The $\mathsf{FailureCertificate}^{\uparrow}$ packet realizes the typed failure-certificate discipline of subsection 9462.30.9 as a finite $\mathsf{NameCert}$ carrier for rejected gate attempts. It also sits beside chapter 901, chapter 1163, chapter 1224, chapter 554, and chapter 1059: those siblings expose audit witnesses, reality-constrained defeat surfaces, registry export gates, cannot-claim rows, and machine-facing sockets, while this packet binds a typed failure to the exact theory axis, verification axis, and combined gate it blocks.

Definition 1233.1 (Failure certificate carrier)**.** *A* $\mathsf{FailureCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (N_0, C, V, A, B, D, H, K, P, L)$$

with the following displayed rows:

1. N_0 *is the named claim, chapter, or packet whose gate attempt is being rejected;*
2. C *is the theory-closure row, recording the claimed theory grade and the denied source, classifier, exactness, descent, ledger, stability, scope, bridge, or no-host-leak clause;*
3. V *is the verification-status row, recording the claimed formal grade and the denied checked theorem, encoded definition, audit-clean, axiom-clean, or bridge-checked clause;*
4. A *is the failed-axis row, choosing theory-side failure, verification-side failure, or axis-confusion failure as typed audit data;*
5. B *is the blocked-gate row, naming the theory gate, formal-status gate, or verified gate that the failed-axis row blocks;*
6. D *is the diagnostic row, importing a concrete witness from* $\mathsf{AuditGateFailureWitness}^{\uparrow}$, $\mathsf{RealityConstrainedFailureSu}$ $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, *or* $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ *when the rejected packet crosses those surfaces;*
7. H *stores componentwise* hsame *transport for claim name, closure grade, formal grade, failed axis, blocked gate, diagnostic witness, replay, provenance, and local naming rows;*
8. K *stores displayed* Cont *replay for reading* N_0, C, V, A, B, D *without adding a host repair route;*
9. P *is the* Pkg *provenance over* $\mathsf{FailureCertificate}^{\uparrow}$, $\mathsf{AuditGateFailureWitness}^{\uparrow}$, $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{MachineInterfaceSocket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

10. L is the local $\mathsf{NameCert}_{\mathsf{FailureCertificate}^{\uparrow}}$ *row.*
The carrier contains no coordinate for a private gate override, prose repair, host equality, hidden verifier result, or untyped failure reason outside A, B, D.

Lean4 (definition) `BEDC.Derived.FailureCertificateUp.FailureCertificateUp`

Theorem 1233.2 (Failure certificate gate blocking)**.** *For every accepted* $\mathsf{FailureCertificate}^{\uparrow}$ *packet $F = (N_0, C, V, A, B, D, H, K, P, L)$, the failed-axis row A and blocked-gate row B jointly determine which gate is blocked for the named claim N_0. A theory-side failure blocks the theory gate named by B, a verification-side failure blocks the formal-status gate named by B, and an axis-confusion failure blocks the combined verified gate named by B. No accepted packet can recover the blocked gate from D, H, K, P, L alone.*

Lean4 ✓ `BEDC.Derived.FailureCertificateUp.FailureCertificate gate blocking`

Proof. Project the finite carrier of Definition 1233.1. The row A records the typed failure branch, while B records the gate whose acceptance is denied. These rows are read before diagnostic replay, provenance, or local naming can be consumed.

For a theory-side failure, the denied clause lies in C and the gate named by B is the theory gate. For a verification-side failure, the denied clause lies in V and the gate named by B is the formal-status gate. For axis confusion, A records that the two axes have been collapsed, so the verified gate is blocked even when one row is read without the other.

Finally inspect D, H, K, P, L. The diagnostic row only records the concrete witness, and the remaining rows only transport, replay, package, and name the same packet. Since none of them supplies a fresh axis row or a fresh blocked-gate row, the gate-blocking conclusion depends on A and B together. □

Theorem 1233.3 (Failure certificate axis separation)**.** *The* $\mathsf{FailureCertificate}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{AuditGateFailureWitness}^{\uparrow}$, $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, *or* $\mathsf{MachineInterfaceSocket}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.FailureCertificateUp.FailureCertificate axis separation`

Proof. Compare the displayed rows. $\mathsf{AuditGateFailureWitness}^{\uparrow}$ supplies concrete audit failure evidence, $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$ supplies finite defeat surfaces, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ supplies export consistency checks, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ supplies refusal rows, and $\mathsf{MachineInterfaceSocket}^{\uparrow}$ supplies machine-facing target sockets.

None of those siblings carries the joint two-axis gate-blocking row of A together with B for the same named claim, while also preserving C, V, D, H, K, P, L. A row-preserving bijection would have to preserve that joint failure-axis and blocked-gate pair, so no such bijection exists. □

Lean4 ✓ `BEDC.Derived.FailureCertificateUp.FailureCertificate axis row separation`

Theorem 1233.4 (Failure certificate public axis export)**.** *The exported* $\mathsf{FailureCertificate}^{\uparrow}$ *public row consists exactly of the typed failure branch, the blocked axis, the diagnostic evidence row, the non-collapse of theory and verification axes, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. A public consumer may read A, B, D, H, K, P, L together with the named claim N_0 and the separate closure rows C, V, but it cannot reinterpret the packet as a private gate override, hidden verifier result, host equality, prose repair route, or untyped failure reason.*

Proof. Project the carrier in Definition 1233.1. The rows A and B expose the typed failure branch and blocked gate, while C and V keep the theory and verification axes separate.

Apply gate blocking and axis separation, Definition 1233.2 and Definition 1233.3. These force the failure evidence to remain tied to the selected axis and prevent sibling audit packets from collapsing the two-axis certificate surface.

The remaining rows D, H, K, P, L provide diagnostic evidence, transport, replay, provenance, and local naming for the same packet. Since no private override, hidden verifier, host equality, prose repair, or untyped reason is a carrier coordinate, the listed rows are exactly the public export surface. □

Theorem 1233.5 (Failure certificate bridged interface)**.** *Every bridge-facing consumer of an accepted* $\mathsf{FailureCertificate}^{\uparrow}$ *packet must preserve the named claim row* N_0*, the separate theory row* C*, the separate verification row* V*, the failed-axis row* A*, the blocked-gate row* B*, the diagnostic row* D*, componentwise transport* H*, displayed replay* K*, provenance* P*, and the local* $\mathsf{NameCert}$ *row* L*. The bridge-facing surface may transport those rows to a standard bridge consumer, but it cannot collapse theory and verification status, drop the failed-axis row, replace the blocked-gate row by a private override, omit the diagnostic witness, or detach the local NameCert row.*

Proof. Start with gate blocking in Definition 1233.2. It makes the failed-axis row A and blocked-gate row B jointly responsible for the refused gate of the named claim N_0, so a bridge consumer cannot preserve the failure certificate after dropping either row.

Use axis separation in Definition 1233.3. The rows C and V remain distinct from the sibling audit packets, and the failed-axis row records whether the refusal is theory-side, verification-side, or axis-confusion data.

Apply the public axis export of Definition 1233.4. The export surface already names $N_0, C, V, A, B, D, H, K, P, L$ as the public rows and excludes private overrides, hidden verifier results, host equality, prose repair, and untyped failure reasons.

Finally read the checked TasteGate witness. Field faithfulness keeps $N_0, C, V, A, B, D, H, K, P, L$ as distinct carrier rows, while nontriviality prevents the bridge-facing packet from degenerating into a vacuous single-row object. Hence any bridge consumer must preserve exactly the listed interface. □

The Lean TasteGate file provides explicit $\mathsf{Nontrivial}\ \mathsf{FailureCertificate}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{FailureCertificate}^{\uparrow}$ instances in `lean4/BEDC/Derived/FailureCertificateUp/TasteGate.lean`. The field-faithfulness witness keeps $N_0, C, V, A, B, D, H, K, P, L$ distinct so the failed-axis row and blocked-gate row cannot be merged.

