is the* Pkg *provenance over* $\mathsf{PhysicalNameCertAudit}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalNameCertAudit}^{\uparrow}}$ *row naming exactly this packet.*

The carrier has no coordinate for final truth, source-domain identity, unledgered approximation, host physical law, or an external model-selection oracle.

Theorem 1191.2 (PhysicalNameCertAudit obligation surface)**.** *For the carrier of Definition 1191.1, the local* $\mathsf{NameCert}_{\mathsf{PhysicalNameCertAudit}^{\uparrow}}$ *surface consists exactly of the finite obligations for source exposure in S, observed-signature extraction in O, model-signature presentation in M, classifier comparison in C, stability certification in Y, ledger policy in L, failure-surface accounting in F, componentwise transport in H, displayed routing in R, provenance in Q, and local naming in N.*

Proof. Project the carrier tuple of Definition 1191.1. It exposes the source, observed signature, model signature, classifier, stability, ledger, failure, transport, route, provenance, and local naming rows as the only packet coordinates.

The observation side is read through chapter 1126. That sibling supplies the finite source and observed-signature route, but it does not by itself certify a physical model name.

The audit and stability rows are read through chapter 1129 and chapter 1149. These give the classifier-facing model audit and continuation stability surfaces needed before the local naming row can be consumed.

Finally use chapter 1161. The boundary row keeps the certificate open to later defeating observations, so the ledger and failure rows remain part of the same finite NameCert surface rather than hidden host evidence. □

Lean4 ✓ `BEDC.Derived.PhysicalNameCertAuditUp.PhysicalNameCertAuditTasteGate single carrier alignment`

Theorem 1191.3 (PhysicalNameCertAudit non-escape)**.** *Every accepted* $\mathsf{PhysicalNameCertAudit}^{\uparrow}$ *packet exports only the displayed rows*

$$S, O, M, C, Y, L, F, H, R, Q, N.$$

A consumer may promote a model signature to a certified physical name only through those rows. It cannot replace them by an unrecorded source, a detached pattern, an implicit classifier, an unstated stability principle, an absent ledger policy, a hidden failure surface, final truth, source-domain identity, or host physical-law semantics.

Proof. Inspect Definition 1191.1. The packet has explicit rows for each certificate-template field and no additional coordinate for a hidden source, detached pattern, final truth, or host physical law.

Apply Definition 1191.2. Source, observed signature, model signature, classifier, stability, ledger, and failure data must all be read before the route, provenance, and local name are consumed.

The non-escape boundary follows because any missing source, classifier, stability, or ledger datum is recorded in F as a blocker rather than supplied by an external oracle. The local NameCert row can therefore name only the displayed packet. □

Theorem 1191.4 (PhysicalNameCertAudit certification handoff)**.** *If a* $\mathsf{PhysicalNameCertAudit}^{\uparrow}$ *packet admits source row S, observed-signature row O, model-signature row M, classifier row C, stability row Y, ledger row L, failure-surface row F, transport row H, displayed route R, provenance row Q, and local name N, then the only certification handoff available to a downstream physical-model consumer is the displayed route from O, M, C, Y, L, F to N. If the source, classifier, stability, or ledger row is absent, the handoff stops at the failure surface and no certified physical name is exported.*

Proof. Start with the obligation surface of Definition 1191.2. It requires the source, signature, classifier, stability, ledger, and failure rows before the local naming row is available.

Use non-escape from Definition 1191.3. Since no hidden source, classifier, stability principle, ledger policy, or host law can be projected from the packet, the handoff cannot be repaired outside the displayed carrier.

Thus a complete carrier hands the model signature to the local NameCert through R, Q, N. An incomplete carrier reaches F and remains a failed naming attempt rather than a certified physical name. □

Falsifiable prediction: If the source, classifier, stability, or ledger row is absent, a PhysicalNameCertAuditUp packet cannot promote a model signature to a certified physical name.

Independence witness: observationreflectionpacket, physicalmodelaudit, reflectivestability, reflectiongapboundary, physicaltruthcertificate: no sibling is bijective because PhysicalNameCertAuditUp uniquely binds the certificate-template rows for physical model naming rather than only routing, audit strength, reflection stability, gap boundary, or truth status.

The Lean follow-up in `lean4/BEDC/Derived/PhysicalNameCertAuditUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{PhysicalNameCertAudit}^{\uparrow}$ and FieldFaithful $\mathsf{PhysicalNameCertAudit}^{\uparrow}$ instances preserving $S, O, M, C, Y, L, F, H, R, Q, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{PhysicalNameCertAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{PhysicalNameCertAudit}^{\uparrow}$ packet is generated from finite source rows, observed signatures, model signatures, a classifier, stability certificate, ledger policy, failure surface, componentwise transport, displayed route, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PhysicalNameCertAudit}^{\uparrow}}$, seed)

Scope closed: Definition 1191.1, Definition 1191.2, Definition 1191.3, and Definition 1191.4 bind the physical NameCert analogue as a finite source, signature, classifier, stability, ledger, failure, route, provenance, and naming packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PhysicalNameCertAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert final truth, source-domain identity, host physical-law semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of the carrier, non-escape boundary, certification handoff, and TasteGate field-faithful rows for $S, O, M, C, Y, L, F, H, R, Q, N$.

Chapter 1192

A Concrete Naming Certificate for $\mathsf{FiniteObservationReflectionSeal}^{\uparrow}$

The $\mathsf{FiniteObservationReflectionSeal}^{\uparrow}$ packet realizes the observation–reflection equivalence of section 9414.38 as a finite NameCert seal. It sits after the observation handoff of chapter 1126, the finite window discipline of chapter 126, and the reflective inquiry carrier of chapter 1151. Those siblings expose observation, stream, or inquiry rows separately; this carrier binds physical observation and MetaCIC reflection to one shared classifier, ledger, and non-finalization surface.

Definition 1192.1 (Finite observation-reflection seal carrier)**.** *A* $\mathsf{FiniteObservationReflectionSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (P, M, S, K, C, L, H, Q, N)$$

with the following displayed rows:

1. *P is the physical-observation source row, read through finite reality-facing traces;*
2. *M is the MetaCIC-reflection source row, read through finite formal self-study traces;*
3. *S is the shared finite signature row comparing the physical observation surface with the formal reflection surface;*
4. *K is the classifier row accepting the displayed observation-reflection role correspondence;*
5. *C is the shared* Cont *route under which both inquiry directions remain extendable;*
6. *L is the non-finalization ledger recording rejected final physical or MetaCIC truth-oracle demands;*
7. *H records componentwise* hsame *transport for P, M, S, K, C, L;*
8. *Q records* Pkg *provenance for the same finite packet and its sibling observation-reflection, stream, and reflective-inquiry rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationReflectionSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a final physical truth oracle, a final MetaCIC truth oracle, source-domain identity, host validation, quotient stream equality, or an unbounded observation schedule.

Lean4 ✓ `BEDC.Derived.FiniteObservationReflectionSealUp.FiniteObservationReflectionSealTasteGate`
`single carrier alignment`

Theorem 1192.2 (Finite observation-reflection seal NameCert obligations)**.** *For the carrier of Definition 1192.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationReflectionSeal}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for* $F = (P, M, S, K, C, L, H, Q, N)$*;*
2. *physical-observation exposure through* P *and formal-reflection exposure through* M*;*
3. *shared signature and classifier acceptance through* S *and* K*;*
4. *continuation and non-finalization through the shared route* C *and ledger* L*;*
5. *componentwise transport, provenance, and local naming through* H, Q, N*.*

Thus the seal certifies a finite correspondence between physical inquiry and MetaCIC self-study without identifying their sources and without closing either inquiry direction.

Proof. Carrier admission projects the displayed packet $F = (P, M, S, K, C, L, H, Q, N)$. The two source rows P and M are separate coordinates, so the seal can expose physical observation and MetaCIC reflection while refusing source identity.

The signature and classifier rows provide the shared correspondence. Row S records the finite signature comparison, and row K records the accepted classifier judgment. These rows consume the observation-reflection packet and reflective inquiry surfaces rather than replacing them.

The route and ledger rows then close the non-finality condition. The shared continuation row C keeps both directions extendable, while L records rejected final truth-oracle demands. Rows H, Q, N transport, package, and name exactly the same displayed route, so no further NameCert obligation remains outside the packet. □

Theorem 1192.3 (Finite observation-reflection seal non-escape)**.** *No accepted* $\mathsf{FiniteObservationReflectionSeal}^{\uparrow}$ *packet exports a final physical truth oracle, a final MetaCIC truth oracle, source-domain identity, host validation, quotient stream equality, or an unbounded observation schedule beyond the rows*

$$P, M, S, K, C, L, H, Q, N.$$

Every consumer of the seal must read the displayed physical-observation row, MetaCIC-reflection row, shared signature, classifier, continuation, non-finalization ledger, transport, provenance, and local NameCert rows.

Proof. Inspect the carrier of Definition 1192.1. Its only source-facing rows are P and M, its only correspondence rows are S and K, and its only future-facing and refusal rows are C and L.

Apply the obligation theorem Definition 1192.2. It forces every seal read through physical exposure, formal exposure, shared signature comparison, classifier acceptance, continuation, and the non-finalization ledger before the local name is consumed.

The sibling packets do not add the missing oracle rows. $\mathsf{ObservationReflectionPacket}^{\uparrow}$ supplies finite observation-reflection roles, $\mathsf{StreamName}^{\uparrow}$ supplies finite window discipline, and $\mathsf{ReflectiveInquiry}^{\uparrow}$ supplies the paired inquiry carrier, but none of them contributes a final physical oracle, final MetaCIC oracle, source identity, quotient stream equality, or unbounded schedule to this seal. □

Falsifiable prediction: A finite observation-reflection seal is refuted by any accepted consumer that exports a final physical or MetaCIC truth oracle from the same finite packet.

Independence witness: observationreflectionpacket, streamname, reflectiveinquiry, realityconstrainedobservationreflection, namecert: the seal is not bijective to any sibling because it binds

both physical-observation and MetaCIC-reflection rows plus the shared non-finalization ledger in one packet.

The Lean follow-up must provide Nontrivial FiniteObservationReflectionSeal$^{\uparrow}$ and FieldFaithful FiniteObservationR instances in `lean4/BEDC/Derived/FiniteObservationReflectionSealUp/TasteGate.lean`, preserving $P, M, S, K, C, L, H, Q, N$.

Closure status for NameCert$_{\text{FiniteObservationReflectionSeal}^{\uparrow}}$.

Constructive story: A FiniteObservationReflectionSeal$^{\uparrow}$ packet is generated from physical-observation, MetaCIC-reflection, shared signature, classifier, continuation, non-finalization ledger, transport, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{FiniteObservationReflectionSeal}^{\uparrow}}$, seed)

Scope closed: Definition 1192.1, Definition 1192.2, and Definition 1192.3 bind the finite observation-reflection seal and its non-finalization boundary.

Formal verification: FormalStatus(NameCert$_{\text{FiniteObservationReflectionSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert final physical truth, final MetaCIC truth, source-domain identity, host validation, quotient stream equality, unbounded observation schedules, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of the carrier, five NameCert obligations, non-escape theorem, TasteGate nontriviality, and field faithfulness for $P, M, S, K, C, L, H, Q, N$.

Chapter 1193

A Concrete Naming Certificate for $\mathsf{PhysicalOperationDescent}^{\uparrow}$

The $\mathsf{PhysicalOperationDescent}^{\uparrow}$ packet realizes the operation-descent demand of chapter 9414 as a finite NameCert carrier. It sits beside the signature-fit packet of **??**, the endpoint audit of chapter 1176, the paired-tower boundary of chapter 1143, and the physical audit packet of chapter 1129. Those siblings expose physical-signature compatibility, endpoint-operation audit, tower comparison, and model-facing audit rows; this packet isolates the descent route of a single operation across source and endpoint classifiers before a consumer may apply the operation after classification.

Definition 1193.1 (PhysicalOperationDescent carrier)**.** *A* $\mathsf{PhysicalOperationDescent}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (O, S, E, R, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the operation row, naming the operation, predicate, or comparison whose post-classifier use is requested.*
2. *S is the source-classifier row, read through the physical-signature and representation data of* $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$*.*
3. *E is the endpoint-classifier row, read through the compressed or tower-facing endpoint at which O is intended to act.*
4. *R is the descent-route row, recording the displayed proof route that O respects S and lands in E.*
5. *F is the failure-exposure row, naming absent classifier compatibility, missing source signature, missing endpoint classifier, failed operation preservation, and audit defeat as displayed refusal reasons.*
6. *H records componentwise* hsame *transport for O, S, E, R, F.*
7. *C records displayed* Cont *replay through the same operation, classifier, route, and failure rows.*
8. *P is the* Pkg *provenance over* $\mathsf{PhysicalOperationDescent}^{\uparrow}$, $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, CompressionDescentAu $\mathsf{TowerEquivalence}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalOperationDescent}^{\uparrow}}$ *row.*

The carrier has no coordinate for applying O after a classifier step without a displayed descent route, no endpoint-only operation oracle, no hidden physical-signature source, and no refusal surface outside F.

Lean4 ✓ `BEDC.Derived.PhysicalOperationDescentUp.TasteGate.PhysicalOperationDescentTasteGate single carrier alignment`

Definition 1193.2 (PhysicalOperationDescent classifier)**.** *For accepted packets*

$$D = (O, S, E, R, F, H, C, P, N) \quad \text{and} \quad D' = (O', S', E', R', F', H', C', P', N'),$$

the predicate $\mathsf{PhysicalOperationDescentClassifier}(D, D')$ *holds when H transports operation rows, source classifiers, endpoint classifiers, descent routes, failure rows, continuation replays, provenance, and local names componentwise, and when the transported route still records that the operation respects the source classifier and lands in the endpoint classifier.*

Classifier agreement is therefore not equality of endpoint results and not equality of operation syntax alone. It is agreement of the finite operation, source-classifier, endpoint-classifier, descent-route, failure-exposure, transport, replay, provenance, and local-name rows as one packet.

Theorem 1193.3 (PhysicalOperationDescent NameCert obligations)**.** *For the carrier of Definition 1193.1, the local* $\mathsf{NameCert}_{\mathsf{PhysicalOperationDescent}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission: the accepted object is exactly $D = (O, S, E, R, F, H, C, P, N)$;*
2. *classifier stability: every accepted comparison uses the classifier of Definition 1193.2;*
3. *route exposure: every accepted post-classifier operation read displays the operation row O, source classifier S, endpoint classifier E, and descent route R in the same packet;*
4. *failure exposure: every missing source signature, endpoint classifier, operation-preservation proof, or model-audit defeat appears through the failure row F before acceptance is refused;*
5. *non-escape: no consumer may apply O after a classifier step, export endpoint operation validity, or suppress a descent failure from rows outside $O, S, E, R, F, H, C, P, N$.*

Proof. Carrier admission is projection from Definition 1193.1. The displayed tuple lists the operation, source classifier, endpoint classifier, descent route, failure row, transport, replay, provenance, and local name as the only available rows.

Classifier stability follows from Definition 1193.2. Transport preserves the operation row and the two classifier rows together with the route that relates them, so an accepted comparison cannot replace route preservation by endpoint syntax or host equality.

Route exposure is the operational content of the packet. A post-classifier application of O is accepted only when O, S, E, R appear together, because R is the row that records respect for the source classifier and landing in the endpoint classifier.

Failure exposure and non-escape are the finite-packet boundary. Missing classifier compatibility, missing signatures, failed preservation, and audit defeat live in F, while every accepted or refused read remains inside $O, S, E, R, F, H, C, P, N$. □

Theorem 1193.4 (PhysicalOperationDescent signature preservation)**.** *Let*

$$D = (O, S, E, R, F, H, C, P, N)$$

be an accepted $\mathsf{PhysicalOperationDescent}^{\uparrow}$ *packet. If a consumer applies O after reading the source classifier S, the resulting endpoint read is physically admissible only through the displayed route R and endpoint classifier E, with the failure row F still visible in the same packet.*

Proof. Use the route-exposure clause of Definition 1193.3. The source classifier S is not a permission to apply O at an endpoint; it is one row of the accepted descent packet.

The descent route R supplies the displayed preservation claim from the source classifier to the endpoint classifier. The endpoint classifier E records the target comparison in which the result of O is read.

The failure row F remains part of the same carrier. If preservation fails, or if source-signature or endpoint-classifier data are missing, that refusal is still visible and the operation cannot be exported as a physically admissible endpoint read. □

Theorem 1193.5 (PhysicalOperationDescent ledger non-escape)**.** *Every accepted* $\mathsf{PhysicalOperationDescent}^{\uparrow}$ *consumer route factors through*

$$O, S, E, R, F, H, C, P, N.$$

In particular, a consumer that applies an operation after a classifier step is rejected unless the descent route and failure row are displayed in the same packet.

Proof. The carrier definition exposes exactly the nine rows $O, S, E, R, F, H, C, P, N$. The classifier definition transports those rows componentwise and keeps the operation, two classifiers, descent route, and failure exposure tied together.

Apply the NameCert obligations. Route exposure forces O, S, E, R into every accepted post-classifier operation read, and failure exposure forces F to remain available for every refusal reason attached to that read.

Therefore an operation application that keeps the source classifier while omitting the route or failure row has no coordinate in the accepted packet. The consumer has left the finite $\mathsf{PhysicalOperationDescent}^{\uparrow}$ carrier rather than reading it. □

Falsifiable prediction: A consumer that applies an operation after a classifier step is rejected unless the descent route and failure row are displayed in the same packet.

Independence witness: realityconstrainedsignaturefit, compressiondescentaudit, towerequivalence, physicalmodelaudit, openfitpacket: none is bijective because PhysicalOperationDescentUp isolates operation, source classifier, endpoint classifier, descent proof route, and failure exposure in one carrier.

The Lean chapter `TasteGate.lean` for $\mathsf{PhysicalOperationDescent}^{\uparrow}$ is expected to provide explicit $\mathsf{Nontrivial\ PhysicalOperationDescent}^{\uparrow}$ and $\mathsf{FieldFaithful\ PhysicalOperationDescent}^{\uparrow}$ instances. Its gate-facing theorem is expected at `BEDC.Derived.PhysicalOperationDescentUp.taste_gate`.

Closure status for $\mathsf{NameCert}_{\mathsf{PhysicalOperationDescent}^{\uparrow}}$.

Constructive story: A $\mathsf{PhysicalOperationDescent}^{\uparrow}$ packet is generated from operation, source-classifier, endpoint-classifier, descent-route, failure-exposure, componentwise transport, continuation replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhysicalOperationDescent}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1193.1, Definition 1193.2, Definition 1193.3, Definition 1193.4, and Definition 1193.5 bind operation descent through reality-constrained approximation classifiers to a finite NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhysicalOperationDescent}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.PhysicalOperationDescentUp.TasteGate.PhysicalOperationDescentTasteGate\_single\_carrier`

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert bridge checking, endpoint-only operation validity, total descent for all operations, host physical truth, or operation application without the displayed failure surface.

Upgrade path: Obligation closure requires Lean encoding of classifier stability, signature preservation, and ledger non-escape beyond the carrier alignment theorem for $O, S, E, R, F, H, C, P, N$.

Chapter 1194

A Concrete Naming Certificate for $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$

The $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ carrier realizes the Inter-Hist Locality vision of chapter 9419 as one finite two-history NameCert packet. It sits after the observer-history identity surface of chapter 479, the local time-stream surface of chapter 603, the inter-Hist invariant carrier of chapter 656, the cross-Hist causal route of chapter 875, and the no-global-synchronization boundary of chapter 1003. Its role is to bind two displayed histories, a locality witness, an invariant row, observer symmetry, transport, replay, provenance, and local naming before any downstream consumer reads cross-history locality.

Falsifiable prediction: Any accepted FiniteHistLocalityPacketUp read that inserts a global synchronization row or deletes one displayed Hist row refutes the carrier.

Independence witness: observerhistidentity, histtimestream, interhistinvariant, crosshistcausal, noglobalsyncboundary: none is bijective because this packet simultaneously carries two displayed Hist rows, locality witness, invariant row, symmetry row, transport, Cont route, provenance, and local NameCert.

Definition 1194.1 (Finite Hist locality packet carrier)**.** *A* $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (H_0, H_1, L, I, S, T, C, Q, N)$$

with the following displayed rows:

1. H_0 *is the first displayed* BHist *row;*
2. H_1 *is the second displayed* BHist *row;*
3. L *is the finite locality-witness row relating the two displayed histories;*
4. I *is the inter-Hist invariant row read through the same locality witness;*
5. S *is the observer-symmetry row that prevents either history from becoming privileged;*
6. T *records componentwise* hsame *and* psame *transport for* H_0, H_1, L, I, S*;*
7. C *is the displayed* Cont *replay route for the same two-history surface;*
8. Q *is the* Pkg *provenance over observer-history identity, local time streams, inter-Hist invariants, cross-Hist causal dependence, no-global-synchronization boundaries,* BHist*,* hsame*,* psame*,* Cont*, and* NameCert *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteHistLocalityPacket}^{\uparrow}}$ *row.*
The carrier has no coordinate for a global synchronization row, shared host clock, preferred observer frame, ambient metric tensor, or host-valued cross-history equality.

Lean4 (definition) `BEDC.Derived.FiniteHistLocalityPacketUp.FiniteHistLocalityPacketUp`
Lean4 ✓ `BEDC.Derived.FiniteHistLocalityPacketUp.taste gate`

Theorem 1194.2 (Finite Hist locality packet obligation surface)**.** *For the carrier of Definition 1194.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteHistLocalityPacket}^{\uparrow}}$ *surface consists of five finite obligation rows: carrier admission for P, two displayed Hist rows H_0, H_1 with locality witness L, invariant and observer-symmetry exposure through I, S, componentwise* hsame/psame *transport and* Cont *replay through T, C, and package provenance with local naming through Q, N.*

Lean4 ✓ `BEDC.Derived.FiniteHistLocalityPacketUp.FiniteHistLocalityPacketObligationSurface`

Proof. Project the carrier rows of Definition 1194.1. The two histories, locality witness, invariant row, symmetry row, transport, replay, provenance, and local name are the complete displayed inventory.

Group that inventory into the five NameCert obligations stated above. The first admits the packet, the second exposes the two Hist rows and their locality witness, the third reads the invariant and symmetry rows, the fourth transports and replays the surface, and the fifth records provenance and local naming.

No remaining coordinate can supply a global synchronizer, shared host clock, preferred frame, ambient metric tensor, or host-valued equality, because none appears in P. □

Theorem 1194.3 (Finite Hist locality packet no-global-sync refusal)**.** *Every accepted* $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *read preserves both displayed Hist rows H_0, H_1 and routes locality through L, I, S, T, C, Q, N. It cannot insert a global synchronization row, collapse the two histories into one host clock, or replace observer symmetry by a privileged frame.*

Proof. Start from the obligation surface of Definition 1194.2. The packet has two displayed history rows and a locality witness before the invariant row or symmetry row can be read.

The no-global-synchronization sibling of chapter 1003 supplies the refusal shape consumed by Q, while the local time-stream sibling of chapter 603 keeps time rows attached to their source histories.

Thus an accepted read remains inside $H_0, H_1, L, I, S, T, C, Q, N$. A global synchronizer, one-host-clock collapse, or privileged observer frame would require a row outside that inventory. □

Lean4 ✓ `BEDC.Derived.FiniteHistLocalityPacketUp.FiniteHistLocalityPacketNoGlobalSyncRefusal`

Theorem 1194.4 (Finite Hist locality packet transport stability)**.** *Componentwise* hsame *and* psame *transport through T preserves the two displayed Hist rows, locality witness, invariant row, observer-symmetry row,* Cont *replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{FiniteHistLocalityPacket}^{\uparrow}}$ *row. Transport cannot turn the packet into a single-history surface or a global-frame certificate.*

Proof. Read T in Definition 1194.1. It transports the displayed rows H_0, H_1, L, I, S and is paired with the replay row C, provenance row Q, and local name N.

Apply Definition 1194.2. The transported rows remain the same five-obligation surface, so no consumer obtains a hidden synchronizer or a replacement history row.

Finally use Definition 1194.3. Since global-frame and one-clock coordinates are absent before transport, componentwise transport cannot create them afterward. □

Lean4 ✓ `BEDC.Derived.FiniteHistLocalityPacketUp.FiniteHistLocalityPacketTransportStability`

Theorem 1194.5 (Finite Hist locality packet consumer handoff)**.** *Every cross-Hist causal, maximum-rate, or observer-locality consumer of an accepted* $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *packet receives only*

$$H_0, H_1, L, I, S, T, C, Q, N.$$

The handoff supplies a two-history locality route with invariant and symmetry data, but it supplies no global synchronization row, selected global clock, privileged observer frame, ambient metric tensor, or host-valued equality.

Proof. Use Definition 1194.2 to identify the public packet rows. Any consumer receives the two histories, locality witness, invariant row, observer-symmetry row, transport, replay, provenance, and local name.

Apply Definition 1194.4 to preserve that inventory under hsame/psame transport. The consumer therefore sees the same finite route after transport as before transport.

The refusal theorem, Definition 1194.3, excludes every route through global synchronization, selected global clocks, privileged frames, ambient metric tensors, or host-valued equality. Hence the handoff is exactly the finite two-history locality packet. □

Lean4 ✓ `BEDC.Derived.FiniteHistLocalityPacketUp.FiniteHistLocalityPacketConsumerHandoff`

Theorem 1194.6 (Finite Hist locality packet TasteGate handoff)**.** *The same displayed inventory* $H_0, H_1, L, I, S, T, C, Q, N$ *is the paper-side obligation surface that later Lean development must use for* Nontrivial $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *and* FieldFaithful $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *instances in* `lean4/BEDC/Derived/FiniteHistLocalityPacketUp/TasteGate.lean`*.*

Proof. The carrier definition supplies the single concrete field inventory. The obligation-surface theorem identifies those fields as the complete local NameCert surface, while transport stability keeps the same fields under hsame and psame movement.

The consumer handoff then shows that downstream readers obtain no field beyond $H_0, H_1, L, I, S, T, C, Q, N$. Therefore the later Lean TasteGate instances must be Nontrivial and FieldFaithful for this displayed carrier rather than for a hidden global-frame object. □

Lean4 ✓ `BEDC.Derived.FiniteHistLocalityPacketUp.FiniteHistLocalityPacketTasteGate single carrier alignment`

Theorem 1194.7 (Finite Hist locality packet obligation-closure package)**.** *For every accepted* $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *carrier*

$$P = (H_0, H_1, L, I, S, T, C, Q, N),$$

the obligationClosure surface consists exactly of carrier admission, the two displayed Hist rows H_0, H_1*, the locality witness* L*, the invariant row* I*, observer symmetry through* S*, componentwise* hsame/psame *transport through* T*, displayed* Cont *replay through* C*, package provenance through* Q*, and local* $\mathsf{NameCert}_{\mathsf{FiniteHistLocalityPacket}^{\uparrow}}$ *naming through* N*.*

Every accepted read must preserve that full row order before any cross-Hist causal, maximum-rate, observer-locality, or TasteGate consumer receives the packet. No obligation row is supplied by a global synchronization coordinate, shared host clock, privileged observer frame, ambient metric tensor, or host-valued equality.

Proof. Carrier admission is projection from Definition 1194.1. The projected inventory is the displayed tuple $H_0, H_1, L, I, S, T, C, Q, N$, with no hidden row outside the packet.

Apply Definition 1194.2. It groups the inventory into carrier admission, two Hist rows with locality witness, invariant and symmetry exposure, transport and replay, and provenance with local naming.

Use Definition 1194.4 and Definition 1194.5 for downstream reads. Transport preserves the same displayed tuple, and every consumer handoff receives only the two-history locality route.

Finally apply Definition 1194.3 and the TasteGate handoff of Definition 1194.6. They exclude global synchronization and require later Nontrivial and FieldFaithful reads to use the same displayed carrier, so the listed rows exhaust the obligationClosure package. □

Lean4 ✓ `BEDC.Derived.FiniteHistLocalityPacketUp.FiniteHistLocalityPacketCarrier obligation closure package`

Theorem 1194.8 (FiniteHistLocalityPacket scoped kernel scope)**.** *For every accepted* $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *carrier*

$$P = (H_0, H_1, L, I, S, T, C, Q, N),$$

every cross-Hist causal, maximum-rate, observer-locality, and TasteGate consumer factors through the displayed rows $H_0, H_1, L, I, S, T, C, Q, N$*. The closed scope is limited to the two* BHist *rows,* H_0, H_1*, the locality witness* L*, the inter-Hist invariant row* I*, observer symmetry* S*,* hsame/psame *transport through* T*,* Cont *replay through* C*,* Pkg *provenance through* Q*, the local* $\mathsf{NameCert}_{\mathsf{FiniteHistLocalityPacket}^{\uparrow}}$ *row* N*, and the sibling routes cited by this chapter.*

Lean4 ✓ `BEDC.Derived.FiniteHistLocalityPacketUp.FiniteHistLocalityPacketScopedKernelScope`

Proof. Project the carrier in Definition 1194.1. The only available rows are the displayed tuple $H_0, H_1, L, I, S, T, C, Q, N$, with no global synchronization coordinate and no hidden host-clock row.

Apply the obligation package of Definition 1194.7. It binds carrier admission, both displayed Hist rows, locality, invariant exposure, observer symmetry, transport, replay, provenance, and local naming into one obligationClosure surface.

Use the refusal and stability theorems next. Definition 1194.3 blocks any route through global synchronization, while Definition 1194.4 keeps T as componentwise hsame/psame transport rather than a host equality.

Now read the consumer handoff. Definition 1194.5 sends cross-Hist causal, maximum-rate, and observer-locality consumers only through the displayed two-history packet, and Definition 1194.6 requires the TasteGate surface to use the same carrier inventory.

The cited sibling chapters supply observer-history identity, local time streams, inter-Hist invariants, cross-Hist causal dependence, and the no-global-synchronization boundary. Since the carrier, obligations, refusal, transport, consumer handoff, and TasteGate handoff all name the same finite rows, the scoped kernel dependency theorem closes exactly that displayed scope. □

Lean4 ✓ `BEDC.Derived.FiniteHistLocalityPacketUp.FiniteHistLocalityPacketCarrier scoped kernel scope`

Theorem 1194.9 (Finite Hist locality packet bridge surface)**.** *Every standard cross-Hist locality reading of an accepted* $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *public packet factors through the displayed rows*

$$H_0, H_1, L, I, S, T, C, Q, N$$

and through the sibling routes for observer-history identity, inter-Hist invariants, and no-global-synchronization. The bridge surface is therefore the finite two-history packet exposed by the chapter, not a global clock, privileged observer frame, ambient metric tensor, or host-valued equality of histories.

Proof. Start with the consumer handoff of Definition 1194.5. It exposes exactly the two displayed Hist rows, the locality witness, the invariant row, observer symmetry, transport, replay, provenance, and local naming to cross-Hist causal, maximum-rate, and observer-locality consumers.

Use the scoped kernel scope theorem Definition 1194.8. It keeps those same rows inside the cited sibling routes for observer-history identity, local time streams, inter-Hist invariants, cross-Hist causal dependence, and the no-global-synchronization boundary.

Finally apply the no-global-sync refusal of Definition 1194.3. Since the packet has no global synchronization row, shared host clock, privileged observer frame, ambient metric tensor, or host-valued equality coordinate, every standard locality reading factors through the displayed finite bridge surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteHistLocalityPacket}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ packet is generated from two displayed Hist rows, a locality witness, inter-Hist invariant row, observer-symmetry row, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteHistLocalityPacket}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1194.9 completes the mature paper surface for finite locality examples by factoring standard cross-Hist locality readings through the displayed public packet rows, the cross-chapter observer-history, local time-stream, inter-Hist invariant, cross-Hist causal, and no-global-synchronization routes, and the explicit refusal of host synchronization claims.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteHistLocalityPacket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close global synchronization, a host clock, a privileged observer frame, an ambient metric tensor, host-valued equality, analytic spacetime structure, or checked Lean carrier instances.

Upgrade path: A checked standard bridge requires Lean verification of the displayed cross-Hist locality bridge surface.

Chapter 1195

A Concrete Naming Certificate for $\mathsf{TowerEndpointReflection}^{\uparrow}$

The $\mathsf{TowerEndpointReflection}^{\uparrow}$ packet realizes the endpoint/source reflection boundary of section 9414.20 as a finite BEDC NameCert carrier. It consumes the tower-compression packet of chapter 1142, the endpoint-equivalence discipline of chapter 1143, the composite-ledger classifier of chapter 1162, and the descent decision surface of chapter 1176. Those siblings expose endpoint rows, tower ledgers, functorial composition, and descent audits; this carrier binds endpoint reflection back to a displayed source row without collapsing endpoint truth into source truth.

Definition 1195.1 (TowerEndpointReflection carrier)**.** *A* $\mathsf{TowerEndpointReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (E, S, K, Q, F, D, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the endpoint row, naming the terminal visible package whose reflection is being queried.*
2. *S is the source row, naming the base system, trace family, or observation process to which reflection is proposed.*
3. *K is the* $\mathsf{RealityConstrainedTowerCompression}^{\uparrow}$ *row, exposing the source, tower, classifier, endpoint, and composite-ledger surface.*
4. *Q is the* $\mathsf{TowerEquivalence}^{\uparrow}$ *row, recording endpoint agreement together with ledger and descent compatibility.*
5. *F is the* $\mathsf{CompressionLedgerFunctor}^{\uparrow}$ *row, recording the composite-ledger route assigned to the displayed tower arrows.*
6. *D is the* $\mathsf{CompressionDescentAudit}^{\uparrow}$ *row, recording the accepted or refused descent route for the endpoint operation under reflection.*
7. *O is the obstruction row, listing the finite reasons that block reflection, including missing composite ledger, failed descent audit, endpoint-only equivalence, source mismatch, and model-facing non-descent.*
8. *H records componentwise* hsame *transport for E, S, K, Q, F, D, O.*
9. *C is the displayed* Cont *replay route through the same endpoint, source, ledger, equivalence, descent, and obstruction rows.*

10. *P is the* Pkg *provenance over* $\mathsf{TowerEndpointReflection}^{\uparrow}$*, the four cited tower siblings,* $\mathsf{RealWindowBudget}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{TowerEndpointReflection}^{\uparrow}}$ *row.*

The carrier has no coordinate for endpoint truth as source truth, source identity from endpoint equivalence, unledgered reflection, private descent repair, or a model-facing acceptance route outside R.

Lean4 (definition) `BEDC.Derived.TowerEndpointReflectionUp.TowerEndpointReflectionUp`

Theorem 1195.2 (TowerEndpointReflection descent boundary)**.** *Let*

$$R = (E, S, K, Q, F, D, O, H, C, P, N)$$

be an accepted $\mathsf{TowerEndpointReflection}^{\uparrow}$ *packet. Any endpoint/source reflection exported from E to S requires both the composite-ledger row carried by K, F and the descent-audit row D. A consumer that keeps endpoint equivalence through Q while omitting either the composite ledger or the descent audit has an endpoint comparison, not a source-facing reflection.*

Proof. Project the carrier of Definition 1195.1. The endpoint row E and source row S are displayed together with tower compression K, tower equivalence Q, ledger functor F, descent audit D, and obstruction row O.

The tower-compression row exposes the source, classifier, endpoint, and composite-ledger discipline of chapter 1142. The ledger-functor row then records the composite route by which the tower arrows transport hidden-source material to the endpoint-facing ledger.

The descent-audit row supplies the separate decision surface required by chapter 1176. It is not implied by endpoint equivalence, because chapter 1143 binds agreement only when ledger and descent compatibility are also displayed.

Thus endpoint/source reflection is licensed only through the joint route K, F, D transported by H and replayed by C. If the composite-ledger row or the descent-audit row is absent, the packet has no carrier coordinate that can move an endpoint claim from E to S. □

Theorem 1195.3 (TowerEndpointReflection NameCert obligations)**.** *For the carrier of Definition 1195.1, the local* $\mathsf{NameCert}_{\mathsf{TowerEndpointReflection}^{\uparrow}}$ *surface consists exactly of seven obligation rows:*

1. *carrier admission for $R = (E, S, K, Q, F, D, O, H, C, P, N)$;*
2. *endpoint and source exposure through E, S;*
3. *tower-compression exposure through K;*
4. *endpoint-equivalence exposure through Q;*
5. *composite-ledger exposure through F;*
6. *descent-audit and obstruction exposure through D, O;*
7. *componentwise transport, replay, provenance, and local naming closure through H, C, P, N.*

Every accepted endpoint/source reflection must display these rows before a consumer may treat an endpoint operation as source-facing.

Proof. The carrier definition gives exactly the eleven-row packet $R = (E, S, K, Q, F, D, O, H, C, P, N)$. The local NameCert therefore sees endpoint, source, tower-compression, equivalence, ledger-functor, descent-audit, obstruction, transport, replay, provenance, and naming coordinates.

Rows E and S name the boundary being reflected. Rows K, Q, F, D import the four cited siblings, separating tower compression, endpoint equivalence, composite-ledger routing, and descent audit instead of treating any one of them as sufficient.

The obstruction row O records the finite refusal surface whenever a ledger, descent, equivalence, or source-facing requirement is missing. The rows H, C, P, N keep the same packet stable under transport, replay, provenance, and local naming.

Since the carrier admits no further coordinate, the seven displayed obligations exhaust the NameCert surface. A consumer that lacks one of them is reading a different packet rather than an accepted $\mathsf{TowerEndpointReflection}^{\uparrow}$ carrier. □

The Lean development in `lean4/BEDC/Derived/TowerEndpointReflectionUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ TowerEndpointReflection}^{\uparrow}$ and $\mathsf{FieldFaithful\ TowerEndpointReflection}^{\uparrow}$ instances preserving $E, S, K, Q, F, D, O, H, C, P, N$.

Falsifiable prediction: An accepted TowerEndpointReflectionUp packet without a composite-ledger row or descent-audit row refutes the carrier.

Independence witness: realityconstrainedtowercompression, towerequivalence, compressionledgerfunctor, compressiondescentaudit, realwindowbudget: none is bijective because only $\mathsf{TowerEndpointReflection}^{\uparrow}$ binds endpoint row, source row, composite-ledger row, descent audit, obstruction row, componentwise transport, replay, provenance, and local NameCert as one reflection carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{TowerEndpointReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{TowerEndpointReflection}^{\uparrow}$ packet is generated from endpoint, source, tower-compression, tower-equivalence, composite-ledger, descent-audit, obstruction, componentwise transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TowerEndpointReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1195.1, Definition 1195.2, and Definition 1195.3 bind endpoint/source reflection to a finite carrier with displayed composite-ledger and descent-audit obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TowerEndpointReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not assert Lean verification, bridge checking, endpoint truth as source truth, source identity from endpoint equivalence, unledgered reflection, private descent repair, or model-facing acceptance outside the displayed packet.

Upgrade path: Obligation closure requires Lean encoding of carrier admission, composite-ledger exposure, descent-audit exposure, obstruction non-escape, TasteGate nontriviality, and field faithfulness for $E, S, K, Q, F, D, O, H, C, P, N$.

Chapter 1196

A Concrete Naming Certificate for $\mathsf{AxisCarryRefusalLedger}^{\uparrow}$

The $\mathsf{AxisCarryRefusalLedger}^{\uparrow}$ packet realizes the cannot-claim registry of chapter 9350 as one transportable finite refusal ledger. It sits after the concrete registry packet of chapter 554, reads the bridge boundary of chapter 9344, and keeps the $\mathsf{AxisNat}^{\uparrow}$ and $\mathsf{Nat}^{\uparrow}$ interfaces of chapter 276 and chapter 28 distinct.

It is an ai over the $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{UnaryDirectionBridge}^{\uparrow}$, $\mathsf{AxisNat}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, and $\mathsf{FullAxis}^{\uparrow}$ sibling surfaces, with the ledger row serving as the finite transportable refusal bundle.

Falsifiable prediction: Any consumer that treats ZCarry as hsame, FullAxisUp as RealUp, or AxisNatUp as replacing NatUp is rejected unless the corresponding refusal row is absent from the packet.

Independence witness: axiszeckendorfcannotclaim, unarydirectionbridge, axisnat, nat, fullaxis: no sibling is bijective because this packet uniquely binds checked negative rows and horizon refusal rows into one transportable refusal ledger.

Definition 1196.1 (Axis carry-refusal ledger carrier)**.** *An* $\mathsf{AxisCarryRefusalLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (G, Z, F, A, B, L, H, C, P, N)$$

with the following displayed rows:

1. *G is the accepted* $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ *registry row containing the checked negative claims and horizon refusals;*
2. *Z is the checked row witnessing that a displayed* $\mathsf{ZCarry}^{\uparrow}$ *edge is not an* hsame *identification;*
3. *F is the horizon row refusing to read* $\mathsf{FullAxis}^{\uparrow}$ *as* $\mathsf{Real}^{\uparrow}$ *or as a complete metric object;*
4. *A is the horizon row refusing to read* $\mathsf{AxisNat}^{\uparrow}$ *as a replacement for* $\mathsf{Nat}^{\uparrow}$*;*
5. *B records the* $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *boundary through which any comparison between axis and unary naturals must pass;*
6. *L is the refusal ledger binding the negative rows Z, F, A to their registry source G and bridge boundary B;*
7. *H records componentwise* hsame *transport for $G, Z, F, A, B, L, C, P, N$ without converting a refused identification into equality;*

8. *C records displayed* Cont *replay for the registry row, refusal rows, bridge boundary, ledger, transports, provenance, and local naming;*
9. *P is the* Pkg *provenance over* AxisZeckendorfCannotClaim$^{\uparrow}$, ZCarry$^{\uparrow}$, FullAxis$^{\uparrow}$, Real$^{\uparrow}$, AxisNat$^{\uparrow}$, Nat$^{\uparrow}$, UnaryDirectionBridge$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert*;*
10. *N is the local* NameCert$_{\text{AxisCarryRefusalLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for turning ZCarry$^{\uparrow}$ *into* hsame*, promoting* FullAxis$^{\uparrow}$ *to* Real$^{\uparrow}$*, replacing* Nat$^{\uparrow}$ *by* AxisNat$^{\uparrow}$*, or bypassing the bridge boundary B.*

Lean4 ✓ `BEDC.Derived.AxisCarryRefusalLedgerUp.AxisCarryRefusalLedgerTasteGate single carrier alignment`

Theorem 1196.2 (Axis carry-refusal ledger realizes registry refusals)**.** *Every accepted* AxisCarryRefusalLedger$^{\uparrow}$ *packet $R = (G, Z, F, A, B, L, H, C, P, N)$ exposes the cannot-claim registry as a finite ledger of negative rows. The carry refusal Z, full-axis horizon refusal F, axis-natural refusal A, bridge boundary B, ledger L, transport H, continuation replay C, provenance P, and local naming row N must be read together before a consumer may cite the registry as a transportable refusal packet.*

Proof. Project the carrier of Definition 1196.1. The registry row G supplies the source cannot-claim packet, while Z, F, A are the displayed refusal rows selected from it.

Read the bridge and ledger rows next. The bridge boundary B records where any AxisNat$^{\uparrow}$–Nat$^{\uparrow}$ comparison must pass, and L binds the carry, full-axis, and axis-natural refusals to the same registry source.

Finally replay the support rows. Transport through H preserves the displayed refusal components, C replays only those components, P records their provenance, and N names the finite packet. Since no excluded identification is a coordinate of R, every accepted consumer remains inside the ledger above. □

Theorem 1196.3 (Axis carry-refusal ledger non-identification)**.** *For an accepted* AxisCarryRefusalLedger$^{\uparrow}$ *packet, no consumer can derive* hsame *from the* ZCarry$^{\uparrow}$ *row, a* Real$^{\uparrow}$ *field surface from the* FullAxis$^{\uparrow}$ *row, or a replacement of* Nat$^{\uparrow}$ *by* AxisNat$^{\uparrow}$ *from the axis-natural row. Each such reading is rejected unless its corresponding refusal row Z, F, or A is absent, in which case the packet is not the accepted carrier of Definition 1196.1.*

Lean4 ✓ `BEDC.Derived.AxisCarryRefusalLedgerUp.AxisCarryRefusalLedgerCarrier nonidentification rows`

↪ variant `BEDC.Derived.AxisCarryRefusalLedgerUp.AxisCarryRefusalLedgerCarrier refusal rows nonidentification`

Proof. Use Definition 1196.2. The accepted carrier exposes Z, F, A as part of the same finite refusal ledger, so none of the three rows is optional for this packet.

The structural rows do not add hidden identifications. The transport row H preserves displayed components, C replays the same refusal route, and P, N only record provenance and local naming.

Coordinate exhaustion gives the claim. The carrier contains no host equality, no Real field-operation surface for FullAxis$^{\uparrow}$, and no replacement map from AxisNat$^{\uparrow}$ to Nat$^{\uparrow}$; therefore the proposed readings are rejected by the ledger classifier. □

Theorem 1196.4 (Axis carry-refusal ledger negative-row exactness)**.** *For an accepted* AxisCarryRefusalLedger$^{\uparrow}$ *packet*

$$R = (G, Z, F, A, B, L, H, C, P, N),$$

the negative rows Z, F, A are exactly the refusal rows sourced from the $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ *registry row G and bound into the ledger row L. The row Z refuses to identify* $\mathsf{ZCarry}^{\uparrow}$ *with* hsame*, the row F refuses to read* $\mathsf{FullAxis}^{\uparrow}$ *as* $\mathsf{Real}^{\uparrow}$ *or as a complete metric object, and the row A refuses to replace* $\mathsf{Nat}^{\uparrow}$ *by* $\mathsf{AxisNat}^{\uparrow}$*. Transport through H, replay through C, provenance through P, and local naming through N preserve those refusals without converting them into equalities or quotients.*

Lean4 ✓ `BEDC.Derived.AxisCarryRefusalLedgerUp.AxisCarryRefusalLedgerCarrier negative row layer separation`

Proof. Project the carrier of Definition 1196.1. The rows $G, Z, F, A, B, L, H, C, P, N$ are all displayed, and Z, F, A are the only negative rows carried by the packet.

Use Definition 1196.2. It reads the $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ registry through G and binds the carry, full-axis, and axis-natural refusals into the same finite ledger L.

Now apply the non-identification theorem Definition 1196.3. Since H, C, P, N only preserve, replay, source, and name the displayed rows, no refusal row can become an equality, a quotient witness, or a Real field surface. □

Theorem 1196.5 (Axis carry-refusal ledger bridge-boundary preservation)**.** *Every accepted comparison between the* $\mathsf{AxisNat}^{\uparrow}$ *side and the* $\mathsf{Nat}^{\uparrow}$ *side of an* $\mathsf{AxisCarryRefusalLedger}^{\uparrow}$ *packet*

$$R = (G, Z, F, A, B, L, H, C, P, N)$$

passes through the displayed $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *boundary row B. The refusal rows Z, F, A and ledger row L may be transported along H and replayed through C, but the packet does not permit a consumer to bypass B by treating* $\mathsf{AxisNat}^{\uparrow}$ *as* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{FullAxis}^{\uparrow}$ *as* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{ZCarry}^{\uparrow}$ *as an* hsame *equality.*

Lean4 ✓ `BEDC.Derived.AxisCarryRefusalLedgerUp.AxisCarryRefusalLedgerCarrier bridge boundary preservation`

Proof. Read the bridge coordinate in the carrier. The row B is the only displayed route through which axis and unary natural comparisons are admitted.

The refusal ledger theorem Definition 1196.2 binds B together with $G, Z, F, A, L, H, C, P, N$. Thus the bridge is not a decorative witness; it is part of the same transportable packet as the cannot-claim registry and the three negative rows.

Finally use Definition 1196.3. Any route that bypasses B would have to identify one of the refused surfaces, but the carrier contains no coordinate for such an identification. The bridge boundary is therefore preserved by every accepted transport and replay of the ledger. □

Theorem 1196.6 (Axis carry-refusal ledger local NameCert exhaustion)**.** *The local* $\mathsf{NameCert}_{\mathsf{AxisCarryRefusalLedger}^{\uparrow}}$ *row of an accepted packet*

$$R = (G, Z, F, A, B, L, H, C, P, N)$$

exposes exactly the registry row G, refusal rows Z, F, A, $\mathsf{UnaryDirectionBridge}^{\uparrow}$ *boundary row B, ledger row L, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming row N. It exposes no additional equality between* $\mathsf{ZCarry}^{\uparrow}$ *and* hsame*, no quotient identifying* $\mathsf{FullAxis}^{\uparrow}$ *with* $\mathsf{Real}^{\uparrow}$*, no replacement of* $\mathsf{Nat}^{\uparrow}$ *by* $\mathsf{AxisNat}^{\uparrow}$*, and no private route around the NameCert anchors.*

Lean4 ✓ `BEDC.Derived.AxisCarryRefusalLedgerUp.AxisCarryRefusalLedgerCarrier local namecert exhaustion`

Proof. Begin with the carrier definition. Its finite packet has exactly the rows $G, Z, F, A, B, L, H, C, P, N$, and the provenance row P names the relevant AxisZeckendorfCannotClaim$^{\uparrow}$, UnaryDirectionBridge$^{\uparrow}$, AxisNat$^{\uparrow}$, Nat$^{\uparrow}$, FullAxis$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert anchors.

Apply negative-row exactness to fix the meaning of Z, F, A. Apply bridge-boundary preservation to fix the only admissible route between the axis and unary natural sides.

It remains to account for local naming. The row N names the same finite packet after H and C have transported and replayed it; it does not create new carrier coordinates. Hence the local NameCert surface is exhausted by the displayed registry, refusal, bridge, ledger, transport, continuation, provenance, and naming rows. □

Closure status for NameCert$_{\text{AxisCarryRefusalLedger}^{\uparrow}}$.

Constructive story: An AxisCarryRefusalLedger$^{\uparrow}$ packet is generated from the AxisZeckendorf cannot-claim registry, checked carry refusal, FullAxis horizon refusal, AxisNat replacement refusal, unary-direction bridge boundary, ledger, componentwise transport, displayed replay, provenance, and local NameCert rows.

Lean4 ✓ `BEDC.Derived.AxisCarryRefusalLedgerUp.taste gate`

Theory closure: TheoryGate(NameCert$_{\text{AxisCarryRefusalLedger}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1196.1, Definition 1196.2, Definition 1196.3, and Definition 1196.6 specify the public carrier-facing route for the finite refusal ledger, including negative-row exactness, bridge-boundary preservation, and local NameCert exhaustion.

Formal verification: FormalStatus(NameCert$_{\text{AxisCarryRefusalLedger}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.AxisCarryRefusalLedgerUp.AxisCarryRefusalLedgerCarrier\_bridge\_boundary\_preservation`

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not prove Lean verification, bridge checking, ZCarry-to-hsame identification, FullAxis-to-Real identification, AxisNat replacement of Nat, or any hidden host quotient.

Upgrade path: Bridge closure requires a checked standard bridge over the same public carrier-facing route, negative-row exactness, bridge-boundary preservation, transport, provenance, and local naming rows.

Chapter 1197

A Concrete Naming Certificate for $\mathsf{TerminationRefusalBoundary}^{\uparrow}$

The $\mathsf{TerminationRefusalBoundary}^{\uparrow}$ packet realizes the halting distinction of chapter 9368 as a finite NameCert surface that separates positive finite Cont traces from refusal-to-decide rows. It sits beside chapter 496, chapter 490, chapter 508, and chapter 854: those sibling packets record diagonal fixed-point pressure, obstruction ledgers, permitted finite refutation, and certificate truth-branch boundaries, while this carrier stores the positive trace row and the refusal row without converting either into a global halting decision.

Definition 1197.1 (Termination-refusal boundary carrier)**.** *A* $\mathsf{TerminationRefusalBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, I, T, F, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the source certificate row naming the local* $\mathsf{NameCert}_P$ *whose continuation chain is being inspected;*
2. *I is the input-history row naming the starting history h;*
3. *T is the positive finite trace row, either displaying a finite* Cont_P *chain ending at a terminal history or recording that no such displayed trace is present;*
4. *F is the finite trace verifier row, checking that every displayed step in T is a local* Cont_P *step and that a positive trace ends at the stated terminal history;*
5. *U is the refusal-to-decide row, recording that absence of a displayed finite trace is not reclassified as divergence, nontermination, or a total halting answer;*
6. *H records componentwise* hsame *transport for source certificates, input histories, trace rows, verifier rows, refusal rows, routes, provenance, and local names;*
7. *C records the displayed* Cont *routes by which consumers read S, I, T, F, U, H as one packet;*
8. *P is the* Pkg *provenance over chapter 9368, chapter 496, chapter 490, chapter 508, chapter 854,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TerminationRefusalBoundary}^{\uparrow}}$ *row.*

The carrier stores no divergence oracle, no unbounded search over continuation histories, no certificate-indexed truth branch, and no host evaluator for arbitrary certificate-history pairs.

Lean4 (definition) `BEDC.Derived.TerminationRefusalBoundaryUp.TerminationRefusalBoundaryCarrier`

Theorem 1197.2 (Termination-refusal boundary NameCert obligations)**.** *For the carrier of Definition 1197.1, the local* $\mathsf{NameCert}_{\mathsf{TerminationRefusalBoundary}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the displayed packet* $R = (S, I, T, F, U, H, C, P, N)$*;*
2. *source and input exactness, requiring every accepted read to preserve the certificate row* S *and input-history row* I*;*
3. *positive trace exactness, requiring a positive termination witness to be read only from the finite trace row* T *together with the verifier row* F*;*
4. *refusal exactness, requiring every no-trace read to remain in the refusal row* U *rather than becoming a divergence classifier;*
5. *transport and provenance closure, requiring all comparisons, consumer routes, package provenance, and local naming to be exactly the displayed rows* H, C, P, N*.*

Thus an accepted packet may expose a positive finite trace or a refusal boundary, but it cannot decide the global halting predicate of Definition 9368.2.

Lean4 ✓ `BEDC.Derived.TerminationRefusalBoundaryUp.TerminationRefusalBoundaryCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1197.1. The accepted rows are exactly $S, I, T, F, U, H, C, P, N$.

Source and input exactness keep the read attached to the same local certificate and starting history. A consumer therefore cannot change the inspected $\mathsf{NameCert}_P$ or history h while preserving the packet.

Positive trace exactness reads T together with F. If T displays a finite Cont_P chain, the verifier row checks only the listed steps and the stated terminal endpoint.

Refusal exactness reads U only when no displayed finite trace is being exported. The row records refusal to decide from missing finite evidence; it does not assert divergence, nontermination, or a total negative answer.

Finally H, C, P, N transport, replay, package, and name the same finite surface. The sibling references supply provenance for the diagonal, obstruction, finite-refutation, and truth-branch boundary contexts, but none adds an unbounded search, host evaluator, or global halting classifier. □

Theorem 1197.3 (Termination-refusal boundary non-escape)**.** *Every accepted* $\mathsf{TerminationRefusalBoundary}^{\uparrow}$ *packet exports only the displayed rows* $S, I, T, F, U, H, C, P, N$*. A consumer may read a verified finite* Cont *trace from* T, F *or a refusal-to-decide boundary from* U*, but it cannot obtain a divergence oracle, a total halting predicate, an unbounded continuation search, a host evaluator, or a certificate-indexed truth branch from the packet.*

Lean4 ✓ `BEDC.Derived.TerminationRefusalBoundaryUp.TerminationRefusalBoundaryCarrier nonescape`

Proof. Project the carrier and the NameCert obligations. The source, input, trace, verifier, refusal, transport, route, provenance, and local naming rows are the whole accepted surface.

For a positive trace read, the consumer must pass through T and F. The verifier row checks only the displayed finite continuation chain, so the read is a finite witness rather than an evaluator for other histories.

For a no-trace read, the consumer must pass through U. That row is a refusal boundary and not a negative halting proof.

The listed escape routes require rows absent from R: a divergence oracle, total classifier, unbounded search surface, host evaluator, or certificate-indexed truth branch. Since no such coordinate is carried, no accepted consumer route can export one. □

Theorem 1197.4 (Termination-refusal boundary independence)**.** *The* $\mathsf{TerminationRefusalBoundary}^{\uparrow}$ *carrier is not bijective to the carrier of chapter 496, chapter 490, chapter 508, or chapter 854 while preserving local* NameCert *obligations. Its distinguishing data are the simultaneous presence of a positive finite trace row* T, F *and a refusal-to-decide row* U *for the same source certificate and input history.*

Lean4 ✓ `BEDC.Derived.TerminationRefusalBoundaryUp.TerminationRefusalBoundary trace refusal row separation`

Proof. Compare the sibling roles one at a time. The halting diagonal packet carries fixed-point diagonal pressure, while the termination-refusal boundary must additionally store the positive trace verifier and refusal row for one inspected continuation chain.

The halting obstruction packet carries an obstruction ledger, not the paired positive finite trace and refusal-to-decide rows as one carrier. A bijection preserving NameCert obligations would have to send the verifier row F and refusal row U to distinct displayed coordinates, and those coordinates are not both present there.

The finite-refutation boundary carries a permitted falsity route and optional local decision row for a proposition, not a continuation trace verifier paired with refusal to decide halting. The certificate truth-branch boundary carries a branch-refusal surface, not a positive trace verifier for Cont_P chains.

Thus no listed sibling preserves $S, I, T, F, U, H, C, P, N$ with the same obligation surface. The carrier remains a separate finite boundary between positive termination evidence and refusal to decide. □

Theorem 1197.5 (Termination-refusal boundary TasteGate obligation)**.** *The Lean TasteGate file for* $\mathsf{TerminationRefusalBoundary}^{\uparrow}$ *will include explicit* Nontrivial $\mathsf{TerminationRefusalBoundary}^{\uparrow}$ *and* FieldFaithful $\mathsf{TerminationRefusalBoundary}^{\uparrow}$ *instances for the same carrier rows* $S, I, T, F, U, H, C, P, N$*. These instances must preserve the distinction between positive finite trace rows and refusal-to-decide rows.*

Lean4 ✓ `BEDC.Derived.TerminationRefusalBoundaryUp.TerminationRefusalBoundaryTasteGate single carrier alignment`

Proof. Nontriviality is forced by the separation of T, F from U. A carrier with a verified finite trace and a carrier with only the refusal row cannot collapse without losing the distinction recorded by Definition 9368.1.

Field faithfulness records preservation of each displayed row. In particular, it keeps source certificate, input history, positive trace, verifier, refusal, transport, route, package, and local naming data visible to the same carrier, so the TasteGate surface cannot identify a refusal boundary with a positive termination witness. □

Falsifiable prediction: A packet with no displayed finite Cont trace may carry a refusal boundary but cannot be read as a positive termination witness.

Independence witness: haltingdiagonal, haltingobstruction, finiterefutationboundary, certificatetruthbranchboundary: no sibling is bijective because this carrier stores both positive finite trace rows and refusal-to-decide rows while preserving their separation.

Closure status for $\mathsf{NameCert}_{\mathsf{TerminationRefusalBoundary}^{\uparrow}}$.

Constructive story: The termination-refusal boundary is generated from $BHist$ rows that name a boundary carrier, a refusal verdict, and the TasteGate obligation that consumes that verdict. The carrier is built bottom-up: first the history records the termination claim under inspection, then a refusal row marks the exact point where the claim leaves the admitted route, and finally Cont extensions may carry that refusal forward without changing its boundary. The $hsame$ relation keeps the verdict stable across equivalent histories. Non-escape and independence then show that the boundary is not a disguised termination proof, but a visible certificate of where such a proof is absent.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TerminationRefusalBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the termination-refusal boundary carrier, NameCert obligations, non-escape, independence, and TasteGate-obligation theorems.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TerminationRefusalBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim termination, decidability of all termination questions, or a route through any proof object outside the refusal boundary.

Upgrade path: Reaching obligationClosure requires a formal refusal-boundary carrier and checked non-escape for routes that omit the refusal row.

The $\mathsf{CofinalModulusSeal}^{\uparrow}$ hub routes the cofinal-tail modulus seal through chapter 698, chapter 1171, chapter 1164, chapter 386, chapter 126, chapter 301, chapter 291, and chapter 38.

Chapter 1198

A Concrete Naming Certificate for $\mathsf{CofinalModulusSeal}^{\uparrow}$

The $\mathsf{CofinalModulusSeal}^{\uparrow}$ packet realizes the cofinal-tail modulus route of chapter 9238 as one finite completion-seal naming surface. It sits after the shared threshold budget of chapter 698, the tail-modulus seal route of chapter 1171, the window-budget route of chapter 1164, and the terminal Cauchy-limit seal of chapter 386. The packet is not a Real-completeness principle: it records the finite rows a consumer must expose before the Real-completion seal can be read.

Falsifiable prediction: Every accepted CofinalModulusSealUp consumer must expose the cofinal tail budget, CauchyTailModulusSeal, RealWindowBudget, CauchyLimitSeal, RegSeqRat, StreamName, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert rows before any Real-completion seal read is public.

Independence witness: cofinaltailbudget, cauchytailmodulusseal, realwindowbudget, cauchylimitseal, real: no sibling is bijective because each supplies only a proper route segment while CofinalModulusSealUp binds the cofinal modulus-to-seal route in one local packet.

Definition 1198.1 (Cofinal modulus seal carrier)**.** *A* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, W, L, R, T, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{CofinalTailBudget}^{\uparrow}$ *row fixing the shared cofinal-tail threshold;*
2. *M is the* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *row that binds the shared modulus route to the tail seal;*
3. *W is the* $\mathsf{RealWindowBudget}^{\uparrow}$ *row exposing the finite observation window budget for the same route;*
4. *L is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row consumed only after B, M, W have fixed the cofinal modulus route;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from the displayed tail windows;*
6. *T is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by the cofinal threshold and the window budget;*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and readback ledger attached to T;*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached through R, D, L;*
9. *H records componentwise* hsame *transport for the route rows and the local naming row;*

10. *C records displayed* Cont *replay from B, M, W through T, D, R, L, E;*
11. *P is the* Pkg *provenance over* CofinalTailBudget$^{\uparrow}$, CauchyTailModulusSeal$^{\uparrow}$, RealWindowBudget$^{\uparrow}$, CauchyLimitSeal$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* NameCert$_{\text{CofinalModulusSeal}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, an undisplayed completion seal, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.CofinalModulusSealUp.CofinalModulusSealTasteGate single carrier alignment`

Theorem 1198.2 (Cofinal modulus seal NameCert obligations)**.** *For the carrier of Definition 1198.1, the local* NameCert$_{\text{CofinalModulusSeal}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for $S = (B, M, W, L, R, T, D, E, H, C, P, N)$;*
2. *cofinal route synchronization, stating that B, M, W expose one shared tail threshold, tail-modulus seal, and observation-window budget;*
3. *completion-seal handoff, stating that L, R, T, D, E are read only through the synchronized cofinal route;*
4. *structural replay, stating that H, C, P transport, replay, and source exactly the displayed coordinates;*
5. *non-escape, stating that every public consumer remains inside the displayed* NameCert$_{\text{CofinalModulusSeal}^{\uparrow}}$ *row N and cannot import quotient equality, host equality, selected limits, countable choice, or ambient completeness.*

Proof. Project the carrier. The tuple lists the cofinal tail budget, Cauchy tail-modulus seal, Real window budget, Cauchy-limit seal, RegSeqRat handoff, StreamName window, DyadicRatCore ledger, RealUp seal, transport, continuation, provenance, and local naming rows.

Read the three route-source rows next. The CofinalTailBudget$^{\uparrow}$ sibling fixes the shared cofinal threshold, the CauchyTailModulusSeal$^{\uparrow}$ sibling binds the modulus route to the tail seal, and the RealWindowBudget$^{\uparrow}$ sibling exposes the finite observation window budget for the same route.

Now attach the completion-seal side. The CauchyLimitSeal$^{\uparrow}$ row L can be consumed only after B, M, W have fixed the route, and the rows T, D, R, E display the StreamName, dyadic, RegSeqRat, and RealUp faces of that handoff.

The rows H, C, P, N only transport, replay, source, and name the displayed packet. Since no excluded object is a coordinate of the carrier, the five obligation rows exhaust the local NameCert surface. □

Theorem 1198.3 (Cofinal modulus seal RegSeqRat window factorization)**.** *Every* RegSeqRat$^{\uparrow}$ *handoff accepted by* CofinalModulusSeal$^{\uparrow}$ *factors through the same* StreamName$^{\uparrow}$ *window row T and* DyadicRatCore$^{\uparrow}$ *tolerance row D selected by the cofinal tail budget B and the* RealWindowBudget$^{\uparrow}$ *row W.*

Lean4 ✓ `BEDC.Derived.CofinalModulusSealUp.CofinalModulusSealRegSeqRatWindowFactorization`

Proof. Project the carrier of Definition 1198.1. The RegSeqRat row R is reached from the displayed tail windows, while T is selected by the cofinal threshold and window budget and D is attached to that selected window.

Apply Definition 1198.6 and Definition 1198.7. The shared-route theorem binds B, M, W before the completion side is public, and the window-handoff theorem places T, D, R behind the same B and W rows.

Finally use Definition 1198.9 and Definition 1198.10. These identify the selected window and tolerance ledger as the only public window route for R, so a RegSeqRat handoff cannot factor through a detached StreamName, a second dyadic tolerance row, or an independent RealWindowBudget. □

Theorem 1198.4 (Cofinal modulus seal tail-budget transport)**.** *Componentwise* hsame *transport in an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet preserves the cofinal tail budget B, the* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *row M, and the* $\mathsf{RealWindowBudget}^{\uparrow}$ *row W together as one source route.*

Proof. Start with the source-row synchronization theorem. Definition 1198.9 states that B, M, W are synchronized as one cofinal tail budget, Cauchy tail-modulus seal, and Real window budget before any downstream row is consumed.

Read the transport coordinate H from the carrier. By the obligation surface in Definition 1198.2, H records componentwise hsame transport for the displayed route rows and the local naming row, rather than a separate source selector.

The window-budget exactness theorem then fixes the downstream use of the transported source. Definition 1198.10 makes T, D, R consume the same B, W pair, while the shared-route obligation keeps M on that source route. Thus transport preserves B, M, W together and cannot move only one of the three rows. □

Theorem 1198.5 (Cofinal modulus seal NameCert route coverage)**.** *The local* $\mathsf{NameCert}_{\mathsf{CofinalModulusSeal}^{\uparrow}}$ *route covers exactly the displayed rows*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

It cannot import quotient stream equality, host real equality, selected limits, countable choice, or ambient Real completeness.

Proof. First use Definition 1198.2. Its carrier admission, route synchronization, completion handoff, structural replay, and non-escape clauses are all written over the rows of Definition 1198.1.

Next combine the route theorems. Definition 1198.6 fixes the source rows B, M, W, Definition 1198.3 factors the RegSeqRat handoff through T, D, and Definition 1198.4 keeps source transport componentwise.

It remains to exclude external completion data. The completion non-escape theorem, Definition 1198.8, removes quotient stream equality, countable choice, selected host limits, host real equality, and ambient Real completeness from the consumer boundary. Therefore the local NameCert route covers exactly the displayed finite rows and nothing beyond them. □

Theorem 1198.6 (Cofinal modulus seal shared route obligation)**.** *For the carrier of Definition 1198.1, rows B, M, W must name one shared cofinal route before T, D, R, L, E are public. A completion-facing consumer may not read the StreamName, DyadicRatCore, RegSeqRat, CauchyLimitSeal, or RealUp rows from separate cofinal sources.*

Proof. Project the carrier $S = (B, M, W, L, R, T, D, E, H, C, P, N)$. The source side of the packet is exactly the cofinal tail budget row B, the Cauchy tail-modulus seal row M, and the Real window budget row W.

Apply Definition 1198.2. Its cofinal route synchronization clause binds those three rows as one shared threshold, tail-modulus seal, and observation-window budget before the completion-seal handoff is readable.

The sibling chapters named in the introduction supply only their local route segments: $\mathsf{CofinalTailBudget}^{\uparrow}$ supplies the budget, $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ supplies the modulus seal, and $\mathsf{RealWindowBudget}^{\uparrow}$ supplies the window budget. The support rows H, C, P, N preserve that same route, so T, D, R, L, E cannot be public from separate sources. □

Theorem 1198.7 (Cofinal modulus seal window handoff obligation)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exported by an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet reads through the same* $\mathsf{CofinalTailBudget}^{\uparrow}$ *row* B *and* $\mathsf{RealWindowBudget}^{\uparrow}$ *row* W.

Proof. Read the displayed rows in Definition 1198.1. The StreamName row T is selected by the cofinal threshold and window budget, the DyadicRatCore row D is attached to that selected window, and the RegSeqRat row R is reached from the displayed tail windows.

Apply Definition 1198.2 and then Definition 1198.6. The first theorem supplies the local certificate clauses, and the second locks B, M, W as the shared source route before T, D, R are public.

The introduction's StreamName, DyadicRatCore, and RegSeqRat sibling routes therefore enter the packet only through the same cofinal tail budget and Real window budget rows. Since the carrier has no second B or W coordinate, every handoff reads through that single pair. □

Theorem 1198.8 (Cofinal modulus seal completion non-escape obligation)**.** *No completion-facing consumer accepted by* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *can import quotient stream equality, countable choice, selected host limits, host real equality, or ambient Real completeness. The consumer boundary is the displayed route*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

Proof. First project the carrier and use Definition 1198.2. The carrier admission and non-escape clauses enumerate the public surface and exclude quotient equality, host equality, selected limits, countable choice, and ambient completeness as local NameCert coordinates.

Next apply Definition 1198.6 and Definition 1198.7. They force the StreamName, DyadicRatCore, and RegSeqRat handoffs through the same B and W rows before the CauchyLimitSeal and RealUp rows can be consumed.

Finally use the CauchyLimitSeal and RealUp sibling routes named in the introduction. Those siblings receive only the displayed finite handoff $B, M, W, T, D, R, L, E, H, C, P, N$ from this packet. Since no excluded completion principle appears in the carrier, the accepted consumer cannot escape the finite route. □

Theorem 1198.9 (Cofinal modulus seal source-row synchronization)**.** *Every accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet must name one shared cofinal source route before any of the rows* T, D, R, L, E *can be consumed. In particular, the rows* B, M, W *are synchronized as the cofinal tail budget, Cauchy tail-modulus seal, and Real window budget for the same displayed route.*

Proof. Project the carrier of Definition 1198.1. The source side contains exactly the rows B, M, W before the StreamName, DyadicRatCore, RegSeqRat, CauchyLimitSeal, and RealUp rows are read.

Apply Definition 1198.2. Its cofinal route synchronization row states that B, M, W expose one shared threshold, tail-modulus seal, and observation-window budget in the same packet.

The support rows H, C, P, N transport, replay, source, and name that packet without adding another route source. Therefore any consumer of T, D, R, L, E must first pass through the synchronized B, M, W route. □

Theorem 1198.10 (Cofinal modulus seal window-budget exactness)**.** *Every* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{RegSeqRat}^{\uparrow}$ *window read exported by an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet is routed through the same* $\mathsf{RealWindowBudget}^{\uparrow}$ *row* W *and* $\mathsf{CofinalTailBudget}^{\uparrow}$ *row* B*.*

Proof. Start with the synchronized source route of Definition 1198.9. It fixes B, M, W before any read of T, D, R is public.

The StreamName row T is selected by the cofinal threshold and the window budget, the DyadicRatCore row D is attached to that selected window, and the RegSeqRat row R is reached from the displayed tail windows. Thus the three readbacks share the same B and W rows.

No alternate window-budget coordinate appears in the carrier. The rows H, C, P, N preserve the displayed route, so every exported window read is exact for the same RealWindowBudget and CofinalTailBudget rows. □

Lean4 ✓ `BEDC.Derived.CofinalModulusSealUp.CofinalModulusSealWindowBudgetExactness`

Theorem 1198.11 (Cofinal modulus seal completion readback boundary)**.** *Every completion-facing readback from an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet passes through* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. The packet does not claim Real completeness.*

Proof. Use Definition 1198.9 to locate the source route and Definition 1198.10 to locate the window reads. Together they force completion-facing readback through the displayed M, L, R, T, D, E rows and the synchronized source rows.

Now apply the existing Real handoff in Definition 1198.13. The Real-facing consumer reaches E only through $B, M, W, T, D, R, L, E, H, C, P, N$.

Finally use non-escape from Definition 1198.14. Since the carrier has no coordinate for host completeness, quotient equality, selected limits, or countable choice, the readback boundary is the finite packet rather than a Real-completeness principle. □

Theorem 1198.12 (Cofinal modulus seal cofinal route)**.** *Every accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet exposes one cofinal modulus-to-seal route*

$$B, M, W \to T, D, R, L, E$$

through the support rows H, C, P, N*. A public route that omits the cofinal tail budget, the Cauchy tail-modulus seal, or the Real window budget is outside the packet.*

Proof. Start from the NameCert obligations. The cofinal route synchronization row ties B, M, W to the same accepted packet before any completion-facing row is read.

Use the sibling boundaries in order. The cofinal tail budget supplies the shared threshold, the Cauchy tail-modulus seal binds the threshold to the modulus route, and the Real window budget exposes the selected observation window and regular handoff surface.

It remains to identify the public route. The completion-seal handoff row reads T, D, R, L, E only downstream of B, M, W, while H, C, P, N preserve the same packet. If any of B, M, W is omitted, no displayed route reaches the seal side. □

Theorem 1198.13 (Cofinal modulus seal Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet factors through the displayed rows*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

The handoff exposes the $\mathsf{Real}^{\uparrow}$ *seal only after the* $\mathsf{CofinalTailBudget}^{\uparrow}$, $\mathsf{CauchyTailModulusSeal}^{\uparrow}$, $\mathsf{RealWindowBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *rows have been read on the same route.*

Proof. Project the carrier to the Real-facing rows. The only RealUp coordinate is E, and it appears after the StreamName window T, dyadic ledger D, RegSeqRat handoff R, and Cauchy-limit seal L.

Apply Definition 1198.12. That theorem places T, D, R, L, E downstream of the synchronized source rows B, M, W, so no Real-facing consumer can reach E from a detached window, a private modulus, or an independent limit seal.

Finally read the support rows. Transport through H, replay through C, provenance through P, and local naming through N preserve exactly the same route. Thus the Real handoff is the displayed finite packet rather than a host completeness assertion. □

Theorem 1198.14 (Cofinal modulus seal non-escape)**.** *No accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *consumer can read beyond*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

In particular, the packet exports no quotient stream equality, host real equality, selected host limit, countable-choice selector, undisplayed completion seal, independent RealUp equality row, or ambient Real-completeness principle.

Proof. Use the NameCert obligations to enumerate the public surface. Carrier admission exposes only $B, M, W, L, R, T, D, E, H, C, P, N$, and the route synchronization and completion-seal handoff rows keep the consumer on those coordinates.

For StreamName, DyadicRatCore, and RegSeqRat reads, the route stops at T, D, R after the cofinal source rows have been displayed. For RealUp and completion-facing reads, the route continues through L, E and then through the same transport, continuation, provenance, and local naming rows.

The excluded objects require coordinates absent from the carrier. Since H, C, P, N only preserve and name the displayed packet, no consumer can reinterpret the cofinal modulus seal as quotient equality, selected limit data, countable choice, independent Real equality, or ambient completeness. □

Corollary 1198.15 (Cofinal modulus seal strict obstruction)**.** *Let*

$$S = (B, M, W, L, R, T, D, E, H, C, P, N)$$

be an accepted $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet. Suppose a completion-facing,* $\mathsf{Real}^{\uparrow}$*-facing,* $\mathsf{RegSeqRat}^{\uparrow}$*-facing,* $\mathsf{StreamName}^{\uparrow}$*-facing, or* $\mathsf{DyadicRatCore}^{\uparrow}$*-facing consumer displays a failure, refusal, separation, or countermodel row against a named converse or reuse route for* S*. Then that displayed row is a strict local obstruction: it blocks only the named route whose consumer-facing read factors through*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

It rejects every unlisted coordinate and cannot be reinterpreted as a global impossibility theorem, a host theorem, hidden external validation of the blocked route, quotient stream equality, countable choice, a selected host limit, host real equality, an undisplayed completion seal, or ambient Real completeness.

Proof. Start with the local obligation surface of Definition 1198.2. Its carrier-admission row lists exactly the displayed packet coordinates, its cofinal route synchronization row binds B, M, W as the shared source route, its completion-seal handoff row places L, R, T, D, E downstream of that route, its structural replay row restricts H, C, P to transport, replay, and provenance over those same coordinates, and its non-escape row keeps every public consumer inside the local $\mathsf{NameCert}_{\mathsf{CofinalModulusSeal}^{\uparrow}}$ row N.

Apply the completion non-escape obligation, Definition 1198.8. It says that no completion-facing consumer accepted by $\mathsf{CofinalModulusSeal}^{\uparrow}$ can import quotient stream equality, countable choice, selected host limits, host real equality, or ambient Real completeness, and that the consumer boundary is the displayed route

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

Thus every consumer-facing use of a displayed failure, refusal, separation, or countermodel row must be read as a row of this finite route. The row may obstruct the named converse or reuse route exactly where that route asks to read, replace, or bypass one of the displayed coordinates, but it has no access to any coordinate outside the route.

A stronger interpretation would require data not exported by the packet. A global impossibility theorem would require a theorem surface beyond the local $\mathsf{NameCert}_{\mathsf{CofinalModulusSeal}^{\uparrow}}$ boundary; a host theorem would require host equality, host limits, host completeness, or a host proof channel; hidden external validation would require an off-packet certificate route; and quotient stream equality, countable choice, selected host limits, host real equality, undisplayed completion seals, and ambient Real completeness are precisely the coordinates excluded by Definition 1198.8. Since Definition 1198.2 supplies only the displayed finite rows, the obstruction remains strict and local to the named converse or reuse route. □

Theorem 1198.16 (Cofinal modulus seal window lock)**.** *Before a* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *completion seal is public, the cofinal tail budget,* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$*,* $\mathsf{RealWindowBudget}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows must all be displayed in the same finite carrier.*

Proof. Project the carrier of Definition 1198.1. Its rows are exactly $B, M, W, L, R, T, D, E, H, C, P, N$, so the cofinal budget, tail-modulus seal, window budget, StreamName window, dyadic ledger, regular-sequence handoff, limit seal, Real seal, transport, replay, provenance, and local name are all visible before the public read.

Apply Definition 1198.2 and Definition 1198.12. They lock the seal side T, D, R, L, E downstream of the synchronized B, M, W source route.

Finally use Definition 1198.14. No hidden completion seal, ambient completeness witness, quotient equality, or choice selector can supply a missing row, so the displayed finite carrier is the public window lock. □

Theorem 1198.17 (Cofinal modulus seal tail readback totality)**.** *Every tail readback accepted by* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *is total only on the displayed rows* $B, M, W, T, D, R, L, E, H, C, P, N$*. In particular, the tail budget, Cauchy tail-modulus seal, Real window budget, StreamName, DyadicRatCore, RegSeqRat, Cauchy limit seal, RealUp, hsame, Cont, Pkg, and NameCert rows must be present before the readback can be consumed.*

Proof. Use Definition 1198.10. It routes StreamName, DyadicRatCore, and RegSeqRat reads through the same cofinal tail budget and Real window budget.

Then apply the Real handoff of Definition 1198.13. The readback continues to the CauchyLimitSeal and RealUp rows only through the same support rows H, C, P, N.

The TasteGate requirement for this chapter asks the later Lean carrier to keep Nontrivial and FieldFaithful instances for the same finite surface. In the paper carrier this means totality is row-total on $B, M, W, T, D, R, L, E, H, C, P, N$, not a route through ambient Real completeness. □

Theorem 1198.18 (Cofinal modulus seal completion consumer boundary)**.** *A completion-facing consumer of* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *may consume the seal only after the cofinal tail budget,* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$*,* $\mathsf{RealWindowBudget}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows have all been displayed. The consumer boundary contains no choice row, quotient stream equality, or ambient completeness premise.*

Proof. Start from Definition 1198.11. It already places completion-facing readback on the finite sequence of cofinal source, StreamName, dyadic, regular-sequence, CauchyLimitSeal, RealUp, transport, replay, provenance, and naming rows.

Now combine the window lock with tail readback totality. The first theorem requires the rows to be displayed before the seal is public, and the second makes the readback total only on that row inventory.

Finally apply non-escape. Since the carrier has no coordinate for quotient stream equality, selected limits, countable choice, or ambient completeness, every completion consumer stops at the displayed finite boundary. □

Theorem 1198.19 (Cofinal modulus seal tail cofinality lock)**.** *Every accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet locks a completion read to the shared cofinal tail budget before the read may inspect the seal side. In particular, a public completion read must pass through the* $\mathsf{CofinalTailBudget}^{\uparrow}$*,* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$*,* $\mathsf{RealWindowBudget}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{CofinalModulusSeal}^{\uparrow}}$ *rows in the same finite carrier.*

Proof. Project the carrier of Definition 1198.1. The rows B, M, W form the source side of the cofinal tail route, while T, D, R, L, E form the StreamName, dyadic, regular-sequence, Cauchy-limit, and Real-facing seal side.

Use source-row synchronization and window-budget exactness. Definition 1198.9 identifies B, M, W as one shared cofinal route, and Definition 1198.10 routes the T, D, R windows through that same budget.

The Real handoff then places L and E downstream of the synchronized rows, while H, C, P, N preserve transport, replay, provenance, and local naming. Thus the completion read has no entry point except the displayed cofinal tail lock. □

Theorem 1198.20 (Cofinal modulus seal shared budget exhaustion)**.** *For every accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *consumer, the shared budget rows* B, M, W *exhaust the admissible cofinal-tail supply for the downstream rows* $T, D, R, L, E, H, C, P, N$*. No consumer may replace that supply by a private modulus, a detached RealWindowBudget, a hidden StreamName, quotient stream equality, selected host limits, or ambient Real completeness.*

Proof. Begin with the NameCert obligations. They admit only the displayed carrier $S = (B, M, W, L, R, T, D, E, H$ and require cofinal route synchronization before completion-seal handoff.

The tail cofinality lock above gives the budget use required by each completion read. The lock forces $\mathsf{CofinalTailBudget}^{\uparrow}$, $\mathsf{CauchyTailModulusSeal}^{\uparrow}$, and $\mathsf{RealWindowBudget}^{\uparrow}$ to be the same route source for StreamName, DyadicRatCore, RegSeqRat, CauchyLimitSeal, and RealUp reads.

Finally apply non-escape. Since the carrier has no coordinate for a private modulus, detached window budget, hidden stream selector, quotient equality, selected host limit, or ambient completeness principle, the shared budget rows exhaust the public supply. □

Theorem 1198.21 (Cofinal modulus seal completion scope factorization)**.** *Every completion-facing scope exported by* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *factors through the finite row sequence*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

Thus downstream $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *consumers may cite only the cofinal budget, CauchyTailModulusSeal, RealWindowBudget, CauchyLimitSeal, hsame, Cont, Pkg, and NameCert rows displayed by the same accepted packet.*

Proof. First use the completion consumer boundary. It already states that a completion-facing consumer may consume the seal only after every row in the displayed carrier has been exposed.

Next apply shared budget exhaustion. The rows B, M, W supply the only admissible cofinal-tail budget, while T, D, R, L, E are the only StreamName, dyadic, regular-sequence, limit-seal, and Real-facing rows downstream of that budget.

The support rows H, C, P, N then factor the scope through componentwise transport, displayed continuation, provenance, and local naming. Hence the completion-facing export is a finite scope factorization, not a route through endpoint-only Real validation or hidden completion data. □

Theorem 1198.22 (Cofinal modulus seal root-unblock package)**.** *The carrier of Definition 1198.1, together with the window lock, tail readback totality, completion consumer boundary, tail cofinality lock, shared budget exhaustion, and completion scope factorization, packages* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *as the shared root surface for tail-budget,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumers.*

Proof. Start with the carrier inventory. Its rows B, M, W expose the cofinal tail budget, Cauchy tail-modulus seal, and Real window budget before any downstream completion row is read.

Use the window lock and tail readback totality to display the consumer-facing route. These theorems require the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows to be present in the packet before a completion read is public.

Finally apply shared budget exhaustion and completion scope factorization. The first theorem states that B, M, W exhaust the admissible cofinal-tail supply, while the second factors every completion-facing scope through $B, M, W, T, D, R, L, E, H, C, P, N$. Thus all listed consumers share the same root surface. □

Theorem 1198.23 (Cofinal modulus seal formal-target handoff)**.** *The rows* $B, M, W, T, D, R, L, E, H, C, P, N$ *are the exact future Lean target surface for* $\mathsf{CofinalModulusSeal}^{\uparrow}$*. Any formal target for this packet must expose the cofinal budget row, Cauchy tail-modulus row, Real window-budget row, StreamName row, dyadic row, regular-sequence row, Cauchy-limit row, Real seal row, componentwise transport row, continuation replay row, provenance row, and local* NameCert *row, with no extra host-limit or choice coordinate.*

Proof. Apply Definition 1198.22. It packages the shared root surface for tail-budget, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers from the displayed carrier.

Use Definition 1198.21. That theorem factors every completion-facing scope through the same rows $B, M, W, T, D, R, L, E, H, C, P, N$.

Finally apply Definition 1198.29 and Definition 1198.30. The first gives no local naming coordinate beyond the displayed rows, and the second excludes choice, quotient, hidden selector, host-limit, and ambient-completeness coordinates from the window ledger. □

Theorem 1198.24 (Cofinal modulus seal dependency-ready package)**.** *The chapter exposes a dependency-ready package over* $\mathsf{CofinalTailBudget}^{\uparrow}$*,* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$*,* $\mathsf{RealWindowBudget}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Each dependency is read through the shared cofinal route of* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *rather than through a detached completion premise.*

Proof. Start with Definition 1198.22. It names the downstream tail-budget, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers of the same root surface.

Next use Definition 1198.27. It keeps every tail-budget read inside the finite route $B, M, W, T, D, R, L, E, H, C, P$ and rejects host-selected limits, quotient streams, private moduli, hidden selectors, and ambient completeness.

The completion-scope factorization then supplies the $\mathsf{CauchyTailModulusSeal}^{\uparrow}$, $\mathsf{RealWindowBudget}^{\uparrow}$, and $\mathsf{CauchyLimitSeal}^{\uparrow}$ rows as part of that same route. Thus the named dependencies are ready as one shared package, not as independent imports. □

Theorem 1198.25 (Cofinal modulus seal Lean-frontier readiness)**.** *Any Lean formalization of* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *must preserve the shared cofinal route and the no-choice nonescape rows. In particular, it must keep* B, M, W *as the common cofinal source for* T, D, R, L, E *and must preserve* H, C, P, N *as support rows that do not introduce countable choice, quotient equality, selected limits, hidden* $\mathsf{StreamName}^{\uparrow}$ *selectors, or ambient Real completeness.*

Proof. Begin with Definition 1198.27. It makes all accepted tail-budget reads factor through the displayed finite route.

Apply Definition 1198.28. The readback route passes from B, M, W through T, D, R, L to E and then through H, C, P, N, so a formalization must preserve that order.

Finish with Definition 1198.30. The no-choice boundary rules out countable-choice selectors, hidden stream selectors, quotient equality, selected host limits, and ambient Real completeness. Therefore the Lean frontier is exactly the shared cofinal route with those nonescape rows intact. □

Theorem 1198.26 (Cofinal modulus seal StreamName–Real consumer route)**.** *Every public Real-completion consumer route through* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *passes through the displayed cofinal budget,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows in the same finite carrier. A consumer may not read* $\mathsf{Real}^{\uparrow}$ *from a detached stream name, a detached regular-sequence row, or a hidden cofinal budget.*

Proof. Use Definition 1198.18. It places every completion-facing consumer on the displayed sequence of cofinal source, StreamName, dyadic, regular-sequence, Cauchy-limit, Real seal, transport, replay, provenance, and naming rows.

Apply Definition 1198.22. The root package makes the cofinal budget row B, StreamName row T, RegSeqRat row R, and RealUp seal row E part of one public consumer surface.

The non-escape theorem then excludes detached stream names, private regular sequences, selected limits, quotient equality, and hidden completion data. Therefore a Real-completion consumer reaches $\mathsf{Real}^{\uparrow}$ only through the displayed cofinal-budget-to-StreamName-to-RegSeqRat-to-Real route. □

Theorem 1198.27 (Cofinal modulus seal tail-budget factorization)**.** *Every tail-budget read accepted by* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *factors through the finite rows* $B, M, W, T, D, R, L, E, H, C, P, N$*. It cannot import a host-selected limit, quotient stream, private modulus, hidden StreamName selector, or ambient Real-completeness premise.*

Proof. Begin with Definition 1198.19. It locks each completion read to the shared cofinal tail budget before the seal side may be inspected.

Next apply Definition 1198.20. The rows B, M, W exhaust the public cofinal-tail supply for downstream StreamName, DyadicRatCore, RegSeqRat, CauchyLimitSeal, and RealUp reads.

Finish with Definition 1198.21. Since every completion-facing scope factors through $B, M, W, T, D, R, L, E, H, C$ no host-selected limit, quotient stream, private modulus, hidden selector, or ambient completeness row is available to a tail-budget consumer. □

Theorem 1198.28 (Cofinal modulus seal cofinal readback factorization)**.** *Every completion-facing readback from the source rows B, M, W to the Real-facing row E factors first through the seal rows T, D, R, L and then through the support rows H, C, P, N. Equivalently, a public* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *readback has the finite route*

$$B, M, W \longrightarrow T, D, R, L \longrightarrow E \longrightarrow H, C, P, N$$

and has no direct source-to-Real edge outside the displayed carrier.

Proof. Start with Definition 1198.19. It places every completion read behind the shared cofinal source route B, M, W before any StreamName, dyadic, regular-sequence, Cauchy-limit, or Real-facing row is public.

Next apply Definition 1198.21. The completion-facing scope is exactly the finite row sequence $B, M, W, T, D, R, L, E, H, C, P, N$, so the readback must pass through T, D, R, L before it reaches E.

Finally use Definition 1198.27. Its tail-budget factorization excludes host-selected limits, quotient streams, private moduli, hidden selectors, and ambient completeness, leaving only the support rows H, C, P, N to transport, replay, source, and name the completed readback. □

Theorem 1198.29 (Cofinal modulus seal route NameCert exhaustion)**.** *The local* $\mathsf{NameCert}_{\mathsf{CofinalModulusSeal}^{\uparrow}}$ *route is exhausted by the rows*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

Every accepted carrier, public completion readback, root-unblock consumer, and non-escape check for $\mathsf{CofinalModulusSeal}^{\uparrow}$ *is a statement about these rows, and no additional naming coordinate is available.*

Proof. Project Definition 1198.1. The carrier contains exactly the cofinal source rows B, M, W, the seal and readback rows T, D, R, L, E, and the support rows H, C, P, N.

Apply Definition 1198.2. Its carrier admission, route synchronization, completion handoff, structural replay, and non-escape clauses are all written over the displayed rows.

Use Definition 1198.22 to read the downstream package boundary. The root-unblock surface for tail-budget, StreamName, RegSeqRat, DyadicRatCore, and RealUp consumers is built from the same finite packet.

Finally apply Definition 1198.14. Since quotient equality, host equality, selected limits, countable choice, ambient completeness, and undisplayed completion seals are absent from the carrier, the local NameCert route has no coordinate beyond $B, M, W, T, D, R, L, E, H, C, P, N$. □

Theorem 1198.30 (Cofinal modulus seal window ledger no-choice boundary)**.** *Window-budget reads in an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet cannot introduce countable-choice selectors, hidden* $\mathsf{StreamName}^{\uparrow}$ *selectors, quotient stream equality, selected host limits, or ambient Real completeness. The window ledger is bounded by the shared rows B, W, T, D, R and by the non-escape boundary of the same carrier.*

Proof. Begin with Definition 1198.10. It routes every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ window read through the same $\mathsf{RealWindowBudget}^{\uparrow}$ row W and $\mathsf{CofinalTailBudget}^{\uparrow}$ row B.

Next use Definition 1198.20. The shared budget rows B, M, W exhaust the admissible cofinal-tail supply for the downstream rows $T, D, R, L, E, H, C, P, N$, so no private selector or detached window ledger can be inserted.

Finish with Definition 1198.14. The carrier has no coordinate for countable choice, hidden StreamName selection, quotient stream equality, selected host limits, or ambient Real completeness. Therefore the window ledger remains a finite no-choice boundary inside the displayed packet. □

Theorem 1198.31 (Cofinal modulus seal RegSeqRat route exhaustion)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing read through an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet factors through the finite rows*

$$B, M, W, T, D, R, H, C, P, N.$$

In particular, the regular-sequence row is consumed only after the cofinal budget, modulus, window, StreamName, and dyadic rows have been displayed, and its public readback is transported, replayed, sourced, and named only through H, C, P, N*.*

Proof. Project the carrier of Definition 1198.1. The regular-sequence row R is not an independent source; it sits behind the cofinal source rows B, M, W and the StreamName and dyadic rows T, D.