Lean4 ✓ `BEDC.Derived.FailureCertificateUp.taste gate`

Falsifiable prediction: Removing either the failed-axis row or blocked-gate row breaks the gate-blocking theorem for an accepted packet.

Independence witness: auditgatefailurewitness, realityconstrainedfailuresurface, registryexportconsistencygate, axiszeckendorfcannotclaim, machineinterfacesocket: none is bijective to $\mathsf{FailureCertificate}^{\uparrow}$ because the joint two-axis gate-blocking row A, B is preserved only by the finite failure-certificate packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FailureCertificate}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FailureCertificate}^{\uparrow}$ packet is generated from a named claim row, separate theory-closure and verification-status rows, a failed-axis row, a blocked-gate row, a diagnostic witness row, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FailureCertificate}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1233.1, Definition 1233.2, Definition 1233.3, Definition 1233.4, Definition 1233.5, and the checked TasteGate witness bind gate blocking, axis separation, public axis export, the bridged interface, TasteGate evidence, and the sibling audit lattice.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FailureCertificate}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, private gate overrides, host equality, hidden verifier results, or untyped failure reasons.

Upgrade path: Verification closure requires checked Lean coverage for the mature failure-certificate carrier, gate-blocking surface, public export, bridged interface, TasteGate evidence, and sibling lattice.

Chapter 1234

A Concrete Naming Certificate for $\mathsf{AuditTranscriptEnvelope}^{\uparrow}$

The $\mathsf{AuditTranscriptEnvelope}^{\uparrow}$ packet realizes the writing-item discipline of Definition 9462.1984 as a finite transcript object. It sits between the machine consumer of chapter 1232, the registry coherence check of chapter 1223, and the proof-readback witness of chapter 1219. As a composite over those sibling audit surfaces, the packet bundles their report, registry, and proof-trace rows into one transcript envelope. Those siblings read reports, compare registry rows, and expose proof traces; this carrier names the per-claim envelope that keeps status, source, replay, gap, ledger, and refusal data together before any audit export is consumed.

Definition 1234.1 (Audit transcript envelope carrier)**.** *An* $\mathsf{AuditTranscriptEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, C, L, S, G, A, R, U, H, T, P, N)$$

with the following displayed rows:

1. *K is the claim-kind row, recording whether the writing item is read as a definition, theorem, corollary, proof, schema, report, roadmap, or refusal;*
2. *C is the carrier/classifier row, recording the BEDC carrier and the classifier or equality surface under which the item is read;*
3. *L is the ledger row, recording package provenance, dependency entries, and hidden-material refusals visible to the item;*
4. *S is the theory/formal-status pair, recording the theory-closure grade and formal-verification grade as two separate axes;*
5. *G is the gap-report row, recording open gaps, refused gaps, closed gaps, and the reason each gap is or is not consumable;*
6. *A is the source-anchor row, recording the manuscript label, file site, or registry entry from which the writing item is read;*
7. *R is the replay-checksum row, recording the displayed replay route by which the envelope is reconstructed;*
8. *U is the not-claimed surface, recording the strongest nearby readings that the envelope explicitly refuses;*

9. *H records componentwise* hsame *transport for claim kind, carrier/classifier, ledger, status-pair, gap, anchor, replay, and not-claimed rows;*
10. *T records displayed* Cont *replay from the source anchor through the checksum row to the machine-readable export boundary;*
11. *P is the* Pkg *provenance over* $\mathsf{AuditTranscriptEnvelope}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$, RegistryConsistencyAud ProofTraceAuditWitness$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditTranscriptEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden proof object, unanchored prose claim, single-axis status collapse, off-ledger gap repair, unchecked replay substitute, or erased not-claimed surface.

Lean4 (definition) `BEDC.Derived.AuditTranscriptEnvelopeUp.AuditTranscriptEnvelopeUp`

Theorem 1234.2 (Audit transcript envelope field coverage)**.** *For the carrier of Definition 1234.1, the local* $\mathsf{NameCert}_{\mathsf{AuditTranscriptEnvelope}^{\uparrow}}$ *surface consists exactly of five obligation groups:*

1. *carrier admission for $E = (K, C, L, S, G, A, R, U, H, T, P, N)$;*
2. *writing-item exposure through the claim-kind row K and carrier/classifier row C;*
3. *audit-status exactness through the ledger row L, theory/formal-status pair S, and gap-report row G;*
4. *source and replay accountability through the source-anchor row A, replay-checksum row R, not-claimed row U, transport row H, and replay row T;*
5. *package provenance and local naming through P and N.*

Thus every auditable writing item consumed through this packet is read as one finite transcript envelope, not as a prose sentence with detachable audit metadata.

Proof. Project the carrier of Definition 1234.1. The rows $K, C, L, S, G, A, R, U, H, T, P, N$ are the only coordinates available to the local certificate.

First read the writing-item rows. The kind row K fixes the permitted claim type, and C fixes the carrier/classifier surface on which that claim is meaningful.

Next read the audit rows. The ledger row L, status pair S, and gap row G state what the claim depends on, which paper-side and verification-side grades it carries, and which gaps are exposed or refused.

Finally inspect A, R, U, H, T, P, N. These rows anchor the claim, replay the envelope, preserve the not-claimed surface, transport the displayed coordinates, record provenance, and name the packet. Since no further coordinate remains, the five obligation groups exhaust the local $\mathsf{NameCert}_{\mathsf{AuditTranscriptEnvelope}^{\uparrow}}$ surface. □

Theorem 1234.3 (Audit transcript envelope non-evidence refusal)**.** *If an* $\mathsf{AuditTranscriptEnvelope}^{\uparrow}$ *carrier lacks either the theory/formal-status pair S or the replay-checksum row R, then no accepted* $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ *export may consume the envelope as theorem evidence.*

Proof. Begin with an accepted envelope

$$E = (K, C, L, S, G, A, R, U, H, T, P, N).$$

The machine-readable consumer of chapter 1232 reads audit data through displayed schema, checker, export, refusal, report, transport, replay, provenance, and local naming rows.

If S is absent, the consumer cannot distinguish paper-side closure from Lean-side verification status. If R is absent, the consumer has no checksum row tying the displayed transcript to a replay route.

In either case the requested theorem-evidence reading is stronger than the envelope supplies. The only available response is the non-evidence refusal recorded by the audit interface, so the envelope may still be reported but not consumed as theorem evidence. □

Theorem 1234.4 (Audit transcript envelope sibling independence)**.** *The* $\mathsf{AuditTranscriptEnvelope}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{MachineReadableAuditInterface}^{\uparrow}$*,* $\mathsf{ProofTraceAuditWitn}$ $\mathsf{RegistryConsistencyAudit}^{\uparrow}$*, or* $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$*.*

Proof. Compare row inventories. $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ supplies schema, checker, export, refusal, and report rows for a machine consumer, but it does not store the per-claim source anchor, replay checksum, and not-claimed surface as one writing-item envelope.

$\mathsf{ProofTraceAuditWitness}^{\uparrow}$ binds a proof trace to source, classifier, transport, forbidden-resource refusal, verdict, provenance, and local naming. It does not carry the theory/formal-status pair or the gap report required for a general writing item.

$\mathsf{RegistryConsistencyAudit}^{\uparrow}$ compares registry entries and status agreement across exports, while $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$ stores formal target skeletons and machine-facing target data. Neither is a per-claim transcript envelope with all of K, C, L, S, G, A, R, U displayed together.

Any NameCert-row-preserving bijection would have to preserve each of claim kind, carrier/classifier row, ledger row, status pair, gap report, source anchor, replay checksum, and not-claimed surface. Each named sibling omits at least one of those rows, so no such bijection exists. □

Theorem 1234.5 (Audit transcript envelope falsifiable prediction)**.** *An* $\mathsf{AuditTranscriptEnvelope}^{\uparrow}$ *carrier is rejected as a machine-consumable audit transcript exactly when a consumer asks for a theorem-evidence, registry-consistency, or proof-readback consequence not backed by its displayed kind, carrier/classifier, ledger, status-pair, gap, source-anchor, replay-checksum, not-claimed, transport, replay, provenance, and local naming rows.*

Proof. Use Definition 1234.2 to read the complete envelope inventory. Every accepted read factors through $K, C, L, S, G, A, R, U, H, T, P, N$.

For theorem-evidence reads, inspect the status pair S and replay checksum R together with Definition 1234.3. For registry-consistency reads, inspect L, S, G, A and the provenance row P naming the registry audit surface. For proof-readback reads, inspect C, L, A and the provenance row naming the proof-trace witness.

If one of those rows is absent, disagrees with the requested consequence, or is refused by U, the consumer has left the envelope. Conversely a consequence backed by the displayed rows is precisely the finite audit transcript reading exposed by this carrier. □

Falsifiable prediction: If an envelope omits either the closure-status row or the replay checksum row, then it cannot be consumed by a MachineReadableAuditInterfaceUp export without a non-evidence refusal.

Independence witness: machinereadableauditinterface, prooftraceauditwitness, registryconsistencyaudit, machineinterfaceformalizationtarget: none is bijective to AuditTranscriptEnvelopeUp because each omits at least one of per-claim status-pair, source-anchor, replay-checksum, or not-claimed rows.

The Lean follow-up must provide explicit Nontrivial AuditTranscriptEnvelope$^{\uparrow}$ and FieldFaithful AuditTranscriptEn instances in `lean4/BEDC/Derived/AuditTranscriptEnvelopeUp/TasteGate.lean`. The field-faithfulness witness must preserve $K, C, L, S, G, A, R, U, H, T, P, N$ as separate displayed fields before BEDC.Derived.AuditTranscriptEnvelopeUp.taste_gate can be cited by a checked paper marker.

Lean4 ✓ `BEDC.Derived.AuditTranscriptEnvelopeUp.taste gate`

Closure status for NameCert$_{\text{AuditTranscriptEnvelope}^{\uparrow}}$.

Constructive story: An AuditTranscriptEnvelope$^{\uparrow}$ packet is generated from claim kind, carrier/classifier, ledger, theory/formal-status, gap, source-anchor, replay-checksum, not-claimed, transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{AuditTranscriptEnvelope}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1234.1, Definition 1234.2, Definition 1234.3, Definition 1234.4, and Definition 1234.5 bind auditable writing items to finite transcript envelopes.

Formal verification: FormalStatus(NameCert$_{\text{AuditTranscriptEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, registry completeness, proof-trace correctness, machine export schema completeness, or global audit log finality.

Upgrade path: Public export is the next paper-side step; Lean verification still requires checked carrier admission, five-row NameCert coverage, non-evidence refusal, sibling independence, TasteGate nontriviality, and field faithfulness for $K, C, L, S, G, A, R, U, H, T, P, N$.

Chapter 1235

A Concrete Naming Certificate for WritingItemAudit$^{\uparrow}$

The WritingItemAudit$^{\uparrow}$ packet realizes the writing-item discipline of subsection 9462.30.1 as a concrete NameCert carrier. It turns kind, carrier, classifier, ledger, theory status, formal status, gap exposure, claim text, transport, continuation, provenance, and local naming into one finite object that registry and export chapters can read without identifying paper closure with machine verification.

Theorem 1235.1 (Writing item audit sibling dependency)**.** *Every accepted* WritingItemAudit$^{\uparrow}$ *packet consumes* AuditWritingDiscipline$^{\uparrow}$ *from chapter 1227 for legal writing discipline and* WritingItemAuditPacket$^{\uparrow}$ *from chapter 1222 for packet export shape. The former supplies the rule surface for claim legality, while the latter supplies the export packet read by registries.*

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit sibling dependency`

Proof. Read the opening carrier role of WritingItemAudit$^{\uparrow}$. Its item kind, claim text, status rows, and gap row are legal only against a writing-discipline surface, so the rule side is supplied by AuditWritingDiscipline$^{\uparrow}$.

The same packet must also be exported to registry and audit consumers. That outward shape is supplied by WritingItemAuditPacket$^{\uparrow}$, which records how the item audit is packaged for downstream readers.

Since these siblings supply different surfaces, the present carrier consumes both without identifying them: one governs legality of the writing item, and the other governs the registry-readable packet shape. □

Falsifiable prediction: If the theory-status row or formal-status row is removed, no accepted WritingItemAuditUp packet can distinguish paper closure from machine verification.

Independence witness: registryexportsurface, axiszeckendorfcannotclaim, physical-namecert-audit, focused-multi-hist-ledger, runtimecandidateboundary: registry export controls machine-facing export but not the eight-field item legality packet; cannot-claim rows refuse overstrong claims but do not carry both closure axes; physical NameCert audit checks naming surfaces without item kind and claim text; focused ledgers restrict histories but not writing-item status; runtime candidates record object-level execution boundaries without prose claim legality.

Definition 1235.2 (Writing item audit carrier)**.** *A* $\mathsf{WritingItemAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (K, C, R, L, T, F, G, Q, H, U, P, N)$$

with the following displayed rows:

1. *K is the item-kind row, naming whether the writing item is a definition, theorem, corollary, proof, reading, schema, roadmap, or refusal.*
2. *C is the carrier row on which the item lives.*
3. *R is the classifier row, recording the identity or comparison discipline used by the item.*
4. *L is the ledger row, exposing hidden material, refusal material, or the absence of such material.*
5. *T is the theory-closure status row, recording only the paper-side closure grade.*
6. *F is the formal-verification status row, recording only the Lean-side and audit-side verification grade.*
7. *G is the gap-report row, exposing open obligations, refusal boundaries, and non-closed scope.*
8. *Q is the claim-text row, carrying the strongest sentence the packet permits the reader to believe.*
9. *H records componentwise* hsame *transport for the kind, carrier, classifier, ledger, status, gap, claim, continuation, provenance, and naming rows.*
10. *U records displayed* Cont *continuations through which registry, export, closure-status, and refusal consumers read the packet.*
11. *P is the* Pkg *provenance over* $\mathsf{WritingItemAudit}^{\uparrow}$, BHist, hsame, Cont, *writing-item legality, closure-status blocks, registry export rows, and local naming rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{WritingItemAudit}^{\uparrow}}$ *row.*

The carrier exports only these rows. It has no coordinate for proving the claim text, upgrading a theory grade, upgrading a formal grade, filling a gap report, or licensing a stronger registry export.

Lean4 (definition) `BEDC.Derived.WritingItemAuditUp.WritingItemAuditUp`

Theorem 1235.3 (Writing item audit NameCert obligations)**.** *For the carrier of Definition 1235.2, the local* $\mathsf{NameCert}_{\mathsf{WritingItemAudit}^{\uparrow}}$ *surface consists exactly of carrier admission for* $W = (K, C, R, L, T, F, G, Q, H, U,$ *item-kind admission through K, carrier and classifier exactness through C, R, ledger exposure through L, independent status exposure through T, F, gap exposure through G, claim-text binding through Q, componentwise* hsame *transport through H, displayed* Cont *replay through U,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit namecert obligations`

Proof. Project the accepted carrier. Its coordinates list the item kind, carrier, classifier, ledger, two status rows, gap report, claim text, transport, continuation, provenance, and local name.

Read the writing-item legality rules from Definition 9462.1984 and Definition 9462.1985. The rows K, C, R, L, T, F, G, Q are precisely the finite packet fields required there.

The remaining rows are structural. The transport row H preserves the displayed fields componentwise, the continuation row U exposes the allowed consumers, the provenance row P records the source surfaces, and the local row N names the packet. These rows exhaust the NameCert obligations. □

Theorem 1235.4 (Writing item audit axis separation)**.** *In every accepted* WritingItemAudit$^{\uparrow}$ *packet, the theory-closure status is read only from T and the formal-verification status is read only from F. A consumer may compare, report, or jointly display the two rows, but no accepted projection can derive either status row from the other.*

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit axis separation`

Proof. Begin with the carrier inventory of Definition 1235.2. The two status rows are separate coordinates: T records paper-side closure, while F records Lean-side and audit-side verification.