Apply Definition 1198.10. It identifies the common window budget used by the StreamName, dyadic, and regular-sequence consumers, so a $\mathsf{RegSeqRat}^{\uparrow}$ read cannot bypass B, M, W, T, D.

Use Definition 1198.22 and Definition 1198.29. The downstream package and the local NameCert route have no naming coordinate beyond the displayed finite carrier rows.

Finish with Definition 1198.30. It excludes hidden selectors, quotient stream equality, selected host limits, and choice-like completion data, leaving H, C, P, N as the only structural support for the regular-sequence readback. □

Theorem 1198.32 (Cofinal modulus seal StreamName window consistency)**.** *In an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet, the* $\mathsf{StreamName}^{\uparrow}$ *row* T *and the window row* W *are consumed on the same cofinal route. No public route may read a StreamName selector from* T *while using a different window ledger than the displayed* W*.*

Proof. Start from Definition 1198.1. The carrier lists W before T in the same finite packet, so both rows are coordinates of one accepted cofinal route.

Apply Definition 1198.10. It binds the StreamName-facing window read to the same budget row W used by the dyadic and regular-sequence rows.

Then use Definition 1198.22 and Definition 1198.29. Any downstream root-unblock consumer of T is named only through the exhausted route of the same carrier.

Finally apply Definition 1198.30. A hidden StreamName selector or detached window ledger would be a choice-like coordinate outside the packet, so the accepted route must consume T and W together. □

Theorem 1198.33 (Cofinal modulus seal RealUp non-completeness boundary)**.** *The* $\mathsf{Real}^{\uparrow}$ *row* E *in an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet is only a finite seal handoff. It carries no Real-completeness premise, quotient-real equality, selected-limit operator, countable-choice selector, or ambient host-completion assumption.*

Proof. Inspect Definition 1198.1. The row E is displayed after the cofinal source, window, StreamName, dyadic, regular-sequence, and Cauchy-limit rows, and before the structural support rows H, C, P, N.

Apply Definition 1198.22. The Real-facing handoff is part of the finite downstream package for tail-budget, StreamName, RegSeqRat, DyadicRatCore, and RealUp consumers; it is not a separate completeness service.

Use Definition 1198.29 to exhaust the naming route. Since the NameCert has no coordinate outside $B, M, W, T, D, R, L, E, H, C, P, N$, the Real-facing row cannot import an external completion principle.

Finish with Definition 1198.30. Countable choice, quotient equality, selected host limits, and ambient Real completeness are all excluded from the same finite ledger, so E remains a handoff row rather than a Real-completeness claim. □

Theorem 1198.34 (Cofinal modulus seal tail-budget row)**.** *Every accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *read exposes the shared tail-budget source* B, M, W *before any* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *row is public. The public source row is the displayed cofinal route, not a detached modulus service or host-selected tail choice.*

Proof. Start with Definition 1198.9. It identifies B, M, W as the synchronized cofinal tail budget, tail-modulus seal, and window budget for the same route.

Use Definition 1198.10 and Definition 1198.22. The first places T, D, R behind the same B, W rows, and the second packages the downstream tail-budget, StreamName, RegSeqRat, DyadicRatCore, and RealUp consumers from the same finite carrier.

Finally apply Definition 1198.29. Since the route has no naming coordinate beyond $B, M, W, T, D, R, L, E, H, C,$ no public consumer can bypass the source row. □

Lean4 ✓ `BEDC.Derived.CofinalModulusSealUp.CofinalModulusSeal tail budget row`

Theorem 1198.35 (Cofinal modulus seal window readback row)**.** *The window/readback segment* T, D, R *of an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet is exact only inside the same cofinal route. It cannot be replaced by a hidden* $\mathsf{StreamName}^{\uparrow}$ *selector, quotient stream, selected host limit, countable-choice row, or detached readback service.*

Proof. Use Definition 1198.10. It binds every StreamName, DyadicRatCore, and RegSeqRat window read to the same $\mathsf{RealWindowBudget}^{\uparrow}$ row W and $\mathsf{CofinalTailBudget}^{\uparrow}$ row B.

Apply Definition 1198.30. The window ledger excludes countable-choice selectors, hidden StreamName selectors, quotient stream equality, selected host limits, and ambient Real completeness.

The route exhaustion theorem, Definition 1198.29, leaves T, D, R as the only displayed window/readback segment. Thus exactness is internal to the same cofinal route. □

Theorem 1198.36 (Cofinal modulus seal dependency-unblock triad)**.** *The tail-budget row of Definition 1198.34, the window readback row of Definition 1198.35, the route exhaustion of Definition 1198.29, and the RealUp boundary of Definition 1198.33 make* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *dependency-ready for* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers without asserting Real completeness.*

Proof. First combine the tail-budget and window-readback rows. They force every downstream consumer to enter through B, M, W and then read T, D, R inside the same cofinal route.

Next use route NameCert exhaustion. It says that accepted carriers, readbacks, root-unblock consumers, and non-escape checks all live on $B, M, W, T, D, R, L, E, H, C, P, N$.

Finally apply the RealUp non-completeness boundary. The row E remains a finite handoff rather than a Real-completeness premise, so downstream consumers can cite the package as a dependency surface without importing ambient completion data. □

Theorem 1198.37 (Cofinal modulus seal diagonal representative handoff)**.** *Every diagonal representative consumer of* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *factors through the same finite route*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

The consumer may read the diagonal representative only after the cofinal budget, Cauchy tail-modulus seal, Real window budget, StreamName, DyadicRatCore, RegSeqRat, CauchyLimitSeal, RealUp, hsame, Cont, Pkg, *and local* NameCert *rows are all displayed in the carrier.*

Proof. Begin with Definition 1198.1. The carrier already displays the cofinal source rows B, M, W, the diagonal-facing rows T, D, R, L, E, and the support rows H, C, P, N in one packet.

Use Definition 1198.30. It prevents the diagonal read from importing a selected host limit, quotient equality, hidden selector, or countable-choice coordinate.

Apply Definition 1198.31 and Definition 1198.32. The regular-sequence and StreamName reads remain behind the same window ledger, so a diagonal representative consumer cannot detach D or R from B, M, W, T.

Finally use Definition 1198.33. The Real-facing row E is only a finite handoff, so the diagonal representative route is exactly $B, M, W, T, D, R, L, E, H, C, P, N$ and not a completeness premise. □

Theorem 1198.38 (Cofinal modulus seal tail-modulus handoff)**.** *The* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *row in an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet cannot be detached from* $\mathsf{CofinalTailBudget}^{\uparrow}$ *and* $\mathsf{RealWindowBudget}^{\uparrow}$*. Any public tail-modulus read must keep M between the cofinal budget row B and the window row W, and must continue through $T, D, R, L, E, H, C, P, N$ before reaching a named completion-facing consumer.*

Proof. Project the carrier of Definition 1198.1. The rows B, M, W are adjacent source rows for the shared cofinal route, while $T, D, R, L, E, H, C, P, N$ are downstream rows of the same packet.

Apply Definition 1198.9. It identifies the cofinal budget, tail-modulus seal, and window budget as one synchronized source route.

Next use Definition 1198.10. The downstream StreamName, DyadicRatCore, and RegSeqRat reads consume the same window row W, so the tail-modulus row M cannot be replaced by a detached modulus service.

Finish with Definition 1198.27 and Definition 1198.33. The factorization keeps every tail-budget read inside the displayed route, and the Real-facing handoff remains a finite seal rather than a Real-completeness premise. □

Theorem 1198.39 (Cofinal modulus seal finite route scope)**.** *The full public scope of* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *is exactly the finite BEDC row sequence*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

It closes the cofinal-budget, tail-modulus, window, StreamName, dyadic, regular-sequence, Cauchy-limit, Real handoff, transport, replay, provenance, and local naming route, but it does not claim Real completeness, quotient-real equality, selected host limits, countable choice, or an ambient completion operator.

Proof. Start from Definition 1198.21. It states the completion-facing scope over the displayed route $B, M, W, T, D, R, L, E, H, C, P, N$.

Use Definition 1198.29. The local NameCert route has no naming coordinate beyond the same finite carrier rows.

Apply Definition 1198.30. It removes choice, quotient equality, selected limits, hidden selectors, and ambient Real completeness from the window ledger.

Finally apply Definition 1198.33. The RealUp row is a finite handoff row only, so the full scope is the displayed BEDC route and not a Real-completeness theorem. □

Theorem 1198.40 (Cofinal modulus seal budget-window regularity chain)**.** *Every accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet first synchronizes the cofinal budget row B, tail-modulus row M, and window-budget row W. Only after that source synchronization may it read the StreamName row T, DyadicRatCore row D, and RegSeqRat row R, and those reads remain inside the same window route.*

Proof. Apply Definition 1198.9. It makes B, M, W a single synchronized source route for the accepted packet.

Next use Definition 1198.10. The window row W is the exact budget row consumed by the StreamName, DyadicRatCore, and RegSeqRat reads, so T, D, R cannot be read from a detached window service.

Finally apply Definition 1198.31. The regular-sequence readback has no coordinate beyond the displayed route, hence the readback segment T, D, R stays downstream of the same synchronized B, M, W source. □

Theorem 1198.41 (Cofinal modulus seal terminal Real seal factorization)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet factors through the finite BEDC route*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

The consumer reaches the terminal Real-facing seal only through the displayed cofinal budget, tail modulus, window, StreamName, dyadic, regular-sequence, Cauchy-limit, Real handoff, transport, replay, provenance, and local naming rows.

Proof. First use Definition 1198.40. It fixes the entry segment B, M, W and the readback segment T, D, R inside one cofinal route.

Apply Definition 1198.29. The remaining accepted carrier coordinates are precisely the Cauchy-limit row L, Real-facing row E, transport row H, replay row C, package row P, and local NameCert row N.

Finally use Definition 1198.33. The terminal Real-facing row is a finite seal and not a Real-completeness premise, so any terminal $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumer factors through $B, M, W, T, D, R, L, E, H$ □

Theorem 1198.42 (Cofinal modulus seal open-phase exit surface)**.** *The* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *chapter supplies the Phase Real and Completion handoff surface for* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers. This surface is the finite route $B, M, W, T, D, R, L, E, H, C, P, N$ and it does not claim Real completeness, quotient equality, selected limits, countable choice, or a* $\mathsf{StandardBridge}$.

Proof. Use Definition 1198.41. It makes the completion-facing and Real-facing consumer path factor through the full displayed route.

Next apply Definition 1198.39. The route already records the exact public scope of the chapter and excludes Real completeness, quotient-real equality, selected host limits, countable choice, and ambient completion operators.

The remaining bridge boundary follows from Definition 1198.33. Since E is only a finite Real-facing handoff row, the chapter exposes an exit surface for Phase Real and Completion consumers without asserting a StandardBridge. □

Theorem 1198.43 (Cofinal modulus seal observation-budget factorization)**.** *Every observation-budget read accepted by* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *factors through the displayed finite row route*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

The read must expose the cofinal tail budget, tail-modulus seal, Real window budget, StreamName, dyadic tolerance, regular sequence, Cauchy-limit seal, Real handoff, componentwise transport, continuation replay, package, and local NameCert *rows before it can be consumed by a Real-facing or completion-facing observer.*

Proof. Start with Definition 1198.1. It displays $B, M, W, T, D, R, L, E, H, C, P, N$ as the only finite carrier rows available to an accepted packet.

Use Definition 1198.29 and Definition 1198.21. The first theorem exhausts the local naming route on exactly these rows, and the second factors completion-facing scope through the same row sequence.

Apply Definition 1198.10. The observation budget cannot detach T, D, R from B, M, W, because the StreamName, dyadic, and regular-sequence reads consume the same Real-window row.

Finally use Definition 1198.42. The public exit surface is the same finite route, so any observation-budget read for a Real-facing or completion-facing observer factors through $B, M, W, T, D, R, L, E, H, C, P, N$. □

Theorem 1198.44 (Cofinal modulus seal Real and Completion consumer exactness)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet receives exactly the cofinal modulus route*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

It receives no quotient stream, selected host limit, countable-choice selector, ambient completeness row, hidden $\mathsf{StreamName}^{\uparrow}$ *selector, or detached window-budget service.*

Proof. Begin with Definition 1198.43. It gives the only observation-budget route available to Real-facing and completion-facing consumers.

Next apply Definition 1198.30. This removes quotient stream equality, selected host limits, countable-choice selectors, hidden StreamName selectors, and ambient Real completeness from the window ledger.

Use Definition 1198.33. The row E is a finite Real handoff and not a completeness premise, so a $\mathsf{Real}^{\uparrow}$ consumer receives only the displayed cofinal modulus route.

Finish with Definition 1198.41. Terminal $\mathsf{Real}^{\uparrow}$ and $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumers already factor through the same rows, which makes the consumer boundary exact. □

Theorem 1198.45 (Cofinal modulus seal L10 exit boundary)**.** *The* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet is a Phase Real and Completion exit boundary over* $\mathsf{CofinalTailBudget}^{\uparrow}$, $\mathsf{CauchyTailModulusSeal}^{\uparrow}$, $\mathsf{RealWindowBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Its public boundary is the finite row route*

$$B, M, W, T, D, R, L, E, H, C, P, N,$$

and no consumer route exits through quotient streams, selected host limits, countable choice, ambient completeness, detached windows, or a separate completion operator.

Proof. First use Definition 1198.24. It places the named upstream and terminal rows in one dependency-ready package over the shared cofinal route.

Apply Definition 1198.43. The observation side of the exit boundary is forced through $B, M, W, T, D, R, L, E, H,$

Next use Definition 1198.44. The Real and Completion consumers receive exactly that route and no external quotient, choice, selected-limit, detached-window, or completeness row.

Finally apply Definition 1198.42. The packet is already the Phase Real and Completion handoff surface for the finite cofinal modulus route, so the displayed rows form the L10 exit boundary. □

Theorem 1198.46 (Cofinal modulus seal L10 four-object factorization)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet factors first through the cofinal source rows* B, M, W *and then through the Real L10 four-object handoff packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Equivalently, after the cofinal source rows are displayed, the consumer can use only the dyadic tolerance row D*, the finite stream-name row* T*, the regular rational sequence row* R*, and the Real handoff row* E*, together with* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *support. It receives no quotient stream, host real equality, selected limit, countable choice, ambient completeness, detached window, or bridge coordinate.*

Proof. Begin with Definition 1198.45. It places the accepted packet on the Phase Real and Completion exit route and forces the public boundary through $B, M, W, T, D, R, L, E, H, C, P, N$.

Next apply Definition 1198.44. A Real-facing or completion-facing consumer receives exactly that route, so the first source data available to the consumer are the cofinal rows B, M, W, followed by the displayed terminal rows that feed the Real side.

Now use Definition 38.515. The Real-facing part of the route can be read as a four-object handoff through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with support confined to BHist, hsame, Cont, Pkg, and local NameCert rows.

Finally apply Definition 38.520. Since the Real handoff packet exports none of the forbidden coordinates, the cofinal seal consumer cannot acquire a quotient stream, host real equality, selected limit, countable-choice selector, ambient completeness row, detached window, or bridge coordinate after the factorization. □

Theorem 1198.47 (Cofinal modulus seal row-predicate admission)**.** *For an accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *packet, each displayed row*

$$B, M, W, T, D, R, L, E, H, C, P, N$$

is admitted only through the named BEDC primitives and sibling certificates carried by the cofinal modulus route. The rows are respectively read as cofinal tail budget, tail-modulus seal, Real-window budget, StreamName, DyadicRatCore tolerance, regular rational sequence, Cauchy-limit seal, Real handoff, hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *evidence. No row may be replaced by an unnamed predicate, quotient-stream witness, selected host limit, detached window service, countable-choice selector, or ambient completeness premise.*

Proof. Start with Definition 1198.1. The carrier display names exactly the rows $B, M, W, T, D, R, L, E, H, C, P, N$ and gives their BEDC reading through BHist, hsame, Cont, Pkg, and NameCert data.

Use Definition 1198.9. It synchronizes the source-side rows with the same finite route, so the admission test cannot introduce a second classifier beside the displayed carrier rows.

Apply Definition 1198.10 and Definition 1198.30. These identify the window ledger rows and exclude detached windows, quotient streams, selected limits, countable choice, and ambient completeness.

Finally use Definition 1198.45. The exit boundary exposes the same finite row route to downstream consumers, so every admitted row is one of the named primitives or sibling certificates. □

Theorem 1198.48 (Cofinal modulus seal obligation surface packaging)**.** *The* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *route packages carrier admission, source synchronization, window ledger exactness, the Real and Completion handoff, nonescape boundaries, and consumer exactness as one finite* NameCert *obligation surface over*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

Every obligation row in that surface is discharged by the displayed carrier route or by a cited sibling certificate, and no additional global completion, quotient, selector, or choice obligation is part of the package.

Proof. First combine Definition 1198.47 with Definition 1198.2. The former fixes the row predicates, while the latter places the local NameCert obligations on the same carrier route.

Next use Definition 1198.9 and Definition 1198.10. These two results bind the source rows and the window ledger rows to the displayed packet rather than to any external witness.

Apply Definition 1198.44. The Real-facing and completion-facing handoff consumes exactly the same route.

It remains to exclude escape obligations. Use Definition 1198.30 and Definition 1198.45. They remove quotient streams, selected limits, countable choice, detached windows, and ambient completeness from the public surface, leaving one finite NameCert obligation package. □

Theorem 1198.49 (Cofinal modulus seal consumer exactness obligation)**.** *Any* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of the* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *obligation surface receives exactly the displayed route*

$$B, M, W, T, D, R, L, E, H, C, P, N$$

through the packaged carrier, source, window, handoff, nonescape, and exactness rows. The consumer receives no detached selector, quotient stream, countable-choice row, ambient completeness row, hidden completion operator, or separate window service beyond that finite route.

Proof. Begin with Definition 1198.48. It identifies the public obligation surface with the finite NameCert package over $B, M, W, T, D, R, L, E, H, C, P, N$.

Use Definition 1198.44. Real-facing and completion-facing consumers already receive exactly the cofinal modulus route and no external quotient, selector, choice, or completeness witness.

Apply Definition 1198.30. This keeps the window ledger from smuggling in a detached selector or separate completion row.

Finally use Definition 1198.45. The L10 exit boundary is the same finite route, so consumer exactness is an obligation of that surface and not a separate downstream premise. □

Theorem 1198.50 (Cofinal modulus seal scoped source inventory)**.** *The scoped source inventory of* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *is exactly the finite row family*

$$B, M, W, T, D, R, L, E, H, C, P, N$$

over $\mathsf{CofinalTailBudget}^{\uparrow}$, $\mathsf{CauchyTailModulusSeal}^{\uparrow}$, $\mathsf{RealWindowBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

Proof. Use the carrier definition together with Definition 1198.5. The named rows are precisely the admitted source, transport, package, and certificate rows of the displayed route.

Then apply Definition 1198.9. It identifies the route rows with the same BHist, hsame, Cont, Pkg, and NameCert inventory, so no further source primitive is available inside the scoped package. □

Theorem 1198.51 (Cofinal modulus seal primitive route exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read from* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *factors through the displayed primitive rows* $B, M, W, T, D, R, L, E, H, C, P, N$ *No such read uses a quotient stream, selected host limit, countable choice, detached window, or ambient completeness coordinate.*

Proof. Apply Definition 1198.44. It already places each Real-facing and completion-facing read on the cofinal route.

Use Definition 1198.30 and Definition 1198.45. Together they rule out the excluded coordinates and leave only the primitive rows of the finite route. □

Theorem 1198.52 (Cofinal modulus seal scoped closure package)**.** *The obligation surface, route coverage, Real handoff, nonescape boundary, L10 exit boundary, Definition 1198.50, and Definition 1198.51 form the scoped* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *closure package.*

Proof. Combine Definition 1198.48, Definition 1198.5, Definition 1198.13, Definition 1198.14, and Definition 1198.45.

Finally add the scoped inventory and primitive exhaustion theorems. They identify the available sources and the allowed consumer reads, so the same finite route is a scoped closure package rather than an open obligation surface. □

Theorem 1198.53 (Cofinal modulus seal public route export)**.** *The finite route*

$$B, M, W, T, D, R, L, E, H, C, P, N$$

exports a reusable public $\mathsf{CofinalModulusSeal}^{\uparrow}$ *surface for downstream* $\mathsf{Real}^{\uparrow}$ *and completion-facing consumers. The public surface is exactly the scoped closure package, primitive route exhaustion, Real-completion consumer exactness, and L10 exit boundary; it does not assert Real completeness, quotient-stream equality, selected host limits, countable choice, detached windows, or a checked bridge.*

Lean4 ✓ `BEDC.Derived.CofinalModulusSealUp.CofinalModulusSealUp StdBridge`

Proof. First invoke Definition 1198.52. It packages the obligation surface, route coverage, Real handoff, nonescape boundary, L10 exit boundary, scoped source inventory, and primitive exhaustion on the same finite route.

Next use Definition 1198.51 together with Definition 1198.44. Every downstream $\mathsf{Real}^{\uparrow}$ or completion-facing read factors through the displayed route, so the route is public as a reusable consumer surface rather than a private local certificate.

Finally apply Definition 1198.45. The exclusions remain part of the exported surface: no Real completeness claim, quotient stream, selected host limit, countable-choice row, detached window, or bridge check is added by making the finite route public. □

Theorem 1198.54 (Cofinal modulus seal mature route package)**.** *The carrier, scoped closure package, primitive route exhaustion, public route export, and checked StdBridge row form the mature* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *package over the finite route*

$$B, M, W, T, D, R, L, E, H, C, P, N$$

The package remains internal to that route: it excludes Real completeness, quotient stream equality, selected host limits, countable choice, detached windows, and external completion operators.

Proof. Start with Definition 1198.52. It binds the carrier, obligation surface, route coverage, Real handoff, nonescape boundary, L10 exit boundary, scoped source inventory, and primitive exhaustion as one route package.

Use Definition 1198.53. The same package is exported as a reusable public surface for downstream $\mathsf{Real}^{\uparrow}$ and completion-facing consumers.

Now apply Definition 1198.51. It keeps every admitted read on the displayed primitive route and rules out quotient streams, selected host limits, countable choice, detached windows, and external completion operators.

Finally use the checked StdBridge row recorded by `BEDC.Derived.CofinalModulusSealUp.CofinalModulusSe` The bridge row supplies the acceptance-bridge witness for the public surface, while the exclusions above keep the mature package finite and do not add Real completeness. □

Corollary 1198.55 (Cofinal modulus seal window-lock strict obstruction)**.** *Suppose a public* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *consumer displays a failure, refusal, separation, or countermodel against a route that tries to reuse the window lock outside the rows*

$$B, M, W, T, D, R, L, E, H, C, P, N.$$

Then the obstruction is strict and local: it blocks only the named converse or reuse route that omits, detaches, or replaces one of the displayed cofinal source, window, readback, Real-handoff, transport, replay, provenance, or local naming rows. It is not a global impossibility result, a host-completeness theorem, or hidden external validation of an undisplayed completion principle.

Proof. Start with Definition 1198.25. It identifies the rows that any formal or consumer-facing reading must preserve: B, M, W remain the common cofinal source for T, D, R, L, E, and H, C, P, N remain support rows that do not introduce countable choice, quotient equality, selected limits, hidden $\mathsf{StreamName}^{\uparrow}$ selectors, or ambient Real completeness.

Apply Definition 1198.21. Every completion-facing scope exported by the packet factors through exactly the displayed row sequence $B, M, W, T, D, R, L, E, H, C, P, N$. Hence a consumer-facing obstruction can only be evaluated against a route coordinate in that finite factorization or against an attempted reuse that bypasses it.

Now inspect the possible reuse attempts. If the attempted route detaches the window, replaces the cofinal source, skips T, D, R, L, E, or reads support from outside H, C, P, N, the obstruction blocks precisely that omitted or replaced coordinate. If the attempted route asks for quotient equality, a selected host limit, countable choice, hidden StreamName selection, ambient Real completeness, or an undisplayed completion seal, the Lean-frontier boundary says that no such coordinate belongs to the packet. In both cases the displayed row blocks only the attempted converse or reuse route.

The same factorization also prevents a stronger reinterpretation. Since every public completion-facing use has already been forced through the finite route, the obstruction has no remaining coordinate from which to assert a global impossibility theorem, no host-completeness premise from

which to prove a host result, and no external validation row hidden behind the window lock. Thus the window-lock obstruction is strict, local, and exhausted by the displayed carrier surface. □

Lean TasteGate formalization for this route must provide `Nontrivial CofinalModulusSealUp` and `FieldFaithful CofinalModulusSealUp` instances in `BEDC.Derived.CofinalModulusSealUp`.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalModulusSeal}\uparrow}$.

Constructive story: The cofinal modulus seal is generated from a large finite BHist route containing cofinal tail budget, tail-modulus seal, Real-window budget, StreamName, DyadicRatCore, RegSeqRat, CauchyLimitSeal, RealUp, hsame transport, Cont replay, Pkg provenance, and local NameCert rows. The carrier convention reads each row through hsame and connects them by explicit Cont handoffs, so a consumer receives the same cofinal modulus route under representative change. The factorization, synchronization, non-escape, and exhaustion theorems all refine the same bottom-up object: no quotient stream, selected host limit, detached window, or ambient completeness principle can enter unless it is already one of the displayed route rows.

Chapter 1199

A Concrete Naming Certificate for $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$

The $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$ packet is a composite finite audit surface for the StreamName–RegSeqRat–Real seal route of chapter 9238. It bundles the existing $\mathsf{StreamName}^{\uparrow}$ finite stream interface of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ dyadic tolerance ledger of chapter 291, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback surface of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the audit-refusal rows that exclude hidden completion routes. Its role is to bind the displayed finite window, dyadic tolerance, RegSeqRat readback, RealUp seal, audit-refusal, hsame, Cont, Pkg, and NameCert rows into one NameCert carrier, not to supply quotient streams, selected host limits, host real equality, countable choice, or ambient completeness.

Falsifiable prediction: A RealUp seal consumer that bypasses the displayed finite-window, dyadic-tolerance, and RegSeqRat readback rows refutes the FiniteWindowRealSealAuditUp packet.

Independence witness: streamname, regseqrat, dyadicratcore, real, real-completion-seal-classifier: no sibling is bijective because only this packet binds finite windows, dyadic tolerance, RegSeqRat readback, Real seal, and audit-refusal rows into one NameCert carrier.

Definition 1199.1 (Finite-window Real-seal audit carrier)**.** *A* $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the visible request window;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic tolerance and readback row attached to that same window;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row reached from W and D;*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row read only after W, D, R have been displayed;*
5. *F is the audit-refusal row stating that no accepted consumer may replace W, D, R, E by a hidden completion route, quotient stream, selected limit, host real equality, countable-choice row, or ambient-completeness row;*
6. *H records componentwise* hsame *transports for the displayed rows;*
7. *C records the displayed* Cont *replay from finite-window admission through dyadic tolerance, RegSeqRat readback, audit refusal, and the terminal Real seal;*

8. *P is the* Pkg *provenance over the cited sibling packets,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowRealSealAudit}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient streams, selected host limits, host real equality, detached Real seals, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSealAuditUp.FiniteWindowRealSealAuditTasteGate single carrier alignment`

Theorem 1199.2 (Finite-window Real-seal audit NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$ *carrier*

$$A = (W, D, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteWindowRealSealAudit}^{\uparrow}}$ *surface consists exactly of finite-window exposure through W, dyadic-tolerance exposure through D, RegSeqRat readback through R, terminal Real-seal exposure through E, audit-refusal exposure through F, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 1199.1. Its displayed inventory is the StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback, terminal Real seal, audit-refusal row, and the structural support rows.

Read the seal route in dependency order. The row W fixes the finite request window, the row D fixes the dyadic tolerance ledger attached to that window, the row R fixes the regular-rational readback, and the row E is the RealUp seal reached by that displayed route.

The audit row F blocks the absent completion, quotient, selected-limit, host-equality, choice, and ambient-completeness coordinates. The rows H, C, P, N only transport, replay, package, and name the same finite packet, so the listed rows exhaust the local NameCert surface. □

Theorem 1199.3 (Finite-window Real-seal audit non-escape)**.** *Every accepted* $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$ *consumer factors through the finite route*

$$W, D, R, E, F, H, C, P, N.$$

The consumer may inspect the StreamName finite window, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, audit-refusal row, componentwise transports, continuations, provenance, and local NameCert row. It receives no quotient stream equality, selected host limit, host real equality, detached Real seal, countable-choice row, hidden completion route, or ambient-completeness coordinate.

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSealAuditUp.FiniteWindowRealSealAuditCarrier nonescape`

Proof. Start from Definition 1199.2. The local certificate exposes the complete route inventory for the accepted packet and gives no second source for window, tolerance, readback, seal, refusal, transport, continuation, provenance, or naming data.

Attach the sibling faces. The cited StreamName, DyadicRatCore, RegSeqRat, and Real chapters supply the four route faces W, D, R, E in the order needed by a RealUp seal consumer.

Inspect the refusal row. Since F records the excluded coordinates and the carrier has no other coordinate through which to read them, any consumer that bypasses W, D, R before reaching E has left the accepted audit packet. □

Theorem 1199.4 (Finite-window Real-seal audit four-face minimality)**.** *For every accepted* FiniteWindowRealSealA *carrier*

$$A = (W, D, R, E, F, H, C, P, N),$$

each of the four source faces W, D, R, E is individually necessary for the accepted route. The row W supplies the $\mathsf{StreamName}^{\uparrow}$ *finite-window face, D supplies the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and readback face, R supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback face, and E supplies the terminal* $\mathsf{Real}^{\uparrow}$ *seal face.*

Replacing or omitting any one of W, D, R, E leaves no accepted $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$ *packet with the same route role. The rows F, H, C, P, N can refuse, transport, replay, package, and name only after the four source faces have been displayed; they cannot manufacture a missing StreamName window, dyadic tolerance ledger, RegSeqRat readback, or terminal Real seal.*

Proof. Project the carrier of Definition 1199.1. The four rows W, D, R, E are not auxiliary annotations: they are the source faces from which the displayed route obtains its finite window, dyadic tolerance ledger, regular-rational readback, and terminal Real seal.

Apply Definition 1199.2. The exact row inventory places W, D, R, E in the local certificate before the audit-refusal, transport, continuation, provenance, and naming rows. Thus each of the four faces has a distinct certificate role not repeated by F, H, C, P, N.

Apply Definition 1199.3. An accepted consumer has no bypass coordinate through which a missing window, tolerance ledger, readback, or seal can be recovered. Therefore dropping or replacing any one of W, D, R, E breaks the accepted finite-window Real-seal audit route componentwise. □

Theorem 1199.5 (Finite-window Real-seal audit refusal transport)**.** *Let*

$$A = (W, D, R, E, F, H, C, P, N)$$

and

$$A' = (W', D', R', E', F', H', C', P', N')$$

be accepted $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$ *carriers. If the rows of A are transported componentwise by* hsame *to the corresponding rows of A', then the audit-refusal row is preserved. Every transported Real-seal consumer must pass through W', D', R' before reading E'.*

The transported packet has no quotient stream, selected host limit, host real equality, countable-choice row, hidden completion route, or ambient-completeness coordinate. These coordinates are still refused by F' and cannot be recovered from H', C', P', N'.

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSealAuditUp.FiniteWindowRealSealAuditCarrier refusal transport`

Proof. Start with the NameCert obligations of Definition 1199.2. They identify the complete local inventory of an accepted carrier and make F the row that records the audit refusal.

Apply the componentwise hsame transport recorded by H and H'. Since the transported rows are exactly $W', D', R', E', F', H', C', P', N'$, the refusal row travels with the same finite packet rather than opening a detached completion coordinate.

Use Definition 1199.3 for the target carrier A'. Any transported consumer that reaches the terminal Real seal must read the displayed route through W', D', R' before E'.

Finally apply Definition 1199.4. The four source faces cannot be replaced by F', H', C', P', N', so the refused quotient, selected-limit, host-equality, choice, hidden-completion, and ambient-completeness routes remain absent after transport. □

Theorem 1199.6 (Finite-window Real-seal audit obligation closure)**.** *The carrier definition, the local NameCert obligations, the non-escape theorem, four-face minimality, the refusal-transport theorem, and the displayed TasteGate alignment target together bind the carrier, classifier, stability, exactness, and ledger-refusal obligations for* $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$*.*

Concretely, Definition 1199.1 supplies the carrier and classifier rows; Definition 1199.2 supplies the exact local NameCert inventory; Definition 1199.3 supplies ledger refusal for non-displayed Real-seal routes; Definition 1199.4 supplies exactness of the four displayed faces; and Definition 1199.5 supplies stability under componentwise hsame *transport.*

Proof. The carrier and classifier obligations are read from Definition 1199.1. The definition lists the displayed rows and says that accepted comparison has no coordinate outside those rows.

The exactness obligation is supplied by Definition 1199.2 and Definition 1199.4. Together they identify the complete NameCert inventory and show that the four source faces W, D, R, E are all necessary.

The ledger-refusal obligation is supplied by Definition 1199.3. It rules out quotient streams, selected host limits, host real equality, detached Real seals, countable-choice rows, hidden completion routes, and ambient-completeness coordinates for accepted consumers.

The stability obligation is supplied by Definition 1199.5. Componentwise hsame transport carries the refusal row and preserves the forced route through the displayed finite-window, dyadic-tolerance, RegSeqRat, and Real-seal faces. The TasteGate alignment target records that the same single carrier is the Lean-side audit surface for this packet, so the listed rows form the obligation-closure boundary for $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$. □

Theorem 1199.7 (Finite-window Real-seal audit StreamName–Dyadic scope)**.** *For every accepted* $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$ *carrier*

$$A = (W, D, R, E, F, H, C, P, N),$$

the visible request window W is scoped by the displayed $\mathsf{StreamName}^{\uparrow}$ *finite-window row, and the tolerance ledger D is scoped by the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row attached to the same window. No accepted consumer may replace W or D by a hidden stream, quotient stream equality, selected tolerance, host real equality, countable-choice row, or ambient-completeness row.*

Proof. Project the carrier of Definition 1199.1. The first two route faces are W and D: W names the visible StreamName request window, and D records the dyadic tolerance ledger attached to that same window.

Apply the NameCert obligations of Definition 1199.2. They place W and D in the local certificate before the RegSeqRat readback, terminal Real seal, audit refusal, transport, continuation, provenance, and naming rows.

Use non-escape and four-face minimality, Definition 1199.3 and Definition 1199.4. A consumer has no bypass coordinate for a hidden stream or selected tolerance, and neither F, H, C, P, N can manufacture a missing StreamName window or DyadicRatCore ledger.

Finally apply refusal transport, Definition 1199.5. Componentwise hsame transport carries the same W, D scope to any accepted target carrier, so the StreamName–Dyadic entry remains the displayed finite-window scope for the route. □

Theorem 1199.8 (Finite-window Real-seal audit RegSeqRat scope)**.** *For every accepted* FiniteWindowRealSealAudi *carrier*

$$A = (W, D, R, E, F, H, C, P, N),$$

the row R is a $\mathsf{RegSeqRat}^{\uparrow}$ *readback row whose admissibility is scoped by the preceding finite* BHist *packet, componentwise* hsame *transport through H, and displayed* Cont *replay through C. The readback cannot be detached from W, D or replaced by a quotient stream, selected host limit, host real equality, countable-choice row, or ambient-completeness row.*

Proof. Read the carrier in Definition 1199.1. The row R is not a free regular-rational name; it is the RegSeqRat readback reached from the already displayed W, D rows inside the same finite BHist packet.

Apply the NameCert obligations of Definition 1199.2. The certificate inventory records R together with the componentwise hsame row H and the displayed Cont replay row C, so the readback is scoped by the same finite route rather than by an external completion object.

Use Definition 1199.3 and Definition 1199.4. Since accepted consumers must pass through W, D, R, E and each face is necessary, R cannot be recovered from the refusal, continuation, provenance, or naming rows after the fact.

Apply refusal transport, Definition 1199.5. Transported carriers preserve the refusal row and force the target consumer through W', D', R' before E', which keeps the RegSeqRat readback under the transported BHist, hsame, and Cont scope. □

Theorem 1199.9 (Finite-window Real-seal audit Real-seal non-escape scope)**.** *For every accepted* $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$ *carrier*

$$A = (W, D, R, E, F, H, C, P, N),$$

the terminal row E is scoped as the displayed $\mathsf{Real}^{\uparrow}$ *seal reached only after W, D, R have been exposed. The row F records the non-escape refusal, P records* Pkg *provenance for the sibling packets and kernel rows, and N records the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowRealSealAudit}^{\uparrow}}$ *name; none of these rows exports a hidden completion route, detached Real seal, selected limit, quotient stream equality, host real equality, countable-choice row, or ambient-completeness coordinate.*

Proof. Project the carrier of Definition 1199.1. The row E is the terminal RealUp seal row, while F, P, N are respectively the audit-refusal row, the package provenance row, and the local NameCert row for the same finite packet.

Apply the NameCert obligations of Definition 1199.2. They identify E, F, P, N as displayed rows of one certificate and place the Real seal after the StreamName, DyadicRatCore, and RegSeqRat faces.

Use non-escape and four-face minimality, Definition 1199.3 and Definition 1199.4. A Real-seal consumer must reach E through W, D, R, and the supporting rows F, P, N can refuse, package, and name only that route.

Finally apply refusal transport, Definition 1199.5. Under componentwise hsame transport the target carrier still exposes only $W', D', R', E', F', H', C', P', N'$, so the Real seal remains non-escaping and the Pkg and $\mathsf{NameCert}$ rows remain local to the displayed route. □

Lean development for this route provides `Nontrivial FiniteWindowRealSealAuditUp` and `FieldFaithful FiniteWindowRealSealAuditUp` in `lean4/BEDC/Derived/FiniteWindowRealSealAuditUp/Tast`

Theorem 1199.10 (Finite-window Real-seal audit scoped dependency)**.** *For every accepted* FiniteWindowRealSealA *carrier*

$$A = (W, D, R, E, F, H, C, P, N),$$

the row W is scoped by $\mathsf{StreamName}^{\uparrow}$*, the row D by* $\mathsf{DyadicRatCore}^{\uparrow}$*, the row R by* $\mathsf{RegSeqRat}^{\uparrow}$*, the row E by* $\mathsf{Real}^{\uparrow}$*, the row F by the finite* BHist *audit refusal, the row H by* hsame*, the row C by* Cont*,*

the row P by Pkg*, and the row N by* NameCert*. Thus each obligation named by the audit packet has a displayed BEDC primitive or sibling-chapter scope before any Real-seal consumer route is admitted.*

Proof. Project the carrier of Definition 1199.1. Its displayed rows already name the four route faces W, D, R, E, the audit row F, and the structural rows H, C, P, N.

Apply the three explicit scope lemmas, Definition 1199.7, Definition 1199.8, and Definition 1199.9. They bind the StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, audit refusal, package provenance, and local naming rows to the displayed finite route.

Use the obligation-closure theorem, Definition 1199.6, to package the same rows through carrier admission, classifier scope, stability, exactness, and ledger refusal. Thus every dependency has an explicit BEDC primitive or sibling-chapter scope. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowRealSealAudit}\uparrow}$ **.**

Constructive story: The finite-window Real-seal audit is generated from a $BHist$ packet whose window rows, tolerance rows, audit witness, and Real-seal handoff are all visible before any consumer route is admitted. The carrier convention first names the finite window, then records the audit row that checks the handoff, and finally allows Cont only to continue that audited route. If the representing history changes, $hsame$ transports the same audit packet rather than creating a new window. The resulting NameCert object is a local audit surface: it certifies that Real-seal use is confined to the displayed finite packet and that forbidden coordinates remain absent.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteWindowRealSealAudit}\uparrow}$, scopedClosed)

Scope closed: This chapter binds the finite-window Real-seal audit carrier, NameCert obligations, non-escape theorem, four-face minimality, refusal transport of Definition 1199.5, obligation closure of Definition 1199.6, explicit scope lemmas of Definition 1199.7, Definition 1199.8, and Definition 1199.9, and scoped dependency theorem of Definition 1199.10.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteWindowRealSealAudit}\uparrow}$, axiomClean)

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSealAuditUp.taste gate`

Lean target: `BEDC.Derived.FiniteWindowRealSealAuditUp.FiniteWindowRealSealAuditTasteGate\_single\_carrier\_alignm`

Bridge status: none

Origin: ai

Not claimed: It does not claim all Real windows are audited, that finite windows are complete, or that unaudited host limits are admissible.

Upgrade path: The next paper-side step is public export of the scoped audit consumer route; Lean-side axiom-clean status remains independent.

Chapter 1200

A Concrete Naming Certificate for RealModulusPurityBoundary$^{\uparrow}$

The RealModulusPurityBoundary$^{\uparrow}$ packet realizes the axiom-purity boundary of the Real-completeness vision in chapter 9238. It collects the no-choice boundary of chapter 1173, the selected-window refusal of chapter 695, the shared-modulus normal form of chapter 778, the finite-window Real seal audit of chapter 1199, and the fused Real-modulus route of **??**. Its role is to bind dyadic observations, finite StreamName windows, RegSeqRat readbacks, RealUp seals, explicit modulus budgets, transports, continuations, provenance, local naming, and an axiom-refusal row into one finite carrier. It is not a quotient stream, selected host limit, host real equality, countable-choice schedule, ambient completeness principle, or proof by Classical.choice, Quot.sound, or propext.

Falsifiable prediction: Any accepted RealModulusPurityBoundaryUp packet with a selected-host-limit, quotient-stream, or countable-choice coordinate fails the local NameCert carrier predicate.

Independence witness: cauchychoiceboundary, choicefreediagonalselector, regular-cauchy-modulus-normalizer, finite-window-real-seal-audit, realmodulusfusion: none is bijective to this packet because each omits at least one of the explicit axiom-purity refusal row, four-face Real route, modulus budget, or local NameCert non-escape obligation.

Definition 1200.1 (Real modulus-purity boundary carrier)**.** *A* RealModulusPurityBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, S, R_0, L, B, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *observation row that records the finite dyadic tolerance read by the Real-completion consumer;*
2. *S is the* StreamName$^{\uparrow}$ *finite-window row naming the visible request window attached to D;*
3. *R_0 is the* RegSeqRat$^{\uparrow}$ *readback row reached from the same dyadic and stream-window data;*
4. *L is the* Real$^{\uparrow}$ *seal row reached only after D, S, R_0 have been displayed;*
5. *B is the explicit modulus-budget and axiom-refusal row, carrying the selected finite modulus threshold and recording refusal of quotient streams, selected host limits, countable choice,* Classical.choice*,* Quot.sound*, and* propext*;*
6. *H records componentwise* hsame *transports for D, S, R_0, L, B and the local packet shape;*

7. *C records the displayed* Cont *replay from dyadic observation and window admission through RegSeqRat readback, modulus budget, refusal, Real seal, and local naming;*
8. *P is the* Pkg *provenance over chapter 1173, chapter 695, chapter 778, chapter 1199,* **??**, BHist, hsame, Cont, Pkg, *and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealModulusPurityBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for selected host limits, quotient streams, detached Real seals, countable-choice schedules, ambient completeness, or proof-irrelevant host equality.

Lean4 (definition) `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundaryUp`

Theorem 1200.2 (Real modulus-purity boundary NameCert obligations)**.** *For every accepted* $\mathsf{RealModulusPurityBoundary}^{\uparrow}$ *carrier*

$$R = (D, S, R_0, L, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealModulusPurityBoundary}^{\uparrow}}$ *surface consists exactly of dyadic observation exposure through D, finite-window exposure through S, RegSeqRat readback through R_0, RealUp seal exposure through L, explicit modulus-budget and axiom-refusal exposure through B, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundary namecert obligations`

Proof. Project the carrier of Definition 1200.1. Its displayed inventory is the dyadic observation, StreamName window, RegSeqRat readback, RealUp seal, modulus-budget refusal row, and the structural support rows.

Read the Real route in dependency order. The dyadic row D fixes the tolerance observation, the window row S fixes the finite request surface, the readback row R_0 fixes the regular-rational stream read from those data, and the seal row L is reached only after the four-face route has been displayed.

The budget row B supplies the explicit modulus threshold and records the refusal of quotient, choice, selected-limit, and proof-extensional coordinates. The rows H, C, P, N only transport, replay, package, and name the same finite packet, so the listed rows exhaust the local NameCert surface. □

Theorem 1200.3 (Real modulus-purity boundary non-escape)**.** *Every accepted* $\mathsf{RealModulusPurityBoundary}^{\uparrow}$ *consumer factors through the finite route*

$$D, S, R_0, L, B, H, C, P, N.$$

The consumer may inspect dyadic observations, StreamName windows, RegSeqRat readbacks, RealUp seals, explicit modulus budgets, axiom-refusal rows, componentwise transports, continuations, provenance, and the local NameCert row. It receives no selected host limit, quotient-stream equality, host real equality, countable-choice coordinate, detached Real-completion object, ambient-completeness row, Classical.choice *row,* Quot.sound *row, or* propext *row.*

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundary nonescape`

Proof. Start from Definition 1200.2. The local certificate exposes the complete route inventory for the accepted packet and gives no second source for dyadic, window, readback, seal, budget, refusal, transport, continuation, provenance, or naming data.

Attach the five sibling boundaries. The Cauchy choice-boundary and choice-free selector chapters exclude hidden selected limits and countable-choice schedules; the regular-Cauchy modulus normalizer supplies the displayed modulus route; the finite-window Real-seal audit and Real-modulus fusion chapters keep the StreamName, RegSeqRat, dyadic, and RealUp faces on the same finite route.

Inspect the refusal row. Since B records the excluded coordinates and the carrier has no other coordinate through which to read them, any consumer that asks for selected host limits, quotient streams, ambient completeness, or proof-extensional host equality has left the accepted boundary packet. □

Theorem 1200.4 (Real modulus-purity boundary constructive prediction)**.** *Let a Real-completion consumer accept a* RealModulusPurityBoundary$^{\uparrow}$ *packet and preserve the displayed route*

$$D, S, R_0, L, B, H, C, P, N.$$

Then every later RealUp or RegSeqRat read is predicted by the explicit modulus budget in B together with the dyadic observation D, finite window S, RegSeqRat readback R_0, and RealUp seal L. A consumer that replaces this prediction by a selected-host-limit, quotient-stream, countable-choice, Classical.choice*,* Quot.sound*, or* propext *coordinate fails the local carrier predicate.*

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundary constructive prediction`

Proof. First read the displayed route. The rows D, S, R_0, L give the four Real-facing observations in order, while B supplies the finite modulus budget that selects the visible part of the route.

Use componentwise transport and replay next. The rows H and C preserve the same dyadic, window, readback, seal, and budget data under accepted consumer motion, so downstream RealUp and RegSeqRat requests return to the displayed finite packet.

Finally apply non-escape. The forbidden selected-limit, quotient, choice, and proof-extensional rows are absent from the carrier and explicitly refused by B. Hence constructive prediction is exactly the finite modulus-budget route, and any attempted replacement fails the carrier predicate. □

Theorem 1200.5 (Real modulus-purity boundary host-choice refusal)**.** *Let a Real-and-Completion consumer accept a* RealModulusPurityBoundary$^{\uparrow}$ *packet*

$$R = (D, S, R_0, L, B, H, C, P, N).$$

If the consumer asks for a selected host limit, quotient-stream equality, countable-choice schedule, host real equality, or ambient-completeness coordinate, then the request is refused by the displayed row B. The only admissible route through the packet remains the finite dyadic observation D, StreamName window S, RegSeqRat readback R_0, RealUp seal L, modulus budget B, componentwise transport H, continuation replay C, package provenance P, local NameCert row N, and the refusal information carried by B.

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundary host choice refusal`

Proof. Project the carrier in Definition 1200.1. Its row B is not merely a modulus budget: it also displays refusal of quotient streams, selected host limits, countable choice, Classical.choice, Quot.sound, and propext.

Apply Definition 1200.2. The local NameCert surface exposes exactly the dyadic observation, StreamName window, RegSeqRat readback, RealUp seal, modulus-budget refusal row, componentwise transport, continuation replay, package provenance, and local naming rows.

Apply Definition 1200.3. Since the accepted packet has no quotient, host-limit, host-equality, countable-choice, or ambient-completeness coordinate, a consumer that asks for one of those coordinates cannot obtain it from any hidden field.

Finally use Definition 1200.4. Downstream RealUp and RegSeqRat reads are predicted by the finite modulus route already displayed by $D, S, R_0, L, B, H, C, P, N$, so the host-choice request is isolated as a refusal obligation of B rather than as an admissible Real-completion operation. □

Theorem 1200.6 (Real modulus-purity boundary scoped obligation package)**.** *The carrier of Definition 1200.1, together with Definition 1200.2, Definition 1200.3, Definition 1200.4, and Definition 1200.5, assembles the full obligation surface over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$*, explicit modulus budget, axiom-refusal row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert*. Every admitted consumer of the packet must expose the same row tuple*

$$D, S, R_0, L, B, H, C, P, N$$

before any Real-facing read is exported.

Proof. Project the carrier as $R = (D, S, R_0, L, B, H, C, P, N)$. The dyadic row D, finite StreamName window S, RegSeqRat readback R_0, Real seal L, and modulus-refusal row B are the analytic coordinates of the packet.

Use the NameCert obligations to expose those coordinates in dependency order. The dyadic and window rows precede the readback, the readback precedes the Real seal, and the explicit budget row records both the finite modulus path and the refused axiom imports.

Apply non-escape and constructive prediction. These theorems force every downstream RealUp or RegSeqRat read to return to the displayed finite route and prevent a selected limit, quotient stream, countable choice, Classical.choice, Quot.sound, or propext coordinate from being repacked as an admitted consumer field.

Finally apply host-choice refusal. The support rows H, C, P, N transport, replay, source, and name only the same displayed route, so no hidden selected limit, quotient stream, countable choice, proof-extensional coordinate, or host-completeness coordinate remains outside the scoped obligation package. □

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundaryScopePackage`
↪ variant `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundary scope package`

The Lean file `lean4/BEDC/Derived/RealModulusPurityBoundaryUp/TasteGate.lean` provides explicit `Nontrivial RealModulusPurityBoundaryUp` and `FieldFaithful RealModulusPurityBoundaryUp` instances for the carrier of Definition 1200.1.

Theorem 1200.7 (Real modulus purity boundary tail-budget exhaustion)**.** *Let*

$$R = (D, S, R_0, L, B, H, C, P, N)$$

be an accepted $\mathsf{RealModulusPurityBoundary}^{\uparrow}$ *packet whose displayed modulus windows pass through the L10 route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Then R has no additional tail-budget coordinate outside the displayed dyadic observation D, StreamName window S, RegSeqRat readback R_0, RealUp seal L, modulus-budget refusal row B, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. Every completion-facing read of R factors through these rows plus* hsame, Cont, Pkg, *and* NameCert*; it cannot read ambient Real completeness, quotient streams, host-selected limits, hidden moduli, or proof-extensional tail data.*

Proof. Project the carrier of Definition 1200.1. The only analytic rows are D, S, R_0, L, B, and the only structural rows are H, C, P, N.

Apply the NameCert obligations of Definition 1200.2. They expose the dyadic observation, finite StreamName window, RegSeqRat readback, RealUp seal, and explicit modulus-budget refusal row before any Real-facing consumer can read the packet.

Use the non-escape theorem Definition 1200.3 and the host-choice refusal theorem Definition 1200.5. The window-scope and refusal rows exclude selected host limits, quotient streams, countable-choice schedules, host Real equality, and ambient-completeness coordinates.

Finally read the scoped obligation package of Definition 1200.6. It forces every admitted consumer to expose the same tuple $D, S, R_0, L, B, H, C, P, N$, so no hidden tail-budget coordinate remains outside the L10 four-object route and its structural certificate rows. □

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundaryTailBudgetExhaustion`

Theorem 1200.8 (Real modulus-purity boundary dyadic witness stability)**.** *Let*

$$R = (D, S, R_0, L, B, H, C, P, N)$$

be an accepted RealModulusPurityBoundary$^{\uparrow}$ *packet. If a finite dyadic observation row D is replaced inside the same* StreamName$^{\uparrow}$ *window S by an* hsame*-transported* DyadicRatCore$^{\uparrow}$ *witness recorded by H, then the resulting finite packet preserves the* RealModulusPurityBoundary$^{\uparrow}$ *carrier, the local classifier, the tail-budget ledger B, and the refusal of* Classical.choice, Quot.sound, *and* propext*. No new host-limit coordinate, quotient-stream equality, hidden modulus, or ambient Real-completeness row is introduced by the replacement.*

Proof. Project the carrier of Definition 1200.1. The dyadic observation row, StreamName window, RegSeqRat readback, RealUp seal, tail-budget ledger, transport, replay, provenance, and local naming rows are the only available coordinates.

Use the scoped obligation package and tail-budget exhaustion. The accepted packet must expose the same tuple $D, S, R_0, L, B, H, C, P, N$, and no second tail-budget or host-limit coordinate is available outside that tuple.

Transport the dyadic witness by the displayed row H. Because the replacement remains inside the same StreamName window S, the RegSeqRat readback R_0, RealUp seal L, and ledger B are replayed by the same Cont row C rather than by a new completion principle.

Finally inspect the refusal information in B. It continues to reject Classical.choice, Quot.sound, propext, selected host limits, quotient streams, and ambient completeness, so the hsame-transported dyadic witness preserves the carrier and classifier surface. □

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundaryDyadicWitnessStability`
Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.taste gate`

Theorem 1200.9 (Real modulus-purity boundary scope binding)**.** *Every accepted* RealModulusPurityBoundary$^{\uparrow}$ *packet binds exactly the dyadic row D, StreamName window S, RegSeqRat readback R_0, Real seal*

L, finite modulus-budget row B, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N as its scoped primitive dependency surface. No additional modulus, completion, quotient-stream, or host-Real row is part of the scoped carrier.*

Proof. Project the carrier of Definition 1200.1. Its displayed tuple is $D, S, R_0, L, B, H, C, P, N$, so each accepted packet first exposes precisely those rows.

Use the NameCert obligations and dyadic witness stability. They keep the dyadic observation, StreamName window, RegSeqRat readback, Real seal, finite modulus budget, transport, replay, provenance, and local naming rows componentwise stable under admitted replacements.

The TasteGate marker identifies the same carrier surface on the Lean side, while the paper scope remains a theory-axis statement. Thus the scoped primitive dependency surface is exactly the displayed tuple and no hidden row is available. □

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundaryScopeBinding`

Theorem 1200.10 (Real modulus-purity boundary source nonescape)**.** *No consumer of an accepted* RealModulusPurityBoundary$^{\uparrow}$ *packet may replace the scoped rows $D, S, R_0, L, B, H, C, P, N$ by hidden modulus extraction, quotient streams, selected host limits,* Classical.choice*,* Quot.sound*,* propext*, or ambient* Real$^{\uparrow}$ *completeness. Every Real-facing read remains routed through the displayed dyadic observation, StreamName window, RegSeqRat readback, Real seal, finite modulus-budget, transport, replay, provenance, and local NameCert rows.*

Proof. Start from the scoped binding theorem. It gives the complete list of rows available to any accepted consumer, with D, S, R_0, L, B as the analytic surface and H, C, P, N as the structural surface.

Apply non-escape, host-choice refusal, tail-budget exhaustion, and dyadic witness stability. These results exclude hidden modulus coordinates, quotient streams, selected host limits, proof-extensional rows, and ambient completeness while preserving the displayed dyadic and StreamName route.

Finally replay through C and record through P, N. Since transport and replay only preserve the displayed rows, a consumer cannot introduce Classical.choice, Quot.sound, propext, or a host Real-completeness principle as a replacement source. □

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundarySourceNonescape`

Theorem 1200.11 (Real modulus-purity boundary RegSeqRat readback induction)**.** *Let*

$$R = (D, S, R_0, L, B, H, C, P, N)$$

be an accepted RealModulusPurityBoundary$^{\uparrow}$ *packet. Any finite induction over the displayed* StreamName$^{\uparrow}$ *windows of S preserves the* RegSeqRat$^{\uparrow}$ *readback row R_0, the terminal* Real$^{\uparrow}$ *seal L, and the axiom-refusal budget B through componentwise* hsame *transport and displayed* Cont *replay. In particular, an inductive consumer that extends, refines, or exhausts the visible windows may not replace R_0, L, B by a quotient stream, selected host limit, hidden modulus, ambient Real-completeness row,* Classical.choice *row,* Quot.sound *row, or* propext *row.*

Proof. The base window is the carrier projection of Definition 1200.1. The displayed tuple already contains the dyadic observation D, StreamName window S, RegSeqRat readback R_0, Real seal L, refusal budget B, transport H, replay C, provenance P, and local naming row N.

For the induction step, apply the NameCert obligations of Definition 1200.2. Each admitted window extension must still expose the dyadic row, finite StreamName row, RegSeqRat readback, RealUp seal, and budget-refusal row before any Real-facing read is exported.

Tail-budget exhaustion, Definition 1200.7, prevents the step from creating a second modulus or hidden tail coordinate. Dyadic witness stability, Definition 1200.8, keeps replacements inside the same StreamName window routed through H and replayed by C.

The Lean-checked TasteGate alignment marker for the carrier identifies the same packet shape used by these paper obligations. Therefore the finite induction can only transport and replay R_0, L, B along the displayed rows, and the refused host-choice and proof-extensional coordinates remain outside the accepted packet. □

Lean4 ✓ `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundaryRegSeqRatReadbackInduction`

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusPurityBoundary}\uparrow}$.

Constructive story: The Real modulus-purity boundary is generated by taking the modulus rows already recorded in $BHist$ and making them the only admissible path to a Real-facing consumer. The carrier first reads the dyadic, window, readback, seal, and finite modulus-budget rows, then records the purity boundary that forbids hidden completion or host-real rows, and finally carries a constructive prediction through Cont extensions of that same route. The $hsame$ relation ensures that a different representative of the history cannot alter the modulus path or weaken the boundary. Thus the object is a visible purity test for Real use, grounded in ledger rows rather than ambient real analysis.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealModulusPurityBoundary}\uparrow}, \mathsf{obligation})$

Scope closed: This chapter binds the Real modulus-purity boundary carrier, NameCert obligations, non-escape theorem, constructive-prediction theorem, dyadic witness stability, scoped primitive dependency surface, source nonescape theorem, RegSeqRat readback induction, and the TasteGate marker.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealModulusPurityBoundary}\uparrow}, \mathsf{scaffoldChecked})$

Lean target: `BEDC.Derived.RealModulusPurityBoundaryUp.RealModulusPurityBoundaryScopeBinding`

Bridge status: none

Origin: ai

Not claimed: It does not claim ambient Real completeness, hidden modulus extraction, or equality of Real representatives beyond the recorded modulus boundary.

Upgrade path: Scoped closure requires checked source nonescape, readback induction, and transport replay obligations without bridge checking.

Chapter 1201

A Concrete Naming Certificate for $\mathsf{InterHistTransportSeal}^{\uparrow}$

The $\mathsf{InterHistTransportSeal}^{\uparrow}$ packet realizes a finite transport boundary for the Inter-Hist Locality chain of chapter 9419. It sits after the locality ledger of chapter 759, reads invariant rows from chapter 656, and requires the observer-locality cell surface of chapter 513 before any route can be consumed by a maximum-rate geometry.

Definition 1201.1 (Inter-Hist transport-seal carrier)**.** *An* $\mathsf{InterHistTransportSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, L, I, O, R, H, C, P, N)$$

with the following visible rows:

1. *A and B are the paired source-history rows naming the two histories under comparison;*
2. *L is the inter-Hist locality-ledger row that records the admissible two-history locality surface;*
3. *I is the inter-Hist invariant row that mediates observer-symmetric readback;*
4. *O is the observer-locality cell row that identifies the local observer-facing consumption site;*
5. *R is the cross-Hist causal-route row through which a* $\mathsf{MaxCausalRate}$ *consumer may read the sealed packet;*
6. *H records componentwise* hsame *and* psame *transports for the paired histories, locality ledger, invariant row, observer-locality cell, route, provenance, and local name;*
7. *C records displayed* Cont *replay from the locality ledger to the observer-locality cell, from the invariant row to the route, and from the accepted seal to downstream rate consumers;*
8. *P is the* Pkg *provenance over the locality-ledger, invariant, observer-locality-cell, cross-Hist causal-route,* BHist, hsame, psame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{InterHistTransportSeal}^{\uparrow}}$ *row.*

The classifier for accepted carriers compares exactly $A, B, L, I, O, R, H, C, P, N$. It has no coordinate for a global synchronization row, a host frame, an unsealed cross-Hist route, an invariant detached from observer locality, or a maximum-rate consumer that bypasses the displayed cell and invariant rows.

Lean4 (definition) `BEDC.Derived.InterHistTransportSealUp.InterHistTransportSealUp`

Theorem 1201.2 (Inter-Hist transport-seal NameCert obligations)**.** *For every accepted* $\mathsf{InterHistTransportSeal}^{\uparrow}$ *carrier*

$$T = (A, B, L, I, O, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{InterHistTransportSeal}^{\uparrow}}$ *surface consists exactly of paired source-history admission, locality-ledger admission, inter-Hist invariant readback, observer-locality cell admission, cross-Hist causal-route export, componentwise* hsame *and* psame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.InterHistTransportSealUp.InterHistTransportSeal namecert obligations`

Proof. Project the carrier. The positive route is the finite row sequence A, B, L, I, O, R, while H, C, P, N transport, replay, locate, and name those same rows.

The locality-ledger row L supplies the admissible paired-history comparison, the invariant row I supplies observer-symmetric content, and the observer-locality cell row O supplies the local consumption site. The route row R is therefore not a standalone causal edge; it is readable only after the ledger, invariant, and cell rows are present.

The structural rows preserve that surface. Componentwise transport cannot introduce a global frame or detached invariant, continuation replay cannot synthesize a missing observer-locality cell, and package provenance records only the displayed dependencies. Thus the listed obligations exhaust the local NameCert surface. □

Theorem 1201.3 (Inter-Hist transport-seal nonescape)**.** *An accepted* $\mathsf{InterHistTransportSeal}^{\uparrow}$ *packet cannot export a cross-Hist causal route to a* MaxCausalRate *consumer unless the same packet displays both its observer-locality cell row and its inter-Hist invariant row. A route missing either row remains outside the accepted seal, even when paired histories,* hsame *transport,* psame *transport,* Cont *replay,* Pkg *provenance, and a local* NameCert *row are present.*

Proof. Start with the carrier classifier of Definition 1201.1. The route row R is accepted only as one coordinate of the displayed packet $T = (A, B, L, I, O, R, H, C, P, N)$.

Apply the NameCert obligation surface of Definition 1201.2. It makes invariant readback and observer-locality cell admission mandatory before route export.

The remaining rows are structural. They transport and replay accepted coordinates but do not create a replacement for I or O. Hence a packet lacking either row cannot escape into a maximum-rate consumer as a sealed route. □

Lean4 ✓ `BEDC.Derived.InterHistTransportSealUp.InterHistTransportSeal nonescape`
↪ variant `BEDC.Derived.InterHistTransportSealUp.InterHistTransportSealCarrier nonescape`

Theorem 1201.4 (Inter-Hist transport-seal sibling independence)**.** *The* $\mathsf{InterHistTransportSeal}^{\uparrow}$ *carrier is independent of the sibling packets for* InterHistLocalityLedger*,* InterHistInvariant*,* ObserverLocalityCell*,* CrossHistCausalRoute*, and* MaxCausalRate*. It consumes their displayed rows but adds the seal-specific boundary that jointly requires locality-ledger admission, invariant readback, observer-locality-cell admission, route export, transport, replay, provenance, and local naming in one finite packet.*

Proof. Compare the row inventories. The locality ledger supplies the paired-history locality surface, the invariant packet supplies observer-symmetric readback, the observer-locality cell supplies a local consumption site, the causal-route packet supplies route data, and the maximum-rate packet supplies the downstream rate boundary.

The seal requires all of those rows simultaneously and adds the nonescape condition of Definition 1201.3. No sibling chapter carries that joint boundary as a single classifier surface, and no sibling can consume a missing row on behalf of the seal.

Therefore the transport seal is not a restatement of any one sibling. It is the finite packet that makes their rows jointly consumable by downstream rate geometry. □

Theorem 1201.5 (Inter-Hist transport-seal falsifiable prediction)**.** *A transport-seal packet that lacks either the observer-locality cell row or the inter-Hist invariant row cannot be consumed by a* MaxCausalRate *route.*

Proof. This is the consumer-facing form of Definition 1201.3. A MaxCausalRate route reads only the sealed route coordinate R of an accepted packet, and acceptance requires both O and I.

If either row is absent, the candidate has no accepted $\mathsf{InterHistTransportSeal}^{\uparrow}$ classifier surface. The downstream route therefore has no finite sealed packet to consume. □

Falsifiable prediction: A transport-seal packet that lacks either the observer-locality cell row or the inter-Hist invariant row cannot be consumed by a MaxCausalRate route.

Independence witness: interhistlocalityledger, interhistinvariant, observerlocalitycell, crosshistcausalroute, maxcausalrate: locality ledgers lack the sealed route export, invariant packets lack observer-cell admission, observer-locality cells lack the paired invariant route, causal routes lack the joint nonescape boundary, and maximum-rate packets are downstream consumers rather than transport seals.

The Lean TasteGate file for BEDC.Derived.InterHistTransportSealUp provides Nontrivial $\mathsf{InterHistTransportSeal}^{\uparrow}$ and FieldFaithful $\mathsf{InterHistTransportSeal}^{\uparrow}$ instances for the displayed carrier $A, B, L, I, O, R, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{InterHistTransportSeal}^{\uparrow}}$**.**

Constructive story: The Inter-Hist transport seal is generated from named $BHist$ rows for locality, invariant data, observer-cell admission, and the sealed transport route between histories. The seal begins with the source-facing row, reads the target-facing invariant through the declared transport path, and uses Cont only when the continuation preserves that path. The $hsame$ relation is the mechanism that lets equivalent source or target presentations retain the same seal without appealing to host identity. Non-escape, sibling independence, and the falsifiable prediction all express the same construction: any valid inter-history transport must expose its observer-locality, invariant, and continuation witness in the ledger.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{InterHistTransportSeal}^{\uparrow}}$, seed)

Scope closed: This chapter binds the Inter-Hist transport-seal carrier, NameCert obligations, nonescape, sibling-independence, and falsifiable-prediction theorems.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{InterHistTransportSeal}^{\uparrow}}$, encodedDef)

Bridge status: none

Origin: ai

Not claimed: It does not claim arbitrary history equivalence, transport without a visible continuation witness, or host-level identity between source and target histories.

Upgrade path: Reaching obligationClosure requires formal source-target transport rows and checked non-escape for transports lacking the carrier witness.

Chapter 1202

A Concrete Naming Certificate for $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$

The $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ packet realizes the Real-completeness separation surface of chapter 9238 as a finite NameCert object. It consumes the dyadic tolerance row of chapter 291, the StreamName and RegSeqRat readback rows of chapter 126 and chapter 301, the RealUp seal of chapter 38, the exact completion boundary of chapter 1120, the budgeted seal route of chapter 913, and the shared threshold route of chapter 560. Its role is to make Real separation readable only through a shared finite window, dyadic tolerance, regular-rational readback, componentwise transport, displayed replay, provenance, and local naming packet, not through quotient streams, host real equality, selected representatives, or an ambient completeness oracle.

Falsifiable prediction: If the shared finite-window row is removed, no accepted $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ packet can expose RealUp separation readback.

Independence witness: finitewindowrealsealaudit, locatedreal, realcompletionexactboundary, budgetedrealsealroute, regularcauchytailmeet: none is bijective because none simultaneously carries the shared finite-window row W, dyadic tolerance row D, StreamName and RegSeqRat readback row S, RealUp separation readback row R, componentwise transport row H, displayed replay row C, provenance row P, and local NameCert row N.

Definition 1202.1 (Finite-window Real-separation carrier)**.** *A* $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the shared finite-window row naming the common observation window for the two Real-facing reads;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to exactly that shared window;*
3. *S is the combined* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the stream-name schedule and the regular-rational readback reached from W and D;*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *separation readback row reached only after W, D, S have been displayed;*
5. *H records componentwise* hsame *transport for the shared window, tolerance, readback, separation, and local packet rows;*

6. *C records the displayed* Cont *replay from window admission through dyadic tolerance, StreamName and RegSeqRat readback, RealUp separation readback, and local naming;*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RealCompletionExactBoundaryU BudgetedRealSealRoute$^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowRealSeparation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eight rows. It has no coordinate for host real equality, quotient-stream equality, selected representatives, detached Real separation witnesses, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparationCarrier admission`

Theorem 1202.2 (Shared-window refusal for Real separation)**.** *For every accepted* $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ *carrier*

$$F = (W, D, S, R, H, C, P, N),$$

no consumer can expose the RealUp separation readback row R without first preserving the shared finite-window row W, the dyadic tolerance row D, and the StreamName/RegSeqRat readback row S. Any route that asks for host real equality, quotient-stream equality, a selected representative, or a detached separation witness is outside the accepted carrier.

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation window refusal`

Proof. Project the carrier of Definition 1202.1. The only Real-facing coordinate is R, and the carrier lists it after the shared window, tolerance, and readback rows.

Read the route in dependency order. The row W fixes the common finite observation window, D fixes the dyadic tolerance for that window, and S fixes the StreamName and RegSeqRat readback that the Real-facing separation row consumes.

The remaining rows H, C, P, N only transport, replay, package, and name the same displayed packet. Since no quotient stream, host equality, selected representative, or detached separation coordinate appears in the carrier, a consumer that omits W, D, S has no accepted path to R. □

Theorem 1202.3 (Finite-window Real-separation NameCert surface)**.** *For every accepted* FiniteWindowRealSepara *carrier*

$$F = (W, D, S, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteWindowRealSeparation}^{\uparrow}}$ *surface consists exactly of shared finite-window exposure through W, dyadic-tolerance exposure through D, StreamName and RegSeqRat readback through S, RealUp separation readback through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation namecert surface`

Proof. Start with the carrier inventory. The rows W, D, S, R are the full Real-separation route, while H, C, P, N are the structural rows that preserve and expose that route.

Attach the Real-completion faces. The dyadic row D supplies the finite tolerance, S supplies the StreamName schedule and RegSeqRat readback, and R supplies the RealUp separation readback under the exact-boundary, budgeted-seal, and shared-tail-meet provenance recorded by P.

No further row is available. Thus the local NameCert surface is exhausted by W, D, S, R, H, C, P, N, and any read requiring host equality, quotient streams, selected representatives, or ambient completeness is not a read of this packet. □

Theorem 1202.4 (Finite-window Real-separation obligation surface)**.** *For every accepted* FiniteWindowRealSeparat *carrier*

$$F = (W, D, S, R, H, C, P, N),$$

the RealUp separation obligation surface is exposed only through the common finite window W, the dyadic tolerance row D, the StreamName/RegSeqRat readback row S, the RealUp readback row R, and the structural rows H, C, P, N. No accepted separation consumer can replace these rows by quotient streams, host equality of reals, selected representatives, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation obligation surface`

Proof. Project the carrier of Definition 1202.1. Its only Real-separation coordinates are W, D, S, R, followed by the structural rows H, C, P, N.

Apply the NameCert surface of Definition 1202.3. It lists the same eight rows as the whole local surface, so no further obligation coordinate is available to a consumer.

Now use the shared-window obligation of Definition 1202.5. The row W is common to the two Real-facing reads, D fixes the dyadic tolerance for that window, S supplies the StreamName and RegSeqRat readback, and R is the RealUp readback reached only after those rows are displayed.

The refusal clauses follow from absence of carrier coordinates. Quotient streams, host real equality, selected representatives, and ambient completeness are not fields of F, and the structural rows H, C, P, N only transport, replay, source, and name the same finite surface. □

Theorem 1202.5 (Finite-window Real-separation shared-window obligation)**.** *Every separation read exported by an accepted* $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ *carrier*

$$F = (W, D, S, R, H, C, P, N)$$

must display one common finite window row W before the dyadic tolerance row D, the $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback row S, the* $\mathsf{Real}^{\uparrow}$ *seal row R, componentwise transport H, displayed replay C, provenance P, and the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowRealSeparation}^{\uparrow}}$ *row N are consumed. The obligation is constructive: it supplies no quotient stream equality, no host Real equality, no selected representative, and no ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation shared window obligation`

Proof. Project the carrier of Definition 1202.1. The row W is the only coordinate that names the common observation window for the two Real-facing reads.

Apply the shared-window refusal of Definition 1202.2. It blocks access to the RealUp separation readback R unless W, D, S have already been displayed in that order.

Now use the NameCert surface of Definition 1202.3. The structural rows H, C, P, N transport, replay, source, and name the same finite route; they do not add a second window, a quotient equality, a host representative, or an ambient completeness object.

Thus every separation read has to expose the common finite window before any dyadic, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, or local naming row is consumed. □

Theorem 1202.6 (Finite-window Real-separation TasteGate obligation)**.** *The Lean TasteGate surface for* $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ *must provide* $\mathsf{Nontrivial\ FiniteWindowRealSeparation}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ FiniteWindowRealSeparation}^{\uparrow}$ *instances for the same finite carrier $F = (W, D, S, R, H, C, P, N)$. These instances must keep RealUp separation readback behind the displayed dyadic tolerance and StreamName/RegSeqRat rows and must not introduce host equality, quotient streams, selected representatives, or ambient completeness.*

Proof. The obligation is read from Definition 1202.1. Nontriviality must inhabit the displayed finite packet rather than a detached Real value, because the only admissible carrier is $F = (W, D, S, R, H, C, P, N)$.

Field faithfulness must preserve the same route. By Definition 1202.2, the separation row R is not public until W, D, S have been displayed, so any TasteGate classifier faithful to the chapter must transport Real separation only through those finite rows.

The excluded coordinates are absent from the carrier and from the NameCert surface of Definition 1202.3. The Lean file `TasteGate.lean` therefore has to expose the instances for the finite route, not for host equality, quotient streams, selected representatives, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparationTasteGate single carrier alignment`

Theorem 1202.7 (Finite-window Real-separation obligation closure route)**.** *For every accepted* $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ *carrier*

$$F = (W, D, S, R, H, C, P, N),$$

the full obligation route is exposed through the shared finite-window row W, dyadic tolerance row D, StreamName and RegSeqRat readback row S, RealUp separation readback row R, componentwise transport H, displayed replay C, provenance P, and local naming N before any Real separation read is consumed. No accepted route may read R before the packet has displayed W, D, S, H, C, P, N as the finite support of that read.

Proof. Start with the carrier of Definition 1202.1. It lists exactly the rows W, D, S, R, H, C, P, N, so every accepted Real-separation consumer is already bounded by those displayed coordinates.

Apply the shared-window refusal of Definition 1202.2. It prevents access to the RealUp row R until the common finite window W, dyadic tolerance D, and StreamName/RegSeqRat readback S have been displayed.

Use the NameCert surface and shared-window obligation, Definition 1202.3 and Definition 1202.5. These bind the structural rows H, C, P, N to the same finite packet, so transport, replay, provenance, and local naming cannot escape the displayed route.

Finally apply the TasteGate obligation of Definition 1202.6. It forces any Lean-side gate for the packet to preserve the same finite carrier and refuses host equality, quotient streams, selected representatives, and ambient completeness before the Real separation read. □

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation obligation closure route`

Theorem 1202.8 (Finite-window Real-separation window-budget determinacy)**.** *Let*

$$F = (W, D, S, R, H, C, P, N) \qquad \text{and} \qquad F' = (W, D, S, R', H, C', P', N')$$

be accepted $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ *packets with the same shared finite-window row W, the same dyadic tolerance row D, the same* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback row S, and the same componentwise* hsame *transport row H. Then F and F' expose the same admissible* $\mathsf{Real}^{\uparrow}$ *separation readback budget: any consumer of R or R' must pass through the identical finite window W, dyadic budget D, readback row S, and transport row H before it can read a Real-separation handoff. The packet has no second budget coordinate, detached Real witness, quotient stream equality, selected representative, host Real equality, or ambient completeness row from which an alternate readback budget could be obtained.*

Proof. Project the two eight-row carriers from Definition 1202.1. The only rows that can govern a Real-separation budget are the shared finite window W, dyadic tolerance D, StreamName/RegSeqRat readback S, Real readback row, transport H, replay, provenance, and local naming.

Apply the refusal, NameCert surface, and shared-window obligation of Definition 1202.2, Definition 1202.3, and Definition 1202.5. They force every admissible Real-separation read to enter through W, D, S and then preserve the same route through H before the Real-facing row is public.

Finally use the obligation closure route Definition 1202.7. Since the accepted packets agree on W, D, S, H, the admissible budget visible to any consumer is the same finite dependency route. The remaining rows C, P, N and C', P', N' replay, source, and name that route, while the excluded coordinates are not fields of the carrier. □

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation window budget determinacy`

Theorem 1202.9 (Finite-window Real-separation scoped kernel route)**.** *For every accepted* FiniteWindowRealSepar *carrier*

$$F = (W, D, S, R, H, C, P, N),$$

the scoped kernel route is exactly the finite route over the DyadicRatCore$^{\uparrow}$ *tolerance row,* StreamName$^{\uparrow}$ *window row,* RegSeqRat$^{\uparrow}$ *readback row,* Real$^{\uparrow}$ *separation readback row,* RealCompletionExactBoundaryUp*,* BudgetedRealSealRoute$^{\uparrow}$*,* RegularCauchyTailMeet$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The carrier exposes no route through quotient streams, host real equality, selected representatives, countable choice, detached separation witnesses, or ambient Real completeness.*

Proof. Project the carrier of Definition 1202.1. The rows W, D, S, R, H, C, P, N are the only rows available to a consumer, and the provenance row P names the exact-boundary, budgeted-seal, and shared-tail-meet sources of the Real-facing read.

Apply shared-window refusal and the NameCert surface, Definition 1202.2 and Definition 1202.3. They force the RealUp separation row to be read only after the shared finite window, dyadic tolerance, and StreamName/RegSeqRat readback rows have been displayed, while H, C, P, N preserve and name the same route.

Use the shared-window obligation and obligation closure route, Definition 1202.5 and Definition 1202.7. These bind the structural rows to the displayed kernel dependencies and reject every outside coordinate before the Real-separation read is consumed.

Finally apply window-budget determinacy, Definition 1202.8. Since the visible budget is determined by the same W, D, S, H route, the scoped kernel surface is exactly the listed dyadic, stream, regular-rational, Real, completion-boundary, seal-route, tail-meet, history, transport, continuation, provenance, and local naming inventory. □

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation scoped kernel route`

Theorem 1202.10 (Finite-window Real-separation witness exhaustion)**.** *Every Real-separation witness accepted by a* FiniteWindowRealSeparation$^{\uparrow}$ *carrier is exhausted by the rows*

$$W, D, S, R, H, C, P, N.$$

No detached Real separation witness can be consumed, and no witness route may replace the shared finite window, dyadic tolerance, StreamName and RegSeqRat readback, Real readback, transport, replay, provenance, and local naming rows by quotient streams, host equality, selected representatives, or ambient completeness.

Proof. Project the carrier of Definition 1202.1. The witness-facing coordinates are exactly W, D, S, R, H, C, P, N.

Use shared-window refusal, the NameCert surface, and the shared-window obligation from Definition 1202.2, Definition 1202.3, and Definition 1202.5. They force every Real-separation read to display the common finite window, tolerance, and readback rows before the Real-facing row is consumed.

Finally apply the obligation-closure route of Definition 1202.7. The structural rows preserve the same finite packet, and the carrier contains no quotient-stream, host-equality, selected-representative, or ambient-completeness coordinate. □

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation witness exhaustion`

Theorem 1202.11 (Finite-window Real-separation scoped completion route)**.** *Every accepted* $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ *separation read that reaches a completion-facing consumer factors through the finite route*

$$W \longmapsto D \longmapsto S \longmapsto R \longmapsto \mathsf{RealCompletionExactBoundaryUp} \longmapsto \mathsf{BudgetedRealSealRoute}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailM}$$

The route first displays the common finite window W, dyadic tolerance D, $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback S, and* $\mathsf{Real}^{\uparrow}$ *seal R; it then reads exact-boundary, budgeted-seal, and tail-meet rows only through the provenance already carried by P. It exposes no quotient stream, host real equality, selected representative, detached completion witness, or ambient completeness principle.*

Proof. Project the carrier of Definition 1202.1. The only separation-facing rows are W, D, S, R, H, C, P, N, and the provenance row names the exact-boundary, budgeted-seal, and shared-tail-meet siblings consumed by the Real-facing route.

Apply the shared-window refusal and NameCert surface theorems, Definition 1202.2 and Definition 1202.3. They force any RealUp read to pass through the same finite window, dyadic tolerance, and StreamName/RegSeqRat readback before R becomes public.

Use the shared-window obligation and obligation-closure route, Definition 1202.5 and Definition 1202.7. These bind H, C, P, N to the same displayed packet, so completion-facing consumers cannot detach the exact-boundary or seal rows from the carrier.

Finally apply the scoped kernel route and witness exhaustion theorems, Definition 1202.9 and Definition 1202.10. The scoped route already lists the dyadic, stream, regular-rational, Real, exact-boundary, budgeted-seal, and tail-meet dependencies, while witness exhaustion blocks every outside completion witness. □

Theorem 1202.12 (Finite-window Real-separation shared-budget normalization)**.** *Let*

$$F = (W, D, S, R, H, C, P, N) \qquad \textit{and} \qquad F' = (W, D, S, R', H, C', P', N')$$

be accepted $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ *packets with the same shared finite-window row W and the same dyadic tolerance row D. Any* $\mathsf{Real}^{\uparrow}$ *separation read exposed by either packet factors through one normalized finite budget route*

$$W, D, S, R, H, C, P, N$$

after replacing the replay, provenance, and local naming rows of the second packet by the displayed route for the same window, tolerance, readback, and transport budget. No normalized route may use quotient streams, selected representatives, or ambient completeness.

Proof. Start with the shared-window refusal of Definition 1202.2. It blocks any RealUp read until the common window row W, dyadic tolerance row D, and StreamName/RegSeqRat readback row S have been displayed.

Apply the NameCert surface and shared-window obligation of Definition 1202.3 and Definition 1202.5. These theorems bind the readback row, transport row, replay, provenance, and local name to the same finite packet once W and D are fixed.

Use the window-budget determinacy theorem Definition 1202.8. Agreement on the shared finite window and dyadic tolerance forces the visible Real-separation budget through the same finite route, so the normalized read can be recorded as W, D, S, R, H, C, P, N.

The refusal clauses are structural. Quotient streams, selected representatives, and ambient completeness are not fields of the accepted carrier, and replay or provenance cannot create a second budget outside the displayed finite route. □

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation shared budget normalization`

Theorem 1202.13 (Finite-window Real-separation common-window exactness)**.** *Let*

$$F = (W, D, S, R, H, C, P, N) \qquad \textit{and} \qquad F' = (W, D, S, R', H', C', P', N')$$

be accepted $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ *packets with the same shared finite-window row W, the same dyadic tolerance row D, and the same* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback row S. Every admissible* $\mathsf{Real}^{\uparrow}$ *separation read exposed by either packet factors through the same W, D, S route before reading R or R'. Disagreement in replay, provenance, local naming, or the remaining transport rows cannot create a second separation budget outside that common finite window.*

Proof. Start with the shared-window refusal of Definition 1202.2. It blocks every RealUp separation read until the common finite window W, dyadic tolerance D, and StreamName/RegSeqRat readback row S have been displayed.

Use the NameCert surface and shared-window obligation of Definition 1202.3 and Definition 1202.5. These bind the Real-facing row, transport, replay, provenance, and local name to the finite route whose first three rows are W, D, S.

Apply window-budget determinacy and shared-budget normalization, Definition 1202.8 and Definition 1202.12. Once the two packets agree on W, D, S, any admissible read of R or R' has the same finite budget prefix, while H, C, P, N and H', C', P', N' only preserve, replay, source, and name that displayed route.

The refusal clause follows from the carrier inventory. The packet has no coordinate for a detached budget, quotient stream equality, selected representative, host Real equality, or ambient completeness, so disagreement in replay, provenance, or local naming cannot supply another route to a RealUp separation read. □

Lean4 ✓ `BEDC.Derived.FiniteWindowRealSeparationUp.FiniteWindowRealSeparation common window exactness`

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowRealSeparation}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$ packet is generated from a shared finite-window row, a DyadicRatCore tolerance row, StreamName and RegSeqRat readback, RealUp separation readback, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWindowRealSeparation}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1202.1, Definition 1202.4, Definition 1202.5, Definition 1202.6, Definition 1202.10, and Definition 1202.12 bind the finite Real-separation carrier, obligation surface, shared-window obligation, TasteGate obligation, witness exhaustion, and shared-budget normalization rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteWindowRealSeparation}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: ai
Not claimed: This chapter does not close Lean verification, bridge checking, quotient reals, host real equality, selected representatives, or ambient Real completeness.
Upgrade path: Obligation closure requires checked carrier admission and TasteGate-visible Nontrivial and FieldFaithful instances for the same finite Real-separation packet.

Chapter 1203

A Concrete Naming Certificate for $\mathsf{BorrowedRecursorBoundary}^{\uparrow}$

The $\mathsf{BorrowedRecursorBoundary}^{\uparrow}$ packet concretizes the borrowed-recursor boundary of chapter 9396 as a finite NameCert carrier. It sits beside the strict gate packet of chapter 526, the socket refusal surface of chapter 536, and the failed-gate witness of chapter 901. The packet allows host Lean recursors to serve as checking infrastructure only after proof ancestry, gate verdict, socket refusal, and local naming rows are displayed.

Definition 1203.1 (Borrowed-recursor boundary carrier)**.** *A* $\mathsf{BorrowedRecursorBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, A, S, F, H, C, P, N)$$

with the following displayed rows:

1. *R is the borrowed host-recursor use, recorded as a checking route rather than theorem content;*
2. *A is the proof-ancestry audit row classifying whether the route depends on forbidden host commitments;*
3. *S is the visible* $\mathsf{ApophaticSocket}^{\uparrow}$ *row that names the external host supply position;*
4. *F is the* $\mathsf{AuditGateFailureWitness}^{\uparrow}$ *row used when the ancestry row refuses the route;*
5. *H records componentwise* hsame *transport for recursor use, ancestry, socket, failure witness, provenance, and local naming rows;*
6. *C records displayed* Cont *replay from the recursor use through ancestry audit, socket naming, refusal, and local consumption;*
7. *P records* Pkg *provenance over auditgateboundary, apophaticsocket, apophaticname, certificateauditgate, auditgatefailurewitness,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BorrowedRecursorBoundary}^{\uparrow}}$ *row.*

The carrier exports a boundary certificate for checked host-recursion use. It exports no host recursion principle, global kernel completeness theorem, hidden eliminator, or proof dependency absent from the ancestry row.

Lean4 (definition) `BEDC.Derived.BorrowedRecursorBoundaryUp.taste gate`
Lean4 (definition) `BEDC.Derived.BorrowedRecursorBoundaryUp.BorrowedRecursorBoundaryUp`

Theorem 1203.2 (Borrowed-recursor boundary nonescape)**.** *Every accepted* $\mathsf{BorrowedRecursorBoundary}^{\uparrow}$ *packet exposes the proof-ancestry row A before any consumer may use the borrowed recursor row R. If A records a forbidden dependency or lacks the displayed ancestry report, the route must pass through the socket row S and the failure witness row F as an apophatic refusal rather than as theorem content.*

Proof. Unfold Definition 1203.1. The only accepted recursor use is the displayed row R, and the next row in the packet is the proof-ancestry audit A.

The socket row S names the host supply position without internalizing it. If the ancestry row is absent or refuses the route, the failure witness F is the only displayed consumer-facing continuation.

The transport, replay, provenance, and local naming rows H, C, P, N can repack only these visible rows. Thus a consumer receives either an ancestry-cleared checking route or a visible refusal path, never an uninspected host-recursion principle. □

Theorem 1203.3 (Borrowed-recursor gate correspondence)**.** *For an accepted* $\mathsf{BorrowedRecursorBoundary}^{\uparrow}$ *packet, the strict audit gate may certify host-recursion nonescape exactly through the displayed tuple R, A, S, F, H, C, P, N. The gate consumes the proof-ancestry row A, the socket row S, the failure-witness row F, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before it treats the borrowed recursor as a BEDC checking route.*

Proof. Start with the carrier of Definition 1203.1. Its rows separate host-recursion use R from proof ancestry A, socket naming S, and refusal witness F.

Use the gate sibling of chapter 526. The strict gate can inspect only the finite audit-facing rows it is given, so it reads ancestry and refusal through A, S, F rather than through a hidden host predicate.

The remaining rows H, C, P, N supply transport, replay, provenance, and local naming. Together they are exactly the finite route through which the borrowed recursor is admitted as checking infrastructure, with no extra host-recursion content exported. □

Falsifiable prediction: A BorrowedRecursorBoundaryUp packet without the proof-ancestry row cannot certify host-recursion nonescape.

Independence witness: auditgateboundary, apophaticsocket, apophaticname, certificateauditgate, auditgatefailurewitness: the borrowed-recursor boundary combines proof ancestry, visible host-socket naming, failed-gate refusal, transport, replay, provenance, and local naming; none of the named siblings carries all rows R, A, S, F, H, C, P, N together.

The Lean follow-up lives at `lean4/BEDC/Derived/BorrowedRecursorBoundaryUp/TasteGate.lean` and must provide `Nontrivial BorrowedRecursorBoundaryUp` and `FieldFaithful BorrowedRecursorBoundaryU` instances for the same displayed carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{BorrowedRecursorBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{BorrowedRecursorBoundary}^{\uparrow}$ packet is generated from a borrowed recursor-use row, proof-ancestry audit row, socket row, failure-witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorrowedRecursorBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1203.1, Definition 1203.2, and Definition 1203.3 bind borrowed host-recursion use to displayed proof ancestry, audit refusal, socket naming, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorrowedRecursorBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, a public standard bridge, host kernel completeness, a global recursion theorem, or theorem content for refused host dependencies.

Upgrade path: Obligation closure requires checked carrier admission, proof-ancestry exactness, strict-gate correspondence, socket refusal, componentwise transport, displayed continuation, provenance, and local naming rows.

Chapter 1204

A Concrete Naming Certificate for $\mathsf{TailCompatibleCauchySection}^{\uparrow}$

The $\mathsf{TailCompatibleCauchySection}^{\uparrow}$ packet realizes the finite-window route behind the regular-Cauchy diagonal-limit construction of chapter 9238. It is structurally composite over the stream windows of chapter 126, the dyadic ledgers of chapter 291, the regular-rational readbacks of chapter 301, the real-name seal of chapter 38, and the finite observation-budget selector of chapter 782. The packet names a compatible finite section, not a host limit, quotient stream, selected infinite subsequence, or ambient completeness principle.

Because the carrier is composite over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$, its falsifiability and independence witnesses are inherited from those component packets. The atomic falsifiability and independence rows used for primitive carriers are therefore not used here.

Definition 1204.1 (Tail-compatible Cauchy section carrier)**.** *A* $\mathsf{TailCompatibleCauchySection}^{\uparrow}$ *carrier is a finite packet*

$$S = (X, \mu, n, k, i, W, B, R, D, E, H, C, P, N)$$

with the following rows:

1. *X is the displayed regular-Cauchy family from section 9238.1;*
2. *μ is the modulus row selecting tail indices for X;*
3. *n is the visible precision request;*
4. *$k = \mu(1/(n+1))$ and $i = k + n + 1$ are the displayed diagonal-section indices;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite window exposing the i-th read of the k-th regular-rational member;*
6. *B is the* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *budget row certifying that the same window is admissible for the section read;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected regular-rational member along W;*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic ledger attached to the selected readback;*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached by repacking the selected regular-rational read through the displayed finite route;*
10. *H records componentwise* hsame *transport for $X, \mu, n, k, i, W, B, R, D, E$ and the local certificate row;*

11. *C records* Cont *replay from the precision request through the budgeted window, readback, dyadic ledger, and real seal;*
12. *P is the* Pkg *provenance over* TailCompatibleCauchySection$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, FiniteObservationBudgetSelector$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
13. *N is the local* NameCert$_{\text{TailCompatibleCauchySection}^{\uparrow}}$ *row.*

The carrier exports only the displayed finite section rows and their transport, replay, provenance, and naming support.

Definition 1204.2 (Tail-compatible Cauchy section classifier)**.** *Two accepted* TailCompatibleCauchySection$^{\uparrow}$ *carriers classify together exactly when their regular-Cauchy family rows and modulus rows select the same displayed diagonal-section route, their precision requests yield the same finite index pair k, i, and their* StreamName$^{\uparrow}$, FiniteObservationBudgetSelector$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, *transport, continuation, package, and local naming rows are related componentwise by the recorded* hsame *comparisons and* Cont *routes.*

Theorem 1204.3 (Tail-compatible Cauchy section NameCert obligations)**.** *For the carrier of Definition 1204.1, the local* NameCert$_{\text{TailCompatibleCauchySection}^{\uparrow}}$ *surface consists exactly of carrier admission, the finite diagonal-section computations $k = \mu(1/(n+1))$ and $i = k+n+1$,* StreamName$^{\uparrow}$ *window exposure,* FiniteObservationBudgetSelector$^{\uparrow}$ *budget admission,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* Real$^{\uparrow}$ *seal exposure, componentwise transport, continuation replay, package provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.TailCompatibleCauchySectionUp.TailCompatibleCauchySectionTasteGate single carrier alignment`

Proof. Project the packet S. Its coordinates list the regular-Cauchy family, modulus, precision request, computed section indices, stream window, budget selector, regular-rational readback, dyadic ledger, real seal, transport, replay, provenance, and local naming rows.

The finite index computation is internal to the packet. The modulus row supplies k, the request supplies n, and the displayed arithmetic supplies $i = k+n+1$, matching the diagonal representative of Definition 9238.3.

The remaining rows are precisely the component certificate surfaces. The stream window, budget selector, regular-rational readback, dyadic ledger, and real seal are consumed in that order, while H, C, P, N only transport, replay, source, and name those rows. No further NameCert obligation remains. □

Theorem 1204.4 (Tail-compatible Cauchy section index determinacy)**.** *For an accepted* TailCompatibleCauchySect *carrier*

$$S = (X, \mu, n, k, i, W, B, R, D, E, H, C, P, N),$$

the displayed regular-Cauchy family row X, modulus row μ, and precision request n determine the section route indices. The only admitted route is

$$k = \mu(1/(n+1)) \qquad \textit{and} \qquad i = k + n + 1,$$

followed by the ordered read through W, B, R, D, E.

Proof. Project the carrier of Definition 1204.1. Its fourth coordinate is the displayed computation of k from the modulus row and the visible precision request, and its fifth coordinate is the displayed computation of i from k and n.

The classifier of Definition 1204.2 admits carriers together only when those same rows select the same diagonal-section route. The obligation theorem Definition 1204.3 then fixes the subsequent order of the stream window, budget row, regular-rational readback, dyadic ledger, and RealUp seal. □

Theorem 1204.5 (Tail-compatible Cauchy section classifier transport)**.** *Let* $S = (X, \mu, n, k, i, W, B, R, D, E, H, C,$ *and* $S' = (X', \mu', n', k', i', W', B', R', D', E', H', C', P', N')$ *be accepted* $\mathsf{TailCompatibleCauchySection}^{\uparrow}$ *carriers. If the recorded componentwise* hsame *row relates*

$$X, \mu, n, k, i, W, B, R, D, E$$

to

$$X', \mu', n', k', i', W', B', R', D', E',$$

then the carrier admission and classifier verdict transport from S *to* S' *along the same finite section route.*

Proof. Use the transport coordinate H in Definition 1204.1. It records the componentwise hsame comparisons for the regular-Cauchy row, modulus, precision request, index pair, stream window, budget row, readback, dyadic ledger, RealUp seal, and local certificate row.

Apply the classifier definition. Its equality test is not a detached predicate: it is exactly the conjunction of same route selection and componentwise transport through those rows. The NameCert-obligation theorem supplies the carrier admission surface for the transported packet, so the classifier verdict follows with the same ordered route. □

Theorem 1204.6 (Tail-compatible Cauchy section continuation replay)**.** *For every accepted* $\mathsf{TailCompatibleCauchyS}$ *packet, any* Cont *replay recorded by the carrier preserves the ordered route*

$$W, B, R, D, E.$$

In particular, the $\mathsf{Real}^{\uparrow}$ *seal coordinate* E *cannot be exposed before the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *budget row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger have been displayed on the same packet.*

Proof. Project the continuation coordinate C from the carrier. By Definition 1204.1, it replays the precision request through the budgeted stream window, regular-rational readback, dyadic ledger, and RealUp seal in that order.

The NameCert-obligation theorem records the same order as part of the local certificate surface. The seal-boundary theorem Definition 1204.8 identifies the RealUp-facing boundary as the end of this finite route, so a continuation replay cannot make E available before the component rows W, B, R, D have already appeared. □

Theorem 1204.7 (Tail-compatible Cauchy section component scope binding)**.** *Every accepted* $\mathsf{TailCompatibleCauchySection}^{\uparrow}$ *packet factors its displayed section route through exactly the component scopes*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{FiniteObservationBudgetSelector}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The only support rows available to that factorization are the displayed BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{TailCompatibleCauchySection}^{\uparrow}}$ *rows. No further carrier, classifier, host-real equality, quotient-stream equality, selector, or ambient completeness scope is exported by the packet.*

Proof. Project the carrier tuple of Definition 1204.1. Its displayed coordinates first determine the regular-Cauchy family, modulus, precision request, and diagonal indices, and then expose the component rows W, B, R, D, E in the order fixed by Definition 1204.3 and Definition 1204.4.

Read those rows as scope witnesses. The stream window is the $\mathsf{StreamName}^{\uparrow}$ scope, the budget row is the $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ scope, the readback row is the $\mathsf{RegSeqRat}^{\uparrow}$ scope, the tolerance ledger is the $\mathsf{DyadicRatCore}^{\uparrow}$ scope, and the seal row is the $\mathsf{Real}^{\uparrow}$ scope. These are the only component rows listed by the carrier surface.

Use Definition 1204.5 to transport the classifier along the recorded hsame support, and use Definition 1204.6 to preserve the same ordered route under Cont replay. The remaining Pkg and local $\mathsf{NameCert}$ rows only source and name that finite factorization.

Finally, Definition 1204.8 closes the route at the $\mathsf{Real}^{\uparrow}$ seal. Since the boundary theorem excludes host reals, quotient-stream equality, chosen limits, detached selectors, countable-choice rows, and ambient completeness witnesses, no component scope outside the displayed five can be read from an accepted packet. □

Theorem 1204.8 (Tail-compatible Cauchy section RealUp seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer read of an accepted* $\mathsf{TailCompatibleCauchySection}^{\uparrow}$ *packet factors through the finite route*

$$X, \mu, n, k, i, W, B, R, D, E, H, C, P, N.$$

The seal coordinate E is reachable only after the shared tail-compatible $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *budget row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger have been displayed on the same carrier. The packet exports no host real, quotient stream equality, chosen limit, detached selector, countable-choice row, or ambient completeness witness.*

Proof. Start with Definition 1204.3. It forces every accepted packet to expose the modulus-selected index pair before any readback or seal-facing row is available.

Next read the component surfaces in order. The $\mathsf{StreamName}^{\uparrow}$ row supplies the finite tail-compatible window, the $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ row admits that window as a finite budgeted request, the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the selected regular-rational readback, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row records the tolerance ledger attached to that readback.

Only then can the $\mathsf{Real}^{\uparrow}$ seal row be consumed, and it is preserved solely through the displayed transport, replay, provenance, and local naming rows. Since none of the carrier coordinates is a host real, quotient stream equality, chosen limit, detached selector, countable-choice row, or ambient completeness witness, no Real-facing consumer can obtain such data from the section packet. □

Theorem 1204.9 (Tail-compatible Cauchy section scoped component readiness)**.** *Every accepted* $\mathsf{TailCompatibleCauchySection}^{\uparrow}$ *section route is scoped by the displayed* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *budget admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and* $\mathsf{Real}^{\uparrow}$ *seal, together with the supporting* BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{TailCompatibleCauchySect}}$ *rows. These rows are the whole component scope exported by the packet: they do not expose a host real, quotient stream equality, detached selector, countable-choice row, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.BHistArity14TupleNameCertUp.BHistArity14TupleNameCertCarrierAdmission`

Proof. Start with the NameCert obligations of Definition 1204.3. They list the carrier admission surface, the two displayed diagonal-section computations, and the ordered component rows from stream window through RealUp seal.

The index-determinacy theorem Definition 1204.4 fixes the route selected by the regular-Cauchy family, modulus, and precision request. The component-scope binding theorem Definition 1204.7 then identifies the only component scopes available along that route as $\mathsf{StreamName}^{\uparrow}$, $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Use classifier transport and continuation replay from Definition 1204.5 and Definition 1204.6 to keep the same rows under hsame transport and Cont replay. The Pkg and local NameCert rows source and name the same finite factorization rather than adding a further carrier scope.

Finally apply the RealUp seal boundary theorem Definition 1204.8. It makes the $\mathsf{Real}^{\uparrow}$ seal the terminal read of the finite route and excludes host reals, quotient-stream equality, detached selectors, countable-choice rows, and ambient completeness witnesses from the exported packet surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{TailCompatibleCauchySection}^{\uparrow}}$.

Constructive story: The tail-compatible Cauchy section is generated from a $BHist$ packet that records a Cauchy section, its modulus-selected index pair, finite tail witnesses, and the classifier that checks compatibility with the RealUp seal boundary. The carrier reads the section only through those tail rows; $hsame$ transports the same finite witness data when a history representative changes. Continuation data may extend the section route, but Cont must preserve the tail-compatible classifier already recorded. The NameCert surface is therefore a composite certificate: it connects a Cauchy section to StreamName, finite observation budget, RegSeqRat, DyadicRatCore, and RealUp through visible tail evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TailCompatibleCauchySection}^{\uparrow}}$, scopedClosed)

Scope closed: This chapter binds the tail-compatible Cauchy-section carrier, classifier, index-determinacy row, classifier-transport row, continuation-replay row, NameCert obligations, component scope binding, RealUp seal boundary, and scoped component readiness for the displayed section route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TailCompatibleCauchySection}^{\uparrow}}$, axiomClean)

Lean4 ✓ `BEDC.Derived.TailCompatibleCauchySectionUp.taste gate`

Lean target: `BEDC.Derived.TailCompatibleCauchySectionUp.TailCompatibleCauchySectionTasteGate\_single\_carrier\_al`

Bridge status: none

Origin: ai

Not claimed: It does not claim arbitrary Cauchy section choice, quotient-stream equality, host real equality, or Real equality outside the finite tail-compatible witness route.

Upgrade path: Public closure requires an exported consumer surface or bridge evidence for the same StreamName, finite-budget, RegSeqRat, DyadicRatCore, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

$\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ reads its finite root route through chapter 126, chapter 301, chapter 291, and chapter 38, with the root-index child below making that route visible at the hub surface.

Chapter 1205

A Concrete Naming Certificate for $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$

The $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ packet realizes the diagonal representative of section 9238.1 as a finite naming certificate. It sits after the diagonal-modulus surface of chapter 390, and it consumes the finite windows, readbacks, dyadic ledgers, and terminal real-name seal supplied by chapter 126, chapter 301, chapter 291, and chapter 38. The same terminal real-facing handoff is the Cauchy-limit seal boundary of chapter 386; the diagonal representative consumes it only as a displayed finite route, not as quotient-stream equality, a selected host limit, choice, or ambient Real completeness. The packet names the representative row itself; it is not a Real-completeness principle and it does not choose a host limit.

Definition 1205.1 (Diagonal-limit representative carrier)**.** *A* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N)$$

with the following displayed rows:

1. *X is the regular-Cauchy family over* $\mathsf{RegSeqRat}^{\uparrow}$ *whose diagonal representative is being inspected;*
2. *μ is the explicit modulus row read through chapter 390;*
3. *n is the displayed precision request;*
4. *$k = \mu(1/(n+1))$ is the selected family index;*
5. *$i = k + n + 1$ is the selected readback index;*
6. *w is the* $\mathsf{StreamName}^{\uparrow}$ *window exposing the i-th read of the k-th family member;*
7. *r is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for that selected member and window;*
8. *d is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording the tolerance and rational arithmetic of the readback;*
9. *e is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the selected regular-rational readback has been repacked;*
10. *H records componentwise* hsame *transport for $X, \mu, n, k, i, w, r, d, e$ and the local certificate row;*
11. *C records displayed* Cont *replay from the modulus request through the window, readback, dyadic ledger, and real seal;*

12. *P is the* Pkg *provenance over* DiagonalLimitRepresentative$^\uparrow$, RegSeqRat$^\uparrow$, StreamName$^\uparrow$, DyadicRatCore$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert*;*
13. *N is the local* NameCert$_{\text{DiagonalLimitRepresentative}^\uparrow}$ *row.*

The carrier exports no host real, quotient stream equality, hidden tail selector, countable choice row, or ambient Real$^\uparrow$ *completeness field.*

Definition 1205.2 (Diagonal-limit representative classifier)**.** *Two accepted* DiagonalLimitRepresentative$^\uparrow$ *carriers are classified together exactly when their modulus rows select the same displayed diagonal route and their selected family index, readback index,* StreamName$^\uparrow$ *window,* RegSeqRat$^\uparrow$ *readback,* DyadicRatCore$^\uparrow$ *ledger,* Real$^\uparrow$ *seal row, transport rows, continuation rows, package rows, and local naming rows are related componentwise by the recorded* hsame *comparisons and* Cont *routes.*

Theorem 1205.3 (Diagonal-limit representative NameCert obligations)**.** *For the carrier of Definition 1205.1, the local* NameCert$_{\text{DiagonalLimitRepresentative}^\uparrow}$ *surface consists exactly of carrier admission, diagonal-index computation $k = \mu(1/(n+1))$ and $i = k + n + 1$, finite-window exposure through w, regular-rational readback through r, dyadic ledger exposure through d, terminal seal exposure through e, componentwise transport through H, continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the packet D. The carrier lists the family row, modulus row, request row, computed index rows, selected window, regular-rational readback, dyadic ledger, real seal, transport, continuation, provenance, and local naming row.

The diagonal-index computation is finite. The modulus surface supplies k, the unary request supplies n, and the readback index i is obtained by the displayed rational-index arithmetic used in Definition 9238.3.

The remaining rows expose the route through the four concrete sibling surfaces: StreamName$^\uparrow$ for w, RegSeqRat$^\uparrow$ for r, DyadicRatCore$^\uparrow$ for d, and Real$^\uparrow$ for e. Since H, C, P, N only transport, replay, source, and name those displayed rows, the listed obligations exhaust the local certificate. □

Lean4 ✓ `BEDC.Derived.DiagonallimitrepresentativeUp.DiagonalLimitRepresentativeNameCertObligations`

Theorem 1205.4 (Diagonal-limit representative route predicate obligation)**.** *For an accepted* DiagonalLimitRepresentative$^\uparrow$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the accepted route predicates are exactly the displayed rows $X, \mu, n, k, i, w, r, d, e, H, C, P, N$. The family and readback rows are read through RegSeqRat$^\uparrow$*, the selected window through* StreamName$^\uparrow$*, the dyadic ledger through* DyadicRatCore$^\uparrow$*, and the terminal seal through* Real$^\uparrow$*. The support predicates are precisely componentwise* hsame *transport through H,* Cont *replay through C,* Pkg *provenance through P, and the local* NameCert$_{\text{DiagonalLimitRepresentative}^\uparrow}$ *row N.*

Proof. Project the carrier of Definition 1205.1. Its rows already name the family, modulus, request, selected indices, selected window, readback, dyadic ledger, Real seal, and the four support coordinates.

Apply the NameCert obligations of Definition 1205.3. They certify the two index computations and expose the sibling rows in the order StreamName$^\uparrow$, RegSeqRat$^\uparrow$, DyadicRatCore$^\uparrow$, and Real$^\uparrow$.

It remains to exclude additional route predicates. The classifier of Definition 1205.2 allows transport only by componentwise hsame and replay only by the recorded Cont routes, while P and

N source and name the same packet. Hence the accepted route predicate surface is exactly the displayed carrier row. □

Theorem 1205.5 (Diagonal-limit representative terminal stability obligation)**.** *Let*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N)$$

and

$$D' = (X', \mu', n', k', i', w', r', d', e', H', C', P', N')$$

be accepted $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carriers classified together by their recorded componentwise* hsame *rows and replayed* Cont *routes. Then the selected diagonal indices, selected* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal remain on the displayed route*

$$\mu, n, k, i, w, r, d, e.$$

The transport does not introduce a hidden selector, detached window, alternate readback, second dyadic ledger, or off-packet terminal Real seal.

Proof. First read index stability. By Definition 1205.12, the displayed equations for k, i and k', i' are part of the accepted route and remain tied to the modulus request under classifier transport.

Next read the terminal route. The window-ledger exhaustion theorem, Definition 1205.13, confines public reads of w, r, d, e to the displayed sibling rows, and Definition 1205.10 places every Real-facing read downstream of those rows.

Finally use the support rows. Componentwise hsame and replayed Cont preserve the rows already present in the packet; Pkg and NameCert name that same packet. Therefore terminal stability is stability of the displayed route, not permission to manufacture a hidden selector or an off-packet terminal seal. □

Theorem 1205.6 (Diagonal-limit representative obligation-closure package)**.** *The chapter's* DiagonalLimitRepresen *obligation surface is the package consisting of the carrier of Definition 1205.1, the classifier of Definition 1205.2, the NameCert obligations of Definition 1205.3, the route predicate obligation of Definition 1205.4, and the terminal stability obligation of Definition 1205.5. This package is the concrete diagonal representative surface available to later Lean formalization; it contains no quotient stream equality, host limit, selected completed limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. The carrier and classifier supply the accepted packet and its componentwise comparison rule. The NameCert obligations certify the displayed diagonal-index computations, sibling rows, and support rows.

The route predicate obligation identifies the exact predicate surface consumed by downstream readers. The terminal stability obligation then proves that componentwise transport and continuation replay preserve the selected diagonal route through the terminal Real seal.

Combining these pieces yields the chapter's obligation surface. The exclusions are inherited from the carrier and from the already established nonchoice and completion boundaries, so the package closes the obligation level without adding quotient, host-limit, choice, or ambient-completeness data. □

Theorem 1205.7 (Diagonal-limit representative primitive-scope exhaustion)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the displayed route predicates are scoped exactly by BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*, and the sibling rows supplied by* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*, and* FinitePrefixLimitBudget$^{\uparrow}$*. The representative route uses $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ together with the shared-terminal finite-prefix rows of Definition 1205.32; it has no primitive outside those listed BEDC rows.*

Proof. Project the carrier. The only local rows are the family, modulus, request, selected indices, window, readback, ledger, seal, transport, continuation, provenance, and naming rows listed in Definition 1205.1.

Read the sibling surfaces. The route predicate obligation places w, r, d, e respectively in StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$, and the shared-terminal carrier adds only the finite-prefix budget rows from FinitePrefixLimitBudget$^{\uparrow}$.

The support rows are exactly H, C, P, N. Thus every transport, replay, source, and local name is accounted for by hsame, Cont, Pkg, and NameCert over BHist. Since the carrier and the shared-terminal extension export no further coordinates, the primitive scope is exhausted by the listed rows. □

Theorem 1205.8 (Diagonal-limit representative support-scope nonescape)**.** *All accepted transport and replay for the* DiagonalLimitRepresentative$^{\uparrow}$ *route occurs through the recorded support rows H, C, P, N. No hidden selector, quotient stream, host limit, ambient completeness field, countable-choice row, detached window, alternate dyadic ledger, or off-packet terminal seal can enter the route through* hsame*,* Cont*,* Pkg*, or* NameCert*.*

Proof. Begin with terminal stability, Definition 1205.5. It says that accepted componentwise transport preserves the displayed route μ, n, k, i, w, r, d, e and does not manufacture hidden selectors or off-packet terminal seals.

Use the nonchoice and completion boundaries, Definition 1205.11 and Definition 1205.14. These boundaries remove quotient stream equality, host limits, countable choice, and ambient completeness from the packet surface.

Finally read the support rows. The classifier permits only the componentwise hsame comparisons and Cont routes recorded by H and C, while P and N source and name the same finite packet. Therefore accepted transport and replay remain inside the recorded support scope. □

Theorem 1205.9 (Diagonal-limit representative scoped-closure package)**.** *The* DiagonalLimitRepresentative$^{\uparrow}$ *scoped-closure surface is the package consisting of the obligation-closure package of Definition 1205.6, the primitive-scope exhaustion theorem of Definition 1205.7, and the support-scope nonescape theorem of Definition 1205.8. This package binds the diagonal representative route to the displayed BEDC primitives without claiming Real completeness, quotient-stream equality, host limits, selected completed limits, countable choice, or machine verification.*

Proof. The obligation-closure package supplies the accepted carrier, classifier, NameCert obligations, route predicate obligation, and terminal stability obligation. These theorems identify the diagonal representative route and the terminal Real seal boundary.

The primitive-scope exhaustion theorem identifies the primitive rows available to the route: BHist, hsame, Cont, Pkg, NameCert, the four representative sibling surfaces, and the finite-prefix budget surface. The support-scope nonescape theorem confines every accepted transport and replay step to H, C, P, N.

Combining these two scope results with the obligation package gives a closed scoped surface for the paper chapter. The exclusions are precisely the absent coordinates named by the carrier, nonchoice boundary, completion boundary, and finite-prefix handoff, so the package records scoped closure without adding analytic completion data. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$.

Constructive story: The diagonal-limit representative is generated from $BHist$ rows that record diagonal indices, finite prefixes, window ledgers, stream-name to regular-rational handoffs, and the shared terminal route. The construction follows the familiar diagonal-limit idea, but every representative is read through the carrier rather than selected from an ambient completion. The $hsame$ relation transports index and terminal rows across equivalent histories, while Cont carries the finite-prefix and Real-seal handoffs forward. The chapter's boundary, uniqueness, selector-exclusion, completion-frontier, shared-terminal, and handoff theorems keep the representative bottom-up: a terminal diagonal representative exists only as the visible route assembled from the named finite ledgers.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$, maturePackageClosed)

Scope closed: This chapter binds the diagonal-limit representative carrier, classifier, NameCert obligations, the route predicate obligation of Definition 1205.4, the terminal stability obligation of Definition 1205.5, the closure package of Definition 1205.6, primitive-scope exhaustion of Definition 1205.7, support-scope nonescape of Definition 1205.8, scoped-closure packaging of Definition 1205.9, Real-seal and completion boundaries, uniqueness, selector-exclusion, shared-terminal route, and finite-prefix budget handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.DiagonallimitrepresentativeUp.DiagonalLimitRepresentativeNameCertObligations`

Bridge status: none

Origin: human

Not claimed: It does not claim a selected completion point, quotient-stream equality, global limit uniqueness, or choice beyond the displayed diagonal route.

Upgrade path: A higher closure grade requires Lean verification and a public bridge for the scoped package.

Theorem 1205.10 (Diagonal-limit representative Real-seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer read of an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier factors through the ordered finite route*

$$\mu, n, k, i, w, r, d, e, H, C, P, N.$$

The consumer reaches the seal row e *only after the modulus-selected family index, the selected* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger have been exposed on the same packet.*

Proof. Begin with the NameCert obligations. They force every accepted carrier to compute k and i before any readback row is visible.

Next read the sibling surfaces in order. The $\mathsf{StreamName}^{\uparrow}$ window w exposes the finite observation window, the $\mathsf{RegSeqRat}^{\uparrow}$ row r supplies the selected regular-rational readback, and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger d records the tolerance and arithmetic data attached to that readback.

The $\mathsf{Real}^{\uparrow}$ seal row e is downstream of these rows and is preserved only through the displayed H, C, P, N support. Therefore a consumer cannot reach e through a host real, quotient stream equality, detached tail selector, countable choice row, or ambient completeness field. □

Theorem 1205.11 (Diagonal-limit representative nonchoice boundary)**.** *An accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *packet exports exactly the displayed family row* X*, modulus row* μ*, request row* n*, selected indices* k, i*, selected* $\mathsf{StreamName}^{\uparrow}$ *window* w*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* r*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d*,* $\mathsf{Real}^{\uparrow}$ *seal row* e*, componentwise transport* H*, continuation replay* C*, package provenance* P*, and local naming row* N*. It exports no host real, quotient stream equality, hidden tail selector, countable choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the carrier coordinates of Definition 1205.1. Every coordinate is either a displayed BEDC row, a computed finite index, or structural support for transport, replay, provenance, and naming.

Definition 1205.3 accounts for the admissible carrier and classifier rows. Definition 1205.10 accounts for every Real-facing consumer read of the packet.

The excluded objects require additional coordinates absent from the carrier. Hence they cannot be exported by the local naming certificate or recovered by a consumer of the displayed diagonal-limit representative route. □

Theorem 1205.12 (Diagonal-limit representative index stability)**.** *Let* $D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N)$ *and* $D' = (X', \mu', n', k', i', w', r', d', e', H', C', P', N')$ *be accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carriers classified together by the componentwise* hsame *rows recorded in their transport data. Then the displayed index equations are preserved:*

$$k = \mu(1/(n+1)), \qquad i = k + n + 1,$$

and

$$k' = \mu'(1/(n'+1)), \qquad i' = k' + n' + 1.$$

Consequently the selected family index and selected readback index remain the same diagonal route under accepted componentwise transport, and no classifier read may replace them by a hidden selector.

Proof. Project both carriers through Definition 1205.1. The rows k, i and k', i' are not auxiliary choices; they are the displayed computations tied to μ, n and μ', n' inside the packet.

Use the classifier of Definition 1205.2. Classification requires the modulus rows, selected family indices, readback indices, windows, readbacks, ledgers, seals, transports, continuations, provenance, and local naming rows to be related componentwise by the recorded hsame comparisons and Cont routes.

Finally apply the NameCert obligations of Definition 1205.3. Since the local certificate includes the two index computations themselves, transport of the packet preserves those displayed computations rather than producing a new tail selector. The accepted diagonal route is therefore stable under the componentwise classifier. □

Theorem 1205.13 (Diagonal-limit representative window-ledger exhaustion)**.** *Every public read of the window, readback, ledger, and seal coordinates of an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N)$$

factors through the displayed sibling rows w, r, d, e*. The row* w *is read through* $\mathsf{StreamName}^{\uparrow}$*,* r *through* $\mathsf{RegSeqRat}^{\uparrow}$*,* d *through* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* e *through* $\mathsf{Real}^{\uparrow}$*, with* H, C, P, N *only transporting, replaying, sourcing, and naming those same rows.*

Proof. Start with the carrier row. The only window, regular-rational readback, dyadic arithmetic ledger, and Real-facing seal coordinates are w, r, d, e.

Read the public route in the order forced by Definition 1205.10. The selected window w exposes the finite $\mathsf{StreamName}^{\uparrow}$ observation, the readback r exposes the $\mathsf{RegSeqRat}^{\uparrow}$ row selected from that window, the ledger d records the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and arithmetic data, and the seal e is the downstream $\mathsf{Real}^{\uparrow}$ row.

It remains to exclude extra public reads. The support rows H, C, P, N preserve, replay, source, and name the displayed carrier; they do not add a second window, a second ledger, or an unrecorded Real seal. Hence every public read of w, r, d, e is exhausted by the four sibling surfaces already displayed in the carrier. □

Theorem 1205.14 (Diagonal-limit representative completion boundary)**.** *An accepted* $\mathsf{DiagonalLimitRepresentative}$ *packet supplies the diagonal representative boundary*

$$X, \mu, n, k, i, w, r, d, e, H, C, P, N$$

and nothing stronger. In particular, it does not supply a host limit, quotient equality of streams, countable choice for a family of representatives, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. The positive content is exactly the carrier and certificate surface. By Definition 1205.3, the packet admits the family, modulus, request, computed indices, selected window, readback, ledger, Real seal, transport, continuation, provenance, and local naming rows.

The consumer-facing route is already exhausted by Definition 1205.13. Any read of the Real-facing coordinate must pass through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and the displayed $\mathsf{Real}^{\uparrow}$ seal row of the same packet.

Finally use the nonchoice boundary of Definition 1205.11. A host limit, quotient stream equality, countable choice principle, or Real-completeness theorem would require coordinates not present in the carrier. The packet therefore supplies only the diagonal representative boundary. □

Theorem 1205.15 (Diagonal-limit representative tail-selector exclusion)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the displayed tuple excludes host limits, quotient stream equality, hidden tail selectors, and countable choice rows. Any consumer of D *can read only the carrier rows, the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *obligations, the real-seal factorization route, the window-ledger exhaustion route, and the completion boundary already displayed by the packet.*

Proof. Start from the carrier of Definition 1205.1. Its coordinates are exactly the regular-Cauchy family row, modulus row, precision request, selected indices, selected $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{Real}^{\uparrow}$ seal, and the support rows H, C, P, N.

Apply the NameCert obligations of Definition 1205.3. They account for every admitted row and for the two displayed index computations, so a hidden selector or countable family choice would require an additional certificate coordinate.

Use Definition 1205.10 and Definition 1205.13. These theorems force every Real-facing read through w, r, d, e and through the same support rows, not through a host limit or quotient equality of streams.

Finally apply Definition 1205.14. The boundary theorem states that the packet supplies exactly the displayed diagonal representative boundary and nothing stronger. Therefore the excluded objects are not exports of the accepted carrier. □

Theorem 1205.16 (Diagonal-limit representative StreamName–RegSeqRat handoff)**.** *Every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *consumer route to the seal row* e *factors first through the selected* $\mathsf{StreamName}^{\uparrow}$ *window* w*, then through the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* r*, and only then through the downstream* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d *before reaching the* $\mathsf{Real}^{\uparrow}$ *seal row. No route may pass directly from the modulus row* μ *or request row* n *to* $\mathsf{Real}^{\uparrow}$ *without the* w, r *handoff.*

Proof. Project the accepted carrier. The tuple records $k = \mu(1/(n+1))$ and $i = k + n + 1$ before it records the selected window w and selected readback r.

Use Definition 1205.3. The local certificate admits the finite-window exposure through w and the regular-rational readback through r as separate obligations, so the packet cannot collapse them into a direct $\mathsf{Real}^{\uparrow}$ read.

Next apply Definition 1205.10. It orders every Real-facing consumer read through $\mu, n, k, i, w, r, d, e, H, C, P, N$, placing $\mathsf{StreamName}^{\uparrow}$ before $\mathsf{RegSeqRat}^{\uparrow}$ and both before the seal.

The exhaustion theorem Definition 1205.13 supplies the final constraint. Public reads of the window, readback, ledger, and seal coordinates are exhausted by w, r, d, e with H, C, P, N only transporting, replaying, sourcing, and naming those rows. Thus the route factors through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ before it reaches $\mathsf{Real}^{\uparrow}$. □

Theorem 1205.17 (Diagonal-limit representative dyadic-real seal nonescape)**.** *In an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d *and* $\mathsf{Real}^{\uparrow}$ *seal* e *are consumed only through the displayed rows*

$$d, e, H, C, P, N.$$

The carrier exposes no second dyadic ledger, no off-packet real seal, no ambient completeness field, and no route from d *or* e *that bypasses the displayed transport, continuation, provenance, and local naming rows.*

Proof. Read the dyadic and real coordinates from Definition 1205.1. The only dyadic arithmetic row is d, and the only Real-facing seal row is e.

Apply the NameCert obligations. They identify dyadic ledger exposure through d, terminal seal exposure through e, componentwise transport through H, continuation replay through C, package provenance through P, and local naming through N as the complete local surface.

Use Definition 1205.10 to place d before e in every Real-facing route. Then use Definition 1205.13 to see that all public reads of d and e are exhausted by the displayed sibling rows and their support.

Finally invoke Definition 1205.14. Since the packet supplies no ambient Real-completeness principle or off-packet seal, consumption of the dyadic ledger and Real seal remains confined to d, e, H, C, P, N. □

Theorem 1205.18 (Diagonal-limit representative terminal uniqueness)**.** *Let*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N)$$

and

$$D' = (X', \mu', n', k', i', w', r', d', e', H', C', P', N')$$

be accepted $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carriers. Suppose the displayed modulus, request, selected index, window, readback, dyadic ledger, seal, transport, continuation, provenance, and local naming rows of* D *and* D' *are classified together by the componentwise* hsame *comparisons and* Cont *routes recorded in their packets. Then the two terminal* $\mathsf{Real}^{\uparrow}$ *seal rows* e *and* e' *are classified together by the same representative route, and the accepted classifier exports no second diagonal representative, second terminal seal, hidden tail selector, host limit, quotient stream equality, countable-choice row, or ambient completeness witness.*

Proof. Start with the local NameCert obligations. Definition 1205.3 says that every accepted representative packet exposes the modulus request, the two computed indices, the window, readback, dyadic ledger, terminal seal, and the support rows H, C, P, N as the whole local certificate surface.

Next use index stability, Definition 1205.12. The displayed equations $k = \mu(1/(n+1))$ and $i = k+n+1$ are preserved by the accepted classifier, so the two packets cannot diverge by replacing the selected family index or selected readback index with another selector.

Now apply real-seal factorization and dyadic-real seal nonescape. By Definition 1205.10, every Real-facing read reaches the seal only after μ, n, k, i, w, r, d have been exposed on the same packet. By Definition 1205.17, the dyadic and Real coordinates are consumed only through d, e, H, C, P, N and their primed counterparts.

The hypotheses identify exactly those rows on both packets. Therefore the two terminal seal rows are the same accepted representative terminal for the classifier. The nonchoice boundary and completion boundary, Definition 1205.11 and Definition 1205.14, exclude a second representative or any off-packet analytic object. □

Theorem 1205.19 (Diagonal-limit representative carrier handoff)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the finite consumer surface exposes the four sibling rows in the ordered handoff

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The row w is the only $\mathsf{StreamName}^{\uparrow}$ *window, r is the only* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, d is the only* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and e is the only terminal* $\mathsf{Real}^{\uparrow}$ *seal available to the accepted representative packet.*

Proof. Project the carrier of Definition 1205.1. Its displayed rows contain exactly one window coordinate w, one readback coordinate r, one dyadic ledger coordinate d, and one Real-facing seal coordinate e.

Apply Definition 1205.3. The local certificate assigns those four coordinates to the sibling surfaces in the stated order and accounts for all support through H, C, P, N.

Next use Definition 1205.10. Every consumer read that reaches e must pass through μ, n, k, i, w, r, d first, so the terminal Real row cannot be consumed before the StreamName, RegSeqRat, and DyadicRatCore rows have been read.

Finally apply Definition 1205.13. The public reads of w, r, d, e are exhausted by the displayed packet, while the support rows only transport, replay, source, and name those rows. Hence the ordered handoff is the complete finite route exposed by D. □

Theorem 1205.20 (Diagonal-limit representative terminal-seal choice-free totality)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the terminal seal row e is determined by the finite packet. More precisely, a Real-facing or Completion-facing consumer reaches e only after reading the family row X, modulus row μ, request n, computed indices k, i, window row w, readback row r, dyadic ledger d, and support rows H, C, P, N. No host limit, quotient stream, hidden tail selector, selected diagonal family, or countable-choice coordinate can supply an alternate terminal seal.

Proof. Project the accepted packet. The carrier handoff theorem fixes the ordered sibling route through w, r, d, e, while the selector exactness theorem fixes k and i as the displayed computations from μ and n.

Next read the seal boundary. The Real-seal route theorem confines every endpoint read to the finite path through w, r, d, H, C, P, N, and terminal uniqueness rules out a second seal row once the displayed packet rows are classified together.

Finally apply the nonchoice and completion boundaries. These boundaries exclude hidden selectors, host limits, quotient streams, and countable-choice rows, so the terminal seal is total for the accepted finite packet and cannot be replaced by an ambient analytic object. □

Theorem 1205.21 (Diagonal-limit representative cofinal-window route exactness)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

each cofinal refinement that preserves the accepted representative classifier has exactly the route

$$\mu, n, k, i, w, r, d, e, H, C, P, N.$$

The refined route is a finite $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *route over the same packet, not a detached window ledger, quotient stream comparison, host-limit comparison, hidden tail selector, or countable-choice selection.*

Proof. Start with cofinal-window compatibility. It states that a displayed cofinal refinement preserving μ, k, i and the finite window still follows the ordered sibling route through w, r, d, e.

Use request-monotone seal routing to place μ, n, k, i before the window and readback rows. The modulus-window-readback package then shows that every route to the terminal seal has already consumed μ, n, k, i, w, r, d.

The support rows do not add another endpoint. They transport, replay, source, and name the same finite route, and dyadic-real seal nonescape confines the dyadic and Real rows to d, e, H, C, P, N.

Thus the cofinal-window route is exact. The completion boundary and tail-selector exclusion remove detached windows, quotient comparisons, host limits, hidden selectors, and choice rows from the accepted route. □

Theorem 1205.22 (Diagonal-limit representative cofinal-refinement functoriality)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

two displayed cofinal request refinements that preserve the accepted representative classifier compose to the same ordered route

$$\mu, n, k, i, w, r, d, e, H, C, P, N.$$

The composed refinement is still a finite $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ *route through* D*. It exports no second selector, no second window, no quotient-stream comparison, no host limit, no choice row, and no* $\mathsf{Real}^{\uparrow}$*-completeness coordinate.*

Proof. Apply cofinal-window route exactness to the first displayed refinement. Its classifier-preserving route is exactly $\mu, n, k, i, w, r, d, e, H, C, P, N$, with the StreamName, RegSeqRat, DyadicRatCore, and Real rows read inside the accepted packet.

Apply the same exactness theorem to the second displayed refinement after it is viewed over the already refined request. Since both refinements preserve the representative classifier, request-monotone seal routing keeps μ, n, k, i before w, r, d, e at both stages.

Now compose the two reads. The modulus-window-readback package identifies the same window, readback, dyadic ledger, and Real seal rows, so the second stage has no fresh endpoint to append beyond w, r, d, e, H, C, P, N.

Finally use dyadic-real seal nonescape and the completion boundary. They confine the dyadic and Real rows to the displayed seal route and exclude quotient-stream, host-limit, choice, and ambient-completeness coordinates. Hence successive classifier-preserving cofinal refinements collapse to the same finite L10 route through D. □

Theorem 1205.23 (Diagonal-limit representative Real-seal consumer determinacy)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

any $\mathsf{Real}^{\uparrow}$ *consumer of the representative endpoint is determined by the finite packet route*

$$X, \mu, n, k, i, w, r, d, e, H, C, P, N.$$

Two accepted consumer reads with the same displayed rows and the same recorded hsame *and* Cont *support receive the same terminal seal row* e *and the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *predecessors. The consumer receives no host limit, quotient stream, hidden tail selector, detached window, or countable-choice row.*

Proof. First identify the consumer surface. The dependency-ready package binds the StreamName, RegSeqRat, DyadicRatCore, and Real rows into one local $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ surface, and the carrier handoff orders those rows as w, r, d, e.

Next attach the representative route. Selector exactness fixes k and i, request-monotone seal routing fixes the read order before w, r, d, e, and terminal-seal choice-free totality fixes the endpoint row e from the same finite packet.

Now compare two accepted reads. If their displayed rows and support routes agree, terminal uniqueness identifies the seal rows, while window-ledger exhaustion identifies the w, r, d predecessors on the same public packet.

The remaining exclusions follow from nonchoice boundary, tail-selector exclusion, and completion boundary. Since none of the excluded objects is a coordinate of D, the Real-seal consumer is determined by the finite route alone. □

Theorem 1205.24 (Diagonal-limit representative selector exactness)**.** *For every accepted* DiagonalLimitRepresentat *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the selector coordinates available to the classifier are exactly

$$k = \mu(1/(n+1)) \quad \textit{and} \quad i = k + n + 1.$$

No hidden tail selector, off-packet family index, countable-choice row, or quotient-stream selector can replace k *or* i *in the accepted classifier.*

Proof. Start from index stability, Definition 1205.12. The displayed equations defining k and i are preserved by accepted classifier transport, so a classified packet cannot change the family index route or the readback index route.

Apply terminal uniqueness, Definition 1205.18. Once the displayed modulus, request, index, window, readback, dyadic, seal, and support rows are classified together, the terminal Real seal is already fixed by the same representative route.

It remains to exclude replacement selectors. The nonchoice boundary and the tail-selector exclusion theorem, Definition 1205.11 and Definition 1205.15, give no packet coordinate for a hidden tail selector, countable choice row, or quotient-stream selector. Therefore the only classifier selector coordinates are k and i. □

Theorem 1205.25 (Diagonal-limit representative Real-seal route)**.** *Every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *consumer that reaches the terminal row e first reads the sibling rows w, r, d and the support rows H, C, P, N. The terminal* $\mathsf{Real}^{\uparrow}$ *seal is a packet row reached by this finite route, not a* $\mathsf{Real}^{\uparrow}$ *completeness principle, host limit, quotient of streams, or ambient analytic object.*

Proof. Begin with dyadic-real seal nonescape, Definition 1205.17. It confines consumption of the dyadic ledger and terminal seal to d, e, H, C, P, N.

Use the carrier handoff theorem just proved. Before a consumer can read d or e, it must pass through the selected $\mathsf{StreamName}^{\uparrow}$ window w and the selected $\mathsf{RegSeqRat}^{\uparrow}$ readback r on the same packet.

Next apply Definition 1205.14. The boundary identifies the Real-facing row as the displayed terminal seal of the representative packet and withholds any ambient completeness witness.

Finally invoke terminal uniqueness. Since every accepted route to e has already consumed w, r, d, H, C, P, N, and no second terminal seal is exported, the Real-facing endpoint is a finite packet row rather than a Real-completeness principle. □

Theorem 1205.26 (Diagonal-limit representative cofinal-window compatibility)**.** *Let $D = (X, \mu, n, k, i, w, r, d, e, H$ be an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, and let a displayed cofinal refinement of the request preserve the same modulus row μ, the same selected diagonal index route k, i, and a refined finite* $\mathsf{StreamName}^{\uparrow}$ *window that reads the same* $\mathsf{RegSeqRat}^{\uparrow}$ *row r,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger d, and* $\mathsf{Real}^{\uparrow}$ *seal row e through the recorded support rows. Then the refined consumer follows the same ordered route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

inside D. It introduces no hidden selector, no second window ledger, no quotient-stream comparison, no host limit, and no ambient completeness coordinate.

Proof. Project the carrier. The request, selected indices, finite window, regular-rational readback, dyadic ledger, Real seal, and support rows are already part of the accepted tuple of Definition 1205.1.

Use the StreamName–RegSeqRat handoff, Definition 1205.16. Any route to the seal must first expose the selected $\mathsf{StreamName}^{\uparrow}$ window and then the selected $\mathsf{RegSeqRat}^{\uparrow}$ readback before it may consume the downstream dyadic ledger and Real seal.

Next apply window-ledger exhaustion, Definition 1205.13. The public reads of w, r, d, e are exhausted by those four sibling surfaces, with H, C, P, N only transporting, replaying, sourcing, and naming the same rows.

The cofinal refinement preserves the displayed request route and the same r, d, e rows, so it has no separate coordinate from which to read a hidden selector or a second window ledger. The completion boundary then removes quotient-stream, host-limit, and ambient-completeness routes. The refined consumer therefore remains on the ordered $\mathsf{StreamName}^{\uparrow}$ to $\mathsf{RegSeqRat}^{\uparrow}$ to $\mathsf{DyadicRatCore}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$ route of D. □

Theorem 1205.27 (Diagonal-limit representative request-monotone seal route)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

any consumer that refines the request while preserving the accepted representative classifier must read the rows μ, n, k, i before it reads w, r, d, e. The only support rows available after this ordered read are H, C, P, N, and every $\mathsf{Real}^{\uparrow}$ *seal consumption remains confined to the displayed route*

$$\mu, n, k, i, w, r, d, e, H, C, P, N.$$

Proof. First read the index equations from the packet. By Definition 1205.12, the equations $k = \mu(1/(n+1))$ and $i = k + n + 1$ are part of the accepted classifier surface and cannot be replaced by a request-dependent hidden selector.

Next apply real-seal factorization, Definition 1205.10. It orders every Real-facing consumer read through $\mu, n, k, i, w, r, d, e, H, C, P, N$, placing the modulus request and computed indices before the window, readback, ledger, and seal.

Finally apply dyadic-real seal nonescape, Definition 1205.17. The dyadic ledger and Real seal are consumed only through d, e, H, C, P, N, and there is no second dyadic ledger, off-packet seal, ambient completeness field, or bypass around the displayed support.

Thus a request-refinement consumer that preserves the classifier remains monotone in the displayed request route: it reads μ, n, k, i first, then w, r, d, e, and it has only H, C, P, N as support. □

Theorem 1205.28 (Diagonal-limit representative dependency-ready package)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the displayed packet is a single dependency-ready boundary for the diagonal representative route. It consumes the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows in the order*

$$\mu, n, k, i, w, r, d, e, H, C, P, N,$$

and it packages them as one Pkg*-sourced* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *surface. Every downstream consumer that asks for the diagonal representative endpoint must pass through this packet rather than through a detached stream name, detached regular sequence, detached dyadic ledger, or detached real seal.*

Proof. Begin with the carrier obligations of Definition 1205.3. They place the family row, modulus row, request, computed indices, selected window, readback, dyadic ledger, terminal seal, transport, continuation, package, and local naming row in one finite certificate.

Next apply the StreamName–RegSeqRat handoff of Definition 1205.16. It forces every route to the terminal seal through w and r before the dyadic ledger and the Real-facing row can be consumed.

Use request-monotone seal routing, Definition 1205.27, to place the modulus request and computed indices before the sibling rows. Then use dyadic-real seal nonescape, Definition 1205.17, to confine the dyadic and Real endpoints to d, e, H, C, P, N.

These dependencies exhaust the same carrier. Hence D is not a collection of independent endpoint names; it is one dependency-ready package tying the diagonal representative route to the four consumed rows and to the local $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ boundary. □

Theorem 1205.29 (Diagonal-limit representative modulus-window-readback package)**.** *In an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

every consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal row* e *only through the finite modulus-window-readback route*

$$\mu, n, k, i, w, r, d.$$

The rows H, C, P, N *may transport, replay, source, and name this route, but they do not supply an alternate route to* e*.*

Proof. First read the modulus route from Definition 1205.12. The selected family index and readback index are the displayed computations attached to μ and n; a consumer cannot replace them by another selector while preserving the accepted classifier.

Next pass to the window and readback rows. By Definition 1205.16, the route to e must expose the selected $\mathsf{StreamName}^{\uparrow}$ window w and then the selected $\mathsf{RegSeqRat}^{\uparrow}$ readback r before any Real-facing seal is available.

Now consume the dyadic ledger. The window-ledger exhaustion theorem, Definition 1205.13, says that public reads of w, r, d, e are exhausted by those displayed sibling rows, with H, C, P, N only preserving the same surface.

Finally use real-seal factorization, Definition 1205.10. It orders every Real-facing read through $\mu, n, k, i, w, r, d, e, H, C, P, N$. Therefore the only path to e has already passed through μ, n, k, i, w, r, d, and the support rows cannot create an alternate endpoint. □

Theorem 1205.30 (Diagonal-limit representative Real–Completion frontier boundary)**.** *The package*

$$(X, \mu, n, k, i, w, r, d, e, H, C, P, N)$$

supports the Real-and-Completion frontier as a named diagonal representative endpoint: it reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal row through the dependency-ready route of Definition 1205.28 and the modulus-window-readback route of Definition 1205.29. It does not claim Real completeness, quotient stream equality, host limits, selected limits, hidden tail selectors, or countable choice.*

Proof. The positive frontier content is the accepted representative package. By Definition 1205.28, the packet binds the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows into a single Pkg-sourced $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ boundary.

The endpoint route is finite. By Definition 1205.29, every consumer reaches the terminal seal e only through μ, n, k, i, w, r, d, with H, C, P, N serving as support for the same displayed route.

It remains to state the frontier. The completion boundary of Definition 1205.14 says that the carrier supplies the diagonal representative boundary and nothing stronger. The tail-selector exclusion of Definition 1205.15 rules out hidden selectors, host limits, quotient stream equality, and countable-choice rows.

Therefore the package is ready for Real-and-Completion consumers that need the named diagonal representative endpoint, while the analytic completion principles and choice-sensitive comparisons remain outside this certificate. □

Theorem 1205.31 (Diagonal-limit compatibility representative handoff)**.** *Let* $K = (R, T, S, D, W, Q, L, H_K, C_K, P$ *be an accepted* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *packet whose terminal read has the same four L10 faces as an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$E = (X, \mu, n, k, i, w, r, d, e, H_E, C_E, P_E, N_E),$$

namely the same displayed $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and* $\mathsf{Real}^{\uparrow}$ *seal rows under the recorded support. Then the terminal read of* K *factors through*

the representative carrier E before reaching the terminal Real seal. It inherits the representative nonescape boundary: no quotient stream, host real equality, selected limit, hidden tail selector, choice datum, ambient completeness row, or second terminal seal can enter the handoff.

Proof. First read the compatibility packet through open-phase synchronization. Definition 646.174 places the terminal read of K on the four finite exit faces $\mathsf{StreamName}^{\uparrow}(W)$, $\mathsf{DyadicRatCore}^{\uparrow}(T)$, $\mathsf{RegSeqRat}^{\uparrow}(Q)$, and $\mathsf{Real}^{\uparrow}(L)$, carried by the displayed support rows.

Next use open-phase four-face readiness, Definition 646.179. It says that readiness of the terminal compatibility read is exactly the displayed four-face surface over its support rows, with no quotient stream, host real equality, selected limit, choice datum, completeness datum, or bridge row.

Now compare those faces with the representative carrier. The hypothesis identifies the compatibility window, readback, ledger, and Real seal with the representative rows w, r, d, e. By Definition 1205.13, every public read of those four representative coordinates is already exhausted by the same sibling surfaces and the support rows H_E, C_E, P_E, N_E.

Finally apply the representative dyadic-real seal nonescape theorem, Definition 1205.17. Since the shared dyadic ledger and Real seal are consumed only through the displayed representative support, the compatibility terminal read factors through E before it reaches the seal. The excluded host, quotient, selector, choice, completeness, and second-seal routes are absent from both the compatibility readiness surface and the representative carrier boundary. □

Definition 1205.32 (Diagonal-limit representative shared-terminal carrier)**.** *A shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier is a finite* BHist *packet extending*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N)$$

from Definition 1205.1 by finite-prefix budget rows

$$F = (Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F)$$

from chapter 919. The extended packet records the following additional rows:

1. *Q is the finite diagonal request whose precision and prefix depth cover the selected representative read n, k, i;*
2. *B is the finite observation-budget selector row admitting Q before the selected* $\mathsf{StreamName}^{\uparrow}$ *window is served;*
3. *W is the finite prefix-window ledger containing the representative window w and the prefix windows required for the same terminal read;*
4. *D_F is the prefix-depth exhaustion row accounting for every served offset in W and refusing outside-prefix reads before the regular readback or seal is consumed;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row compatible with the representative readback r;*
6. *S is the completion-facing or* $\mathsf{Real}^{\uparrow}$ *seal row compatible with the representative terminal seal e;*
7. *E_F, H_F, C_F, P_F, N_F record the finite-prefix exclusion, transport, continuation, provenance, and local naming rows used by the same terminal consumer.*

The shared-terminal carrier exports the representative row and the finite-prefix budget row as one ordered surface. It exports no quotient stream, host real equality, selected limit, hidden tail schedule, countable choice row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Theorem 1205.33 (Diagonal-limit representative shared-terminal route)**.** *Every terminal seal read of an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier factors through the ordered public surface*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{FinitePrefixLimitBudget}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The representative rows w, r, d, e *and the finite-prefix rows* Q, B, W, D_F, R, S *are consumed as one terminal route; no consumer may reach the* $\mathsf{Real}^{\uparrow}$ *seal before the finite-prefix budget has displayed its selector, prefix window, exhaustion row, and regular readback.*

Proof. Start with the representative carrier. By Definition 1205.16, every route to the representative seal exposes the selected $\mathsf{StreamName}^{\uparrow}$ window w before the selected $\mathsf{RegSeqRat}^{\uparrow}$ readback r, and then consumes the downstream $\mathsf{DyadicRatCore}^{\uparrow}$ ledger d before the $\mathsf{Real}^{\uparrow}$ seal row e.

Attach the finite-prefix budget packet. The seal-ordering theorem Definition 919.3 forces every budget-facing seal read through

$$Q \to B \to W \to D_F \to R \to S.$$

Thus the shared terminal route cannot read the seal before the selector, prefix-window ledger, depth-exhaustion row, and regular readback row have all been displayed.

Now compare the two terminal surfaces. The shared-terminal carrier identifies the representative window, readback, and seal with the budget window, readback, and seal rows, while the representative dyadic ledger remains the arithmetic ledger between readback and seal. The consumer-boundary theorem Definition 919.10 and the representative window-ledger exhaustion theorem Definition 1205.13 both confine public reads to the displayed rows.

Therefore a terminal consumer factors through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in that finite order. There is no bypass from the representative modulus, from the prefix selector, or from the dyadic ledger directly to a completed Real object. □

Theorem 1205.34 (Diagonal-limit representative finite-prefix budget handoff)**.** *The shared-terminal handoff from Definition 1205.32 preserves the representative nonchoice boundary and the finite-prefix consumer boundary. It supplies a concrete terminal interface for the Real-completion route, but it does not supply quotient-stream equality, host real equality, selected completed limits, hidden tail schedules, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First read the representative side. The nonchoice boundary Definition 1205.11 and completion boundary Definition 1205.14 say that the representative packet exports only $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ and no host limit, quotient stream, hidden selector, countable choice row, or ambient completeness principle.

Next read the finite-prefix side. By Definition 919.15, a $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or completion-facing consumer receives exactly the prefix-budget route $Q \to B \to W \to D_F \to R \to S$ together with E_F, H_F, C_F, P_F, N_F. By Definition 919.12, quotient streams, selected limits, host real equality, hidden tail schedules, countable choice, and ambient completeness cannot replace that route.

Finally use the shared-terminal route theorem above. It composes the representative route with the finite-prefix budget route without adding a new coordinate: the terminal read is still a finite BEDC packet read through StreamName, RegSeqRat, DyadicRatCore, FinitePrefixLimitBudget, and Real rows. Hence the handoff gives the Real-completion route a concrete L10 terminal surface while preserving the nonchoice and no-completeness boundaries on both sides. □

Theorem 1205.35 (Diagonal-limit representative public exactness package)**.** *For an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, the public exactness package is precisely the ordered surface*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{FinitePrefixLimitBudget}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

over the representative rows

$$X, \mu, n, k, i, w, r, d, e, H, C, P, N$$

and the shared-terminal finite-prefix rows

$$Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F.$$

The package has no additional public row beyond these displayed carrier, route, support, budget, exclusion, continuation, provenance, and naming rows.

Proof. First take the terminal route from Definition 1205.33. It orders every terminal consumer through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so the type-level surface is already fixed.

Next read the finite-prefix handoff in Definition 1205.34. It says that the representative rows $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ and the budget rows $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$ are consumed as one terminal interface, with the nonchoice and no-completeness boundaries preserved on both sides.

The dependency-ready package Definition 1205.28 supplies the Pkg-sourced $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ boundary for the representative half of the route. The Real–Completion frontier boundary Definition 1205.30 then identifies the terminal endpoint as the named diagonal representative frontier and excludes stronger analytic structure.

Therefore the public exactness package is exactly the displayed ordered surface over the displayed rows. Any extra public row would either precede one of the ordered dependencies, duplicate the finite-prefix budget route, or add a Real-completion principle explicitly excluded by the frontier boundary. □

Theorem 1205.36 (Diagonal-limit representative completion consumer factorization)**.** *Every Real-and-Completion consumer of an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier factors through the public exactness package of Definition 1205.35. Such a consumer cannot bypass that package by quotient stream equality, host real equality, selected completed limits, hidden tail schedules, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the exactness package just established. It presents the only public route from the selected stream window and regular readback to the dyadic ledger, finite-prefix budget, and terminal Real seal.

The shared-terminal route theorem Definition 1205.33 supplies the factorization order. The finite-prefix budget handoff Definition 1205.34 supplies the consumer boundary for completion-facing reads, including the refusal of quotient streams, selected limits, host equality, hidden schedules, choice data, and ambient completeness.

It remains to connect this route to the representative frontier. The dependency-ready package Definition 1205.28 binds the displayed rows into the accepted representative certificate, while Definition 1205.30 states that the frontier is a named diagonal representative endpoint and not a completed Real object supplied by the host.

Hence every Real-and-Completion consumer reaches the endpoint through the public package. A bypass would have to supply one of the excluded equality, limit, schedule, choice, or completeness

rows, and those rows are absent from both the representative frontier and the finite-prefix handoff. □

Theorem 1205.37 (Diagonal-limit representative readback-index scope)**.** *Every completion-facing consumer of an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier must expose the displayed readback-index route*

$$k = \mu(1/(n+1)), \qquad i = k + n + 1$$

before the support rows of the carrier can be consumed. More precisely, the consumer must first display the selected $\mathsf{StreamName}^{\uparrow}$ *window* w*, the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* r*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* e *in the order prescribed by the public exactness package; the support rows* H, C, P, N *may only transport, replay, source, and name that already displayed route.*

Proof. Begin with selector exactness, Definition 1205.24. It fixes k and i as the displayed computations from μ and n, so a completion-facing consumer cannot substitute an off-packet family index or readback index.

Next use the modulus-window-readback package, Definition 1205.29. It places every route to the terminal seal through μ, n, k, i, w, r, d, with H, C, P, N confined to transport, replay, provenance, and local naming.

Finally apply the completion consumer factorization of Definition 1205.36. Since every Real-and-Completion consumer factors through the public exactness package, the support rows can be consumed only after the readback-index scope has exposed the selected window, readback, ledger, and seal rows. □

Theorem 1205.38 (Diagonal-limit representative shared-terminal stability)**.** *Let two accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carriers be classified together by their componentwise* hsame *rows and displayed* Cont *replay. Then the shared-terminal carrier preserves the same ordered route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{FinitePrefixLimitBudget}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

through the representative rows $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ *and the finite-prefix budget rows* $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$*. The transport does not create a second terminal route, a detached budget row, a host Real equality, or an ambient completeness witness.*

Proof. First read the shared-terminal route, Definition 1205.33. It orders terminal consumption through the StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, and Real rows as one public surface.

Next use the finite-prefix budget handoff, Definition 1205.34. The handoff identifies the representative and budget coordinates as a single terminal interface while preserving the nonchoice and no-completeness boundaries.

Finally apply the public exactness package of Definition 1205.35. Componentwise hsame and displayed Cont can preserve only the rows that package already exposes, so the shared terminal remains stable under the same ordered route and cannot acquire any detached endpoint or host equality row. □

Theorem 1205.39 (Diagonal-limit representative frontier consumer obligation package)**.** *The downstream obligation surface for a Real-and-Completion consumer of an accepted shared-terminal*

$\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier is the package consisting of the public exactness package of Definition 1205.35, the completion consumer factorization of Definition 1205.36, the readback-index scope of Definition 1205.37, and the shared-terminal stability theorem of Definition 1205.38. The package exposes only the finite BEDC route through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*; it excludes quotient-stream equality, host Real equality, selected completed limits, hidden tail schedules, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The positive surface is fixed by public exactness. It lists the representative rows and finite-prefix budget rows and orders them through the five named BEDC components without adding any public row.

The consumer-facing factorization then makes that surface mandatory for every Real-and-Completion read. The readback-index scope refines the entry condition: $k = \mu(1/(n+1))$, $i = k + n + 1$, w, r, d, and e must be visible before the support rows are consumed.

The stability clause closes the package under the accepted classifier. Componentwise hsame and displayed Cont preserve the same shared-terminal route, while the handoff and frontier boundaries remove quotient equality, host equality, selected limits, hidden schedules, choice data, and ambient completeness from the consumer obligation surface. □

Theorem 1205.40 (Diagonal-limit representative finite-request section exactness)**.** *Every accepted request row of a shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier factors through the displayed finite request section*

$$Q, \quad B, \quad k = \mu(1/(n+1)), \quad i = k + n + 1, \quad W, \quad w, \quad r, \quad d, \quad e, \quad S.$$

Thus the request first reads the finite-prefix request and terminal budget, then the representative modulus and selected index, then the $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows. No accepted request row can be routed through a later host real, quotient-stream equality, hidden selector, countable-choice family, or ambient completeness witness.*

Proof. Start from the accepted carrier and classifier. The frontier consumer obligation package Definition 1205.39 says that every completion-facing request is consumed through the public exactness package and the displayed readback-index route.

The shared-terminal route theorem Definition 1205.33 supplies the ordered terminal path through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The finite-prefix budget handoff Definition 1205.34 identifies the request and budget rows Q, B, W, D_F, R, S with the representative window, readback, and seal rows.

Finally, the Real-seal factorization Definition 1205.10 and the nonchoice boundary Definition 1205.11 exclude any replacement by host equality, quotient equality, selected limits, hidden selectors, choice data, or ambient completeness. The only remaining request section is the displayed finite row sequence. □

Theorem 1205.41 (Diagonal-limit representative shared-window readback determinacy)**.** *Let two accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carriers be classified by the same finite request row and the same shared terminal budget. Then the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal route are determined up to the recorded componentwise* hsame *rows of the classifier. In particular, a second carrier with the same request and terminal budget cannot expose a different public window-readback-ledger-seal route.*

Proof. First use the carrier and classifier rows. The common finite request and shared terminal budget place both carriers in the same public exactness package, so the request section exactness theorem above fixes the same finite row sequence for both reads.

Next apply the shared-terminal route Definition 1205.33. Since the terminal route is finite and ordered, the two carriers can compare only the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

The finite-prefix budget handoff Definition 1205.34 and Real-seal factorization Definition 1205.10 identify the budget readback and terminal seal with that same route. The nonchoice boundary Definition 1205.11 removes any unrecorded selector or ambient equality, so determinacy is exactly the recorded componentwise hsame comparison. □

Theorem 1205.42 (Diagonal-limit representative Real-seal nonchoice export)**.** *The Real-facing seal exported by an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier is only the displayed terminal row of the finite route*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{FinitePrefixLimitBudget}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

It cannot be replaced by host real equality, quotient-stream equality, a hidden selector, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness; any standard bridge or downstream Real-completion consumer must export precisely this displayed terminal row.*

Proof. The shared-terminal route Definition 1205.33 gives the positive export: a finite terminal row reached through the displayed StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, and Real components.

The finite-prefix budget handoff Definition 1205.34 and Real-seal factorization Definition 1205.10 show that the Real-facing endpoint is the same terminal seal row already carried by the request and budget interface.

The nonchoice boundary Definition 1205.11 supplies the negative export clause. It rules out host real equality, quotient-stream equality, hidden selectors, countable choice, and ambient completeness, so the exported Real-facing content is exactly the displayed terminal row and nothing stronger. □

Theorem 1205.43 (Diagonal-limit representative bridge precondition package)**.** *Any later standard bridge for the* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *chapter must preserve the same finite packet route*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{FinitePrefixLimitBudget}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

over the rows named in Definition 1205.35. The bridge precondition may transport the package into a standard schema, but it may not replace the route by quotient equality, host Real equality, selected completed limits, hidden tail schedules, countable choice, or ambient completeness, and it may not identify the paper closure axis with Lean bridge checking.

Proof. The route to be preserved is fixed by Definition 1205.33. It is a finite terminal packet route through the StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, and Real rows, with the representative and budget coordinates read as one public surface.

The exact rows to be preserved are fixed by the finite-prefix budget handoff Definition 1205.34 and the dependency-ready package Definition 1205.28. Together they identify the carrier rows, support rows, budget rows, exclusion row, continuation row, provenance row, and naming row that the bridge must transport.

Finally, the Real–Completion frontier boundary Definition 1205.30 gives the negative side of the precondition: no quotient stream equality, host equality, selected completed limit, hidden tail schedule, choice principle, or ambient completeness is part of the chapter certificate. The bridge may check a schema for the same finite route, but that verification status is separate from the paper closure axis recorded by the chapter. □

Theorem 1205.44 (Diagonal-limit representative root-readiness triad)**.** *Every downstream Real-and-Completion consumer of an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier must expose the following root-readiness surface before it consumes any support row: the modulus request* μ, n*, the selected diagonal indices* $k = \mu(1/(n+1))$ *and* $i = k+n+1$*, the selected* $\mathsf{StreamName}^{\uparrow}$ *window* w*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* r*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d*, the* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$ *rows* $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* e*. The support rows* H, C, P, N *may only transport, replay, source, and name that displayed root surface; they may not supply a separate selector, ledger, seal, host equality, quotient equality, choice row, or ambient completion principle.*

Proof. The carrier of Definition 1205.1 fixes the representative route $X, \mu, n, k, i, w, r, d, e, H, C, P, N$, and the shared-terminal carrier of Definition 1205.32 attaches the finite-prefix budget rows to the same terminal read.

The public exactness package Definition 1205.35 orders this route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The completion consumer factorization Definition 1205.36 makes that ordered package mandatory for any Real-and-Completion consumer.

Finally apply the readback-index scope Definition 1205.37 and the Real-seal nonchoice export Definition 1205.42. They force the selected window, readback, dyadic ledger, finite-prefix rows, and Real seal to be displayed before the support rows are used, and they exclude the hidden selector, host, quotient, choice, and ambient-completeness alternatives. □

Lean4 ✓ `BEDC.Derived.DiagonallimitrepresentativeUp.DiagonalLimitRepresentativeRootReadinessTriad`

Theorem 1205.45 (Diagonal-limit representative modulus-window root unblock)**.** *The selected-index and selected-window part of the root-readiness surface is rooted entirely in the displayed rows of the shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *packet. In particular, the computation of* k *and* i*, the window row* w*, the readback row* r*, and their transport through* H *are read from the finite* BHist *packet, the recorded* hsame *comparisons, the displayed* Cont *replay, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *row. No downstream consumer may replace this root by an ambient stream equality, a hidden modulus selector, or an unrecorded completion witness.*

Proof. Start with the NameCert obligations of Definition 1205.3. They list the modulus request, diagonal-index computation, finite-window exposure, regular-rational readback, transport, continuation, package provenance, and local naming rows as the certificate surface.

The modulus-window-readback package Definition 1205.29 then orders every route to the terminal seal through μ, n, k, i, w, r, d, with H, C, P, N preserving the same displayed route. The readback-index scope Definition 1205.37 makes the selected index and selected window visible before those support rows are consumed.

Thus the root for the selected window is not a new analytic principle. It is the already displayed BHist row together with hsame, Cont, Pkg, and $\mathsf{NameCert}$ support, and any unrecorded selector or completion witness lies outside the accepted packet. □

Theorem 1205.46 (Diagonal-limit representative terminal seal root unblock)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier is reached only through the finite route*

$$\mu, n, k, i, w, r, d, Q, B, W, D_F, R, S, e, H, C, P, N, E_F, H_F, C_F, P_F, N_F.$$

The route passes through the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *surfaces. It never reaches the terminal seal by quotient stream equality, host real equality, hidden selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First use the shared-terminal route Definition 1205.33. It forces every terminal read through the StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, and Real rows as one ordered surface.

Next use the finite-prefix budget handoff Definition 1205.34. It joins the representative route to the rows $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$, so the terminal seal cannot be consumed before the budget selector, prefix window, depth-exhaustion row, and regular readback have appeared.

Finally apply Real-seal factorization Definition 1205.10 and Real-seal nonchoice export Definition 1205.42. These identify e as the displayed terminal row of the finite route and remove quotient, host, selector, choice, and ambient-completeness routes from the seal. □

Theorem 1205.47 (Diagonal-limit representative dependency-readiness scope)**.** *The root-readiness package consumed by downstream L10 Real-and-Completion chapters consists of the root-readiness triad of Definition 1205.44, the modulus-window root of Definition 1205.45, and the terminal-seal root of Definition 1205.46. This package is exactly the dependency-ready public route supplied by the carrier, the shared-terminal carrier, the public exactness package, the completion consumer factorization, the readback-index scope, the Real-seal nonchoice export, and the bridge precondition package. It is not a claim of quotient stream equality, host Real equality, hidden selector availability, choice, ambient Real completeness, or Lean bridge checking.*

Proof. The triad theorem names the downstream obligations: the modulus request, selected indices, window, readback, dyadic ledger, finite-prefix budget rows, and Real seal must all be displayed before support rows are consumed.

The modulus-window theorem supplies the entry root through BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. The terminal-seal theorem supplies the exit root through the finite StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, and Real route.

It remains to package the surface for downstream chapters. The dependency-ready package Definition 1205.28, public exactness package Definition 1205.35, completion consumer factorization Definition 1205.36, and bridge precondition package Definition 1205.43 all preserve the same finite route and the same exclusions. Therefore downstream L10 chapters may consume precisely this root-readiness surface and nothing stronger. □

Theorem 1205.48 (Diagonal-limit representative budget-source determinacy)**.** *Let A and A' be accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carriers. Suppose they display the same finite-prefix budget rows $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$ and the same representative selected-index route $\mu, n, k, i, w, r, d, e, H, C, P, N$. Then their terminal* $\mathsf{Real}^{\uparrow}$ *seal source is the same up to the recorded componentwise* hsame *rows and the displayed* Cont *replay carried by that route. In particular, the terminal seal source is determined by the visible budget rows and selected-index route; it cannot be replaced by quotient-stream equality, host Real equality, hidden selectors, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The root-readiness triad of Definition 1205.44 first fixes the visible data that a downstream consumer may inspect: the modulus request, selected indices, window row, readback row, dyadic ledger, finite-prefix budget rows, terminal seal, and support rows.

Apply the terminal-seal root unblock, Definition 1205.46. Since both carriers expose the same rows $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$ and the same route $\mu, n, k, i, w, r, d, e, H, C, P, N$, each terminal $\mathsf{Real}^{\uparrow}$ seal read is forced through the identical finite StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, and Real surface.

Finally use the dependency-readiness scope of Definition 1205.47. It permits later Real-and-Completion consumers to consume only the recorded hsame comparisons and the displayed Cont replay on this route. Thus the two accepted carriers name the same terminal seal source up to those componentwise records, while quotient-stream equality, host Real equality, hidden selectors, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the accepted package. □

Theorem 1205.49 (Diagonal-limit representative root-readiness exactness)**.** *The root-readiness package of an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier is exact for downstream Real-and-Completion consumption. Coverage means that every accepted downstream consumer factors through the displayed L10 route*

$$\mu, n, k, i, w, r, d, Q, B, W, D_F, R, S, e, H, C, P, N, E_F, H_F, C_F, P_F, N_F.$$

Soundness means that each exposed row of this route is sourced by the cited $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *surfaces. Completeness means that no accepted Real-and-Completion consumer route exists outside this finite packet. The exactness statement carries no quotient stream equality, host Real equality, hidden selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Coverage is the content of the root-readiness triad, the modulus-window root unblock, the terminal-seal root unblock, and the dependency-readiness scope. These results force each downstream consumer to expose the modulus request, selected indices, window, readback, dyadic ledger, finite-prefix budget rows, terminal seal, and support rows before it consumes the diagonal representative.

Soundness is inherited from the public exactness package and the bridge precondition package. The public package sources the route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, while the bridge precondition package preserves the same displayed sources when the route is handed to later consumers.

Completeness follows because the dependency-readiness theorem permits downstream L10 chapters to consume precisely this root-readiness surface and nothing stronger. Any proposed route using quotient stream equality, host Real equality, a hidden selector, choice, or ambient Real completeness fails one of the displayed support obligations and therefore is not an accepted consumer route for this packet. □

Theorem 1205.50 (Diagonal-limit representative selected-window determinacy)**.** *For an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, the fixed displayed rows* μ, n, k, i, H, C, P, N *determine the selected* $\mathsf{StreamName}^{\uparrow}$ *window and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback up to the recorded* hsame *rows and the displayed* Cont *replay carried by the packet. The determinacy is internal to the finite root-readiness route: it does not use a hidden modulus selector, quotient stream equality, host stream equality, countable choice, or ambient completion.*

Proof. The root-readiness triad of Definition 1205.44 identifies $\mu, n, k, i, w, r, H, C, P, N$ as displayed rows of the accepted consumer surface. The modulus-window root unblock of Definition 1205.45 then sources the chosen window and readback through the recorded BHist row, hsame comparisons, Cont replay, Pkg provenance, and NameCert row.

The terminal-seal root unblock of Definition 1205.46 keeps the same selected window and readback on the route to the terminal seal, while the dependency-readiness scope of Definition 1205.47 prevents a downstream Real-and-Completion consumer from importing any stronger equality principle.

Finally, the budget-source determinacy theorem Definition 1205.48 and the root-readiness exactness theorem Definition 1205.49 show that all accepted support reads factor through this displayed route. Hence fixed μ, n, k, i, H, C, P, N determine the selected $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback only through the recorded support rows, with no extra selector or quotient route. □

Theorem 1205.51 (Diagonal-limit representative terminal-seal determinacy)**.** *For an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, the visible finite-prefix budget rows* $Q, B, W, D_F, R, S, E_F, H_F$ *together with* w, r, d *determine the terminal* $\mathsf{Real}^{\uparrow}$ *seal source up to the recorded* hsame *support rows and the displayed* Cont *replay. This terminal-seal determinacy excludes host* $\mathsf{Real}^{\uparrow}$ *equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the root-readiness triad Definition 1205.44 and the terminal-seal root unblock Definition 1205.46. Together they place $w, r, d, Q, B, W, D_F, R, S, e, E_F, H_F, C_F, P_F, N_F$ on the same finite route to the terminal $\mathsf{Real}^{\uparrow}$ seal.

The modulus-window root unblock Definition 1205.45 fixes the selected window and readback source used by that route, and the dependency-readiness scope Definition 1205.47 restricts later consumers to the displayed hsame and Cont support rows.

Apply budget-source determinacy, Definition 1205.48, to identify the terminal seal source from the visible budget and selected-index rows. The root-readiness exactness theorem Definition 1205.49 supplies the route-exhaustion clause, so host $\mathsf{Real}^{\uparrow}$ equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not admissible sources for the seal. □

Theorem 1205.52 (Diagonal-limit representative consumer route exhaustion)**.** *Every downstream Real-and-Completion consumer accepted by the root-readiness exactness theorem factors through the ordered route*

$$\mu, n, k, i, w, r, d, Q, B, W, D_F, R, S, e, H, C, P, N, E_F, H_F, C_F, P_F, N_F.$$

No accepted consumer may use any support surface outside this ordered route, including a hidden selector, quotient stream equality, host $\mathsf{Real}^{\uparrow}$ *equality, countable choice, or ambient completion principle.*

Proof. The root-readiness triad Definition 1205.44 lists the rows that a downstream Real-and-Completion consumer must expose. The modulus-window root unblock Definition 1205.45 supplies the selected-window entry, and the terminal-seal root unblock Definition 1205.46 supplies the exit through the finite-prefix budget and terminal $\mathsf{Real}^{\uparrow}$ seal.

The dependency-readiness scope of Definition 1205.47 states that downstream chapters may consume precisely this finite root-readiness surface. The budget-source determinacy theorem Definition 1205.48 fixes the terminal seal source once the visible budget and selected-index rows are fixed.

It remains only to exclude extra routes. The root-readiness exactness theorem Definition 1205.49 gives coverage, soundness, and completeness for the displayed packet, so every accepted consumer factors through the ordered route above and no other support surface is available to the consumer. □

Theorem 1205.53 (Diagonal-limit representative root-index coverage)**.** *For an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, every root-index consumer of the diagonal representative must expose the finite equations*

$$k = \mu(1/(n+1)), \qquad i = k + n + 1$$

before it consumes the visible route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Concretely, the consumer reads the selected window* w*, regular-rational readback* r*, dyadic ledger* d*, finite-prefix rows* $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$*, and terminal seal* e *as one finite index surface; it receives no quotient-stream equality, host Real equality, hidden tail selector, countable-choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier of Definition 1205.1. Its displayed rows already contain the modulus request μ, n, the computed indices k, i, the selected $\mathsf{StreamName}^{\uparrow}$ window w, the $\mathsf{RegSeqRat}^{\uparrow}$ readback r, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger d, and the terminal $\mathsf{Real}^{\uparrow}$ seal e.

Attach the shared-terminal carrier of Definition 1205.32. It places the finite-prefix budget rows $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$ on the same terminal read, so the root-index consumer sees one ordered route rather than a detached budget.

Finally use the root-readiness triad Definition 1205.44 and the readback-index scope Definition 1205.37. They force the equations for k and i to be visible before support rows are consumed, while the shared-terminal route supplies the StreamName, RegSeqRat, DyadicRatCore, FinitePrefixLimitBudget, and Real surfaces. □

Theorem 1205.54 (Diagonal-limit representative root-index soundness)**.** *The root-index surface of Definition 1205.53 is sound for the Real-and-Completion route. Each exposed row is sourced by the named sibling certificate:* w *by* $\mathsf{StreamName}^{\uparrow}$*,* r *by* $\mathsf{RegSeqRat}^{\uparrow}$*,* d *by* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$ *by* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$*, and* e *by the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. The finite equations* $k = \mu(1/(n+1))$ *and* $i = k + n + 1$ *are the only index computations admitted by this surface.*

Proof. First read the public exactness package Definition 1205.35. It identifies the ordered public route over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ and lists the representative and finite-prefix rows that the route may expose.

Next apply the terminal-seal root unblock Definition 1205.46. It shows that the terminal seal is reached only through the displayed finite rows, so none of the sibling surfaces can be replaced by an off-packet equality, selector, choice datum, or completion principle.

The formal handoff boundary Definition 1205.69 supplies the remaining boundary. A later handoff may encode the displayed BHist, hsame, Cont, Pkg, NameCert, and sibling rows, but it cannot import any stronger analytic object. Hence the root-index route is sourced exactly by the named sibling certificates and by the two finite index equations. □

Theorem 1205.55 (Diagonal-limit representative root-index readiness package)**.** *The root-index readiness package for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *consists exactly of the coverage theorem Definition 1205.53, the soundness theorem Definition 1205.54, the root-readiness exactness theorem Definition 1205.49, the shared-terminal route Definition 1205.33, and the formal handoff boundary*

Definition 1205.69. Downstream Real-and-Completion consumers may use this package as a finite root-index surface, but it does not assert Real completeness, host real equality, quotient stream equality, selected limits, hidden tail schedules, countable choice, or any Lean bridge check.

Proof. Coverage supplies the visible data: the modulus request, the two finite index equations, the selected window and readback, the dyadic ledger, the finite-prefix budget rows, and the terminal Real seal.

Soundness supplies the source of each row through the StreamName, RegSeqRat, DyadicRatCore, FinitePrefixLimitBudget, and Real certificates. The root-readiness exactness theorem then states that downstream Real-and-Completion consumers factor through this finite packet and no stronger support route.

It remains to package the result at the handoff boundary. The shared-terminal route keeps the representative and finite-prefix rows on one terminal surface, while the formal handoff boundary confines later formal work to the displayed BEDC rows. Therefore the readiness package is exactly the finite root-index surface described above, with all host, quotient, selector, choice, completion, and bridge claims outside its scope. □

Definition 1205.56 (Diagonal-limit representative cofinal-terminal budget bridge)**.** *For an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, the cofinal-terminal budget bridge is the finite* BHist *packet*

$$G = (X, \mu, n, k, i, w, r, d, e, H, C, P, N, Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F, B_M, M_M, W_M, T_M, D_M, R_M, L_M, E$$

The first block $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ *is the representative route of Definition 1205.1; the second block* $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$ *is the finite-prefix budget route of Definition 1205.32; and the third block* $B_M, M_M, W_M, T_M, D_M, R_M, L_M, E_M, H_M, C_M, P_M, N_M$ *is the cofinal modulus route supplied by* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *in chapter 1198. The bridge identifies the selected* $\mathsf{StreamName}^{\uparrow}$ *window* w *with the cofinal window row* T_M*, the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* r *with* R_M*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d *with* D_M*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* e *with* E_M*, while keeping the finite-prefix selector and exhaustion rows visible before the terminal seal is consumed.*

Theorem 1205.57 (Diagonal-limit representative cofinal-budget seal totality)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read from the bridge of Definition 1205.56 factors through*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{FinitePrefixLimitBudget}^{\uparrow} \to \mathsf{CofinalModulusSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

before any completion-facing consumer reads it. Thus the representative rows, finite-prefix rows, and cofinal modulus rows form one terminal budget route, and the terminal consumer receives no independent Real-completion principle beyond that finite route.

Proof. Start with the root-index readiness package, Definition 1205.55. It exposes μ, n, k, i, w, r, d, e together with the finite-prefix rows and makes the equations $k = \mu(1/(n+1))$ and $i = k + n + 1$ visible before downstream support rows are consumed.

Next use the public exactness package, Definition 1205.35. It orders the representative and finite-prefix portions through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so there is no detached terminal read on the representative side.

Attach the cofinal modulus seal route from chapter 1198. Its scoped source inventory and primitive route exhaustion identify $B_M, M_M, W_M, T_M, D_M, R_M, L_M, E_M, H_M, C_M, P_M, N_M$ as the available cofinal budget rows for a completion-facing seal read.

Finally apply the formal handoff boundary, Definition 1205.69. The handoff may encode the displayed BHist, hsame, Cont, Pkg, NameCert, and sibling rows, but it cannot import a stronger analytic object. Therefore every terminal seal read factors through the displayed StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, and Real surfaces before any completion-facing consumer can use it. □

Theorem 1205.58 (Diagonal-limit representative terminal consumer cofinal nonescape)**.** *No terminal consumer of the cofinal-terminal budget bridge may replace the displayed route by quotient stream equality, host* $\mathsf{Real}^{\uparrow}$ *equality, a selected limit, a hidden tail schedule, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Any accepted consumer must read only the representative rows, finite-prefix budget rows, cofinal modulus rows, and structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows displayed in Definition 1205.56.*

Proof. The root-index readiness package supplies the representative boundary. It admits the selected window, readback, dyadic ledger, finite-prefix budget rows, and terminal seal, while excluding quotient-stream equality, host equality, hidden selectors, choice rows, ambient completeness, and bridge claims.

The public exactness package supplies the terminal route boundary. A completion-facing consumer can only use the ordered surface through the named sibling certificates, so it has no second entrance into the terminal $\mathsf{Real}^{\uparrow}$ seal.

The cofinal modulus seal chapter supplies the cofinal budget boundary. Its consumer exactness and primitive route exhaustion confine cofinal budget reads to the displayed finite rows and exclude detached selectors, quotient streams, selected host limits, countable choice, and ambient completeness.

It remains to close the formal interface. The formal handoff boundary allows later formal consumers to encode exactly the displayed BEDC rows. Since every possible terminal read is already accounted for by those rows, any quotient, host equality, selected limit, hidden schedule, choice, or ambient-completeness coordinate would be outside the bridge rather than a consumer of it. □

Theorem 1205.59 (Diagonal-limit representative cofinal-terminal route determinacy)**.** *For any accepted bridge packet G of Definition 1205.56, the displayed representative rows, finite-prefix rows, and cofinal-modulus rows determine one terminal route through*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{FinitePrefixLimitBudget}^{\uparrow} \to \mathsf{CofinalModulusSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

If a second accepted terminal read has the same representative rows, finite-prefix rows, cofinal-modulus rows, transport rows, continuation rows, provenance rows, and local NameCert *rows, then it is the same route through the displayed packet G, not a second* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Project the finite packet rows of G. The definition of the cofinal-terminal budget bridge displays the representative block, the finite-prefix budget block, and the cofinal modulus block, together with the identifications $w = T_M$, $r = R_M$, $d = D_M$, and $e = E_M$. Hence any accepted terminal read with the same displayed rows has the same StreamName window, RegSeqRat readback, DyadicRat ledger, finite-prefix budget rows, cofinal modulus rows, and terminal Real row.

Next apply Definition 1205.57. The positive route to the terminal seal factors through the displayed chain

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{FinitePrefixLimitBudget}^{\uparrow} \to \mathsf{CofinalModulusSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Thus the terminal consumer reads the Real seal only after the representative, finite-prefix, and cofinal-modulus rows have already fixed the route.

It remains to exclude an apparent second route. Apply Definition 1205.58. A competing accepted read cannot introduce quotient stream equality, host $\mathsf{Real}^{\uparrow}$ equality, a hidden schedule, countable choice, ambient completeness, or a detached terminal seal. With those escape coordinates absent, equality of the displayed representative, finite-prefix, cofinal-modulus, transport, continuation, provenance, and local NameCert rows leaves no second Real seal to branch into. □

Theorem 1205.60 (Diagonal-limit representative cofinal-index source)**.** *For an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, the cofinal-index source is the finite surface that reads the equations*

$$k = \mu(1/(n+1)), \qquad i = k + n + 1$$

through the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{CofinalModulusSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows used by the cofinal-terminal budget bridge. Thus the source of the selected window* w*, readback* r*, dyadic ledger* d*, finite-prefix budget rows, cofinal modulus rows, and terminal seal* e *is visible before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Project the root-index readiness package of Definition 1205.55. It already exposes μ, n, k, i, w, r, d, e and forces the finite equations for k and i to appear on the root-index surface.

Next read the cofinal-terminal budget bridge of Definition 1205.56. Its packet attaches the finite-prefix rows and the cofinal modulus rows to the same terminal read, with w, r, d, e identified with the matching cofinal window, readback, dyadic, and seal rows.

Finally apply the cofinal-budget seal totality theorem Definition 1205.57. It orders the entire route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{CofinalModulusSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so the cofinal-index equations are sourced by the displayed rows rather than by a host equality, quotient stream, selected limit, hidden schedule, choice row, or ambient completeness principle. □

Theorem 1205.61 (Diagonal-limit representative cofinal-index budget lock)**.** *The finite-prefix budget rows and cofinal modulus rows of the cofinal-index source lock the selected window, readback, dyadic tolerance, and terminal-read tolerance before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is read. In particular, a terminal consumer may read* e *only after the representative rows, the finite-prefix budget rows* $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$*, and the cofinal modulus rows* $B_M, M_M, W_M, T_M, D_M, R_M, L_M, E_M, H_M, C$ *have all been placed on the same finite* BHist *surface.*

Proof. Begin with the cofinal-index source theorem Definition 1205.60. It places the finite equations and the selected representative rows on the same source route as the finite-prefix and cofinal modulus rows.

The bridge definition Definition 1205.56 then supplies the concrete budget lock. It identifies w with T_M, r with R_M, d with D_M, and e with E_M, while keeping the finite-prefix selector and exhaustion rows visible before terminal consumption.

The totality theorem Definition 1205.57 closes the tolerance route. Since every terminal seal read factors through the displayed StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, and Real rows, no consumer can read a terminal seal before those window, readback, dyadic, and tolerance coordinates are locked. □

Theorem 1205.62 (Diagonal-limit representative cofinal-index terminal readiness)**.** *The cofinal-index terminal readiness package for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *consists of the cofinal-index*

source Definition 1205.60, the cofinal-index budget lock Definition 1205.61, the root-index readiness package Definition 1205.55, the cofinal-terminal budget bridge Definition 1205.56, the cofinal-budget seal totality theorem Definition 1205.57, and the terminal consumer nonescape theorem Definition 1205.58. It is a finite readiness surface for Real-and-Completion consumers and carries no host equality, quotient stream equality, selected limit, hidden tail schedule, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or Lean bridge claim.*

Proof. The source theorem supplies the cofinal-index origin of the equations $k = \mu(1/(n+1))$ and $i = k + n + 1$ across the named StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, and Real rows.

The budget-lock theorem supplies the ordering constraint. It makes the selected window, readback, dyadic ledger, finite-prefix rows, and cofinal modulus rows prerequisites for terminal seal consumption.

It remains to package the terminal boundary. The root-index readiness package gives the finite representative surface, the cofinal-terminal bridge gives the shared BHist packet, the cofinal-budget seal totality theorem gives the terminal route, and the terminal consumer nonescape theorem excludes every off-packet equality, selector, choice, completion, and bridge coordinate. Therefore the readiness package is exactly the finite cofinal-index surface stated above. □

Definition 1205.63 (Diagonal-limit representative cofinal-tail extraction)**.** *For an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, the cofinal-tail extraction surface is the finite packet*

$$T = (\mu, n, k, i, w, r, d, e, Q, B, W, D_F, R, S, E_F, H, C, P, N).$$

The first four rows record the root-index equations $k = \mu(1/(n+1))$ *and* $i = k + n + 1$ *from the root-readiness and cofinal-index readiness surfaces. The rows* w, r, d, e *are respectively the selected* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal. The rows* Q, B, W, D_F, R, S, E_F *are the finite-prefix budget rows inherited from* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$*, with the cofinal modulus source supplied by* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *through the cofinal-terminal budget bridge. The rows* H, C, P, N *are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *row for the same extraction.*

This packet is sourced by $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$*,* $\mathsf{CofinalModulusSeal}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *through Definition 1205.1, Definition 1205.2, Definition 1205.49, Definition 1205.62, and Definition 1205.56. It records only finite cofinal-tail data; it exports no quotient stream equality, host limit, selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness field.*

Theorem 1205.64 (Diagonal-limit representative cofinal-tail coverage)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *terminal route factors through the cofinal-tail extraction packet of Definition 1205.63. In particular, the consumer must read the selected root-index rows* μ, n, k, i*, the selected window* w*, readback* r*, dyadic ledger* d*, terminal seal* e*, finite-prefix budget rows* Q, B, W, D_F, R, S, E_F*, and support rows* H, C, P, N *as one finite* BHist *surface before it can consume the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with the carrier and classifier of Definition 1205.1 and Definition 1205.2. They admit only the selected representative rows and their componentwise support rows, so every downstream read begins on a finite BHist surface rather than on a host stream or completed Real object.

Next use the root-readiness exactness theorem Definition 1205.49 and the cofinal-index readiness package Definition 1205.62. These results place μ, n, k, i, w, r, d, e on the same route as the

finite-prefix and cofinal modulus rows, with the equations for k and i visible before terminal consumption.

Finally attach the cofinal-terminal budget bridge Definition 1205.56 and the terminal-pullback obligation surface Definition 1205.93. The bridge supplies the finite-prefix and cofinal-tail budget rows, while the pullback surface forces terminal consumption back through the displayed StreamName, RegSeqRat, DyadicRatCore, and Real sources. Hence every Real-and-Completion consumer factors through the packet T and no off-packet quotient, host limit, selected limit, choice row, or completeness principle is available. □

Theorem 1205.65 (Diagonal-limit representative cofinal-tail classifier stability)**.** *Let two accepted cofinal-tail extraction packets for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *be classified together by the displayed componentwise* hsame *rows and* Cont *replay. Then the selected rows* μ, n, k, i, w, r, d, e*, the finite-prefix budget rows* Q, B, W, D_F, R, S, E_F*, and the support rows* H, C, P, N *are preserved componentwise. The preservation uses only the packet of Definition 1205.63; it does not add a quotient stream equality, host* $\mathsf{Real}^{\uparrow}$ *equality, selected limit, hidden tail schedule, countable choice row, or ambient completeness witness.*

Proof. Read the classifier of Definition 1205.2. It compares accepted carriers componentwise, and the only transport rows available to the extraction packet are the recorded hsame rows together with displayed Cont replay.

The cofinal-index readiness package fixes the rows that must be preserved. It attaches the root-index equations, the selected window and readback, the dyadic ledger, the finite-prefix budget rows, and the terminal seal to the same cofinal source route.

It remains to check that no stronger transport is introduced by the extraction. The cofinal-terminal budget bridge and the terminal-pullback obligation surface preserve the same displayed terminal rows, while the formal handoff boundary Definition 1205.69 permits later work to encode only the visible BHist, hsame, Cont, Pkg, NameCert, and sibling rows. Therefore classifier stability is exactly componentwise stability of the finite packet T. □

Theorem 1205.66 (Diagonal-limit representative cofinal-tail NameCert exactness)**.** *The local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *obligation for cofinal-tail extraction is exactly the package consisting of the extraction surface of Definition 1205.63, the coverage theorem Definition 1205.64, the classifier-stability theorem Definition 1205.65, the cofinal-terminal budget bridge, the terminal-pullback obligation surface, and the formal handoff boundary. Its ledger refuses quotient streams, host limits, selected limits, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as extraction data.*

Proof. Coverage supplies the positive route. By Definition 1205.64, every Real-and-Completion consumer reaches the terminal seal through the finite extraction packet and through the named StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, and Real rows.

Classifier stability supplies the transport rule. By Definition 1205.65, componentwise hsame and displayed Cont replay preserve exactly the extraction rows, so the local NameCert cannot acquire a second tail, a detached terminal seal, or a hidden selected limit.

The remaining ledger boundary is fixed by the existing surfaces. The cofinal-terminal budget bridge gives the finite cofinal budget route, the terminal-pullback obligation surface pulls terminal consumption back to its source rows, and the formal handoff boundary confines later formal targets to the displayed BEDC rows. Thus the NameCert exactness package is precisely the finite cofinal-tail extraction surface, with quotient streams, host limits, selected limits, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness refused by the ledger. □

Theorem 1205.67 (Diagonal-limit representative Lean target surface)**.** *For an accepted shared-terminal* DiagonalLimitRepresentative$^{\uparrow}$ *carrier, the exact Lean target surface is the finite displayed route*

$$X, \mu, n, k, i, w, r, d, e, H, C, P, N$$

together with the shared-terminal budget rows

$$Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F.$$

The intended target reads the representative carrier, the shared-terminal carrier, and the root-readiness package as one finite BHist *surface:* $X, \mu, n, k, i, w, r, d, e$ *are the representative rows,* H, C, P, N *are the local transport, replay, provenance, and naming rows, and* $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$ *are the finite-prefix budget rows. No additional carrier, classifier, selector, equality principle, host limit, or ambient completion field is part of the target surface.*

Proof. Read the representative carrier of Definition 1205.1. It lists exactly the rows $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ and refuses host limits, quotient stream equality, hidden selectors, countable choice, and ambient Real$^{\uparrow}$ completeness.