Apply Definition 1235.3. Its independent status-exposure clause forces both rows to be displayed before a closure-status or registry consumer can use the packet.

Since H, U, P, N transport, replay, source, and name the displayed rows without adding a computation from one status to the other, the packet permits joint reporting but not status derivation across axes. □

Theorem 1235.5 (Writing item audit non-escape)**.** *Every registry, export, closure-status, or refusal consumer of an accepted* WritingItemAudit$^{\uparrow}$ *packet factors through the finite route*

$$K, C, R, L, T, F, G, Q, H, U, P, N.$$

The consumer receives the item kind, carrier, classifier, ledger, theory status, formal status, gap report, claim text, and structural support rows. It receives no proof of the claim text, no theory-status upgrade, no formal-status upgrade, no hidden gap discharge, and no license to export a stronger claim.

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit nonescape`

Proof. Read the carrier coordinates. The only claim-bearing row is Q, and it is bound to the displayed kind, carrier, classifier, ledger, two status rows, and gap report.

Use Definition 1235.3. It requires the consumer route to expose $K, C, R, L, T, F, G, Q, H, U, P, N$ before the packet can serve as a legal writing item.

The excluded objects are not coordinates of the carrier. Because H, U, P, N only preserve, replay, source, and name the visible rows, no accepted projection can create a proof of Q, improve T or F, erase G, or authorize a claim stronger than the displayed text. □

Theorem 1235.6 (Writing item audit TasteGate obligation)**.** *The later Lean boundary* lean4/BEDC/Derived/Writin *must provide explicit* Nontrivial WritingItemAudit$^{\uparrow}$ *and* FieldFaithful WritingItemAudit$^{\uparrow}$ *instances over the same carrier. These instances must preserve $K, C, R, L, T, F, G, Q, H, U, P, N$ and must keep the theory-status row separate from the formal-status row.*

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit tastegate obligation`

Proof. Nontriviality is required because a writing-item audit packet is meaningful only when the kind, claim text, status rows, and gap report can be jointly inhabited as a finite carrier.

Field faithfulness is the corresponding projection discipline. It prevents a TasteGate consumer from identifying two packets while forgetting the item kind, carrier, classifier, ledger, either status row, the gap report, the claim text, or the structural route.

The same carrier must witness both instances. Otherwise a consumer could certify nonemptiness for one packet shape while checking field preservation for another, which would break the audit surface named by WritingItemAudit$^{\uparrow}$. □

Theorem 1235.7 (Writing item audit obligation closure route)**.** *The carrier, NameCert obligations, axis-separation route, nonescape boundary, and TasteGate obligation rows exhaust the* $\mathsf{WritingItemAudit}^{\uparrow}$ *obligation surface. Every accepted consumer must read the finite packet*

$$K, C, R, L, T, F, G, Q, H, U, P, N$$

together with the displayed $\mathsf{NameCert}_{\mathsf{WritingItemAudit}^{\uparrow}}$ *obligation theorem, and no consumer can obtain a proof of the claim text, a closure-grade upgrade, a formal-grade upgrade, or a registry export stronger than the claim row.*

Proof. Start with the carrier of Definition 1235.2. It lists the item kind, carrier, classifier, ledger, two independent status rows, gap report, claim text, transport, continuation, provenance, and local naming rows.

Apply Definition 1235.3 to expose the NameCert surface, then use Definition 1235.4 and Definition 1235.5 to keep the paper-closure row, verification row, gap row, and claim row from escaping their displayed coordinates.

Finally read Definition 1235.6. Its visible TasteGate requirement keeps the same carrier under nontriviality and field-faithfulness checks. The listed rows therefore exhaust the obligation surface without producing public closure, scoped closure, bridge checking, or verification beyond the existing Lean marker. □

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit obligation closure route`

Theorem 1235.8 (Writing item audit scoped kernel route)**.** *Every scoped consumer of an accepted* $\mathsf{WritingItemAudit}^{\uparrow}$ *packet must read*

$$K, C, R, L, T, F, G, Q, H, U, P, N$$

together with the writing-item legality definitions of Definition 9462.1984 and Definition 9462.1985, the axis-separation theorem of Definition 1235.4, the nonescape theorem of Definition 1235.5, and the TasteGate obligation of Definition 1235.6. No scoped projection derives T *from* F*, derives* F *from* T*, proves* Q*, discharges* G*, or exports a registry claim stronger than the displayed claim-text row.*

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit scoped kernel route`

Proof. Project the carrier of Definition 1235.2. The finite packet gives the item kind, carrier, classifier, ledger, paper-closure row, formal-verification row, gap row, claim row, transport, continuation, provenance, and local name as separate displayed coordinates.

Apply Definition 1235.3. It forces the scoped consumer to read the same carrier rows through the local $\mathsf{NameCert}_{\mathsf{WritingItemAudit}^{\uparrow}}$ surface and to keep the writing-item legality definitions visible before the packet is used.

Use Definition 1235.4 and Definition 1235.5. These keep T, F, G, and Q in their own coordinates and rule out proofs of the claim text, status upgrades, hidden gap discharge, and stronger registry exports.

Finally read Definition 1235.6. It attaches nontriviality and field-faithfulness to the same carrier rows, so the scoped route is a kernel-local reading discipline rather than a projection from one axis or claim row into another. □

Theorem 1235.9 (Writing item audit public axis export)**.** *Every registry or export consumer of an accepted* WritingItemAudit$^{\uparrow}$ *packet receives the paper-closure row T and the formal-verification row F as separate public audit fields. The export may display the two rows together with $K, C, R, L, G, Q, H, U, P, N$, but it cannot derive either audit row from the other, discharge the gap row G, prove the claim row Q, or publish a stronger status than the displayed rows carry.*

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit public axis export`

Proof. Begin with the scoped kernel route of Definition 1235.8. A public registry or export consumer must read the same finite packet $K, C, R, L, T, F, G, Q, H, U, P, N$, so both audit rows are visible before the consumer may publish the item.

Apply Definition 1235.4. It permits joint reporting of T and F while forbidding a projection that derives the paper-closure row from the formal-verification row or derives the formal-verification row from the paper-closure row.

Finally use Definition 1235.5. Since no accepted projection can prove Q, discharge G, upgrade either status row, or authorize a stronger registry claim, the public export surface consists exactly of the two displayed audit fields together with their carrier, ledger, claim, transport, replay, provenance, and naming rows. □

Theorem 1235.10 (Writing item audit public status)**.** *The public export of an accepted* WritingItemAudit$^{\uparrow}$ *packet is exactly the separated packet*

$$K, C, R, L, T, F, G, Q, H, U, P, N.$$

The rows T and F are read as independent public audit fields: T records paper closure, while F records formal verification. The export may cite the TasteGate obligation surface for nontriviality and field-faithfulness of the same carrier, but it does not derive either axis from the other, prove the claim row, discharge the gap row, or publish a stronger status than the displayed rows carry.

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit public status`

Proof. Start with Definition 1235.9. It already forces every registry or export consumer to read the separated rows $K, C, R, L, T, F, G, Q, H, U, P, N$ before publishing the item.

Use Definition 1235.4 to keep the paper-closure row and formal-verification row independent. The public packet can display them together, but no projection computes one from the other.

Finally apply Definition 1235.6. Its nontriviality and field-faithfulness requirements attach to the same displayed carrier rows, so the public status record is a public-facing packet surface rather than a verification upgrade or a proof of the claim text. □

Theorem 1235.11 (Writing item audit bridge-schema route)**.** *Every public export of an accepted* WritingItemAudit$^{\uparrow}$ *packet factors through* AuditWritingDiscipline$^{\uparrow}$ *and* WritingItemAuditPacket$^{\uparrow}$ *before any registry consumer reads the separated theory-status and formal-status rows. The bridge-schema route preserves the finite packet*

$$K, C, R, L, T, F, G, Q, H, U, P, N$$

as the writing-discipline carrier, packet-export shape, axis-separation surface, public status record, nonescape boundary, and TasteGate obligation surface.