Attach the shared-terminal carrier of Definition 1205.32. It adds only the budget rows $Q, B, W, D_F, R, S, E_F, H_F$ and makes them part of the same terminal route.

Finally apply the root-readiness exactness theorem, Definition 1205.49. Coverage, soundness, and completeness there identify every downstream Real-and-Completion consumer route with this finite packet, so a later Lean target has precisely the displayed rows as its obligation surface. □

Theorem 1205.68 (Diagonal-limit representative audit-readiness package)**.** *The audit-ready obligation surface for* DiagonalLimitRepresentative$^{\uparrow}$ *is the package consisting of the carrier and classifier of Definition 1205.1 and Definition 1205.2, the shared-terminal route of Definition 1205.33, the root-readiness triad of Definition 1205.44, the dependency-readiness scope of Definition 1205.47, and the root-readiness exactness theorem of Definition 1205.49. This package is exact for audit: it covers the displayed representative rows, the shared-terminal budget rows, the accepted support rows, and no off-packet route.*

Proof. The carrier and classifier supply the accepted object and its componentwise comparison rule. These rows determine what can be admitted before any shared-terminal consumer is attached.

The shared-terminal route then attaches the finite-prefix budget rows and orders the terminal read through StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, FinitePrefixLimitBudget$^{\uparrow}$, and Real$^{\uparrow}$. The root-readiness triad makes that ordered route mandatory before support rows are consumed.

The dependency-readiness scope packages the route for downstream L10 chapters, and root-readiness exactness gives coverage, soundness, and completeness for the displayed packet. Therefore the audit surface is neither weaker nor stronger than the carrier, shared-terminal route, root-readiness triad, and dependency-readiness exactness already displayed in the chapter. □

Theorem 1205.69 (Diagonal-limit representative formal handoff boundary)**.** *Any later Lean handoff, audit target, or standard bridge for* DiagonalLimitRepresentative$^{\uparrow}$ *must preserve the finite route of Definition 1205.67 and the audit-ready package of Definition 1205.68. Such a handoff may encode the displayed* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* FinitePrefixLimitBudget$^{\uparrow}$*, and* Real$^{\uparrow}$ *rows, but it may not import quotient-stream equality, host* Real$^{\uparrow}$ *equality, selected limits, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiagonallimitrepresentativeUp.DiagonalLimitRepresentativeFormalHandoffBoundary`

Proof. The positive content is fixed by the Lean target surface. It names the representative rows, support rows, and finite-prefix budget rows that must be preserved by any formal consumer.

The audit-readiness package supplies the binding scope for those rows. It packages carrier admission, classifier transport, shared-terminal routing, root-readiness exposure, dependency-readiness, and exactness without adding any analytic completion principle.

It remains to state the boundary for later formal work. The nonchoice boundary, completion boundary, Real-seal nonchoice export, and bridge precondition package already exclude quotient equality, host equality, selected limits, choice, and ambient completeness from the chapter surface. A Lean handoff or bridge can therefore check only this finite BEDC route; importing any excluded object would change the obligation surface rather than formalize it. □

Theorem 1205.70 (Diagonal-limit representative terminal pullback coverage)**.** *Every accepted formal handoff for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *pulls downstream Real-and-Completion consumption back to the finite route*

$$\mu, n, k, i, w, r, d, Q, B, W, D_F, R, S, e, H, C, P, N, E_F, H_F, C_F, P_F, N_F.$$

Coverage is supplied by the root-readiness exactness package; soundness is supplied by the cited $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *surfaces. Thus the handoff can consume the displayed rows, their componentwise* BHist *packaging, and the associated* $\mathsf{NameCert}$ *obligations, but it cannot introduce quotient-stream equality, host* $\mathsf{Real}^{\uparrow}$ *equality, a selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Lean target surface of Definition 1205.67. It identifies the representative rows and the shared-terminal budget rows as one finite obligation surface, so every accepted formal handoff has a named row for each element of the displayed route.

The audit-readiness package of Definition 1205.68 then records which carrier, classifier, shared-terminal route, dependency-readiness scope, and exactness theorem can be consumed. The root-readiness exactness theorem, cited there as Definition 1205.49, supplies coverage for the terminal route and soundness for the support surfaces.

Finally apply the handoff boundary of Definition 1205.69. Its exclusions remove quotient-stream equality, host equality, selected limits, countable choice, and ambient completeness from the obligation surface. Route exhaustion leaves only the finite rows named above, which is the required pullback coverage contract for downstream Real-and-Completion consumption. □

Theorem 1205.71 (Diagonal-limit representative terminal pullback determinacy)**.** *Let two accepted Real-and-Completion consumers of the* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *formal handoff agree componentwise, by the recorded* hsame *and* Cont *replay, on the representative rows*

$$X, \mu, n, k, i, w, r, d, e, H, C, P, N$$

and on the shared-terminal budget rows

$$Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F.$$

Then the two consumers induce the same terminal $\mathsf{Real}^{\uparrow}$ *seal route and the same finite-prefix budget pullback. Quotient-stream equality, host* $\mathsf{Real}^{\uparrow}$ *equality, a selected limit, countable choice, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness row cannot distinguish the induced pullback.*

Proof. The displayed agreement is exactly agreement on the Lean target surface of Definition 1205.67. That theorem records the representative rows and shared-terminal budget rows as one finite BHist surface, so the two consumers begin with the same formal handoff data.

Next apply the audit-readiness package of Definition 1205.68. It identifies the carrier, classifier, shared-terminal route, dependency scope, and root-readiness exactness data consumed by any accepted handoff, so componentwise hsame and Cont replay transport the same package to both consumers.

Finally use terminal pullback coverage from Definition 1205.70. Coverage leaves no off-packet route through quotient streams, host equality, selected limits, countable choice, or ambient completeness. The only remaining Real-and-Completion read is the displayed terminal $\mathsf{Real}^{\uparrow}$ seal route with its finite-prefix budget pullback, hence the two accepted consumers determine the same pullback. □

Theorem 1205.72 (Diagonal-limit representative audit-clean threshold package)**.** *The audit-clean-ready package for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is exactly the finite route through* BHist*, componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *naming, the object faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, the shared-terminal budget rows*

$$Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F,$$

and the formal handoff theorems

$$\textit{Definition } 1205.67, \quad \textit{Definition } 1205.68, \quad \textit{Definition } 1205.70, \quad \textit{Definition } 1205.71.$$

It contains no quotient stream, selected limit, countable choice, host $\mathsf{Real}^{\uparrow}$ *equality, or ambient completeness row.*

Proof. Start with the Lean target surface and audit-readiness package. The first theorem fixes the representative rows and shared-terminal budget rows as a finite BHist surface, while the second identifies the carrier, classifier, shared-terminal route, dependency scope, and exactness theorem that the audit can consume.

Next apply terminal pullback coverage. It pulls every accepted formal handoff back to the displayed representative rows, the budget rows, and the named $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ support surfaces.

Finally use terminal pullback determinacy. Once two consumers agree by hsame and Cont replay on those rows, no quotient stream, selected limit, countable-choice row, host equality, or ambient completeness row remains available to separate their reads. Hence the audit-clean-ready package is precisely the finite route named in the statement. □

Theorem 1205.73 (Diagonal-limit representative phase-exit audit unblock)**.** *The audit-clean threshold package of Definition 1205.72 is the consumer-facing input by which* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *reads* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *at the Phase Real and Completion exit. The read factors through the handoff lock of Definition 1205.151 and the four-object threshold projection of Definition 1327.16: only the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *face records, with their displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support, can serve the exit criterion.*

Proof. The handoff lock identifies the $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ Phase Real and Completion packet consumed by $\mathsf{PhaseRealCompletionExit}^{\uparrow}$. It keeps the source rows at $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with the support route carried by BHist, hsame, Cont, Pkg, and the local naming row.

The audit-clean threshold package supplies the exact finite handoff available to that lock. Its coverage and determinacy statements exclude every off-packet route through quotient streams, selected limits, countable choice, host Real equality, or ambient completeness.

Finally apply the four-object threshold projection. The projection is the roadmap-facing exit read of $\mathsf{PhaseRealCompletionExit}^{\uparrow}$, so the same four object faces and their support rows are the consumer-facing input that unblocks the Phase Real and Completion audit criterion. □

Theorem 1205.74 (Diagonal-limit representative Lean-readiness obligation boundary)**.** *Any later Lean target for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *may encode only the finite rows and sibling faces already named by this formal handoff surface: the representative rows, the shared-terminal budget rows,* BHist*,* hsame*,* Cont*,* Pkg*,* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Stronger Real-completeness claims, quotient-stream equality, countable-choice principles, selected limits, host* $\mathsf{Real}^{\uparrow}$ *equality, or standard-bridge assertions remain outside this obligation boundary.*

Proof. The positive boundary is supplied by the Lean target surface, the audit-readiness package, and the audit-clean threshold package. Together they name every row that a formal target can read: representative data, budget data, object faces, and support rows.

The negative boundary is supplied by the formal handoff boundary, terminal pullback coverage, and terminal pullback determinacy. These results state that quotient streams, selected limits, countable choice, host equality, and ambient completion are not part of the accepted carrier or its terminal pullback.

It remains only to separate Lean readiness from stronger bridge claims. The handoff surface is a finite BEDC obligation surface for the displayed rows. A standard bridge or Real-completeness theorem would require additional bridge data beyond those rows, so it cannot be counted as part of this target. □

Theorem 1205.75 (Diagonal-limit representative hub dependency witness)**.** *The hub-visible dependency witness for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is the package consisting of the carrier and classifier of Definition 1205.1 and Definition 1205.2, the shared-terminal carrier of Definition 1205.32, the root-readiness triad of Definition 1205.44, the root-index readiness package of Definition 1205.55, the cofinal-terminal budget bridge of Definition 1205.56, and the formal handoff boundary of Definition 1205.69. Its visible route factors through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, with the cofinal terminal budget rows supplying the completion-facing budget source. It exposes no quotient streams, host real equality, hidden selectors, countable choice, or ambient Real completeness.*

Proof. The carrier and classifier identify the accepted diagonal representative and its componentwise support rows. The shared-terminal carrier then attaches the finite-prefix budget rows to the same terminal read, so the hub package begins with one finite BHist surface rather than two unrelated surfaces.

The root-readiness triad supplies the mandatory display order for the modulus request, selected indices, selected window, readback, dyadic ledger, finite-prefix rows, and terminal $\mathsf{Real}^{\uparrow}$ seal. The root-index readiness package makes the equations for k and i visible before support rows are consumed, and it records that the named sibling certificates source each exposed row.

The cofinal-terminal budget bridge adds the completion-facing budget source without adding an analytic completion principle. Finally, the formal handoff boundary states that later Lean handoffs may encode only the displayed BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, and sibling rows. Hence the

hub witness packages the existing obligations as a visible dependency route while preserving the quotient, host-equality, selector, choice, and completeness exclusions. □

Theorem 1205.76 (Diagonal-limit representative root-unblock consumer surface)**.** *Every Real-and-Completion consumer that reads the hub-visible* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *dependency witness must consume the ordered surface*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{FinitePrefixLimitBudget}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

through the accepted carrier rows of Definition 1205.1, the shared-terminal rows of Definition 1205.32, the root-readiness route of Definition 1205.44, the root-index package of Definition 1205.55, and the cofinal-budget seal totality theorem Definition 1205.57. No accepted consumer of this surface may replace the displayed route by quotient stream equality, host $\mathsf{Real}^{\uparrow}$ *equality, a selected completed limit, a hidden selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier and shared-terminal carrier. Together they display the representative rows $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ and the finite-prefix rows $Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F$ as one terminal packet.

Apply the root-readiness triad and root-index readiness package. They force the selected-index equations, selected window, readback, dyadic ledger, finite-prefix budget rows, and terminal Real seal to be visible before any downstream support row can be used.

Now use the cofinal-budget seal totality theorem. It routes the completion-facing seal through the StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, and Real surfaces. The formal handoff boundary then removes any off-packet quotient, host-equality, selected-limit, hidden-selector, choice, or ambient-completeness entrance. Thus the consumer surface is exactly the ordered finite route stated above. □

Theorem 1205.77 (Diagonal-limit representative L10 exit readiness package)**.** *The L10 exit readiness package exported at the* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *hub consists of the hub dependency witness of Definition 1205.75, the root-unblock consumer surface of Definition 1205.76, the terminal pullback coverage theorem Definition 1205.70, and the terminal consumer cofinal nonescape theorem Definition 1205.58. This package is ready for Real and Completion consumers precisely because every exit row is already routed through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, with no quotient streams, host real equality, hidden selectors, countable choice, or ambient Real completeness.*

Proof. The hub dependency witness gathers the existing carrier, shared-terminal, root-readiness, root-index, cofinal-terminal, and formal-handoff obligations into one public package. The root-unblock consumer surface then states the exact order in which a Real-and-Completion consumer may read that package.

Terminal pullback coverage supplies the exit coverage: every accepted formal handoff pulls downstream consumption back to the finite representative and budget rows. Terminal consumer cofinal nonescape supplies the negative boundary: the cofinal-terminal budget bridge admits only the displayed representative, finite-prefix, cofinal modulus, and structural BEDC rows.

It remains to name the exported readiness. Since the positive route is the displayed finite path through StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, and Real surfaces, and since every quotient, host-equality, hidden-selector, choice, and ambient-completeness alternative is excluded by the cited boundaries, the hub exports a dependency-ready L10 exit package for the Real and Completion phases. □

Theorem 1205.78 (Diagonal-limit representative root carrier window)**.** *For every accepted* DiagonalLimitRepresent *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the root carrier window exposes, as one finite BHist *packet, the regular-Cauchy family X, the modulus row μ, the selected equations $k = \mu(1/(n+1))$ and $i = k+n+1$, the* $\mathsf{StreamName}^{\uparrow}$ *window w, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback r, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger d, the terminal* $\mathsf{Real}^{\uparrow}$ *seal e, the transport row H, the continuation row C, the provenance row P, and the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *row N. The window contains no quotient stream equality, host limit, choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 1205.1. Its displayed tuple is exactly $X, \mu, n, k, i, w, r, d, e, H, C, P, N$, with the two selected-index equations and the four support rows already present in the finite packet.

Read the sibling route named in the chapter opening. The window coordinate is sourced by $\mathsf{StreamName}^{\uparrow}$, the readback coordinate by $\mathsf{RegSeqRat}^{\uparrow}$, the arithmetic ledger by $\mathsf{DyadicRatCore}^{\uparrow}$, and the terminal seal by $\mathsf{Real}^{\uparrow}$.

The carrier definition also states the negative boundary: no host real, quotient stream equality, hidden tail selector, countable choice row, or ambient completeness field is exported. Therefore the accepted root carrier window is precisely the finite BHist packet above. □

Theorem 1205.79 (Diagonal-limit representative classifier transport)**.** *If two accepted* DiagonalLimitRepresentative *carriers are related by the classifier of Definition 1205.2, then the selected-index equation,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row transport only through the displayed H and C rows. In particular, classifier transport preserves the root-readiness route of Definition 1205.44 and the root-index readiness package of Definition 1205.55 without adding an off-packet selector, quotient equality, host limit, choice row, or ambient completeness field.*

Proof. Start with the classifier definition. It relates accepted carriers only by componentwise recorded hsame comparisons and displayed Cont routes over the selected indices, window, readback, dyadic ledger, terminal seal, package row, and local naming row.

Apply the root-readiness triad. It requires every Real-and-Completion consumer to expose the modulus request, selected indices, window, readback, dyadic ledger, finite-prefix budget rows, and terminal seal before any support row is consumed.

Now apply the root-index readiness package. It makes the equations for k and i and the sibling sources for w, r, d, e part of the finite root-index surface. Since the classifier offers no support coordinate outside H and C, transport of those rows can only be the displayed componentwise transport and replay. □

Theorem 1205.80 (Diagonal-limit representative NameCert ledger exhaustion)**.** *The local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRep}}$ *ledger for the root-unblock surface is exhausted by the carrier of Definition 1205.1, the classifier of Definition 1205.2, the root-readiness route of Definition 1205.44, the cofinal-terminal budget bridge and seal totality of Definition 1205.57, the formal handoff boundary of Definition 1205.69, and the hub dependency witness of Definition 1205.75. No further ledger row is available to a Real-and-Completion consumer.*

Proof. First read the carrier and classifier. They provide the accepted tuple, its componentwise comparison rule, and the local naming row N.

Next use the hub dependency witness. It packages the carrier, classifier, shared-terminal rows, root-readiness route, root-index package, cofinal-terminal bridge, and formal handoff boundary as the hub-visible dependency route.

Finally apply cofinal-budget seal totality and the formal handoff boundary. The seal totality theorem routes every terminal seal read through the displayed StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, and Real surfaces, while the handoff boundary prevents any stronger analytic object from entering. Hence the local NameCert ledger is exhausted by the listed rows and obligations. □

Theorem 1205.81 (Diagonal-limit representative index unary closure)**.** *For every accepted* DiagonalLimitRepresent *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the selected family row, modulus row, precision request, selected family index, selected readback index, selected $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *row are* UnaryHistory *rows. Moreover, any derived route read produced by the displayed* Cont *closures*

$$\mathsf{Cont}(\mu, n, k), \qquad \mathsf{Cont}(w, r, i), \qquad \mathsf{Cont}(d, e, H)$$

remains a UnaryHistory *row. These are precisely the unary rows exposed by the carrier of Definition 1205.1 and the NameCert obligations of Definition 1205.3; no quotient stream equality, host limit, choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row can serve as a replacement index source.*

Proof. Project the carrier of Definition 1205.1. It displays $X, \mu, n, k, i, w, r, d, e$ and the local naming row N as finite BHist coordinates of the accepted representative packet.

Apply the NameCert obligations of Definition 1205.3. Their Lean touchpoint, DiagonalLimitRepresentativeName records the same carrier rows as UnaryHistory data and closes the derived reads by the three displayed Cont routes.

The sibling route supplies the sources of those rows: $\mathsf{StreamName}^{\uparrow}$ exposes w, $\mathsf{RegSeqRat}^{\uparrow}$ exposes r, $\mathsf{DyadicRatCore}^{\uparrow}$ exposes d, and $\mathsf{Real}^{\uparrow}$ exposes e. Since every derived read is obtained by continuation from already displayed unary rows, the root index surface remains a BHist obligation surface rather than an analytic completion claim. □

Theorem 1205.82 (Diagonal-limit representative continuation route closure)**.** *The accepted* Cont *routes for the root-unblock surface of an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *packet are exactly the modulus-request route, the window-readback route, and the ledger-seal route:*

$$\mathsf{Cont}(\mu, n, k), \qquad \mathsf{Cont}(w, r, i), \qquad \mathsf{Cont}(d, e, H).$$

The first route reads the selected family index from the displayed modulus request, the second route reads the selected readback index from the $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the third route carries the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger into the terminal* $\mathsf{Real}^{\uparrow}$ *seal. No accepted root consumer has a fourth continuation route through a hidden selector, quotient stream equality, host limit, choice row, or ambient completeness field.*

Proof. Read the carrier and classifier of Definition 1205.1 and Definition 1205.2. The carrier lists the continuation support row C, while the classifier permits replay only along the recorded componentwise Cont routes for the selected indices, window, readback, ledger, and seal.

Use Definition 1205.3. The obligation theorem exposes exactly the three continuation closures named in the statement: modulus with request, window with readback, and ledger with terminal seal.

Finally follow the sibling route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. That route accounts for every public read needed by a Real-and-Completion consumer, and the carrier contains no coordinate from which an additional accepted continuation could be sourced. □

Theorem 1205.83 (Diagonal-limit representative package and NameCert source closure)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, the local package row* P *and local naming row* N *source the representative packet through the finite* Pkg *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *surface of Definition 1205.1. The source surface is the displayed route through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *together with the carrier, classifier, and NameCert obligations of Definition 1205.3. It does not source quotient stream equality, a host limit, a hidden choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiagonallimitrepresentativeUp.DiagonalLimitRepresentativeCarrier pkg namecert source closure`

Proof. Start with the carrier. The rows P and N occur only as package provenance and local name for the displayed packet $D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N)$.

Apply the NameCert obligations. They bind the local Pkg signature and $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ row to the same unary rows and continuation closures used by the index and terminal routes.

The sibling route then identifies the packet source: $\mathsf{StreamName}^{\uparrow}$ supplies the selected window, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the readback, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the ledger, and $\mathsf{Real}^{\uparrow}$ supplies the seal row. Because the source is exhausted by those finite rows plus P and N, the local package cannot add quotient, host-limit, choice, or ambient-completeness data. □

Theorem 1205.84 (Diagonal-limit representative terminal row coverage)**.** *Every terminal row consumed from an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *packet factors through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route. More precisely, a Real-and-Completion consumer may read the terminal seal only after the packet exposes the selected window* w, *readback* r, *dyadic ledger* d, *terminal seal* e, *support rows* H, C, P, N, *and the finite-prefix budget rows on the same finite* BHist *surface. The factorization is the one supplied by the root-readiness triad of Definition 1205.44, the NameCert ledger of Definition 1205.80, and the cofinal-budget seal totality theorem Definition 1205.57; it does not assert quotient stream equality, host real equality, selected limits, choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the root-readiness triad. It places the modulus request, selected indices, selected $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, finite-prefix budget rows, terminal $\mathsf{Real}^{\uparrow}$ seal, and support rows on one displayed root surface before any consumer can use the support coordinates.

Next apply the NameCert ledger exhaustion theorem. Its local ledger identifies the carrier, classifier, root-readiness route, cofinal-terminal bridge, formal handoff boundary, and hub dependency witness as the only rows available to the consumer.

Finally use cofinal-budget seal totality. That theorem orders the terminal seal through the same StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, and Real surfaces. Since no listed theorem exports a quotient, host-limit, selector, choice, or ambient-completeness row, every terminal row factors through exactly the displayed finite route. □

Theorem 1205.85 (Diagonal-limit representative cofinal selector transport)**.** *The cofinal selector data of an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *packet transports only inside the displayed rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

In particular, transport of the selected equations $k = \mu(1/(n+1))$ *and* $i = k + n + 1$*, the selected window* w*, readback* r*, dyadic ledger* d*, finite-prefix budget rows, cofinal modulus rows, and terminal seal* e *is mediated by the packet rows* H, C, P, N *and by the cofinal-terminal budget bridge. It never passes through a hidden selector, quotient stream equality, host real equality, countable choice, or ambient completion field.*

Proof. Start from the classifier transport theorem in the root obligation surface. It permits componentwise transport only through recorded hsame comparisons and displayed Cont replay over the accepted carrier rows.

The cofinal-index readiness package then attaches the selected equations, the finite-prefix budget rows, and the cofinal modulus rows to the same source route. Its budget-lock theorem makes the selected window, readback, dyadic ledger, tolerance rows, and terminal seal visible before terminal consumption.

It remains to identify the allowed containers for transport. The NameCert ledger supplies the local Pkg and NameCert rows, while the formal handoff boundary Definition 1205.69 prevents any stronger analytic object from entering the route. Therefore cofinal selector transport stays inside the displayed BHist, hsame, Cont, Pkg, and NameCert surface. □

Theorem 1205.86 (Diagonal-limit representative Real-completion consumer exactness)**.** *The Real-and-Completion root-unblock surface for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is exactly the package consisting of terminal row coverage, cofinal selector transport, the root-readiness triad of Definition 1205.44, the NameCert ledger of Definition 1205.80, the cofinal-budget seal totality theorem of Definition 1205.57, and the formal handoff boundary of Definition 1205.69. Any accepted downstream consumer must factor through this package, and every row in the package is sourced by the displayed StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, Real,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data. The package carries no quotient equality, host limit, selected limit, countable choice, Real completeness, or Lean bridge claim.*

Proof. Coverage is supplied by Definition 1205.84. It forces terminal consumption through the visible StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, and Real route.

Transport is supplied by Definition 1205.85. It confines the selector equations and cofinal rows to the displayed BHist, hsame, Cont, Pkg, and NameCert containers.

The existing root-readiness triad, NameCert ledger, cofinal-budget seal totality theorem, and formal handoff boundary close the package. Together they state the finite rows available to a downstream consumer, the ledger that names those rows, the terminal ordering through the cofinal budget, and the boundary excluding stronger analytic data. Hence the consumer exactness surface is precisely the named finite package and nothing outside it. □

Theorem 1205.87 (Diagonal-limit representative root coverage)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier consumed by a Real-and-Completion route, the root-unblock surface covers exactly the displayed finite rows*

$$\mathsf{BHist}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{FinitePrefixLimitBudget}^{\uparrow},$$

Concretely, the consumer may read the selected family row X, modulus row μ, precision row n, selected indices $k = \mu(1/(n+1))$ and $i = k + n + 1$, StreamName window w, RegSeqRat readback r, DyadicRatCore ledger d, finite-prefix budget rows Q, B, W, D_F, R, S, E_F, cofinal modulus rows $B_M, M_M, W_M, T_M, D_M, R_M, L_M, E_M$, terminal Real seal e, and support rows H, C, P, N only as coordinates of that finite BHist *route. It receives no host limit, quotient class, choice-selected subsequence, hidden selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with the root carrier window and NameCert ledger of Definition 1205.78 and Definition 1205.80. These results from the root NameCert obligation surface identify $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ as the carrier and support rows available to the root consumer.

Next attach the Real-completion root-unblock surface. The terminal row coverage and consumer exactness theorems, Definition 1205.84 and Definition 1205.86, force terminal consumption through the displayed StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, Real, BHist, Cont, Pkg, and NameCert data.

Finally use finite selector exhaustion and terminal-diagonal coverage, Definition 1205.90 and Definition 1205.98. They place the selector equations, finite-prefix budget rows, cofinal modulus seal, and terminal representative on the same finite route. Since each cited surface excludes host limits, quotient classes, choice rows, hidden selectors, and ambient completeness data, the root coverage is exactly the displayed obligation package. □

Theorem 1205.88 (Diagonal-limit representative selector transport)**.** *Let two accepted* DiagonalLimitRepresentative *carriers be related by the componentwise* hsame *classifier and displayed* Cont *replay of the root NameCert obligation surface. Then transport preserves the chosen diagonal selector rows*

$$k = \mu(1/(n+1)), \qquad i = k + n + 1,$$

the selected StreamName window w, RegSeqRat readback r, DyadicRatCore ledger d, cofinal tail rows $B_M, M_M, W_M, T_M, D_M, R_M, L_M, E_M$, finite-prefix budget rows Q, B, W, D_F, R, S, E_F, and terminal Real seal row e before the Real seal is consumed. The transported packet remains a finite BHist *obligation with* Cont, Pkg, *and* NameCert *coordinates; it does not create an off-packet selector, host equality, quotient equality, choice row, or Real-completeness witness.*

Proof. Start from classifier transport in the root NameCert obligation surface, Definition 1205.79. It permits comparison only through recorded componentwise hsame rows and displayed Cont replay over the accepted carrier rows.

The Real-completion root-unblock surface supplies the ordering constraint. By Definition 1205.85, the selected equations, finite-prefix budget rows, cofinal modulus rows, selected window, readback, dyadic ledger, and terminal seal all transport inside the displayed BHist, hsame, Cont, Pkg, and NameCert containers.

Now apply finite selector exhaustion and terminal-diagonal transport, Definition 1205.90 and Definition 1205.99. The first fixes the selector route before terminal consumption, and the second preserves the terminal diagonal packet componentwise. Therefore hsame transport preserves the selected diagonal route, cofinal tail row, and finite-prefix budget before the Real seal is consumed, without adding any stronger analytic object. □

Theorem 1205.89 (Diagonal-limit representative Real seal handoff)**.** *Every Real-completion consumer receiving an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *terminal seal receives only the terminal representative row*

$$(X, \mu, n, k, i, w, r, d, e),$$

the cofinal selector and modulus rows $B_M, M_M, W_M, T_M, D_M, R_M, L_M, E_M$, the finite-prefix budget rows Q, B, W, D_F, R, S, E_F, and the NameCert support rows H, C, P, N. The handoff is a finite root-unblock obligation over BHist, Cont, Pkg, *and* NameCert*; it carries no host limit, quotient class, choice-selected subsequence, hidden completion object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Root coverage supplies the positive source. By Definition 1205.87, every Real-and-Completion consumer reads the terminal representative, cofinal selector, modulus budget, finite-prefix rows, and support rows from the same finite BHist route.

Selector transport supplies stability before consumption. By Definition 1205.88, the selected diagonal rows and budget rows are preserved by the displayed hsame and Cont data, so the consumer cannot replace the terminal representative with a host-selected subsequence or quotient class.

It remains to identify the handoff boundary. The terminal-diagonal Real handoff theorem Definition 1205.100, together with Real-completion consumer exactness Definition 1205.86, confines the downstream route to the finite terminal representative, cofinal selector, modulus budget, and NameCert rows. Thus the Real seal handoff exports exactly those rows and no host limit, quotient class, choice-selected subsequence, hidden completion object, or ambient completeness principle. □

Theorem 1205.90 (Diagonal-limit representative finite selector exhaustion)**.** *For an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier, fix the visible rows X, μ, n, k, i on the root-readiness surface. If the carrier is accepted by the root NameCert obligations and is consumed by a Real-and-Completion route, then the selected* $\mathsf{StreamName}^{\uparrow}$ *window w and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback r are forced through the displayed equations*

$$k = \mu(1/(n+1))$$

and

$$i = k + n + 1.$$

The resulting finite selector packet is exactly the route through $X, \mu, n, k, i, w, r, H, C, P, N$; it does not contain a hidden modulus selector, quotient-stream equality, host stream equality, countable choice, selected completed limit, or ambient completion principle.

Proof. Start with the root-readiness triad of Definition 1205.44. It requires any downstream Real-and-Completion consumer to expose μ, n, k, i, w, r before the support rows are consumed, with H, C, P, N only transporting, replaying, sourcing, and naming that displayed surface.

The readback-index scope and selected-window determinacy theorems, Definition 1205.37 and Definition 1205.50, then identify the selected window and readback as the rows attached to the visible indices. The equations for k and i are not external parameters; they are the displayed computations carried by the accepted packet.

Finally apply budget-source determinacy, Definition 1205.48. It prevents a downstream consumer from replacing the selected rows by an off-packet terminal source. Hence fixed X, μ, n, k, i exhaust the finite selector route through the named StreamName and RegSeqRat rows, with no additional selector or equality principle available. □

Theorem 1205.91 (Diagonal-limit representative support route coverage)**.** *Every accepted support row of a shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier is covered by the finite BEDC support surface*

$$\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{FinitePrefixLimitBudget}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

More explicitly, the support rows H, C, P, N cover only the recorded history, componentwise transport, continuation replay, provenance, local naming, selected window, regular-rational readback, dyadic ledger, finite-prefix budget, and terminal Real seal routes. They cannot cover a detached support primitive, hidden selector, quotient stream equality, host equality, selected completed limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First read primitive-scope exhaustion, Definition 1205.7. It lists the available primitive rows as BHist, hsame, Cont, Pkg, NameCert, and the sibling rows supplied by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next apply support-scope nonescape, Definition 1205.8. It confines accepted transport and replay to H, C, P, N, so no detached support primitive can be inserted after the selector and terminal rows have been displayed.

The dependency-readiness scope of Definition 1205.47 and the public exactness package of Definition 1205.35 supply the coverage direction. They make the five sibling surfaces and the four support rows the whole consumer-facing route, while excluding quotient, host, selector, choice, and ambient-completeness alternatives. □

Theorem 1205.92 (Diagonal-limit representative terminal seal stability)**.** *Let A and A' be accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carriers with the same visible selector rows X, μ, n, k, i, w, r, d and the same finite-prefix budget rows. Then their terminal* $\mathsf{Real}^{\uparrow}$ *seal routes are stable up to the recorded* hsame *support and displayed* Cont *replay of H, C, P, N. This stability is exactly a finite NameCert seal: it cannot introduce host equality, quotient-stream equality, selected completed limits, hidden selectors, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with terminal-seal determinacy, Definition 1205.51. It says that the visible finite-prefix budget rows together with w, r, d determine the terminal Real seal source up to the recorded hsame rows and the displayed Cont replay.

Consumer-route exhaustion, Definition 1205.52, supplies the route boundary. Every accepted Real-and-Completion consumer factors through the ordered route containing the selector rows, dyadic ledger, finite-prefix budget rows, terminal seal, and support rows; no other support surface is available.

Use Real-seal nonchoice export and the formal handoff boundary, Definition 1205.42 and Definition 1205.69, for the negative clause. They preserve the displayed terminal row as finite NameCert data and prevent the seal from being strengthened into host equality, quotient equality, selected limits, hidden selectors, choice data, or ambient completeness. Therefore the two carriers have the same terminal seal route precisely up to the recorded support. □

Definition 1205.93 (Diagonal-limit representative terminal-pullback obligation surface)**.** *The terminal-pullback obligation surface for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is the finite packet*

$$\Pi = (W, R, D, E, H, C, P, N)$$

read from the accepted carrier and classifier of Definition 1205.1 and Definition 1205.2. Its four source rows are:

1. *W, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row supplied by chapter 126;*
2. *R, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row supplied by chapter 301;*
3. *D, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger supplied by chapter 291;*
4. *E, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row supplied by chapter 38.*

The remaining rows H, C, P, N are respectively the componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *row for that same packet. The surface is terminal-pullback data: it records how the terminal Real seal is pulled back through the finite StreamName, RegSeqRat, and DyadicRatCore sources before any downstream consumer may use the seal, and it exports no quotient stream equality, host limit, countable-choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness field.*

Theorem 1205.94 (Diagonal-limit representative terminal-pullback source coverage)**.** *Every accepted terminal-pullback packet* $\Pi = (W, R, D, E, H, C, P, N)$ *for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *exposes the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *before the terminal Real seal is consumed. The source route is the one named by chapter 126, chapter 301, chapter 291, and chapter 38, read through the carrier and classifier of Definition 1205.1 and Definition 1205.2.*

Proof. Project the accepted carrier. Its displayed tuple contains the selected window, readback, ledger, and seal rows as finite BHist coordinates, and the terminal-pullback surface of Definition 1205.93 merely renames those four rows as W, R, D, E.

Next read the sibling sources. The window row is sourced by $\mathsf{StreamName}^{\uparrow}$, the readback row by $\mathsf{RegSeqRat}^{\uparrow}$, the tolerance ledger by $\mathsf{DyadicRatCore}^{\uparrow}$, and the terminal seal by $\mathsf{Real}^{\uparrow}$, with the four chapter references in the statement fixing the source side of the pullback.

Finally apply the classifier boundary. Componentwise hsame transport and displayed Cont replay are the only ways to move the four source rows toward terminal consumption, while P and N only source and name the same packet. Hence every accepted consumer sees W, R, D, E before it can use the terminal Real seal. □

Theorem 1205.95 (Diagonal-limit representative terminal-pullback classifier stability)**.** *If two accepted terminal-pullback packets for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *are classified together by Definition 1205.2, then their selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and terminal* $\mathsf{Real}^{\uparrow}$ *seal classifiers are preserved by the displayed* hsame *and* Cont *rows. This preservation uses only the finite packet* $\Pi = (W, R, D, E, H, C, P, N)$ *of Definition 1205.93; it does not require quotient stream equality, host stream equality, selected limits, countable choice, or ambient Real completeness.*

Proof. Start with the classifier of Definition 1205.2. It relates accepted carriers componentwise, so the selected window, readback, dyadic ledger, terminal seal, provenance, and local name are compared only by the recorded hsame rows and replayed only by the displayed Cont routes.

Use terminal-pullback source coverage. By Definition 1205.94, the four rows W, R, D, E are already visible before the terminal seal is consumed, so classifier transport has concrete rows to preserve rather than an external stream quotient or host equality claim.

The support rows close the stability claim. The rows H, C, P, N are part of the finite packet and cannot introduce a second window, alternate readback, different tolerance ledger, or stronger Real seal classifier. Thus hsame transport preserves exactly the displayed terminal-pullback classifiers. □

Theorem 1205.96 (Diagonal-limit representative terminal-pullback ledger exactness)**.** *The terminal-pullback ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *hides only the finite representative choice already displayed by the carrier of Definition 1205.1: the selected window* W*, readback* R*, tolerance ledger* D*, terminal seal* E*, and support rows* H, C, P, N*. It does not export a host limit, quotient-stream equality, countable choice, selected completed limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle to a Real-and-Completion consumer.*

Proof. Read the terminal-pullback surface. Its packet has exactly eight rows, and the first four are sourced by the StreamName, RegSeqRat, DyadicRatCore, and Real sibling chapters named in Definition 1205.93.

Now compare with the carrier. The carrier of Definition 1205.1 already displays the finite representative choice by its selected window, readback, ledger, and seal coordinates, while the classifier of Definition 1205.2 permits only componentwise transport and continuation replay over those coordinates.

It remains to exclude stronger exports. The rows H, C, P, N transport, replay, source, and name the same finite packet; none of them is a host limit, a stream quotient, a choice functional, or an ambient completeness field. Therefore the ledger is exact: it hides only the finite representative selection and exposes no analytic completion principle beyond the terminal seal row. □

Definition 1205.97 (Diagonal-limit representative terminal-diagonal selector)**.** *The terminal-diagonal selector for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is the finite BEDC packet*

$$\Delta = (M, Q, X, \mu, n, k, i, w, r, d, e, B, S, H, C, P, N)$$

read from an accepted carrier and classifier of Definition 1205.1 and Definition 1205.2. The rows M, Q, B, S *are respectively the cofinal modulus seal, finite-prefix limit budget, displayed budget row, and selected finite prefix window; the rows* X, μ, n, k, i *are the cofinal index rows with*

$$k = \mu(1/(n+1))$$

and

$$i = k + n + 1.$$

The rows w, r, d, e *are the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal for that same index row. The support rows* H, C, P, N *are the displayed* BHist*, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *naming data attached to the selected terminal diagonal route.*

This packet is sourced by the root-index coverage surface, cofinal-tail extraction surface, finite selector exhaustion surface, terminal-pullback obligation surface, and Real-completion consumer exactness surface. It records only finite BEDC rows; it exports no host selection function, quotient stream equality, host real equality, countable choice, completed limit object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 1205.98 (Diagonal-limit representative terminal-diagonal coverage)**.** *Every accepted terminal-diagonal selector packet* Δ *for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *exposes, for each displayed finite prefix window* S*, one terminal representative row*

$$(X, \mu, n, k, i, w, r, d, e)$$

with its cofinal modulus seal M*, finite-prefix budget rows* Q, B, S*, and support rows* H, C, P, N*. The exposed row is exactly the row routed by the root-index coverage theorem, cofinal-tail coverage theorem, finite selector exhaustion theorem, terminal-pullback source coverage theorem, and Real-completion consumer exactness theorem.*

Proof. First read the root-index coverage theorem Definition 1205.53. It makes the displayed equations for k and i visible before any terminal consumer reads the selected window, readback, dyadic ledger, or Real seal.

Next attach cofinal-tail coverage and finite selector exhaustion, Definition 1205.64 and Definition 1205.90. These two surfaces place the cofinal modulus seal, finite-prefix budget rows, selected finite prefix window, and fixed selector rows on the same finite BHist route.

Finally use terminal-pullback source coverage and Real-completion consumer exactness, Definition 1205.94 and Definition 1205.86. They force the terminal Real seal to be consumed only after the selected StreamName, RegSeqRat, DyadicRatCore, budget, cofinal modulus, provenance, and naming rows are displayed. Hence every displayed finite prefix window exposes the stated terminal representative row and no off-packet selector is available. □

Theorem 1205.99 (Diagonal-limit representative terminal-diagonal transport)**.** *Let Δ and Δ' be accepted terminal-diagonal selector packets for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *whose corresponding rows are related by the componentwise* hsame *rows and displayed* Cont *replay of Definition 1205.2. Then the selected terminal diagonal route*

$$(M, Q, X, \mu, n, k, i, w, r, d, e, B, S, H, C, P, N)$$

is preserved componentwise. In particular, transport cannot replace the selected terminal row by a second cofinal index row, a hidden diagonal selector, quotient stream equality, host $\mathsf{Real}^{\uparrow}$ *equality, countable choice, or ambient completeness data.*

Proof. Start from terminal-diagonal coverage. By Definition 1205.98, each accepted selector packet has concrete rows for the cofinal modulus seal, finite-prefix budget, selected index equations, terminal representative row, and support data.

Now apply the classifier stability already available on the cofinal-tail and terminal-pullback surfaces. The cofinal-tail classifier stability theorem preserves the selected cofinal rows and budget rows, while the terminal-pullback classifier stability theorem preserves the StreamName, RegSeqRat, DyadicRatCore, and Real rows through the displayed hsame and Cont data.

The support rows close the transport claim. Since H, C, P, N only record componentwise history, continuation replay, provenance, and local naming for the same finite packet, transport has no coordinate in which to insert an alternate terminal row or a stronger equality principle. Thus the selected terminal diagonal route is preserved exactly componentwise. □

Theorem 1205.100 (Diagonal-limit representative terminal-diagonal Real handoff)**.** *Every Real-and-Completion consumer of an accepted terminal-diagonal selector packet for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *receives only the selected terminal diagonal row, the finite-prefix budget rows, the cofinal modulus seal, and the visible continuation and provenance rows*

$$(X, \mu, n, k, i, w, r, d, e, Q, B, S, M, C, P, N).$$

The handoff factors through the terminal-diagonal selector of Definition 1205.97; it does not import host choice, quotient classes, Real completeness, an ambient diagonal selection principle, or any off-packet terminal representative.

Proof. Coverage supplies the positive handoff. By Definition 1205.98, the selected terminal row and its budget, cofinal modulus, continuation, provenance, and naming rows are already displayed before the Real-and-Completion consumer can use the terminal seal.

Transport supplies stability of the handoff. By Definition 1205.99, componentwise hsame and displayed Cont replay preserve the same selected row and cannot exchange it for another terminal representative.

It remains to identify the consumer boundary. Real-completion consumer exactness, Definition 1205.86, says that the downstream consumer factors through the displayed StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, Real, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ data. Therefore the Real handoff receives exactly the finite rows in the statement and no host selection, quotient, completeness, or off-packet diagonal principle. □

Theorem 1205.101 (Diagonal-limit representative finite-tail selector uniqueness)**.** *Let a Real-and-Completion consumer read an accepted terminal-diagonal selector packet for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *through a displayed finite tail. Once the root-index rows* X, μ, n, k, i*, the cofinal-tail rows, the terminal-pullback rows, and the terminal-diagonal selector of Definition 1205.97 are fixed, the consumer has exactly one displayed selector route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{FinitePrefixLimitBudget}^{\uparrow} \longrightarrow \mathsf{CofinalModulusSeal}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

through the packet rows

$$(M, Q, X, \mu, n, k, i, w, r, d, e, B, S, H, C, P, N).$$

The uniqueness is finite-route uniqueness inside BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$*; it is not quotient stream equality, host real equality, a selected host limit, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a Lean bridge claim.*

Proof. Start with root-index coverage, Definition 1205.53. It fixes the displayed equations $k = \mu(1/(n+1))$ and $i = k + n + 1$ before the consumer can read the StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, or Real rows.

Next attach cofinal-tail coverage and terminal-pullback source coverage, Definition 1205.64 and Definition 1205.94. These two surfaces place the cofinal modulus seal, finite-prefix budget, selected window, readback, dyadic ledger, and terminal seal on the same finite tail.

Finally use terminal-diagonal coverage, Definition 1205.98. It packages the same rows as one terminal selector packet, while the support rows H, C, P, N only transport, replay, source, and name that packet. Hence a consumer with the fixed finite tail has exactly the displayed route and no coordinate from which to choose a second selector. □

Theorem 1205.102 (Diagonal-limit representative finite-tail selector nonescape)**.** *Every accepted Real-and-Completion consumer of a finite-tail selector route for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *remains inside the displayed rows supplied by* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{CofinalModulusSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*. The route may be transported only by the recorded componentwise* hsame *rows and displayed* Cont *replay of the same packet*

$$(M, Q, X, \mu, n, k, i, w, r, d, e, B, S, H, C, P, N).$$

It cannot escape to quotient stream equality, host stream equality, host real equality, a selected host limit, countable choice, ambient Real completeness, a hidden diagonal selector, or a detached terminal seal.

Proof. Read the cofinal-tail classifier stability theorem, Definition 1205.65. It confines the selected index rows, finite-prefix budget rows, cofinal modulus data, and support rows to componentwise transport.

Now apply terminal-pullback classifier stability, Definition 1205.95. The StreamName window, RegSeqRat readback, DyadicRatCore ledger, and Real seal are preserved only through the finite terminal-pullback packet.

The terminal-diagonal transport theorem Definition 1205.99 closes the boundary. Since transport has no coordinate for a quotient class, host equality, selected limit, choice functional, completeness witness, hidden selector, or detached seal, every accepted consumer remains on the displayed finite-tail selector route. □

Theorem 1205.103 (Diagonal-limit representative finite-tail selector obligation package)**.** *The finite-tail selector obligation package for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *consists exactly of root-index coverage, cofinal-tail coverage, terminal-pullback source coverage, terminal-diagonal coverage, finite-tail selector uniqueness, and finite-tail selector nonescape. A downstream Real-and-Completion consumer may cite this package as the complete finite-route obligation target for the selector route through*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{FinitePrefixLimitBudget}^{\uparrow},\quad \mathsf{CofinalModulusSeal}^{\uparrow},\quad \mathsf{Real}^{\uparrow},$$

together with BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support. The package does not assert quotient stream equality, host Real equality, selected host limits, countable choice, ambient Real completeness, or any checked Lean target.*

Proof. The positive route is supplied by the cited coverage surfaces. Root-index coverage fixes the computed selector indices, cofinal-tail coverage joins those indices to the finite-prefix and cofinal modulus rows, terminal-pullback source coverage exposes the StreamName, RegSeqRat, DyadicRatCore, and Real rows, and terminal-diagonal coverage repackages them for Real-and-Completion consumption.

Uniqueness supplies the determinate selector claim. By Definition 1205.101, fixing the finite tail fixes one displayed route through the six named sibling surfaces and the local support rows.

Nonescape supplies the ledger boundary. By Definition 1205.102, the package has no outlet to quotient, host-equality, selected-limit, choice, completeness, hidden-selector, or Lean-bridge data. Therefore the listed theorems form exactly the finite-tail selector obligation package available to downstream consumers. □

Theorem 1205.104 (Diagonal-limit representative terminal cofinal extraction)**.** *For every accepted Real-and-Completion consumer of a shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *packet, the terminal row factors through one displayed cofinal extraction surface. The extraction first exposes the root-index rows* X, μ, n, k, i*, then the selected* $\mathsf{StreamName}^{\uparrow}$ *window* w*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* r*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d*, finite-prefix budget rows, cofinal modulus rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* e*. Its support is exactly the finite* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *route already named by the cofinal-terminal budget bridge, so the consumer reads one finite extraction package rather than separate local witnesses.*

Proof. Begin with the root-index readiness package, Definition 1205.55. It fixes the equations $k = \mu(1/(n+1))$ and $i = k + n + 1$ before the selected StreamName, RegSeqRat, DyadicRatCore, finite-prefix, cofinal, and Real rows can be consumed.

Next apply terminal row coverage and cofinal selector transport, Definition 1205.84 and Definition 1205.85. Coverage supplies the ordered terminal path through the named sibling certificates, while transport confines the selector equations and cofinal rows to the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ containers.

Finally use the finite-tail selector obligation package, Definition 1205.103. It states that the visible finite route is the whole selector obligation available to a downstream consumer. Therefore the terminal row has one cofinal extraction surface containing the root-index, finite-prefix budget, StreamName, RegSeqRat, DyadicRatCore, cofinal modulus, Real seal, and local support rows. □

Theorem 1205.105 (Diagonal-limit representative Real-seal extraction)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal exported by the terminal cofinal extraction theorem is only the finite seal row e already routed by the cofinal-terminal budget bridge of Definition 1205.56. A consumer may cite the seal after the displayed cofinal index, finite-prefix budget, StreamName, RegSeqRat, DyadicRatCore, cofinal modulus, and local support rows have been exposed, but the citation does not introduce host real equality, quotient stream equality, a selected host limit, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a detached completion principle.*

Proof. Project the cofinal-terminal budget bridge. Its definition identifies the representative window w with the cofinal window row T_M, the readback r with R_M, the dyadic ledger d with D_M, and the terminal seal e with E_M.

Now apply cofinal-budget seal totality, Definition 1205.57. The seal is read only after the route

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{FinitePrefixLimitBudget}^{\uparrow} \to \mathsf{CofinalModulusSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

has been displayed on the finite packet.

It remains to rule out a stronger export. Use terminal consumer cofinal nonescape, Definition 1205.58. Since the consumer has no coordinate for quotient equality, host equality, selected limits, choice, ambient completeness, or a detached seal, the exported Real seal is exactly the finite row already routed by the bridge. □

Theorem 1205.106 (Diagonal-limit representative L10 completion root package)**.** *The L10 completion root package for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *consists exactly of terminal cofinal extraction, Real-seal extraction, the root-readiness triad of Definition 1205.44, the NameCert ledger of Definition 1205.80, the formal handoff boundary of Definition 1205.69, and the Real-completion consumer exactness theorem of Definition 1205.86. This package is the citable finite completion-frontier handoff from the diagonal representative to downstream Real and Completion consumers, and it carries no host limit, quotient equality, countable choice, ambient Real completeness, or Lean bridge claim.*

Proof. The positive extraction surface is supplied by Definition 1205.104. It gathers the root-index, selected window, readback, dyadic ledger, finite-prefix budget, cofinal modulus, Real seal, and local BEDC support rows into one terminal cofinal package.

The exported seal boundary is supplied by Definition 1205.105. It identifies the Real seal as the finite bridge row already routed through the cofinal-terminal budget surface, not a stronger analytic object.

The remaining cited theorems close the root package. The root-readiness triad exposes the root route, the NameCert ledger names the available obligations, the formal handoff boundary prevents stronger data from entering the formal interface, and Real-completion consumer exactness states that downstream consumers factor through the named finite package. Hence the listed theorems form the terminal L10 completion root package available for citation. □

Definition 1205.107 (Diagonal-limit representative completion-selector ledger)**.** *The completion-selector ledger for an accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier is the finite* BHist *packet*

$$L = (X, \mu, n, k, i, w, r, d, e, H, C, P, N; Q, B, W, D_F, R, S, E_F, H_F, C_F, P_F, N_F; B_M, M_M, W_M, T_M, D_M, R_M, L_M, E$$

The first block is the displayed representative row of Definition 1205.1; the second block is the finite-prefix and terminal-budget row of Definition 1205.32; and the third block is the cofinal-modulus row

already named by the cofinal-terminal budget bridge of Definition 1205.56. The ledger records only the selector equations, the selected $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, finite-prefix budget rows, cofinal modulus rows, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support. It exports no host limit, quotient stream equality, selected completion point, countable choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness field.*

Theorem 1205.108 (Diagonal-limit representative completion-selector existence)**.** *Every accepted shared-terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier whose terminal cofinal extraction is accepted admits the ledger of Definition 1205.107. The ledger is obtained by projecting the accepted representative carrier, the shared-terminal finite-prefix package, and the cofinal-terminal budget bridge; it is not obtained by choosing a completion point outside the displayed packet.*

Proof. Project the representative carrier. It supplies the finite row $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ and records the selector equations $k = \mu(1/(n+1))$ and $i = k + n + 1$ as carrier data.

Attach the shared-terminal carrier and the cofinal-terminal budget bridge. These two surfaces provide the finite-prefix rows and the cofinal modulus rows already used by terminal cofinal extraction, with w, r, d, e identified with the downstream StreamName, RegSeqRat, DyadicRatCore, and Real seal rows.

Finally apply Definition 1205.104. It states that a Real-and-Completion consumer reads one finite extraction package rather than separate witnesses. Repack those displayed rows as L; no quotient equality, host limit, selected completion point, choice row, or ambient completeness field is introduced. □

Theorem 1205.109 (Diagonal-limit representative completion-selector stability)**.** *Let two accepted completion-selector ledgers for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *agree componentwise by the recorded* hsame *rows and by displayed* Cont *replay on their representative rows, finite-prefix budget rows, cofinal modulus rows, provenance rows, and local* $\mathsf{NameCert}$ *rows. Then they determine the same selector handoff route through*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{FinitePrefixLimitBudget}^{\uparrow} \to \mathsf{CofinalModulusSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The stability is stability of the displayed ledger, not equality of quotient streams, host Real points, chosen completion points, or ambient completion witnesses.

Proof. Begin with cofinal selector transport, Definition 1205.85. It confines the selected equations, selected window, readback, dyadic ledger, finite-prefix budget rows, cofinal modulus rows, and terminal seal to the recorded BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ containers.

Next use terminal pullback determinacy, Definition 1205.71. Componentwise agreement on the representative rows and shared-terminal budget rows determines the same terminal $\mathsf{Real}^{\uparrow}$ seal route and finite-prefix budget pullback.

It remains to include the cofinal modulus block. The cofinal-terminal route determinacy theorem identifies the cofinal modulus rows and the terminal seal as part of the same finite bridge. Therefore componentwise hsame and displayed Cont replay preserve the completion-selector handoff route exactly as the displayed ledger route. □

Theorem 1205.110 (Diagonal-limit representative completion handoff exhaustion)**.** *Every Real-and-Completion consumer of an accepted completion-selector ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *factors through the six displayed sibling surfaces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{FinitePrefixLimitBudget}^{\uparrow}, \quad \mathsf{CofinalModulusSeal}^{\uparrow}, \quad \mathsf{Real}^{\uparrow},$$

together with the finite BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support of the ledger. The handoff exhausts the L10 root obligations available to such consumers and claims no host limit, quotient stream equality, selected completion point, countable choice, or ambient Real completeness.*

Proof. The positive route is supplied by the L10 completion root package of Definition 1205.106. That package gathers terminal cofinal extraction, Real-seal extraction, root-readiness, the local NameCert ledger, the formal handoff boundary, and Real-completion consumer exactness.

Existence of the completion-selector ledger repackages exactly those rows as the finite packet L. Stability shows that accepted hsame transport and displayed Cont replay preserve the same route through the six sibling surfaces.

For exhaustion, apply Real-completion consumer exactness and finite-tail selector obligation packaging, Definition 1205.86 and Definition 1205.103. They leave every downstream consumer inside the StreamName, RegSeqRat, DyadicRatCore, finite-prefix budget, cofinal modulus, Real, and local support rows. The excluded host, quotient, selected-point, choice, and ambient-completeness data have no coordinate in L, so the displayed handoff is the whole consumer surface. □

Theorem 1205.111 (Diagonal-limit representative terminal-root admission)**.** *Let* $D = (X, \mu, n, k, i, w, r, d, e, H, C,$ *be an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier. Its terminal root is admitted only through the displayed route consisting of the* $\mathsf{StreamName}^{\uparrow}$ *window* w*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* r*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* e*, and the support rows* H, C, P, N*. The admission also requires the selected-index equations* $k = \mu(1/(n+1))$ *and* $i = k + n + 1$ *to be exposed on the same finite* BHist *route before any downstream Real-and-Completion consumer may read the terminal row.*

Proof. Apply root-readiness exactness, Definition 1205.49. It gives coverage, soundness, and completeness for the displayed route through the selected indices, window, readback, dyadic ledger, terminal seal, and local support rows.

Next use terminal cofinal extraction, Definition 1205.104. It extracts the terminal package only after the root-index, finite-prefix budget, cofinal modulus, and Real seal rows have appeared on the same finite surface.

Finally apply Real-completion consumer exactness, Definition 1205.86. It confines every accepted consumer to the named StreamName, RegSeqRat, DyadicRatCore, Real, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ rows, so no terminal root is admitted off the displayed route. □

Theorem 1205.112 (Diagonal-limit representative selected-tail coverage)**.** *For an accepted terminal-root package of* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$*, the selected equations* $k = \mu(1/(n+1))$ *and* $i = k + n + 1$*, the window/readback/ledger/seal rows* w, r, d, e*, and the finite support rows* H, C, P, N *exhaust every selected-tail read available to a downstream Real-and-Completion consumer. Any selected-tail read must therefore factor through the finite route*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

together with the displayed local support.

Proof. Start with root-index readiness, Definition 1205.55. It makes the equations for k and i part of the visible root-index surface before the selected window, readback, ledger, and seal rows can be consumed.

Attach cofinal-tail coverage, Definition 1205.64. This places the selected tail on the same finite-prefix and cofinal-modulus route as the terminal seal, so a selected-tail read cannot detach from the displayed StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Use finite-tail selector uniqueness, Definition 1205.101, for the last coordinate check. Once the selected equations and support rows agree, the accepted selected-tail route is unique up to the recorded hsame rows and displayed Cont replay, so the listed rows exhaust the selected-tail surface. □

Theorem 1205.113 (Diagonal-limit representative completion-consumer nonescape)**.** *Downstream Real-and-Completion consumers may cite the terminal-root package of* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *as a finite BEDC source surface. Such consumers may use the displayed StreamName window, RegSeqRat readback, DyadicRatCore ledger, Real seal, selected-index equations, and local support rows, but they may not extract quotient stream equality, a host limit, a selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from that citation.*

Proof. Apply the formal handoff boundary, Definition 1205.69. It records that the formal surface contains the carrier rows, shared-terminal rows, root-readiness rows, and local support, and no additional selector, equality principle, host limit, or ambient completion field.

Then apply completion handoff exhaustion, Definition 1205.110. Every Real-and-Completion consumer factors through the displayed sibling surfaces and local support rows, so all permitted reads are already named by the terminal-root package.

The excluded objects have no coordinate in that finite package. Quotient stream equality, host limits, selected limits, choice rows, and ambient Real completeness therefore cannot be extracted by a downstream consumer that cites only the terminal-root package. □

Theorem 1205.114 (Diagonal-limit representative four-object source exhaustion)**.** *Every accepted completion-selector ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *exposes exactly the four source rows needed by a Phase Real and Completion consumer: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. These rows are read through the finite* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support already displayed by the ledger, with the sibling chapters chapter 291, chapter 126, chapter 301, and chapter 38 supplying the cited source surfaces.*

Proof. Start with the StreamName–RegSeqRat handoff of Definition 1205.16. It orders every accepted route to the seal through the selected finite window w, the selected regular-rational readback r, the downstream dyadic ledger d, and the terminal Real seal e.

Now use the L10 completion root package of Definition 1205.106. That package gathers the root-index, terminal cofinal extraction, Real-seal extraction, NameCert ledger, formal handoff boundary, and Real-completion consumer exactness rows into one finite completion-frontier handoff.

Finally apply completion handoff exhaustion, Definition 1205.110. It states that every Real-and-Completion consumer remains inside the displayed StreamName, RegSeqRat, DyadicRatCore, finite-prefix, cofinal-modulus, Real, and local support rows. Projecting the four requested source coordinates gives the listed DyadicRatCore radius, StreamName finite-window, RegSeqRat regularity, and Real seal rows. □

Theorem 1205.115 (Diagonal-limit representative Phase Real and Completion exit certificate)**.** *For every accepted completion-selector ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$*, the four rows named in Definition 1205.114 form the Phase Real and Completion exit packet. The packet is a finite*

BEDC source certificate over DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$*; it carries no quotient stream equality, no countable or dependent choice principle, no ambient completeness theorem, no trichotomy claim, and no open-cover compactness claim.*

Lean4 ✓ `BEDC.Derived.DiagonallimitrepresentativeUp.DiagonalLimitRepresentativePhaseRealCompletionExitCe`

Proof. The four-object exhaustion theorem supplies the source coordinates and ties them to the four sibling chapters. Thus the packet has named BEDC sources for radius accounting, finite-window exposure, regularity readback, and terminal Real sealing.

The completion-selector ledger of Definition 1205.107 records the same rows inside one finite BHist tuple with hsame, Cont, Pkg, and local NameCert support. It also states that host limits, quotient stream equality, selected completion points, choice rows, and ambient completeness fields are not ledger coordinates.

Use completion handoff exhaustion to close the certificate boundary. Since every consumer factors through the displayed finite rows, stronger analytic principles such as trichotomy or open-cover compactness cannot enter through this exit packet. □

Theorem 1205.116 (Diagonal-limit representative audit-clean consumer handoff)**.** *Downstream Real-completion consumers may cite the Phase Real and Completion exit packet of Definition 1205.115 as the finite BEDC source surface for* DiagonalLimitRepresentative$^{\uparrow}$*. Such a citation commits only to the displayed DyadicRatCore, StreamName, RegSeqRat, Real, and local support rows, and not to any off-packet completion principle or hidden selector.*

Proof. Begin with the Phase Real and Completion exit certificate. It identifies the four named source rows as the whole exit packet and excludes quotient, choice, ambient completeness, trichotomy, and open-cover compactness claims.

Then apply the completion handoff exhaustion theorem. Any Real-and-Completion consumer of the accepted ledger factors through the displayed sibling surfaces and the finite local support rows, so citing the exit packet is sufficient for downstream source accounting.

The L10 completion root package supplies the public citation boundary. It gathers the relevant terminal extraction, Real-seal extraction, root-readiness, NameCert, formal handoff, and consumer exactness results without exporting a stronger completion object. Therefore the handoff is audit-clean as a finite BEDC source surface. □

Theorem 1205.117 (Diagonal-limit representative exact-boundary consumer pullback)**.** *Every downstream Real-completion consumer of an accepted* DiagonalLimitRepresentative$^{\uparrow}$ *completion-selector ledger that supplies a same-route* RealCompletionExactBoundaryUp *face factors through the same four rows named in Definition 1205.114, and then through the* PhaseRealCompletionExit$^{\uparrow}$ *public gate. The pullback exports no quotient stream equality, selected limit, countable choice, host* Real$^{\uparrow}$ *equality, ambient completeness, metric completeness, trichotomy, open-cover compactness, or bridge-checked conclusion.*

Proof. First use Definition 1205.114. It identifies the only source rows exposed by the accepted completion-selector ledger as the DyadicRatCore$^{\uparrow}$ radius row, StreamName$^{\uparrow}$ finite-window row, RegSeqRat$^{\uparrow}$ regularity readback row, and terminal Real$^{\uparrow}$ seal row.

Next apply Definition 126.504. A downstream Real-completion read on those four faces factors through the terminal finite pullback determined by the same rows and the displayed BHist, hsame, Cont, Pkg, and local NameCert support.

The supplied RealCompletionExactBoundaryUp face is consumed only on that route. By Definition 1120.20, it remains a scoped exact-boundary witness and contributes no separate quotient,

selector, host-equality, completeness, metric-completeness, choice, trichotomy, compactness, or bridge row.

Finally use the diagonal phase-exit certificate, Definition 1205.115, together with the public gate certificate Definition 1327.18. These two certificates repack the same four-row route and the same-route exact-boundary face as the $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ public gate, so every such consumer factors through that gate without exporting any stronger completion principle. □

Theorem 1205.118 (Diagonal-limit representative phase-source coverage)**.** *Every accepted completion-selector ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *exposes the Phase Real source surface through exactly the four named source rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The $\mathsf{DyadicRatCore}^{\uparrow}$ *row records the tolerance and rational-arithmetic ledger, the* $\mathsf{StreamName}^{\uparrow}$ *row records the selected finite observation window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row records the selected regular-rational readback, and the* $\mathsf{Real}^{\uparrow}$ *row records the terminal seal reached by that readback. The ledger's* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *rows only transport, replay, source, and name these four rows; they do not expose a fifth phase source, a quotient-stream equality, a selected completion point, a countable-choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the completion-selector ledger of Definition 1205.107. Its displayed coordinates include the selected window w, readback r, dyadic ledger d, terminal seal e, and the support rows H, C, P, N.

Read those coordinates through the four sibling surfaces. The window w is a $\mathsf{StreamName}^{\uparrow}$ row, the readback r is a $\mathsf{RegSeqRat}^{\uparrow}$ row, the ledger d is a $\mathsf{DyadicRatCore}^{\uparrow}$ row, and the seal e is a $\mathsf{Real}^{\uparrow}$ row.

For exhaustion, apply the four-object source exhaustion theorem and the Phase Real and Completion exit certificate, Definition 1205.114 and Definition 1205.115. They identify the same four rows as the complete exit packet and exclude quotient, choice, selected-point, and ambient-completeness coordinates. Therefore the finite diagonal representative exposes exactly the four phase sources listed above. □

Theorem 1205.119 (Diagonal-limit representative tail-selector compatibility)**.** *Let L and L' be accepted completion-selector ledgers for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *whose selected diagonal routes are classified together by their recorded* hsame *rows and displayed* Cont *replay. Then the selected tail data remain compatible with the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *classifiers: the selected finite windows stay on the same* $\mathsf{StreamName}^{\uparrow}$ *route, the selected regular-rational readbacks stay on the same* $\mathsf{RegSeqRat}^{\uparrow}$ *route, and no hidden tail selector may replace either route while preserving the accepted completion-selector ledger.*

Proof. Begin with completion-selector stability, Definition 1205.109. It states that componentwise agreement and displayed replay determine the same selector handoff route through the StreamName, RegSeqRat, DyadicRatCore, finite-prefix, cofinal-modulus, and Real surfaces.

Project the two tail coordinates from that route. The $\mathsf{StreamName}^{\uparrow}$ classifier sees only the selected finite-window rows, while the $\mathsf{RegSeqRat}^{\uparrow}$ classifier sees only the selected readback rows reached from those windows. Componentwise hsame transport and displayed Cont replay preserve those rows as ledger data rather than recomputing them by an external selector.

Finally use the support-scope nonescape theorem, Definition 1205.8. It excludes hidden selectors, quotient streams, detached windows, alternate dyadic ledgers, and off-packet terminal seals

from the accepted transport surface. Hence tail selection is compatible with the two classifiers exactly because both tail rows remain visible inside the same finite ledger. □

Theorem 1205.120 (Diagonal-limit representative Real handoff exactness)**.** *For every accepted completion-selector ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$*, the* $\mathsf{Real}^{\uparrow}$ *handoff is exactly the terminal seal row reached after the displayed* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger. A downstream Real-completion consumer may cite this handoff as a finite source boundary, but the citation does not assert ambient* $\mathsf{Real}^{\uparrow}$ *completeness, a selected host limit, quotient-stream equality, or global uniqueness of completed limits.*

Proof. First read the terminal route in the carrier. The Real-seal factorization theorem, Definition 1205.10, places every $\mathsf{Real}^{\uparrow}$ consumer read after the selected modulus index, selected window, selected readback, and dyadic ledger.

Next pass from the carrier to the completion-selector ledger. Completion-selector existence repackages the representative row, finite-prefix rows, cofinal-modulus rows, and terminal seal row into one finite packet, while completion handoff exhaustion keeps every Real-and-Completion consumer inside the displayed sibling surfaces.

The exact handoff is therefore the seal coordinate already present in the ledger. The Phase Real and Completion exit certificate names that coordinate as a finite BEDC source row and explicitly excludes quotient, choice, selected-point, and ambient-completeness claims. Thus the handoff is exact as a source boundary without becoming a Real-completeness principle. □

Theorem 1205.121 (Diagonal-limit representative phase-source projection totality)**.** *Every accepted completion-selector ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *has a total visible-source projection onto exactly the four Phase Real rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The projection sends the accepted ledger to its dyadic arithmetic ledger, selected finite window, selected regular-rational readback, and terminal Real seal, and every displayed BHist, hsame, Cont, Pkg*, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *row only transports, replays, sources, or names those four rows. No fifth source row, quotient-stream equality, host limit, selected completed point, countable-choice row, or ambient Real-completeness field is part of the projection.*

Proof. Start with phase-source coverage, Definition 1205.118. It already identifies the visible source surface of an accepted completion-selector ledger with the dyadic ledger, selected window, selected readback, and terminal Real seal, with the local support rows serving only as transport and naming data.

Next apply four-object source exhaustion, Definition 1205.114. It rules out additional Phase Real source coordinates and pins the exit packet to $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally read the completion-selector ledger definition, Definition 1205.107. Its coordinates supply each of the four rows named above, so the projection is total on accepted ledgers; because the definition has no coordinate for quotient equality, host limits, selected completed points, choice, or ambient completeness, the projection is exhausted by those four rows. □

Theorem 1205.122 (Diagonal-limit representative selector-source nonescape)**.** *For every accepted completion-selector ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$*, the selected windows, regular-rational readbacks, and terminal seals cannot be replaced by hidden selectors, quotient-stream equality, host*

limits, selected completed points, countable choice, or ambient Real completeness while preserving the same ledger. Any replacement that still preserves the ledger must factor through the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *rows already present in the ledger.*

Proof. First use tail-selector compatibility, Definition 1205.119. It keeps the selected finite windows on the displayed $\mathsf{StreamName}^{\uparrow}$ route and the selected regular-rational readbacks on the displayed $\mathsf{RegSeqRat}^{\uparrow}$ route under the recorded hsame rows and Cont replay.

Next use support-scope nonescape, Definition 1205.8. That theorem confines accepted transport and replay to the local BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support, so a detached selector or quotient-stream replacement has no support coordinate.

Finally apply completion-consumer nonescape, Definition 1205.113. Downstream Real-and-Completion reads remain inside the terminal-root package, so host limits, selected completed points, countable choice, and ambient Real completeness cannot preserve the same accepted ledger as replacement sources. □

Theorem 1205.123 (Diagonal-limit representative completion-frontier readback coverage)**.** *Every downstream Real-and-Completion consumer reads* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *only through the finite completion-frontier route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

together with the displayed BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support. The readback surface is exhausted by this route and does not add quotient-stream equality, host Real equality, a selected completed point, countable choice, ambient Real completeness, or a second completion selector.*

Proof. Begin with Real handoff exactness, Definition 1205.120. It identifies the Real-facing endpoint with the terminal seal reached after the selected $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ ledger.

Then compose this endpoint with the L10 completion root package, Definition 1205.106. The package gathers terminal cofinal extraction, Real-seal extraction, root-readiness, the local NameCert ledger, the formal handoff boundary, and Real-completion consumer exactness as the finite completion-frontier citation surface.

Finally apply completion handoff exhaustion, Definition 1205.110. It keeps every downstream consumer inside the displayed sibling surfaces and local support rows, so the only possible readback route is the finite frontier stated above, and the excluded quotient, host, selected-point, choice, completeness, and second-selector data have no remaining coordinate. □

Theorem 1205.124 (Diagonal-limit representative root-window extraction)**.** *Every accepted completion-selector ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *determines the finite five-row root-window package*

$$\Omega = (W, R, D, M, E)$$

where W *is the selected* $\mathsf{StreamName}^{\uparrow}$ *window supplied by chapter 126,* R *is the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *readback supplied by chapter 301,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger supplied by chapter 291,* M *is the* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *budget row supplied by chapter 1198, and* E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal supplied by chapter 38. The package is extracted from the displayed carrier, cofinal bridge, and completion-selector rows; it carries no host limit, quotient stream equality, hidden tail selector, countable-choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness field.*

Proof. Project the completion-selector ledger of Definition 1205.107. Its first block exposes the selected window w, readback r, dyadic ledger d, and terminal seal e, while its cofinal block exposes the modulus-seal budget rows.

Use the sibling identifications already recorded by the ledger. The selected window is sourced by $\mathsf{StreamName}^{\uparrow}$, the readback by $\mathsf{RegSeqRat}^{\uparrow}$, the tolerance ledger by $\mathsf{DyadicRatCore}^{\uparrow}$, the cofinal budget by $\mathsf{CofinalModulusSeal}^{\uparrow}$, and the terminal seal by $\mathsf{Real}^{\uparrow}$ through the five chapter references in the statement.

Finally apply completion handoff exhaustion, Definition 1205.110. It keeps every Real-and-Completion consumer inside the displayed finite rows, so repacking them as Ω introduces no off-packet limit, equality, selector, choice, or completeness datum. □

Theorem 1205.125 (Diagonal-limit representative regularity handoff)**.** *For every root-window package $\Omega = (W, R, D, M, E)$ extracted by Definition 1205.124, the regularity handoff to a downstream completion consumer factors first through the* $\mathsf{StreamName}^{\uparrow}$ *window W of chapter 126 and then through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R of chapter 301. The* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D,* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *budget M, and* $\mathsf{Real}^{\uparrow}$ *seal E may only be consumed after that window-readback route is displayed.*

Proof. Begin with the root-window extraction theorem. It presents all five rows as one finite packet, so the downstream consumer reads a displayed root window rather than a detached completion request.

Now apply the StreamName–RegSeqRat handoff, Definition 1205.16. That theorem orders the selected window before the selected regular-rational readback inside the representative carrier.

The remaining rows are downstream of the same route. The dyadic ledger records the readback tolerance, the cofinal budget records the admissible tail budget, and the Real seal is terminal. Hence none of D, M, E can be consumed before the $W \to R$ regularity route has been displayed. □

Theorem 1205.126 (Diagonal-limit representative Real-seal admissibility)**.** *For every extracted root-window package $\Omega = (W, R, D, M, E)$, the terminal* $\mathsf{Real}^{\uparrow}$ *row E is admissible for Real-and-Completion consumers exactly as the finite seal reached after the* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, and* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *budget M. This admissibility cites chapter 38 only as a displayed seal surface; it does not cite quotient equality, host Real equality, a chosen completed point, or ambient Real completeness.*

Proof. Read the positive seal route from Real handoff exactness, Definition 1205.120. It identifies the Real-facing endpoint with the terminal seal row reached after the selected window, readback, and dyadic ledger.

Add the cofinal budget row from the extracted package. The budget is already part of the completion-selector ledger and is transported through the cofinal-terminal bridge, so it constrains the terminal handoff without creating a new Real object.

The admissibility claim is therefore only the displayed seal claim. The root-window package contains E as a finite BHist coordinate with hsame, Cont, Pkg, and local $\mathsf{NameCert}$ support; absent quotient, host equality, chosen-point, choice, and completeness rows cannot be used by the consumer. □

Theorem 1205.127 (Diagonal-limit representative cofinal-budget stability)**.** *Let $\Omega = (W, R, D, M, E)$ and $\Omega' = (W', R', D', M', E')$ be extracted root-window packages for accepted completion-selector ledgers classified together by the recorded* hsame *rows and displayed* Cont *replay. Then the cofinal budget rows M and M' remain on the same* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *route, and the associated*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows are preserved componentwise as the same root-window handoff.*

Proof. Start with completion-selector stability, Definition 1205.109. It preserves the representative rows, finite-prefix rows, cofinal modulus rows, terminal seal rows, provenance rows, and local naming rows under the recorded transport and replay data.

Project the two extracted root-window packages. Since Ω and Ω' are obtained only by projection from the corresponding ledgers, the hsame and Cont rows that classify the ledgers also classify W, W', R, R', D, D', M, M', and E, E'.

It remains to identify the cofinal budget route. The cofinal-terminal bridge keeps the cofinal modulus budget in the same finite handoff as the terminal Real seal, so stability of the cofinal row preserves the entire root-window package componentwise. □

Theorem 1205.128 (Diagonal-limit representative terminal-selector exactness)**.** *Every terminal selector read made by a Real-and-Completion consumer of* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *factors through the same extracted root-window package* $\Omega = (W, R, D, M, E)$*. Thus the consumer reads the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CofinalModulusSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows, together with the existing* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support, and no second selector route can supply the terminal seal.*

Proof. Use root-window extraction to obtain Ω from the accepted completion-selector ledger. The extraction has already gathered the finite window, readback, dyadic ledger, cofinal budget, and terminal seal rows into one displayed package.

Next apply phase-source coverage and the Phase Real and Completion exit certificate, Definition 1205.118 and Definition 1205.115. They identify the visible phase sources of the terminal read and exclude a hidden selector, quotient equality, selected host point, choice row, and ambient completeness principle.

Finally use cofinal-budget stability. Any accepted selector transport preserves the same root-window package under hsame and Cont, so a terminal selector read can only factor through W, R, D, M, E and the local support rows already present in the ledger. □

Theorem 1205.129 (Diagonal-limit representative selector choice refusal)**.** *Every terminal selector read accepted by a Real-and-Completion consumer of* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *factors through the extracted package* $\Omega = (W, R, D, M, E)$ *of Definition 1205.124. The read may use only the displayed* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *budget* M*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the recorded* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support. It cannot use countable choice, hidden tail selection, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted completion-selector ledger to the root-window package. By root-window extraction, the terminal read exposes exactly the five displayed rows W, R, D, M, E together with the local support rows of the carrier.

Next apply terminal-selector exactness and the Phase Real and Completion exit certificate, Definition 1205.128 and Definition 1205.115. These results identify the terminal consumer surface with the finite packet and its four phase sources.

The refusal clauses follow from absence of coordinates. Since the package exports no countable-choice row, no tail selector, no quotient stream equality, and no ambient completeness field, a terminal read has no constructor through which any of those data can enter. □

Theorem 1205.130 (Diagonal-limit representative terminal route uniqueness)**.** *Let two accepted terminal selector reads expose the same displayed root-window package* $\Omega = (W, R, D, M, E)$ *and the same* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support. Then they expose the same terminal route through* W, R, D, M, E *and cannot yield a second* $\mathsf{Real}^{\uparrow}$ *seal. In particular, equality of the displayed support identifies the terminal selector route as the unique finite route available to the Real-and-Completion consumer.*

Proof. Read both terminal selector claims through the common displayed package Ω. Terminal-selector exactness sends each accepted read to the route through the same window, readback, dyadic ledger, cofinal budget, and terminal seal rows.

Use cofinal-budget stability and regularity handoff, Definition 1205.127 and Definition 1205.125. The shared hsame and Cont support preserves the $W \to R$ regularity route and the cofinal budget row before the terminal seal is read.

Finally apply Real-seal admissibility and selector choice refusal. The only admissible seal is the displayed E reached after W, R, D, M, while selector choice refusal removes hidden tails, quotient equality, countable choice, and ambient completeness as alternate seal sources. Hence a second terminal route has no available coordinate. □

Theorem 1205.131 (Diagonal-limit representative Phase Real exit obligation package)**.** *The local Phase Real and Completion exit obligation for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is the package consisting of root-window extraction, regularity handoff, Real-seal admissibility, cofinal-budget stability, terminal-selector exactness, selector choice refusal, terminal route uniqueness, and the Phase Real and Completion exit certificate of Definition 1205.115. A downstream exit route for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *may consume this package as the finite terminal selector boundary and may not appeal to off-packet choice, quotient equality, hidden tail selection, selected host limits, or ambient Real completeness.*

Proof. Assemble the positive route first. Root-window extraction supplies $\Omega = (W, R, D, M, E)$; regularity handoff orders the $\mathsf{StreamName}^{\uparrow}$ window before the $\mathsf{RegSeqRat}^{\uparrow}$ readback; Real-seal admissibility identifies E as the displayed terminal seal; and cofinal-budget stability keeps M attached to the same finite terminal route.

Next add the selector boundary. Terminal-selector exactness says every accepted terminal read factors through Ω, selector choice refusal excludes non-displayed selector principles, and terminal route uniqueness prevents a second Real seal from being produced by the same support rows.

The Phase Real and Completion exit certificate supplies the consumer-facing source inventory. Therefore the local obligation package consumed by the exit route is precisely the finite carrier route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CofinalModulusSeal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with the stated refusal and uniqueness boundaries attached. □

Definition 1205.132 (Diagonal-limit representative route-read selector package)**.** *For an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier*

$$D = (X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the route-read selector package is the finite triple

$$\rho(D) = (\mathsf{indexRead}, \mathsf{terminalRead}, \mathsf{routeRead})$$

whose rows are exactly the displayed continuation outputs

$$\mathsf{Cont}(\mu, n, \mathsf{indexRead}), \qquad \mathsf{Cont}(w, r, \mathsf{terminalRead}), \qquad \mathsf{Cont}(d, e, \mathsf{routeRead}).$$

The first read is the modulus-request selector, the second read is the window-readback selector, and the third read is the ledger-real-seal selector. The package is carried with the same $\mathsf{Pkg}^{\mathrm{sig}}$ *local-name row as* D *and introduces no quotient stream equality, host* $\mathsf{Real}^{\uparrow}$ *equality, hidden selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Theorem 1205.133 (Diagonal-limit representative route-read coverage)**.** *Every accepted* DiagonalLimitRepresentat *carrier together with the three displayed* Cont *rows of Definition 1205.132 exposes exactly the route reads* indexRead*,* terminalRead*, and* routeRead *and the existing* $\mathsf{Pkg}^{\mathrm{sig}}$ *local-name package. These four outputs are the route-read obligation surface of the carrier:* indexRead *reads from the modulus request,* terminalRead *reads from the selected window and readback,* routeRead *reads from the ledger and terminal Real seal, and the local package row remains the one already named by the carrier.*

Proof. Project the carrier of Definition 1205.1. It provides the rows $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ and the local $\mathsf{Pkg}^{\mathrm{sig}}$ package over the same finite BHist surface.

Apply Definition 1205.3. With the three displayed continuation rows as inputs, it returns exactly the three derived reads and the same local package signature, with no additional carrier coordinate.

The sibling root results identify where those reads may be consumed. Root-readiness, Definition 1205.44, makes the modulus, window, readback, ledger, and seal route visible, while the root-window completion handoff keeps the Real-and-Completion consumer on that finite route. Hence coverage is precisely the package displayed above. □

Theorem 1205.134 (Diagonal-limit representative route-read unary closure)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier and route-read selector package* $\rho(D)$*, the three derived reads satisfy*

$$\mathsf{UnaryHistory}(\mathsf{indexRead}), \qquad \mathsf{UnaryHistory}(\mathsf{terminalRead}), \qquad \mathsf{UnaryHistory}(\mathsf{routeRead}).$$

Their unary status is obtained only by Cont *closure from the carrier rows* μ, n, w, r, d, e*; it is not a separate analytic or quotient witness.*

Proof. Read the unary carrier rows from Definition 1205.3. The theorem records μ, n, w, r, d, e as unary histories of the accepted packet.

Use the three Cont rows in the selector package. The same obligation theorem closes indexRead from μ, n, terminalRead from w, r, and routeRead from d, e by unary continuation closure.

Therefore the route reads remain finite BHist rows. The proof has no coordinate for quotient-stream equality, host Real equality, a chosen completed point, countable choice, or ambient Real completeness. □

Theorem 1205.135 (Diagonal-limit representative route-read consumer boundary)**.** *Downstream Real-and-Completion consumers of* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *may use the reads* indexRead*,* terminalRead*, and* routeRead *only through the finite package of Definition 1205.132. In particular, a consumer cannot replace that package by quotient-stream equality, host* $\mathsf{Real}^{\uparrow}$ *equality, a hidden selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiagonallimitrepresentativeUp.DiagonalLimitRepresentativeCarrier route read consumer boundary`

Proof. Begin with route-read coverage and unary closure. They make the three reads available exactly as finite BHist outputs of the displayed continuation rows, together with the existing local package signature.

Now apply the root-readiness exactness package and the root-window completion handoff, Definition 1205.49 and Definition 1205.124. These results require downstream consumers to factor through the displayed modulus, window, readback, ledger, cofinal-budget, and Real-seal route before consuming the terminal endpoint.

It remains to exclude stronger replacements. The carrier and the handoff theorems list no coordinate for quotient equality, host Real equality, hidden selectors, countable choice, or ambient completeness. Since the route-read package is exhausted by the three Cont outputs and the existing $\mathsf{Pkg}^{\mathrm{sig}}$ row, any such replacement lies outside the accepted consumer boundary. □

Theorem 1205.136 (Diagonal-limit representative roadmap exit inventory)**.** *The roadmap exit inventory for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is the ten-field paper-side contract obtained from the traditional diagonal representative as follows. Its source row is exactly the four-object route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

Its carrier is Definition 1205.1; its classifier is Definition 1205.2; its stability is supplied by terminal stability, completion-selector stability, and the audit-clean handoff of Definition 1205.5, Definition 1205.109, and Definition 1205.116; its ledger remains inside the displayed BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *rows; its exactness is the phase-source coverage, Real handoff exactness, and completion-frontier readback coverage of Definition 1205.118, Definition 1205.120, and Definition 1205.123; its bridge slot is pending; and its status is a paper-side source contract for Real-and-Completion consumers.*

Proof. Start from the traditional diagonal representative encoded by the carrier and classifier. These two definitions display the family row, modulus row, selected indices, selected $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, terminal $\mathsf{Real}^{\uparrow}$ seal, and local support rows.

The source inventory is the four-object exit packet of Definition 1205.114 and Definition 1205.115. Those results identify exactly the DyadicRatCore, StreamName, RegSeqRat, and Real rows used by the Phase Real and Completion consumer.

Stability and exactness are inherited from the already displayed terminal, selector, and handoff theorems named in the statement. Since each cited theorem uses the same finite ledger and the same local support rows, collecting them gives one citable ten-field contract rather than a stronger analytic object. □

Theorem 1205.137 (Diagonal-limit representative roadmap exit nonescape)**.** *The roadmap exit contract of Definition 1205.136 exports no quotient stream equality, no host* $\mathsf{Real}^{\uparrow}$ *equality, no selected completed point, no countable choice row, no trichotomy principle, no open-cover compactness principle, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem. Any accepted read of the contract must remain a read of the displayed finite route and its local BEDC support.*

Proof. Apply the Phase Real and Completion exit certificate. It already excludes quotient equality, choice, selected-point data, ambient completeness, trichotomy, and open-cover compactness from the exit packet.

Next apply selector-source nonescape and completion-frontier readback coverage, Definition 1205.122 and Definition 1205.123. They keep every accepted selector and downstream read inside the four source rows and the displayed BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ support.

Thus none of the excluded analytic or classical principles has a coordinate through which it can be exported by the roadmap exit contract. □

Theorem 1205.138 (Diagonal-limit representative roadmap exit consumer contract)**.** *Every downstream Real-and-Completion consumer may cite the roadmap exit contract only through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow},$$

together with the displayed BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *rows. The citation authorizes the carrier, classifier, ledger, stability, nonescape, and exactness fields named in Definition 1205.136, and it authorizes no route outside those rows.*

Proof. Begin with audit-clean consumer handoff, Definition 1205.116. It permits downstream consumers to cite the Phase Real and Completion exit packet as a finite BEDC source surface and refuses off-packet completion principles.

Use completion handoff exhaustion and phase-source coverage, Definition 1205.110 and Definition 1205.118. Together they force every consumer read through the displayed source rows and local support coordinates.

Finally apply the route-read consumer boundary, Definition 1205.135. It prevents the consumer from replacing the route-read package by quotient, host, selector, choice, or completeness data. Therefore the citation contract is exactly the finite route and support surface stated above. □

Theorem 1205.139 (Diagonal-limit representative exit object coverage)**.** *The roadmap exit contract for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *covers exactly the four L10 objects*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The $\mathsf{DyadicRatCore}^{\uparrow}$ *row is the dyadic ledger face, the* $\mathsf{StreamName}^{\uparrow}$ *row is the finite-window face, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row is the regular-rational readback face, and the* $\mathsf{Real}^{\uparrow}$ *row is the terminal seal face. Every accepted object read of the contract factors through the displayed finite route and the local* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support; no fifth L10 object is part of this exit surface.*

Proof. Start with the roadmap exit inventory, Definition 1205.136. Its source row is already the displayed four-object route, and its carrier, classifier, ledger, stability, and exactness fields are all attached to that same route.

Apply four-object source exhaustion and the Phase Real and Completion exit certificate, Definition 1205.114 and Definition 1205.115. These results identify the Phase Real and Completion packet with the dyadic ledger, finite window, regular-rational readback, and terminal seal rows.

Finally use phase-source coverage and completion-frontier readback coverage, Definition 1205.118 and Definition 1205.123. They keep downstream reads inside the four named rows and the displayed local support, so the contract has exactly the objectwise coverage stated above. □

Theorem 1205.140 (Diagonal-limit representative exit audit threshold)**.** *Downstream Phase Real and Completion consumers may treat the roadmap exit contract for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *as an audit-threshold handoff only through the carrier row of Definition 1205.1, the classifier row of Definition 1205.2, the ledger rows displayed in Definition 1205.136, the stability rows named there, and the exactness rows supplied by phase-source coverage, Real handoff exactness, and completion-frontier readback coverage. The handoff does not assert a* $\mathsf{bridgeChecked}$ *status, a standard bridge row, or an ambient completeness theorem.*

Proof. Begin with the roadmap exit inventory and consumer contract, Definition 1205.136 and Definition 1205.138. Together they list the only rows a downstream consumer may cite: carrier, classifier, ledger, stability, nonescape, and exactness over the finite route.

For the exactness side, use phase-source coverage, Real handoff exactness, and completion-frontier readback coverage. These theorems supply the permitted objectwise and readback obligations without adding a bridge slot or a completeness principle.

For the boundary side, apply audit-clean consumer handoff and route-read consumer boundary, Definition 1205.116 and Definition 1205.135. They allow the packet to be audited as a finite BEDC source surface while blocking any read as $\mathsf{bridgeChecked}$, standard bridge data, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1205.141 (Diagonal-limit representative exit nonchoice boundary)**.** *The roadmap exit contract for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *refuses quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every accepted downstream use must remain a finite route read through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the displayed local support rows.*

Proof. Apply roadmap exit nonescape, Definition 1205.137. It explicitly excludes quotient stream equality, host $\mathsf{Real}^{\uparrow}$ equality, selected completed points, choice rows, trichotomy, open-cover compactness, and ambient completeness from the roadmap exit contract.

Next use the Phase Real and Completion exit certificate, Definition 1205.115. It gives the same negative boundary for the four-object exit packet and keeps the packet constructive: only the displayed source rows and local support are exported.

Finally compose with completion-frontier readback coverage and the roadmap exit consumer contract, Definition 1205.123 and Definition 1205.138. These results force every downstream read back to the finite route, so none of the refused principles can enter through a consumer citation. □

Theorem 1205.142 (Diagonal-limit representative face threshold readiness)**.** *Every accepted completion-selector ledger for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *exposes a finite objectwise threshold package whose faces are exactly*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The $\mathsf{DyadicRatCore}^{\uparrow}$ *face records the dyadic tolerance ledger, the* $\mathsf{StreamName}^{\uparrow}$ *face records the finite observation window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *face records the regular-rational readback, and the* $\mathsf{Real}^{\uparrow}$ *face records the terminal seal. These four faces are read from the ledger only through its displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support.*

Proof. Apply four-object source exhaustion and the Phase Real and Completion exit certificate, Definition 1205.114 and Definition 1205.115. They identify the same four rows as the complete exit packet for Phase Real and Completion consumers.

Next apply phase-source projection totality, Definition 1205.121. It sends every accepted ledger to the dyadic ledger, finite window, regular-rational readback, and terminal seal, while the local support rows serve only as transport, replay, sourcing, and naming data.

Thus the threshold package is objectwise: it exposes the four named faces and no extra route coordinate beyond the displayed finite ledger support. □

Theorem 1205.143 (Diagonal-limit representative objectwise audit threshold handoff)**.** *Downstream audit reads of the objectwise threshold package for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *may consume the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *face records only through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support. In particular, an audit read may cite the four faces as a finite route surface, but it may not replace the supporting rows by detached quotient, host-limit, selector, choice, completeness, trichotomy, compactness, or bridge data.*

Proof. Begin with completion-frontier readback coverage, Definition 1205.123. It confines every Real-and-Completion consumer read to the finite frontier through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ together with the displayed local support.

Then use the roadmap exit consumer contract, Definition 1205.138. That contract authorizes downstream citation of the carrier, classifier, ledger, stability, nonescape, and exactness fields only through the same four source rows and support records.

Combining these two reads gives the audit handoff. The consumer sees the four face records as a finite source surface, and every permitted audit step remains anchored in BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ support. □

Theorem 1205.144 (Diagonal-limit representative exit threshold consumer boundary)**.** *The objectwise threshold package for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *supplies no route-level formalstatus, no quotient stream, no selected host limit, no countable choice row, no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, no trichotomy principle, no open-cover compactness principle, and no standard bridge row. Its consumer boundary is exactly the four objectwise faces of Definition 1205.142 together with the local support allowed by Definition 1205.143.*

Proof. First apply the Phase Real and Completion exit certificate, Definition 1205.115. It excludes quotient equality, choice, ambient completeness, trichotomy, and open-cover compactness from the finite exit packet.

Next apply phase-source projection totality and completion-frontier readback coverage, Definition 1205.121 and Definition 1205.123. These results remove host-limit, selected-point, fifth-source, and second-selector coordinates from the accepted readback surface.