Thus the registry-facing read may publish the displayed audit rows only after the sibling writing discipline and packet shape have exposed them. It cannot identify T with F, derive either row from the other, discharge G, prove Q, erase the claim-text boundary, or turn the public export into a Lean verification claim.

Lean4 ✓ `BEDC.Derived.WritingItemAuditUp.WritingItemAudit bridge schema route`

Proof. Start with the sibling dependency route at the beginning of the chapter. It forces every accepted $\mathsf{WritingItemAudit}^{\uparrow}$ packet to consume $\mathsf{AuditWritingDiscipline}^{\uparrow}$ for legal writing discipline and $\mathsf{WritingItemAuditPacket}^{\uparrow}$ for the outward packet shape before a registry reader sees the item.

Apply Definition 1235.10. The public status theorem identifies the registry-facing packet as $K, C, R, L, T, F, G, Q, H, U, P, N$, with T and F displayed as independent audit fields.

Use Definition 1235.4 and Definition 1235.5. These theorems keep the two status axes separated and prevent any public export from proving the claim row, discharging the gap row, or publishing a stronger registry status.

Finally apply Definition 1235.6. Its field-faithfulness condition attaches to the same carrier rows, so the bridge-schema route preserves the displayed packet through the writing-discipline and packet-export siblings without adding machine verification or a stronger claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{WritingItemAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{WritingItemAudit}^{\uparrow}$ packet is generated from item kind, carrier, classifier, ledger, theory-status, formal-status, gap-report, claim-text, hsame transport, Cont continuation, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WritingItemAudit}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1235.2, Definition 1235.3, Definition 1235.4, Definition 1235.5, Definition 1235.6, and Definition 1235.11 bind writing-item legality, axis separation, nonescape, the Lean-marked TasteGate obligation row, registry export rows, bridge-schema routing through $\mathsf{AuditWritingDiscipline}^{\uparrow}$ and $\mathsf{WritingItemAuditPacket}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert to finite packets with separated closure and verification axes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WritingItemAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, proof of the claim text, grade upgrades, gap discharge, or registry export beyond the displayed claim row.

Upgrade path: Further progress is Lean verification and bridge checking; the paper-side mature packet remains independent of the formal-status axis.

Chapter 1236

A Concrete Naming Certificate for $\mathsf{HardProblemClosure}^{\uparrow}$

The $\mathsf{HardProblemClosure}^{\uparrow}$ packet realizes the hard-problem form of subsection 9462.27.8 as a finite NameCert carrier. It sits beside the focused multi-history ledger of chapter 1109, the consciousness-universe-space carrier of chapter 1206, the observer-history identity carrier of chapter 477, and the inter-Hist locality ledger of chapter 759. Those siblings provide focused records, a finite universe slice, observer identity rows, and local relation rows; this packet names the finite closure-question surface that keeps traditional hard-problem readings as inspectable boundary obligations.

Definition 1236.1 (Hard-problem closure carrier)**.** *A* $\mathsf{HardProblemClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, L, C, W, I, B, H, Q, P, N)$$

with the following displayed rows:

1. *R is the generated-record row, recording the finite histories, focused records, universe-slice records, observer-identity records, and local relation records available to the question;*
2. *L is the ledgered-local-choice row, recording the finite choices, selectors, focus windows, and refusal entries used by the read;*
3. *C is the compression-provenance row, recording which summaries, digests, or compressed presentations preserve their* Pkg *source;*
4. *W is the witnessed-relation row, recording the finite relation witnesses required before a consciousness, universe, observer, time, space, or identity reading is admitted;*
5. *I is the classifier-stable invariant row, recording exactly the invariants preserved by the displayed classifier and no others;*
6. *B is the boundary-pressure row, recording the gap and* T*-boundary readings that remain exposed rather than being internalised as substance;*
7. *H records componentwise* hsame *transport for $R, L, C, W, I, B, Q, P, N$;*
8. *Q records displayed* Cont *replay from generated records through local choices, compression provenance, relation witnesses, invariant readback, and boundary exposure;*
9. *P records* Pkg *provenance over* $\mathsf{HardProblemClosure}^{\uparrow}$, $\mathsf{FocusedMultiHistLedger}^{\uparrow}$, $\mathsf{ConsciousUniverseSpace}^{\uparrow}$, $\mathsf{ObserverHistoryIdentity}^{\uparrow}$, $\mathsf{InterHistLocalityLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{HardProblemClosure}^{\uparrow}}$ *row.*
The carrier has no coordinate for a consciousness substance, complete universe object, detached observer, global time, ambient space substrate, host identity equality, hidden relation witness, or boundary-free closure of the displayed hard-problem readings.

Theorem 1236.2 (Hard-problem closure NameCert obligations)**.** *For the carrier of Definition 1236.1, the local* $\mathsf{NameCert}_{\mathsf{HardProblemClosure}^{\uparrow}}$ *surface consists exactly of carrier admission for* $K = (R, L, C, W, I, B, H, Q, P,$ *ledger coverage for* L*, compression-provenance accountability for* C*, relation-witness coverage for* W*, invariant classifier stability for* I*, boundary exposure for* B*, no-substance refusal for every reading not backed by* R, L, C, W, I, B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* Q*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.HardProblemClosureUp.HardProblemClosureTasteGate single carrier alignment`

Proof. Project the carrier. The displayed rows $R, L, C, W, I, B, H, Q, P, N$ are the full inventory available to a hard-problem closure reader.

Read the evidence rows in order. Generated records, local choices, compression provenance, witnessed relations, classifier-stable invariants, and boundary pressure are exposed before transport, replay, provenance, or local naming can consume the packet.

The sibling surfaces supply only parts of this inventory. Focused multi-history ledgers provide record and ledger rows, consciousness-universe-space packets provide universe, time, space, and trace rows, observer-history identity packets provide identity comparison rows, and inter-Hist locality ledgers provide relation routes. None supplies a substance coordinate or a hidden hard-problem solution row.

Finally use H, Q, P, N. These rows transport, replay, source, and name the same packet. Since the carrier contains no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 1236.3 (Hard-problem closure boundary exposure)**.** *Every consciousness, universe, observer, time, space, or identity reading of an accepted* $\mathsf{HardProblemClosure}^{\uparrow}$ *packet remains a boundary row unless the displayed packet supplies generated records* R*, ledgered local choices* L*, compression provenance* C*, witnessed relations* W*, classifier-stable invariants* I*, and boundary-pressure audit rows* B *for that reading. A route preserving only the structural rows* H, Q, P, N *cannot turn the reading into consciousness substance, complete universe object, detached observer, global time, ambient space substrate, or host identity equality.*

Lean4 ✓ `BEDC.Derived.HardProblemClosureUp.HardProblemClosure boundary exposure`

Proof. Start with the boundary-pressure row B. It records which traditional reading is still exposed as gap or T pressure, and it is read only after the packet displays the generated records, choices, provenance, witnesses, and invariants that support the local question.

If those rows are displayed, the reading remains an accepted closure-question carrier rather than a substance theorem. The rows R, L, C, W, I supply finite records-side evidence, while B keeps the pressure visible as a boundary obligation.

If any required evidence row is absent, the NameCert obligation theorem routes the attempted read to no-substance refusal. The structural rows H, Q, P, N can preserve and replay a displayed packet, but they cannot create a hidden witness, detached observer, global time, ambient space, or host identity coordinate. □

Falsifiable prediction: A purported HardProblemClosureUp packet that omits either the witnessed-relation row or the boundary-pressure row is not an accepted closure-question carrier.

Independence witness: focused-multi-hist-ledger, consciousuniversespace, observerhistoryidentity, inter-hist-locality-ledger: each sibling supplies one surface of focused records, universe slice, observer identity, or locality relation, but none is bijective to the full records-ledger-witness-invariant-boundary packet.