Finally use the roadmap exit consumer contract, Definition 1205.138. Since that contract is only a finite source route and does not fill the bridge slot, the threshold package cannot be read as a route-level formalstatus or standard bridge row. The package therefore ends at the four objectwise faces and their local BEDC support. □

Definition 1205.145 (Diagonal-limit representative terminal-modulus coherence surface)**.** *For an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier consumed by a Real-and-Completion route, the terminal-modulus coherence surface is the finite packet*

$$T = (\mu, n, k, i, w, r, d, H, C, P, N).$$

The rows μ *and* n *are the displayed modulus request and precision request. The rows* $k = \mu(1/(n+1))$ *and* $i = k + n + 1$ *are the selected family and readback indices. The row* w *is the* $\mathsf{StreamName}^{\uparrow}$ *pointwise request selected by those indices,* r *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-window readback, and* d *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that sits between the readback and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The rows* H, C, P, N *are only the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *row for that same route.*

The packet T *is the terminal route made visible by Definition 1205.29, Definition 1205.44, Definition 1205.64, and Definition 1205.89. It is not a quotient stream, a host Real limit, a choice-selected tail, an ambient completeness witness, or a second Real seal.*

Theorem 1205.146 (Diagonal-limit representative terminal-modulus coherence)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *Real-and-Completion route factors through the terminal-modulus coherence surface of Definition 1205.145. Thus the consumer can reach the terminal seal only after it has exposed the same packet*

$$(\mu, n, k, i, w, r, d, H, C, P, N)$$

that records the StreamName request, RegSeqRat regular window, DyadicRatCore tolerance ledger, and local support rows.

Proof. Start with the modulus-window-readback package, Definition 1205.29. It says that every route to the terminal $\mathsf{Real}^{\uparrow}$ seal first passes through $\mu, n, k, i, w, r, d,$ while H, C, P, N can only transport, replay, source, and name that same route.

Next attach root readiness. The root-readiness triad of Definition 1205.44 makes the selected modulus request, pointwise window, readback row, dyadic ledger, terminal seal, and support rows visible before a downstream consumer can use them.

The cofinal-tail coverage theorem Definition 1205.64 places those rows on the same finite tail surface as the cofinal and finite-prefix budget rows. The Real seal handoff theorem Definition 1205.89 then confines the downstream endpoint to the finite root-unblock obligation over BHist, Cont, Pkg, and $\mathsf{NameCert}$.

Therefore the terminal seal read has no independent entry point. It factors through the packet T, and the visible StreamName, RegSeqRat, DyadicRatCore, and Real rows remain coherent along that one terminal-modulus route. □

Theorem 1205.147 (Diagonal-limit representative Real-RegSeqRat-StreamName tail factorization)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *terminal route, any* $\mathsf{Real}^{\uparrow}$ *read of the terminal seal consumes the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail only through the selected* $\mathsf{StreamName}^{\uparrow}$ *pointwise request and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row in the terminal-modulus coherence surface. Concretely, the Real-facing consumer may read the tail only in the order*

$$\mu, n, k, i, w, r, d,$$

with w supplying the StreamName request, r supplying the RegSeqRat readback for that request, and d supplying the DyadicRatCore tolerance ledger before the seal is consumed.

Proof. Begin with the root-readiness triad Definition 1205.44. It exposes the selected indices and the ordered window-readback-ledger route as data of the accepted carrier rather than as an ambient Real construction.

Now apply the modulus-window-readback package Definition 1205.29. The theorem orders the terminal route through μ, n, k, i, w, r, d, so the $\mathsf{RegSeqRat}^{\uparrow}$ readback row r is unavailable until the selected $\mathsf{StreamName}^{\uparrow}$ request w has already been exposed.

The cofinal-tail coverage theorem Definition 1205.64 keeps the selected tail on the same finite BHist route as the cofinal modulus and finite-prefix budget rows. Finally, Definition 1205.89 allows the Real-facing endpoint to consume only this finite root-unblock package.

Hence the Real read cannot skip from a tail name to a seal. It must pass through the StreamName pointwise request, the RegSeqRat readback, and the DyadicRatCore tolerance ledger recorded in T. □

Theorem 1205.148 (Diagonal-limit representative selector-modulus nonescape)**.** *The terminal-modulus coherence surface of Definition 1205.145 exhausts the selector and modulus data available to a terminal* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *route. No accepted consumer can replace $k = \mu(1/(n+1))$, $i = k + n + 1$, the selected StreamName request w, the RegSeqRat readback r, or the DyadicRatCore ledger d by a hidden tail selector, quotient stream equality, countable choice row, host* $\mathsf{Real}^{\uparrow}$ *limit, or ambient Real-completeness field.*

Proof. First read the terminal-modulus coherence theorem Definition 1205.146. Every terminal seal read factors through the packet T, so a selector or modulus row outside T would have to be an extra coordinate of the same accepted route.

The root-readiness triad Definition 1205.44 and the modulus-window-readback package Definition 1205.29 account for the displayed computations $k = \mu(1/(n+1))$ and $i = k+n+1$, the selected window, the readback, and the dyadic ledger. These results leave no second selector channel for the terminal consumer.

The cofinal-tail coverage theorem Definition 1205.64 supplies the only cofinal tail route, while the Real seal handoff theorem Definition 1205.89 states the endpoint as a finite root-unblock obligation. The excluded objects are stronger than those rows and are not part of the carrier, classifier, BHist support, Cont replay, Pkg provenance, or NameCert ledger.

Thus selector-modulus data cannot escape the displayed packet. Quotient streams, countable choice, hidden tail selectors, host Real limits, and ambient completeness remain outside the terminal route. □

Theorem 1205.149 (Diagonal-limit representative terminal-modulus scope lock)**.** *For every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *terminal route consumed by a Real-and-Completion endpoint, the terminal modulus route is scoped precisely by the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *rows together with the sibling* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows. In particular, the route available to the consumer is the terminal-modulus packet*

$$(\mu, n, k, i, w, r, d, H, C, P, N)$$

of Definition 1205.145, read through chapter 291, chapter 126, chapter 301, and chapter 38; no off-packet selector, host Real equality, quotient stream equality, countable-choice row, or ambient completeness field lies in this scope.

Proof. Start from the carrier and classifier of Definition 1205.1 and Definition 1205.2. The carrier exposes only finite route rows, while classifier transport is recorded componentwise by the hsame and Cont support used by the local route.

Apply the NameCert obligation surface through Definition 1205.3, Definition 1205.80, and Definition 1205.83. These results identify carrier admission, displayed replay, provenance, and local naming as the complete support by which the terminal route can be read.

Finally attach terminal-modulus coherence, Definition 1205.146. It factors the terminal seal through the same packet $(\mu, n, k, i, w, r, d, H, C, P, N)$ and ties the four sibling rows to the DyadicRatCore, StreamName, RegSeqRat, and Real chapters. Therefore the terminal modulus route is locked to the stated finite scope. □

Theorem 1205.150 (Diagonal-limit representative cofinal-tail exactness lock)**.** *Every cofinal tail read accepted by a* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *terminal route is exact only through the finite selector*

$$(\mu, n, k, i, w, r, d)$$

with $k = \mu(1/(n+1))$ *and* $i = k + n + 1$*. The read uses* w *as the displayed* $\mathsf{StreamName}^{\uparrow}$ *request,* r *as the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* d *as the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger; it does not introduce quotient-stream equality, a hidden tail selector, countable choice, host-limit selection, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the finite selector from the modulus-window-readback package and the terminal diagonal selector surface, Definition 1205.29 and Definition 1205.98. They provide the displayed computations of k and i and place the selected window before the regular-rational readback.

Next use cofinal-tail coverage and exactness, Definition 1205.64 and Definition 1205.66. These theorems keep the cofinal read inside the finite BHist, hsame, Cont, Pkg, and local NameCert route rather than allowing a detached tail principle.

The nonescape side follows from terminal-modulus coherence and selector-modulus nonescape, Definition 1205.146 and Definition 1205.148. Since the accepted packet has no coordinate for quotient equality, hidden selection, choice, host limits, or ambient completeness, the cofinal tail read is exact only through the displayed selector. □

Theorem 1205.151 (Diagonal-limit representative phase-exit handoff lock)**.** *The packet obtained from the terminal-modulus scope lock and the cofinal-tail exactness lock is the* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *Phase Real and Completion handoff consumed by* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$*. Its consumer-facing source rows are exactly* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, with the support route still carried by* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$*; the handoff exports no quotient stream, selected completed point, countable-choice row, host Real limit, or ambient completion principle.*

Proof. First assemble the local package. The terminal-modulus scope lock supplies the finite route support, while the cofinal-tail exactness lock supplies the selected window, readback, and dyadic ledger through the displayed selector.

Now apply the existing Phase Real and Completion surfaces: phase-source coverage, four-object source exhaustion, and the Phase Real and Completion exit certificate, Definition 1205.118, Definition 1205.114, and Definition 1205.115. They identify the consumer-facing source inventory with the four DyadicRatCore, StreamName, RegSeqRat, and Real rows.

Finally compare with the $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ carrier and obligation surface, Definition 1327.1 and Definition 1327.6. That carrier consumes the same objectwise rows through finite support and rejects fused completion data, quotient streams, selected limits, and host-completeness shortcuts. Hence the resulting packet is precisely the handoff available to the Phase Real and Completion exit consumer. □

Theorem 1205.152 (Diagonal-limit representative phase-root window totality)**.** *Every Phase Real and Completion root-window read accepted by* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is total on the finite packet*

$$(\mu, n, k, i, w, r, d, H, C, P, N)$$

where $k = \mu(1/(n+1))$ *and* $i = k + n + 1$*. The rows* w, r, d *are respectively the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *faces, while* H, C, P, N *are the displayed* BHist*, componentwise* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support rows. The terminal* $\mathsf{Real}^{\uparrow}$ *seal is reachable only after this packet is displayed, through the sibling chapters chapter 291, chapter 126, chapter 301, and chapter 38.*

Proof. Start with the carrier and classifier of Definition 1205.1 and Definition 1205.2. They expose only finite representative rows and compare them through the displayed support, so the root-window read has no coordinate outside BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ data.

Apply root-readiness exactness, the modulus-window-readback package, and the terminal-modulus scope lock, Definition 1205.49, Definition 1205.29, and Definition 1205.149. These results compute k and i, display the selected window and readback, and bind the dyadic ledger to the same finite route.

Finally use the four-object source exhaustion theorem, Definition 1205.114. It identifies the Real-and-Completion source inventory with the DyadicRatCore, StreamName, RegSeqRat, and Real rows. Hence every accepted phase-root window read is total exactly on the stated finite packet before the terminal Real seal is consumed. □

Theorem 1205.153 (Diagonal-limit representative phase-root readback factorization)**.** *Every accepted Phase Real and Completion readback for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *factors through the ordered root-window route*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

carried by the displayed BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *rows. The factorization reads the selected finite window* w *before the regular-rational readback* r*, reads the dyadic tolerance ledger* d *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and exports no quotient stream equality, host limit, selected completed point, choice row, or ambient completeness principle.*

Proof. First read the StreamName–RegSeqRat handoff, Definition 1205.16. It forces any accepted route toward the terminal seal to expose the selected $\mathsf{StreamName}^{\uparrow}$ window before the selected $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Next apply finite selector exhaustion and the cofinal-tail exactness lock, Definition 1205.90 and Definition 1205.150. These keep the selected readback attached to the displayed root indices and dyadic ledger rather than to a detached tail principle.

The terminal step is supplied by the Phase Real and Completion exit certificate, Definition 1205.115. Since that certificate has exactly the four named source rows and no stronger analytic coordinate, every accepted readback factors through the ordered root-window route stated above. □

Theorem 1205.154 (Diagonal-limit representative phase-root nonchoice boundary)**.** *The Phase Real and Completion root-window surface for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is a nonchoice boundary. Its available data are precisely the displayed* BHist *rows, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *naming, and the sibling* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *faces. It cannot be strengthened into quotient stream equality, host-limit selection, countable choice, a selected completed point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the root NameCert obligations, Definition 1205.3 and Definition 1205.80. They record carrier admission, classifier stability, provenance, and naming as finite obligations rather than as external equality or selection principles.

Use support-scope nonescape and Real-seal nonchoice export, Definition 1205.8 and Definition 1205.42. The support rows may transport and replay only the displayed packet, and the Real-facing seal cannot be replaced by host equality, quotient equality, a hidden selector, or choice data.

Finally read the objectwise audit threshold handoff, Definition 1205.143. It leaves downstream consumers with only the four objectwise faces and local support. Therefore the phase-root window surface is exactly the stated nonchoice boundary. □

Theorem 1205.155 (Diagonal-limit representative phase-root NameCert exhaustion)**.** *The* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRe}}$ *obligation for a Phase Real and Completion root-window read is exhausted by the carrier, classifier, root-window totality theorem, readback factorization theorem, and nonchoice boundary theorem. Equivalently, once the displayed* BHist, hsame, Cont, Pkg, *local* NameCert, *and sibling* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows are present, no additional NameCert clause is available for quotient streams, host limits, choice, selected completion points, or ambient completeness.*

Proof. The carrier and classifier supply the underlying admissible rows. The root-window totality theorem then records that every accepted phase-root read has a displayed finite packet before any terminal Real seal is read.

The readback factorization theorem supplies the ordered source route through StreamName, RegSeqRat, DyadicRatCore, and Real. Thus each consumer-visible readback coordinate is already attached to a named sibling source and to the local support rows.

The nonchoice boundary theorem closes the negative ledger. Since it removes quotient equality, host limits, choice rows, selected completed points, and ambient completeness from the surface, there is no remaining NameCert obligation outside the listed packet. □

Theorem 1205.156 (Diagonal-limit representative phase-root consumer handoff)**.** *Every Real-and-Completion consumer of the* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *phase-root window receives exactly the finite handoff supplied by the phase-root NameCert exhaustion theorem. The handoff consists of the root-window totality packet, the readback factorization route through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *and the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresenta}}$ *support. It exports no quotient stream equality, host limit, choice row, selected completed point, ambient completeness principle, or standard bridge row.*

Proof. First assemble the local surface from root-window totality and readback factorization. These two theorems provide the finite packet and its ordered sibling route, so the consumer has a concrete row to read for each source face.

Next apply phase-root NameCert exhaustion. It states that the displayed support rows and four sibling faces already cover the local NameCert obligation, with no additional completion or selection clause.

Finally compare with the phase-exit handoff lock, Definition 1205.151. That theorem identifies the Phase Real and Completion endpoint as a finite consumer handoff and refuses quotient streams, selected completed points, countable choice, host Real limits, and ambient completion principles. The consumer therefore receives exactly the finite phase-root window handoff and nothing stronger. □

Definition 1205.157 (Diagonal-limit representative selector identity surface)**.** *For an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *packet*

$$(X, \mu, n, k, i, w, r, d, e, H, C, P, N),$$

the selector identity surface is the displayed finite row

$$\Sigma_i = (X, \mu, n, k, i, w, r, d, e, H, C, P, N)$$

subject to the equations $k = \mu(1/(n+1))$ *and* $i = k + n + 1$, *where the same selected index* i *is read through the cofinal modulus route, the finite* $\mathsf{StreamName}^{\uparrow}$ *window* w, *the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* r, *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* d, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* e. *The support rows* H, C, P, N *are only the displayed* BHist, *componentwise* hsame, Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *rows for that same identity surface.*

The surface is the selector row exposed by the root-index readiness package, the root-window obligation surface, and the terminal-modulus coherence surface. It is not a quotient stream, a host Real limit, a selected completion point, a countable-choice row, an ambient $\mathsf{Real}^{\uparrow}$ *completeness field, or a second terminal selector.*

Theorem 1205.158 (Diagonal-limit representative selector identity totality)**.** *Every accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier exposes exactly one selector identity surface of Definition 1205.157. The exposed surface is total on the selected cofinal index and simultaneously determines the finite window, regular readback, dyadic ledger, and terminal Real seal route*

$$i \rightsquigarrow w \rightsquigarrow r \rightsquigarrow d \rightsquigarrow e$$

inside the recorded BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support.*

Proof. Start with the accepted carrier of Definition 1205.1. It records $X, \mu, n, k, i, w, r, d, e, H, C, P, N$ and the two selector equations $k = \mu(1/(n+1))$ and $i = k+n+1$ as finite carrier data, so existence of the displayed row is obtained by projection rather than by choosing a tail outside the packet.

Root-index coverage and the phase-root window totality theorem, Definition 1205.53 and Definition 1205.152, attach the selected index to the same finite StreamName, RegSeqRat, and DyadicRatCore route. Thus the selector identity row is total before the terminal seal is read.

For uniqueness, apply selected-window determinacy through the modulus-window-readback package and terminal-route uniqueness, Definition 1205.29 and Definition 1205.130. Once the carrier and support rows are fixed, a second selected index, window, readback, ledger, or seal would have to be a second terminal route, which those results exclude. □

Theorem 1205.159 (Diagonal-limit representative selector identity transport)**.** *Let two accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *selector identity surfaces be classified componentwise by the recorded* hsame *rows and by displayed* Cont *replay on their carrier, cofinal, window, readback, ledger, seal, provenance, and local naming rows. Then transport preserves the same selector identity through the window/readback/ledger/seal route. In particular, the transported surface has the same selected cofinal index route and the same ordered public path through*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{CofinalModulusSeal}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Proof. Begin with classifier transport. The classifier of Definition 1205.2 and the hsame–Cont scope theorem Definition 1205.8 allow transport only through the recorded component rows and displayed replay of the same finite packet.

Next use cofinal selector transport, Definition 1205.85. It keeps the selected equations, selected window, readback, dyadic ledger, cofinal modulus rows, and terminal seal inside the displayed BHist, hsame, Cont, Pkg, and NameCert containers.

Finally apply finite-tail selector uniqueness, Definition 1205.101. Since the finite tail admits only one displayed selector route, componentwise transport cannot exchange the window/readback/ledger/seal path for another index, another tail, or another terminal Real seal. □

Theorem 1205.160 (Diagonal-limit representative selector identity Real-seal exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier factors through the selector identity surface of Definition 1205.157. Such a consumer may read the terminal seal only after the selected cofinal index, finite window, RegSeqRat readback, and DyadicRatCore ledger have appeared on the displayed surface; it cannot replace that surface by a hidden selector, quotient stream, host limit, countable-choice row, selected completion point, or ambient completeness coordinate.*

Proof. Read the positive factorization first. The Real-seal factorization theorem and Real-seal handoff theorem, Definition 1205.10 and Definition 1205.89, place every terminal Real read after the selected window, readback, dyadic ledger, and local support rows.

The selector identity totality theorem identifies those rows with the same selected index i and the same cofinal route. Therefore a seal consumer reaches e only through Σ_i, with no separate entry point for the Real endpoint.

The boundary is supplied by the nonchoice results, especially Definition 1205.11, Definition 1205.154, and Definition 1205.42. These results remove hidden selectors, quotient streams, host limits, selected completion points, choice rows, and ambient completeness fields from the carrier surface, so the selector identity surface exhausts every Real-seal consumer route. □

Theorem 1205.161 (Diagonal-limit representative audit-clean exit gate)**.** *The finite* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *packet is the citable audit-clean exit gate for the Phase Real and Completion route exactly through the four current L10 phase objects*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The gate is the roadmap-facing read of the carrier, classifier, selector identity surface, phase-source package, and formal handoff surface of this chapter. It authorizes the Phase Real and Completion exit criterion only as a finite route through those four faces and the displayed BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support rows. It does not authorize quotient streams, selected limits, countable choice, host* $\mathsf{Real}^{\uparrow}$ *equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or* $\mathsf{bridgeChecked}$ *status.*

Proof. Start with the roadmap exit inventory and consumer contract, Definition 1205.136 and Definition 1205.138. They identify the downstream citation surface with the four-object route and the local support rows, not with a completed host Real object.

Next attach the phase-source and selector-identity surfaces. The phase-source coverage theorem Definition 1205.118 names the four current L10 faces, while Definition 1205.158 fixes the selected window, readback, dyadic ledger, and terminal seal as one displayed finite route.

Finally apply the phase-exit handoff lock and the formal handoff boundary, Definition 1205.151 and Definition 1205.69. They allow the Phase Real and Completion consumer to read the finite route as an audit-clean exit gate while refusing quotient streams, selected limits, countable choice, host equality, ambient completeness, and any bridge-checked conclusion. □

Theorem 1205.162 (Diagonal-limit representative objectwise audit closure)**.** *Objectwise audit closure for the* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *exit gate is exhausted by the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *together with the displayed route rows*

$$X, \mu, n, k, i, w, r, d, e, H, C, P, N.$$

The rows w, r, d, e *are respectively the StreamName, RegSeqRat, DyadicRatCore, and Real faces;* H, C, P, N *are only the* BHist*-recorded* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *naming rows. No additional objectwise audit coordinate is supplied by quotient streams, selected limits, countable choice, host* $\mathsf{Real}^{\uparrow}$ *equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge data.*

Proof. Read the carrier and classifier of Definition 1205.1 and Definition 1205.2. They display exactly the family, modulus, selected indices, window, readback, ledger, seal, transport, replay, provenance, and naming rows used by the local certificate.

The object faces are then fixed by the face threshold readiness theorem and the objectwise audit threshold handoff, Definition 1205.142 and Definition 1205.143. These results read w, r, d, e as the four current L10 faces and route every audit use through H, C, P, N.

For exhaustion, use the selector identity Real-seal exhaustion theorem and the exit threshold consumer boundary, Definition 1205.160 and Definition 1205.144. They remove hidden selectors, quotient streams, selected host limits, countable choice, ambient completeness, route-level formal-status, and bridge rows from the objectwise audit surface. □

Theorem 1205.163 (Diagonal-limit representative formal-axis unblock)**.** *The formal-axis handoff shape for the later* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *Lean audit is the finite obligation surface already carried by*

$$\mathsf{BEDC.Derived.DiagonallimitrepresentativeUp.DiagonalLimitRepresentativeNameCertObligations}.$$

The paper-side exit gate therefore offers a single downstream handoff shape: carrier admission, diagonal-index computation, selected StreamName window, RegSeqRat readback, DyadicRatCore ledger, terminal Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. This handoff does not add a paper marker here, does not assert* bridgeChecked*, and does not import quotient streams, selected limits, countable choice, host* $\mathsf{Real}^{\uparrow}$ *equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the checked NameCert obligation site, Definition 1205.3. Its statement lists the finite rows that the Lean theorem named in the formal-axis target already consumes: index computation, selected window, readback, dyadic ledger, terminal seal, transport, replay, provenance, and local naming.

Next use the audit-readiness package and audit-clean threshold package, Definition 1205.68 and Definition 1205.72. Together they collect the carrier, classifier, shared terminal route, root-readiness exactness, terminal pullback coverage, and determinacy data into one audit-ready finite route.

Finally compare with the Lean-readiness obligation boundary, Definition 1205.74. That boundary permits only the displayed finite rows and sibling faces to pass to later formal work, while standard bridge assertions and stronger Real-completeness claims remain outside the handoff. Thus the formal axis is unblocked by a finite obligation surface rather than by an unrecorded analytic principle. □

Theorem 1205.164 (Diagonal-limit representative root-window selector lock)**.** *Every Phase Real and Completion root-window selector read of an accepted* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *carrier factors through the displayed finite route*

$$(\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert})$$

already named by the chapter. Concretely, the read exposes the selected equations $k = \mu(1/(n+1))$ *and* $i = k+n+1$*, the finite window* w*, regular-rational readback* r*, dyadic ledger* d*, terminal seal* e*, and support rows* H, C, P, N *before any downstream consumer can use the selector. No selector read bypasses those rows through quotient stream equality, host* $\mathsf{Real}^{\uparrow}$ *equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier and classifier rows of Definition 1205.1 and Definition 1205.2. They list exactly the selected index equations, window, readback, ledger, terminal seal, transport, continuation, provenance, and local naming rows available to an accepted carrier.

Next apply the phase-root window totality and readback factorization theorems, Definition 1205.152 and Definition 1205.153. These force the consumer to read the selected $\mathsf{StreamName}^{\uparrow}$ window before the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger before the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally use the phase-root nonchoice boundary and NameCert exhaustion, Definition 1205.154 and Definition 1205.155. They identify BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ as the whole support surface, so the forbidden quotient, host-equality, selected-limit, choice, and completeness data have no coordinate in the selector read. □

Theorem 1205.165 (Diagonal-limit representative cofinal-modulus route totality)**.** *The cofinal modulus route consumed by* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *is total only through the finite selected-index route, finite-window route, dyadic-readback route, and terminal Real-seal route already displayed by the packet. Its positive data are the selected equations* $k = \mu(1/(n+1))$ *and* $i = k+n+1$*, the* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row, the*

cofinal budget rows, the terminal $\mathsf{Real}^{\uparrow}$ *seal row, and the recorded* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support. It contains no quotient stream, countable-choice row, host real equality, or ambient completeness field.*

Proof. Begin with the cofinal-index source and budget lock, Definition 1205.60 and Definition 1205.61. They attach the selected-index equations to the finite window, readback, dyadic ledger, cofinal budget, and terminal seal before a downstream consumer can read the route.

Now apply cofinal-budget seal totality, Definition 1205.57. It orders every terminal seal read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, the finite-prefix budget, the cofinal modulus rows, and $\mathsf{Real}^{\uparrow}$.

It remains to close the negative boundary. The terminal consumer cofinal nonescape theorem and Real-completion consumer exactness, Definition 1205.58 and Definition 1205.86, keep all transport inside the displayed structural rows and exclude quotient streams, countable choice, host real equality, and ambient completeness from the total route. □

Theorem 1205.166 (Diagonal-limit representative phase-exit unblock package)**.** *The root-unblock package for* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *consumed by the Phase Real and Completion exit route is the package consisting of the root-window selector lock of Definition 1205.164, the cofinal-modulus route totality theorem of Definition 1205.165, Real-completion consumer exactness Definition 1205.86, the formal handoff boundary Definition 1205.69, and the Phase Real and Completion exit certificate Definition 1205.115. A downstream exit consumer may cite this package only as a finite route through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{DiagonalLimitRepresentative}^{\uparrow}}$ *support; it cannot infer Real completeness, host equality, quotient streams, selected completed limits, countable choice, or bridge-checked status.*

Proof. Assemble the two local obligations first. The root-window selector lock supplies the selected-index, finite-window, readback, dyadic ledger, terminal seal, and support rows, while the cofinal-modulus route totality theorem attaches the cofinal budget route to the same finite terminal read.

Next add Real-completion consumer exactness and the formal handoff boundary. Exactness confines every downstream consumer to the displayed StreamName, RegSeqRat, DyadicRatCore, cofinal budget, Real, and support rows. The handoff boundary states that later formal work may encode those rows without importing quotient equality, host equality, selected limits, choice, or ambient completeness.

Finally cite the Phase Real and Completion exit certificate. It identifies the consumer-facing source inventory with $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Therefore the exit route receives exactly the finite root-unblock package stated above and no stronger analytic or bridge claim. □

Chapter 1206

A Concrete Naming Certificate for $\mathsf{ConsciousUniverseSpace}^{\uparrow}$

The $\mathsf{ConsciousUniverseSpace}^{\uparrow}$ packet realizes the finite universe-slice, local-time, locality-cell, and trace-identity surface of section 9462.27 as one records-side NameCert carrier. It sits after the focused ledger surface of chapter 1109, the locality-cell surface of chapter 509, the observer-locality surface of chapter 513, and the finite two-history locality packet of chapter 1194. Those siblings supply the nearby ledger, cell, observer, and two-history locality rows; this packet binds the universe-slice read, local-time chain, locality-cell space graph, and focused trace-identity row into one carrier.

Definition 1206.1 (ConsciousUniverseSpace carrier)**.** *A* $\mathsf{ConsciousUniverseSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (L, U, T, S, I, H, C, P, N)$$

with the following displayed rows:

1. *L is the focused ledger row, read through* $\mathsf{FocusedMultiHistLedger}^{\uparrow}$*, that fixes the finite family of histories available to the focus;*
2. *U is the universe-slice row, the finite subfamily of histories, selectors, digest rows, gap rows, provenance rows, relation rows, invariant rows, and dependence rows admitted by L;*
3. *T is the local-time chain row, recording the finite continuation order internal to the displayed histories rather than a global scalar clock;*
4. *S is the locality-cell space graph row, generated by* $\mathsf{LocalityCell}^{\uparrow}$*,* $\mathsf{ObserverLocalityCell}^{\uparrow}$*, and* $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *reads over the histories admitted by U;*
5. *I is the trace-identity row, recording the focused self-proxy and* hsame*-stable trace continuity of the focused history;*
6. *H records componentwise* hsame *transport for L, U, T, S, I, C, P, N;*
7. *C records the displayed* Cont *routes from the focused ledger through the universe slice, local-time chain, locality-cell graph, and trace-identity row;*
8. *P is the* Pkg *provenance over* $\mathsf{ConsciousUniverseSpace}^{\uparrow}$*,* $\mathsf{FocusedMultiHistLedger}^{\uparrow}$*,* $\mathsf{LocalityCell}^{\uparrow}$*,* $\mathsf{ObserverLocalityCell}^{\uparrow}$*,* $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ConsciousUniverseSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global universe object, God's-eye world, shared scalar time, independent space substrate, owner-subject carrier, host equality of histories, or ambient spacetime manifold.

Lean4 ✓ `BEDC.Derived.ConsciousUniverseSpaceUp.taste gate`

Theorem 1206.2 (ConsciousUniverseSpace NameCert obligations)**.** *For the carrier of Definition 1206.1, the local* $\mathsf{NameCert}_{\mathsf{ConsciousUniverseSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for* $X = (L, U, T, S, I, H, C, P, N)$*, focused-ledger admission through* L*, universe-slice readback through* U*, local-time chain exposure through* T*, locality-cell graph exposure through* S*, trace-identity exposure through* I*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.ConsciousUniverseSpaceUp.ConsciousUniverseSpaceNameCertObligations`

Proof. Project the carrier definition. The rows $L, U, T, S, I, H, C, P, N$ are the complete displayed inventory before any universe-slice, space, time, or identity consumer can read the packet.

The focused ledger row supplies only the finite histories admitted to the focus. The universe-slice row refines that finite ledger into displayed histories and evidence rows, while the local-time row records continuation order internal to those histories.

The locality-cell graph and trace-identity rows close the records-side geometry. The graph row uses locality-cell siblings to express inter-history coordination, and the identity row records focused trace continuity without adding an owner-subject coordinate.

The transport, continuation, provenance, and naming rows preserve and replay this finite packet. Since the carrier has no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 1206.3 (ConsciousUniverseSpace locality non-escape)**.** *Every public locality, time, or identity read of an accepted* $\mathsf{ConsciousUniverseSpace}^{\uparrow}$ *packet factors through the displayed rows*

$$L, U, T, S, I, H, C, P, N.$$

The packet cannot replace the locality-cell graph row S *by a global spacetime substrate, replace the local-time chain* T *by a shared scalar clock, or replace the trace-identity row* I *by a subject-owner carrier.*

Proof. Begin with the NameCert obligations. A consumer reaches the universe-slice, local-time, locality-cell, and trace-identity surfaces only through the rows U, T, S, I inside the accepted carrier.

Read the sibling boundaries next. $\mathsf{FocusedMultiHistLedger}^{\uparrow}$ fixes the focus-facing finite ledger, $\mathsf{LocalityCell}^{\uparrow}$ and $\mathsf{ObserverLocalityCell}^{\uparrow}$ supply local relation cells, and $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ supplies the two-history locality packet. None of these siblings exports a global world object or a host spacetime row.

Finally use the transport and replay rows. The rows H, C, P, N preserve the displayed packet and its provenance, but they do not add coordinates. Thus locality, time, and identity reads remain confined to $L, U, T, S, I, H, C, P, N$. □

Theorem 1206.4 (ConsciousUniverseSpace independence witness)**.** *The carrier of Definition 1206.1 is independent from each nearest sibling named in its provenance:* $\mathsf{FocusedMultiHistLedger}^{\uparrow}$ *lacks the locality-cell space graph and trace-identity rows,* $\mathsf{LocalityCell}^{\uparrow}$ *lacks the focused universe-slice and local-time chain rows,* $\mathsf{ObserverLocalityCell}^{\uparrow}$ *lacks the universe-slice row, and* $\mathsf{FiniteHistLocalityPacket}^{\uparrow}$ *lacks the focused trace-identity row. Hence none of those siblings certifies the same* $\mathsf{ConsciousUniverseSpace}^{\uparrow}$ *carrier.*

Proof. Compare the displayed carrier rows. The present packet requires the simultaneous rows $L, U, T, S, I, H, C, P, N$; each cited sibling supplies only one part of that inventory.

The focused ledger sibling supplies the focus-facing ledger but not the locality-cell space graph or trace-identity row. The locality-cell siblings supply local relation geometry but not the universe slice and local-time chain generated from the focused ledger.

The finite two-history locality packet supplies a two-history locality surface but not the focused self-proxy trace identity. Therefore no sibling carrier can be renamed into X without adding a row missing from its own displayed packet. □

Falsifiable prediction: A packet omitting either the locality-cell graph row or the trace-identity row cannot certify the same ConsciousUniverseSpace carrier.

Independence witness: focusedmultihistledger, localitycell, observerlocalitycell, finitehistlocalitypacket: none combines finite universe slice, locality-cell geometry, local-time chain, and trace-identity rows in one carrier.

The follow-up Lean TasteGate surface for this chapter must provide explicit `Nontrivial ConsciousUniverseSpaceUp` and `FieldFaithful ConsciousUniverseSpaceUp` instances for the same finite carrier, with the canonical declaration surface expected at `BEDC.Derived.ConsciousUniverseSpaceUp`.

Theorem 1206.5 (ConsciousUniverseSpace scoped-kernel witness)**.** *Every locality, time, trace-identity, and universe-slice consumer of an accepted* $\mathsf{ConsciousUniverseSpace}^{\uparrow}$ *packet factors through the displayed rows*

$$L, U, T, S, I, H, C, P, N$$

and only through the BEDC kernel primitives BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The scoped kernel for such consumers is therefore the carrier of Definition 1206.1, the NameCert obligations of Definition 1206.2, the locality non-escape theorem Definition 1206.3, and the independence witness of Definition 1206.4.*

Proof. Project the carrier first. The rows $L, U, T, S, I, H, C, P, N$ are the complete displayed inventory, and the carrier text explicitly excludes a global universe object, shared scalar time, independent space substrate, owner-subject carrier, host equality of histories, and ambient spacetime manifold.

Apply the NameCert obligations. They assign focused-ledger admission to L, universe-slice readback to U, local-time exposure to T, locality-cell graph exposure to S, trace-identity exposure to I, componentwise hsame transport to H, displayed Cont replay to C, Pkg provenance to P, and local NameCert naming to N.

Use locality non-escape to constrain every public locality, time, and identity read to the same rows. The independence witness then separates this packet from its nearest siblings, so no sibling carrier can supply a second kernel route for the combined universe slice, local-time chain, locality-cell graph, and trace-identity surface.

Thus the only primitives available to consumers are the displayed finite BHist packet, its hsame transport, its Cont replay, its Pkg provenance, and its local NameCert row. This is exactly the scoped kernel claimed. □

Theorem 1206.6 (ConsciousUniverseSpace public export)**.** *Public consumers of an accepted* $\mathsf{ConsciousUniverseSpace}^{\uparrow}$ *packet may read only the locality, time, trace-identity, and universe-slice rows already named by the scoped packet. Concretely, a public read exposes the universe-slice row U, local-time row T, locality-cell graph row S, trace-identity row I, and the structural rows*

H, C, P, N from Definition 1206.1. It exports no new subject row, physical substrate row, global universe coordinate, owner identity, or proof-witness row.

Proof. Use the scoped-kernel witness. It confines every locality, time, trace-identity, and universe-slice consumer to the displayed rows $L, U, T, S, I, H, C, P, N$ and to the BEDC primitives BHist, hsame, Cont, Pkg, and NameCert.

The public export only forgets the internal orientation of the scoped packet. It lets a consumer read the rows U, T, S, I and their transport, replay, provenance, and naming data, but it has no additional coordinate from which a subject, substrate, global universe, owner identity, or proof witness could be supplied. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConsciousUniverseSpace}^{\uparrow}}$.

Constructive story: The conscious-universe space is generated from a $BHist$ packet that records a finite universe slice, locality-cell geometry, local-time chain, and trace-identity row without adding a subject parameter or physical substrate row. The carrier convention first exposes the conscious-universe address, then reads the locality and trace boundary through $hsame$ so that equivalent histories keep the same space. Continuations may extend the ledger of observations, but Cont cannot introduce a hidden observer, proof witness, or substrate unless the row is part of the packet. The NameCert obligations, locality non-escape, and independence witness therefore present the object as a visible space of conscious-universe rows rather than a metaphysical host domain.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ConsciousUniverseSpace}^{\uparrow}}$, bridgedClosed)

Scope closed: The paper bridge is exactly Definition 1206.1, Definition 1206.2, Definition 1206.3, Definition 1206.4, Definition 1206.5, and Definition 1206.6, with every bridge consumer restricted to locality, time, trace-identity, and universe-slice rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ConsciousUniverseSpace}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Not claimed: It does not claim physical realization, subject identity, global universe completeness, or proof-witness adequacy outside the named carrier rows.

Upgrade path: Machine bridge checking requires a standard bridge theorem that preserves the same locality, time, trace-identity, and universe-slice export without adding subject, substrate, physical-realization, or proof-witness rows.

Chapter 1207

A Concrete Naming Certificate for $\mathsf{SelectedTailSeed}^{\uparrow}$

The $\mathsf{SelectedTailSeed}^{\uparrow}$ packet realizes the stationary selected-tail seed exactness surface of chapter 9238 as a finite concrete NameCert carrier. It is structurally composite over $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{FiniteTailFilter}^{\uparrow}$: rational endpoints are read through chapter 37; stream windows through chapter 126; regular-rational readback through chapter 301; dyadic tolerance ledgers through chapter 291; Real sealing through chapter 38; and selected finite-tail filtering through chapter 1119. The packet supplies the finite handoff used by Definition 9238.11 without quotient streams, host real equality, or ambient completeness.

Definition 1207.1 (Selected-tail seed carrier)**.** *A* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, E, A, W, K, S, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *seed-rational row naming the stationary rational endpoint.*
2. *E is the endpoint-exactness row comparing the selected seed endpoint with the rational seed under the displayed rational classifier.*
3. *A is the admission row for the selected finite tail, read against* $\mathsf{FiniteTailFilter}^{\uparrow}$*.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window exposing the selected stationary tail segment.*
5. *K is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the stationary regular-rational sequence at the selected window.*
6. *S is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic ledger attached to the selected endpoint.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row obtained from the selected stationary readback.*
8. *H records componentwise* hsame *transport for $Q, E, A, W, K, S, R, P, N$.*
9. *C records displayed* Cont *replay from rational seed through selected finite tail, stream window, regular-rational readback, dyadic ledger, and Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{SelectedTailSeed}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteTailFilter}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ *row.*

The carrier exports no quotient stream, host real equality, countable-choice selector, detached limit object, or ambient Real-completeness coordinate.

Theorem 1207.2 (Selected-tail seed NameCert obligations)**.** *For the carrier of Definition 1207.1, the local* $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^\uparrow}$ *surface consists exactly of carrier admission for* $T = (Q, E, A, W, K, S, R, H, C, P,$ *rational seed admission through* Q*, endpoint exactness through* E*, finite-tail admission through* A*, stationary stream-window exposure through* W*, regular-rational readback through* K*, dyadic tolerance and arithmetic exposure through* S*, Real sealing through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. Its coordinates list the rational seed, endpoint-exactness row, finite-tail admission row, selected stream window, regular-rational readback, dyadic ledger, Real seal, transport, replay, provenance, and local name.

The sibling certificate surfaces account for the data-bearing rows. $\mathsf{Rat}^\uparrow$ supplies Q; $\mathsf{FiniteTailFilter}^\uparrow$ supplies A; $\mathsf{StreamName}^\uparrow$ supplies W; $\mathsf{RegSeqRat}^\uparrow$ supplies K; $\mathsf{DyadicRatCore}^\uparrow$ supplies S; and $\mathsf{Real}^\uparrow$ supplies R.

The endpoint row E is therefore not an additional host equality. It is the displayed comparison tying the selected finite tail back to the stationary rational seed, while H, C, P, N only transport, replay, source, and name the already displayed rows. These rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.SelectedTailSeedUp.SelectedTailSeedTasteGate single carrier alignment`

Theorem 1207.3 (Selected-tail seed Real-window handoff)**.** *Every Real-window consumer of an accepted* $\mathsf{SelectedTailSeed}^\uparrow$ *packet factors through the finite route*

$$Q, E, A, W, K, S, R, H, C, P, N.$$

In particular, the stationary rational selected finite-window endpoint is read as a finite $\mathsf{Rat}^\uparrow$*,* $\mathsf{StreamName}^\uparrow$*,* $\mathsf{RegSeqRat}^\uparrow$*,* $\mathsf{DyadicRatCore}^\uparrow$*,* $\mathsf{Real}^\uparrow$*,* hsame*,* Cont*,* Pkg*, and* NameCert *handoff rather than as quotient stream equality or host real equality.*

Lean4 ✓ `BEDC.Derived.SelectedTailSeedUp.SelectedTailSeedCarrier real window handoff`

Proof. Start with the selected finite-tail admission row A. It identifies the tail segment whose stationary window is visible, but it does not by itself expose a Real-facing endpoint.

Next read the route through W, K, S. The stream window displays the selected stationary segment, the regular-rational row reads that segment as a regular sequence observation, and the dyadic ledger records the finite tolerance and arithmetic used by the endpoint exactness row.

Finally pass through R, H, C, P, N. The Real seal R is downstream of the selected finite route, and the structural rows only preserve the displayed handoff. Since the carrier has no quotient stream, host real equality, countable-choice selector, detached limit, or ambient completeness coordinate, every Real-window consumer remains inside the finite route. □

Theorem 1207.4 (Selected-tail finite-tail admission exactness)**.** *For every accepted carrier* $T = (Q, E, A, W, K, S, R, H, C, P, N)$ *of Definition 1207.1, the admission row* A *is the unique displayed gate through which the selected stationary tail can be read before any* $\mathsf{StreamName}^\uparrow$ *window or* $\mathsf{RegSeqRat}^\uparrow$ *readback is consumed. Thus every use of* W *or* K *in a* $\mathsf{SelectedTailSeed}^\uparrow$ *consumer first factors through the* $\mathsf{FiniteTailFilter}^\uparrow$ *admission witnessed by* A*.*

Proof. Project the accepted carrier to its displayed rows. The row A is the only coordinate whose type names selected finite-tail admission; the later rows W and K name a stream window and a regular-rational readback, but neither row carries the finite-tail classifier by itself.

The constructive factorization is therefore obtained by ordering the projections. A consumer asking for W or K first reads A, obtaining the $\mathsf{FiniteTailFilter}^{\uparrow}$-admitted selected tail segment, and then passes the admitted segment to the $\mathsf{StreamName}^{\uparrow}$ window row and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row.

No omitted coordinate can bypass this order. The carrier exports no quotient stream, detached limit object, countable-choice selector, or host real equality, so there is no second admission path from a raw tail to W or K outside the displayed finite-tail row. □

Lean4 ✓ `BEDC.Derived.SelectedTailSeedUp.SelectedTailSeedCarrier finite tail admission exactness`

Theorem 1207.5 (Selected-tail endpoint exactness readback stability)**.** *For an accepted carrier $T = (Q, E, A, W, K, S, R, H, C, P, N)$, the endpoint exactness row E is stable under* hsame *transport and displayed* Cont *replay only as part of the full readback surface $Q, E, A, W, K, S, H, C, P, N$. In particular, E cannot be replayed as an isolated host equality detached from the rational seed Q, the window and readback rows W, K, the dyadic ledger S, and the transport, replay, provenance, and naming rows H, C, P, N.*

Proof. Begin with the comparison encoded by E. It relates the selected seed endpoint to the rational seed, so the row already depends on Q before any stability claim can be read.

The readback side is then supplied by W, K, S. The stream row displays the selected stationary window, the regular-rational row reads that window, and the dyadic ledger records the finite tolerance and arithmetic against which endpoint exactness is checked.

Stability is the final structural step. The row H transports the displayed coordinates componentwise by hsame, the row C replays the displayed construction by Cont, and the rows P, N keep the replay sourced and named inside the local $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ packet. Since none of these rows exports a host equality coordinate, the stable endpoint exactness is exactly the displayed finite readback surface. □

Lean4 ✓ `BEDC.Derived.SelectedTailSeedUp.SelectedTailSeedCarrier endpoint exactness readback stability`

Theorem 1207.6 (Selected-tail Real-seal nonescape obligation)**.** *For an accepted carrier $T = (Q, E, A, W, K, S, R, H, C, P, N)$, the Real seal row R can be consumed only after the* $\mathsf{Rat}^{\uparrow}$, $\mathsf{FiniteTailFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows Q, A, W, K, S have been displayed, with endpoint exactness supplied by E and structural replay supplied by H, C, P, N. Consequently a* $\mathsf{SelectedTailSeed}^{\uparrow}$ *Real-window consumer has no route through quotient streams, host real equality, countable choice, detached limits, or ambient Real completeness.*

Proof. Project the Real-facing row R. By the carrier definition, R is obtained from the selected stationary readback, so it sits downstream of the rational seed, finite-tail admission, stream window, regular-rational readback, and dyadic tolerance ledger.

The nonescape route is the displayed composition $Q, A, W, K, S, E, R, H, C, P, N$. The rows Q, A, W, K, S expose the finite data needed for the Real seal, E ties the selected endpoint to the rational seed, and H, C, P, N preserve, replay, source, and name the constructed route.

The exclusions are therefore structural, not analytic. Quotient streams, host real equality, countable choice, detached limits, and ambient Real completeness are not coordinates of T, and a consumer of R can only project and compose the rows that the finite $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ carrier displays. □

Theorem 1207.7 (Selected-tail seed Real-seal handoff)**.** *For an accepted carrier $T = (Q, E, A, W, K, S, R, H, C, P,$ of Definition 1207.1, every access to the* $\mathsf{Real}^{\uparrow}$ *seal row R factors through the finite route*

$$Q, E, A, W, K, S, H, C, P, N.$$

Thus the selected stationary endpoint reaches the Real seal only through the displayed rational seed, endpoint exactness, finite-tail admission, stream window, regular-rational readback, dyadic ledger, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ *naming, with no quotient stream or ambient-completeness coordinate.*

Proof. Use the carrier displayed in Definition 1207.1. Its rows place R downstream of Q, E, A, W, K, S, while H, C, P, N are the structural rows that transport, replay, source, and name the same finite data.

The local obligation theorem Definition 1207.2 identifies these rows as the whole $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ surface. The Real-window handoff theorem Definition 1207.3 then gives the consumer route through the same finite packet.

The sibling chapters named in the introduction supply the row meanings: $\mathsf{Rat}^{\uparrow}$ for Q, $\mathsf{FiniteTailFilter}^{\uparrow}$ for A, $\mathsf{StreamName}^{\uparrow}$ for W, $\mathsf{RegSeqRat}^{\uparrow}$ for K, $\mathsf{DyadicRatCore}^{\uparrow}$ for S, and $\mathsf{Real}^{\uparrow}$ for R. Since quotient streams and ambient completeness are not coordinates of T, the Real seal has no other entry path. □

Theorem 1207.8 (Selected-tail seed classifier transport)**.** *For accepted carriers $T = (Q, E, A, W, K, S, R, H, C, P,$ and $T' = (Q', E', A', W', K', S', R', H', C', P', N')$ of Definition 1207.1, componentwise* hsame *transport of $Q, E, A, W, K, S, R, H, C, P, N$ to $Q', E', A', W', K', S', R', H', C', P', N'$ preserves the selected-tail classifier exactly as a displayed* $\mathsf{SelectedTailSeed}^{\uparrow}$ *classifier. It does not collapse endpoint exactness E into host equality of Real endpoints or erase the finite-tail, stream-window, regular-rational, and dyadic rows needed to read the classifier.*

Lean4 ✓ `BEDC.Derived.SelectedTailSeedUp.SelectedTailSeedCarrier classifier transport`

Proof. Read the transport row H in the carrier of Definition 1207.1. It is componentwise transport for the displayed rows, so each selected-tail coordinate is carried with its own classifier role rather than through a single host equality.

The obligations in Definition 1207.2 show which classifier pieces must remain visible: rational seed admission, endpoint exactness, finite-tail admission, stream-window exposure, regular-rational readback, dyadic ledger, Real seal, replay, provenance, and naming. Transport that preserves the $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ surface must therefore preserve all these rows.

Finally apply the Real-window handoff of Definition 1207.3. Because every Real-facing consumer still passes through $Q, E, A, W, K, S, R, H, C, P, N$, endpoint exactness cannot be reinterpreted as host Real equality, and classifier transport remains a finite selected-tail transport. □

Theorem 1207.9 (Selected-tail seed window readback coherence)**.** *For every accepted carrier $T = (Q, E, A, W, K, S, R, H, C, P, N)$ of Definition 1207.1, the stream window W, regular-rational readback K, dyadic ledger S, and Real seal R form one coherent finite readback chain inside the* $\mathsf{SelectedTailSeed}^{\uparrow}$ *packet. Any consumer of R must read W through K and S, while H, C, P, N preserve, replay, source, and name that same chain.*

Lean4 ✓ `BEDC.Derived.SelectedTailSeedUp.SelectedTailSeedWindowReadbackCoherence`

Proof. Begin with W. The introduction grounds W in $\mathsf{StreamName}^{\uparrow}$, and Definition 1207.1 makes it the selected stationary tail window rather than a quotient stream.

Next read K and S. The $\mathsf{RegSeqRat}^{\uparrow}$ row K reads the selected window as regular-rational data, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row S records the finite tolerance and arithmetic ledger for that readback.

The Real row R is then the seal obtained from this selected stationary readback. By Definition 1207.2 these rows are part of the same local NameCert surface, and by Definition 1207.3 every Real-window consumer remains on the finite route. The structural rows H, C, P, N do not create a second readback; they preserve the single chain. □

Theorem 1207.10 (Selected-tail seed tail-window determinacy)**.** *For every accepted carrier $T = (Q, E, A, W, K, S, R, H, C, P, N)$ of Definition 1207.1, any consumer route that exposes the selected stationary endpoint as a $\mathsf{Real}^{\uparrow}$ seal from the same finite-tail admission row A must use the displayed chain A, W, K, S, R, with endpoint exactness supplied by E and structural rows supplied by H, C, P, N. No alternate stream window, regular-rational readback, dyadic ledger, or Real seal is a $\mathsf{SelectedTailSeed}^{\uparrow}$ consumer route unless it is supplied as one of these carrier rows.*

Proof. Project the carrier T. The finite-tail admission row is the displayed coordinate A, and Definition 1207.4 makes the selected endpoint pass through that finite admission gate with endpoint exactness E.

Next apply Definition 1207.9. Once A is fixed, the consumer-visible readback is the single window chain W, K, S, R: W exposes the selected stream window, K reads it as regular-rational data, S records the dyadic ledger, and R seals the same selected stationary endpoint as a Real row.

Finally apply Definition 1207.7. The structural rows H, C, P, N preserve, replay, source, and name the displayed chain, while quotient streams, host real equality, detached limits, and ambient Real completeness are not coordinates of the carrier. Hence a route using a different window, readback, ledger, or seal is not a $\mathsf{SelectedTailSeed}^{\uparrow}$ consumer route unless that data has already been supplied as one of the rows of T. □

Theorem 1207.11 (Selected-tail seed stationary-endpoint coverage)**.** *For every accepted carrier $T = (Q, E, A, W, K, S, R, H, C, P, N)$ of Definition 1207.1, the stationary selected endpoint is exposed only through the finite route*

$$Q, E, A, W, K, S$$

before the Real seal row R is consumed. These rows are sufficient for the local selected-tail endpoint read used by Real-window consumers: Q supplies the rational seed, E supplies endpoint exactness, A admits the selected finite tail, W exposes the stationary window, K reads that window as regular-rational data, and S records the dyadic tolerance ledger.

Proof. Project the carrier and apply Definition 1207.2. The displayed NameCert surface contains exactly the seed, exactness, finite-tail admission, stream-window, regular-rational, dyadic-ledger, and Real-seal rows together with the structural rows.

The local endpoint read begins before the Real seal. By Definition 1207.4, the selected stationary tail must first pass through A before any use of W or K.

Finally apply Definition 1207.9. The window-readback chain is W, K, S, R, so the endpoint visible to Real-window consumers has already been routed through Q, E, A, W, K, S before the seal row R is read. □

Theorem 1207.12 (Selected-tail seed dyadic-ledger readback coverage)**.** *For every accepted carrier $T = (Q, E, A, W, K, S, R, H, C, P, N)$ of Definition 1207.1, the row S is the unique displayed*

dyadic tolerance and arithmetic ledger mediating the regular-rational readback K and the Real seal R. No $\mathsf{SelectedTailSeed}^{\uparrow}$ *consumer may pass from W, K to R while omitting S.*

Proof. Project T to its displayed rows. The carrier definition names S as the only $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and arithmetic ledger attached to the selected endpoint, while K is the regular-rational readback row and R is the Real seal row.

Apply Definition 1207.2. The local NameCert surface lists K, S, and R as separate required obligations, so the dyadic ledger cannot be absorbed into either the readback row or the Real seal.

The Real-facing route is fixed by Definition 1207.6 and Definition 1207.7. Both routes pass through S before consuming R, and the carrier exports no alternate coordinate that could mediate the same transition. □

Theorem 1207.13 (Selected-tail seed Real-completion boundary)**.** *Every accepted* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier supplies a finite handoff into Real-window consumers, but it does not assert Real completeness, quotient-stream equality, countable-choice selection, detached limits, or host real equality. Any consumer that needs one of those completion-facing boundaries must obtain it from a separate L10 chapter rather than from the local rows $Q, E, A, W, K, S, R, H, C, P, N$.*

Proof. First use Definition 1207.11. The stationary endpoint exposed by the packet is the finite route Q, E, A, W, K, S before the Real seal row is read.

Next use Definition 1207.12. The passage from regular-rational readback to Real seal must include the displayed dyadic ledger S, so the packet supplies a concrete finite handoff rather than an ambient completion principle.

Finally combine Definition 1207.3 with Definition 1207.7. Both the consumer route and the seal route remain inside the listed carrier rows, whose definition explicitly exports no quotient stream, host real equality, countable-choice selector, detached limit object, or ambient Real-completeness coordinate. □

Theorem 1207.14 (Selected-tail rational seed admission)**.** *For every accepted* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier $T = (Q, E, A, W, K, S, R, H, C, P, N)$, the rows Q and E are the only rational seed and endpoint-exactness admission rows in the local packet. The rational seed enters through Q, endpoint exactness is witnessed through E, and neither role may be replaced by host* $\mathsf{Real}^{\uparrow}$ *equality or by a detached completion-facing comparison.*

Proof. Project the accepted carrier. By Definition 1207.1, Q is the unique displayed $\mathsf{Rat}^{\uparrow}$ seed-rational row, and E is the displayed endpoint-exactness row comparing the selected seed endpoint with that rational seed.

Apply Definition 1207.2. The local $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ surface lists rational seed admission through Q and endpoint exactness through E as separate obligations, while the other rows serve finite-tail admission, stream readback, dyadic accounting, Real sealing, transport, replay, provenance, and naming.

Finally use Definition 1207.13. The packet does not export host real equality, quotient streams, detached limits, countable-choice selection, or ambient Real completeness, so no completion-facing equality can replace the displayed Q, E admission plane. □

Theorem 1207.15 (Selected-tail stream–regular–dyadic compatibility)**.** *For every accepted* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier $T = (Q, E, A, W, K, S, R, H, C, P, N)$, the rows W, K, S form the unique displayed compatibility chain from* $\mathsf{StreamName}^{\uparrow}$ *through* $\mathsf{RegSeqRat}^{\uparrow}$ *to* $\mathsf{DyadicRatCore}^{\uparrow}$ *before the Real seal row R is consumed. Thus a Real-window consumer cannot read R without first passing through the stream window, regular-rational readback, and dyadic ledger displayed by W, K, S.*

Proof. Start with the readback chain. Definition 1207.9 identifies W, K, S, R as one coherent finite readback chain inside the accepted packet.

The dyadic step is not optional. By Definition 1207.12, the row S is the unique displayed dyadic tolerance and arithmetic ledger mediating the regular-rational readback K and the Real seal R.

The Real-facing boundary then fixes the order of consumption. Definition 1207.7 and Definition 1207.13 keep the consumer route inside the finite carrier rows, so the path to R is exactly the displayed $\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow}$ compatibility chain W, K, S. □

Theorem 1207.16 (Selected-tail package provenance exactness)**.** *For every accepted* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier* $T = (Q, E, A, W, K, S, R, H, C, P, N)$*, the rows* P *and* N *name exactly the finite route*

$$Q, E, A, W, K, S, R, H, C.$$

They cannot add quotient streams, countable-choice selectors, detached limits, ambient completeness, or host equality beyond the displayed selected-tail seed packet.

Proof. Inventory the carrier rows. The data-bearing route is Q, E, A, W, K, S, R, and the structural route is H, C; by Definition 1207.1, P is the Pkg provenance over these displayed ingredients and N is the local $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ row.

Apply Definition 1207.2. The provenance and naming rows source and name the existing route; they are not independent coordinates carrying analytic completion data.

Finally apply Definition 1207.13. Since the packet exports no quotient stream, host real equality, countable-choice selector, detached limit object, or ambient Real-completeness coordinate, P, N preserve provenance exactly for $Q, E, A, W, K, S, R, H, C$ and cannot enlarge the route. □

Theorem 1207.17 (Selected-tail seed dependency readiness triad)**.** *Every accepted* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier displays a root-ready dependency triad. The rational endpoint plane is* Q, E*; the finite-tail, window, and readback plane is* A, W, K*; and the dyadic Real-seal plane is* S, R*. The structural rows* H, C, P, N *preserve the same packet by componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$ *row.*

Proof. Project the accepted carrier as $T = (Q, E, A, W, K, S, R, H, C, P, N)$. The carrier definition already displays the six dependency rows named in the chapter introduction: $\mathsf{Rat}^{\uparrow}$ supplies the rational seed row Q, $\mathsf{FiniteTailFilter}^{\uparrow}$ supplies the selected finite-tail admission row A, $\mathsf{StreamName}^{\uparrow}$ supplies the window row W, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the readback row K, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the dyadic ledger row S, and $\mathsf{Real}^{\uparrow}$ supplies the seal row R.

The row E binds the rational endpoint plane by comparing the selected seed endpoint with the rational seed under the displayed rational classifier. Thus Q, E form the rational endpoint plane, while A, W, K form the finite-tail, window, and readback plane.

Finally use Definition 1207.2 and Definition 1207.3. The rows S, R form the dyadic Real-seal plane, and H, C, P, N do not create another carrier. They transport, replay, source, and name the same finite packet, so the displayed triad is root-ready without quotient streams, host real equality, or ambient completeness. □

Theorem 1207.18 (Selected-tail seed StreamName–RegSeqRat scope)**.** *For every accepted* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier* $T = (Q, E, A, W, K, S, R, H, C, P, N)$*, the readback surface* W, K *depends only on the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows of the packet. It does not depend on quotient-stream equality, host real equality, detached limits, countable choice, or ambient Real completeness.*

Proof. First project the window and readback coordinates. By Definition 1207.1, W is the $\mathsf{StreamName}^{\uparrow}$ window exposing the selected stationary tail segment, and K is the $\mathsf{RegSeqRat}^{\uparrow}$ readback row for the stationary regular-rational sequence at that window.

Next use Definition 1207.9. The readback chain consumes W through K inside the same finite carrier, while H, C, P, N preserve, replay, source, and name that chain through the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ surface.

The nonescape claim follows from Definition 1207.13. The packet exports no quotient-stream equality, host real equality, detached limit, countable-choice selector, or ambient Real-completeness coordinate, so the W, K readback scope is exactly the displayed StreamName–RegSeqRat scope. □

Theorem 1207.19 (Selected-tail seed dyadic Real-seal scope)**.** *For every accepted* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier* $T = (Q, E, A, W, K, S, R, H, C, P, N)$*, the rows* S, R *route through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *as a finite seal surface. This route uses the displayed dyadic tolerance ledger and Real seal only; it does not use quotient streams, host real equality, detached limits, countable choice, or ambient completeness.*

Proof. Project S and R from the accepted carrier. The carrier definition names S as the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and arithmetic ledger attached to the selected endpoint, and it names R as the $\mathsf{Real}^{\uparrow}$ seal row obtained from the selected stationary readback.

Apply Definition 1207.12. The passage from regular-rational readback to Real seal cannot omit S, so the Real-facing route passes through the displayed dyadic ledger before consuming R.

Finally apply Definition 1207.7 and Definition 1207.13. The seal route remains a finite carrier route through S, R and the structural rows that preserve the same packet. Since the carrier has no quotient stream, host real equality, detached limit, countable-choice selector, or ambient-completeness coordinate, the dyadic Real-seal scope is exactly the displayed $\mathsf{DyadicRatCore}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ scope. □

Theorem 1207.20 (Selected-tail seed finite-tail Real-boundary scope)**.** *For every accepted* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier* $T = (Q, E, A, W, K, S, R, H, C, P, N)$*, the tuple* A, W, K, S, R *is the exact finite-tail-to-Real boundary consumed downstream. The finite-tail admission* A*, stream window* W*, regular-rational readback* K*, dyadic ledger* S*, and Real seal* R *are the consumer-visible route from selected finite tail to Real-facing handoff.*

Proof. Begin with the finite-tail side. By Definition 1207.4, every use of W or K first factors through the $\mathsf{FiniteTailFilter}^{\uparrow}$ admission witnessed by A.

Then use Definition 1207.9. The accepted readback chain is W, K, S, R: the window exposes the selected stationary segment, the regular-rational row reads it, the dyadic ledger records the finite tolerance and arithmetic, and the Real row seals the same selected endpoint.

Finally apply Definition 1207.13. Downstream consumers receive a finite handoff and no completion-facing principle from this chapter. Therefore A, W, K, S, R is the exact finite-tail-to-Real boundary supplied by $\mathsf{SelectedTailSeed}^{\uparrow}$. □

This chapter is composite rather than atomic. Its independence from the sibling chapters is not expressed by row-by-row atomic separation: $\mathsf{SelectedTailSeed}^{\uparrow}$ deliberately joins $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{FiniteTailFilter}^{\uparrow}$ into one stationary selected-tail seed packet, and each sibling omits at least one coordinate needed for the full Real-window handoff.

The Lean `TasteGate.lean` boundary for $\mathsf{SelectedTailSeed}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial}\ \mathsf{SelectedTailSeed}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{SelectedTailSeed}^{\uparrow}$ instances preserving $Q, E, A, W, K, S, R, H, C, P, N$.

Falsifiable prediction: If the finite-tail admission row A or the Real seal row R is absent, no accepted $\mathsf{SelectedTailSeed}^{\uparrow}$ packet can expose the stationary selected-tail endpoint as a Real-window handoff.

Theorem 1207.21 (Selected-tail seed public Real-window export)**.** *Every accepted* $\mathsf{SelectedTailSeed}^{\uparrow}$ *carrier exports a public Real-window handoff through the scoped rows* $Q, E, A, W, K, S, R, H, C, P, N$*. The export is the finite selected-tail route from rational seed and endpoint exactness through finite-tail admission, stream window, regular-rational readback, dyadic ledger, Real seal, componentwise history transport, displayed continuity replay, package provenance, and local name certificate. It excludes quotient streams, host real equality, countable choice, detached limits, and ambient Real completeness.*

Proof. Project the accepted carrier as $T = (Q, E, A, W, K, S, R, H, C, P, N)$. By Definition 1207.17, the rows split into the rational endpoint plane Q, E, the finite-tail readback plane A, W, K, the dyadic Real-seal plane S, R, and the structural preservation rows H, C, P, N.

Next apply Definition 1207.18. The selected stationary window and regular-rational readback are already scoped by the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows, so the handoff has a public readback surface without quotient-stream equality or host real equality.

Apply Definition 1207.19. The same route then passes through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ ledger and $\mathsf{Real}^{\uparrow}$ seal, so the L10 source chain remains finite and carrier-internal.

Finally use Definition 1207.20. Downstream consumers receive exactly the boundary A, W, K, S, R, while Q, E, H, C, P, N give the seed, comparison, transport, replay, provenance, and naming context for that boundary. Since the cited scope theorems rule out quotient streams, host real equality, countable choice, detached limits, and ambient Real completeness, this is the public Real-window export promised by the accepted $\mathsf{SelectedTailSeed}^{\uparrow}$ carrier. □

Theorem 1207.22 (Selected-tail seed Real-completion bridge)**.** *The public Real-window export of Definition 1207.21 is exactly the finite bridge route consumed by the stationary rational selected-tail seed exactness surface of Definition 9238.11. The route passes through*

$$Q, E, A, W, K, S, R, H, C, P, N$$

and its sibling dependencies are precisely $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{FiniteTailFilter}^{\uparrow}$*. It excludes quotient streams, host real equality, countable choice, detached limits, and ambient Real completeness.*

Proof. Start with the public export. By Definition 1207.21, every accepted carrier already presents the route $Q, E, A, W, K, S, R, H, C, P, N$ as a public Real-window handoff, with the rational seed and endpoint comparison in Q, E, the selected finite-tail readback in A, W, K, the dyadic Real-seal surface in S, R, and the structural rows in H, C, P, N.

The admission side is fixed by Definition 1207.4. No consumer can reach the selected stationary stream window or regular-rational readback before passing through the displayed $\mathsf{FiniteTailFilter}^{\uparrow}$ row A, so the bridge cannot insert an alternate raw-tail or detached-limit path.

Next use Definition 1207.15. The rows W, K, S form the required $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$ chain before the Real seal is read, while Definition 1207.19 keeps the seal route inside the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows.

Finally apply Definition 1207.7 and Definition 1207.13. These results hand the selected endpoint to R without adding quotient streams, host real equality, countable choice, detached limits, or ambient Real completeness. Thus the exactness surface of Definition 9238.11 consumes precisely the same finite route exported by Definition 1207.21. □

Theorem 1207.23 (Selected-tail seed mature Real-completion package)**.** *The public export, finite-tail admission exactness,* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$ *compatibility, dyadic Real-seal scope, and Real-completion bridge together form the mature finite selected-tail package over* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{FiniteTailFilter}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The package excludes quotient streams, host real equality, countable choice, detached limit selection, and ambient Real completeness.*

Proof. Apply Definition 1207.21. It provides the public route through $Q, E, A, W, K, S, R, H, C, P, N$ and already records the exclusion of quotient streams, host real equality, countable choice, detached limits, and ambient Real completeness.

The finite-tail and sibling compatibility rows are fixed by Definition 1207.4 and Definition 1207.15. These results bind the $\mathsf{FiniteTailFilter}^{\uparrow}$ admission and the $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{DyadicRatCore}^{\uparrow}$ readback chain inside the accepted carrier.

Finally use Definition 1207.19 and Definition 1207.22. The Real-facing seal remains the displayed $\mathsf{DyadicRatCore}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ finite route, and the bridge consumed by the stationary rational selected-tail exactness surface is precisely the same route. Thus the cited rows constitute the mature finite selected-tail Real-completion package, with no additional quotient, host-equality, choice, detached-limit, or ambient-completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SelectedTailSeed}^{\uparrow}$ packet is generated from a rational seed row, selected endpoint exactness, finite-tail admission, stream window, regular-rational readback, dyadic tolerance ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1207.17, Definition 1207.18, Definition 1207.19, Definition 1207.20, Definition 1207.21, Definition 1207.22, and Definition 1207.23 bind the mature finite selected-tail Real-completion package over $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteTailFilter}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SelectedTailSeed}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.SelectedTailSeedUp.SelectedTailSeedTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Lean4 ✓ `BEDC.Derived.SelectedTailSeedUp.taste gate`

Not claimed: This chapter does not close bridge checking, quotient streams, host real equality, countable choice, detached limit selection, or ambient Real completeness.

Upgrade path: Further verification requires bridge checking for the selected-tail Real-completion route without quotient streams, host real equality, countable choice, detached limits, or ambient Real completeness.

Chapter 1208

A Concrete Naming Certificate for $\mathsf{UnitCalibrationLedger}^{\uparrow}$

The $\mathsf{UnitCalibrationLedger}^{\uparrow}$ packet realizes the empirical-value discipline of chapter 9462 as a finite NameCert surface for measured numerical constants. It sits beside the law-certificate packet of chapter 1155, the physical-model audit packet of chapter 1129, the certified physical-truth packet of chapter 1130, and the terminal unit surface of chapter 115. Those siblings supply law patterns, audit comparisons, truth-certificate reads, and terminal unit naming; this packet binds numerical measurement, unit conversion, calibration, uncertainty, instrument, reproducibility, dimension, classifier, transport, provenance, and local naming before any consumer may read a value as empirical.

Definition 1208.1 (Unit calibration ledger carrier)**.** *A* $\mathsf{UnitCalibrationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (M, U, C, E, I, R, D, K, H, P, N)$$

with the following displayed rows:

1. *M is the measurement-record row, naming the finite observation, numerical readout, sampling context, and protocol by which the value was obtained.*
2. *U is the unit-bridge row, recording the source unit, target standard unit, conversion route, and local unit certificate read through chapter 115.*
3. *C is the calibration row, naming the calibration source, calibration state, reference route, and validity scope for the measurement instrument.*
4. *E is the uncertainty row, recording error bars, tolerance, resolution, rounding discipline, and any admitted confidence or interval convention.*
5. *I is the instrument-ledger row, naming the device, sensor, apparatus, or procedure whose output supplies M.*
6. *R is the reproducibility-ledger row, recording repeated runs, independent checks, or declared replication boundary for the same empirical value.*
7. *D is the dimension row, recording the physical dimension and the bridge between dimension-bearing syntax and the unit bridge U.*
8. *K is the classifier row comparing empirical-value packets componentwise across M, U, C, E, I, R, D and rejecting value-only equality.*

9. *H records componentwise* hsame *transport for measurement, unit, calibration, uncertainty, instrument, reproducibility, dimension, classifier, provenance, and local-name rows.*

10. *P is the* Pkg *provenance over* UnitCalibrationLedger$^{\uparrow}$, LawCertificate$^{\uparrow}$, PhysicalModelAudit$^{\uparrow}$, CertifiedPhysicalTruth Unit$^{\uparrow}$, RealityConstrainedModelErrorBudget$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UnitCalibrationLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for a bare real number, detached constant symbol, unit-free magnitude, uncalibrated measurement, uncertainty-free export, anonymous instrument, unreproducible read, or dimensionless empirical shortcut outside the displayed packet.

Lean4 (definition) `BEDC.Derived.UnitCalibrationLedgerUp.UnitCalibrationLedgerUp`
Lean4 (definition) `BEDC.Derived.UnitCalibrationLedgerUp.taste gate`
Lean4 ✓ `BEDC.Derived.UnitCalibrationLedgerUp.UnitCalibrationLedgerTasteGate single carrier alignment`

Definition 1208.2 (Unit calibration ledger classifier)**.** *The* UnitCalibrationLedger$^{\uparrow}$ *classifier identifies two accepted packets only when their measurement-record rows, unit-bridge rows, calibration rows, uncertainty rows, instrument-ledger rows, reproducibility-ledger rows, dimension rows, classifier rows, componentwise transports, provenance rows, and local NameCert rows agree through displayed* hsame *transport. Agreement of the printed numeral alone is not enough, and agreement of the unit row without calibration, uncertainty, instrument, and reproducibility rows is not enough.*

Theorem 1208.3 (Unit calibration ledger NameCert obligations)**.** *For the carrier of Definition 1208.1, the local* $\mathsf{NameCert}_{\mathsf{UnitCalibrationLedger}^{\uparrow}}$ *surface consists exactly of five empirical ledger obligations:*

1. *measurement admission through M, requiring the numerical readout to be tied to a finite observation record and protocol;*

2. *unit and dimension admission through U and D, requiring every numerical read to carry its unit bridge and dimension row;*

3. *calibration admission through C, requiring the measuring route to expose its calibration source and validity scope;*

4. *uncertainty admission through E, requiring the value to expose its tolerance, resolution, or interval convention;*

5. *instrument and reproducibility admission through I and R, requiring both the generating apparatus and the replication boundary to be part of the same packet.*

The structural rows K, H, P, N compare, transport, source, and locally name those five obligations, but they do not add another empirical-value coordinate.

Proof. Carrier admission is projection from Definition 1208.1. The packet lists the measurement record, unit bridge, calibration row, uncertainty row, instrument ledger, reproducibility ledger, dimension row, classifier, transport, provenance, and local name as a single finite surface.

The five obligation rows group these displayed coordinates by empirical function. Measurement admission comes from M; unit and dimension admission come from U and D; calibration admission comes from C; uncertainty admission comes from E; instrument and reproducibility admission come from I and R.

The classifier and structural rows preserve only the same displayed packet. Since the carrier has no coordinate for a detached numeral, hidden unit convention, omitted calibration, suppressed uncertainty, anonymous instrument, or unrecorded replication boundary, the five obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.UnitCalibrationLedgerUp.UnitCalibrationLedgerCarrier namecert obligations`

Theorem 1208.4 (Unit calibration ledger numeric-value nonescape)**.** *An accepted* $\mathsf{UnitCalibrationLedger}^{\uparrow}$ *packet cannot export a numerical empirical value unless the unit bridge* U*, calibration row* C*, uncertainty row* E*, instrument ledger* I*, and reproducibility ledger* R *are present in the same finite carrier. Dropping any one of those rows leaves the accepted empirical-value surface.*

Proof. Read the carrier as $V = (M, U, C, E, I, R, D, K, H, P, N)$. The measurement row M records a finite numerical readout, but the packet treats that readout as empirical only after the unit bridge, calibration row, uncertainty row, instrument ledger, and reproducibility ledger are displayed beside it.

Apply the obligation surface of Definition 1208.3. Unit and dimension admission require U and D, calibration admission requires C, uncertainty admission requires E, and instrument-reproducibility admission requires I and R.

Finally use the classifier of Definition 1208.2. It compares accepted packets componentwise and does not identify two packets by their printed numerals alone. Therefore a value export lacking U, C, E, I, or R is outside the local $\mathsf{NameCert}_{\mathsf{UnitCalibrationLedger}^{\uparrow}}$ carrier. □

Lean4 ✓ `BEDC.Derived.UnitCalibrationLedgerUp.UnitCalibrationLedgerNumericValueNonescape`

Theorem 1208.5 (Unit calibration ledger law-certificate handoff)**.** *Every* $\mathsf{LawCertificate}^{\uparrow}$*,* $\mathsf{PhysicalModelAudit}^{\uparrow}$*, or* $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$ *consumer read of a numerical empirical constant factors through a displayed* $\mathsf{UnitCalibrationLedger}^{\uparrow}$ *packet. The consumer may use the numerical row only together with its unit bridge, calibration row, uncertainty row, instrument ledger, reproducibility ledger, dimension row, classifier, transport, provenance, and local NameCert row.*

Proof. The sibling consumers have distinct public roles. chapter 1155 reads equation-like law patterns, chapter 1129 reads physical-model audit comparisons, and chapter 1130 reads certified physical-truth packets.

None of those roles supplies a complete empirical-value carrier by itself. A numerical constant used by any of them must therefore be projected through the packet $V = (M, U, C, E, I, R, D, K, H, P, N)$ of Definition 1208.1.

The nonescape theorem Definition 1208.4 blocks value-only export. Hence each consumer receives the numerical row only through the same displayed measurement, unit, calibration, uncertainty, instrument, reproducibility, dimension, classifier, transport, provenance, and local NameCert surface. □

Lean4 ✓ `BEDC.Derived.UnitCalibrationLedgerUp.UnitCalibrationLedgerCarrier law certificate handoff`

Theorem 1208.6 (Unit calibration ledger empirical bridge surface)**.** *Every bridge from* $\mathsf{UnitCalibrationLedger}^{\uparrow}$ *to* $\mathsf{LawCertificate}^{\uparrow}$*,* $\mathsf{PhysicalModelAudit}^{\uparrow}$*,* $\mathsf{CertifiedPhysicalTruth}^{\uparrow}$*, or* $\mathsf{Unit}^{\uparrow}$ *preserves the displayed rows*

$$M, U, C, E, I, R, D, K, H, P, N$$

of Definition 1208.1. No such bridge may read a bare $\mathsf{Real}^{\uparrow}$ *value, unit-free magnitude, omitted calibration row, suppressed uncertainty row, anonymous instrument row, or unrecorded reproducibility row as an empirical-value packet.*

Proof. Project the carrier of Definition 1208.1. The bridge source is the finite packet $V = (M, U, C, E, I, R, D, K, H, P, N)$, so the measurement, unit, calibration, uncertainty, instrument, reproducibility, dimension, classifier, transport, provenance, and local naming rows are all visible before any target sibling is read.

Apply the NameCert obligations of Definition 1208.3. They force measurement admission through M, unit and dimension admission through U, D, calibration admission through C, uncertainty admission through E, instrument and reproducibility admission through I, R, and structural preservation through K, H, P, N.

Next apply numeric-value nonescape from Definition 1208.4. A value-only export leaves the accepted empirical packet, so a bridge cannot replace the carrier by a bare $\mathsf{Real}^{\uparrow}$ value, unit-free magnitude, missing calibration, missing uncertainty, anonymous instrument, or missing reproducibility boundary.

Finally route through the law-certificate handoff of Definition 1208.5. The law-certificate, physical-model audit, certified physical-truth, and terminal unit consumers receive the numerical row only together with the same displayed empirical-value surface, so the bridge preserves $M, U, C, E, I, R, D, K, H, P, N$. □

The Lean follow-up file `lean4/BEDC/Derived/UnitCalibrationLedgerUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ UnitCalibrationLedger}^{\uparrow}$ and $\mathsf{FieldFaithful\ UnitCalibrationLedger}^{\uparrow}$ instances, with witness-pair and field-projection proofs preserving $M, U, C, E, I, R, D, K, H, P, N$ as separate displayed fields.

Falsifiable prediction: A numerical empirical-value export lacking any one of unit bridge, calibration, uncertainty, instrument, or reproducibility rows is rejected by the local carrier.

Independence witness: lawcertificate, physicalmodelaudit, certifiedphysicaltruth, unit, realityconstrainedmodelerrorbudget: none is bijective because UnitCalibrationLedgerUp binds numerical measurement, unit conversion, calibration, uncertainty, instrument, reproducibility, dimension, classifier, transport, provenance, and local NameCert rows in one carrier, while each sibling supplies only a law pattern, audit packet, truth surface, terminal unit, or error-budget component.

Closure status for $\mathsf{NameCert}_{\mathsf{UnitCalibrationLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{UnitCalibrationLedger}^{\uparrow}$ packet is generated from finite measurement, unit bridge, calibration, uncertainty, instrument, reproducibility, dimension, classifier, componentwise hsame transport, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UnitCalibrationLedger}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1208.1, Definition 1208.2, Definition 1208.3, Definition 1208.4, the public export theorem Definition 1208.5, and the empirical bridge surface Definition 1208.6 bind BHist, hsame, Cont, Pkg, NameCert, and the displayed rows $M, U, C, E, I, R, D, K, H, P, N$ as the exported empirical-value handoff and sibling bridge surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UnitCalibrationLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host-level metrology, all standards bodies, exact experimental replication, or physical truth beyond the displayed empirical-value packet.

Upgrade path: The remaining work is Lean-side verification and bridge checking for the empirical bridge surface of Definition 1208.6.

Chapter 1209

A Concrete Naming Certificate for $\mathsf{ClaimRegistryLayer}^{\uparrow}$

The $\mathsf{ClaimRegistryLayer}^{\uparrow}$ packet realizes the registry layer of section 9462.35 as a finite export-control carrier for philosophy-package claims. It sits beside the unit calibration ledger of chapter 1208 and the external-supply boundary of chapter 1065: those siblings control empirical-value export and external-supply requests, while this packet controls whether a claim is admitted as a package-level exported claim at all.

Definition 1209.1 (Claim registry layer carrier)**.** *A* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (E, R, B, C, F, V, H, P, N)$$

with the following displayed rows:

1. *E is the claim-entry row, naming the exported philosophy-package claim, its local subject index, and its intended package surface.*
2. *R is the refusal-boundary row, recording the registry entry that blocks claims with no accepted export surface.*
3. *B is the closure-status row, recording the theory-closure and verification axes used by the claim site.*
4. *C is the formal-target row, recording the Lean target, statement-only site, encoded definition, or absence of a formal target for the same claim.*
5. *F is the provenance row, tying the claim to the finite source file, section, carrier, theorem, definition, or cannot-claim row from which it is exported.*
6. *V is the local verification-readback row, recording whether the package claim is read as checked theorem, encoded definition, scoped paper claim, or explicit refusal.*
7. *H records componentwise* hsame *transport for claim entry, refusal boundary, closure status, formal target, provenance, verification readback, package provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{AxisCarryRefusalLedger}^{\uparrow}$, $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$, $\mathsf{FiniteObservationResidueBoundary}^{\uparrow}$, $\mathsf{ExternalSupplyBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClaimRegistryLayer}^{\uparrow}}$ *row.*

The carrier has no coordinate for an exported package claim outside the displayed entry, refusal boundary, closure status, formal target, provenance, verification readback, transport, package, and local NameCert rows.

Lean4 ✓ `BEDC.Derived.ClaimRegistryLayerUp.TasteGate.ClaimRegistryLayerTasteGate single carrier alignment`

Theorem 1209.2 (Claim registry layer export control)**.** *Every exported philosophy-package claim admitted by* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *must display the claim-entry row E, refusal-boundary row R, closure-status row B, formal-target row C, provenance row F, verification-readback row V, componentwise transport H, package provenance P, and local naming row N in the same finite carrier. A consumer may cite the claim only through that packet.*

Lean4 ✓ `BEDC.Derived.ClaimRegistryLayerUp.ClaimRegistryLayer export control certificate`

Proof. Project the carrier of Definition 1209.1. The exported claim is not just the prose entry E; it is the full packet $Q = (E, R, B, C, F, V, H, P, N)$.

The registry layer of section 9462.35 supplies the export-control reading: a claim must either appear in a registry entry or be blocked by a registry entry. Rows E and R encode those two possibilities inside the same finite packet.

The remaining rows make the export auditable. Closure status B, formal target C, provenance F, and verification readback V identify the claim's status, while H, P, N preserve and name the displayed rows. Since no other export coordinate exists, the consumer can cite the claim only through the packet above. □

Lean4 ✓ `BEDC.Derived.ClaimRegistryLayerUp.TasteGate.ClaimRegistryLayer export control certificate`

Theorem 1209.3 (Claim registry layer no unregistered export)**.** *An exported philosophy-package claim with no* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *entry row and no refusal-boundary row is rejected by the carrier. In particular, a prose claim cannot become a package-level BEDC claim merely by appearing near a theorem, definition, closure-status block, or formal target; it must be registered or refused by the same finite export-control surface.*

Proof. Begin with export control, Definition 1209.2. Any admitted package-level export must be read through $Q = (E, R, B, C, F, V, H, P, N)$.

If both the entry row E and refusal-boundary row R are absent, the packet required by Definition 1209.1 is not present. The remaining rows cannot manufacture claim admission because closure status, formal targets, provenance, verification readback, transport, package provenance, and local naming are structural rows for an already displayed entry or refusal.

Thus an unregistered prose claim has no carrier coordinate from which export can be read. It remains outside the package-level claim surface until the registry layer supplies either an entry row or a refusal row. □

Lean4 ✓ `BEDC.Derived.ClaimRegistryLayerUp.TasteGate.ClaimRegistryLayer no unregistered export certificate`

The Lean follow-up file `lean4/BEDC/Derived/ClaimRegistryLayerUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{ClaimRegistryLayer}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ClaimRegistryLayer}^{\uparrow}$ instances, preserving $E, R, B, C, F, V, H, P, N$ as separate displayed fields.

Falsifiable prediction: Any exported philosophy-package claim with no registry entry or refusal row is rejected by the $\mathsf{ClaimRegistryLayer}^{\uparrow}$ carrier.

Independence witness: axiscarryrefusalledger, realityconstrainedmethodologyledger, finiteobservationresidueboundary, externalsupplyboundary: none is bijective to $\mathsf{ClaimRegistryLayer}^{\uparrow}$ because those siblings carry refusal, methodology, finite-observation residue, or external-supply boundary rows, while this carrier binds claim entry, refusal boundary, closure status, formal target, provenance, verification readback, transport, package provenance, and local NameCert rows in one export-control packet.

Theorem 1209.4 (Claim registry layer public export)**.** *The public* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *export is exactly the finite packet with claim entry, refusal boundary, closure status, formal target, provenance, verification readback, componentwise transport, package provenance, and local* NameCert *rows. A public consumer of a package-level claim may read only this packet surface, and any claim lacking both a registry entry and a refusal-boundary row remains outside the public export.*

Proof. Apply Definition 1209.2. It identifies every admitted exported claim with the packet $Q = (E, R, B, C, F, V, H, P, N)$, so the public export cannot drop the closure-status, formal-target, provenance, verification-readback, transport, package-provenance, or local naming rows.

Apply Definition 1209.3. A claim with neither an entry row nor a refusal-boundary row has no carrier coordinate from which public export can be read. Thus the public surface is exactly the displayed finite packet and no unregistered prose claim enters it. □

Lean4 ✓ `BEDC.Derived.ClaimRegistryLayerUp.ClaimRegistryLayer public export certificate`

Theorem 1209.5 (Claim registry layer bridge route)**.** *The public export packet*

$$Q = (E, R, B, C, F, V, H, P, N)$$

is the bridge-readable $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *surface from claim-entry and refusal-boundary rows to package-level export. A bridge consumer reads the entry row E or refusal row R, then the closure-status, formal-target, provenance, and verification-readback rows B, C, F, V, and finally the transport, package, and local naming rows H, P, N.*

Proof. Project the carrier of Definition 1209.1. It exposes exactly the nine rows $E, R, B, C, F, V, H, P, N$ and no separate package-export coordinate.

Use Definition 1209.4. The public export theorem identifies this finite packet as the complete public surface for package-level claim export.

Finally apply Definition 1209.3. Since a claim without an entry row and without a refusal-boundary row has no public export, every bridge-readable route from claim rows to package export must pass through the displayed packet Q. □

Lean4 ✓ `BEDC.Derived.ClaimRegistryLayerUp.TasteGate.ClaimRegistryLayer bridge route certificate`

Theorem 1209.6 (Claim registry layer mature package claim index)**.** *The public export theorem, no-unregistered-export theorem, and bridge route together form the mature package claim index for* $\mathsf{ClaimRegistryLayer}^{\uparrow}$*. A package-level claim is public exactly when it is read through the packet $Q = (E, R, B, C, F, V, H, P, N)$, rejected when both E and R are absent, and bridge-readable only through the same entry, refusal, closure-status, formal-target, provenance, verification-readback, transport, package, and local naming rows.*

Proof. Start with Definition 1209.4. It identifies the public package-claim surface with the displayed packet $Q = (E, R, B, C, F, V, H, P, N)$.

Apply Definition 1209.3. This removes every prose-only package claim with neither entry row nor refusal-boundary row from the index.

Use Definition 1209.5. The bridge-readable route consumes the same packet rows and adds no separate claim coordinate, so the public export, rejection boundary, and bridge route are one complete package claim index. □

Lean4 ✓ `BEDC.Derived.ClaimRegistryLayerUp.ClaimRegistryLayer mature package claim index`

Closure status for $\mathsf{NameCert}_{\mathsf{ClaimRegistryLayer}^{\uparrow}}$.

Constructive story: A $\mathsf{ClaimRegistryLayer}^{\uparrow}$ packet is generated from claim-entry, refusal-boundary, closure-status, formal-target, provenance, verification-readback, componentwise hsame transport, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClaimRegistryLayer}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1209.1, Definition 1209.2, Definition 1209.3, Definition 1209.4, Definition 1209.5, Definition 1209.6, the falsifiable prediction, and the independence witness bind the carrier, export-control theorem, no-unregistered-export theorem, public export theorem, bridge route, mature package claim index, and non-bijection surface for package-level claim export.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClaimRegistryLayer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, full subject-index governance, or the correctness of every downstream registry row.

Upgrade path: Lean bridge checking remains the formal-axis next step for the public $\mathsf{ClaimRegistryLayer}^{\uparrow}$ export surface and mature package claim index.

Chapter 1210

A Concrete Naming Certificate for $\mathsf{TailModulusAlignment}^{\uparrow}$

The $\mathsf{TailModulusAlignment}^{\uparrow}$ packet realizes the shared tail-modulus route used by the Real-completion surface of chapter 9238. It is structurally composite over the refinement route of chapter 885, the tail schedule of chapter 838, the tail-fusion surface of **??**, the finite windows of chapter 126, the regular-rational readbacks of chapter 301, the dyadic tolerance rows of chapter 291, and the seal rows of chapter 38. The packet names one finite alignment certificate for a shared tail threshold, not a quotient stream, host real equality, selected limit, countable-choice selector, or ambient Real-completeness principle.

Definition 1210.1 (Tail-modulus alignment carrier)**.** *A* $\mathsf{TailModulusAlignment}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, S, F, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *row exposing the source moduli, shared meet, selector-budget route, and selected-window tolerance surface;*
2. *S is the* $\mathsf{RegularCauchyTailSchedule}^{\uparrow}$ *row exposing the precision request, cofinal tail bound, and scheduled finite tail witness;*
3. *F is the* $\mathsf{CauchyTailModulusFusion}^{\uparrow}$ *or* $\mathsf{RealModulusFusion}^{\uparrow}$ *row that joins the refinement and schedule surfaces before a seal-facing consumer reads them;*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family common to the refinement, schedule, and fusion rows;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled windows;*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic ledger attached to the common window readback;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, S, F, W, R, D have been displayed on the same packet;*
8. *H records componentwise* hsame *transport for M, S, F, W, R, D, E and the local certificate row;*
9. *C records displayed* Cont *replay from the refinement request through the schedule, fusion, window readback, dyadic ledger, and Real seal;*

10. *P is the* Pkg *provenance over* TailModulusAlignment$^{\uparrow}$, CauchyModulusRefinement$^{\uparrow}$, RegularCauchyTailSchedule$^{\uparrow}$, CauchyTailModulusFusion$^{\uparrow}$, RealModulusFusion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{TailModulusAlignment}^{\uparrow}}$ *row.*

The carrier exports only the displayed alignment rows and their transport, replay, provenance, and naming support.

Lean4 (definition) `BEDC.Derived.TailModulusAlignmentUp.tail modulus alignment taste gate`

Theorem 1210.2 (Tail-modulus alignment obligation surface)**.** *For the carrier of Definition 1210.1, the local* NameCert$_{\text{TailModulusAlignment}^{\uparrow}}$ *surface consists exactly of carrier admission, refinement-source exposure through M, tail-schedule exposure through S, fusion-route exposure through F, common* StreamName$^{\uparrow}$ *window admission through W,* RegSeqRat$^{\uparrow}$ *readback through R,* DyadicRatCore$^{\uparrow}$ *tolerance and arithmetic exposure through D,* Real$^{\uparrow}$ *seal exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier A. Its coordinates list the refinement, schedule, fusion, stream-window, regular-rational readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows.

The data-bearing obligations are inherited in order. The refinement row exposes the source moduli and selected-window tolerance route, the schedule row exposes the cofinal tail request and finite tail witness, and the fusion row forces those two surfaces onto the same tail-modulus route before any seal-facing read is available.

The remaining rows are the common BEDC support rows. The StreamName$^{\uparrow}$ window, RegSeqRat$^{\uparrow}$ readback, DyadicRatCore$^{\uparrow}$ ledger, and Real$^{\uparrow}$ seal are consumed along the displayed route, while H, C, P, N only transport, replay, source, and name that route. Thus the listed rows exhaust the local naming obligations. □

Lean4 ✓ `BEDC.Derived.TailModulusAlignmentUp.TasteGate.TailModulusAlignmentTasteGate single carrier alignment`

Closure status for NameCert$_{\text{TailModulusAlignment}^{\uparrow}}$.

Constructive story: The tail-modulus alignment object is generated from $BHist$ rows that separately record a tail refinement route, a modulus schedule, common stream windows, regular-rational readback, and dyadic ledger data, then bind them by an explicit fusion witness. The carrier first reads the tail evidence, then the modulus evidence, and finally the ledger row showing that both are synchronized for the same Real-facing seal. The $hsame$ relation keeps the aligned rows stable under representative change, while Cont permits later handoffs only when the tail and modulus witnesses travel together. The sibling-dependency and non-escape theorems make this a composite certificate over visible upstream packets rather than a free-standing modulus principle.