The Lean follow-up for this chapter must provide explicit Nontrivial HardProblemClosure$^{\uparrow}$ and FieldFaithful HardProblemClosure$^{\uparrow}$ instances in `lean4/BEDC/Derived/HardProblemClosureUp/TasteGate.lean`. The field-faithfulness witness must preserve $R, L, C, W, I, B, H, Q, P, N$ as distinct rows before BEDC.Derived.HardProblemClosureUp.taste_gate can be cited by a checked paper marker.

Closure status for NameCert$_{\text{HardProblemClosure}\uparrow}$.

Constructive story: The hard-problem closure object is generated from a $BHist$ packet that records focused records, a ledger row, conscious-universe row, witnessed relation, invariant row, and boundary-pressure row. The carrier convention is deliberately local: it reads the problem-facing closure evidence, transports it through $hsame$, and lets Cont carry the boundary forward only as the same named row. The NameCert obligations and boundary-exposure theorem do not solve or dissolve the problem; they certify the visible closure surface available in the ledger. This makes the object a bottom-up boundary certificate whose meaning is fixed by recorded rows rather than by an external philosophical conclusion.

Theory closure: TheoryGate(NameCert$_{\text{HardProblemClosure}\uparrow}$, seed)

Scope closed: This chapter binds the hard-problem closure carrier, NameCert obligations, boundary-exposure theorem, falsifiable prediction, and independence witness.

Formal verification: FormalStatus(NameCert$_{\text{HardProblemClosure}\uparrow}$, unformalized)

Ledger evidence: BEDC.Meta.DiscoveryDeltaLedger.hardProblemClosureDeltaLedger

Bridge status: none

Origin: ai

Not claimed: It does not claim a solution to the hard problem, subjective identity, physical reduction, or closure outside the displayed boundary row.

Upgrade path: Reaching obligationClosure requires formal closure and boundary rows plus checked preservation of boundary exposure under $hsame$.

Chapter 1237

A Concrete Naming Certificate for $\mathsf{TypedFailureCertificate}^{\uparrow}$

The $\mathsf{TypedFailureCertificate}^{\uparrow}$ packet realizes the failure-certificate discipline of subsection 9462.30.9 inside the auditable-generativity programme of chapter 9462. It sits beside the failed-gate witness of chapter 901, the registry export surface of chapter 1216, the cannot-claim packet of chapter 554, and the standard-bridge audit packet of chapter 1217. Those siblings expose local gate failure, registry blocking, axis-specific refusal, and bridge-audit rows; this packet names the typed failure itself before any consumer may treat a gap, failure, or bridge refusal as public audit data.

Definition 1237.1 (Typed failure certificate carrier)**.** *A* $\mathsf{TypedFailureCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (N, C, V, S, R, D, H, P, L)$$

with the following displayed rows:

1. *N is the object-name row for the object, chapter, theorem site, bridge site, or registry entry whose claimed status is being tested;*
2. *C is the theory-grade row, recording the claimed paper-side closure grade and the theory-side gate that fails when the branch is theory-facing;*
3. *V is the formal-status row, recording the claimed verification grade and the verification-side gate that fails when the branch is checker-facing;*
4. *S is the failed-site row, recording the exact source, classifier, exactness, descent, gap, scope, bridge, host-leak, checker, audit, or axis site at which the claimed gate is blocked;*
5. *R is the refusal-route row, recording the gate, registry, bridge, or export route that consumes the failure as refusal data;*
6. *D is the diagnostic-branch row, recording whether the failure is theory-side, verification-side, or axis-confusion data, together with the typed branch named by the failure-certificate discipline;*
7. *H records componentwise* hsame *transport for object name, theory grade, formal status, failed site, refusal route, and diagnostic branch;*
8. *P is the* Pkg *provenance over* $\mathsf{TypedFailureCertificate}^{\uparrow}$, $\mathsf{AuditGateFailureWitness}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

9. L is the local $\mathsf{NameCert}_{\mathsf{TypedFailureCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for a failed gate without a diagnostic branch, a verification failure read as theory closure, a theory failure read as verification status, a bridge refusal detached from its route, or an export permission that bypasses the displayed refusal data.

Lean4 ✓ `BEDC.Derived.TypedFailureCertificateUp.TypedFailureCertificateTasteGate single carrier alignment`

Theorem 1237.2 (Typed failure certificate NameCert obligations)**.** *For the carrier of Definition 1237.1, the local* $\mathsf{NameCert}_{\mathsf{TypedFailureCertificate}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for $F = (N, C, V, S, R, D, H, P, L)$;*
2. *object-and-status readback through the object name N, theory-grade row C, and formal-status row V;*
3. *failure localization through the failed-site row S and diagnostic-branch row D;*
4. *refusal consumption through the route row R and componentwise transport row H;*
5. *package provenance and local naming through P and L.*

Thus every accepted failure certificate is a finite NameCert packet over the named object, the two independent status axes, the failed site, the refusal route, the diagnostic branch, transport, provenance, and local naming.

Proof. Project the displayed carrier of Definition 1237.1. The rows $N, C, V, S, R, D, H, P, L$ are the only coordinates available to a local certificate.

First read the object and status rows. The object row N fixes the site being tested, while C and V keep the theory-grade and formal-status claims as separate rows.

Next read the failure rows. The failed-site row S locates the gate that did not pass, and the diagnostic branch D states whether the failure is theory-side, verification-side, or axis-confusion data.

Finally read R, H, P, L. The refusal route consumes the failure, transport preserves the same displayed coordinates, provenance lists the sibling surfaces through which the certificate may be consumed, and the local name seals the packet. Since no further coordinate remains, the five obligation rows exhaust the local $\mathsf{NameCert}_{\mathsf{TypedFailureCertificate}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.TypedFailureCertificateUp.TypedFailureCertificateNameCertObligations`

Theorem 1237.3 (Typed failure certificate axis separation)**.** *For every accepted* $\mathsf{TypedFailureCertificate}^{\uparrow}$ *carrier*

$$F = (N, C, V, S, R, D, H, P, L),$$

the theory-side failures, verification-side failures, and axis-confusion failures remain separated by the diagnostic branch D. A consumer may use a theory-side branch to block the theory gate named by C, a verification-side branch to block the formal-status gate named by V, and an axis-confusion branch to block the verified-gate pairing, but no branch may be read as a failure of the other axis.

Proof. Use Definition 1237.2. The second obligation row exposes C and V separately, and the third obligation row requires the diagnostic branch D before a failed site can be consumed.

If D is theory-side, the refused content is read through the theory-grade row C and the failed site S. The formal-status row V remains displayed but does not become the failed gate.

If D is verification-side, the refused content is read through V and S. The theory-grade row C remains displayed but does not become the failed gate.

If D is axis-confusion data, the failure is the attempted collapse of the two rows. The branch blocks the verified-gate pairing while preserving the separate theory and verification rows for downstream audit.

The transport, provenance, and local-name rows H, P, L preserve the same packet. They cannot replace D with a branch-free reading, so the three failure classes remain separated. □

Lean4 ✓ `BEDC.Derived.TypedFailureCertificateUp.TypedFailureCertificateAxisSeparation`

Theorem 1237.4 (Typed failure certificate export blocking)**.** *No* RegistryExportSurface$^{\uparrow}$, AxisZeckendorfCannotCla AuditGateFailureWitness$^{\uparrow}$, *or* StandardBridgeAuditPacket$^{\uparrow}$ *consumer may export a public route past a displayed* TypedFailureCertificate$^{\uparrow}$ *failure unless it consumes both the diagnostic branch D and the refusal route R of*

$$F = (N, C, V, S, R, D, H, P, L).$$

An export route that reads only N, C, V, S, H, P, L is not an accepted export of the failed claim, failed status, or failed bridge.

Proof. Begin with the obligation surface of Definition 1237.2. Failure localization uses S together with D, and refusal consumption uses R together with the transport row H.

For registry export, the sibling surface of chapter 1216 requires the blocking and audit rows before a claim may leave the registry. A typed failure certificate supplies those data only through D and R.