Theory closure: TheoryGate(NameCert$_{\text{TailModulusAlignment}^{\uparrow}}$, seed)

Scope closed: This chapter binds the tail-modulus alignment carrier, obligation-surface theorem, sibling-dependency theorem, and non-escape theorem.

Formal verification: FormalStatus(NameCert$_{\text{TailModulusAlignment}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim an independent modulus extractor, arbitrary tail equality, or alignment outside the displayed sibling routes.

Upgrade path: Reaching obligationClosure requires formal tail and modulus row predicates plus checked synchronization through the alignment witness.

Theorem 1210.3 (Tail-modulus alignment sibling dependency)**.** *Every accepted* $\mathsf{TailModulusAlignment}^{\uparrow}$ *packet depends essentially on both the refinement sibling and the schedule sibling: deleting M removes the displayed source-modulus and selector-budget route, while deleting S removes the displayed precision-to-cofinal-tail schedule. In either deletion, the remaining rows cannot determine the common* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *handoff through* hsame*,* Cont*,* Pkg*, and* NameCert *alone.*

Proof. First remove the refinement row. The schedule row still displays a precision request and a cofinal tail witness, but it no longer carries the source-modulus meet, selector-budget route, or selected-window tolerance readback needed to identify the common window W as the refinement window.

Next remove the schedule row. The refinement row still displays source moduli and a selected-window route, but it no longer carries the cofinal-tail request and finite tail witness that make the route usable as a Real-completion tail schedule.

The structural rows cannot repair either absence. The hsame and Cont rows transport and replay displayed data; Pkg and NameCert record provenance and naming for displayed data. None of them creates a missing refinement or schedule coordinate, so both siblings are genuine dependencies of the alignment packet. □

Theorem 1210.4 (Tail-modulus alignment non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{TailModulusAlignment}^{\uparrow}$ *packet factors through the finite route*

$$M, S, F, W, R, D, E, H, C, P, N.$$

The consumer receives a shared tail-modulus alignment over displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It receives no quotient stream, host sequence equality, selected host limit, hidden tail oracle, countable-choice selector, independent Real seal, or ambient Real-completeness witness.*

Proof. Begin with the accepted carrier. The only Real-facing coordinate is the seal row E, and it is downstream of the refinement row M, the schedule row S, the fusion row F, the common stream windows W, the regular-rational readback R, and the dyadic ledger D.

Apply Definition 1210.2. It forces every accepted consumer to read the refinement, schedule, fusion, window, readback, ledger, and seal rows through the displayed continuation route before the local NameCert row can be used.

Finally apply Definition 1210.3. Since neither sibling route can be omitted, the packet has no alternate route to a Real-facing output. The excluded objects are not coordinates of the carrier and are not introduced by hsame, Cont, Pkg, or NameCert, so no consumer can project them from the alignment certificate. □

Chapter 1211

A Concrete Naming Certificate for DyadicToleranceTriangleLedger$^{\uparrow}$

The DyadicToleranceTriangleLedger$^{\uparrow}$ packet realizes the three-leg diagonal-regularity estimate of Definition 9238.4 inside the Real-completeness route of chapter 9238. It is a dyadic ledger layer over the existing RegularCauchyTriangleBound$^{\uparrow}$ estimate of chapter 466: DyadicRatCore$^{\uparrow}$ supplies tolerance arithmetic through chapter 291, StreamName$^{\uparrow}$ supplies the finite diagonal and intermediate windows through chapter 126, RegSeqRat$^{\uparrow}$ supplies endpoint regularity reads through chapter 301, and Real$^{\uparrow}$ is the downstream seal surface of chapter 38. The packet does not select a limit, quotient a stream, or appeal to ambient completeness; it records the finite tolerance rows that the diagonal proof must read before the Real-facing handoff.

Definition 1211.1 (Dyadic tolerance triangle ledger carrier)**.** *A* DyadicToleranceTriangleLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D_m, D_n, I_m, I_n, E_m, E_n, M, Q, T, H, C, P, N)$$

with the following displayed rows:

1. D_m *and* D_n *are the two* StreamName$^{\uparrow}$ *diagonal observation rows for the requested indices* m *and* n*.*
2. I_m *and* I_n *are the two intermediate* StreamName$^{\uparrow}$ *rows used by the diagonal-regularity triangle.*
3. E_m *and* E_n *are the endpoint* RegSeqRat$^{\uparrow}$ *regularity reads for the legs* $D_m \longrightarrow I_m$ *and* $I_n \longrightarrow D_n$*.*
4. M *is the middle Cauchy-modulus read for the leg* $I_m \longrightarrow I_n$*.*
5. Q *is the* DyadicRatCore$^{\uparrow}$ *ledger carrying the two endpoint tolerances, the middle tolerance, and the displayed dyadic output bound.*
6. T *is the consumed* RegularCauchyTriangleBound$^{\uparrow}$ *row that assembles the same three legs as one diagonal estimate.*
7. H *records componentwise* hsame *transport for the four window rows, the three leg rows, the dyadic ledger, the consumed triangle-bound row, provenance, and the local name.*
8. C *records displayed* Cont *routes for reading endpoint legs, reading the middle leg, summing dyadic tolerances, checking the consumed triangle-bound row, and handing the packet to the Real-facing diagonal consumer.*

9. *P is the* Pkg *provenance over* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, RegularCauchyTriangleBound$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{DyadicToleranceTriangleLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for a missing endpoint leg, a missing middle modulus leg, quotient stream equality, host real equality, selected limits, or ambient completeness.

Definition 1211.2 (Dyadic tolerance triangle ledger classifier)**.** *Two accepted* DyadicToleranceTriangleLedger$^{\uparrow}$ *carriers classify as the same ledger only when their four* StreamName$^{\uparrow}$ *windows, two* RegSeqRat$^{\uparrow}$ *endpoint reads, middle modulus read,* DyadicRatCore$^{\uparrow}$ *tolerance row, consumed* RegularCauchyTriangleBound$^{\uparrow}$ *row, and* BHist/hsame/Cont/Pkg/NameCert *support rows are componentwise transported by the displayed* hsame *data. The classifier does not identify packets by host equality of real numbers, by quotienting streams, or by forgetting one of the three triangle legs.*

Theorem 1211.3 (Dyadic tolerance triangle ledger obligations)**.** *For every accepted* DyadicToleranceTriangleLedger *carrier $L = (D_m, D_n, I_m, I_n, E_m, E_n, M, Q, T, H, C, P, N)$, the local* NameCert$_{\text{DyadicToleranceTriangleLedger}^{\uparrow}}$ *surface consists exactly of carrier exposure, classifier transport, endpoint-leg coverage for E_m, E_n, middle-leg coverage for M, dyadic tolerance addition through Q, consumed* RegularCauchyTriangleBound$^{\uparrow}$ *compatibility through T, Real-facing continuation through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.DyadicToleranceTriangleLedgerUp.DyadicToleranceTriangleLedger window endpoint separation`

Proof. Carrier exposure is projection from Definition 1211.1. The displayed rows name the two diagonal windows, the two intermediate windows, the two endpoint legs, the middle leg, the dyadic ledger, the consumed triangle-bound packet, and the support rows.

Classifier transport is exactly the relation of Definition 1211.2. It keeps the four windows, three leg rows, dyadic ledger, consumed triangle-bound row, and support rows on one componentwise transported surface.

The endpoint and middle obligations are then read from the sibling surfaces. The endpoint reads use RegSeqRat$^{\uparrow}$ through chapter 301; the middle read is the Cauchy-modulus leg already assembled by chapter 466; and the tolerance addition is the DyadicRatCore$^{\uparrow}$ row of chapter 291.

Finally C, P, N hand this finite ledger to the Real$^{\uparrow}$ diagonal consumer. Since the carrier omits quotient streams, selected limits, host real equality, missing-leg shortcuts, and ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 1211.4 (Dyadic tolerance triangle ledger nonescape)**.** *Every diagonal-regularity consumer of an accepted* DyadicToleranceTriangleLedger$^{\uparrow}$ *packet reads the two endpoint legs E_m, E_n, the middle Cauchy-modulus leg M, the dyadic tolerance ledger Q, the consumed triangle-bound row T, and the displayed* BHist/hsame/Cont/Pkg/NameCert *support rows. It cannot replace any leg by a host real equality, quotient-stream comparison, selected limit, detached completion witness, or ambient completeness row.*

Proof. Begin with the obligation surface of Definition 1211.3. It exposes the two endpoint legs, the middle leg, the tolerance ledger, and the consumed triangle-bound row as required rows of the local certificate.

Use the classifier of Definition 1211.2. A consumer that transports the ledger must transport all three leg rows and the dyadic output row together; forgetting one leg changes the accepted packet.

The excluded objects have no coordinate in Definition 1211.1. Therefore no continuation route can export host equality, quotient-stream comparison, selected limits, detached completion witnesses, or ambient completeness in place of the displayed three-leg ledger. □

Theorem 1211.5 (Dyadic tolerance triangle ledger window handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or diagonal-limit consumer that uses a* $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$ *packet receives the finite handoff*

$$D_m, D_n, I_m, I_n, E_m, E_n, M, Q, T, H, C, P, N$$

after the four $\mathsf{StreamName}^{\uparrow}$ *windows have been read and before any Real seal is consumed. The handoff realizes the three-leg estimate of Definition 9238.4 as finite* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Proof. First read the carrier. The four window rows D_m, D_n, I_m, I_n are the only stream observations available to the packet, and the leg rows E_m, E_n, M are attached to those windows.

Next apply the obligation theorem. It requires the dyadic output bound to be read through Q and the compatibility with the existing three-leg estimate to be read through T.

Finally use non-escape. Since no selected limit, quotient stream, host real equality, detached completion witness, or ambient completeness row can be exported, the Real-facing consumer receives exactly the displayed finite handoff. □

Theorem 1211.6 (Dyadic tolerance triangle ledger middle-leg coverage)**.** *For every accepted* $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$ *carrier* $L = (D_m, D_n, I_m, I_n, E_m, E_n, M, Q, T, H, C, P, N)$*, the row* M *is the only admissible middle Cauchy-modulus leg. Any accepted consumer of* L *that reaches from* I_m *to* I_n *must read* M *through the displayed* Cont *route and cannot replace it by an endpoint regularity row, a quotient stream equality, a selected limit, a detached completion witness, or ambient completeness.*

Proof. Read the carrier of Definition 1211.1. Among the displayed rows, only M is assigned to the leg $I_m \longrightarrow I_n$; the rows E_m and E_n are bound to the two endpoint legs, and no extra coordinate records a second middle modulus.

Use the classifier of Definition 1211.2. Componentwise hsame transport keeps the middle leg as the M coordinate, so a transported packet cannot silently exchange M for an endpoint row or for an external real-completion witness.

Finally apply non-escape from Definition 1211.4. The excluded host, quotient, limit-selection, detached-completion, and ambient-completeness objects have no coordinate in the packet, hence no accepted middle-leg consumer can read them in place of M. □

Theorem 1211.7 (Dyadic tolerance triangle ledger tolerance addition)**.** *For every accepted* DyadicToleranceTriangle*carrier* $L = (D_m, D_n, I_m, I_n, E_m, E_n, M, Q, T, H, C, P, N)$*, the row* Q *is the only dyadic tolerance-addition ledger combining the two endpoint tolerances and the middle tolerance. The packet exposes no second dyadic output row and no route that can compute the displayed output bound outside* $\mathsf{DyadicRatCore}^{\uparrow}$.

Proof. The carrier assigns exactly one row to dyadic tolerance addition, namely Q. The endpoint tolerances are supplied by E_m and E_n, the middle tolerance is supplied by M, and the displayed output bound is part of the same $\mathsf{DyadicRatCore}^{\uparrow}$ ledger row.

Classifier transport preserves Q as the dyadic ledger coordinate. Thus a consumer that transports the accepted packet must transport the endpoint tolerances, the middle tolerance, and the output bound together rather than recomputing one of them through a detached route.

The non-escape theorem blocks the remaining shortcuts. Since the packet has no coordinate for host real equality, quotient streams, selected limits, detached completion witnesses, or ambient completeness, the only accepted tolerance-addition read is the Q row. □

Theorem 1211.8 (Dyadic tolerance triangle ledger triangle-bound compatibility)**.** *For every accepted* $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$ *carrier* $L = (D_m, D_n, I_m, I_n, E_m, E_n, M, Q, T, H, C, P, N)$*, the consumed row* T *uses the same three legs* E_m, E_n, M *as the* $\mathsf{RegularCauchyTriangleBound}^{\uparrow}$ *packet. It may package the three-leg estimate for the Real-facing handoff, but it cannot introduce a fourth leg, omit the middle leg, or identify endpoint and middle evidence by host equality.*

Proof. The carrier binds T as the consumed $\mathsf{RegularCauchyTriangleBound}^{\uparrow}$ row and lists exactly three leg rows beside it: E_m, E_n, and M. These are the two endpoint regularity reads and the middle Cauchy-modulus read used by the diagonal-regularity triangle.

The obligation theorem forces compatibility through the same displayed rows. It does not expose an independent triangle-bound coordinate that could ignore M or introduce a fourth leg.

The window handoff theorem then sends $D_m, D_n, I_m, I_n, E_m, E_n, M, Q, T, H, C, P, N$ to the Real-facing consumer as one finite packet. Because non-escape forbids host equality and quotient-stream replacement, T remains compatible with the same three concrete legs. □

Theorem 1211.9 (Dyadic tolerance triangle ledger tastegate obligation closure)**.** *The* DyadicToleranceTriangleLedg *packet is obligation-closed for its displayed L10 ledger surface. The carrier, classifier, nonescape theorem, window handoff, falsifiable prediction, independence witness, Lean* `ChapterTasteGate`*,* Nontrivial $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$*, and* FieldFaithful $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$ *evidence jointly bind the rows* $D_m, D_n, I_m, I_n, E_m, E_n, M, Q, T, H, C, P, N$ *as the local* $\mathsf{NameCert}_{\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}}$ *obligation surface.*

Lean4 ✓ `BEDC.Derived.DyadicToleranceTriangleLedgerUp.taste gate`

Proof. Carrier and classifier exposure are supplied by Definition 1211.1 and Definition 1211.2. The aggregate obligation theorem names the endpoint, middle, dyadic-addition, triangle-bound, Real-continuation, package, and local-name clauses.

The three separated compatibility theorems above isolate the middle leg M, the dyadic addition row Q, and the consumed triangle-bound row T. Together with endpoint separation, they make the finite ledger surface checkable row by row.

Nonescape and window handoff then bind the consumer behavior: no quotient stream, selected limit, host equality, detached completion witness, or ambient-completeness row can replace the displayed finite packet.

Finally the falsifiable prediction and independence witness record the negative tests, while the checked Lean `ChapterTasteGate` supplies the formal gate together with its Nontrivial and FieldFaithful evidence. These ingredients exhaust the stated obligation surface without claiming a public Real-completion seal. □

Falsifiable prediction: A diagonal-regularity consumer that omits one of the two endpoint legs or the middle Cauchy-modulus leg refutes the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, regular-cauchy-triangle-bound: none is bijective to $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$, because the dyadic core lacks stream windows, the stream-name surface lacks rational tolerance addition, the regular-rational surface

lacks the middle Cauchy-modulus leg, the Real surface is downstream of the seal, and the regular-cauchy triangle-bound packet does not isolate the dyadic tolerance ledger as its own classifier and Real-window handoff.

Lean `TasteGate.lean` for DyadicToleranceTriangleLedger$^{\uparrow}$ must provide explicit Nontrivial DyadicToleranceTriang and FieldFaithful DyadicToleranceTriangleLedger$^{\uparrow}$ instances for $D_m, D_n, I_m, I_n, E_m, E_n, M, Q, T, H, C, P, N$.

Closure status for NameCert$_{\text{DyadicToleranceTriangleLedger}^{\uparrow}}$.

Constructive story: A DyadicToleranceTriangleLedger$^{\uparrow}$ packet is generated from four stream windows, two endpoint regularity reads, one middle Cauchy-modulus read, a dyadic tolerance-addition ledger, a consumed RegularCauchyTriangleBound row, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicToleranceTriangleLedger}^{\uparrow}}$, obligation)

Scope closed: Definition 1211.1, Definition 1211.2, Definition 1211.3, Definition 1211.4, Definition 1211.5, Definition 1211.6, Definition 1211.7, Definition 1211.8, and Definition 1211.9 bind the finite dyadic ledger surface for the diagonal-regularity triangle.

Formal verification: FormalStatus(NameCert$_{\text{DyadicToleranceTriangleLedger}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.DyadicToleranceTriangleLedgerUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close bridge checking, scoped downstream Real-completion closure, the full Real-completeness theorem, quotient stream equality, selected limits, host real equality, detached completion witnesses, or ambient completeness.

Upgrade path: Scoped closure requires downstream diagonal-regularity consumers to reuse the same endpoint rows, middle row, dyadic tolerance row, triangle-bound row, and Real-window handoff without adding nonlocal witnesses.

Chapter 1212

A Concrete Naming Certificate for $\mathsf{DyadicModulusLadder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicModulusLadder}^{\uparrow}$ packet records a finite ladder for dyadic tolerance requests, unary precision indices, finite stream windows, regular rational readback, DyadicRatCore arithmetic, and the terminal Real seal. It sits beside the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives the L10 open phase a finite schedule object for later regular-Cauchy and RealUp routes, not a quotient stream, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1212.1 (Dyadic modulus ladder carrier)**.** *A* $\mathsf{DyadicModulusLadder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, U, S, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request row naming the dyadic precision request that begins the ladder.*
2. *U is the unary precision index row, recording the finite stage at which the request is read.*
3. *S is the monotone ladder step row, advancing the precision request through a displayed finite order.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing the observed stages of the ladder.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, carrying the regular rational response to the displayed window.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row, recording the finite dyadic comparison and reuse of the request.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after T, U, S, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for $T, U, S, W, R, D, E, C, P, N$.*
9. *C records displayed* Cont *replay from the dyadic request through the unary index, ladder step, stream window, regular rational readback, dyadic arithmetic, Real seal, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{DyadicModulusLadder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicModulusLadder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, U, S, W, R, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1212.2 (Dyadic modulus ladder NameCert obligations)**.** *For every accepted* $\mathsf{DyadicModulusLadder}^{\uparrow}$ *carrier $L = (T, U, S, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicModulusLadder}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, unary precision-index exposure, monotone ladder-step exposure, finite-window exposure, regular rational readback, DyadicRatCore arithmetic, Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 1212.1. The rows T, U, S display the request, its unary index, and the monotone ladder step that advances the request through the finite schedule.

The window row W and readback row R then expose the finite observation and regular rational response. The arithmetic row D keeps the dyadic comparison internal to the same packet rather than turning it into a host-level modulus function.

Finally read E, H, C, P, N. The Real seal is downstream of the displayed dyadic request, unary index, ladder step, window, readback, and arithmetic rows, while the structural rows transport, replay, source, and name the same finite route. □

Theorem 1212.3 (Dyadic modulus ladder regular-sequence route)**.** *Every accepted* $\mathsf{DyadicModulusLadder}^{\uparrow}$ *packet used by a regular-sequence consumer factors through the displayed route*

$$T, U, S, W, R, D, E, H, C, P, N.$$

The consumer reads the dyadic request, unary precision index, monotone ladder step, finite stream window, regular rational readback, DyadicRatCore arithmetic, and terminal $\mathsf{Real}^{\uparrow}$ *seal before it can use the ladder as a regular-sequence route.*

Proof. Begin with the NameCert obligations. They force the dyadic request, unary index, ladder step, finite window, readback, arithmetic, and seal to be displayed before the packet can be consumed.

The finite ladder step is what keeps the route monotone. It carries the request forward through a visible unary stage rather than selecting a limit representative or a quotient stream.

The structural rows H, C, P, N preserve the same route under transport and replay. Since no carrier coordinate stores quotient stream equality, selected limits, countable choice, or ambient completeness, the regular-sequence consumer remains on the displayed ladder. □

Theorem 1212.4 (Dyadic modulus ladder Real seal boundary)**.** *Every Real-facing consumer of an accepted* $\mathsf{DyadicModulusLadder}^{\uparrow}$ *packet must read the dyadic request row T, unary precision index U, monotone ladder step S, finite stream-window row W, regular rational readback row R, and DyadicRatCore arithmetic row D before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E is consumed. The boundary exports no quotient-stream equality, selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The Real-facing route is already forced through the displayed request, unary index, ladder step, window, readback, and arithmetic rows.

Apply the regular-sequence route theorem. It keeps the consumer on the same monotone finite ladder and prevents a detour through a selected limit or quotient stream.

The remaining structural rows H, C, P, N preserve and name this route. No extra completion coordinate is available in the carrier, so the displayed boundary is the whole Real seal surface. □

Falsifiable prediction: Every accepted $\mathsf{DyadicModulusLadder}^{\uparrow}$ Real or regular-sequence consumer reads one dyadic request row, one unary precision-index row, one monotone ladder-step row, one $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic row, one $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert before using the displayed ladder.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{DyadicModulusLadder}^{\uparrow}$ is not bijective to any listed sibling because the siblings separately provide tolerance comparison, finite windows, regular rational readback, and terminal Real sealing, while this packet binds them into one monotone finite ladder route.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicModulusLadder}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicModulusLadder}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance request, a unary precision index, a monotone ladder step, a StreamName finite-window row, a RegSeqRat readback row, a DyadicRatCore arithmetic row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicModulusLadder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1212.1, Definition 1212.2, Definition 1212.3, and Definition 1212.4 seed the finite ladder route from displayed dyadic requests to Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicModulusLadder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient-stream equality, selected limits, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, unary index exposure, monotone ladder-step exposure, finite-window exposure, RegSeqRat handoff, Real seal handoff, transport, replay, and ledger non-escape for BEDC.Derived.DyadicModulusLadderUp.

Chapter 1213

A Concrete Naming Certificate for $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$

The $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ packet realizes the representation-gap row of section 9414.1, especially section 9414.1, as a finite NameCert object. It sits downstream of the signature-fit carrier of **??**, the open-fit carrier of chapter 1132, the relational-objectivity carrier of chapter 1138, and the methodology-ledger carrier of chapter 1185. Those siblings record successful compatibility, admitted open fit routes, objectivity rows, and method provenance; this packet records the remaining reality-facing signature separation after a mathematical classifier has already identified the compared representations.

Definition 1213.1 (Reality-constrained signature residue carrier)**.** *A* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (M, S, G, R, W, H, C, P, N)$$

with the following visible rows:

1. *M is the mathematical classifier row, recording that the compared representations are identified by the selected mathematical classifier;*
2. *S is the physical signature row, recording the reality-facing signature bundle and the exposed physical-fit comparison;*
3. *G is the GAP and methodology-ledger row, naming the admitted representation gap, the observation scope, and the provenance route through the methodology ledger;*
4. *R is the residue row, storing the remaining physical-signature separation that survives the mathematical identification in M;*
5. *W is the witness route, displaying the finite observation or audit route that exposes the residue rather than inferring it from host disagreement;*
6. *H stores componentwise* hsame *transport for the classifier row, physical signature row, GAP and ledger row, residue row, witness route, continuation rows, provenance row, and local naming row;*
7. *C stores displayed* Cont *replay for mathematical-classifier inspection, physical-signature inspection, GAP-ledger inspection, residue exposure, witness replay, and NameCert comparison;*

8. *P is the* Pkg *provenance row over* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$, $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, $\mathsf{RelationalObjectivity}^{\uparrow}$, $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ *row.*

The carrier contains no coordinate that turns mathematical classifier agreement alone into physical adequacy. A physical-adequacy read must display S, G, R, W in the same finite packet.

Theorem 1213.2 (Reality-constrained signature residue NameCert obligations)**.** *For the carrier of Definition 1213.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the finite packet $Z = (M, S, G, R, W, H, C, P, N)$;*

2. *classifier separation, requiring M to be read as mathematical agreement and S as the physical-signature comparison rather than a consequence of M;*

3. *residue exposure, requiring G, R, W to display the representation gap, remaining signature separation, and finite witness route before any consumer can mention physical inadequacy;*

4. *transport and replay stability, requiring H and C to preserve the classifier, signature, ledger, residue, witness, provenance, and local naming rows componentwise;*

5. *provenance and local naming, requiring P and N to cite the signature-fit, open-fit, relational-objectivity, methodology-ledger,* BHist, hsame, Cont, Pkg, *and* NameCert *surfaces used by the packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedSignatureResidueUp.TasteGate.RealityConstrainedSignatureResidueT`
`single carrier alignment`

Proof. Project the finite packet of Definition 1213.1. Its coordinates already separate mathematical agreement, physical signature comparison, GAP-ledger data, residue exposure, witness route, transport, replay, provenance, and local naming.

The classifier-separation obligation reads M and S as different rows of the same packet. The residue-exposure obligation then requires G, R, W before any consumer can use the gap as evidence against physical adequacy.

Finally, the rows H, C, P, N keep the packet stable under componentwise transport and displayed replay. Since no further coordinate exists, the five listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedSignatureResidueUp.RealityConstrainedSignatureResidueTasteGate`
`single carrier alignment`

Theorem 1213.3 (Reality-constrained signature residue consumer boundary)**.** *Let $Z = (M, S, G, R, W, H, C, P, N)$ be an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet. Every public consumer of the residue packet factors through exactly the displayed carrier route*

$$M, S, G, R, W, H, C, P, N.$$

It may read mathematical classifier agreement, physical-signature comparison, GAP and methodology-ledger data, residue, witness route, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ *row. It has no direct consumer coordinate for host physical adequacy, objectivity completion, or physical-fit resolution outside that route.*

Proof. Project the carrier of Definition 1213.1. Its only visible rows are $M, S, G, R, W, H, C, P, N$, so a consumer of the local packet has no additional carrier coordinate to inspect.

Apply the NameCert obligations of Definition 1213.2. They require classifier separation, residue exposure through G, R, W, componentwise transport and replay through H, C, and provenance plus local naming through P, N.

The sibling anchors in **??**, chapter 1132, chapter 1138, and chapter 1185 are cited only through the provenance route. Hence a public consumer factors through the displayed route and not through a hidden adequacy or objectivity-completion output. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedSignatureResidueUp.RealityConstrainedSignatureResidueConsumerBou`

Theorem 1213.4 (Reality-constrained signature residue dependency handoff)**.** *The* RealityConstrainedSignatureRes *packet consumes exactly the reality-constrained sibling surfaces*

$$\mathsf{RealityConstrainedSignatureFit}^{\uparrow},\quad \mathsf{RealityConstrainedOpenFit}^{\uparrow},\quad \mathsf{RelationalObjectivity}^{\uparrow},\quad \mathsf{RealityConstrainedMethod}$$

for signature-fit compatibility, open-fit admission, objectivity rows, and methodology provenance. Beyond those consumed sibling surfaces and the ambient BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *structure, the packet contributes only the residual signature-separation row R together with its displayed witness route W and local naming row N.*

Proof. Read the dependency row in the carrier definition. The row P names $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ together with $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, $\mathsf{RelationalObjectivity}^{\uparrow}$, $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$, and the structural BHist, hsame, Cont, Pkg, and NameCert surfaces.

The four sibling chapters cited in the introduction provide the consumed reality-constrained surfaces: signature fit, open fit, relational objectivity, and methodology ledger. The carrier does not name a fifth reality-constrained sibling dependency.

Apply the NameCert obligations. Their classifier-separation and residue-exposure rows force the new local contribution to be the displayed separation R with its witness route W and name N, rather than a duplicate of the consumed sibling packets or an adequacy conclusion. □

Theorem 1213.5 (Reality-constrained signature residue obligation closure)**.** *The obligation surface of an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet is exactly the finite package consisting of carrier admission, classifier separation, residue exposure, witness-route display, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ *naming for the route $M, S, G, R, W, H, C, P, N$. This closure is the local TasteGate-facing obligation surface of the packet and does not assert bridge checking or public physical adequacy.*

Proof. Start with Definition 1213.1. It supplies the carrier rows $M, S, G, R, W, H, C, P, N$ and separates mathematical agreement from physical-signature comparison before the residue row can be read.

Apply Definition 1213.2. The five NameCert rows expand to carrier admission, classifier separation, residue exposure, stability under H, C, and provenance plus naming under P, N.

Use the consumer boundary and dependency handoff theorems above. The first keeps every consumer on the displayed route, while the second fixes the four consumed sibling surfaces and isolates the residual signature-separation contribution.

The TasteGate alignment already displayed at this NameCert site is therefore read only as a local obligation alignment. Since no standard bridge row or public-adequacy row is present in the carrier, the closure reached here is the obligation surface and not a bridge-checked or physical-adequacy claim. □

Theorem 1213.6 (Reality-constrained signature residue non-escape)**.** *Let $Z = (M, S, G, R, W, H, C, P, N)$ be an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet. No consumer may export physical adequacy, physical inadequacy, or physical-fit resolution from the mathematical classifier row M alone. Every public physical-fit consumer must first expose the physical signature row S, GAP and methodology-ledger row G, residue row R, witness route W, transport row H, replay row C, provenance row P, and local naming row N.*

Proof. Start from the NameCert obligations of Definition 1213.2. They make classifier separation and residue exposure mandatory before any physical-fit claim can leave the packet.

If a route reads only M, it has mathematical classifier agreement but no displayed physical-signature comparison, GAP ledger, residue row, or witness route. Such a route therefore lacks the rows required for a physical adequacy or inadequacy claim.

Reading S, G, R, W, H, C, P, N restores the displayed packet route. The conclusion is a non-escape boundary: the consumer may use the accepted residue packet only through its visible rows, never through a direct export from mathematical classifier agreement. □

Theorem 1213.7 (Reality-constrained signature residue sibling independence)**.** *The* RealityConstrainedSignatureRe *carrier is not bijective to* $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, $\mathsf{RelationalObjectivity}^{\uparrow}$, *or* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$. *SignatureFit records successful compatibility, OpenFit records admitted open fit routes, RelationalObjectivity records objectivity rows, and MethodologyLedger records method provenance, while the residue packet records the remaining reality-facing signature separation after mathematical identification.*

Proof. Compare the displayed coordinates. The signature-fit packet supplies compatibility rows but need not carry a remaining residue row R or a witness route W for a failed physical-signature descent. The open-fit packet supplies continuation and finite refutation surfaces, but it does not by itself bind the mathematical classifier row M to a surviving representation-gap residue.

The relational-objectivity packet supplies objectivity rows, and the methodology ledger supplies method provenance. Neither one alone contains the joint classifier, physical-signature, GAP, residue, witness, transport, replay, provenance, and local naming coordinates of Z.

Thus each sibling may be consumed by the residue packet, but none is interchangeable with it. The carrier independence is exactly the remaining row R displayed between mathematical identification and physical adequacy. □

Falsifiable prediction: If a RealityConstrainedSignatureResidueUp packet is accepted, every public physical-fit consumer must expose the residue row before claiming adequacy; a route from mathematical classifier agreement directly to physical adequacy refutes the packet.

Independence witness: reality-constrained-signature-fit, reality-constrained-open-fit, relational-objectivity, reality-constrained-methodology-ledger: SignatureFit records successful compatibility, OpenFit records admitted open fit routes, RelationalObjectivity records objectivity rows, and MethodologyLedger records method provenance, while the residue packet records the remaining reality-facing signature separation after mathematical identification.

Theorem 1213.8 (Reality-constrained signature residue scope lock)**.** *Let $Z = (M, S, G, R, W, H, C, P, N)$ be an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet. The residue scope is locked to the displayed dependencies on* $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, $\mathsf{RelationalObjectivity}^{\uparrow}$, *and* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$*: M reads the signature-fit classifier, S and G read the open-fit and relational-objectivity comparison surface, R stores only the remaining signature*

residue, and W, H, C, P, N expose the methodology-ledger witness, transport, replay, provenance, and local naming rows. No consumer may enlarge the scope to a host physical-adequacy judgment or shrink it to mathematical classifier agreement alone.

Proof. Project the carrier of Definition 1213.1. The rows $M, S, G, R, W, H, C, P, N$ already list the classifier, physical signature, gap ledger, residue, witness, transport, replay, provenance, and local naming surfaces.

Apply the NameCert obligations of Definition 1213.2. They force classifier separation and residue exposure before any physical-fit consumer can read the packet.

Finally invoke the non-escape theorem, Definition 1213.6. A route from M alone lacks S, G, R, W, while a route to host physical adequacy lacks a coordinate in the carrier; hence the displayed sibling dependencies are exactly the locked scope. □

Theorem 1213.9 (Reality-constrained signature residue witness-route totality)**.** *For every accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet* $Z = (M, S, G, R, W, H, C, P, N)$*, every public witness of the residue row R factors through the finite route*

$$M, S, G, R, W, H, C, P, N$$

with P citing $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$*,* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$*,* $\mathsf{RelationalObjectivity}^{\uparrow}$*, and* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$*. Conversely, that displayed route supplies all witness data available to a consumer of the residue packet.*

Lean4 ✓ `BEDC.Derived.RealityConstrainedSignatureResidueUp.RealityConstrainedSignatureResidueWitnessRout`

Proof. First read the witness row in the carrier. The row W is placed after the mathematical classifier, physical signature, gap-ledger, and residue rows, so a witness to R is not detached from M, S, G.

The NameCert obligations identify G, R, W as the residue-exposure surface. The transport and replay rows H, C then preserve that same exposure under componentwise movement and displayed continuation replay.

The provenance row P supplies the listed sibling dependencies, and N locally names the same packet. Since the non-escape theorem rules out physical-fit resolution from M alone or from any hidden host coordinate, the displayed route is total for residue witnesses. □

Theorem 1213.10 (Reality-constrained signature residue consumer adequacy refusal)**.** *An accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *consumer that exposes $M, S, G, R, W, H, C, P, N$ may report the remaining signature residue, but it may not report physical adequacy, physical-fit resolution, or objectivity completion unless a separate packet supplies those claims through* $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$*,* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$*,* $\mathsf{RelationalObjectivity}^{\uparrow}$*, or* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$*. The residue packet itself is a refusal boundary for adequacy by mathematical agreement alone.*

Proof. Begin with the sibling independence theorem, Definition 1213.7. It separates the residue carrier from the signature-fit, open-fit, relational-objectivity, and methodology-ledger carriers.

Next use non-escape, Definition 1213.6. The mathematical classifier row M cannot export physical adequacy, physical inadequacy, or physical-fit resolution without the rows S, G, R, W, H, C, P, N.

The accepted residue consumer therefore receives a residue report, not an adequacy closure. Any positive adequacy or objectivity-completion claim must come from a separate accepted sibling packet, while this packet refuses the shortcut from mathematical classifier agreement to physical adequacy. □

Theorem 1213.11 (Reality-constrained signature residue sibling-route exactness)**.** *For an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet, the sibling route is exactly the displayed dependency on* $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$*,* $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$*,* $\mathsf{RelationalObjectivity}^{\uparrow}$*, and* $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ *through the rows*

$$M, S, G, R, W, H, C, P, N.$$

No sibling alone supplies the residue packet, and no residue consumer may replace the displayed route by a host physical-adequacy judgment.

Proof. Begin with Definition 1213.7. It separates the residue carrier from the signature-fit, open-fit, relational-objectivity, and methodology-ledger carriers.

Apply Definition 1213.9. Every public witness of the residue row factors through $M, S, G, R, W, H, C, P, N$ with P citing the same sibling packets.

Use Definition 1213.10. A host physical-adequacy judgment is not exported by the residue packet, so the sibling route is exactly the displayed finite dependency. □

Theorem 1213.12 (Reality-constrained signature residue mathematical-agreement refusal)**.** *Mathematical classifier agreement in the row* M *of an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet does not imply physical adequacy, physical-fit resolution, or objectivity completion. Any such claim must pass through the physical-signature, GAP, residue, witness, transport, replay, provenance, and local naming rows* S, G, R, W, H, C, P, N *and through a separate accepted sibling packet when the claim is positive.*

Proof. Start with the NameCert obligations of Definition 1213.2. They read M as mathematical agreement and S as the physical-signature comparison, so the two rows cannot be collapsed.

Apply non-escape, Definition 1213.6. A route from M alone cannot export physical adequacy, physical inadequacy, or physical-fit resolution.

Finally use Definition 1213.10. Positive adequacy or objectivity-completion claims must come from a separate accepted sibling packet, while this residue packet refuses the shortcut from classifier agreement to physical adequacy. □

Theorem 1213.13 (Reality-constrained signature residue methodology-ledger totality)**.** *Every public methodology-ledger read used by an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet is contained in the finite route*

$$G, W, H, C, P, N.$$

The ledger is exposed as GAP and method provenance for the residue witness, not as a free-standing proof of physical adequacy or objectivity completion.

Proof. Project the carrier of Definition 1213.1. The methodology-ledger data enters through G, is witnessed through W, and is transported, replayed, sourced, and named by H, C, P, N.

Apply Definition 1213.9. It makes the witness route for R pass through the same GAP, witness, transport, replay, provenance, and local naming rows.

Finish with Definition 1213.10. The residue consumer receives a residue report rather than an adequacy closure, so the methodology ledger is total only for the displayed witness route. □

Theorem 1213.14 (Reality-constrained signature residue carrier row readback)**.** *Every public residue read of an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet projects to the displayed finite route*

$$M, S, G, R, W, H, C, P, N.$$

The read may expose mathematical classifier agreement, physical signature comparison, GAP and methodology-ledger data, residue, witness route, componentwise transport, continuation replay, provenance, and local naming, but it cannot read physical adequacy or objectivity completion outside those rows.

Proof. Project the carrier of Definition 1213.1. Its coordinates are exactly $M, S, G, R, W, H, C, P, N$, so a public residue read has no other row available.

Apply the NameCert obligations and non-escape theorem, Definition 1213.2 and Definition 1213.6. They require classifier separation, residue exposure, transport, replay, provenance, and local naming before a physical-fit consumer may read the packet.

Use witness-route totality and sibling-route exactness, Definition 1213.9 and Definition 1213.11. The public residue read is therefore the displayed route and not a hidden adequacy or objectivity-completion judgment. □

Theorem 1213.15 (Reality-constrained signature residue public consumer factorization)**.** *Every public physical-fit consumer of an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet factors first through* $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, $\mathsf{RelationalObjectivity}^{\uparrow}$, *and* RealityConstrainedM *as recorded by the rows* M, S, G, W, H, C, P, N, *and only then reads the residue row* R. *In particular, signature-fit, open-fit, relational-objectivity, and methodology-ledger surfaces must all be visible before the consumer treats the residue as a physical-fit obstruction.*

Proof. Begin with sibling independence, Definition 1213.7. It separates the residue carrier from the signature-fit, open-fit, relational-objectivity, and methodology-ledger siblings while allowing the residue packet to consume them.

Apply witness-route totality and sibling-route exactness, Definition 1213.9 and Definition 1213.11. The public route to the residue passes through M, S, G, W, H, C, P, N with provenance citing the sibling packets.

Finally use methodology-ledger totality, Definition 1213.13. The methodology row is exposed for the residue witness rather than for a free-standing adequacy claim, so the public consumer must factor through those surfaces before reading R. □

Theorem 1213.16 (Reality-constrained signature residue row-order totality)**.** *Every public residue read of an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet exposes the finite rows in the order*

$$M, S, G, R, W, H, C, P, N.$$

The read may stop at no earlier row as a complete residue report: M *supplies mathematical classifier agreement,* S *supplies the physical-signature comparison,* G *supplies the GAP and methodology-ledger context,* R *supplies the displayed residue,* W *supplies the witness route,* H *and* C *supply transport and replay,* P *supplies provenance, and* N *supplies the local NameCert row.*

Proof. Project the carrier of Definition 1213.1. Its displayed coordinates are exactly $M, S, G, R, W, H, C, P, N$, and the NameCert obligations of Definition 1213.2 read those coordinates as carrier admission, classifier separation, residue exposure, transport and replay stability, provenance, and local naming.

Apply witness-route totality, Definition 1213.9. A public witness of R factors through the same ordered route, so no consumer can present R before M, S, G or detach it from W, H, C, P, N.

Finally use public-consumer factorization, Definition 1213.15. The fit-facing consumer must see the sibling surfaces and methodology ledger before reading R, hence the displayed row order is total for every public residue read. □

Theorem 1213.17 (Reality-constrained signature residue audit consumer readiness)**.** *An audit consumer may treat an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet as actionable only after seeing all nine readiness rows: the classifier row M, the signature row S, the GAP and ledger row G, the residue row R, the witness route W, the transport row H, the replay row C, the provenance row P, and the local NameCert row N. Before those rows are visible, the consumer has at most a partial inspection route and not an actionable residue certificate.*

Proof. Start with the NameCert obligations, Definition 1213.2. They make carrier admission, classifier separation, residue exposure, transport, replay, provenance, and local naming mandatory parts of the packet rather than optional annotations.

Use non-escape, Definition 1213.6. A route from M alone cannot export physical adequacy, physical inadequacy, or physical-fit resolution; the audit consumer must expose S, G, R, W, H, C, P, N before any fit-facing use of the residue is available.

Combine row-order totality and public-consumer factorization, Definition 1213.16 and Definition 1213.15. The actionable audit route is therefore exactly the ordered nine-row surface, with the classifier, signature, GAP, residue, witness, transport, replay, provenance, and local naming rows all present. □

Theorem 1213.18 (Reality-constrained signature residue fit-obstruction handoff)**.** *Every downstream fit-obstruction consumer of an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet receives only the displayed residue obstruction carried by R along the route $M, S, G, R, W, H, C, P, N$. The handoff does not supply physical adequacy, physical-fit resolution, or objectivity completion; those claims require separate accepted sibling packets.*

Proof. Begin with non-escape, Definition 1213.6. It blocks any handoff from exporting adequacy, inadequacy, or fit resolution from mathematical classifier agreement alone.

Apply witness-route totality and public-consumer factorization, Definition 1213.9 and Definition 1213.15. The downstream consumer receives the residue only through the displayed route and through the sibling surfaces named by provenance.

Finally use audit consumer readiness, Definition 1213.17. The consumer may act on the residue obstruction once the nine rows are exposed, but the same readiness surface contains no coordinate for physical adequacy or objectivity completion. □

Theorem 1213.19 (Reality-constrained signature residue methodology provenance nonescape)**.** *In an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet, methodology provenance in G, W, H, C, P, N cannot be exported as physical adequacy, physical-fit resolution, or objectivity completion. It remains provenance for the displayed residue route $M, S, G, R, W, H, C, P, N$ and must be paired with a separate accepted sibling packet before any positive adequacy or objectivity claim is available.*

Proof. Start with methodology-ledger totality, Definition 1213.13. The ledger is total for the route G, W, H, C, P, N, not for adequacy or objectivity completion.

Apply consumer adequacy refusal and mathematical-agreement refusal, Definition 1213.10 and Definition 1213.12. They rule out physical adequacy, physical-fit resolution, and objectivity completion from either M alone or from the residue packet alone.

Finally use the carrier row readback of Definition 1213.14. Since the public read is the same displayed route, methodology provenance cannot leave the packet as an independent physical-adequacy or objectivity-completion certificate. □

Theorem 1213.20 (Reality-constrained signature residue carrier admission)**.** *Every accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet exposes the finite rows*

$$M, S, G, R, W, H, C, P, N$$

as BHist*-carrier data before a public residue consumer may read the local name. These rows respectively carry mathematical classifier agreement, physical signature comparison, GAP and methodology-ledger data, residue, witness route, componentwise transport, displayed replay, package provenance, and local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ *naming.*

Proof. Project the carrier row readback of Definition 1213.14. It states that every public residue read of an accepted packet has exactly the displayed route through $M, S, G, R, W, H, C, P, N$.

Apply public-consumer factorization, Definition 1213.15. The consumer must pass through the signature-fit, open-fit, relational-objectivity, and methodology-ledger surfaces recorded by the same rows before reading R as a physical-fit obstruction.

Finally use methodology-provenance nonescape, Definition 1213.19. Since methodology provenance cannot leave the packet as adequacy or objectivity completion, the admitted carrier data are exactly the displayed finite BHist rows. □

Theorem 1213.21 (Reality-constrained signature residue classifier exactness)**.** *Classifier acceptance for* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *is exactly preservation of the rows* $M, S, G, R, W, H, C, P, N$ *under the local residue route. A transported packet is accepted as the same residue packet precisely when mathematical classifier agreement, signature comparison, methodology ledger, residue, witness, transport, replay, provenance, and local naming remain on that route.*

Proof. Begin with carrier admission, Definition 1213.20. It identifies the carrier surface that a residue classifier is allowed to compare.

Use public-consumer factorization to fix the route order. The consumer does not read R before the sibling surfaces and methodology row have been displayed, so classifier preservation cannot be tested on R alone or on mathematical agreement alone.

The reverse containment follows from carrier row readback. Once $M, S, G, R, W, H, C, P, N$ are preserved along the local route, there is no additional carrier coordinate for the classifier to inspect. Methodology-provenance nonescape prevents a preserved methodology row from being reclassified as physical adequacy or objectivity completion. □

Theorem 1213.22 (Reality-constrained signature residue NameCert ledger)**.** *The* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureR}}$ *ledger is exhausted by methodology, signature, residue, witness, transport, replay, provenance, and local name rows. It contains no additional ledger entry for physical adequacy, physical-fit resolution, objectivity completion, or a detached mathematical classifier certificate.*

Proof. Start with the methodology-provenance nonescape theorem. It keeps the methodology rows G, W, H, C, P, N inside the residue route rather than allowing them to export adequacy or objectivity completion.

Next combine carrier row readback with public-consumer factorization. The public consumer sees signature comparison and sibling fit surfaces through M, S, G, W, H, C, P, N, reads the residue row R only on that route, and then reaches the local name N.

It remains to rule out a second ledger row. Classifier exactness shows that acceptance preserves exactly $M, S, G, R, W, H, C, P, N$ under the local residue route. Since the carrier has no coordinate outside those rows, the NameCert ledger is exhausted by methodology, signature, residue, witness, transport, replay, provenance, and local naming. □

Theorem 1213.23 (Reality-constrained signature residue gap-row exhaustion)**.** *Let $Z = (M, S, G, R, W, H, C, P, N$ be an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet. Every public residue read that reaches the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ *row must expose the gap row G, the residue row R, and the witness route W as* BHist*-carrier data. In particular, the read cannot collapse the packet to mathematical classifier agreement M alone, nor can it replace G, R, W by a detached adequacy, physical-fit resolution, or objectivity-completion entry.*

Proof. Start with the carrier of Definition 1213.1. Its displayed BHist packet contains G, R, W as named coordinates between the classifier and the transport-replay rows.

Apply the NameCert obligations and nonescape theorem, Definition 1213.2 and Definition 1213.6. The obligations make residue exposure a local certificate condition, while nonescape prevents the same packet from exporting adequacy or objectivity completion outside the displayed route.

Use witness-route totality and sibling-route exactness, Definition 1213.9 and Definition 1213.11. They force the public route to pass through the gap, residue, and witness coordinates before a consumer reaches N.

Finally combine carrier row readback with the NameCert ledger theorem, Definition 1213.14 and Definition 1213.22. Since the ledger has no detached mathematical-classifier certificate and no hidden adequacy row, a public residue read cannot be reduced to M alone. □

Theorem 1213.24 (Reality-constrained signature residue physical signature separation)**.** *In every accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet $Z = (M, S, G, R, W, H, C, P, N)$, the physical-signature row S is a visible carrier coordinate independent of mathematical classifier agreement M. Any public adequacy-facing or physical-fit-facing claim must display S together with G, R, W, H, C, P, N before it may cite the residue packet; agreement in M alone is not a substitute for the physical-signature comparison.*

Proof. Read M and S from the carrier of Definition 1213.1. The carrier lists them as different BHist coordinates: M records mathematical classifier agreement, while S records physical signature comparison.

Apply the NameCert obligations, nonescape, and mathematical-agreement refusal, Definition 1213.2, Definition 1213.6, and Definition 1213.12. These results require classifier separation and prohibit export of adequacy, physical-fit resolution, or objectivity completion from M alone.

Next use witness-route totality and sibling-route exactness, Definition 1213.9 and Definition 1213.11. The accepted route carries the sibling physical-fit surfaces through S, G, W, H, C, P, N before the residue row can be read.

Carrier row readback and public-consumer factorization then identify the visible public surface. Because the same read must expose S before it can use the residue packet as a physical-fit obstruction, mathematical classifier agreement cannot absorb the physical-signature coordinate. □

Theorem 1213.25 (Reality-constrained signature residue witness replay stability)**.** *Let $Z = (M, S, G, R, W, H, C, P, N)$ be an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet. The transport row H and replay row C preserve the residue witness route componentwise: under the recorded* hsame *transport in H and displayed* Cont *replay in C, the rows $M, S, G, R, W, H, C, P, N$ remain on the same public residue route, and the witness component W cannot be replayed as a route omitting G, R, or the sibling physical-signature surface.*

Proof. Begin with the carrier and the NameCert obligations. The carrier supplies the rows $M, S, G, R, W, H, C, P, N$, and the obligations require H and C to preserve the displayed residue exposure, provenance, and local naming rows.

Apply nonescape together with witness-route totality, Definition 1213.6 and Definition 1213.9. Nonescape keeps the route inside the residue packet, while witness-route totality makes W a total public route through the gap and residue rows.

Use sibling-route exactness to keep the physical-signature, open-fit, relational-objectivity, and methodology-ledger dependencies on the same route. The hsame data in H can transport only the displayed coordinates, and the Cont data in C can replay only the displayed continuation route.

Finally appeal to carrier row readback and classifier exactness. They identify the transported and replayed read with preservation of exactly $M, S, G, R, W, H, C, P, N$, so no componentwise replay can remove G, remove R, detach W, or hide the physical-signature surface behind mathematical classifier agreement alone. □

Theorem 1213.26 (Reality-constrained signature residue fit readback)**.** *Every public fit-facing read of an accepted* RealityConstrainedSignatureResidue$^{\uparrow}$ *packet is anchored in the* BHist *rows*

$$M, S, G, R, W, H, C, P, N.$$

The read may cite RealityConstrainedSignatureFit$^{\uparrow}$, RealityConstrainedOpenFit$^{\uparrow}$, RelationalObjectivity$^{\uparrow}$, *and* RealityConstrainedMethodologyLedger$^{\uparrow}$ *only through the displayed* Pkg *row P and the same witness route W; it cannot read a physical-fit conclusion from the mathematical classifier row M alone.*

Proof. Begin with carrier row readback, Definition 1213.14. It projects every public residue read to $M, S, G, R, W, H, C, P, N$.

Apply public-consumer factorization and sibling-route exactness, Definition 1213.15 and Definition 1213.11. They force the fit-facing consumer through the sibling surfaces recorded by M, S, G, W, H, C, P, N before the residue row R is read.

Finally use mathematical-agreement refusal, Definition 1213.12. Agreement in M is not a physical-fit conclusion, so the readback remains anchored in the displayed BHist, hsame, Cont, Pkg, and NameCert rows. □

Theorem 1213.27 (Reality-constrained signature residue constraint evidence display)**.** *For every accepted* RealityConstrainedSignatureResidue$^{\uparrow}$ *packet $Z = (M, S, G, R, W, H, C, P, N)$, the reality-constraint evidence used by the residue row is displayed through S, G, R, W and preserved through H, C, P, N. A consumer may not replace those rows by unrecorded observational evidence, host adequacy judgment, or detached methodology provenance.*

Proof. Read the physical-signature separation theorem, Definition 1213.24. It makes S visible independently of M before any adequacy-facing claim can cite the residue packet.

Use gap-row exhaustion and methodology provenance nonescape, Definition 1213.23 and Definition 1213.19. They require G, R, W and keep methodology provenance inside the residue route.

The transport and replay rows are fixed by witness replay stability. Thus H and C preserve the displayed evidence route, while P and N package and name it without adding an unrecorded observational coordinate. □

Theorem 1213.28 (Reality-constrained signature residue unrecorded-evidence nonescape)**.** *No accepted* RealityConstrainedSignatureResidue$^{\uparrow}$ *consumer may export unrecorded reality-constraint evidence, physical adequacy, or objectivity completion from the route $M, S, G, R, W, H, C, P, N$. Any such export must be supplied by a separate accepted sibling packet and must still pass through the displayed* hsame, Cont, Pkg, *and* NameCert *rows when it is cited by the residue packet.*

Proof. Start with constraint evidence display, Definition 1213.27. The reality-facing evidence available to the residue packet is exactly the displayed physical-signature, gap, residue, witness, transport, replay, provenance, and local naming route.

Apply consumer adequacy refusal and methodology provenance nonescape, Definition 1213.10 and Definition 1213.19. They prevent the residue packet from exporting adequacy, fit resolution, objectivity completion, or detached methodology provenance.

Finally use fit readback, Definition 1213.26. A positive sibling claim may be cited only through the displayed route, so unrecorded evidence cannot leave the packet as if it were part of the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ surface. □

Theorem 1213.29 (Reality-constrained signature residue source exactness)**.** *Let $Z = (M, S, G, R, W, H, C, P, N)$ be an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet. Suppose a public residue read of Z exposes the methodology-ledger, open-fit, signature-fit, and relational-objectivity sibling rows together with the displayed* BHist *carrier, the local* hsame *transport row, the* Cont *replay row, the* Pkg *provenance row, and the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ *support. Then its source surface is exactly the source surface of* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$*: no off-ledger physical-signature row, objectivity row, fit row, or detached adequacy witness can enter the packet.*

Proof. Begin with carrier admission and classifier exactness, Definition 1213.20 and Definition 1213.21. They identify the admitted carrier and the accepted classifier with preservation of the rows $M, S, G, R, W, H, C, P, N$ under the local residue route.

Next use the NameCert ledger and gap-row exhaustion, Definition 1213.22 and Definition 1213.23. The ledger has no extra entry for adequacy, physical-fit resolution, objectivity completion, or detached mathematical agreement, while the public read must display G, R, W before it reaches the local name.

Finally combine sibling-route exactness with fit readback. The methodology-ledger, open-fit, signature-fit, and relational-objectivity siblings can be cited only through the displayed BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows. Since those rows already exhaust the route, no off-ledger physical-signature, objectivity, or fit source can be added to the residue packet. □

Theorem 1213.30 (Reality-constrained signature residue transport closure)**.** *Let $Z = (M, S, G, R, W, H, C, P, N)$ be an accepted* $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$ *packet, and let Z' be obtained by an* hsame*-compatible transport that preserves the methodology-ledger, open-fit, signature-fit, and relational-objectivity sibling rows on the displayed residue route. Then Z' again satisfies carrier admission, classifier exactness, the* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$ *ledger, and gap-row exhaustion for the same residue packet.*

Proof. Start with witness replay stability. The hsame row transports only the displayed residue route, and the Cont row replays the same continuation surface through $M, S, G, R, W, H, C, P, N$.

Carrier admission is preserved because the transported packet still exposes the same finite BHist rows. Classifier exactness is preserved because the classifier compares exactly those rows and the assumed transport keeps the four sibling rows on the route.

The ledger and exhaustion claims then follow from the source-exactness theorem and the existing NameCert ledger and gap-row exhaustion theorems. Since transport does not add a carrier coordinate, it cannot create a new physical-signature, objectivity, fit, adequacy, or detached mathematical-agreement row. □

Theorem 1213.31 (Reality-constrained signature residue Lean-facing unblock surface)**.** *The local theorem surface consisting of carrier admission, classifier exactness, the* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}}$

ledger, gap-row exhaustion, source exactness, and transport closure is sufficient as the Lean-facing root-unblock handoff for RealityConstrainedSignatureResidue$^{\uparrow}$. *It presents the carrier, classifier, ledger, gap, source, and transport obligations without adding any off-route physical-signature, objectivity, fit, adequacy, or detached mathematical classifier premise.*

Proof. Read the first four rows from carrier admission, classifier exactness, NameCert ledger, and gap-row exhaustion. These theorems give the admitted BHist carrier, the exact accepted classifier, the exhausted local ledger, and the mandatory gap-residue-witness route.

Source exactness supplies the boundary condition for the handoff. It says that the methodology-ledger, open-fit, signature-fit, and relational-objectivity sibling rows enter only through the displayed BHist, hsame, Cont, Pkg, and local NameCert support.

Transport closure supplies the stability condition. Any hsame-compatible transport preserving those sibling rows preserves the four earlier obligations. Thus the six named results form a compact local surface for downstream Lean work on the chapter without importing an off-ledger source or an unrecorded adequacy premise. □

Closure status for NameCert$_{\text{RealityConstrainedSignatureResidue}^{\uparrow}}$.

Constructive story: The reality-constrained signature residue is generated from a $BHist$ ledger that records methodology rows, physical-signature rows, gap rows, residue rows, witness routes, and explicit separation from mathematical agreement alone. The carrier first reads the residue row under the named constraint, then uses $hsame$ to keep that residue stable across equivalent histories. Cont extensions replay witness and methodology rows only when the same residue carrier remains visible. The chapter develops this packet through non-escape, scope lock, sibling-route exactness, adequacy refusal, methodology totality, carrier admission, classifier exactness, gap-row exhaustion, physical separation, and witness replay, all without converting the residue into host reality.

Theory closure: TheoryGate(NameCert$_{\text{RealityConstrainedSignatureResidue}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1213.1, Definition 1213.8, Definition 1213.4, Definition 1213.21, Definition 1213.23, Definition 1213.24, and Definition 1213.25 bind the carrier, dependency handoff, classifier exactness, gap-row exhaustion, physical separation, and replay-stability surface.

Formal verification: FormalStatus(NameCert$_{\text{RealityConstrainedSignatureResidue}^{\uparrow}}$, axiomClean)

Lean4 ✓ `BEDC.Derived.RealityConstrainedSignatureResidueUp.taste gate`

Lean target: `BEDC.Derived.RealityConstrainedSignatureResidueUp.RealityConstrainedSignatureResidueTasteGate\_singl`

Bridge status: none

Origin: ai

Not claimed: It does not claim physical signature identity, mathematical agreement outside the carrier, or consumer adequacy beyond the recorded witness route.

Upgrade path: The next paper-side grade requires a public consumer theorem or bridge-facing route over the same scoped carrier, dependency, classifier, gap, separation, and replay surface.

Chapter 1214

A Concrete Naming Certificate for $\mathsf{ScientificObject}^{\uparrow}$

The $\mathsf{ScientificObject}^{\uparrow}$ packet realizes the scientific-object surface of Definition 9462.922 and Definition 9462.923 as finite BEDC NameCert data. It sits after the physical-model audit of chapter 1129, the truth-certificate route of chapter 1144, the open-fit packet of chapter 1137, the domain truth certificate of chapter 1181, and the inter-history transport seal of chapter 1201. These siblings provide audit, truth, finite-fit, domain, and invariant rows; this packet binds them into one object-facing carrier before any consumer reads a scientific object as mature.

Definition 1214.1 (Scientific object carrier)**.** *A* $\mathsf{ScientificObject}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, K, I, L, B, G, A, T, O, D, H, C, P, N)$$

with the following displayed rows:

1. *R records the source histories, measurement rows, continuations, or instrument traces that generate the object.*
2. *K is the classifier row specifying which records count as the same object-state presentation.*
3. *I is the inter-history invariant row, read through the transport and invariant discipline of* $\mathsf{InterHistInvariant}^{\uparrow}$*.*
4. *L is the empirical ledger row recording compression, averaging, calibration, fitting, projection, residue, and observed failure data.*
5. *B is the bridge row to a mathematical or scientific model, including the optional model-facing route through* $\mathsf{OpenFitPacket}^{\uparrow}$ *and* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$*.*
6. *G is the gap-report row listing unclosed prediction, domain, bridge, and falsification commitments.*
7. *A is the* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *row exposing source traces, observed signatures, model signatures, classifier comparison, tower data, failure surface, and audit strength.*
8. *T is the* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *row exposing the truth-certificate source, signature, classifier, tower, stability, descent, invariant, ledger, and failure fields.*
9. *O is the* $\mathsf{OpenFitPacket}^{\uparrow}$ *row exposing finite fit, finite defeat, continuation scope, and open residue.*

10. *D is the* $\mathsf{DomainTruthCertificate}^{\uparrow}$ *row exposing the domain in which the object-facing truth claim may be read.*
11. *H records componentwise* hsame *transport for $R, K, I, L, B, G, A, T, O, D$ and the local certificate row.*
12. *C records displayed* Cont *replay from record admission through classifier, invariant, ledger, bridge, gap report, audit, truth, open fit, domain, transport, provenance, and local name.*
13. *P is the* Pkg *provenance over* $\mathsf{ScientificObject}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$, $\mathsf{OpenFitPacket}^{\uparrow}$, $\mathsf{DomainTruthCertificate}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{ScientificObject}^{\uparrow}}$ *row.*

The carrier has no coordinate for bare object existence, unledgered empirical fit, hidden model identity, global synchronization, or final physical truth outside the displayed rows.

Lean4 ✓ `BEDC.Derived.ScientificObjectUp.ScientificObjectUp single carrier alignment`

Definition 1214.2 (Scientific object NameCert obligations)**.** *For the carrier of Definition 1214.1, the local* $\mathsf{NameCert}_{\mathsf{ScientificObject}^{\uparrow}}$ *surface consists exactly of carrier admission for S, record exposure through R, classifier exposure through K, inter-history invariant exposure through I, empirical-ledger exposure through L, bridge exposure through B, gap-report exposure through G, audit exposure through A, reality-constrained truth exposure through T, open-fit exposure through O, domain exposure through D, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Lean4 (definition) `BEDC.Derived.ScientificObjectUp.ScientificObjectNameCertObligations`

Theorem 1214.3 (Scientific object gap-report ledger)**.** *Every accepted* $\mathsf{ScientificObject}^{\uparrow}$ *packet exposes its gap report G before the local name N is readable. A consumer may not replace G by the empirical ledger L, the model bridge B, the physical-model audit A, the truth-certificate row T, or the domain certificate D.*

Proof. Project the carrier of Definition 1214.1. The gap report is a named coordinate of the accepted packet, separate from the record, classifier, invariant, ledger, bridge, audit, truth, open-fit, and domain rows.

Apply Definition 1214.2. The local NameCert surface lists G as an obligation before provenance and local naming are available. The empirical ledger records what has been fitted or compressed, the bridge records model correspondence, the audit records signature comparison, the truth certificate records a reality-constrained claim, and the domain certificate records where that claim may be read.

None of those rows lists the unclosed prediction, domain, bridge, and falsification commitments as the gap-report coordinate. Therefore a consumer that omits G reads only a projection of the scientific-object packet, not an accepted $\mathsf{ScientificObject}^{\uparrow}$ object name. □

Lean4 ✓ `BEDC.Derived.ScientificObjectUp.ScientificObjectGapReportLedger`

Theorem 1214.4 (Scientific object empirical-bridge separation)**.** *In every accepted* $\mathsf{ScientificObject}^{\uparrow}$ *packet, the empirical ledger L and bridge row B are distinct obligation surfaces. The bridge may use* $\mathsf{OpenFitPacket}^{\uparrow}$, $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$, *and* $\mathsf{DomainTruthCertificate}^{\uparrow}$ *routes, but it does not discharge record exposure, invariant exposure, ledger residue, audit strength, or the gap report by itself.*

Lean4 ✓ `BEDC.Derived.ScientificObjectUp.ScientificObjectEmpiricalBridgeSeparation`

Proof. Read the carrier coordinates. The empirical ledger L records compression, averaging, calibration, fitting, projection, residue, and observed failure data, while B records the model-facing bridge.

The sibling rows are downstream supports for bridge discipline. $\mathsf{OpenFitPacket}^{\uparrow}$ supplies finite-fit and finite-defeat visibility, $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ supplies the truth-certificate route, and $\mathsf{DomainTruthCertificate}^{\uparrow}$ supplies the allowed domain of the truth read. These rows do not identify the bridge with the empirical ledger or with the inter-history invariant.

The NameCert obligations keep $R, K, I, L, B, G, A, T, O, D$ as separate rows. Thus an accepted object may have a bridge only together with the ledger, audit, invariant, and gap-report surfaces that make the scientific-object name non-vacuous. □

Theorem 1214.5 (Scientific object NameCert surface)**.** *Every accepted* $\mathsf{ScientificObject}^{\uparrow}$ *object read factors through*

$$R, K, I, L, B, G, A, T, O, D, H, C, P, N.$$

The consumer receives a finite record, classifier, invariant, empirical ledger, bridge, gap report, audit, truth-certificate, open-fit, domain, transport, replay, provenance, and local NameCert packet. It receives no bare scientific object, unrecorded empirical adequacy, host-model identity, final truth oracle, or hidden bridge completion.

Proof. Start from the obligation surface of Definition 1214.2. It exhausts the local certificate by the displayed record, classifier, invariant, ledger, bridge, gap-report, audit, truth, open-fit, domain, transport, replay, provenance, and local-name rows.

Use Definition 1214.3 to keep unclosed commitments visible, and use Definition 1214.4 to keep empirical fit and bridge status distinct.

The structural rows H, C, P, N transport, replay, source, and name the same displayed packet. They do not create a hidden object coordinate or an unrecorded truth route. Hence every accepted object read factors through the stated finite route. □

Lean4 ✓ `BEDC.Derived.ScientificObjectUp.ScientificObjectTasteGate single carrier alignment`

Theorem 1214.6 (Scientific object record-classifier admission)**.** *Every accepted* $\mathsf{ScientificObject}^{\uparrow}$ *packet first exposes its record row R and classifier row K. The carrier transport through H and the displayed replay through C are available before any consumer reads the empirical ledger L, bridge row B, truth row T, domain row D, gap report G, provenance row P, or local name row N.*

Proof. Project the carrier of Definition 1214.1. The displayed packet starts with R and K, and its structural rows H and C record componentwise hsame transport and Cont replay for the same finite data.

Apply Definition 1214.2. Carrier admission, record exposure, and classifier exposure are listed before the later ledger, bridge, gap-report, audit, truth, open-fit, domain, provenance, and local-name reads. Thus a consumer cannot reach the object-facing rows while bypassing the record and classifier admission surface. □

Lean4 ✓ `BEDC.Derived.ScientificObjectUp.ScientificObjectRecordClassifierAdmission`

Theorem 1214.7 (Scientific object truth-domain gap scope)**.** *In every accepted* $\mathsf{ScientificObject}^{\uparrow}$ *packet, the truth row T, domain row D, and gap-report row G remain separate scoped obligations. The reality-constrained truth route is readable only through the domain row, and neither row discharges the gap report.*

Proof. Use Definition 1214.3. The gap report G is a named coordinate before the local name and cannot be replaced by the empirical ledger, bridge, audit, truth, or domain rows.

Use Definition 1214.4. The reality-constrained truth row and the domain certificate row support the model-facing route, but the bridge does not discharge record exposure, invariant exposure, ledger residue, audit strength, or the gap report.

Therefore T supplies only the reality-constrained truth surface, D supplies the domain in which that surface may be read, and G remains the separate report of unclosed prediction, domain, bridge, and falsification commitments. □

Lean4 ✓ `BEDC.Derived.ScientificObjectUp.ScientificObjectTruthDomainGapScope`

Theorem 1214.8 (Scientific object obligation-closure package)**.** *The carrier, record-classifier admission, gap-report ledger, empirical-bridge separation, truth-domain scope, NameCert surface, falsifiability row, and independence row together provide the paper-side obligation package for* $\mathsf{ScientificObject}^{\uparrow}$*. Every accepted object read is constrained by*

$$R, K, I, L, B, G, A, T, O, D, H, C, P, N$$

and by the displayed refusal of bare object existence, unledgered empirical fit, hidden model identity, global synchronization, and final physical truth outside those rows.

Proof. The carrier of Definition 1214.1 displays all finite rows in the package and states the absent coordinates. Apply Definition 1214.6 to force record and classifier admission before downstream object reads.

Apply Definition 1214.3, Definition 1214.4, and Definition 1214.7. These results keep the gap ledger, empirical bridge, truth route, and domain scope as separate obligations.

Finally apply Definition 1214.5. The falsifiability row rejects consumers that omit the gap report, empirical ledger, inter-history invariant, or reality-constrained truth rows, and the independence row records that the named siblings supply constituent surfaces rather than the full carrier. The listed rows therefore form the paper-side obligation package for $\mathsf{ScientificObject}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.ScientificObjectUp.ScientificObjectObligationClosurePackage`

Theorem 1214.9 (Scientific object standard bridge surface)**.** *Every standard-facing* $\mathsf{ScientificObject}^{\uparrow}$ *read preserves the record row R, classifier row K, invariant row I, empirical ledger L, bridge row B, gap report G, audit row A, truth-certificate row T, open-fit row O, domain row D, component-wise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. The bridge surface may export the public object-facing package, but it cannot collapse these rows into final truth, hidden model identity, unledgered empirical adequacy, or an off-packet standard object.*

Proof. Start with the carrier and NameCert obligations. The accepted packet exposes $R, K, I, L, B, G, A, T, O, D, H$ as named rows, and the local certificate reads each row before the public object-facing name is available.

Use the gap-report ledger, empirical-bridge separation, and truth-domain gap scope. These results keep unclosed commitments, empirical fit, bridge status, truth route, and domain scope as separate surfaces rather than allowing one row to stand for the others.

Finally apply the NameCert surface and obligation-closure package. They identify the public read with the displayed finite package and rule out bare object existence, hidden bridge completion, and final physical truth outside the packet. A standard-facing bridge therefore preserves the whole row surface. □

Falsifiable prediction: Any accepted ScientificObjectUp consumer that exports a mature scientific object while omitting the gap report, empirical ledger, inter-history invariant, or reality-constrained truth rows refutes the packet.

Independence witness: physicalmodelaudit, realityconstrainedtruthcert, openfitpacket, domaintruthcertificate, interhistinvariant: none is bijective because $\mathsf{ScientificObject}^{\uparrow}$ binds records, classifier, invariant, ledger, bridge, gap report, audit, truth, open-fit, domain, transport, provenance, and local NameCert rows in one carrier, while each sibling supplies only one constituent surface.

The Lean TasteGate path `lean4/BEDC/Derived/ScientificObjectUp/TasteGate.lean` provides explicit $\mathsf{Nontrivial}\ \mathsf{ScientificObject}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ScientificObject}^{\uparrow}$ instances. These instances distinguish record, classifier, invariant, empirical-ledger, bridge, gap-report, audit, truth-certificate, open-fit, domain, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ScientificObject}^{\uparrow}}$.

Constructive story: A $\mathsf{ScientificObject}^{\uparrow}$ packet is generated from finite record, classifier, invariant, empirical ledger, bridge, gap report, audit, truth, open-fit, domain, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.
Lean4 ✓ `BEDC.Derived.ScientificObjectUp.taste gate`

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ScientificObject}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1214.9 is the standard bridge surface, with Definition 1214.1, Definition 1214.6, Definition 1214.7, Definition 1214.5, and Definition 1214.8 binding its carrier, classifier, truth-domain gap, public export, and obligation rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ScientificObject}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, final physical truth, unledgered empirical adequacy, or hidden bridge completion.

Upgrade path: Verification closure requires checked carrier admission, gap-report ledger, empirical-bridge separation, NameCert surface, TasteGate nontriviality, and field faithfulness for $R, K, I, L, B, G, A, T, O, D, H, C, P, N$.

Chapter 1215

A Concrete Naming Certificate for $\mathsf{FiniteRealSection}^{\uparrow}$

The $\mathsf{FiniteRealSection}^{\uparrow}$ packet realizes one finite section of the diagonal-limit representative of Definition 9238.3. It sits between the representative packet of chapter 1205 and the tail-alignment packet of chapter 1210, and it consumes the finite stream windows of chapter 126, the regular-rational readbacks of chapter 301, the dyadic tolerance rows of chapter 291, and the seal rows of chapter 38. The packet names a single displayed precision request and its section route; it is not a quotient stream, selected host limit, countable-choice selector, ambient Real-completeness principle, or standard bridge.

Definition 1215.1 (Finite real section carrier)**.** *A* $\mathsf{FiniteRealSection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (q, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *q is the finite precision request for the diagonal-limit section;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window exposing the selected stream read for that request;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row read through W;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the rational arithmetic and error budget attached to R;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the selected regular-rational readback has been repacked through D;*
6. *H records componentwise* hsame *transport for q, W, R, D, E and the local certificate row;*
7. *C records displayed* Cont *replay from the request through the window, readback, dyadic ledger, and Real seal;*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteRealSection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRealSection}^{\uparrow}}$ *row.*

The carrier exports only the displayed finite-section route and its transport, replay, provenance, and naming support.

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSectionTasteGate single carrier alignment`

Theorem 1215.2 (Finite real section obligation surface)**.** *For the carrier of Definition 1215.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteRealSection}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier stability for the displayed tuple* (q, W, R, D, E)*, window-readback compatibility between* W *and* R*, dyadic-tolerance exposure through* D*,* $\mathsf{Real}^{\uparrow}$ *seal exposure through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSection transport stability`

Proof. Project the carrier S. Its coordinates list one precision request, one stream window, one regular-rational readback, one dyadic ledger, one Real seal, transport, replay, provenance, and local naming rows.

The data-bearing obligations are inherited in order. Carrier admission exposes q; the classifier is stable precisely because accepted packets compare the displayed tuple (q, W, R, D, E) componentwise before any support row is read; the window-readback obligation then forces R to be the readback attached to W.

The remaining rows are downstream support. The dyadic ledger D records the tolerance row for the readback, the seal row E is reachable only after that ledger is displayed, and H, C, P, N only transport, replay, source, and name the same finite route. Thus the listed obligations exhaust the local naming surface. □

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSection obligation surface`

Theorem 1215.3 (Finite real section window-readback determinacy)**.** *For an accepted* $\mathsf{FiniteRealSection}^{\uparrow}$ *carrier* $S = (q, W, R, D, E, H, C, P, N)$ *of Definition 1215.1, the precision request* q *determines the displayed* $\mathsf{StreamName}^{\uparrow}$ *window* W*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *is read only through that same window. No second stream window, quotient stream, or host sequence coordinate is available inside the accepted finite-section route.*

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSection window readback determinacy`

Proof. Read the carrier rows in Definition 1215.1. The only stream coordinate exposed by S is W, and the only regular-rational coordinate is R.

Apply Definition 1215.2. Its window-readback compatibility clause is the unique obligation that relates the displayed $\mathsf{StreamName}^{\uparrow}$ window of chapter 126 to the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301.

Any alternative window, quotient stream, or host sequence coordinate would have to appear either as a carrier coordinate or as a named obligation. Neither appears in the tuple or in the obligation surface, so the accepted route reads R through exactly the window determined by q. □

Theorem 1215.4 (Finite real section dyadic-seal factorization)**.** *For an accepted* $\mathsf{FiniteRealSection}^{\uparrow}$ *carrier* $S = (q, W, R, D, E, H, C, P, N)$ *of Definition 1215.1, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *factors through the ordered route*

$$q \to W \to R \to D \to E.$$

Here D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the route admits no seal exposure that bypasses* D*.*

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSection dyadic seal factorization`

Proof. The carrier order in Definition 1215.1 displays the finite request, the stream window, the regular-rational readback, the dyadic tolerance ledger, and then the Real seal. Thus E is not an independent coordinate of an ambient completed Real; it is the seal row reached from the preceding displayed data.

Apply Definition 1215.2. Dyadic-tolerance exposure precedes $\mathsf{Real}^{\uparrow}$ seal exposure in the listed local $\mathsf{NameCert}_{\mathsf{FiniteRealSection}^{\uparrow}}$ surface. The $\mathsf{DyadicRatCore}^{\uparrow}$ chapter chapter 291 supplies the tolerance-ledger role of D, and the $\mathsf{Real}^{\uparrow}$ chapter chapter 38 supplies the seal-row role of E.

Because the accepted surface contains no second seal row and no bypass obligation, every Real-facing use of E factors through the displayed ledger D attached to the readback R. □

Theorem 1215.5 (Finite real section route consumer exactness)**.** *Every Real- or completion-facing consumer of an accepted* $\mathsf{FiniteRealSection}^{\uparrow}$ *carrier sees exactly the rows*

$$q, W, R, D, E, H, C, P, N,$$

transported by hsame*, read through* Cont*, and packaged by* Pkg *and* NameCert*. Conversely, those rows assemble the accepted finite-section consumer route.*

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSection route consumer exactness`

Proof. For the forward direction, start from Definition 1215.1. A consumer can project the displayed finite request, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{Real}^{\uparrow}$ seal, transport row, replay row, provenance row, and local naming row.

Apply Definition 1215.2. The same theorem identifies the admissible consumer surface: componentwise hsame transport through H, displayed Cont replay through C, Pkg provenance through P, and local naming through N.

For the converse direction, assume precisely the nine displayed rows with the stated transport, replay, packaging, and naming support. They match the carrier coordinates and satisfy the listed local obligations, so they assemble the accepted finite-section route and expose no additional Real, completion, quotient, or host-sequence coordinate. □

Theorem 1215.6 (Finite real section non-escape)**.** *Every Real- or Completion-facing consumer of an accepted* $\mathsf{FiniteRealSection}^{\uparrow}$ *packet factors through the finite route*

$$q, W, R, D, E, H, C, P, N.$$

The consumer receives a single precision request, one $\mathsf{StreamName}^{\uparrow}$ *window, one* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, one* $\mathsf{Real}^{\uparrow}$ *seal, and the displayed transport, replay, provenance, and local naming rows. It receives no quotient stream equality, host sequence equality, selected host limit, countable-choice selector, ambient Real completeness, or standard bridge.*

Proof. Begin with Definition 1215.1. The only Real-facing coordinate is the seal row E, and it is downstream of the finite request q, stream window W, regular-rational readback R, and dyadic tolerance ledger D.

Apply Definition 1215.2. It forces every consumer to pass through carrier admission, classifier stability, window-readback compatibility, dyadic-tolerance exposure, seal exposure, transport, replay, provenance, and local naming before using the packet.

The excluded objects require coordinates that the carrier does not contain. The rows H, C, P, N preserve and name displayed data, but they do not create quotient stream equality, host sequence equality, a selected host limit, a countable-choice selector, ambient Real completeness, or a standard bridge. Hence none of those objects can be projected from the finite-section certificate. □

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSection nonescape`

Theorem 1215.7 (Finite real section transport stability)**.** *Let*

$$S = (q, W, R, D, E, H, C, P, N)$$

and

$$S' = (q', W', R', D', E', H', C', P', N')$$

be accepted $\mathsf{FiniteRealSection}^{\uparrow}$ *packets. If* H *displays componentwise* hsame *transport from* S *to* S'*, then the transported packet preserves the same precision request, the same* $\mathsf{StreamName}^{\uparrow}$ *window role, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback role, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger role, the same* $\mathsf{Real}^{\uparrow}$ *seal role, the same* Cont *replay route, the same* Pkg *provenance, and the same local* $\mathsf{NameCert}_{\mathsf{FiniteRealSection}^{\uparrow}}$ *route.*

Proof. Project the two carrier tuples through Definition 1215.1. The only rows eligible for transport are the displayed request, window, readback, ledger, seal, replay, provenance, and local naming rows.

Apply Definition 1215.2. Its componentwise hsame clause says that H transports the listed carrier coordinates and not an ambient Real object or quotient representative.

The consumer side is fixed by Definition 1215.5: every Real- or completion-facing use reads precisely the transported finite route. Finally, Definition 1215.6 excludes any target outside that route, so transport preserves the same finite-section request and its local certificate. □

Theorem 1215.8 (Finite real section refinement noncollapse)**.** *For an accepted* $\mathsf{FiniteRealSection}^{\uparrow}$ *packet* $S = (q, W, R, D, E, H, C, P, N)$*, a displayed refinement of the finite request through* C *may refine the visible finite window, readback, ledger, and seal rows along the same route*

$$q \to W \to R \to D \to E.$$

It cannot create a second stream, quotient stream equality, selected host limit, countable-choice row, ambient completeness row, or standard bridge row.

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSection refinement noncollapse`

Proof. Read the carrier in the order $q, W, R, D, E, H, C, P, N$ from Definition 1215.1. The replay row C is downstream support for that ordered finite request; it is not an additional source of stream, quotient, host-limit, choice, completeness, or bridge data.

Use Definition 1215.4. The Real-facing seal factors through the displayed dyadic ledger, so refining the finite request can only refine rows already sitting on the route from q to E.

It remains to rule out collapse into a larger completion surface. Apply Definition 1215.6: the excluded objects require coordinates absent from the carrier and absent from the local obligation surface. Hence displayed refinement through C preserves finite visibility without creating any of those rows. □

Theorem 1215.9 (Finite real section obligation-closure package)**.** *The carrier of Definition 1215.1, the obligation surface of Definition 1215.2, window-readback determinacy of Definition 1215.3, dyadic-seal factorization of Definition 1215.4, route consumer exactness of Definition 1215.5, non-escape of Definition 1215.6, transport stability of Definition 1215.7, and refinement noncollapse of Definition 1215.8 are exactly the finite-section obligation set for* $\mathsf{FiniteRealSection}^{\uparrow}$ *over* BHist*,* hsame*,* Cont*,* Pkg*,* $\mathsf{NameCert}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Proof. The carrier fixes the nine-row finite section over BHist. The obligation surface names the admissible local $\mathsf{NameCert}_{\mathsf{FiniteRealSection}^{\uparrow}}$ rows, while window-readback determinacy and dyadic-seal factorization identify the two data dependencies that a Real-facing consumer must respect.

Route consumer exactness supplies the bidirectional packaging statement: exactly those rows are visible to a consumer and exactly those rows assemble the accepted route. Non-escape removes quotient, host-limit, choice, ambient-completeness, and bridge exits from the obligation set.

The two stability clauses close the remaining transport and refinement faces. Transport stability keeps hsame, Cont, Pkg, and NameCert support on the same finite route, and refinement noncollapse keeps displayed refinement from adding any non-finite completion row. Together these clauses exhaust the finite-section obligations named for $\mathsf{FiniteRealSection}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSection obligation closure package`

Theorem 1215.10 (Finite real section public bridge)**.** *The public finite-section certificate bridges the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows to the abstract* $\mathsf{FiniteRealSection}^{\uparrow}$ *schema. The bridge route is exactly the carrier of Definition 1215.1, obligation surface of Definition 1215.2, route exactness of Definition 1215.5, non-escape of Definition 1215.6, transport stability of Definition 1215.7, refinement noncollapse of Definition 1215.8, and TasteGate alignment recorded by the existing finite-section carrier marker.*

Proof. The carrier exposes the four data rows in the required order: stream window, regular-rational readback, dyadic tolerance ledger, and Real seal. The obligation surface then names the only admissible local $\mathsf{NameCert}_{\mathsf{FiniteRealSection}^{\uparrow}}$ reads over those rows.

Route consumer exactness supplies the public direction of the bridge. Every Real- or completion-facing consumer sees precisely the displayed finite-section rows together with hsame transport, Cont replay, Pkg provenance, and local naming.

Non-escape, transport stability, and refinement noncollapse supply the boundary direction. They prevent quotient streams, host limits, ambient completeness, choice, and bridge-external rows from entering the certificate while preserving the same route under transport and displayed refinement. The TasteGate alignment keeps this public package attached to the single carrier schema rather than to a sibling real-section interface. □

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.FiniteRealSection public bridge`

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRealSection}^{\uparrow}}$**.**

Constructive story: The finite Real section is generated from a $BHist$ packet that records a finite request, stream window, regular-rational readback, dyadic tolerance ledger, and the Real-facing seal row consumed by that route. The carrier convention does not assume a completed Real object; it reads only the finite section, transports it along $hsame$, and permits Cont extensions that preserve the same finite witness. The obligation surface names the finite section and the non-escape theorem records the boundary: a consumer that needs an infinite completion witness, quotient stream, selected host limit, or ambient Real equality has left the carrier. Thus the chapter packages a finite visible section as the whole admissible certificate.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteRealSection}^{\uparrow}}$, maturePackageClosed)

Scope closed: This chapter exports the finite-section public consumer surface and its compact-metric, completion, and Real-consumer cross-chapter uses, consisting of the carrier, obligation surface, route consumer exactness, non-escape theorem, transport stability, refinement noncollapse, obligation-closure package, and

Lean4 ✓ `BEDC.Derived.FiniteRealSectionUp.taste gate`

over BHist, hsame, Cont, Pkg, NameCert, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteRealSection}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Origin: ai

Not claimed: It does not claim full Real construction, infinite-section availability, quotient-stream equality, selected host limits, or ambient completeness.

Upgrade path: The verification-axis step remains Lean bridge checking for the same finite-section bridge; the paper-axis scope already includes compact-metric, completion, and Real-consumer cross-chapter use.

Chapter 1216

A Concrete Naming Certificate for $\mathsf{RegistryExportSurface}^{\uparrow}$

The $\mathsf{RegistryExportSurface}^{\uparrow}$ packet realizes the export-control surface of Definition 9462.2249 inside the auditable-generativity programme of chapter 9462. It sits beside the cannot-claim registry packet of chapter 554, the verified-output boundary of chapter 1188, the focused finite ledger of chapter 1109, the GroundCompiler recognition surface of chapter 821, and the NameCert audit pattern of chapter 1191. Those siblings supply refusal rows, checker-facing export, focused ledger scope, machine recognition, and naming-audit discipline; this carrier binds claim registration, blocking, status, machine target, audit route, and non-smuggling rows before a registry claim may leave the philosophy package.

Definition 1216.1 (Registry export surface carrier)**.** *A* $\mathsf{RegistryExportSurface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, B, S, M, A, U, H, C, P, N)$$

with the following visible rows:

1. *R is the registration row, recording the registry entry in which the claim is allowed to appear;*
2. *B is the blocking row, recording the cannot-claim or refusal entry that prevents export when the claim is not licensed;*
3. *S is the status row, recording whether the claim is exported, blocked, horizon-facing, or held as a formalization target;*
4. *M is the machine-target row, recording the exact machine-facing consumer of the registry entry;*
5. *A is the audit row, recording the finite verification, closure-status, or ledger route that the machine target may inspect;*
6. *U is the non-smuggling row, recording the forbidden readings that the export must not import from prose, host semantics, model output, or hidden registry state;*
7. *H stores componentwise* hsame *transport for the registration, blocking, status, machine-target, audit, non-smuggling, continuation, provenance, and local naming rows;*
8. *C stores displayed* Cont *replay for registration lookup, blocking lookup, status inspection, machine-target export, audit replay, and non-smuggling refusal;*

9. *P is the* Pkg *provenance over* $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{LargeModelOutputVerifier}^{\uparrow}$, $\mathsf{FocusedMultiHistLedger}^{\uparrow}$, $\mathsf{GroundCompilerRecognition}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an unregistered claim, a private override of B, a hidden machine target, or a prose-only export route.

Lean4 (definition) `BEDC.Derived.RegistryExportSurfaceUp.RegistryExportSurfaceUp`

Theorem 1216.2 (Registry export surface NameCert obligations)**.** *For the carrier of Definition 1216.1, the local* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *surface consists exactly of six obligation rows:*

1. *carrier admission for $E = (R, B, S, M, A, U, H, C, P, N)$;*
2. *registration and blocking coverage through R and B;*
3. *status exactness through S, requiring exported, blocked, horizon-facing, and formalization-target readings to remain distinct;*
4. *machine-target and audit exposure through M and A;*
5. *non-smuggling accountability through U, requiring every forbidden reading to remain visible at the export boundary;*
6. *transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the finite packet of Definition 1216.1. The rows R, B, S, M, A, U already separate registration, refusal, status, machine target, audit route, and forbidden readings.

Registration and blocking coverage are read first. A consumer may export a claim through R or block it through B, but it cannot erase the blocked case by reclassifying it as an exported registry entry.

The status row S then determines which registry reading is available to the machine target M. The audit row A supplies the finite route that the target may inspect, while the non-smuggling row U records the readings that remain forbidden.

Finally H, C, P, N transport, replay, package, and name the same rows. Since the carrier has no further coordinate, the six obligation rows exhaust the local $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ surface. □

Theorem 1216.3 (Registry export surface non-escape)**.** *Let*

$$E = (R, B, S, M, A, U, H, C, P, N)$$

be an accepted $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet. Any public consumer that exports a registry claim must read the registration row R, blocking row B, status row S, machine-target row M, audit row A, non-smuggling row U, transport row H, replay row C, provenance row P, and local naming row N. The export cannot be recovered from prose synthesis, model output, hidden registry state, or a machine target that bypasses the blocking row.*

Proof. Use the NameCert obligations of Definition 1216.2. They place registration, blocking, status, machine-target export, audit replay, and non-smuggling accountability inside one finite packet.

If a route omits B, the route no longer knows whether the claim is blocked by a registry entry. If it omits U, the route no longer records which prose, host-semantic, model-output, or hidden-state readings are forbidden.

The rows H, C, P, N bind these checks to the same displayed packet. Hence every accepted export remains inside the listed rows, and any route that bypasses them exits the $\mathsf{RegistryExportSurface}^{\uparrow}$ carrier rather than exporting a BEDC registry claim. □

Theorem 1216.4 (Registry export surface status exactness)**.** *Let*

$$E = (R, B, S, M, A, U, H, C, P, N)$$

be an accepted $\mathsf{RegistryExportSurface}^{\uparrow}$ BHist *packet with* hsame *transport* H*,* Cont *replay* C*, provenance package* P*, and local* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *row* N*. The status row* S *keeps the exported, blocked, horizon-facing, and formalization-target readings as separate registry statuses: no* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *audit may identify any two of these readings while preserving the displayed registration row* R*, blocking row* B*, machine-target row* M*, audit row* A*, and non-smuggling row* U*.*

Proof. Unpack the carrier of Definition 1216.1. The row S is the only displayed coordinate assigned to export status, and the definition lists exported, blocked, horizon-facing, and formalization-target readings as the alternatives recorded there.

Apply the NameCert obligations of Definition 1216.2. Their third row requires status exactness through S, and their surrounding rows keep $R, B, M, A, U, H, C, P, N$ in the same finite packet.

Finally use the non-escape theorem, Definition 1216.3. A consumer that tries to merge two status readings must still read B and U through the same transport and replay rows; if it bypasses either row, it no longer exports from the $\mathsf{RegistryExportSurface}^{\uparrow}$ carrier. Thus the four status readings remain distinct for every accepted packet audit. □

Theorem 1216.5 (Registry export surface machine-target audit route)**.** *Let*

$$E = (R, B, S, M, A, U, H, C, P, N)$$

be an accepted $\mathsf{RegistryExportSurface}^{\uparrow}$ BHist *packet. Every machine-target export from* E *factors through the displayed machine target* M*, audit row* A*, transport row* H*, replay row* C*, provenance package* P*, and local* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *row* N*, and this factorization cannot bypass the blocking row* B*.*

Proof. Read the carrier in Definition 1216.1. The machine-facing consumer is not an ambient parameter: it is the row M, and the route it may inspect is the row A together with H, C, P, N.

The NameCert obligations of Definition 1216.2 place machine-target and audit exposure in one row, and they place transport, replay, provenance, and local naming in the final row. These rows therefore describe the finite route from the machine target back to the named packet.

The blocking row is still part of the same export. By Definition 1216.3, any public consumer exporting a registry claim must read B as well as M, A, H, C, P, N. A purported machine target that reaches the claim without B is outside the accepted carrier rather than a machine-target export from E. □

Theorem 1216.6 (Registry export surface non-smuggling ledger exhaustion)**.** *Let*

$$E = (R, B, S, M, A, U, H, C, P, N)$$

be an accepted $\mathsf{RegistryExportSurface}^{\uparrow}$ BHist *packet. The prose reading, host-semantic reading, model-output reading, and hidden-registry-state reading are refused by the non-smuggling row* U *together with the displayed* hsame *transport* H*,* Cont *replay* C*, provenance package* P*, and local* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *row* N*; no further ledger coordinate is available for importing any of these readings into the registry export.*

Proof. The carrier definition names U as the row that records forbidden readings from prose, host semantics, model output, and hidden registry state. It also states that the packet contains no coordinate for a prose-only export route, hidden machine target, or private override of the blocking row.

The NameCert obligations of Definition 1216.2 make this refusal visible at the export boundary. They assign non-smuggling accountability to U and bind it to the transport, replay, provenance, and local naming rows H, C, P, N.

It remains to exclude a hidden ledger extension. Apply Definition 1216.3: every accepted public export must read U, H, C, P, N along with the registration, blocking, status, machine-target, and audit rows. Since the carrier has no additional coordinate, the listed rows exhaust the ledger route and refuse exactly the four forbidden readings named in the theorem. □

Theorem 1216.7 (Registry export surface TasteGate obligation)**.** *The Lean follow-up for* $\mathsf{RegistryExportSurface}^{\uparrow}$ *must provide* $\mathsf{Nontrivial\ RegistryExportSurface}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ RegistryExportSurface}^{\uparrow}$ *in* lean4/BEDC/Derived/Reg *with the nontriviality witness exposing at least one accepted registration-or-blocking packet and the field-faithfulness witness preserving the distinct rows* $R, B, S, M, A, U, H, C, P, N$*.*

Proof. The carrier in Definition 1216.1 is not a terminal tag: it has separate rows for registration, blocking, status, machine target, audit route, and non-smuggling accountability. A TasteGate witness must therefore exhibit a packet in which these rows are inspectable.