For cannot-claim, audit-gate failure, and standard-bridge reads, the sibling chapters chapter 554, chapter 901, and chapter 1217 consume refusal rows rather than hidden prose. The displayed diagnostic branch tells which gate failed, and the displayed route tells how the refusal is replayed.

If either D or R is omitted, the consumer still sees an object and status pair but cannot tell which typed branch failed or how the refusal is consumed. Such a route is outside the accepted TypedFailureCertificate$^{\uparrow}$ carrier and therefore cannot export the failed claim, failed status, or failed bridge as public BEDC audit data. □

Lean4 ✓ `BEDC.Derived.TypedFailureCertificateUp.TypedFailureCertificateExportBlocking`

Theorem 1237.5 (Typed failure certificate bridge-refusal route)**.** *Any* StandardBridgeAuditPacket$^{\uparrow}$ *consumer of a* TypedFailureCertificate$^{\uparrow}$ *failure*

$$F = (N, C, V, S, R, D, H, P, L)$$

must read the object-name row N, theory-grade row C, formal-status row V, failed-site row S, refusal-route row R, diagnostic-branch row D, transport row H, provenance row P, local NameCert row L, and the TasteGate-aligned packet before treating the bridge as refused. This route blocks axis confusion: the refusal may close the paper-side bridge route, but it cannot be read as bridgeChecked *verification.*

Proof. Start with the export-blocking theorem Definition 1237.4. A standard-bridge audit consumer cannot pass a failed bridge unless it consumes the diagnostic branch D and refusal route R.

Use the NameCert obligations of Definition 1237.2. Those obligations expose the remaining rows N, C, V, S, H, P, L as part of the same finite certificate, so the consumer cannot detach the bridge refusal from the object, status, failed site, transport, provenance, or local naming data.

Finally apply the axis-separation theorem Definition 1237.3. The diagnostic branch identifies the failed route without collapsing the theory-grade row C into the formal-status row V. Therefore the standard-bridge audit reads a paper-side refusal route for the displayed packet, not a checked Lean bridge result. □

Lean4 ✓ `BEDC.Derived.TypedFailureCertificateUp.TypedFailureCertificateBridgeRefusalRoute`

Theorem 1237.6 (Typed failure certificate mature treatment route)**.** *For every accepted* $\mathsf{TypedFailureCertificate}^{\uparrow}$ *carrier*

$$F = (N, C, V, S, R, D, H, P, L),$$

the NameCert obligation surface, axis-separation surface, export-blocking surface, and bridge-refusal surface jointly determine the mature paper-side treatment of the certificate. Every public consumer must read the object name, theory-grade row, formal-status row, failed-site row, refusal-route row, diagnostic branch, componentwise transport, provenance, and local NameCert row before it may treat the failure as audit data, and the route never converts paper-side bridge refusal into bridgeChecked *verification.*

Proof. Start with the NameCert obligations of Definition 1237.2. They expose exactly the finite rows $N, C, V, S, R, D, H, P, L$ and make them the only local carrier surface available to a consumer.

Use axis separation, Definition 1237.3. The diagnostic branch D keeps theory-side, verification-side, and axis-confusion failures apart, so a refused theory gate cannot be read as a failed formal-status gate and a checker-facing failure cannot be read as paper closure.

Next apply export blocking, Definition 1237.4. A registry, cannot-claim, audit-gate, or bridge-audit consumer cannot export the failed claim unless it consumes both D and the refusal route R.

Finally apply the bridge-refusal route of Definition 1237.5. The standard-bridge audit reads the same finite failure packet as a paper-side refusal route. Since the route preserves C and V as separate rows, it closes the mature paper treatment while leaving the Lean verification axis unchanged. □

Lean4 ✓ `BEDC.Derived.TypedFailureCertificateUp.TypedFailureCertificateMatureTreatmentRoute`

Falsifiable prediction: If the diagnostic branch is deleted, a failed theory-grade row and a failed formal-status row become indistinguishable to public consumers.

Independence witness: auditgatefailurewitness, registryexportsurface, axiszeckendorfcannot-claim, standardbridgeauditpacket: AuditGateFailureWitnessUp records a failed gate witness without the full theory-grade, formal-status, and axis-confusion branch surface; RegistryExportSurfaceUp records export blocking without naming every typed failure branch; AxisZeckendorfCannotClaimUp records cannot-claim refusal without checker-facing failure status; StandardBridgeAuditPacketUp records bridge fields and no-host-leak rows without the full failure-certificate branch taxonomy. None is bijective to $\mathsf{TypedFailureCertificate}^{\uparrow}$.

The Lean follow-up must provide explicit Nontrivial $\mathsf{TypedFailureCertificate}^{\uparrow}$ and FieldFaithful TypedFailureCertific instances in `lean4/BEDC/Derived/TypedFailureCertificateUp/TasteGate.lean`. The field-faithfulness witness must preserve $N, C, V, S, R, D, H, P, L$ as distinct rows before BEDC.Derived.TypedFailureCertific can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{TypedFailureCertificate}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TypedFailureCertificate}^{\uparrow}$ packet is generated from object-name, theory-grade, formal-status, failed-site, refusal-route, diagnostic-branch, componentwise transport, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TypedFailureCertificate}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1237.1, Definition 1237.2, Definition 1237.3, Definition 1237.4, Definition 1237.5, Definition 1237.6, and BEDC.Derived.TypedFailureCertificateUp.taste_gate bind the mature paper surface: carrier admission, NameCert obligations, axis separation, export blocking, bridge-refusal routing, and the cited TasteGate marker for the same finite failure-certificate packet.

Formal verification: FormalStatus(NameCert$_{\mathsf{TypedFailureCertificate}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim checked Lean code, public export closure, public bridge closure, standard bridge checking, or a completed TasteGate carrier for TypedFailureCertificate$^{\uparrow}$.

Upgrade path: Lean-side carrier, Nontrivial, FieldFaithful, and bridge-checking work remain separate from the mature paper closure grade.

Chapter 1238

A Concrete Naming Certificate for $\mathsf{ProofWitnessChain}^{\uparrow}$

The $\mathsf{ProofWitnessChain}^{\uparrow}$ packet realizes the BEDC proof form of subsection 9462.25.1 as a concrete finite NameCert carrier. It sits between the proof-trace audit packet of chapter 1219, the accepted-declaration audit surface of chapter 546, the certificate-preserving route of chapter 481, and the proof-object erasure surface of chapter 642. Those siblings audit narrower faces of proof use; this carrier binds the proof trace, source carrier, classifier witness, transport, ledger, refusal, audit verdict, provenance, and local name into one finite witness-chain object.

Definition 1238.1 (Proof witness chain carrier)**.** *A* $\mathsf{ProofWitnessChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, S, K, H, L, F, A, P, N)$$

with the following displayed rows:

1. *T is the proof-trace row, recording the finite witness chain consumed by the proof site.*
2. *S is the source-carrier row, recording the BEDC carrier, source object, theorem surface, or certificate row whose proof evidence is being read.*
3. *K is the classifier-witness row, recording the classifier membership, comparison, stability, or exactness witness licensing the chain.*
4. *H is the displayed-transport row, recording the* hsame *transport needed across classifier, package, bridge, or history-identity surfaces.*
5. *L is the proof ledger row, recording* Cont *replay, package route, local ledger entries, and proof-site handoff rows.*
6. *F is the forbidden-resource refusal row, recording refusal of hidden choice, host equality as BEDC equality, quotient collapse, propositional extensional rewrite, global truth predicate, unledgered compression, and unscoped universal claim.*
7. *A is the audit-verdict row, recording accepted, refused, or displayed-obligation status for the whole witness chain.*
8. *P is the* Pkg *provenance over* $\mathsf{ProofTraceAuditWitness}^{\uparrow}$, $\mathsf{KernelAuditWitness}^{\uparrow}$, $\mathsf{NameCertMorphism}^{\uparrow}$, $\mathsf{ProofTermErasureTrace}^{\uparrow}$, $\mathsf{FiniteWitnessRoute}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ProofWitnessChain}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an untraced proof, implicit classifier crossing, hidden proof source, erased refusal, host equality proof, or audit verdict detached from provenance and local naming.