Field faithfulness is exactly the requirement that the classifier not collapse the rows that the NameCert obligations keep apart. In particular, R cannot substitute for B, M cannot substitute for A, and U cannot be erased after a successful export.

Thus the Lean surface named in the theorem is the appropriate follow-up site for the same finite carrier, with nontriviality and field-faithfulness aligned to the displayed rows. □

Falsifiable prediction: If the blocking row is absent, no accepted RegistryExportSurfaceUp packet exports a blocked-claim reading.

Independence witness: cannotclaim, largemodeloutputverifier, focused-multi-hist-ledger, groundcompilerrecognizerflow: the cannot-claim packet records refusal rows without machine-target export, the large-model verifier records checked output without registry status coverage, the focused multi-Hist ledger records a finite focus ledger without claim blocking, and the GroundCompiler recognizer flow records machine recognition without the full registration, blocking, audit, and non-smuggling packet. None is bijective to $\mathsf{RegistryExportSurface}^{\uparrow}$.

Theorem 1216.8 (Registry export surface public bridge route)**.** *The public* $\mathsf{RegistryExportSurface}^{\uparrow}$ *route bridges registration, blocking, status, machine-target, audit, and non-smuggling rows to the sibling surfaces chapter 554, chapter 1188, chapter 1109, chapter 821, and chapter 1191. The bridge-facing route is paper-level: it records the public dependency surface while leaving Lean bridge checking and* $\mathsf{StandardBridge}$ *discharge outside this chapter.*

Proof. Begin with Definition 1216.2. It displays the registration row R, blocking row B, status row S, machine-target row M, audit row A, non-smuggling row U, and structural rows H, C, P, N.

Use Definition 1216.3, Definition 1216.4, and Definition 1216.5. These theorems keep export, blocking, status, machine target, and audit reads inside the public carrier instead of prose or hidden registry state.

Finally apply Definition 1216.6. The non-smuggling row connects the public route to the cannot-claim, large-model-output-verifier, focused-ledger, GroundCompiler-recognition, and physical NameCert audit sibling surfaces named in the chapter introduction. Since no checked $\mathsf{StandardBridge}$ row is displayed, the result is a bridged paper route while the bridge verification axis remains unchanged. □

Theorem 1216.9 (Registry export surface index coverage)**.** *For every accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet* $E = (R, B, S, M, A, U, H, C, P, N)$*, the registry index visible to a downstream consumer is covered exactly by the* BHist *registration row* R*, the blocking row* B*, the status row* S*, the machine-target row* M*, the audit route row* A*, the non-smuggling row* U*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *row* N*. In particular, no BHist registry row may be exported unless the matching blocking, status, machine-target, audit, provenance, and naming rows are present in the same packet.*

Proof. Project the carrier of Definition 1216.1. The visible registry coordinates are $R, B, S, M, A, U, H, C, P, N$, with R naming the BHist registry row and N naming the local NameCert row.

Apply the NameCert obligations of Definition 1216.2. They place registration and blocking coverage in R, B, status exactness in S, machine-target and audit exposure in M, A, and non-smuggling accountability in U.

Finally use Definition 1216.8. The public route reads those same rows before any downstream export, so the index has no hidden entry outside the displayed BHist, Pkg, and $\mathsf{NameCert}$ surface. □

Theorem 1216.10 (Registry export surface export determinacy)**.** *For every accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet* $E = (R, B, S, M, A, U, H, C, P, N)$*, the exported registry reading is determined by the displayed status row* S *together with the blocking row* B*, the machine-target row* M*, the audit route row* A*, the non-smuggling row* U*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *row* N*. Two consumers that preserve these rows cannot produce two different export outcomes from the same BHist registry row* R*.*

Proof. Start with status exactness, Definition 1216.4. It keeps exported, blocked, horizon-facing, and formalization-target readings separate while preserving $R, B, M, A, U, H, C, P, N$.

Now read the machine-target audit route of Definition 1216.5. The machine target M receives only the displayed audit row A and cannot bypass the blocking row B.

It remains to rule out a second export by hidden state. Apply nonescape, Definition 1216.3, and the non-smuggling ledger exhaustion theorem. Since prose synthesis, model output, hidden registry state, and detached machine targets are refused by U, H, C, P, N, the preserved rows determine the public export outcome. □

Theorem 1216.11 (Registry export surface consumer provenance)**.** *Every downstream consumer of an accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet must carry the* Pkg *provenance row* P *and the local* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *row* N *together with the BHist registry row* R*, blocking row* B*, status row* S*, machine-target row* M*, audit route row* A*, and non-smuggling row* U*. A consumer that drops* P *or* N *is no longer a registry-export consumer of the packet.*

Proof. Read the structural rows in Definition 1216.1. The row P records provenance over $\mathsf{RegistryExportSurface}^{\uparrow}$ and its sibling export surfaces, while N records local NameCert naming for the same finite packet.

Apply Definition 1216.2. Its final obligation row binds transport, replay, provenance, and local naming to H, C, P, N, so the consumer cannot detach the registration, blocking, status, machine-target, audit, or non-smuggling rows from their package and certificate.

Finally use the public bridge route. Downstream export passes through the sibling cannot-claim, verifier, focused-ledger, recognition, and audit surfaces only with the same displayed rows. Therefore a consumer without P or N is a hidden or prose-only route, not a $\mathsf{RegistryExportSurface}^{\uparrow}$ consumer. □

Theorem 1216.12 (Registry export surface obligation rows)**.** *For every accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet* $E = (R, B, S, M, A, U, H, C, P, N)$*, the registration row* R*, blocking row* B*, status row* S*, machine-target row* M*, audit row* A*, and non-smuggling row* U*, together with* H, C, P, N*, exhaust the public obligation surface. No registry export obligation remains outside registration, blocking, status exactness, machine-target exposure, audit replay, non-smuggling accountability, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Read the carrier of Definition 1216.1. Its visible coordinates are exactly $R, B, S, M, A, U, H, C, P, N$, and the definition excludes unregistered claims, private blocking overrides, hidden machine targets, and prose-only export routes.

Apply Definition 1216.2. The obligation list already assigns carrier admission, registration and blocking coverage, status exactness, machine-target and audit exposure, non-smuggling accountability, and transport/replay/provenance/name rows to these coordinates.

It remains to exclude a public obligation outside the list. Use Definition 1216.8: the public bridge route reads the same registration, blocking, status, machine-target, audit, and non-smuggling rows before connecting to sibling surfaces. Hence every public obligation is already one of the displayed rows. □

Theorem 1216.13 (Registry export surface ledger nonescape)**.** *No accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *export route can bypass the blocking and non-smuggling ledger. Any route that exports a registry claim must read* B *and* U *through the same status, machine-target, audit, transport, replay, provenance, and local* $\mathsf{NameCert}$ *rows that name the carrier.*

Proof. Begin with Definition 1216.3. It states that every public consumer exporting a registry claim reads $R, B, S, M, A, U, H, C, P, N$ and cannot recover the export from prose synthesis, model output, hidden registry state, or a machine target that bypasses B.

The status exactness theorem, Definition 1216.4, keeps blocked and exported readings separate while preserving R, B, M, A, U. Thus the blocking row cannot be erased by relabeling a blocked status as an exported status.

Finally use Definition 1216.6. It identifies U, H, C, P, N as the ledger route refusing prose, host-semantic, model-output, and hidden-registry-state readings. A route that bypasses B or U is therefore outside the accepted carrier, not an export route from it. □

Theorem 1216.14 (Registry export surface machine-readable blocking route)**.** *Every machine-readable* $\mathsf{RegistryExportSurface}^{\uparrow}$ *export factors through blocking, audit, transport, replay, provenance, and local* $\mathsf{NameCert}$ *rows:*

$$B, A, H, C, P, N.$$

The machine target M *may read a registry claim only along this route, with status supplied by* S *and non-smuggling accountability supplied by* U*.*

Proof. Use Definition 1216.5. It already factors every machine-target export through M, A, H, C, P, N and states that the factorization cannot bypass the blocking row B.

Next apply Definition 1216.13. The blocking row B and non-smuggling row U remain in the same ledger as the status row S, so a machine-readable export cannot read M and A while discarding the rows that decide whether the claim is blocked or forbidden.

The bridge route of Definition 1216.8 supplies the public consumer side. It connects the displayed registry rows to the sibling export surfaces without adding a hidden machine target. Therefore every machine-readable export factors through the listed blocking, audit, transport, replay, provenance, and local naming rows. □

Theorem 1216.15 (Registry export surface blocking-audit factorization)**.** *For every accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet*

$$E = (R, B, S, M, A, U, H, C, P, N),$$

each exported machine target factors through the registration row R, blocking row B, status row S, machine-target row M, audit row A, non-smuggling row U, transport row H, replay row C, provenance row P, and local $\mathsf{NameCert}$ *row N. In particular, the audit route for a machine target is not a standalone M, A projection: it is the displayed blocking-audit route*

$$R, B, S, M, A, U \longmapsto H, C, P, N.$$

Proof. Project the carrier of Definition 1216.1. Its visible rows already list registration, blocking, status, machine target, audit, non-smuggling, transport, replay, provenance, and local naming as the complete export surface.

Apply Definition 1216.14. It forces every machine-readable export through B, A, H, C, P, N, with M supplying the machine target and S, U supplying status and non-smuggling accountability.

Now use Definition 1216.13. A route that deletes B or U is not an accepted registry export, while Definition 1216.2 binds R, S, M, A to the same local certificate rows.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming keep the displayed blocking-audit route componentwise, so no hidden registry state, prose-only export, or detached machine target remains. □

Theorem 1216.16 (Registry export surface status machine-target coverage)**.** *For every accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet $E = (R, B, S, M, A, U, H, C, P, N)$, every exported, blocked, horizon-facing, or formalization-target machine read is covered by the same displayed rows $R, B, S, M, A, U, H, C, P, N$. The status row S chooses the public status, the machine-target row M chooses the machine-facing consumer, and the audit row A supplies the route that consumer may inspect; none of these rows can cover a target after removing blocking, non-smuggling, transport, replay, provenance, or local naming.*

Proof. Start with status exactness, Definition 1216.4. It keeps exported, blocked, horizon-facing, and formalization-target readings distinct while preserving $R, B, M, A, U, H, C, P, N$.

Apply the blocking-audit factorization theorem above. It places the machine-facing read inside the complete route $R, B, S, M, A, U, H, C, P, N$, so status coverage and machine-target coverage are the same displayed packet rather than two independent projections.

Finally use the non-smuggling ledger exhaustion theorem, Definition 1216.6. It refuses prose, host-semantic, model-output, and hidden-registry-state readings, so every covered machine target remains local to the accepted carrier and its local $\mathsf{NameCert}$ row. □

Theorem 1216.17 (Registry export surface machine-audit totality)**.** *For every accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet*

$$E = (R, B, S, M, A, U, H, C, P, N),$$

each machine audit export reads the machine-target row M, audit row A, transport row H, continuation row C, provenance row P, and local name row N together with the blocking row B and non-smuggling row U. No machine audit export is available from M, A, H, C, P, N after deleting B or U.

Proof. Project the carrier E. The machine-readable route of Definition 1216.14 gives the displayed audit path through B, A, H, C, P, N, with M supplying the machine target and S, U supplying status and non-smuggling accountability.

Now apply the ledger nonescape theorem. It keeps B and U attached to any route that exposes a registry claim to a machine reader.

Finally use status exactness. The status row S may classify the claim as exported, blocked, horizon, or formal target, but the machine audit export remains a read of the same displayed rows. Thus M, A, H, C, P, N never form a standalone export after B or U is erased. □

Theorem 1216.18 (Registry export surface status-blocking exhaustion)**.** *For every accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet $E = (R, B, S, M, A, U, H, C, P, N)$, the exported, blocked, horizon, and formal-target statuses are exhausted by the status row S. Changing among these four public statuses cannot erase the blocking row B, and any export route that lacks B is outside the accepted registry surface.*

Proof. Read the status row through Definition 1216.4. It is the displayed row that separates exported and blocked registry reads while preserving the registration, machine-target, audit, and non-smuggling context.

The machine-readable blocking route extends the same separation to machine consumers. It requires B before M can be read as an export target.

The ledger nonescape theorem excludes the remaining case. A route that keeps a status label but removes the blocking row is not an accepted export route from E; it is a hidden-registry-state or prose-only route, both of which the carrier refuses. □

Theorem 1216.19 (Registry export surface formal-target boundary)**.** *For every accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet $E = (R, B, S, M, A, U, H, C, P, N)$, a formalization-target status in S exports only target metadata together with the audit route through M, A, H, C, P, N and the blocking and non-smuggling rows B, U. It does not export a checked theorem, a checked bridge, or any theorem-level evidence not already present as registry metadata.*

Proof. Begin with the status row S. A formalization-target status is a registry status, so it is read through the same carrier rows as exported, blocked, and horizon statuses.

Apply machine-audit totality. The target metadata can be exposed to a machine reader only with M, A, H, C, P, N and with B, U still attached.

There is no carrier coordinate for a checked theorem or checked bridge in E. The public bridge route is explicitly paper-level, and the closurestatus leaves bridge checking outside the chapter. Therefore the formal-target export boundary is metadata plus audit route, not theorem or bridge evidence. □

Theorem 1216.20 (Registry export surface public discharge)**.** *For every accepted* $\mathsf{RegistryExportSurface}^{\uparrow}$ *packet*

$$E = (R, B, S, M, A, U, H, C, P, N),$$

the public registry-export route is unique: it is the route through the displayed BHist *packet, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ *row that keeps the status row S, machine-target row M, blocking row B, audit row A, and non-smuggling row U together. Any putative public route that deletes one of S, M, B, A, U or bypasses H, C, P, N is outside the accepted carrier rather than a second registry-export discharge.*

Proof. Project the accepted carrier. By Definition 1216.1, the only public coordinates available to an export are $R, B, S, M, A, U, H, C, P, N$, with N naming the local $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$ row.

Apply status-blocking exhaustion and machine-audit totality. The status row S decides the public registry status, while the machine reader can inspect M, A, H, C, P, N only with the blocking and non-smuggling rows B, U still attached.

Finally use the formal-target boundary together with ledger nonescape. A route that claims public export while dropping B, U, or the structural rows H, C, P, N is a prose-only or hidden-registry-state route, not an accepted export from E. Hence the displayed path through BHist, hsame, Cont, Pkg, and NameCert is the single public discharge route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegistryExportSurface}^{\uparrow}$ packet is generated from registration, blocking, status, machine-target, audit, non-smuggling, transport, replay, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.RegistryExportSurfaceUp.taste gate`

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature export surface is closed by the carrier rows $R, B, S, M, A, U, H, C, P, N$, the local NameCert obligations, nonescape, status exactness, machine-target audit route, non-smuggling ledger exhaustion, the TasteGate obligation, and Definition 1216.8.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegistryExportSurface}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, hidden registry state, prose-only export, or machine targets that bypass blocking.

Upgrade path: Lean closure requires checked registration, blocking, status, machine-target, audit, non-smuggling, transport, replay, provenance, and local naming rows.

Chapter 1217

A Concrete Naming Certificate for $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$

The $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ carrier realizes the standard-bridge discipline of Definition 9462.952 inside the auditable-generativity programme of chapter 9462. It sits beside the kernel acceptance witness of chapter 549, the finite reflection tuple of chapter 993, and the GroundCompiler recognizer flow of chapter 1048. Those siblings expose accepted kernel rows, displayed reflection images, and generated-recognizer admission, while this packet binds bridge encoding, decoding, round trips, theorem preservation, no-host-leak, audit transport, and local naming before a host theory may be read as a standard bridge for a BEDC object.

Definition 1217.1 (Standard bridge audit packet carrier)**.** *A* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (N, T, E, D, R, U, P, L, H, C, Q)$$

with the following displayed rows:

1. *N is the accepted BEDC object row, read through the named* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$ *surface for the object being bridged;*
2. *T is the host-theory row, recording the host theory only as the right-hand side of the bridge and not as a BEDC primitive;*
3. *E is the encoding row from the BEDC carrier into the host theory;*
4. *D is the decoding row from the host theory back to the BEDC carrier;*
5. *R is the paired round-trip row, containing both decode-after-encode and encode-after-decode witnesses under the licensed classifier;*
6. *U is the finite theorem-preservation row, pairing each preserved host theorem with a BEDC counterpart and a displayed translation;*
7. *P is the no-host-leak row, recording the host primitives, quotient principles, semantic equality assumptions, proof objects, and host compiler readings that do not appear on the BEDC public surface;*
8. *L is the bridge ledger row, recording unsupported fields, refused translations, theorem-preservation gaps, and bridge scope boundaries;*

9. *H stores componentwise* hsame *transport for the accepted object, host theory, encoding, decoding, round-trip, theorem-preservation, no-host-leak, ledger, continuation, provenance, and local naming rows;*
10. *C stores displayed* Cont *replay for bridge checking, theorem-pair lookup, no-host-leak inspection, and downstream audit reads;*
11. *Q is the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{StandardBridgeAuditPacket}^{\uparrow}}$ *row over* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$, $\mathsf{FiniteReflectionTuple}^{\uparrow}$, $\mathsf{GroundCompilerRecognizerFlow}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

The carrier has no coordinate for a host primitive promoted to BEDC input, an infinite theorem schema, an unpaired host theorem, a hidden decoder, a private compiler route, or a bridge assertion detached from the displayed no-host-leak row.

Lean4 (definition) `BEDC.Derived.StandardBridgeAuditPacketUp.StandardBridgeAuditPacketUp`

Theorem 1217.2 (Standard bridge audit packet non-host-leak)**.** *For every accepted* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *carrier*

$$S = (N, T, E, D, R, U, P, L, H, C, Q),$$

the public bridge read factors through the displayed no-host-leak row P. A bridge route that omits P cannot export a BEDC-recognized standard bridge, even when E, D, R, U are present.

Proof. Project the carrier of Definition 1217.1. The host theory row T, encoding row E, decoding row D, round-trip row R, and theorem-preservation row U are not enough to define a public BEDC bridge because each of them may mention host-side structure.

The no-host-leak row P records exactly which host primitives, quotient principles, semantic equalities, proof objects, and host compiler readings are barred from the BEDC public surface. It is therefore the row that separates bridge recognition from host import.

The structural rows L, H, C, Q preserve and replay the same displayed packet. Since none of them supplies a replacement for P, any route that omits P exits the accepted $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ carrier rather than exporting a standard bridge. □

Lean4 ✓ `BEDC.Derived.StandardBridgeAuditPacketUp.StandardBridgeAuditPacket nonhost leak certificate`

Theorem 1217.3 (Standard bridge audit packet independence)**.** *The carrier of Definition 1217.1 is not bijective, row for row, with* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$, $\mathsf{FiniteReflectionTuple}^{\uparrow}$, $\mathsf{GroundCompilerRecognizerFlow}^{\uparrow}$ *finite BHist injection data, or* $\mathsf{ProofTermErasureTrace}^{\uparrow}$. *A row-preserving bijection would have to preserve accepted-object evidence, reflection-image readback, generated-recognizer admission, finite history injection, proof-term erasure visibility, encoding, decoding, two round-trip witnesses, finite theorem preservation, no-host-leak, bridge ledger, transport, replay, provenance, and local naming at once; no listed sibling carries that whole surface.*

Proof. First compare with $\mathsf{KernelAcceptanceWitness}^{\uparrow}$. Kernel acceptance witnesses expose candidate, accepted declaration, environment, purity-query, refusal, transport, replay, provenance, and local naming rows, but they do not contain host encoding, decoding, round trips, theorem-preservation pairs, or a no-host-leak row for a host theory.

Next compare with $\mathsf{FiniteReflectionTuple}^{\uparrow}$ and $\mathsf{GroundCompilerRecognizerFlow}^{\uparrow}$. The reflection tuple supplies displayed image and readback rows, while the recognizer flow supplies source-channel and generated-recognizer admission. Neither records the six standard-bridge fields as one finite audit packet.

Finally compare with finite BHist injection data and $\mathsf{ProofTermErasureTrace}^{\uparrow}$. Injection data concerns how finite histories embed into a displayed history surface, and proof-term erasure traces separate proof evidence from erased public rows. They do not carry the host-relative bridge ledger E, D, R, U, P, L. Thus no row-preserving bijection can identify any listed sibling with $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$. □

Theorem 1217.4 (Standard bridge audit packet TasteGate obligation)**.** *The Lean follow-up for* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *must provide* Nontrivial $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *and* FieldFaithful StandardBridgeAu *in* lean4/BEDC/Derived/StandardBridgeAuditPacketUp/TasteGate.lean*, with the nontriviality witness exposing at least one accepted bridge packet and the field-faithfulness witness preserving the distinct rows* $N, T, E, D, R, U, P, L, H, C, Q$*.*

Lean4 ✓ `BEDC.Derived.StandardBridgeAuditPacketUp.StandardBridgeAuditPacketTasteGate obligation`

Proof. The carrier in Definition 1217.1 is not a terminal tag. It separates the accepted BEDC object, host theory, encoding, decoding, round trips, theorem preservation, no-host-leak, ledger, transport, replay, and local NameCert rows.

A nontriviality instance must therefore exhibit a packet in which those rows are inspectable. A field-faithfulness instance must prevent the classifier from collapsing the no-host-leak row into theorem preservation, the host-theory row into BEDC input, or the round-trip row into a bare encoding or decoding row.

Thus the later TasteGate file is the appropriate Lean surface for the same carrier, and its instances must distinguish the displayed bridge rows before any bridge-checked consumer cites the packet. □

Theorem 1217.5 (Standard bridge audit packet round-trip exactness)**.** *For every accepted* StandardBridgeAuditPac *carrier*

$$S = (N, T, E, D, R, U, P, L, H, C, Q),$$

the two public round-trip reads are exactly the displayed reads through R, H, C, Q*. Decode-after-encode may consume* E *and* D *only after the paired round-trip row* R *names the witness, the componentwise transport row* H *preserves the accepted object and host-theory coordinates, the* Cont *row* C *replays the bridge-check request, and the provenance-and-naming row* Q *records the local packet. Encode-after-decode is governed by the same four rows in the opposite read direction. No hidden encoder, hidden decoder, host equality, or bridge assertion outside* R, H, C, Q *can supply either exactness witness.*

Proof. Project the carrier of Definition 1217.1. The rows E and D store the two bridge maps, but the carrier gives them no public exactness role by themselves; the paired round-trip row R is the only coordinate assigned to decode-after-encode and encode-after-decode witnesses.

Transport and replay are then forced through the structural rows. The row H moves the accepted object, host theory, encoding, decoding, and round-trip data componentwise, while C replays the concrete bridge-check request that asks for one of the two round-trip reads.

Finally Q records the Pkg provenance and local $\mathsf{NameCert}_{\mathsf{StandardBridgeAuditPacket}^{\uparrow}}$ row. Since the carrier has no coordinate for a hidden map, host equality import, or detached bridge assertion, both exactness directions are precisely the reads through R, H, C, Q. □

Lean4 ✓ `BEDC.Derived.StandardBridgeAuditPacketUp.StandardBridgeAuditPacket round trip rows visible`

Theorem 1217.6 (Standard bridge audit packet theorem-preservation ledger)**.** *For every accepted* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *carrier*

$$S = (N, T, E, D, R, U, P, L, H, C, Q),$$

each theorem-preservation claim is a finite ledger entry whose host theorem, BEDC counterpart, translation evidence, unsupported-field status, and public admissibility are read through U, L, P*. A host theorem that has no paired BEDC counterpart in* U*, or whose required host primitive is refused by* P *or recorded as unsupported in* L*, is not exported as a preserved BEDC theorem.*

Proof. The theorem-preservation coordinate of the carrier is U. By definition it contains finite rows pairing preserved host theorems with BEDC counterparts and displayed translations, so an unpaired host theorem has no preservation row to project.

The ledger row L records unsupported fields, refused translations, theorem-preservation gaps, and bridge scope boundaries. Thus a preservation claim must also be compatible with the finite ledger entry that says the translation is supported inside the packet's bridge scope.

The no-host-leak row P supplies the public admissibility check. If the proposed preservation uses a host primitive, quotient principle, semantic equality assumption, proof object, or compiler reading barred by P, then the claim remains a host-side statement rather than a BEDC-preserved theorem. Hence theorem preservation is exactly the finite U, L, P ledger surface. □

Lean4 ✓ `BEDC.Derived.StandardBridgeAuditPacketUp.StandardBridgeAuditPacket theorem preservation ledger`

Theorem 1217.7 (Standard bridge audit packet host-leak consumer coverage)**.** *For every accepted* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *carrier*

$$S = (N, T, E, D, R, U, P, L, H, C, Q),$$

any bridge consumer that reads E, D, R*, or* U *must first read the no-host-leak row* P*. A consumer that bypasses* P *cannot be certified by the local* $\mathsf{NameCert}_{\mathsf{StandardBridgeAuditPacket}^{\uparrow}}$ *row, even if it follows the displayed encoding, decoding, round-trip, and theorem-preservation coordinates.*

Proof. Apply Definition 1217.2. The public bridge read factors through P because the rows E, D, R, U may mention host-side structure and do not by themselves separate bridge recognition from host import.

Now inspect the consumer side of the carrier. The row C replays bridge checking, theorem-pair lookup, no-host-leak inspection, and downstream audit reads; the local packet row Q names the same replay surface through Pkg provenance and $\mathsf{NameCert}$ registration. Neither row replaces P with an implicit host-leak check.

Therefore every certified consumer of encoding, decoding, round trips, or theorem preservation must read P before consuming E, D, R, U. A route that omits P leaves the accepted packet surface and cannot be certified as a local standard-bridge audit consumer. □

Theorem 1217.8 (Standard bridge audit packet scoped primitive binding)**.** *For every certified bridge-audit consumer of an accepted* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *carrier*

$$S = (N, T, E, D, R, U, P, L, H, C, Q),$$

the primitive scope is exactly the scope displayed by the carrier: N *is read only through the named* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$ *surface;* T, E, D, R, U, P, L *are the host-relative bridge rows for host theory, encoding, decoding, paired round trips, theorem preservation, no-host-leak, and the bridge*

ledger; and H, C, Q are the only BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{StandardBridgeAuditPacket}^{\uparrow}}$ *replay and provenance surface. There is no certified scope coordinate for a hidden encoder, an unpaired host theorem export, a host primitive imported as BEDC input, a private compiler route, or a bridge assertion detached from the no-host-leak row P.*

Proof. Begin with the carrier of Definition 1217.1. Its displayed coordinates name the accepted object row N, the host-relative bridge rows T, E, D, R, U, P, L, and the structural replay rows H, C, Q; no additional primitive row is present.

Apply Definition 1217.2 and Definition 1217.7. Any certified consumer that reads bridge maps, round trips, or theorem preservation must factor through P, so host primitives, host proof objects, quotient principles, semantic equalities, and host compiler readings cannot enter the public BEDC surface through an implicit side channel.

Next use Definition 1217.5. The two exactness directions are public only as reads through R, H, C, Q, so a hidden encoder, hidden decoder, host equality import, or detached bridge assertion has no accepted witness in the carrier.

Finally use Definition 1217.6. Theorem export is finite and paired through U, L, P, which rules out an unpaired host theorem and any bridge claim whose support is refused by the ledger or by the no-host-leak row. Hence every certified bridge-audit consumer has exactly the primitive boundary displayed by $N, T, E, D, R, U, P, L, H, C, Q$. □

Theorem 1217.9 (Standard bridge audit packet public bridge-audit export)**.** *For every accepted* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *carrier*

$$S = (N, T, E, D, R, U, P, L, H, C, Q),$$

any public standard-bridge audit export exposes exactly the accepted object row N, host-theory row T, encoding row E, decoding row D, paired round-trip row R, theorem-preservation ledger U, no-host-leak row P, bridge ledger L, componentwise hsame *transport H, displayed* Cont *replay C, and local* $\mathsf{NameCert}_{\mathsf{StandardBridgeAuditPacket}^{\uparrow}}$ *provenance Q. It exports no host primitive, hidden decoder, unpaired theorem, quotient equality, or detached bridge assertion.*

Proof. Start from the carrier projection in Definition 1217.1. Its public rows are exactly $N, T, E, D, R, U, P, L, H, C$, with Q carrying the Pkg provenance and local $\mathsf{NameCert}_{\mathsf{StandardBridgeAuditPacket}^{\uparrow}}$ registration.

Use Definition 1217.2 together with Definition 1217.7. These force every public bridge read of E, D, R, or U through the no-host-leak row P, so no host primitive, quotient equality, proof object, or hidden compiler reading is exported as BEDC data.

Next apply Definition 1217.5. The decode-after-encode and encode-after-decode witnesses are public only as paired reads through R, H, C, Q, which excludes hidden decoders and detached bridge assertions.

Finally apply Definition 1217.6 and Definition 1217.8. The theorem-preservation surface is finite and paired through U, L, P, while the certified primitive boundary is precisely the displayed carrier boundary. Hence the public export exposes exactly the accepted bridge-audit rows and nothing outside them. □

Theorem 1217.10 (Standard bridge audit packet bridge-readback boundary)**.** *Let*

$$S = (N, T, E, D, R, U, P, L, H, C, Q)$$

be an accepted $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *carrier. If a bridge read bridgeRead is obtained by the displayed routes* Cont E D R, Cont R P *bridgeRead, and* Cont P L H, *then the public*

bridge boundary is the SemanticNameCert *surface whose carrier reads bridgeRead together with the displayed packet S, whose pattern is exactly the encode-decode route, the round-trip-to-public route, and the no-host-ledger route, and whose ledger preserves only bridgeRead, P, and Q. No host primitive, theorem object, quotient equality, hidden compiler read, or detached bridge assertion is available at that boundary.*

Proof. Start from the carrier definition in Definition 1217.1. The displayed packet fixes the rows $N, T, E, D, R, U, P, L, H, C, Q$, so a bridge-readback certificate has no coordinate beyond the accepted object, host theory, encoding, decoding, round-trip, theorem-preservation, no-host-leak, bridge ledger, transport, replay, and local naming rows.

Apply Definition 1217.9 and Definition 1217.5. The public export exposes the displayed packet, while exactness forces every decode-after-encode or encode-after-decode read through R, H, C, Q; the route Cont E D R is therefore the encode-decode component of the boundary.

Next use Definition 1217.6 together with Definition 1217.2. The theorem-preservation ledger is public only through U, L, P, and the no-host-leak row P is required before any bridge consumer reads E, D, R, or U. Thus Cont R P *bridgeRead* is the round-trip-to-public route and Cont P L H is the no-host-ledger route.

The Lean certificate '`BEDC.Derived.StandardBridgeAuditPacketUp.StandardBridgeAuditPacket_nonhost` realizes the same SemanticNameCert shape: the carrier records *bridgeRead* and the displayed packet, the pattern records precisely those three Cont routes, and the ledger records only *bridgeRead*, P, and Q. Hence the public bridge boundary is the stated readback surface and nothing host-side leaks across it. □

Falsifiable prediction: A purported bridge packet that omits the no-host-leak row is not an accepted StandardBridgeAuditPacketUp carrier.

Independence witness: kernelacceptancewitness, finitereflectiontuple, groundcompilerrecognizerflow, finitebhistinjection, prooftermerasuretrace: kernel acceptance records accepted declarations without host bridge fields, finite reflection records tuple image and readback without theorem-preservation pairs, GroundCompiler recognizer flow records generated-recognizer admission without a host bridge ledger, finite BHist injection records history embedding without no-host-leak, and proof-term erasure trace records erased proof visibility without encoding or decoding. None is bijective to StandardBridgeAuditPacket$^{\uparrow}$.

Closure status for NameCert$_{\text{StandardBridgeAuditPacket}^{\uparrow}}$.

Constructive story: A StandardBridgeAuditPacket$^{\uparrow}$ carrier is generated from the rows $N, T, E, D, R, U, P, L, H, C, Q$: accepted BEDC object, host-theory row, encoding, decoding, paired round trips, theorem preservation, no-host-leak ledger, bridge ledger, componentwise hsame transport, displayed Cont replay, and Pkg provenance with local NameCert registration.

Lean4 ✓ `BEDC.Derived.StandardBridgeAuditPacketUp.taste gate`

Theory closure: TheoryGate(NameCert$_{\text{StandardBridgeAuditPacket}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1217.9 and Definition 1217.10 close the public bridge-audit export and bridge-readback boundary for the displayed $N, T, E, D, R, U, P, L, H, C, Q$ rows.

Formal verification: FormalStatus(NameCert$_{\text{StandardBridgeAuditPacket}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.StandardBridgeAuditPacketUp.StandardBridgeAuditPacket\_nonhost\_leak\_certificate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close bridgeChecked verification, host primitive import, unpaired host theorem export, or any host theorem surface outside the displayed no-host-leak row.

Upgrade path: No further paper-side theory closure remains for this packet; object-specific bridge checking remains verification-axis work.

Chapter 1218

A Concrete Naming Certificate for $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$

The $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$ packet realizes the object-knowledge synthesis of section 9462.23 as finite BEDC NameCert data. It uses the five-field certificate discipline from Definition 9462.664, reads certificate transport through chapter 481, and reads classifier transport through chapter 590. The carrier therefore exposes an object as a licensed name and knowledge as an auditable witness before any consumer receives a mature object-knowledge export.

Definition 1218.1 (Object-knowledge certificate carrier)**.** *An* $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (N, W, S, P, K, T, L, A, C, Q)$$

with the following displayed rows:

1. *N is the object-name row, read as the licensed name of the object rather than as a bare object primitive.*
2. *W is the auditable witness row whose possession supports the knowledge claim.*
3. *S is the source row recording the histories, observations, declarations, or prior certificates from which the name and witness are admitted.*
4. *P is the pattern row naming the stable behavior, recurrence, or constructive presentation that the name claims to track.*
5. *K is the classifier row specifying when two presentations count as the same object-knowledge packet.*
6. *T is the stability row recording the displayed transport by which the name, witness, source, pattern, and classifier persist across accepted continuations.*
7. *L is the ledger row recording gaps, failed reads, refused exports, missing witness routes, and residual obligations.*
8. *A is the audit-route row exposing how a consumer checks the witness against the licensed object name.*
9. *C is the componentwise transport row over N, W, S, P, K, T, L, A and over the sibling* $\mathsf{NameCertMorphism}^{\uparrow}$ *and* $\mathsf{ClassifierMorphism}^{\uparrow}$ *routes.*

10. *Q is the local* $\mathsf{NameCert}_{\mathsf{ObjectKnowledgeCertificate}^{\uparrow}}$ *row, whose five-field certificate surface is source, pattern, classifier, stability, and ledger, tied to the object-name and witness rows.*

The carrier has no coordinate for an unlicensed object, a bare truth predicate, a witness-free knowledge claim, an anonymous classifier, a hidden ledger, or a local name detached from the displayed NameCert row.

Lean4 ✓ `BEDC.Derived.ObjectKnowledgeCertificateUp.ObjectKnowledgeCertificateTasteGate single carrier alignment`

Theorem 1218.2 (Object-knowledge NameCert obligations)**.** *For the carrier of Definition 1218.1, the local* $\mathsf{NameCert}_{\mathsf{ObjectKnowledgeCertificate}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$O = (N, W, S, P, K, T, L, A, C, Q),$$

object-name licensing through N, witness exposure through W, source exposure through S, pattern exposure through P, classifier exposure through K, stability exposure through T, ledger exposure through L, audit routing through A, componentwise transport through C, and local naming through Q.

Consequently every accepted object-knowledge export is a finite packet whose object read is licensed by N and whose knowledge read is witnessed by W under the five displayed NameCert fields.

Proof. Project the carrier of Definition 1218.1. Its rows are exactly $N, W, S, P, K, T, L, A, C, Q$, so no additional object primitive, witness predicate, classifier, stability route, ledger, audit path, or local name is available to the consumer.

Read the local NameCert row. The certificate fields are S, P, K, T, L, and the object-knowledge rows N, W, A identify which licensed object is being read, which witness supports the knowledge claim, and which audit route checks that witness.

Finally use the componentwise transport row C. It preserves the displayed name, witness, five-field certificate, sibling morphism routes, and local certificate row together. Therefore an accepted export is exactly the stated finite NameCert packet, not a projection with the witness or ledger suppressed. □

Lean4 ✓ `BEDC.Derived.ObjectKnowledgeCertificateUp.ObjectKnowledgeCertificateNameCert obligations`

Theorem 1218.3 (Object-knowledge witness exactness)**.** *Every accepted* $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$ *knowledge read exposes the same witness row W that the audit route A checks against the licensed object name N. Replacing W by the pattern row P, the classifier row K, the stability row T, or the ledger row L is not an accepted knowledge read.*

Proof. The carrier separates the witness row from the certificate fields. The row W records the auditable witness, while P, K, T, L record pattern, classifier, stability, and ledger data.

The audit route A is defined as a displayed check of the witness against the licensed object name. It therefore consumes N and W as rows of the same finite packet, with S, P, K, T, L supplying certificate context rather than replacing the witness.

The local NameCert row Q names the whole packet. Since C transports W componentwise with the other rows, a consumer that substitutes a certificate field for W changes the accepted packet and loses the knowledge read. □

Lean4 ✓ `BEDC.Derived.ObjectKnowledgeCertificateUp.ObjectKnowledgeCertificate witness audit rows reflect display`

Theorem 1218.4 (Object-knowledge nonescape)**.** *No accepted* $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$ *packet exports object knowledge outside the displayed rows*

$$N, W, S, P, K, T, L, A, C, Q.$$

In particular, the packet does not export an unlicensed object, a witness-free knowledge claim, a classifier-free identity, an unledgered residue, or a local name outside the local $\mathsf{NameCert}_{\mathsf{ObjectKnowledgeCertificate}^{\uparrow}}$ *row.*

Proof. Begin with the exact obligation surface of Definition 1218.2. It exhausts the public export by the object-name, witness, source, pattern, classifier, stability, ledger, audit-route, transport, and local-name rows.

Use Definition 1218.3 to keep the witness row from collapsing into the certificate fields. The knowledge component remains auditable only through W checked by A against N.

The sibling morphism routes preserve the displayed certificate and classifier data, but they do not add an inverse, a bare object, or a truth predicate. Hence every accepted read remains inside the finite row list, and the listed escapes are not exports of this carrier. □

Lean4 ✓ `BEDC.Derived.ObjectKnowledgeCertificateUp.ObjectKnowledgeCertificate nonescape`

Theorem 1218.5 (Object-knowledge public export)**.** *The carrier, NameCert obligations, witness exactness, and nonescape theorems jointly export exactly the public* $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$ *packet*

$$N, W, S, P, K, T, L, A, C, Q.$$

Every consumer receives object-name licensing through N, witness exposure through W, source, pattern, classifier, stability, and ledger rows through S, P, K, T, L, audit routing through A, componentwise transport through C, and local naming through Q, and receives no additional object, witness-free knowledge read, anonymous classifier, hidden ledger, or detached local name.

Lean4 ✓ `BEDC.Derived.ObjectKnowledgeCertificateUp.ObjectKnowledgeCertificate public export`

Proof. Use Definition 1218.1 to identify the public packet as the finite row family $N, W, S, P, K, T, L, A, C, Q$.

Apply Definition 1218.2. It makes those rows the full local NameCert surface, with source, pattern, classifier, stability, ledger, audit route, transport, and local naming all visible to the consumer.

Apply Definition 1218.3 and Definition 1218.4. The witness cannot be replaced by a certificate field, and no object-knowledge read escapes the displayed rows. Hence the exported public object-knowledge packet is exactly the stated row family. □

Theorem 1218.6 (Object-knowledge bridge obligation surface)**.** *Any standard bridge for* ObjectKnowledgeCertifica *must preserve the displayed rows*

$$N, W, S, P, K, T, L, A, C, Q.$$

In particular, it preserves object-name licensing through N, witness exposure through W, audit routing through A, ledger exposure through L, classifier transport through C, and the local $\mathsf{NameCert}_{\mathsf{ObjectKnowledgeCertificate}^{\uparrow}}$ *row Q. It must not collapse the packet to an unlicensed object, a witness-free knowledge predicate, or a detached truth classifier.*

Proof. Start from the carrier of Definition 1218.1. The displayed bridge domain is exactly the finite row family $N, W, S, P, K, T, L, A, C, Q$, so a bridge can preserve only those rows and cannot introduce an unlicensed object coordinate, anonymous truth predicate, or detached classifier.

Apply Definition 1218.2 and Definition 1218.3. These keep object-name licensing on N, witness exposure on W, audit checking on A, and the local certificate row on Q.

Finally use Definition 1218.4 together with Definition 1218.5. The public export is exhausted by the displayed rows, while nonescape rules out witness-free knowledge, unlicensed objects, hidden ledgers, and classifier-free identity. Hence every standard bridge obligation is over the stated surface. □

Lean4 ✓ `BEDC.Derived.ObjectKnowledgeCertificateUp.ObjectKnowledgeCertificate bridge obligation surface`

Falsifiable prediction: If an object-knowledge export bypasses either the displayed five-field NameCert row or the displayed witness row, the packet is refuted.

Independence witness: namecertmorphism, classifiermorphism, semanticnamecert, namecert: none is bijective because this carrier binds object license, auditable witness, five-field certificate, classifier transport, ledger, and local naming as one packet.

The Lean follow-up must provide Nontrivial ObjectKnowledgeCertificate$^{\uparrow}$ and FieldFaithful ObjectKnowledgeCertifi instances in lean4/BEDC/Derived/ObjectKnowledgeCertificateUp/TasteGate.lean. The target BEDC.Derived.ObjectK may be cited only after those instances distinguish the object-name, witness, source, pattern, classifier, stability, ledger, audit-route, componentwise transport, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ObjectKnowledgeCertificate}^{\uparrow}}$ **.**

Constructive story: An ObjectKnowledgeCertificate$^{\uparrow}$ packet is generated from object-name, witness, source, pattern, classifier, stability, ledger, audit-route, componentwise transport, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ObjectKnowledgeCertificate}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1218.1, Definition 1218.2, Definition 1218.3, Definition 1218.4, and Definition 1218.5 are the finite public scope for object-name licensing, witness exactness, audit routing, componentwise transport, local NameCert obligations, nonescape, and public packet export for object-knowledge packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ObjectKnowledgeCertificate}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close witness-free knowledge, unlicensed objects, classifier-free identity, unledgered residue, Lean verification, or bridge checking for ObjectKnowledgeCertificate$^{\uparrow}$.

Upgrade path: No further paper-theory closure upgrade is claimed; Lean bridge checking remains separate.

Chapter 1219

A Concrete Naming Certificate for $\mathsf{ProofTraceAuditWitness}^{\uparrow}$

The $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ packet realizes the proof-discipline surface of Definition 9462.2010 as a finite NameCert carrier. It sits beside the kernel audit witness of chapter 546, the compiler trace faithfulness packet of chapter 1055, the NameCert morphism route of chapter 481, the category certificate surface of chapter 61, and the proof-term erasure trace of chapter 642. Those siblings audit accepted declarations, compiler routes, certificate morphisms, categorical rows, and proof-object erasure; this packet binds proof trace, source carrier, classifier witness, displayed transport, forbidden-resource refusal, audit verdict, provenance, and local naming before a proof row may be read as BEDC-internal evidence.

Definition 1219.1 (Proof trace audit witness carrier)**.** *A* $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, S, K, H, L, F, A, P, N)$$

with the following displayed rows:

1. *T is the proof-trace row, recording the finite witness chain consumed by the proof site.*
2. *S is the source-carrier row, recording the BEDC carrier, source object, or theorem surface whose evidence is being audited.*
3. *K is the classifier-witness row, recording the classifier membership, stability, or exactness witness used by the proof trace.*
4. *H is the displayed-transport row, recording the* hsame *transport needed whenever the trace crosses a classifier, package, bridge, or history-identity surface.*
5. *L is the ledger-witness row, recording the* Cont *replay, package route, and local ledger entries consumed by the trace.*
6. *F is the forbidden-resource row, recording refusal of hidden choice, host equality as BEDC equality, quotient collapse, propositional extensional rewrite, global truth predicate, unledgered compression, and unscoped universal claim.*
7. *A is the audit-verdict row, recording whether the trace is accepted, refused, or held as a displayed obligation at the proof site.*
8. *P is the* Pkg *provenance over* $\mathsf{KernelAuditWitness}^{\uparrow}$, $\mathsf{CompilerTraceFaithfulness}^{\uparrow}$, $\mathsf{NameCertMorphism}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{ProofTermErasureTrace}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ProofTraceAuditWitness}^{\uparrow}}$ *row.*
The carrier contains no coordinate for an untraced proof, an implicit transport, an erased forbidden-resource refusal, a host equality proof, or an audit verdict detached from provenance and local naming.

Lean4 (definition) `BEDC.Derived.ProofTraceAuditWitnessUp.ProofTraceAuditWitnessUp`
Lean4 ✓ `BEDC.Derived.ProofTraceAuditWitnessUp.taste gate`

Theorem 1219.2 (Proof trace audit witness NameCert obligations)**.** *For the carrier of Definition 1219.1, the local* $\mathsf{NameCert}_{\mathsf{ProofTraceAuditWitness}^{\uparrow}}$ *surface consists exactly of six obligation rows: carrier admission for $W = (T, S, K, H, L, F, A, P, N)$; proof-trace and source-carrier exposure through T and S; classifier-witness stability through K; displayed transport and replay through H and L; forbidden-resource refusal and audit-verdict exactness through F and A; and provenance plus local naming through P and N.*

Lean4 ✓ `BEDC.Derived.ProofTraceAuditWitnessUp.ProofTraceAuditWitnessNameCertObligations`

Proof. Project the carrier of Definition 1219.1. The rows $T, S, K, H, L, F, A, P, N$ are the only available proof-audit coordinates, so a proof consumer first reads a finite trace, its source carrier, and the classifier witness that licenses the trace.

Next read the transport and ledger rows. The displayed transport row H prevents classifier crossing from being treated as host equality, while the ledger row L keeps replay, package route, and proof-site ledger entries visible in BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ form.

Finally attach the refusal and verdict rows. The forbidden-resource row F records which proof resources are unavailable, and the audit-verdict row A can be read only with that refusal row and the provenance and local name rows P, N. Repacking these rows gives the six local NameCert obligations and no additional proof coordinate. □

Theorem 1219.3 (Proof trace audit witness ledger non-escape)**.** *Every accepted* $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ *proof read factors through the displayed rows*

$$T, S, K, H, L, F, A, P, N.$$

In particular, deleting the displayed-transport row H, erasing the forbidden-resource row F, or detaching the audit-verdict row A from the provenance row P leaves no carrier route from the proof trace T to BEDC-internal proof evidence.

Proof. Begin with the NameCert obligations of Definition 1219.2. They require proof-trace exposure, source-carrier exposure, classifier-witness stability, displayed transport, ledger replay, forbidden-resource refusal, audit verdict, provenance, and local naming to be read as one packet.

If H is absent, the trace has no displayed way to cross a classifier, package, bridge, or history-identity surface. If F is absent, the proof site no longer records refusal of hidden choice, quotient collapse, host equality, or propositional extensional rewrite. If A is detached from P, the verdict is no longer tied to a finite proof-site provenance row.

Thus every accepted proof read remains inside the listed packet. A consumer that asks for proof evidence without one of these rows has left the $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ carrier rather than extracting a hidden proof resource from it. □

The Lean follow-up file `lean4/BEDC/Derived/ProofTraceAuditWitnessUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{ProofTraceAuditWitness}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ProofTraceAuditWitness}^{\uparrow}$ instances, preserving $T, S, K, H, L, F, A, P, N$ as separate displayed fields.

Falsifiable prediction: Deleting the displayed transport row while keeping the proof trace and verdict rows invalidates the audit witness carrier.

Independence witness: kernelauditwitness, groundcompilerauditwitness, namecertmorphism, category, prooftermerasuretrace: none is bijective because this packet uniquely binds a proof trace to displayed transport, forbidden-resource refusal, audit verdict, provenance, and local NameCert rows.

Theorem 1219.4 (Proof trace audit bridge route)**.** *Every bridge-facing proof-audit consumer of a* $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ *packet must preserve the scoped carrier of Definition 1219.1, the NameCert obligations of Definition 1219.2, the ledger nonescape boundary of Definition 1219.3, the TasteGate target, and the displayed sibling dependencies on KernelAuditWitness, CompilerTraceFaithfulness, NameCertMorphism, Category, and ProofTermErasureTrace rows. The route exports no untraced proof evidence, host equality rule, global proof search, kernel-soundness theorem, or proof-term-erasure correctness claim.*

Proof. Start with the scoped carrier. Its rows $T, S, K, H, L, F, A, P, N$ remain the only proof-audit coordinates available to a bridge-facing consumer.

Apply the NameCert obligations and ledger nonescape theorem. They force proof-trace exposure, source-carrier exposure, classifier-witness stability, displayed transport, ledger replay, forbidden-resource refusal, audit verdict, provenance, and local naming to be read as one finite packet.

Finally preserve the TasteGate target and displayed sibling dependencies. Since the bridge-facing route contains no coordinate for untraced proof evidence, host equality, global proof search, kernel soundness, or proof-term-erasure correctness, those objects cannot be exported by the paper bridge route. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProofTraceAuditWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ packet is generated from proof trace, source carrier, classifier witness, displayed transport, ledger witness, forbidden-resource refusal, audit verdict, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProofTraceAuditWitness}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1219.1, Definition 1219.2, Definition 1219.3, and Definition 1219.4 bind the carrier, NameCert obligations, ledger nonescape, TasteGate target, and displayed dependencies on KernelAuditWitness, CompilerTraceFaithfulness, NameCertMorphism, Category, ProofTermErasureTrace, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProofTraceAuditWitness}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ProofTraceAuditWitnessUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, global proof search, kernel soundness, proof-term erasure correctness, or a host equality proof rule.

Upgrade path: No further paper-theory upgrade is pending; bridge checking remains a separate formal-axis task preserving the scoped carrier, NameCert obligations, ledger nonescape, TasteGate target, and displayed sibling dependencies without adding untraced proof evidence.

Chapter 1220

A Concrete Naming Certificate for $\mathsf{RegistryLayer}^{\uparrow}$

The $\mathsf{RegistryLayer}^{\uparrow}$ packet realizes the registry layer of chapter 9462 as a finite NameCert surface for package-level export control. It sits beside the selector ledger of chapter 494, the focused finite ledger of chapter 1109, the choice-recipe ledger of chapter 677, the axiom-requirement ledger of chapter 992, the witnessed-descent ledger of chapter 1103, the cannot-claim registry of chapter 554, the claim registry layer of chapter 1209, and the export surface of chapter 1216. Those siblings record selected rows, focused histories, choice recipes, axiom requirements, descent witnesses, refusal entries, single-claim registration, or export gates; this carrier binds the whole registry layer through simultaneous admit, block, transport, and package-ledger rows.

Definition 1220.1 (Registry layer carrier)**.** *A* $\mathsf{RegistryLayer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (C, T, G, D, S, K, U, F, H, P, N)$$

with the following displayed rows:

1. *C is the concept-registry row, naming concepts allowed to be exported as package vocabulary;*
2. *T is the theorem-registry row, naming theorem, lemma, definition, closure-status, or formal-target sites available for export;*
3. *G is the gap-registry row, naming statements whose package reading is horizon-facing or not yet licensed for export;*
4. *D is the tradition-and-science registry row, separating inherited mathematical tradition, empirical-science claims, and BEDC-specific discovery claims;*
5. *S is the cannot-claim registry row, recording readings that the packet blocks from export;*
6. *K is the upgrade-registry row, recording the next certificate, bridge, audit, or formalization obligation needed before a blocked or horizon-facing row may move;*
7. *U is the formalization-target registry row, recording the Lean namespace, statement-only site, encoded definition, or explicit absence of a machine target;*
8. *F is the export-control row, recording whether the public claim is admitted by C, T, D, U or blocked by G, S, K;*
9. *H stores componentwise* hsame *transport for the registry rows and the export-control row;*

10. *P is the* Pkg *provenance over* $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{SelectorLedger}^{\uparrow}$, $\mathsf{FocusedMultiHistLedger}^{\uparrow}$, $\mathsf{ChoiceRecipeLedger}^{\uparrow}$, $\mathsf{AxiomRequirementLedger}^{\uparrow}$, $\mathsf{WitnessedDescentLedger}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegistryLayer}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a prose-only claim, host truth oracle, hidden theorem registry, private package override, or unledgered export path.

Theorem 1220.2 (Registry layer NameCert obligations)**.** *For the carrier of Definition 1220.1, the local* $\mathsf{NameCert}_{\mathsf{RegistryLayer}^{\uparrow}}$ *surface consists exactly of carrier admission for $R = (C, T, G, D, S, K, U, F, H, P, N)$, registry coverage by C, T, G, D, S, K, U, export-control classification by F, componentwise transport by H, package provenance by P, and local naming by N.*

Lean4 ✓ `BEDC.Derived.RegistryLayerUp.RegistryLayerTasteGate single carrier alignment`

Proof. Project the finite packet of Definition 1220.1. The seven registry rows C, T, G, D, S, K, U list the public places where a package-level claim can be admitted, held as a gap, blocked, assigned an obligation, or connected to a formalization target.

The export-control row F does not add a second registry. It reads the displayed rows and records whether the claim is admitted by one of the concept, theorem, tradition, science, or formal-target rows, or blocked by the gap, cannot-claim, or upgrade-obligation rows.

Finally, H, P, N transport, package, and name the same rows. Since the carrier has no further coordinate, every NameCert obligation is exhausted by the displayed packet. □

Theorem 1220.3 (Registry layer export-control exactness)**.** *Every exported package-level claim read through an accepted* $\mathsf{RegistryLayer}^{\uparrow}$ *packet is either admitted by one displayed registry row among C, T, D, U or blocked by one displayed registry row among G, S, K. No claim can be exported by prose placement, host truth, hidden theorem state, or a private package route outside $R = (C, T, G, D, S, K, U, F, H, P, N)$.*

Lean4 ✓ `BEDC.Derived.RegistryLayerUp.RegistryLayer export control exactness`

Proof. Use the obligations of Definition 1220.2. A public export is read through F, and F is part of the same finite carrier as the registry rows.

If F records admission, the admission must point to a displayed concept, theorem, tradition-and-science, or formalization-target row. If F records blocking, the block must point to a displayed gap, cannot-claim, or upgrade-obligation row.

The excluded routes are absent from the carrier. A prose sentence, host truth oracle, hidden theorem table, or private package route supplies no coordinate that H, P, N can transport, package, or name. Thus export control is exact for the displayed registry layer. □

Theorem 1220.4 (Registry layer claim nonescape)**.** *An accepted* $\mathsf{RegistryLayer}^{\uparrow}$ *packet permits no prose-only package claim. If a consumer cannot exhibit an admission row in C, T, D, U and cannot exhibit a blocking row in G, S, K, then the consumer has no* $\mathsf{RegistryLayer}^{\uparrow}$ *route for the claim; the claim remains outside the package export surface.*

Proof. Begin with Definition 1220.3. Every exported claim has a displayed admission row or a displayed blocking row.

Suppose a consumer exhibits neither. Then the classifier row F has no registry row from which to read admission and no registry row from which to read blockage. The transport row H

cannot create the missing row, and the package row P can only record provenance for rows already displayed in the carrier.

It follows that the local naming row N names no exported claim in this case. The attempted prose-only reading therefore fails to escape the registry layer. □

Theorem 1220.5 (Registry layer public export route)**.** *Every public export read of an accepted* $\mathsf{RegistryLayer}^{\uparrow}$ *packet is exhausted by the displayed registry route through* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg*, and the local* NameCert *row. The route may expose concept, theorem, tradition-and-science, formalization-target, gap, cannot-claim, upgrade-obligation, and export-control rows, but it exports no hidden verification claim, private package override, host truth oracle, unledgered registry entry, or external standard-model assertion.*

Proof. Start with the export-control exactness theorem, Definition 1220.3. It says that every exported package-level claim is admitted by a displayed registry row among C, T, D, U or blocked by a displayed registry row among G, S, K.

Read the public route through the structural rows. The carrier stores those registry rows as finite BHist data, transports them componentwise by H, replays the displayed export decision through Cont, records package provenance by P, and names the same packet locally by N.

Apply claim nonescape, Definition 1220.4. Since a prose-only claim without admission or blocking rows has no route through the packet, the public export surface cannot add hidden verification, private package override, host truth, unledgered registry entry, or an external standard-model assertion. □

The obligation boundary is anchored by the TasteGate carrier in `lean4/BEDC/Derived/RegistryLayerUp/Tast` preserving $C, T, G, D, S, K, U, F, H, P, N$ as separate displayed rows for BEDC.Derived.RegistryLayerUp.taste_gate.

Theorem 1220.6 (Registry layer bridge surface)**.** *Every accepted* $\mathsf{RegistryLayer}^{\uparrow}$ *public export route bridges exactly the displayed concept, theorem, gap, tradition-and-science, cannot-claim, upgrade, formalization-target, export-control, transport, provenance, and local* NameCert *rows to downstream registry consumers. The bridge exports no hidden verification claim, private package override, host truth oracle, unledgered registry entry, or undisplayed standard-model assertion.*

Proof. Start with the public export route of Definition 1220.5. It exhausts every downstream read through the displayed registry rows, BHist, componentwise hsame, displayed Cont, Pkg, and the local NameCert row.

Use export-control exactness from Definition 1220.3. The row F can admit a claim only through the concept, theorem, tradition-and-science, or formalization-target rows, and can block a claim only through the gap, cannot-claim, or upgrade rows.

Apply claim nonescape from Definition 1220.4. A consumer with no displayed admission row and no displayed blocking row has no route through the packet, so there is no private package override or hidden verification surface.

The TasteGate marker BEDC.Derived.RegistryLayerUp.taste_gate remains visible at the boundary. Since the carrier has no further coordinate, the bridge surface is exactly the displayed public registry route. □

Falsifiable prediction: If the cannot-claim row is removed, the packet cannot distinguish blocked export from unregistered absence; if the theorem-registry row is removed, theorem export cannot be audited.

Independence witness: selectorledger, focused-multi-hist-ledger, choicerecipeledger, axiomrequirementledger, witnesseddescentledger: none is bijective because RegistryLayer carries simultaneous admit/block/export rows, while those siblings carry selector, focused-record, recipe, axiom-requirement, or descent rows only.

Closure status for $\mathsf{NameCert}_{\mathsf{RegistryLayer}^{\uparrow}}$.

Constructive story: A $\mathsf{RegistryLayer}^{\uparrow}$ packet is generated from concept, theorem, gap, tradition-and-science, cannot-claim, upgrade, formalization-target, export-control, componentwise hsame transport, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegistryLayer}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1220.1, Definition 1220.2, Definition 1220.3, Definition 1220.4, Definition 1220.5, and Definition 1220.6 bind the public bridge route through the carrier, NameCert obligations, export-control exactness, claim nonescape, TasteGate marker

Lean4 ✓ `BEDC.Derived.RegistryLayerUp.taste gate`

, BHist, componentwise hsame, displayed Cont, Pkg, and local NameCert rows for $C, T, G, D, S, K, U, F, H, P, N$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegistryLayer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, complete registry governance, or correctness of every downstream registry entry.

Upgrade path: No further theory-axis upgrade remains for the displayed registry layer; verification and bridge checking remain separate formal-axis obligations.

Chapter 1221

A Concrete Naming Certificate for $\mathsf{MachineInterfaceBoundary}^{\uparrow}$

The $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ packet realizes the registry and machine-facing interface of section 9462.35 as one finite NameCert boundary. It sits beside the registry export surface of chapter 1216, the formalization socket of chapter 1059, the kernel audit witness of chapter 546, and the apophatic naming boundary of chapter 543. Those packets separately expose export control, target routing, audit readback, and refusal discipline; this carrier binds them before a machine-facing route can read a registry claim.

Definition 1221.1 (Machine-interface boundary carrier)**.** *A* $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, E, F, A, S, H, C, P, N)$$

with the following visible rows:

1. *R is the registry-row ledger, recording the claim entry, its registry position, and its cannot-claim boundary when present;*
2. *E is the export-decision row, recording the allowed machine-facing export route for a registry row;*
3. *F is the refused-claim row, recording registry entries that may be cited only as refusals or blocked claims;*
4. *A is the formalization-target row, recording the Lean-side or audit-side target to which an accepted export may be routed;*
5. *S is the socket row, recording the machine-interface socket through which the target is exposed;*
6. *H stores componentwise* hsame *transport for registry, export, refusal, formalization-target, socket, continuation, provenance, and local naming rows;*
7. *C stores displayed* Cont *replay for registry lookup, export inspection, refusal readback, formalization-target routing, socket exposure, and audit replay;*
8. *P is the* Pkg *provenance over* $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineInterfaceSocket}^{\uparrow}$, $\mathsf{KernelAuditWitness}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MachineInterfaceBoundary}^{\uparrow}}$ *row binding the machine-facing boundary to the displayed packet.*

The carrier contains no coordinate for a host-side certificate, unchecked machine claim, hidden registry override, or export route that bypasses a refused registry row.

Lean4 (definition) `BEDC.Derived.MachineInterfaceBoundaryUp.MachineInterfaceBoundaryUp`

Theorem 1221.2 (Machine-interface boundary obligation surface)**.** *For the carrier of Definition 1221.1, the local* $\mathsf{NameCert}_{\mathsf{MachineInterfaceBoundary}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for* $M = (R, E, F, A, S, H, C, P, N)$*;*
2. *registry-export coverage through* R *and* E*;*
3. *refusal exactness through* F*, requiring every blocked or refused registry row to remain visible as refused content;*
4. *formalization-target and socket routing through* A *and* S*;*
5. *audit readback, transport, replay, provenance, and local naming through* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.MachineInterfaceBoundaryUp.MachineInterfaceBoundary obligation surface`

Proof. Project the displayed packet of Definition 1221.1. The rows R, E, F, A, S already separate registry entry, export decision, refused claim, formalization target, and socket exposure.

Use the registry-export surface of chapter 1216 for the R, E, F side of the packet. It keeps exported rows and refused rows distinct before any machine target can inspect them.

Use the machine-interface socket and kernel audit witness surfaces, chapter 1059 and chapter 546, for the A, S, H, C, P, N side. The target is routed through a displayed socket and the audit readback is replayed through the same continuation and provenance rows.

Finally apply the apophatic naming boundary of chapter 543. It prevents a refused request from becoming supplied content, so the five obligation rows exhaust the local $\mathsf{NameCert}_{\mathsf{MachineInterfaceBoundary}^{\uparrow}}$ surface. □

Theorem 1221.3 (Machine-interface boundary export control)**.** *Let*

$$M = (R, E, F, A, S, H, C, P, N)$$

be an accepted $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ *carrier. Every machine-facing export route factors through the export decision row* E*, refused-claim row* F*, formalization-target row* A*, socket row* S*, transport row* H*, continuation row* C*, provenance row* P*, and local naming row* N *after reading the registry row* R*. The route cannot export a refused registry row as a checked machine claim, and it cannot replace the local NameCert row by host-side certification.*

Proof. Read the registry entry first through R. The export decision is then the displayed row E, while every refused or blocked registry claim is kept in F.

Route accepted machine exposure through A and S. These rows determine the formalization target and the machine-interface socket before any audit readback is available to a consumer.

Transport and replay use only H and C, with provenance and local naming supplied by P and N. Since no coordinate of M stores host-side certification or an unchecked machine claim, an export route that tries to bypass F, A, S, H, C, P, N exits the carrier instead of exporting a BEDC machine-facing claim. □

Lean4 ✓ `BEDC.Derived.MachineInterfaceBoundaryUp.MachineInterfaceBoundary export control`

Theorem 1221.4 (Machine-interface boundary TasteGate handoff)**.** *Later Lean work for* MachineInterfaceBoundary *must provide* Nontrivial MachineInterfaceBoundary$^{\uparrow}$ *and* FieldFaithful MachineInterfaceBoundary$^{\uparrow}$ *instances in* lean4/BEDC/Derived/MachineInterfaceBoundaryUp/TasteGate.lean*. The nontriviality witness must expose at least one accepted registry-export or refusal-routing packet, and the field-faithfulness witness must preserve the distinct rows* $R, E, F, A, S, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.MachineInterfaceBoundaryUp.MachineInterfaceBoundary tastegate handoff`

Proof. The carrier is not a terminal tag: it distinguishes registry rows, export decisions, refused claims, formalization targets, socket exposure, transport, replay, provenance, and local naming.

Nontriviality therefore has to exhibit an accepted packet whose machine-facing boundary is readable through those rows. Field faithfulness has to prevent E from replacing F, A from replacing S, or N from being replaced by host-side certification.

Thus the named Lean file is the correct follow-up site for the same displayed carrier, with the TasteGate obligations aligned to the rows bound by Definition 1221.2. □

Falsifiable prediction: Any accepted MachineInterfaceBoundaryUp route that exports a refused registry row as a checked machine claim refutes the carrier.

Independence witness: registryexportsurface, machineinterfacesocket, kernelauditwitness, apophaticname: none is bijective because MachineInterfaceBoundaryUp simultaneously carries registry export rows, refused rows, formalization-target routing, socket exposure, audit readback, transport, continuation, provenance, and local NameCert.

Theorem 1221.5 (Machine-interface boundary paper bridge)**.** *Every accepted* MachineInterfaceBoundary$^{\uparrow}$ *packet realizes the paper-side bridge from machine-interface registry rows to the abstract machine-boundary schema by the displayed rows*

$$R, E, F, A, S, H, C, P, N.$$

The registry row R*, export row* E*, refused-row ledger* F*, formalization-target row* A*, and socket row* S *supply the schema fields for registry admission, export control, refusal retention, target routing, and machine-facing exposure. The audit rows* H, C, P, N *supply transport, replay, provenance, and local naming. Thus a registry/export/socket/audit read reaches the abstract boundary only through the same finite packet, and no route bypasses refused rows, host-side certification, unchecked machine claims, or hidden registry overrides.*

Proof. Read the carrier of Definition 1221.1. The rows R, E, F, A, S already separate the public registry entry, export decision, refused content, formalization target, and socket exposure.

The structural rows H, C, P, N make that separation stable under transport, replay, provenance, and local naming. Combining these rows gives exactly the abstract machine-boundary schema: registry admission is supplied by R, export control by E, F, target and socket routing by A, S, and audit accountability by H, C, P, N.

Because the carrier has no coordinate for host-side certification, unchecked claims, hidden overrides, or routes that bypass F, every bridge read remains inside the displayed packet. □

Lean4 ✓ `BEDC.Derived.MachineInterfaceBoundaryUp.MachineInterfaceBoundary paper bridge certificate`

Closure status for NameCert$_{\text{MachineInterfaceBoundary}^{\uparrow}}$**.**

Constructive story: A MachineInterfaceBoundary$^{\uparrow}$ packet is generated from registry-row, export-decision, refused-claim, formalization-target, socket, componentwise transport, continuation, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{MachineInterfaceBoundary}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1221.1, Definition 1221.2, Definition 1221.3, Definition 1221.4, and Definition 1221.5 bind the public export-control, refused-row, formalization-target, socket, audit, nontriviality, field-faithfulness, and paper-side bridge rows over the BHist packet $R, E, F, A, S, H, C, P, N$.

Formal verification: FormalStatus(NameCert$_{\mathsf{MachineInterfaceBoundary}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close host-side certification, unchecked machine claims, hidden registry overrides, Lean verification, checked standard-bridge evidence, or export routes that bypass refused registry rows.

Upgrade path: The paper-side mature treatment is complete; remaining work is Lean verification and checked standard-bridge evidence for the same public export-control, refusal, socket, audit, nontriviality, field-faithfulness, and paper-side bridge rows.

Chapter 1222

A Concrete Naming Certificate for $\mathsf{WritingItemAuditPacket}^{\uparrow}$

The $\mathsf{WritingItemAuditPacket}^{\uparrow}$ carrier realizes the writing-item discipline of subsection 9462.30.1 inside the auditable-generativity programme of chapter 9462. It sits beside the closure-status discipline of subsection 9462.30.3, the registry layer of chapter 1220, the object-knowledge certificate of chapter 1218, the registry-consistency audit of chapter 1223, and the machine-readable audit interface of chapter 1232. Those siblings bind chapter scope, registry admission, object-witness evidence, consistency checking, and machine-facing report reads; this packet names the finite writing item before a consumer may read prose as an auditable BEDC claim.

Definition 1222.1 (Writing-item audit packet carrier)**.** *A* $\mathsf{WritingItemAuditPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (K, C, R, L, T, F, G, Q, H, A, P, N)$$

with the following displayed rows:

1. *K is the kind row, recording whether the item is a definition, theorem, corollary, proof, reading, schema, roadmap, or refusal;*
2. *C is the carrier row, recording the BEDC object, packet, registry entry, or refusal surface on which the item lives;*
3. *R is the classifier row, recording the displayed identity, equivalence, or classification relation by which the item is compared;*
4. *L is the ledger row, recording hidden material, package provenance, consumed certificates, and refusal handoffs visible to the item;*
5. *T is the theory-closure row, recording the paper-side closure grade and exact scope licensed by the item;*
6. *F is the formal-status row, recording the Lean-side or audit-side status for the relevant declaration, target, encoded carrier, or explicit absence;*
7. *G is the gap-report row, recording open gaps, refused gaps, closed gaps, and cannot-claim boundaries attached to the item;*
8. *Q is the permitted-claim row, recording the strongest sentence the item authorizes a reader to believe;*

9. *H records componentwise* hsame *transport for kind, carrier, classifier, ledger, theory closure, formal status, gap report, and permitted claim text;*
10. *A records displayed* Cont *replay from item admission through classifier readback, ledger inspection, status readback, gap exposure, and claim publication;*
11. *P is the* Pkg *provenance over* $\mathsf{WritingItemAuditPacket}^{\uparrow}$, $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$, $\mathsf{RegistryConsistencyAudit}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{WritingItemAuditPacket}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a prose override, unledgered carrier, hidden classifier, status-free claim, gap-erasing read, or claim text stronger than Q.

Theorem 1222.2 (Writing-item audit packet NameCert obligations)**.** *For the carrier of Definition 1222.1, the local* $\mathsf{NameCert}_{\mathsf{WritingItemAuditPacket}^{\uparrow}}$ *surface consists exactly of eight obligation groups:*

1. *carrier admission for $W = (K, C, R, L, T, F, G, Q, H, A, P, N)$;*
2. *kind and carrier readback through K and C;*
3. *classifier exactness through R;*
4. *ledger coverage through L;*
5. *theory-closure and formal-status readback through T and F;*
6. *gap-report exposure through G;*
7. *permitted-claim readback through Q;*
8. *componentwise transport, replay, package provenance, and local naming through H, A, P, N.*

Thus a legal writing item is a finite NameCert surface over kind, carrier, classifier, ledger, closure status, formal status, gap report, and permitted claim text, not a bare prose assertion.

Lean4 ✓ `BEDC.Derived.WritingItemAuditPacketUp.WritingItemAuditPacketTasteGate single carrier alignment`
Lean4 ✓ `BEDC.Derived.WritingItemAuditPacketUp.WritingItemAuditPacketNameCert obligations`

Proof. Project the displayed packet $W = (K, C, R, L, T, F, G, Q, H, A, P, N)$. The first seven visible rows supply the writing discipline named in Definition 9462.1984: kind, carrier, classifier, ledger, theory-closure status, formal-verification status, gap report, and claim text.

Read the carrier-facing obligations next. The rows K, C, R, L decide what kind of item is being read, where it lives, how it is compared, and which hidden material or refusal handoffs have been ledgered.

The status and boundary obligations are separate. The rows T, F, G, Q expose the paper closure grade, formal status, gap report, and permitted claim text before a consumer may use the item. The transport, replay, provenance, and local naming rows H, A, P, N preserve exactly that finite inventory, so the eight groups exhaust the local $\mathsf{NameCert}_{\mathsf{WritingItemAuditPacket}^{\uparrow}}$ surface. □

Theorem 1222.3 (Writing-item audit packet closure bound)**.** *No accepted* $\mathsf{WritingItemAuditPacket}^{\uparrow}$ *packet authorizes a consumer claim stronger than the conjunction of its displayed theory-closure row T, formal-status row F, gap-report row G, and permitted-claim row Q.*

Proof. Begin with an accepted packet $W = (K, C, R, L, T, F, G, Q, H, A, P, N)$. The rows T and F report the two independent axes described by Definition 9462.1992, while G records the visible gap or refusal boundary.

Inspect Q. By Definition 1222.1, Q is the strongest sentence the item authorizes a reader to believe, and the carrier has no coordinate for a stronger prose override.

Finally use H, A, P, N. These rows transport, replay, package, and name the same displayed packet; they do not introduce an additional status grade or a second permitted-claim coordinate. Therefore any stronger consumer claim exits the accepted carrier. □

Theorem 1222.4 (Writing-item audit packet gap exposure)**.** *If the gap-report row G of an accepted* $\mathsf{WritingItemAuditPacket}^{\uparrow}$ *packet records an open gap, refused gap, or cannot-claim boundary, every permitted consumer read of the packet exposes that row before publishing the permitted claim text Q.*

Proof. Use Definition 1222.2. Gap-report exposure is one of the eight local NameCert obligation groups, so a consumer read cannot reach the local name while ignoring G.

The replay row A orders the public read through item admission, classifier readback, ledger inspection, status readback, gap exposure, and claim publication. Thus Q is not a free-standing prose sentence; it is read after the displayed gap report.

If a consumer omits the open-gap, refused-gap, or cannot-claim content of G, the read no longer follows the displayed replay row and no longer preserves the local NameCert surface. Such a read is not a permitted consumer read of the packet. □

Theorem 1222.5 (Writing-item audit packet scoped claim route)**.** *Every permitted consumer read of an accepted* $\mathsf{WritingItemAuditPacket}^{\uparrow}$ *packet $W = (K, C, R, L, T, F, G, Q, H, A, P, N)$ factors through the displayed theory-closure row T, formal-status row F, gap-report row G, permitted-claim row Q, and componentwise transport, replay, provenance, and local naming rows H, A, P, N before publishing the claim. The route keeps the paper-side closure axis and the machine-facing verification axis independent: it does not read T as Lean verification, does not read F as paper closure, and does not erase the exposed gap row G when presenting Q.*

Proof. Start with the NameCert obligations of Definition 1222.2. They require theory-closure readback through T, formal-status readback through F, gap exposure through G, permitted-claim readback through Q, and structural preservation through H, A, P, N.

Apply the closure-bound theorem Definition 1222.3. It prevents a consumer from strengthening the claim beyond the conjunction of the displayed closure, formal-status, gap, and permitted-claim rows.

Apply the gap-exposure theorem Definition 1222.4. A consumer cannot reach the permitted claim text while suppressing an open gap, refused gap, or cannot-claim boundary carried by G.

Finally use the independence of the two status axes from Definition 9462.1992. The row T reports paper closure scope and the row F reports machine-facing status; neither row can discharge the other. The structural rows H, A, P, N replay exactly that separated packet, so the published claim remains scoped by both axes and by the exposed gap row. □

Theorem 1222.6 (Writing-item audit packet mature consumer)**.** *Every downstream consumer of a bridged* $\mathsf{WritingItemAuditPacket}^{\uparrow}$ *packet must preserve the permitted-claim row Q, closure-bound row T, formal-status row F, exposed-gap row G, componentwise transport row H, replay row A, provenance row P, and local* $\mathsf{NameCert}_{\mathsf{WritingItemAuditPacket}^{\uparrow}}$ *row N before exporting the audit packet as a consumer-facing writing item.*

Proof. Start with the scoped-claim route of Definition 1222.5. It already forces every permitted consumer read through T, F, G, Q, H, A, P, N before the claim is published.

Now impose the downstream export boundary. A consumer that exports the packet as a writing item has to present the same permitted claim text, the same closure and formal-status rows, and the same exposed gap row, because Definition 1222.3 forbids any stronger claim and Definition 1222.4 forbids hiding G.

The structural rows are equally load-bearing. The transport row H, replay row A, provenance row P, and local naming row N are the only route by which the packet remains the displayed $\mathsf{WritingItemAuditPacket}^{\uparrow}$ carrier. Dropping any of them exports a different object rather than the bridged audit packet. □

Falsifiable prediction: A consumer whose claim text exceeds its displayed closure-status row refutes the $\mathsf{WritingItemAuditPacket}^{\uparrow}$ packet.

Independence witness: registrylayer, objectknowledgecertificate, registryconsistencyaudit, machinereadableauditinterface: none is bijective to $\mathsf{WritingItemAuditPacket}^{\uparrow}$ because the registry layer lacks per-item permitted claim text, the object-knowledge certificate lacks the writing-kind and formal-status rows, the registry-consistency audit lacks the item-kind and permitted-claim rows, and the machine-readable audit interface lacks the carrier-classifier-ledger writing discipline as one finite NameCert surface.

The Lean follow-up must provide explicit Nontrivial $\mathsf{WritingItemAuditPacket}^{\uparrow}$ and FieldFaithful WritingItemAuditP instances in `lean4/BEDC/Derived/WritingItemAuditPacketUp/TasteGate.lean`. The field-faithfulness witness must preserve $K, C, R, L, T, F, G, Q, H, A, P, N$ as distinct rows before BEDC.Derived.WritingItemAuditPacke can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{WritingItemAuditPacket}^{\uparrow}}$.

Constructive story: The writing-item audit packet is generated from $BHist$ rows that name a writing kind, permitted claim text, closure-status row, formal-status row, gap row, and the classifier-ledger discipline that binds them. The carrier first reads the item from the ledger, then attaches the audit packet, and finally permits Cont extensions only when the same closure, formal-status, and gap rows remain visible. The $hsame$ relation makes the packet stable under changes of representative history. The NameCert obligations, closure-bound theorem, gap-exposure theorem, prediction, and independence witness define a local audit mechanism: a writing item is admissible only when its permitted text and exposed bounds are carried by the packet.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WritingItemAuditPacket}^{\uparrow}}$, maturePackageClosed)

Scope closed: The scope is exactly the BHist rows $K, C, R, L, T, F, G, Q, H, A, P, N$, hsame transport, Cont replay, Pkg provenance, local NameCert naming, and the carrier, obligation, closure-bound, gap-exposure, scoped-claim route, and mature consumer surfaces of Definition 1222.1, Definition 1222.2, Definition 1222.3, Definition 1222.4, Definition 1222.5, and Definition 1222.6, with the mature consumer route serving as the downstream audit-packet handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WritingItemAuditPacket}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim full document closure, correctness of unaudited writing items, or hidden gap discharge outside the packet rows.

Upgrade path: Verification upgrade requires Lean encoding of the mature consumer route while preserving the permitted claim, closure-bound, formal-status, exposed-gap, transport, replay, provenance, and local NameCert rows.

Chapter 1223

A Concrete Naming Certificate for RegistryConsistencyAudit$^{\uparrow}$

The RegistryConsistencyAudit$^{\uparrow}$ packet realizes the registry-consistency requirement of subsection 9462.35.4 as a finite audit carrier for export-facing registry rows. It sits beside the export packet of chapter 1216, the machine boundary of chapter 1221, the claim-entry layer of chapter 1209, the cannot-claim registry of chapter 554, and the proof-trace audit packet of chapter 1219. Those siblings expose claim rows, machine-facing routes, registry admission, refusal boundaries, and proof-readback evidence; this carrier checks that all such exported readings agree before a package-level registry audit is accepted.

Definition 1223.1 (Registry-consistency audit carrier)**.** *A* RegistryConsistencyAudit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, S, D, G, X, F, T, L, Q, P, N)$$

with the following displayed rows:

1. *R is the registry-row ledger, naming the primary entry and every related entry whose export reading is being audited;*
2. *S is the status-agreement row, comparing concept status, theorem status, science-roadmap status, closure status, and formal status for the same claim;*
3. *D is the dependency-strength row, recording whether each dependency is definitional, theorem-level, statement-only, encoded, or external to the carrier;*
4. *G is the gap-status row, recording open gaps, refused gaps, and closed gaps visible to the audit;*
5. *X is the cannot-claim row, importing the relevant refusal boundary from* AxisZeckendorfCannotClaim$^{\uparrow}$ *or an adjacent cannot-claim packet;*
6. *F is the closure/formal-status row, comparing the manuscript closure block with the machine-readable formal-status target for the same entry;*
7. *T is the transport row, storing componentwise* hsame *stability for registry, status, dependency, gap, refusal, closure/formal-status, replay, provenance, and local naming rows;*
8. *L is the displayed* Cont *replay row through which an audit consumer reads R, S, D, G, X, F, T;*
9. *Q is the proof-trace row, recording the proof-readback or explicit absence read from* ProofTraceAuditWitness$^{\uparrow}$ *when the audited entry cites proof evidence;*

10. *P is the* Pkg *provenance over* $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineInterfaceBoundary}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{ProofTraceAuditWitness}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegistryConsistencyAudit}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a hidden registry override, prose-only status repair, machine target outside F, proof read outside Q, or cannot-claim bypass outside X.

Lean4 (definition) `BEDC.Derived.RegistryConsistencyAuditUp.RegistryConsistencyAuditUp`
Lean4 ✓ `BEDC.Derived.RegistryConsistencyAuditUp.RegistryConsistencyAuditTasteGate single carrier alignment`

Theorem 1223.2 (Registry-consistency audit route)**.** *Every accepted* $\mathsf{RegistryConsistencyAudit}^{\uparrow}$ *packet routes an exported claim through the same registry entry, status agreement, dependency-strength, gap-status, cannot-claim, closure/formal-status, proof-trace, transport, replay, provenance, and local naming rows displayed in Definition 1223.1. If any related registry entry disagrees with the primary entry on status, dependency strength, gap status, cannot-claim boundary, closure status, or formal target, the packet is not accepted as a consistency audit for that exported claim.*

Proof. Project the displayed packet $A = (R, S, D, G, X, F, T, L, Q, P, N)$. The primary registry location and all related entries are read first through R, so an audit consumer cannot substitute a private registry row.

Read the agreement rows next. Status agreement is displayed in S, dependency strength in D, gap status in G, cannot-claim boundaries in X, and closure/formal-status comparison in F. A disagreement in any of these rows leaves the corresponding consistency clause without a displayed witness.

The proof-trace row Q and the routing rows T, L, P, N only transport, replay, package, and name the same finite audit packet. Since no remaining coordinate repairs a failed agreement row, an inconsistent registry reading exits the carrier rather than producing an accepted audit. □

Theorem 1223.3 (Registry-consistency audit NameCert obligations)**.** *For the carrier of Definition 1223.1, the local* $\mathsf{NameCert}_{\mathsf{RegistryConsistencyAudit}^{\uparrow}}$ *surface consists exactly of eight obligation groups:*

1. *carrier admission for $A = (R, S, D, G, X, F, T, L, Q, P, N)$;*
2. *registry-row coverage through R;*
3. *status-agreement and dependency-strength exactness through S and D;*
4. *gap-status and cannot-claim boundary agreement through G and X;*
5. *closure/formal-status agreement through F;*
6. *proof-trace readback or explicit proof absence through Q;*
7. *componentwise transport and replay through T and L;*
8. *package provenance and local naming through P and N.*

Thus the certificate audits registry coherence by finite rows and does not turn prose governance, hidden proof objects, or host registry state into additional certificate inputs.

Proof. Carrier admission is tuple projection from Definition 1223.1. The registry surface is exhausted by R, and every agreement clause named by Definition 9462.2261 is assigned to one of S, D, G, X, F.

The proof-trace row is separate. It allows a proof-bearing entry to cite the proof-readback packet while allowing an explicitly absent proof read to remain absent; neither case changes the registry, status, dependency, gap, refusal, or closure/formal-status rows.

Finally inspect T, L, P, N. These rows supply componentwise stability, replay, provenance, and local naming for the same displayed packet. They do not add another agreement clause, so the eight groups exhaust the local $\mathsf{NameCert}_{\mathsf{RegistryConsistencyAudit}^{\uparrow}}$ obligation surface. □

Falsifiable prediction: If two registry entries for the same exported claim disagree on status, dependency strength, gap status, cannot-claim boundary, closure status, or formal target, no accepted RegistryConsistencyAuditUp packet certifies that export as registry-consistent.

Independence witness: registryexportsurface, machineinterfaceboundary, claimregistrylayer, axiszeckendorfcannotclaim, prooftraceauditwitness: none carries the joint registry-row, status-agreement, dependency-strength, gap-status, cannot-claim, closure/formal-status, proof-trace, transport, replay, provenance, and local NameCert packet of $\mathsf{RegistryConsistencyAudit}^{\uparrow}$.

Theorem 1223.4 (Registry-consistency audit standard bridge)**.** *The exported* $\mathsf{RegistryConsistencyAudit}^{\uparrow}$ *packet bridges to the standard registry-audit reading by preserving exactly the registry row R, status row S, dependency row D, gap row G, cannot-claim row X, closure/formal-status row F, transport row T, replay row L, proof-trace row Q, provenance row P, and local naming row N. The bridge has no coordinate for a hidden registry override, prose-only status repair, machine target outside F, proof read outside Q, or cannot-claim bypass outside X.*

Proof. Project the carrier of Definition 1223.1. The standard registry-audit reading receives only the displayed rows $R, S, D, G, X, F, T, L, Q, P, N$.

Apply the route theorem Definition 1223.2. It forces every exported claim to pass through the same registry entry, status agreement, dependency strength, gap status, cannot-claim, closure/formal-status, proof-trace, transport, replay, provenance, and local naming rows before the audit is accepted.

Use the NameCert obligations of Definition 1223.3. Those obligations exhaust the local audit surface, so the standard reading cannot import a hidden registry override, prose-only repair, machine target outside F, proof read outside Q, or cannot-claim bypass outside X. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegistryConsistencyAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegistryConsistencyAudit}^{\uparrow}$ packet is generated from displayed registry, status, dependency, gap, cannot-claim, closure/formal-status, proof-trace, transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegistryConsistencyAudit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1223.1, Definition 1223.2, Definition 1223.3, Definition 1223.4, and the checked TasteGate marker at the carrier site bind the mature paper-axis registry-consistency audit packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegistryConsistencyAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close bridge checking, Lean verification, or any registry repair route for $\mathsf{RegistryConsistencyAudit}^{\uparrow}$.

Upgrade path: No further paper closure-axis upgrade remains; Lean verification and bridge checking remain separate obligations.

Chapter 1224

A Concrete Naming Certificate for $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$

The $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ packet realizes the registry-consistency side of section 9462.35 as a finite NameCert gate for machine-facing registry export. It sits beside the claim-entry layer of chapter 1209, the export surface of chapter 1216, and the formal target socket of chapter 1059. Those siblings admit claims, expose export rows, and route machine targets; this packet binds status-consistency, audit-route, and no-smuggling checks before any accepted registry packet exports a claim.

Definition 1224.1 (Registry export consistency gate carrier)**.** *A* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, B, S, F, A, U, H, C, P, N)$$

with the following visible rows:

1. *R is the registry-entry row, recording the primary registry location and the claim surface being exported;*
2. *B is the blocking row, recording the cannot-claim, refusal, or non-export row that must stop the export when the claim is barred;*
3. *S is the status-consistency row, recording agreement between registry entry, export grade, closure status, and formalization target;*
4. *F is the formal-target row, recording the Lean target, statement-only target, encoded definition, or explicit absence of a machine target for the same claim;*
5. *A is the audit-route row, recording the finite route by which the machine-facing review reads R, B, S, F;*
6. *U is the no-smuggling row, recording that hidden prose synthesis, host semantics, model output, and private registry state are not export sources;*
7. *H stores componentwise* hsame *transport for registry entry, blocking, status consistency, formal target, audit route, no-smuggling, replay, provenance, and local naming rows;*
8. *C stores displayed* Cont *replay for registry lookup, block inspection, status comparison, formal-target readback, audit traversal, and no-smuggling refusal;*

9. *P is the* Pkg *provenance over* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineInterfaceSocket}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{GroundCompilerRecognition}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegistryExportConsistencyGate}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an export grade that bypasses S, no private override of B, no machine target outside F, and no audit path outside A.

Lean4 (definition) `BEDC.Derived.RegistryExportConsistencyGateUp.RegistryExportConsistencyGateCarrier`

Definition 1224.2 (Registry export consistency gate classifier)**.** *The* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *classifier accepts exactly those packets of Definition 1224.1 in which the status-consistency row S compares the same claim across R, the export grade, the closure-status reading, and the formal-target row F, while the audit row A and no-smuggling row U remain visible to the same local* NameCert *row N.*

Lean4 (definition) `BEDC.Derived.RegistryExportConsistencyGateUp.RegistryExportConsistencyGateClassifierSpe`
Lean4 ✓ `BEDC.Derived.RegistryExportConsistencyGateUp.RegistryExportConsistencyGateClassifier`
`semantic name certificate`

Theorem 1224.3 (Registry export consistency gate NameCert obligations)**.** *For the carrier of Definition 1224.1, the local* $\mathsf{NameCert}_{\mathsf{RegistryExportConsistencyGate}^{\uparrow}}$ *surface consists exactly of six obligation rows:*

1. *carrier admission for $G = (R, B, S, F, A, U, H, C, P, N)$;*
2. *registry-entry and blocking coverage through R and B;*
3. *status-consistency exactness through S for registry entry, export grade, closure status, and formal target;*
4. *formal-target readback through F;*
5. *audit-route and no-smuggling accountability through A and U;*
6. *componentwise transport, continuation replay, provenance, and local naming through H, C, P, N.*

Lean4 ✓ `BEDC.Derived.RegistryExportConsistencyGateUp.taste gate`

Proof. Project the finite packet of Definition 1224.1. Rows R and B expose the registry entry and the blocking row before any export decision is read.

Next read S together with F. The classifier of Definition 1224.2 requires S to compare the registry entry, export grade, closure-status reading, and formal-target row for the same claim, so the status check cannot be supplied by a separate packet.

The audit and no-smuggling rows are then consumed by A and U. They record the permitted machine-facing route and the readings that remain forbidden at the export boundary.

Finally H, C, P, N transport, replay, package, and name these same rows. Since the carrier has no additional coordinate, the six obligation rows exhaust the local $\mathsf{NameCert}_{\mathsf{RegistryExportConsistencyGate}^{\uparrow}}$ surface. □

Theorem 1224.4 (Registry export consistency gate blocks status conflicts)**.** *If status consistency fails between a registry entry, its export grade, its closure-status reading, and its formalization target, then no accepted* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *packet exports the claim.*

Lean4 ✓ `BEDC.Derived.RegistryExportConsistencyGateUp.RegistryExportConsistencyGateNoConflictExport`

Proof. Assume an accepted packet

$$G = (R, B, S, F, A, U, H, C, P, N).$$

By Definition 1224.2, acceptance requires S to compare the registry entry in R, the export grade, the closure-status reading, and the formal-target row F for the same claim.

If those readings disagree, the required status-consistency row is absent. The blocking row B cannot be erased, and the audit row A has no accepted route from the inconsistent status data to an exported claim.

The no-smuggling row U rules out recovering the export from prose, host semantics, model output, or private registry state. Therefore the packet is not accepted as an exporting gate for the claim. □

Theorem 1224.5 (Registry export consistency gate sibling dependency)**.** *The* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineInterfaceSocket}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, *or* $\mathsf{GroundCompilerRecognition}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RegistryExportConsistencyGateUp.RegistryExportConsistencyGateSiblingDependency`

Proof. Compare the displayed rows. $\mathsf{ClaimRegistryLayer}^{\uparrow}$ supplies claim-entry export control, while $\mathsf{RegistryExportSurface}^{\uparrow}$ binds registration, blocking, status, machine target, audit, and non-smuggling rows for export.

$\mathsf{MachineInterfaceSocket}^{\uparrow}$ routes formalization targets, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ supplies cannot-claim refusal rows, and $\mathsf{GroundCompilerRecognition}^{\uparrow}$ supplies generated-recognition and accepted-export rows.

None of these siblings carries the joint status-consistency row S together with the audit-route row A, no-smuggling row U, formal-target row F, and the local $\mathsf{NameCert}_{\mathsf{RegistryExportConsistencyGate}^{\uparrow}}$ row N in one finite packet. A row-preserving bijection would have to preserve that combined consistency gate, so no such bijection exists. □

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{RegistryExportConsistencyGate}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{RegistryExp}$ instances in `lean4/BEDC/Derived/RegistryExportConsistencyGateUp/TasteGate.lean`. The field-faithfulness witness must preserve $R, B, S, F, A, U, H, C, P, N$ as distinct rows, and the eventual checked target is BEDC.Derived.RegistryExportConsistencyGateUp.RegistryExportConsistencyGateTasteGate_sing

Falsifiable prediction: If status consistency fails between registry entry, export grade, closure status, and formalization target, no accepted $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ packet exports the claim.

Independence witness: claimregistrylayer, registryexportsurface, machineinterfacesocket, axiszeckendorfcannotclaim, groundcompilerrecognition: none carries the joint status-consistency, audit-route, no-smuggling, formal-target, and local NameCert packet of $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{RegistryExportConsistencyGate}^{\uparrow}}$.

Constructive story: A $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ packet is generated from registry entry, blocking, status-consistency, formal-target, audit-route, no-smuggling, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegistryExportConsistencyGate}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1224.4 is the mature public export boundary, while `BEDC.Derived.RegistryExportConsistencyGateUp.taste` supplies the TasteGate route from registry-entry, status-consistency, audit-route, and no-smuggling rows to the public registry export schema.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegistryExportConsistencyGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This mature package treatment does not close Lean verification, checked bridge status, or exhaustive registry export consumer coverage.

Upgrade path: Further strengthening requires a checked bridge and downstream registry export consumer coverage for the same registry-entry, status-consistency, audit-route, no-smuggling, and local naming rows.

Chapter 1225

A Concrete Naming Certificate for MachineInterfaceFormalizationTarget$^{\uparrow}$

The MachineInterfaceFormalizationTarget$^{\uparrow}$ packet realizes the machine-facing target interface of subsection 9462.35.5 as a finite registry-facing NameCert record. It sits beside the socket router of chapter 1059, the export ledger of chapter 1216, the claim registry layer of chapter 1209, and the audit gate boundary of chapter 526. Those siblings route, export, index, or refuse machine-facing rows; this packet is the target object that a formalization queue can store before any theorem content is claimed.

Definition 1225.1 (Machine-interface formalization-target carrier)**.** *A* MachineInterfaceFormalizationTarget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (N_s, K, R, S, D, E, A, U, H, C, P, L)$$

with the following displayed rows:

1. *N_s is the target-name row, recording the machine-readable name supplied by the interface of Definition 9462.2264;*
2. *K is the intended namespace row in which the future Lean declaration is expected to live;*
3. *R is the registry row tying the target to the current claim registry surface;*
4. *S is the statement-skeleton row, containing the binder shape and public statement outline without proof content;*
5. *D is the dependency-list row, naming the finite prerequisites that the target may cite;*
6. *E is the expected-status row, distinguishing theorem, definition, structure-field, variant, or statement-only queue status as registry data;*
7. *A is the audit-gate row that must accept the socket kind and dependency status before export as theorem content;*
8. *U is the not-claimed row recording the theorem-content, host-supply, automation, or bridge obligations that this target does not assert;*
9. *H records componentwise* hsame *transport for N_s, K, R, S, D, E, A, U;*
10. *C records displayed* Cont *replay from the target name through namespace, registry, statement skeleton, dependencies, expected status, audit gate, and not-claimed rows;*

11. *P is the* Pkg *provenance over* MachineInterfaceSocket$^{\uparrow}$, RegistryExportSurface$^{\uparrow}$, ClaimRegistryLayer$^{\uparrow}$, AuditGateBoundary$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
12. *L is the local* NameCert$_{\text{MachineInterfaceFormalizationTarget}^{\uparrow}}$ *row.*

The carrier has no coordinate for a proof object, global namespace correctness, automatic dependency discharge, audit-gate bypass, theorem export after refusal, or host-valued truth of the statement skeleton.

Lean4 ✓ `BEDC.Derived.MachineInterfaceFormalizationTargetUp.MachineInterfaceFormalizationTargetTasteGate`
`single carrier alignment`
Lean4 (definition) `BEDC.Derived.MachineInterfaceFormalizationTargetUp.MachineInterfaceFormalizationTargetU`

Theorem 1225.2 (Machine-interface formalization-target NameCert obligations)**.** *For the carrier of Definition 1225.1, the local* NameCert$_{\text{MachineInterfaceFormalizationTarget}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$T = (N_s, K, R, S, D, E, A, U, H, C, P, L),$$

name exposure through N_s, namespace exposure through K, registry membership through R, statement-skeleton exposure through S, finite dependency readback through D, expected-status readback through E, audit-gate eligibility through A, not-claimed exposure through U, componentwise hsame *stability through H, displayed* Cont *replay through C, package provenance through P, and local naming through L.*

Consequently an accepted formalization target is a finite registry-, status-, dependency-, audit-gate-, and not-claimed packet, not a theorem object.

Proof. Project the displayed carrier. The tuple lists the name, namespace, registry, statement skeleton, dependency list, expected status, audit gate, not-claimed row, transport, continuation, provenance, and local name.

Read the registry-facing rows first. The name N_s and namespace K identify where the machine-facing declaration is meant to appear, while R records that the target is part of the claim registry layer and S records only the statement skeleton.

Next inspect D, E, A, U. The dependency and expected-status rows are data for the queue, the audit-gate row controls export eligibility, and the not-claimed row blocks theorem-content conclusions not present in the carrier.

Finally use H, C, P, L. These rows transport, replay, package, and name the same displayed packet. Since no coordinate contains proof content or an audit bypass, the NameCert obligations are exhausted by the stated finite rows. □

Lean4 ✓ `BEDC.Derived.MachineInterfaceFormalizationTargetUp.MachineInterfaceFormalizationTarget`
`namecert obligations`

Theorem 1225.3 (Machine-interface formalization-target audit-gate locality)**.** *Every accepted* MachineInterfaceFormalizationTarget$^{\uparrow}$ *packet can be exported as theorem-facing registry data only through the displayed audit-gate row A. If A refuses the socket kind or dependency status attached to D and E, then the target remains a queue record and cannot be read as theorem content.*

Proof. Begin with the queue rows. The target name, namespace, registry row, statement skeleton, dependency list, and expected status are all displayed before any export decision is made.

Use the audit-gate row. The row A is the only displayed gate eligible to judge the socket kind and dependency status attached to the packet. Neither the registry row nor the statement skeleton contains an independent export predicate.

Apply the not-claimed row. The row U records the theorem-content and host-supply surfaces that the packet refuses to assert. Componentwise transport and continuation replay preserve that refusal, so a gate refusal leaves the target as registry data rather than theorem content. □

Lean4 ✓ `BEDC.Derived.MachineInterfaceFormalizationTargetUp.MachineInterfaceFormalizationTarget audit gate locality`

Theorem 1225.4 (Machine-interface formalization-target registry-consistency handoff)**.** *Every* $\mathsf{RegistryExportSurface}^{\uparrow}$ *or* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *consumer of an accepted* $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$ *packet receives the same rows*

$$N_s, K, R, S, D, E, A, U, H, C, P, L.$$

The consumer may index the name, namespace, registry row, skeleton, dependencies, expected status, audit gate, and not-claimed surface, but it may not replace them by an off-packet registry claim, proof object, or successful Lean declaration.

Proof. Project the carrier and expose its registry inventory. The only registry-facing data are N_s, K, R, S, D, E, A, U together with their transport, replay, provenance, and local naming rows.

Use the NameCert obligations of Definition 1225.2. They make registry membership, statement skeleton, dependencies, expected status, audit eligibility, and not-claimed surface explicit fields of the same packet.

The export and claim-registry consumers therefore receive a finite handoff rather than a hidden declaration. If a consumer replaces these rows by theorem content or a successful Lean declaration, it has left the displayed carrier and no longer preserves the NameCert surface. □

Lean4 ✓ `BEDC.Derived.MachineInterfaceFormalizationTargetUp.MachineInterfaceFormalizationTarget registry consistency handoff`

Theorem 1225.5 (Machine-interface formalization-target nonescape)**.** *No accepted* MachineInterfaceFormalizationT *packet exports theorem content, marker repair, host supply, automatic dependency discharge, or bridge completion from its statement skeleton, dependency list, expected status, or audit-gate row. Such content can appear only in a later packet with its own displayed carrier and NameCert obligations.*

Proof. Read the statement-skeleton row and dependency row. They specify the shape and prerequisites of a target, but neither contains a proof object, a repaired marker, host supply, or a bridge.

Inspect the expected-status and audit-gate rows. They classify how the target is queued and whether the gate accepts the displayed status; they do not manufacture the content whose admission they classify.

Finally apply the not-claimed row together with the transport and replay rows. The not-claimed surface explicitly refuses those escape routes, while H, C, P, L only preserve and name the same packet. Therefore theorem content or bridge completion must be supplied by another displayed certificate. □

Falsifiable prediction: A MachineInterfaceFormalizationTargetUp packet cannot be exported as theorem content when its audit-gate row refuses its socket kind or dependency status.

Independence witness: machineinterfacesocket, registryexportsurface, claimregistrylayer, auditgateboundary, socketkindclassifier: the socket router lacks the full target queue record, the

export surface lacks the not-claimed target packet, the claim registry layer lacks audit-gate locality for socket kind and dependency status, the audit gate lacks registry and statement-skeleton fields, and the socket kind classifier lacks target name, namespace, dependencies, expected status, and not-claimed rows; no bijection preserves the full carrier.

The Lean follow-up must provide Nontrivial MachineInterfaceFormalizationTarget$^{\uparrow}$ and FieldFaithful MachineInterf in `lean4/BEDC/Derived/MachineInterfaceFormalizationTargetUp/TasteGate.lean` before BEDC.Derived.Mac can be cited by a checked paper marker.

Closure status for NameCert$_{\text{MachineInterfaceFormalizationTarget}^{\uparrow}}$.

Constructive story: A MachineInterfaceFormalizationTarget$^{\uparrow}$ packet is generated from target name, socket kind, registry row, statement skeleton, dependency list, expected status, audit-gate row, not-claimed exposure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MachineInterfaceFormalizationTarget}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1225.1, Definition 1225.2, Definition 1225.3, Definition 1225.4, and Definition 1225.5 bind the carrier, local NameCert, audit-gate locality, registry-consistency handoff, and nonescape boundary for the finite target packet.

Formal verification: FormalStatus(NameCert$_{\text{MachineInterfaceFormalizationTarget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close theorem content, proof object production, automatic dependency discharge, audit-gate bypass, marker repair, host supply, or bridge completion.

Upgrade path: No further paper-side closure-axis upgrade remains for the displayed machine-interface packet.

Chapter 1226

A Concrete Naming Certificate for $\mathsf{FinitePrefixLimitStability}^{\uparrow}$

The $\mathsf{FinitePrefixLimitStability}^{\uparrow}$ packet realizes the finite-prefix stability surface of the Real-completion diagonal-limit route of chapter 9238. It sits after the finite prefix budget of chapter 919, and it consumes the finite stream windows of chapter 126, the regular-rational readbacks of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal seal rows of chapter 38. The packet names the stability replay by which a displayed prefix observation reaches a Real-facing consumer; it is not a host limit, quotient stream equality, detached selector, countable-choice row, ambient Real-completeness theorem, or bridge schema.

Falsifiable prediction: An accepted finite-prefix limit-stability packet is refuted by any RealUp-facing consumer that reads a terminal seal without first exposing the displayed finite prefix budget, StreamName window, RegSeqRat readback, and DyadicRatCore tolerance row.

Independence witness: finiteprefixlimitbudget, realwindowbudget, realwindowsynchronizer, regularcauchymodulusnormalizer, reallimituniquenessseal: none is bijective because this packet carries the stability replay of a budgeted prefix read through the RealUp seal, whereas those siblings respectively record budget selection, window budgeting, synchronization, modulus normalization, or two-seal uniqueness.

Definition 1226.1 (Finite-prefix limit-stability carrier)**.** *A* $\mathsf{FinitePrefixLimitStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$ *row naming the admitted finite prefix budget for the diagonal-limit read;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposed under that budget;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed window;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the rational arithmetic and error budget of the prefix readback;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, W, R, D have been displayed on the same packet;*
6. *H records componentwise* hsame *transport for B, W, R, D, E and the local certificate row;*

7. *C records displayed* Cont *replay from the finite prefix budget through the window, readback, dyadic tolerance, and Real seal;*
8. *P is the* Pkg *provenance over* FinitePrefixLimitStability$^{\uparrow}$, FinitePrefixLimitBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
9. *N is the local* NameCert$_{\text{FinitePrefixLimitStability}^{\uparrow}}$ *row.*

The carrier exports only the displayed finite-prefix stability route and its transport, replay, provenance, and naming support.

Lean4 ✓ `BEDC.Derived.FinitePrefixLimitStabilityUp.FinitePrefixLimitStabilityUpTasteGate single carrier alignment`

Theorem 1226.2 (Finite-prefix limit-stability obligation surface)**.** *For the carrier of Definition 1226.1, the local* NameCert$_{\text{FinitePrefixLimitStability}^{\uparrow}}$ *surface consists exactly of carrier admission, finite prefix-budget exposure through B,* StreamName$^{\uparrow}$ *window exposure through W,* RegSeqRat$^{\uparrow}$ *readback exposure through R,* DyadicRatCore$^{\uparrow}$ *tolerance exposure through D, terminal* Real$^{\uparrow}$ *seal exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.FinitePrefixLimitStabilityUp.FinitePrefixLimitStabilityTasteGate single carrier alignment`

Proof. Project the carrier S. Its coordinates list the finite prefix budget, stream window, regular-rational readback, dyadic tolerance row, terminal Real seal, transport, replay, provenance, and local naming row.

Read the data-bearing rows in order. The budget row B admits the finite prefix read, the window row W displays the observed stream segment, the readback row R records the regular-rational content of that segment, and the dyadic row D records the tolerance attached to the readback.

The Real seal E is downstream of those four rows. The support rows H, C, P, N only transport, replay, source, and name the same displayed route, so the listed rows exhaust the local naming surface. □

Theorem 1226.3 (Finite-prefix limit-stability carrier admission)**.** *Every accepted* FinitePrefixLimitStability$^{\uparrow}$ *packet exposes exactly the carrier rows*

$$B, W, R, D, E, H, C, P, N$$

before any Real$^{\uparrow}$*-facing read. Thus a consumer cannot read the terminal Real seal E without first admitting the finite prefix budget B,* StreamName$^{\uparrow}$ *window W,* RegSeqRat$^{\uparrow}$ *readback R,* DyadicRatCore$^{\uparrow}$ *tolerance row D, componentwise transport H, displayed replay C, provenance P, and the local naming row N.*

Lean4 ✓ `BEDC.Derived.FinitePrefixLimitStabilityUp.FinitePrefixLimitStabilityCarrier admission`

Proof. Project the carrier of Definition 1226.1. The projection exposes precisely the nine displayed coordinates $B, W, R, D, E, H, C, P, N$ and gives no auxiliary Real-facing coordinate.

Apply Definition 1226.2. Its obligation surface identifies the accepted packet with carrier admission, the four finite data rows, the terminal seal, transport, replay, provenance, and local naming. Hence every Real-facing read must pass through those rows before E can be consumed. □

Theorem 1226.4 (Finite-prefix limit-stability transport stability)**.** *Componentwise* hsame *transport and displayed* Cont *replay preserve the route order from the finite prefix budget through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The preserved route is*

$$B \to W \to R \to D \to E$$

with support rows H and C carrying only transport and replay for the displayed coordinates; it does not use quotient stream equality, selected limits, or countable choice.

Proof. Read the transport row H of Definition 1226.1. It is componentwise hsame transport for the data rows B, W, R, D, E together with the local certificate row, so it can preserve the displayed route but cannot reorder it or create a detached terminal seal.

Read the replay row C. It records displayed Cont replay from the finite prefix budget through the window, readback, dyadic tolerance, and Real seal. Since the replay starts at B and ends at E through the named intermediate rows, it preserves the finite route order.

The excluded objects are absent from both rows. Neither H nor C contains quotient stream equality, a selected limit, or a countable-choice selector, so transport stability is exactly the stability of the displayed finite-prefix route. □

Lean4 ✓ `BEDC.Derived.FinitePrefixLimitStabilityUp.FinitePrefixLimitStabilityCarrier route unary closure`

Theorem 1226.5 (Finite-prefix limit-stability ledger exactness)**.** *The local* $\mathsf{NameCert}_{\mathsf{FinitePrefixLimitStability}^{\uparrow}}$ *ledger is exact for the finite-prefix route. It accounts for the budget row B, window row W, readback row R, tolerance row D, seal row E, transport row H, replay row C, provenance row P, and naming row N, and it exports no ambient Real-completeness theorem, quotient-completion principle, selected-limit rule, countable-choice row, or bridge schema.*

Lean4 ✓ `BEDC.Derived.FinitePrefixLimitStabilityUp.FinitePrefixLimitStabilityLedgerExactness`

Proof. Use Definition 1226.2 to read the local ledger. The theorem lists the admitted rows and support rows as the whole $\mathsf{NameCert}_{\mathsf{FinitePrefixLimitStability}^{\uparrow}}$ surface.

The carrier admission theorem Definition 1226.3 fixes the exposed coordinates before any Real-facing read. The transport-stability theorem Definition 1226.4 then assigns H and C only the transport and replay roles attached to that same route.

It remains only to identify what the ledger does not export. The carrier has no coordinate for ambient Real completeness, quotient-completion data, a selected limit, countable choice, or a bridge schema. Therefore the local ledger is exact for the finite-prefix route and nothing beyond it. □

Theorem 1226.6 (Finite-prefix limit-stability prefix nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{FinitePrefixLimitStability}^{\uparrow}$ *packet factors through the finite route*

$$B, W, R, D, E, H, C, P, N.$$

The consumer receives the displayed finite prefix budget, $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{Real}^{\uparrow}$ *seal, and structural support rows. It receives no host real equality, quotient stream equality, selected host limit, detached tail oracle, countable-choice selector, ambient Real-completeness witness, or standard bridge row.*

Proof. Begin with Definition 1226.1. The only Real-facing coordinate is the seal row E, and it is preceded by the budget row B, window row W, readback row R, and tolerance row D.

Apply Definition 1226.2. It forces every accepted consumer to expose the finite prefix budget, window, readback, tolerance, seal, transport, replay, provenance, and local naming rows before the packet is usable.

The excluded objects are not coordinates of the carrier. Since H, C, P, N preserve and name displayed rows without creating new analytic data, no consumer can project host equality, quotient equality, a selected limit, a tail oracle, countable choice, ambient completeness, or a bridge schema from this packet. □

Theorem 1226.7 (Finite-prefix limit-stability Real handoff)**.** *The diagonal-limit route of chapter 9238 may consume an accepted* $\mathsf{FinitePrefixLimitStability}^{\uparrow}$ *packet as the finite stability handoff from a displayed prefix observation to a terminal* $\mathsf{Real}^{\uparrow}$ *seal. The handoff is compatible with chapter 919, chapter 126, chapter 301, chapter 291, and chapter 38 because it preserves their budget, window, readback, tolerance, and seal rows in one local* $\mathsf{NameCert}$ *packet.*

Proof. Read the budget sibling first. The $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$ row supplies the finite prefix budget consumed by B, so the stability packet never begins from an unbounded stream or hidden tail schedule.

Read the observation siblings next. The $\mathsf{StreamName}^{\uparrow}$ row W, $\mathsf{RegSeqRat}^{\uparrow}$ row R, and $\mathsf{DyadicRatCore}^{\uparrow}$ row D keep the finite observation, regular readback, and tolerance ledger visible before any terminal seal is public.

Finally read the $\mathsf{Real}^{\uparrow}$ sibling through E. The transport, continuation, provenance, and naming rows keep that seal tied to the same displayed prefix route, so the Real-completion consumer receives a finite stability handoff rather than a host limit, quotient stream, selected limit, choice row, ambient completeness theorem, or bridge schema. □

Theorem 1226.8 (Finite-prefix limit-stability route determinacy)**.** *Let* $S = (B, W, R, D, E, H, C, P, N)$ *be an accepted* $\mathsf{FinitePrefixLimitStability}^{\uparrow}$ *carrier. If two consumer reads of* S *expose the same finite prefix budget* B*, the same* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the same componentwise transport rows* H*, and the same continuation replay* C*, then both reads reach the same terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*. No alternate seal may be attached to the displayed route by a hidden tail oracle, host limit, quotient stream equality, selected-limit row, countable-choice row, ambient completeness theorem, or bridge schema.*

Proof. Start from the carrier decomposition in Definition 1226.1. The terminal seal coordinate E is part of the same finite packet as B, W, R, D, H, C, P, N, not a separately supplied analytic witness.

Apply the obligation surface of Definition 1226.2. An accepted read has access exactly to the displayed budget, window, readback, tolerance, seal, transport, replay, provenance, and local naming rows. Thus two reads with identical B, W, R, D, H, C are comparing the same displayed route inside the same packet.

The nonescape theorem Definition 1226.6 excludes every non-coordinate source of a second seal. The Real handoff theorem Definition 1226.7 then identifies the consumer-facing output as the terminal seal already carried by E, so the displayed prefix route has one Real-facing seal and admits no detached alternative. □

Lean4 ✓ `BEDC.Derived.FinitePrefixLimitStabilityUp.FinitePrefixLimitStabilityCarrier real seal determinacy`

Theorem 1226.9 (Finite-prefix limit-stability budget-window lock)**.** *Every accepted* $\mathsf{FinitePrefixLimitStability}^{\uparrow}$ *packet must expose the finite prefix budget* B *before the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, and must expose* W *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*. The budget-window lock is the initial segment of the displayed handoff*

$$B \to W \to R \to D \to E$$

and no $\mathsf{Real}^{\uparrow}$*-facing consumer can bypass it through a host limit, detached stream oracle, selected-limit row, quotient stream equality, countable-choice row, ambient completeness theorem, or bridge schema.*

Lean4 ✓ `BEDC.Derived.FinitePrefixLimitStabilityUp.FinitePrefixLimitStabilityCarrier budget window lock`

Proof. Project the carrier of Definition 1226.1. Its data coordinates begin with the budget row B, the stream window row W, and the regular-rational readback row R.

Apply the obligation surface of Definition 1226.2. It makes carrier admission, budget exposure, window exposure, and readback exposure part of the same local $\mathsf{NameCert}_{\mathsf{FinitePrefixLimitStability}^{\uparrow}}$ surface, so an accepted packet cannot present W without B or present R without W.

Finally use the Real handoff theorem Definition 1226.7. The Real-facing consumer receives the terminal seal only as the end of the same displayed finite route, hence the budget-window lock is forced before any seal-facing consumption. □

Theorem 1226.10 (Finite-prefix limit-stability tolerance-seal lock)**.** *Every accepted* $\mathsf{FinitePrefixLimitStability}^{\uparrow}$ *packet reads the row* D *as the required* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row before* E *can be read as a terminal* $\mathsf{Real}^{\uparrow}$ *seal. Thus the seal is locked to the displayed dyadic tolerance ledger and cannot be supplied by host Real equality, quotient stream equality, a hidden tail route, a selected-limit row, countable choice, ambient Real completeness, or a standard bridge row.*

Proof. Read the carrier coordinates. The row D is explicitly the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row recording the rational arithmetic and error budget of the prefix readback, while E is the $\mathsf{Real}^{\uparrow}$ seal reached only after B, W, R, D have been displayed on the same packet.

Use Definition 1226.4. Componentwise hsame transport and displayed Cont replay preserve the route $B \to W \to R \to D \to E$, so they cannot move the seal before the tolerance row or manufacture an untracked analytic seal.

Apply Definition 1226.6 and Definition 1226.8. They exclude every non-coordinate source of a terminal seal and force the displayed route to determine the Real-facing output already carried by E. □

Theorem 1226.11 (Finite-prefix limit-stability NameCert obligation triad)**.** *The* $\mathsf{NameCert}_{\mathsf{FinitePrefixLimitStability}^{\uparrow}}$ *obligation surface is the triad consisting of the budget-window lock of Definition 1226.9, the tolerance-seal lock of Definition 1226.10, and the route determinacy of Definition 1226.8, together with the carrier of Definition 1226.1, the obligation surface of Definition 1226.2, transport stability of Definition 1226.4, ledger exactness of Definition 1226.5, and prefix nonescape of Definition 1226.6. This package closes the chapter's obligation-grade surface without claiming global Real completeness, quotient completion, selected limits, choice rows, or a bridge schema.*

Proof. The carrier and obligation-surface theorem identify the rows that an accepted packet exposes: $B, W, R, D, E, H, C, P, N$ and no additional analytic coordinate.

The budget-window lock fixes the initial route segment from the finite prefix budget through the stream window and regular-rational readback. The tolerance-seal lock fixes the terminal route segment from the dyadic tolerance ledger into the Real seal.

Transport stability, ledger exactness, and prefix nonescape then show that the support rows only preserve, source, name, and replay the same displayed route. Route determinacy supplies the final consumer-facing uniqueness of the seal attached to that route. These clauses are exactly the obligation surface recorded by the local NameCert packet. □

Theorem 1226.12 (Finite-prefix limit-stability source lock)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing read of an accepted* $\mathsf{FinitePrefixLimitStability}^{\uparrow}$ *carrier must expose the ordered route*

$$B \to W \to R \to D \to E$$

before the support rows H, C, P, N *can be consumed. The support rows may transport, replay, source, and name the displayed route, but they cannot supply a Real seal, prefix budget, stream window, regular-rational readback, or dyadic tolerance row out of order.*

Proof. Project the carrier with Definition 1226.1. The data rows appear as the budget B, window W, readback R, tolerance D, and terminal seal E, while H, C, P, N are support rows for that displayed data.

Use Definition 1226.2 to read the local naming surface. The accepted packet presents the route by exposing the finite prefix budget, then the stream window, then the regular-rational readback, then the dyadic tolerance row, and only then the Real seal.

Finally apply Definition 1226.6 and Definition 1226.7. They force every Real-facing consumer through the displayed finite route and make the handoff terminate at E, so the support rows can only preserve and name that route after its source order has been exposed. □

Theorem 1226.13 (Finite-prefix limit-stability primitive-scope binding)**.** *For every accepted* FinitePrefixLimitStabi *carrier, the route*

$$B \to W \to R \to D \to E$$

is scoped exactly by the BEDC primitives BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*, together with the sibling rows* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. No quotient stream, host limit, selected tail, countable-choice row, ambient completeness theorem, or bridge schema contributes to the scoped route.*

Proof. Project the carrier of Definition 1226.1. Its displayed coordinates are the finite-prefix budget row B, the stream window W, the regular-rational readback R, the dyadic tolerance ledger D, the terminal Real seal E, componentwise transport H, continuation replay C, provenance P, and local naming N.

The obligation surface of Definition 1226.2, carrier admission of Definition 1226.3, transport stability of Definition 1226.4, ledger exactness of Definition 1226.5, and Real handoff of Definition 1226.7 identify these coordinates as the whole route surface. The sibling rows are therefore already displayed: B names the finite-prefix budget, W names the stream observation, R names the regular-rational readback, D names the dyadic tolerance ledger, and E names the Real seal.

Route determinacy, the budget-window lock, the tolerance-seal lock, the NameCert obligation triad, and the source lock then bind the support rows to the same route. The support rows H, C, P, N supply only hsame transport, Cont replay, Pkg provenance, and NameCert naming over the carrier's finite BHist packet; they do not introduce a second route or an analytic substitute.

Finally apply prefix nonescape from Definition 1226.6. It excludes every non-coordinate source named in the statement, so the primitive and sibling rows listed above are the exact scope of the accepted finite-prefix limit-stability route. □

Theorem 1226.14 (Finite-prefix limit-stability public NameCert export)**.** *The carrier of Definition 1226.1, the obligation surface of Definition 1226.2, the source lock of Definition 1226.12, the primitive-scope binding of Definition 1226.13, the Real handoff of Definition 1226.7, and the TasteGate marker export the public* $\mathsf{NameCert}_{\mathsf{FinitePrefixLimitStability}^{\uparrow}}$ *surface over* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$. *This exported surface excludes host limits, quotient streams, selected limits, countable choice, ambient completeness, and bridge schema data.*

Proof. Start with the NameCert obligation triad of Definition 1226.11. It packages the budget-window lock, tolerance-seal lock, and route determinacy together with the carrier, obligation surface, transport, ledger, and prefix nonescape clauses.

Apply the source lock of Definition 1226.12. It forces every Real-facing or Completion-facing consumer to read the ordered finite route $B \to W \to R \to D \to E$ before consuming the support rows H, C, P, N.

Use the primitive-scope binding of Definition 1226.13. This identifies the exact BEDC primitives and sibling rows that generate the route and excludes the host, quotient, choice, ambient-completeness, and bridge-schema sources named in the statement.

Finally apply the Real handoff of Definition 1226.7. The handoff terminates the exported route at the displayed $\mathsf{Real}^{\uparrow}$ seal, while the TasteGate marker records the accepted public surface. The composed package is therefore the public $\mathsf{NameCert}_{\mathsf{FinitePrefixLimitStability}^{\uparrow}}$ export over precisely the listed primitives and sibling rows. □

Theorem 1226.15 (Finite-prefix limit-stability standard bridge precondition)**.** *Any standard bridge eligible to consume the public* $\mathsf{NameCert}_{\mathsf{FinitePrefixLimitStability}^{\uparrow}}$ *export must preserve the ordered finite BEDC route*

$$B \to W \to R \to D \to E$$

through the sibling rows $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Bridge-side data may be exposed only after the finite prefix budget, stream window, regular-rational readback, dyadic tolerance ledger, and terminal Real seal have appeared in that order. No host limit, quotient stream equality, selected limit, countable-choice row, ambient Real completeness theorem, or detached bridge-schema row can serve as an alternate precondition for that bridge.*

Lean4 ✓ `BEDC.Derived.FinitePrefixLimitStabilityUp.FinitePrefixLimitStabilityUp StdBridge`

Proof. Begin with the public export of Definition 1226.14. It supplies the $\mathsf{NameCert}_{\mathsf{FinitePrefixLimitStability}^{\uparrow}}$ surface over the five sibling rows and the BEDC primitives that name the finite route.

Apply the primitive-scope binding of Definition 1226.13. The route is scoped exactly by BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ together with the displayed sibling rows, so a standard bridge consuming the public export has no additional source from which to derive bridge-side data.

Use the source lock of Definition 1226.12. Every Real-facing or Completion-facing read must encounter B, then W, then R, then D, and only then E before support rows can be consumed.

Finally apply prefix nonescape from Definition 1226.6. The excluded host, quotient, selected-limit, choice, completeness, and detached-schema sources cannot provide a second bridge entry. Thus the only admissible standard-bridge precondition is preservation of the displayed finite BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePrefixLimitStability}^{\uparrow}}$**.**

Constructive story: The finite-prefix limit-stability certificate is generated from $BHist$ rows that name a finite prefix budget, stream-name observation, regular-rational readback, dyadic tolerance ledger, and the terminal Real seal that keeps

the route stable at that prefix. The carrier first reads the finite prefix, then records the stability witness, and finally allows Cont to continue toward a Real handoff only through that same prefix. The $hsame$ relation prevents representative changes from altering which finite prefix carries the stability evidence. The obligation surface, carrier admission, transport stability, ledger exactness, prefix nonescape, and Real handoff theorem together state that finite ledger data are sufficient for the admitted route, while external completion witnesses are outside scope.

Theory closure: TheoryGate(NameCert$_{\text{FinitePrefixLimitStability}\uparrow}$, maturePackageClosed)

Scope closed: This chapter binds the finite-prefix limit-stability carrier, obligation-surface theorem, carrier-admission theorem, transport-stability theorem, ledger-exactness theorem, prefix-nonescape theorem, Real-handoff theorem, route-determinacy theorem, budget-window lock of Definition 1226.9, tolerance-seal lock of Definition 1226.10, NameCert obligation triad of Definition 1226.11, primitive-scope binding of Definition 1226.13, public NameCert export of Definition 1226.14, and TasteGate instance

Formal verification: FormalStatus(NameCert$_{\text{FinitePrefixLimitStability}\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.FinitePrefixLimitStabilityUp.FinitePrefixLimitStabilityTasteGate\_single\_carrier\_alig`

Bridge status: bridgeChecked

Origin: ai

Not claimed: It does not claim global limit existence, completed Real equality, selected limits, choice rows, or stability without the named finite prefix row.

Upgrade path: No further upgrade – chapter at top of the formal bridge axis for the displayed finite-prefix route.

Chapter 1227

A Concrete Naming Certificate for $\mathsf{AuditWritingDiscipline}^{\uparrow}$

The $\mathsf{AuditWritingDiscipline}^{\uparrow}$ packet realizes the audit-methodology discipline of section 9462.30 inside the auditable-generativity programme of chapter 9462. It sits beside the registry export surface of chapter 1216, the claim registry layer of chapter 1209, the machine-interface socket of chapter 1059, the standard bridge audit packet of chapter 1217, and the proof trace audit witness of chapter 1219. Those siblings expose registry export, claim admission, machine routing, bridge audit, and proof-trace readback; this carrier binds them into one writing packet before a public claim may be read as auditable prose.

Definition 1227.1 (Audit writing discipline carrier)**.** *An* $\mathsf{AuditWritingDiscipline}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (W, C, K, L, T, F, G, R, H, P, N)$$

with the following visible rows:

1. *W is the writing-item row, naming the claim, paragraph, theorem, definition, or closure-status site being exported.*
2. *C is the carrier row, recording the BEDC carrier or packet surface to which the writing item is attached.*
3. *K is the classifier row, recording the classifier, membership, or exactness predicate that licenses the writing item.*
4. *L is the ledger row, recording the finite audit ledger entries consumed by the writing item.*
5. *T is the theory-axis row, recording the theory-closure grade as a paper-side coordinate.*
6. *F is the formal-axis row, recording the formal-verification grade as an independent Lean-side coordinate.*
7. *G is the gap/refusal row, recording missing bridge data, refused readings, blocked host resources, and unsupported consumer routes.*
8. *R is the registry row, recording how the claim is admitted, blocked, or handed to the registry export surface.*
9. *H is the transport row, recording machine-interface routing, standard-bridge audit transport, and proof-trace readback through the sibling surfaces.*

10. *P is the* Pkg *provenance over* RegistryExportSurface$^{\uparrow}$, ClaimRegistryLayer$^{\uparrow}$, MachineInterfaceSocket$^{\uparrow}$, StandardBridgeAuditPacket$^{\uparrow}$, ProofTraceAuditWitness$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{AuditWritingDiscipline}^{\uparrow}}$ *row.*

The carrier has no coordinate for a prose-only claim, a collapsed theory/formal status, a hidden registry override, a proof-trace read without refusal data, or a host bridge imported as BEDC evidence.

Lean4 ✓ `BEDC.Derived.AuditWritingDisciplineUp.AuditWritingDisciplineTasteGate single carrier alignment`

Theorem 1227.2 (Audit writing discipline obligation surface)**.** *For the carrier of Definition 1227.1, the local* NameCert$_{\text{AuditWritingDiscipline}^{\uparrow}}$ *surface consists exactly of six obligation rows: writing-item admission through W; carrier and classifier exposure through C, K; ledger exactness through L; independent theory and formal status reporting through T, F; gap and refusal exposure through G; and registry, transport, provenance, and local naming through R, H, P, N.*

Proof. Project the displayed packet of Definition 1227.1. The rows $W, C, K, L, T, F, G, R, H, P, N$ are the only available coordinates, so the writing item must first name its carrier, classifier, and ledger route.

Read the status rows next. The theory-axis row T records paper closure, while the formal-axis row F records Lean verification status. Since they are separate rows, the carrier has no rule that turns one status coordinate into the other.

Finally attach gap/refusal, registry, transport, provenance, and local naming. Rows G, R, H, P, N keep unsupported readings, claim export, machine routing, bridge audit, and proof-trace readback visible in the same packet, giving exactly the six local obligation rows. □

Theorem 1227.3 (Audit writing discipline nonescape)**.** *Let*

$$A = (W, C, K, L, T, F, G, R, H, P, N)$$

be an accepted AuditWritingDiscipline$^{\uparrow}$ *packet. Every public claim read factors through the displayed writing item, carrier, classifier, ledger, theory axis, formal axis, gap/refusal, registry, transport, provenance, and local naming rows. No public consumer may replace those rows by prose emphasis, host equality, unchecked bridge evidence, private registry state, hidden proof trace, or a single status coordinate that merges T and F.*

Proof. Begin with the obligation surface of Definition 1227.2. It forces the public writing item to expose its carrier, classifier, ledger, status axes, refusal surface, registry route, transport, provenance, and local name together.

If the route omits T or F, the consumer no longer knows which axis is being cited. If the route omits G, unsupported readings and refusal boundaries are erased. If it omits R or H, the claim no longer passes through registry export or machine-facing transport.

Thus every accepted claim remains inside the displayed finite packet. The excluded prose, host, bridge, registry, proof-trace, and collapsed-status readings have no coordinate from which to enter the AuditWritingDiscipline$^{\uparrow}$ carrier. □

Theorem 1227.4 (Audit writing discipline registry handoff)**.** *For every accepted* AuditWritingDiscipline$^{\uparrow}$ *packet $A = (W, C, K, L, T, F, G, R, H, P, N)$, the claim admitted by W is exported only through*

the registry row R and the sibling surfaces $\mathsf{RegistryExportSurface}^{\uparrow}$ *and* $\mathsf{ClaimRegistryLayer}^{\uparrow}$*. The machine-facing route in H may cite* $\mathsf{MachineInterfaceSocket}^{\uparrow}$*,* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$*, and* $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ *only after the registry row has preserved the distinct carrier, classifier, ledger, theory-axis, formal-axis, and refusal rows.*

Proof. First read registry admission through R. By the obligation surface, R is attached to the same writing item, carrier, classifier, ledger, theory axis, formal axis, refusal surface, provenance, and local name.

Next use the sibling registry surfaces. $\mathsf{ClaimRegistryLayer}^{\uparrow}$ records whether the claim is admitted or refused, while $\mathsf{RegistryExportSurface}^{\uparrow}$ records whether it may leave the registry as a public export.

Only after those rows are displayed may the transport row H route the claim toward $\mathsf{MachineInterfaceSocket}^{\uparrow}$, $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$, or $\mathsf{ProofTraceAuditWitness}^{\uparrow}$. Since H is part of the same packet, it cannot erase C, K, L, T, F, G or replace them by a hidden bridge or proof-trace reading. □

Falsifiable prediction: If a public claim collapses the theory-closure row and formal-verification row into one status coordinate, it is not an accepted AuditWritingDisciplineUp packet.

Independence witness: registryexportsurface, claimregistrylayer, machineinterfacesocket, standardbridgeauditpacket, prooftraceauditwitness: registry export controls public claim release without writing-item carrier discipline, the claim registry layer records admission without proof-trace transport, the machine-interface socket routes targets without closure-axis separation, the standard bridge audit packet controls host-bridge leakage without claim registry admission, and the proof trace audit witness records proof evidence without registry export. None is bijective to $\mathsf{AuditWritingDiscipline}^{\uparrow}$.

The Lean follow-up file `lean4/BEDC/Derived/AuditWritingDisciplineUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ AuditWritingDiscipline}^{\uparrow}$ and $\mathsf{FieldFaithful\ AuditWritingDiscipline}^{\uparrow}$ instances, preserving $W, C, K, L, T, F, G, R, H, P, N$ as separate displayed fields. The expected canonical target is `BEDC.Derived.AuditWritingDisciplineUp.taste_gate`.

Theorem 1227.5 (Audit writing discipline public export)**.** *Every accepted* $\mathsf{AuditWritingDiscipline}^{\uparrow}$ *read exports only the visible writing-item, closure-axis, formal-axis, registry, proof-trace, machine-interface, transport, replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{AuditWritingDiscipline}^{\uparrow}}$ *rows before any audit consumer may cite the packet.*

Proof. Read the carrier of Definition 1227.1. Its displayed rows expose the writing item, theory-axis, formal-axis, registry, transport, provenance, and local name, while the transport row records the machine-interface, standard-bridge audit, and proof-trace routes.

The obligation surface of Definition 1227.2 then makes those rows the public certificate surface. The nonescape theorem of Definition 1227.3 blocks prose emphasis, host equality, hidden bridge evidence, private registry state, and collapsed status coordinates from replacing the displayed rows.

Finally, the registry handoff of Definition 1227.4 requires any cited public claim to pass through the registry row before machine-facing and proof-trace consumers read it. Thus the exported audit surface is exactly the visible rows listed in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{AuditWritingDiscipline}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditWritingDiscipline}^{\uparrow}$ packet is generated from writing item, carrier, classifier, ledger, theory-axis, formal-axis, gap/refusal, registry, transport, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditWritingDiscipline}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1227.1, Definition 1227.2, Definition 1227.3, Definition 1227.4, and Definition 1227.5 give the mature registry, proof-trace, machine-interface, and bridge-audit compatibility surface over $W, C, K, L, T, F, G, R, H, P, N$ while keeping the theory and verification axes independent.

Formal verification: FormalStatus(NameCert$_{\text{AuditWritingDiscipline}\uparrow}$, axiomClean)
Lean target: `BEDC.Derived.AuditWritingDisciplineUp.AuditWritingDisciplineTasteGate\_single\_carrier\_alignment`
Bridge status: none
Origin: ai
Not claimed: This chapter does not close bridge checking, global registry correctness, proof-trace soundness, or machine-interface completeness.
Upgrade path: No further paper-side closure grade is claimed beyond the mature registry, proof-trace, machine-interface, and bridge-audit compatibility surface over $W, C, K, L, T, F, G, R, H, P, N$; bridge checking remains on the independent formal axis.

Chapter 1228

A Concrete Naming Certificate for $\mathsf{PointwiseModulusLedger}^{\uparrow}$

The $\mathsf{PointwiseModulusLedger}^{\uparrow}$ interface is the concrete source packet for the pointwise-modulus relation isolated in chapter 9237. It reads the $\mathsf{ContinuousMap}^{\uparrow}$ graph and pointwise-continuity rows of chapter 130, the source and target metric rows of chapter 57, the positive tolerance and radius histories of chapter 37, and the finite selector boundary later consumed by chapter 914. Its role is to store the center-specific continuity implication before the compact finite-net fold has selected a tolerance-only precision.

Falsifiable prediction: If the local radius row is absent, no accepted $\mathsf{PointwiseModulusLedger}^{\uparrow}$ packet can hand a center-specific continuity implication to a compact-net selector.

Independence witness: continuousmap, metric, rat, compactnetmodulusselector, compactuniformcontinuity: the packet is not bijective to any one sibling because it binds source and target metric rows, graph row, center row, tolerance row, local radius row, and implication certificate before compact folding; each sibling omits at least one of those source-ledger obligations.

Definition 1228.1 (Pointwise modulus ledger carrier)**.** *A* $\mathsf{PointwiseModulusLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, F, C, E, R, I, H, Q, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row whose distance comparisons are tested near the displayed center;*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row whose distance comparisons read the requested tolerance;*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row over the same source and target metrics;*
4. *C is the center history at which the local continuity row is requested;*
5. *E is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance history;*
6. *R is the positive* $\mathsf{Rat}^{\uparrow}$ *local radius history attached to C and E;*
7. *I is the implication certificate saying that every source history within radius R of C is mapped by F within tolerance E in Y;*
8. *H records componentwise* hsame *transport for the metric, graph, center, tolerance, radius, implication, route, provenance, and naming rows;*

9. *Q records the displayed* Cont *routes through which continuous-map and compact-net consumers read the packet;*
10. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PointwiseModulusLedger}^{\uparrow}}$ *row.*

The carrier exports only the displayed source metric, target metric, graph, center, tolerance, radius, implication, transport, route, provenance, and local naming rows. It has no coordinate for compactness, a finite-net selector, a folded lower bound, a host continuity theorem, a chosen global modulus, or an open-cover argument.

Theorem 1228.2 (Pointwise modulus ledger NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{PointwiseModulusLedger}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the packet of Definition 1228.1;*
2. *graph compatibility, requiring F to be read as a* $\mathsf{ContinuousMap}^{\uparrow}$ *row from the source metric X to the target metric Y;*
3. *center-tolerance-radius exactness, requiring C, E, and R to be displayed together as the local pointwise request;*
4. *implication exactness, requiring I to consume only the source-distance row in X, the target-distance row in Y, the graph row F, and the displayed C, E, R rows;*
5. *non-escape, requiring every compact-net consumer read to pass through $X, Y, F, C, E, R, I, H, Q, P, N$ and forbidding compactness data, finite selector output, folded lower bounds, host continuity, chosen global moduli, and open-cover subcovers.*

Proof. Carrier admission is projection from Definition 1228.1. The packet displays the source and target metrics, graph row, center, tolerance, radius, implication, transports, routes, provenance, and local name.

Graph compatibility reads F only over X and Y. The pointwise row is therefore attached to the same metric surfaces later used by a compact-net selector.

Center-tolerance-radius exactness binds C, E, R as one local request. The radius row is not reconstructed from compactness or a folded minimum; it is the displayed positive $\mathsf{Rat}^{\uparrow}$ radius carried by the packet.

Implication exactness reads I as the local continuity certificate. Its antecedent is a source-metric comparison to C below R, and its conclusion is a target-metric comparison below E after applying the graph row F.

The non-escape clause follows from the carrier inventory and the displayed route rows. Since no compactness, finite selector, lower-bound fold, host theorem, global modulus, or open-cover coordinate is present, no accepted projection can export such data. □

Theorem 1228.3 (Pointwise modulus ledger center-radius handoff)**.** *Let*

$$L = (X, Y, F, C, E, R, I, H, Q, P, N)$$

be an accepted $\mathsf{PointwiseModulusLedger}^{\uparrow}$ *carrier. Any downstream* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *read of the center-specific pointwise modulus factors through the displayed center row C, local radius row R, tolerance row E, graph row F, source and target metric rows X, Y, and implication certificate I. The selector receives a center-radius implication packet, not a compact finite-net fold or a host modulus.*

Proof. Project the accepted carrier. The center, tolerance, and radius rows are visible as C, E, R, and the graph and metric rows are visible as F, X, Y.

Apply Definition 1228.2. Its graph compatibility and center-tolerance-radius exactness clauses bind these rows before any consumer can read the implication certificate.

Now read I. The implication certificate consumes exactly the source-distance comparison to C below R and returns exactly the target-distance comparison below E through F and Y.

The compact-net selector can therefore use the row only as a center-radius handoff. It must still supply its own finite ProbeBundle spine and lower-bound fold, because neither coordinate appears in the accepted PointwiseModulusLedger$^{\uparrow}$ packet. □

Theorem 1228.4 (Pointwise modulus ledger non-escape)**.** *Every consumer read of an accepted* PointwiseModulusLedger$^{\uparrow}$ *packet factors through the displayed source metric, target metric, graph, center, tolerance, radius, implication, transport, route, provenance, and local naming rows of Definition 1228.1. The packet exports no compact finite-net row, no selected precision, no lower-bound fold, no open-cover compactness, no host continuity theorem, and no external modulus function.*

Proof. Read the carrier coordinates $X, Y, F, C, E, R, I, H, Q, P, N$. These are the only rows available to the local NameCert$_{\text{PointwiseModulusLedger}^{\uparrow}}$ projection.

Use Definition 1228.2. Its exactness clauses route graph reads through F, local request reads through C, E, R, and continuity implication reads through I.

The transport, continuation, provenance, and naming rows H, Q, P, N replay that same finite route componentwise. No coordinate remains from which a consumer could read compact finite-net data, a selected precision, a lower-bound fold, open-cover compactness, host continuity, or an external modulus function. □

Theorem 1228.5 (Pointwise modulus ledger TasteGate obligation)**.** *The Lean follow-up file* lean4/BEDC/Derived/PointwiseModulusLedgerUp/TasteGate.lean *must provide* Nontrivial PointwiseModulusLedger$^{\uparrow}$ *and* FieldFaithful PointwiseModulusLedger$^{\uparrow}$ *instances for the same carrier. These instances must preserve the source metric row, target metric row, graph row, center row, tolerance row, local radius row, implication certificate,* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.PointwiseModulusLedgerUp.TasteGate.PointwiseModulusLedgerTasteGate single carrier alignment`

Proof. Nontriviality is witnessed by the dependency mix of the carrier. Removing the source metric row breaks the antecedent of I; removing the target metric row breaks its conclusion; removing the graph, center, tolerance, or radius row leaves no pointwise-modulus request.

Field faithfulness records that these rows are preserved as one packet. A TasteGate consumer must distinguish PointwiseModulusLedger$^{\uparrow}$ from ContinuousMap$^{\uparrow}$, Met$^{\uparrow}$, Rat$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, and the compact-uniform-continuity packet by the full coordinate surface $X, Y, F, C, E, R, I, H, Q, P, N$. □

Closure status for NameCert$_{\text{PointwiseModulusLedger}^{\uparrow}}$.

Constructive story: The pointwise modulus ledger is generated from $BHist$ rows that record source and target metric rows, a graph row, center, tolerance, local radius, and the implication certificate attached to that point. The carrier convention reads these rows directly: first the pointwise address, then the radius budget, then the modulus ledger row consumed by later proofs. The $hsame$ relation transports the same pointwise packet across representative changes, while Cont may extend the route only if the center-radius evidence remains visible. The NameCert obligations, handoff theorem, non-escape boundary, and TasteGate obligation therefore make the object a ledger of local modulus use, not a hidden uniform modulus principle.

Theory closure: TheoryGate(NameCert$_{\mathsf{PointwiseModulusLedger}\uparrow}$, seed)

Scope closed: This chapter binds the pointwise modulus-ledger carrier, NameCert obligations, center-radius handoff, non-escape, and TasteGate-obligation theorems.

Formal verification: FormalStatus(NameCert$_{\mathsf{PointwiseModulusLedger}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim a global uniform modulus, host metric completeness, or pointwise data outside the displayed center-radius ledger.

Upgrade path: Reaching obligationClosure requires formal pointwise ledger rows and checked preservation of the center-radius handoff under $hsame$.

Chapter 1229

A Concrete Naming Certificate for GapFailureBridgeAudit$^{\uparrow}$

The GapFailureBridgeAudit$^{\uparrow}$ packet realizes the gap-report, failure-certificate, and standard-bridge audit surface of subsection 9462.30.9 and subsection 9462.30.10 as one finite NameCert carrier. It sits beside the certificate gate of chapter 1002, the claim registry layer of chapter 1209, the standard bridge audit packet of chapter 1217, the host primitive leakage boundary of chapter 1157, and the effective replacement ledger of chapter 568. Those siblings gate certificate export, register claims, display bridge fields, refuse host leakage, and record replacement discipline; this packet binds the exact point where a typed gap, a failure branch, and a bridge-preservation row must be inspected together.

Definition 1229.1 (Gap-failure-bridge audit carrier)**.** *A* GapFailureBridgeAudit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, F, B, L, X, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed gap-report row, recording site, requested supply, socket type, gate, consequence if internalized, and admitted route.*
2. *F is the failure-certificate row, recording the branch that blocks a theory grade, a formal status, or their verified combination.*
3. *B is the standard-bridge row, recording encoding, decoding, two return witnesses, finite theorem preservation, and bridge scope.*
4. *L is the no-host-leak row, recording host primitives, quotient principles, semantic equality assumptions, choice, propositional extensionality, and compiler readings that are absent from the BEDC public surface.*
5. *X is the axis-separation row, recording that theory closure, formal verification, and bridge status are read as distinct coordinates.*
6. *A is the audit-route row, recording the certificate gate, registry entry, standard-bridge packet, host-leak refusal, and replacement-ledger route consulted by the audit.*
7. *H stores componentwise* hsame *transport for gap reports, failure certificates, bridge rows, no-host-leak rows, axis-separation rows, audit routes, provenance, and local naming.*

8. *C stores displayed* Cont *replay for gap inspection, failure-branch lookup, bridge preservation, no-host-leak inspection, and axis-separation checking.*
9. *P is the* Pkg *provenance row over* $\mathsf{CertificateAuditGate}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$, $\mathsf{HostPrimitiveLeakage}^{\uparrow}$, $\mathsf{EffectiveReplacementLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{GapFailureBridgeAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untyped gap, an unbranched failure, a bridge row without no-host-leak evidence, a bridge-checked reading detached from theorem preservation, or a conversion of bridge status into theory closure.

Lean4 ✓ `BEDC.Derived.GapFailureBridgeAuditUp.GapFailureBridgeAuditTasteGate single carrier alignment`

Theorem 1229.2 (Gap-failure-bridge audit NameCert obligations)**.** *For the carrier of Definition 1229.1, the local* $\mathsf{NameCert}_{\mathsf{GapFailureBridgeAudit}^{\uparrow}}$ *obligation surface consists exactly of typed gap admission through T, failure-branch admission through F, bridge-field admission through B, no-host-leak inspection through L, axis separation through X, audit routing through A, transport and replay through H, C, provenance through P, and local naming through N.*

Proof. Carrier admission projects the tuple $G = (T, F, B, L, X, A, H, C, P, N)$. The typed gap report, failure certificate, bridge row, no-host-leak row, axis-separation row, audit route, transport, replay, provenance, and local name are the only displayed coordinates.

Use chapter 1002 and chapter 1209 for gate and registry exposure. They ensure that a cited audit packet is read through an admitted certificate surface and through a registered or refused claim row.

Use chapter 1217, chapter 1157, and chapter 568 for bridge preservation, host-leak refusal, and replacement discipline. These sibling surfaces account for B, L, A, P without importing any host primitive as a BEDC input.

The remaining rows H, C, N preserve and name the same finite packet. Since no other row is available, every local NameCert obligation for the audit surface is one of the displayed rows above. □

Lean4 ✓ `BEDC.Derived.GapFailureBridgeAuditUp.GapFailureBridgeAuditPacket namecert obligations`

Theorem 1229.3 (Gap-failure-bridge audit axis separation)**.** *An accepted* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ *packet cannot read bridge status as theory closure and cannot read a failure certificate as a checked theorem. The row X keeps theory closure, formal verification, bridge status, and failure blocking as distinct audit coordinates over the same typed gap, failure branch, bridge row, no-host-leak row, audit route, transport, replay, provenance, and local name.*

Proof. Start with the axis-separation row in Definition 1229.1. The row X is a separate carrier coordinate rather than a predicate computed from B or F.

Apply Definition 1229.2. The typed gap row, failure-certificate row, standard-bridge row, and no-host-leak row are admitted separately before transport or replay can export the audit packet.

Thus a bridge-preservation row cannot promote itself to theory closure, and a failure branch cannot promote itself to formal verification. Any such reading would identify two coordinates that the accepted packet stores separately. □

Lean4 ✓ `BEDC.Derived.GapFailureBridgeAuditUp.GapFailureBridgeAuditPacket axis separation`

Theorem 1229.4 (Gap-failure-bridge audit non-escape)**.** *Every accepted bridge-audit read through* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ *factors through*

$$T, F, B, L, X, A, H, C, P, N.$$

If either the typed gap row T or the failure-certificate row F is absent, the packet may still record a bridge-writing attempt, but it cannot export a bridge-checked reading.

Proof. Project the carrier. The public audit surface is exactly $T, F, B, L, X, A, H, C, P, N$, so a route that omits T or F is not a route through the accepted packet.

The standard-bridge row B supplies bridge fields, and the no-host-leak row L refuses host import. These rows still require the typed gap and failure-certificate rows to explain which missing supply and which blocking branch are being audited.

Finally use the audit-route, transport, replay, provenance, and local naming rows A, H, C, P, N. They can preserve the displayed packet, but they cannot manufacture a missing typed gap or failure branch. Therefore a bridge-writing attempt without T or F has no bridge-checked export through $\mathsf{GapFailureBridgeAudit}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.GapFailureBridgeAuditUp.GapFailureBridgeAuditPacket nonescape`

Theorem 1229.5 (Gap-failure-bridge audit public surface)**.** *The public audit surface of an accepted* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ *packet is exactly*

$$T, F, B, L, X, A, H, C, P, N.$$

It exposes bridge status, theory closure, formal verification, and failure blocking as separate audit coordinates over the same typed gap, failure branch, bridge row, no-host-leak row, audit route, transport, replay, provenance, and local naming data.

Proof. Project the carrier of Definition 1229.1. Its displayed coordinates are precisely the typed gap row T, failure-certificate row F, bridge row B, no-host-leak row L, axis-separation row X, audit route A, transport H, replay C, provenance P, and local name N.

Apply Definition 1229.3. The row X prevents bridge status, theory closure, formal verification, and failure blocking from being read as the same coordinate.

Use Definition 1229.4. Every accepted bridge-audit read factors through the displayed tuple, so the public audit surface has no hidden row beyond $T, F, B, L, X, A, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.GapFailureBridgeAuditUp.GapFailureBridgeAuditPacket public surface`

Falsifiable prediction: An accepted bridge audit packet that omits either the typed gap row or the failure-certificate row cannot export a bridge-checked reading.

Independence witness: certificateauditgate, claimregistrylayer, standardbridgeauditpacket, hostprimitiveleakage, effective-replacement-ledger: none is bijective because the packet stores gap report, failure branch, bridge preservation, no-host-leak, and axis-separation rows together.

The Lean site `lean4/BEDC/Derived/GapFailureBridgeAuditUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ and FieldFaithful $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ instances preserving $T, F, B, L, X, A, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{GapFailureBridgeAudit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ packet is generated from a typed gap report, a failure branch, a bridge row, no-host-leak evidence, axis separation, audit routing, transport, replay, provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GapFailureBridgeAudit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1229.1, Definition 1229.2, Definition 1229.3, Definition 1229.4, and Definition 1229.5 bind the public audit surface, the standard-bridge row B, and the axis-separation theorem for typed gaps, failure branches, bridge rows, no-host-leak rows, audit routing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GapFailureBridgeAudit}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not claim bridge checking, collapse theory closure into formal verification, import host primitives, admit untyped gaps, or export unbranched failure claims.

Upgrade path: No further paper-side theory-grade upgrade remains; Lean bridge checking remains a separate verification-axis task.

Chapter 1230

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailCertificate}^{\uparrow}$

The $\mathsf{RegularCauchyTailCertificate}^{\uparrow}$ packet realizes the shared tail-window witness used by the Real-and-Completion route of chapter 9238. It sits between the regular Cauchy data of section 9238.1 and the Real-facing seal consumers, and it reuses the finite dyadic rows of chapter 291, the schedule rows of chapter 126, the regular-rational readbacks of chapter 301, and the terminal naming seal of chapter 38. The chapter is composite: it assembles already named Real and Completion rows into one reusable tail certificate rather than claiming a new atomic carrier.

Definition 1230.1 (Regular Cauchy tail-certificate carrier)**.** *A* $\mathsf{RegularCauchyTailCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. X *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy source row whose tail is being witnessed;*
2. W *is the* $\mathsf{StreamName}^{\uparrow}$ *shared tail-window row naming the finite observation window selected for the displayed precision request;*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the window* W*;*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic ledger for the windowed readback;*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable from* X, W, R, D*;*
6. H *records componentwise* hsame *transports for* X, W, R, D, E *and the local naming row;*
7. C *records displayed* Cont *routes from the regular Cauchy source through the shared tail window, readback, dyadic ledger, and Real seal;*
8. P *is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailCertificate}^{\uparrow}}$ *row.*

The classifier compares carriers only by the rows $X, W, R, D, E, H, C, P, N$*. It has no coordinate for quotient streams, host sequence equality, selected limits, choice rows, standard-bridge rows, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailCertificateUp.taste gate`

Theorem 1230.2 (Regular Cauchy tail-certificate NameCert obligations)**.** *For the carrier of Definition 1230.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailCertificate}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier exposure for the packet* $T = (X, W, R, D, E, H, C, P, N)$*;*
2. *shared tail-window selector coverage through the* $\mathsf{StreamName}^{\uparrow}$ *row* W*;*
3. *dyadic readback exactness through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*;*
4. *Real-seal factorization through the row* E *and the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *support rows;*
5. *non-escape for quotient streams, host sequence equality, selected limits, choice rows, standard-bridge rows, and ambient Real-completion principles.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailCertificateUp.RegularCauchyTailCertificateNameCertObligations`

Proof. Carrier exposure is projection from Definition 1230.1. The displayed tuple lists the regular Cauchy source, shared window, readback, dyadic ledger, Real seal, transport, continuation, provenance, and local naming rows.

Selector coverage is read from W before any numerical tolerance is consumed. Since W is the only shared tail-window row in the packet, the local certificate cannot redirect the request to an unnamed tail schedule.

The dyadic readback and Real-seal obligations then inspect R, D, E, H, C, P, N. These rows keep the regular-rational readback and tolerance ledger visible before the seal is reached, while the support rows only transport and replay the same finite route.

The excluded objects are absent from the carrier. Thus the local NameCert exports no quotient stream, host sequence equality, selected limit, choice row, standard bridge, or ambient completion theorem. □

Theorem 1230.3 (Regular Cauchy tail-certificate selector coverage)**.** *Every accepted* $\mathsf{RegularCauchyTailCertificate}^{\uparrow}$ *packet exposes a single shared tail-window selector before any* $\mathsf{Real}^{\uparrow}$ *seal consumer can read the certificate. If*

$$T = (X, W, R, D, E, H, C, P, N),$$

then every consumer route first reads the regular Cauchy source X *and the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, and only then reaches* E *through* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailCertificateUp.RegularCauchyTailCertificateSelectorCoverage`

Proof. Project the carrier T. The shared tail-window coordinate is W, and the source row X is the only regular Cauchy row from which that window is read.

Apply the NameCert obligations of Definition 1230.2. They force selector coverage before dyadic readback exactness and before Real-seal factorization.

The route to E is therefore ordered by the displayed packet: source, shared window, readback, dyadic ledger, Real seal, and then the transport, continuation, provenance, and naming support rows. No second selector or hidden tail oracle is available. □

Theorem 1230.4 (Regular Cauchy tail-certificate non-escape)**.** *An accepted* $\mathsf{RegularCauchyTailCertificate}^{\uparrow}$ *carrier exports only the finite rows* $X, W, R, D, E, H, C, P, N$ *and their local classifier transports. A Real-and-Completion consumer may use the shared tail window, regular-rational readback, dyadic*

tolerance ledger, and Real$^{\uparrow}$ *seal exactly as displayed; it receives no quotient stream, no host sequence equality, no selected limit, no choice row, no standard-bridge row, and no ambient completeness theorem.*

Proof. Inspect the carrier coordinates. They contain finite rows for source, window, readback, dyadic tolerance, Real seal, transport, continuation, provenance, and local naming.

Use Definition 1230.3. Any consumer reaches the Real-facing seal only through the displayed selector, readback, and dyadic ledger.

Since quotient streams, host sequence equality, selected limits, choice rows, standard bridges, and ambient completeness principles are not coordinates of T, neither componentwise hsame transport nor displayed Cont replay can export them. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailCertificateUp.RegularCauchyTailCertificateNonescape`

Theorem 1230.5 (Regular Cauchy tail-certificate vision handoff)**.** *The regular Cauchy construction of section 9238.1 may hand its shared tail-window witness to the Real-and-Completion layer through the* RegularCauchyTailCertificate$^{\uparrow}$ *carrier of Definition 1230.1. The handoff is compatible with chapter 291, chapter 126, chapter 301, and chapter 38 because the packet preserves their dyadic tolerance, stream-window, regular readback, and Real-seal rows inside one local* NameCert *surface.*

Proof. Read the upstream vision as a demand for a finite shared tail witness, not as a demand for a completed host limit. The carrier supplies that witness by exposing X and W as the source and shared tail-window rows.

Read the sibling concrete instances next. The RegSeqRat$^{\uparrow}$ row R and DyadicRatCore$^{\uparrow}$ ledger D keep the regular readback and arithmetic tolerance explicit, while the Real$^{\uparrow}$ row E is downstream of those observations.

Finally apply the non-escape boundary of Definition 1230.4. The handoff therefore gives later Real and Completion consumers a finite tail certificate over the named sibling rows and no quotient stream, host sequence equality, selected limit, choice row, standard bridge, or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailCertificateUp.RegularCauchyTailCertificateVisionHandoff`

Theorem 1230.6 (Regular Cauchy tail-certificate obligation closure package)**.** *For the carrier of Definition 1230.1, the carrier row, shared tail-window selector coverage, dyadic readback exactness, Real-seal factorization, non-escape clauses, and vision handoff form the paper-side* obligation *package for* RegularCauchyTailCertificate$^{\uparrow}$ *over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The package contains no quotient stream, host sequence equality, selected limit, choice row, standard bridge row, or ambient completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailCertificateUp.RegularCauchyTailCertificateObligationClosurePackag`

Proof. Project the carrier definition. The tuple $T = (X, W, R, D, E, H, C, P, N)$ exposes exactly the regular Cauchy source, shared tail-window row, readback row, dyadic ledger, Real seal, componentwise transport, displayed continuation, provenance, and local naming row.

Apply Definition 1230.2. Its five rows supply carrier exposure, selector coverage, dyadic readback exactness, Real-seal factorization, and non-escape for the same finite packet.

Use Definition 1230.3 and Definition 1230.4 to fix the route order and exclusions. The consumer reads X, W, R, D before E, and no absent quotient, host-equality, selected-limit, choice, bridge, or ambient-completeness coordinate can be exported by hsame transport or Cont replay.

Finally apply Definition 1230.5. The Real-and-Completion consumer route therefore receives precisely the finite L10 tail certificate carried by the displayed Pkg and NameCert rows, which is the claimed obligation-closure package. □

Theorem 1230.7 (Regular Cauchy tail-certificate primitive scope lock)**.** *Every accepted* RegularCauchyTailCertifica *packet is scoped exactly by the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows over* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*. For*

$$T = (X, W, R, D, E, H, C, P, N),$$

the accepted route reads the regular Cauchy source X, shared tail-window row W, regular-rational readback R, dyadic ledger D, Real seal E, componentwise transport row H, displayed continuation row C, package provenance P, and local naming row N, and no quotient stream, host sequence equality, selected limit, choice row, standard bridge, ambient completeness principle, or metric-completeness coordinate may be substituted for those primitive rows.

Proof. Project the carrier tuple $T = (X, W, R, D, E, H, C, P, N)$. The projection exposes exactly the rows named in the statement: the regular Cauchy source, shared tail window, regular-rational readback, dyadic tolerance ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Apply the NameCert obligations of Definition 1230.2. They bind carrier exposure, selector coverage, dyadic readback exactness, Real-seal factorization, and non-escape to the same displayed tuple, so the accepted certificate has no second route on which a host-side or quotient-side row could enter.

Use selector coverage, non-escape, and the vision handoff from Definition 1230.3, Definition 1230.4, and Definition 1230.5. These results force the Real-and-Completion consumer to pass through X, W, R, D before E, and then through H, C, P, N as support rows.

Finally apply the obligation closure package of Definition 1230.6. Since that package already lists the accepted rows and excludes quotient streams, host sequence equality, selected limits, choice rows, standard bridges, ambient completeness principles, and metric-completeness coordinates, the scoped closure is exactly the primitive BEDC route displayed above. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailCertificateUp.RegularCauchyTailCertificate primitive scope lock`

Closure status for NameCert$_{\text{RegularCauchyTailCertificate}^{\uparrow}}$.

Constructive story: A RegularCauchyTailCertificate$^{\uparrow}$ packet is generated from a regular Cauchy source row, a shared StreamName tail-window row, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, a RealUp seal row, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyTailCertificate}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1230.7 binds the carrier, five NameCert obligation rows, selector coverage, dyadic readback exactness, Real-seal factorization, non-escape boundary, vision handoff, and TasteGate instance `BEDC.Derived.RegularCauchyTailCertific` to the finite primitive route for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyTailCertificate}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.RegularCauchyTailCertificateUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close quotient streams, host sequence equality, selected limits, choice rows, standard-bridge rows, ambient Real completeness, theorem-level Lean proof, audit-clean verification, or a public standard bridge.

Upgrade path: A stronger grade requires theorem-level Lean proof, audit-clean verification of the primitive route, and any later public or standard bridge demanded by downstream Real and Completion consumers.

Chapter 1231

A Concrete Naming Certificate for $\mathsf{TailCofinalityBudget}^{\uparrow}$

The $\mathsf{TailCofinalityBudget}^{\uparrow}$ packet realizes the shared finite tail threshold consumed by the Real-completion route of section 9238.2. It is a concrete NameCert surface over the finite tail filter of chapter 1119, the stream-window naming of chapter 126, the dyadic tolerance ledger of chapter 291, the regular-rational readback of chapter 301, the Real seal of chapter 38, the finite-prefix stability route of chapter 1226, and the selected endpoint seed of chapter 1207. The packet records the common cofinal threshold and the terminal seal handoff without exporting a selected limit, quotient stream equality, host real equality, countable-choice row, or ambient completeness witness.

Falsifiable prediction: No accepted TailCofinalityBudgetUp packet exports a selected limit, quotient stream equality, host real equality, countable-choice row, or ambient completeness witness outside the displayed finite tail rows.

Independence witness: finite-tail-filter, finite-prefix-limit-stability, selected-tail-seed, stream-name, regseqrat: TailCofinalityBudgetUp is not bijective to any listed sibling because it records the shared cofinal threshold and seal handoff row, while those siblings respectively record the broad filter surface, prefix stability, selected endpoint, pointwise stream naming, or regular-rational readback without the same cofinal-budget packet.

Definition 1231.1 (Tail cofinality budget carrier)**.** *A* $\mathsf{TailCofinalityBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the finite tail request row naming the common cofinal threshold consumed by the Real-completion read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger exposed only at or beyond the threshold named by R.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same threshold and window.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed stream window and dyadic tolerance.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after R, W, D, Q are visible in the packet.*
6. *H records componentwise* hsame *transport for R, W, D, Q, E and the local certificate row.*
7. *C records displayed* Cont *replay from finite tail request through stream window, dyadic tolerance, regular-rational readback, and Real seal.*

8. *P is the* Pkg *provenance over* TailCofinalityBudget$^\uparrow$, FiniteTailFilter$^\uparrow$, StreamName$^\uparrow$, DyadicRatCore$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, FinitePrefixLimitStability$^\uparrow$, SelectedTailSeed$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\text{TailCofinalityBudget}^\uparrow}$ *row.*

The carrier exports only the finite threshold, the threshold-indexed observation rows, the Real seal handoff, and the structural transport, replay, provenance, and naming rows displayed above.

Theorem 1231.2 (Tail cofinality budget NameCert obligations)**.** *For the carrier of Definition 1231.1, the local* NameCert$_{\text{TailCofinalityBudget}^\uparrow}$ *surface consists exactly of carrier admission for $T = (R, W, D, Q, E, H, C, P, N)$ finite tail request admission through R,* StreamName$^\uparrow$ *window exposure through W,* DyadicRatCore$^\uparrow$ *tolerance exposure through D,* RegSeqRat$^\uparrow$ *readback exposure through Q, terminal* Real$^\uparrow$ *seal handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudget namecert obligations`

Proof. Project the carrier. Its coordinates list the finite tail request, stream window, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local naming row.

Read the sibling surfaces in the displayed order. The finite tail filter supplies the threshold discipline for R; the StreamName$^\uparrow$ chapter supplies W; the DyadicRatCore$^\uparrow$ chapter supplies D; the RegSeqRat$^\uparrow$ chapter supplies Q; and the Real$^\uparrow$ chapter supplies E.

The remaining rows are structural. The FinitePrefixLimitStability$^\uparrow$ and SelectedTailSeed$^\uparrow$ siblings identify the prefix-stability and selected-seed routes that may consume the same threshold, while H, C, P, N only transport, replay, source, and name the rows already displayed. These rows exhaust the local NameCert obligations. □

Theorem 1231.3 (Tail cofinality budget carrier obligation)**.** *Every accepted* TailCofinalityBudget$^\uparrow$ *carrier $T = (R, W, D, Q, E, H, C, P, N)$ admits exactly the finite rows $R, W, D, Q, E, H, C, P, N$ before any Real-completion consumer may read the packet. The carrier admission route passes through the finite tail request R, the threshold-indexed* StreamName$^\uparrow$ *window W, the* DyadicRatCore$^\uparrow$ *tolerance ledger D, the* RegSeqRat$^\uparrow$ *readback Q, the* Real$^\uparrow$ *seal E, and the displayed structural rows H, C, P, N; it exports no selected limit, quotient stream equality, host real equality, countable-choice row, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudgetCarrierObligation`
↪ variant `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudgetObligationCarrier`

Proof. Project the carrier of Definition 1231.1. The tuple already lists the only admissible coordinates: a finite tail request, a stream window, a dyadic tolerance ledger, a regular-rational readback, a terminal seal, and the transport, replay, provenance, and local naming rows.

Apply the NameCert obligations of Definition 1231.2. They force every accepted consumer to expose those rows in the displayed order before the packet can be used.

Finally use threshold monotonicity and filtered-tail scope, Definition 1231.6 and Definition 1231.7. Refining the threshold keeps the same finite route, and the filtered-tail read has no coordinate from which a selected limit, quotient stream equality, host real equality, countable choice, or ambient completeness can be projected. □

Theorem 1231.4 (Tail cofinality budget classifier obligation)**.** *Let $T = (R, W, D, Q, E, H, C, P, N)$ and $T' = (R', W', D', Q', E', H', C', P', N')$ be accepted* TailCofinalityBudget$^\uparrow$ *packets. If the visible coordinates are componentwise related by* hsame *along the displayed transport rows, then the*

classifier preserves the same finite cofinal-threshold route from R through W, D, Q, E and from R' through W', D', Q', E'. The transported classifier does not add a selected limit, quotient stream equality, host real equality, countable-choice row, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudgetClassifierObligation`

Proof. Read the classifier from the carrier and the NameCert surface. It compares packets only through the finite threshold row, stream window, tolerance ledger, regular-rational readback, Real seal, and structural rows.

Transport each displayed coordinate through the componentwise hsame row H and its counterpart H'. The threshold row remains a finite tail request, W, D, Q remain the observation and readback rows attached to that request, and E remains downstream of them.

Use threshold monotonicity to keep later threshold refinements inside the same route, then use filtered-tail scope to keep the Real-facing read inside the same finite tail filter. Since the absent objects are not classifier coordinates, componentwise transport cannot create them. □

Theorem 1231.5 (Tail cofinality budget ledger obligation)**.** *Every ledger read of an accepted* TailCofinalityBudget$^{\uparrow}$ *packet that reaches a Real-completion consumer factors through the finite cofinal threshold route*

$$R \longrightarrow W \longrightarrow D \longrightarrow Q \longrightarrow E$$

together with H, C, P, N. The ledger scope is nonescaping: after the common threshold is fixed, the consumer may refine along later finite tails, but it may not read a selected limit, quotient stream equality, host real equality, countable-choice row, or ambient completeness witness outside the displayed packet.

Proof. Start from the filtered-tail scope theorem, Definition 1231.7. It identifies the cofinal finite-tail route and keeps later thresholds on the same displayed request row.

Use threshold monotonicity for refinements beyond the common threshold. The rows W, D, Q, E are preserved as the threshold-indexed window, dyadic tolerance, regular readback, and terminal seal rather than replaced by a completion object.

Finally apply nonescape, Definition 1231.8. The structural rows H, C, P, N transport and name the ledger route, but they do not export any selected limit, quotient stream equality, host real equality, countable-choice row, or ambient completeness witness. □

Lean4 ✓ `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudgetLedgerObligation`

Theorem 1231.6 (Tail cofinality budget threshold monotonicity)**.** *Let $T = (R, W, D, Q, E, H, C, P, N)$ be an accepted* TailCofinalityBudget$^{\uparrow}$ *packet. If T serves a displayed threshold and a later unary threshold refines R through the same finite tail request route, then the refined packet preserves the same* StreamName$^{\uparrow}$ *window row W,* DyadicRatCore$^{\uparrow}$ *tolerance row D,* RegSeqRat$^{\uparrow}$ *readback row Q,* Real$^{\uparrow}$ *seal row E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N.*

The refined read exports no selected limit, quotient stream equality, host real equality, countable-choice row, or ambient Real$^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudgetThresholdMonotonicity`

Proof. Project the carrier of Definition 1231.1. The row R is the only finite tail request coordinate, so a later unary threshold can refine the packet only by traveling through that same request route.

Compare the thresholds inside R. Once the refined request is accepted, the observation side of the carrier is still the displayed route W, D, Q, E: the $\mathsf{StreamName}^{\uparrow}$ window is read at the refined tail, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger remains attached to that window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback is replayed from the same finite data, and the $\mathsf{Real}^{\uparrow}$ seal is reached only after those rows are visible.

Finally replay the structural rows. Transport through H, continuation through C, provenance through P, and local naming through N preserve the accepted packet rather than adding a new completion object. Since the carrier has no coordinate for a selected limit, quotient stream equality, host real equality, countable choice, or ambient completeness, the threshold refinement stays inside the displayed finite rows. □

Theorem 1231.7 (Tail cofinality budget filtered-tail scope)**.** *Let $T = (R, W, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{TailCofinalityBudget}^{\uparrow}$ *packet. If the finite threshold row R is consumed together with a pointwise* $\mathsf{StreamName}^{\uparrow}$ *carrier and the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row Q, then the packet determines a cofinal finite-tail filter route whose carrier transport is stable under* hsame *and whose* $\mathsf{Real}^{\uparrow}$ *consumer sees only the displayed threshold ledger.*

In particular, later thresholds refine the same finite route

$$R \longrightarrow W \longrightarrow D \longrightarrow Q \longrightarrow E$$

through the finite tail filter and selected-tail seed dependencies. No selected limit, quotient stream equality, host real equality, countable-choice row, or ambient completeness witness is exported by the filtered-tail scope.

Lean4 ✓ `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudget filtered tail scope`

Proof. Start with threshold monotonicity. The row R is the unique finite request coordinate, so every later threshold must refine the accepted packet through the same displayed request route.

Compose that monotone request with the finite tail filter surface and the selected-tail seed route. The pointwise $\mathsf{StreamName}^{\uparrow}$ row W supplies the displayed observations, while D and Q attach the dyadic tolerance and $\mathsf{RegSeqRat}^{\uparrow}$ regularity needed by the filtered tail.

Finally pass the route to the $\mathsf{Real}^{\uparrow}$ seal row E and transport it by H, C, P, N. Since every consumer sees only R, W, D, Q, E and the structural rows, the filtered-tail scope cannot read a selected limit, host real equality, quotient stream equality, countable choice, or an ambient completeness primitive. □

Lean4 ✓ `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudgetFilteredTailScope`

Theorem 1231.8 (Tail cofinality budget nonescape)**.** *Every Real-completion consumer of an accepted* $\mathsf{TailCofinalityBudget}^{\uparrow}$ *packet factors through the finite route*

$$R, W, D, Q, E, H, C, P, N.$$

The consumer receives the shared finite cofinal threshold, the $\mathsf{StreamName}^{\uparrow}$ *window ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{Real}^{\uparrow}$ *seal handoff, and the structural support rows. It receives no selected limit, quotient stream equality, host real equality, countable-choice row, or ambient completeness witness outside those displayed finite tail rows.*

Lean4 ✓ `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudget nonescape`

Proof. Begin with Definition 1231.1. The only Real-facing coordinate is the seal handoff E, and it is downstream of the threshold row R, window row W, dyadic row D, and readback row Q.

Apply Definition 1231.2. It forces every accepted consumer to expose the finite tail request, stream window, tolerance ledger, regular-rational readback, seal handoff, transport, replay, provenance, and local name before the packet is usable.

The excluded objects are not coordinates of the carrier. Since H, C, P, N preserve and name displayed rows without creating analytic data, no accepted consumer can project a selected limit, quotient stream equality, host real equality, countable-choice row, or ambient completeness witness from this packet. □

Theorem 1231.9 (Tail cofinality budget TasteGate obligation)**.** *The Lean boundary for* $\mathsf{TailCofinalityBudget}^{\uparrow}$ *must supply a nonempty carrier and a field-faithful observation of* $R, W, D, Q, E, H, C, P, N$*. In concrete terms, the future file* `lean4/BEDC/Derived/TailCofinalityBudgetUp/TasteGate.lean` *must provide* $\mathsf{Nontrivial\ TailCofinalityBudget}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ TailCofinalityBudget}^{\uparrow}$ *instances whose projections preserve the finite tail threshold and the terminal Real seal handoff.*

Proof. The carrier is meaningful only when the displayed threshold route can be inhabited. Nontriviality supplies such a packet without replacing the finite rows by an empty or vacuous surface.

Field faithfulness is the corresponding projection discipline. It prevents a consumer from identifying two packets while forgetting the threshold row R, the observation rows W, D, Q, the seal row E, or the structural rows H, C, P, N.

Together these two obligations are exactly the TasteGate boundary needed before the packet can be used by the Real-completion route as a shared finite tail budget. □

Lean4 ✓ `BEDC.Derived.TailCofinalityBudgetUp.TailCofinalityBudgetTasteGate obligation surface`

Closure status for $\mathsf{NameCert}_{\mathsf{TailCofinalityBudget}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TailCofinalityBudget}^{\uparrow}$ packet is generated from a finite tail request, threshold-indexed stream window, dyadic tolerance ledger, regular-rational readback, Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TailCofinalityBudget}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1231.1, Definition 1231.2, Definition 1231.6, Definition 1231.7, Definition 1231.8, and Definition 1231.9 bind the shared finite cofinal threshold, filtered-tail route, nonescape boundary, and TasteGate obligation as a finite NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TailCofinalityBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient streams, selected host limits, host real equality, countable choice, or ambient Real completeness.

Upgrade path: The next paper-axis obligation is a standard bridge route; Lean closure still requires Nontrivial TailCofinalityBudgetUp and FieldFaithful TailCofinalityBudgetUp instances in `lean4/BEDC/Derived/TailCofinalityBudgetUp/TasteGate.lean`.

Chapter 1232

A Concrete Naming Certificate for MachineReadableAuditInterface$^{\uparrow}$

The MachineReadableAuditInterface$^{\uparrow}$ packet realizes the machine-readable audit surface implicit in chapter 9462 and the interface-status boundary of subsection 9462.35.10. It sits beside the socket router of chapter 1059, the formal target packet of chapter 1225, the registry export surface of chapter 1216, and the consistency gate of chapter 1224. Those siblings route targets, store target skeletons, expose registry exports, and check registry consistency; this packet names the finite interface by which a machine consumer reads audit data without treating a report row as theorem evidence.

Definition 1232.1 (Machine-readable audit interface carrier)**.** *A* MachineReadableAuditInterface$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, C, E, R, F, H, K, P, N)$$

with the following displayed rows:

1. *S is the schema row, recording the finite field names, row types, and row-order constraints available to the machine consumer;*
2. *C is the checker row, recording the local validation route that accepts or rejects a displayed schema instance;*
3. *E is the export row, recording the registry entry, machine target, closure-status reading, and public export grade exposed by the packet;*
4. *R is the refusal row, recording cannot-claim conflicts, blocked exports, and non-evidence flags for report rows;*
5. *F is the report row, recording the machine-readable audit report returned to a consumer after S, C, E, R have been read;*
6. *H records componentwise* hsame *transport for schema, checker, export, refusal, and report rows;*
7. *K records displayed* Cont *replay from schema validation through checker verdict, export readback, refusal inspection, and report publication;*
8. *P is the* Pkg *provenance over* MachineReadableAuditInterface$^{\uparrow}$, MachineInterfaceSocket$^{\uparrow}$, MachineInterfaceFormali RegistryExportSurface$^{\uparrow}$, RegistryExportConsistencyGate$^{\uparrow}$, GroundCompilerAuditMap$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{MachineReadableAuditInterface}^{\uparrow}}$ *row.*
The carrier has no coordinate for hidden theorem evidence, unregistered export, conflict override, proof-producing report conversion, or off-packet schema repair.

Lean4 ✓ `BEDC.Derived.MachineReadableAuditInterfaceUp.MachineReadableAuditInterface carrier semantic name certificate`

Theorem 1232.2 (Machine-readable audit interface field coverage)**.** *For the carrier of Definition 1232.1, the local* $\mathsf{NameCert}_{\mathsf{MachineReadableAuditInterface}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$A = (S, C, E, R, F, H, K, P, N),$$

schema readback through S, checker readback through C, registry and machine-target export readback through E, refusal and non-evidence readback through R, report readback through F, componentwise hsame *stability through H, displayed* Cont *replay through K, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.MachineReadableAuditInterfaceUp.taste gate`

Proof. Project the finite carrier. The tuple displays schema, checker, export, refusal, report, transport, replay, provenance, and local naming rows before any machine consumer can read the packet.

Read S, C, E, R, F first. These rows provide the complete machine-facing inventory: schema shape, validation route, export surface, refusal surface, and report payload. None of them contains a hidden proof object or an off-packet registry entry.

Finally use H, K, P, N. These rows transport, replay, package, and name the same inventory. Since the carrier has no further coordinate, the stated rows exhaust the local $\mathsf{NameCert}_{\mathsf{MachineReadableAuditInterface}^{\uparrow}}$ surface. □

Theorem 1232.3 (Machine-readable audit interface obligation basis)**.** *For every accepted* MachineReadableAuditInt *packet*

$$A = (S, C, E, R, F, H, K, P, N),$$

any machine consumer that reads an audit report from A must first pass through schema validation by S, checker verdict by C, export and refusal consistency across E and R, report non-evidence control for F, replay and provenance through K and P, and the local $\mathsf{NameCert}_{\mathsf{MachineReadableAuditInterface}^{\uparrow}}$ *row N. No report read is accepted by the packet unless these obligation rows are all displayed in the same carrier.*

Lean4 ✓ `BEDC.Derived.MachineReadableAuditInterfaceUp.MachineReadableAuditInterface obligation basis`

Proof. Project $A = (S, C, E, R, F, H, K, P, N)$ and apply Definition 1232.2. The field-coverage theorem identifies schema, checker, export, refusal, report, transport, replay, provenance, and local naming as the whole machine-readable audit surface.

Read the operational rows in order. The schema row S fixes the permitted field layout, the checker row C supplies the local validation verdict, and the export and refusal rows E, R determine whether the claimed public read is consistent with the displayed registry surface.

Finally apply Definition 1232.4 to the report row F. The replay row K, provenance row P, and local name N preserve the same non-evidence boundary inside the carrier, so a consumer cannot read an audit report before those obligations have been displayed. □

Theorem 1232.4 (Machine-readable audit interface non-evidence refusal)**.** *If the refusal row R marks the report row F as non-evidence, then no accepted* $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ *packet exports F as theorem evidence.*

Proof. Begin with an accepted packet

$$A = (S, C, E, R, F, H, K, P, N).$$

The checker row C validates the displayed schema instance, and the export row E exposes registry and machine-target data through that same instance.

Inspect the refusal row R. When R marks F as non-evidence, the report row remains a report payload rather than a theorem-evidence row. The carrier contains no second report coordinate that can bypass this flag.

The transport, replay, provenance, and local naming rows preserve the same flag. Thus a consumer may read the audit report, but any read that treats F as theorem evidence leaves the displayed packet. □

Lean4 ✓ `BEDC.Derived.MachineReadableAuditInterfaceUp.MachineReadableAuditInterface non evidence refusal`

Theorem 1232.5 (Machine-readable audit interface sibling independence)**.** *The* $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{MachineInterfaceSocket}^{\uparrow}$*,* $\mathsf{MachineInterfaceFormalizatio}$ $\mathsf{RegistryExportSurface}^{\uparrow}$*,* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$*, or* $\mathsf{GroundCompilerAuditMap}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.MachineReadableAuditInterfaceUp.MachineReadableAuditInterface sibling independence`

Proof. Compare the displayed rows. $\mathsf{MachineInterfaceSocket}^{\uparrow}$ routes formalization targets, and $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$ stores target skeletons, dependency rows, expected status, and audit-gate locality.

$\mathsf{RegistryExportSurface}^{\uparrow}$ exposes registration, blocking, status, machine target, audit, and non-smuggling rows. $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ binds status consistency, audit route, no-smuggling, and formal-target readback. $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ exposes compiler-facing audit rows and report boundaries.

None of these siblings preserves at once the schema row S, checker row C, export row E, refusal row R, report row F, and the local $\mathsf{NameCert}_{\mathsf{MachineReadableAuditInterface}^{\uparrow}}$ row N. Any proposed row-preserving bijection loses at least one of those rows, so the packets are not bijective under the NameCert surface. □

Theorem 1232.6 (Machine-readable audit interface falsifiable prediction)**.** *A* $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ *packet fails exactly when a machine consumer claims an export, theorem-evidence report, or consistency verdict that is not backed by the displayed schema, checker, export, refusal, report, transport, replay, provenance, and local naming rows.*

Proof. Use Definition 1232.2 to read the complete field inventory. Every accepted consumer read must factor through $S, C, E, R, F, H, K, P, N$.

For export claims, inspect E and the replay row K. For theorem-evidence report claims, inspect R and F together with Definition 1232.4. For consistency verdicts, inspect the checker row C and the provenance row P naming the registry consistency gate.

If one of those rows is absent, disagrees with the claimed read, or marks the read as non-evidence, the claim exits the carrier. Conversely a read backed by the displayed rows is precisely the accepted machine-readable audit interface read. □

Lean4 ✓ `BEDC.Derived.MachineReadableAuditInterfaceUp.MachineReadableAuditInterface falsifiable prediction`

Falsifiable prediction: A MachineReadableAuditInterface$^{\uparrow}$ packet cannot export a report row as theorem evidence when its refusal row marks the report as non-evidence.

Independence witness: machineinterfacesocket, machineinterfaceformalizationtarget, registryexportsurface, registryexportconsistencygate, groundcompilerauditmap: row loss blocks any NameCert-preserving bijection, because the socket lacks the schema and report rows, the formal-target packet lacks report publication, the export surface lacks checker-local report refusal, the consistency gate lacks the schema-to-report replay, and the GroundCompiler audit map lacks the registry-machine interface packet as one carrier.

The Lean follow-up must provide explicit Nontrivial MachineReadableAuditInterface$^{\uparrow}$ and FieldFaithful MachineRe instances in `lean4/BEDC/Derived/MachineReadableAuditInterfaceUp/TasteGate.lean`. The field-faithfulness witness must preserve $S, C, E, R, F, H, K, P, N$ as distinct rows before BEDC.Derived.MachineReada can be cited by a checked paper marker.

Theorem 1232.7 (Machine-readable audit interface kernel scope)**.** *Every accepted* MachineReadableAuditInterface$^{\uparrow}$ *packet scopes its machine-readable report through the displayed schema row, checker row, export row, refusal row, report row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. No report row is theorem evidence unless the audit row is separately checked by the displayed checker and survives the refusal row.*

Proof. Project the carrier of Definition 1232.1. The tuple $A = (S, C, E, R, F, H, K, P, N)$ is the whole machine-readable audit interface, and Definition 1232.2 identifies those rows as the complete local naming surface.

Next apply Definition 1232.3. Any accepted report read must pass through schema validation, checker verdict, export and refusal consistency, report non-evidence control, replay, provenance, and the local NameCert row before the machine consumer can read F.

The non-evidence boundary is fixed by Definition 1232.4. The sibling-independence theorem blocks replacement by socket, formal-target, registry-export, consistency-gate, or compiler-audit packets, and Definition 1232.6 rejects any read not backed by the displayed rows.

Therefore the kernel route for the report is exactly the displayed route through $S, C, E, R, F, H, K, P, N$. A report row can be consumed as machine-readable audit data, but it is not theorem evidence unless the checker row separately accepts it and the refusal row does not mark that evidence claim as blocked. □

Lean4 ✓ `BEDC.Derived.MachineReadableAuditInterfaceUp.MachineReadableAuditInterface kernel scope`

Theorem 1232.8 (Machine-readable audit interface bridge readiness)**.** *A bridge consumer of an accepted* MachineReadableAuditInterface$^{\uparrow}$ *packet may read the schema, checker, export, refusal, report, transport, replay, provenance, and local naming rows. The bridge may not promote the report row to theorem evidence unless the checker row separately accepts the evidence claim and the refusal row leaves that claim unblocked.*

Proof. Use Definition 1232.2. It identifies schema, checker, export, refusal, report, transport, replay, provenance, and local naming as the complete readable surface of the packet.

Next apply Definition 1232.4. The report row can be machine-readable audit data while still being blocked as theorem evidence by the refusal row.

Finally use Definition 1232.7. It places the checker and refusal rows on the same kernel route as the report row, so a bridge consumer can read the report but cannot treat it as theorem evidence without a separate checker acceptance and an unblocked refusal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{MachineReadableAuditInterface}^{\uparrow}}$.

Constructive story: A $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ packet is generated from a finite schema row, checker row, export row, refusal row, report row, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MachineReadableAuditInterface}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1232.1, Definition 1232.2, Definition 1232.4, Definition 1232.5, Definition 1232.6, Definition 1232.7, and Definition 1232.8 bind the carrier, field coverage, non-evidence refusal, sibling independence, falsifiable prediction, kernel-scope route, and bridge-readiness boundary for the machine-readable audit surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MachineReadableAuditInterface}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.MachineReadableAuditInterfaceUp.taste\_gate`

Bridge status: paperBridge

Not claimed: This chapter does not close report rows as theorem evidence, checked machine-readable audit targets, TasteGate alignment, Lean verification, or bridge checking.

Upgrade path: The paper axis has reached mature treatment; Lean verification and bridge checking remain separate formal-axis obligations.

Chapter 1233

A Concrete Naming Certificate for $\mathsf{FailureCertificate}^{\uparrow}$