Lean4 (definition) `BEDC.Derived.ProofWitnessChainUp.ProofWitnessChainUp`

Theorem 1238.2 (Proof witness chain NameCert obligations)**.** *For the carrier of Definition 1238.1, the local* $\mathsf{NameCert}_{\mathsf{ProofWitnessChain}^{\uparrow}}$ *surface consists exactly of the following obligation rows: carrier admission for* $W = (T, S, K, H, L, F, A, P, N)$*; proof-trace and source-carrier exposure through* T *and* S*; classifier-witness stability through* K*; displayed transport through* H*; ledger replay and proof-site handoff through* L*; forbidden-resource refusal and audit-verdict exactness through* F *and* A*; and provenance plus local naming through* P *and* N*.*

Lean4 ✓ `BEDC.Derived.ProofWitnessChainUp.ProofWitnessChainTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1238.1. The rows $T, S, K, H, L, F, A, P, N$ are the only displayed coordinates of an accepted proof witness chain, so the local NameCert first reads a finite proof trace, its source surface, and the classifier witness that licenses the trace.

Next read the transport and ledger rows. The displayed transport row H keeps classifier crossing inside hsame data, while the ledger row L records replay, package route, local ledger entries, and handoff rows in Cont, Pkg, and $\mathsf{NameCert}$ form.

Finally attach the refusal, verdict, provenance, and local name rows. The refusal row F records which proof resources are unavailable, the verdict row A classifies the whole chain, and P, N bind that verdict to finite provenance and local naming. Repacking these rows gives the listed obligations and leaves no coordinate for hidden proof evidence. □

Theorem 1238.3 (Proof witness chain ledger non-escape)**.** *Every accepted* $\mathsf{ProofWitnessChain}^{\uparrow}$ *proof read factors through the displayed rows*

$$T, S, K, H, L, F, A, P, N.$$

Deleting the classifier-witness row K *or the forbidden-resource refusal row* F *invalidates the accepted proof witness chain carrier.*

Proof. Begin with Definition 1238.2. The accepted chain must expose proof trace, source carrier, classifier witness, displayed transport, ledger handoff, forbidden-resource refusal, audit verdict, provenance, and local naming as one finite packet.

If K is absent, the trace has no displayed classifier comparison or stability witness. The source row S and trace row T remain visible, but no NameCert obligation licenses them as a BEDC proof read.

If F is absent, the packet no longer records refusal of hidden choice, quotient collapse, host equality, propositional extensional rewrite, global truth, unledgered compression, or unscoped universal claim. The verdict row A then has no refusal boundary to audit.

Thus every accepted proof read remains inside the displayed packet. A consumer that reads proof evidence without K or F has left the $\mathsf{ProofWitnessChain}^{\uparrow}$ carrier rather than extracting a hidden proof resource from it. □

Theorem 1238.4 (Proof witness chain proof-trace handoff)**.** *Every accepted* $\mathsf{ProofWitnessChain}^{\uparrow}$ *carrier hands its trace row* T *to chapter 1219 before a downstream consumer may read the proof as BEDC-internal evidence. The handoff preserves the source row* S*, classifier row* K*, transport row* H*, ledger row* L*, refusal row* F*, audit verdict* A*, provenance row* P*, and local name* N*.*

Proof. Read the proof-trace component T of Definition 1238.1. The trace is not a standalone proof object; it is the row sent to the proof-trace audit witness surface.

The surrounding rows S, K, H, L, F, A, P, N provide the exact context in which the trace is consumed. The source row and classifier witness determine what the trace is evidence for, transport and ledger rows determine how it is replayed, and the refusal and verdict rows determine whether it is accepted or refused.

The handoff therefore preserves the full packet boundary. A downstream consumer may route through $\mathsf{ProofTraceAuditWitness}^{\uparrow}$, $\mathsf{KernelAuditWitness}^{\uparrow}$, $\mathsf{NameCertMorphism}^{\uparrow}$, or $\mathsf{ProofTermErasureTrace}^{\uparrow}$, but it may not replace the witness chain by any one of those siblings alone. □

The Lean follow-up file `lean4/BEDC/Derived/ProofWitnessChainUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ ProofWitnessChain}^{\uparrow}$ and $\mathsf{FieldFaithful\ ProofWitnessChain}^{\uparrow}$ instances, preserving $T, S, K, H, L, F, A, P, N$ as separate displayed fields.

Falsifiable prediction: Deleting the classifier-witness or forbidden-resource refusal row invalidates the accepted proof witness chain carrier.

Independence witness: prooftraceauditwitness, kernelauditwitness, namecertmorphism, prooftermerasuretrace, finitewitnessroute: none is bijective to $\mathsf{ProofWitnessChain}^{\uparrow}$ because preserving the carrier requires proof trace, source, classifier, transport, ledger, refusal, audit verdict, provenance, and local name together. ProofTraceAuditWitnessUp audits the trace face, KernelAuditWitnessUp audits accepted declarations, NameCertMorphismUp transports certificate rows, ProofTermErasureTraceUp separates erased proof rows, and FiniteWitnessRouteUp records finite route exits; no listed sibling preserves the whole proof witness chain surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ProofWitnessChain}^{\uparrow}}$.

Constructive story: The proof witness chain is generated from $BHist$ rows that list proof trace data, source rows, classifier witnesses, transport, ledger entries, forbidden-resource refusal, audit verdict, provenance, and local naming in order. The carrier first reads each witness row, then checks that the ledger connects adjacent rows as a chain, and finally allows Cont to carry the trace forward without replacing it by an external proof object. The $hsame$ relation keeps the witness sequence stable when histories are represented differently. The NameCert obligations, ledger non-escape, proof-trace handoff, prediction, and independence witness thus make the chain a visible certificate of derivation evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProofWitnessChain}^{\uparrow}}, \mathsf{obligation})$

Scope closed: This chapter binds the proof witness-chain carrier, NameCert obligations, ledger non-escape theorem, proof-trace handoff theorem, falsifiable prediction, and independence witness as the visible obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProofWitnessChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim proof validity outside the witness chain, proof irrelevance, or derivations not recorded in the ledger.

Upgrade path: Reaching obligationClosure requires formal witness-chain rows and checked handoff preservation for the visible proof trace.

Chapter 1239

A Concrete Naming Certificate for $\mathsf{TruthResidueLedger}^{\uparrow}$

The $\mathsf{TruthResidueLedger}^{\uparrow}$ packet realizes the scientific-truth synthesis of chapter 9462 as audited stability rather than final correspondence. It sits beside the scientific-object carrier of chapter 1214, the reality-constrained truth certificate of chapter 1144, the methodology ledger of chapter 1145, the open-fit packet of chapter 1137, and the physical truth certificate of chapter 1141. Those siblings expose object rows, truth-certificate rows, methodology rows, open-fit rows, and physical-truth rows; the residue ledger binds their non-final scientific truth route into one finite NameCert packet.

Falsifiable prediction: If a TruthResidueLedgerUp packet is accepted, no consumer can infer final model truth from model fit without passing through the prediction-gap and falsification rows; a direct route from fit to global truth refutes the packet.

Independence witness: scientificobject, realityconstrainedtruthcert, realityconstrainedmethodologyledger, openfitpacket, physicaltruthcertificate: none is bijective because $\mathsf{TruthResidueLedger}^{\uparrow}$ binds observation records, invariant rows, conservative bridge rows, prediction-gap rows, falsification rows, non-finality rows, transport, replay, provenance, and local NameCert rows in one carrier. ScientificObjectUp names object-facing record structure; RealityConstrainedTruthCertUp names a truth-certificate route; RealityConstrainedMethodologyLedgerUp names methodology export scope; OpenFitPacketUp names finite fit and open defeat; PhysicalTruthCertificateUp names physical-truth export. None carries the complete residue ledger that keeps fit, stability, prediction, falsification, and non-finality jointly visible.

Definition 1239.1 (Truth residue ledger carrier)**.** *A* $\mathsf{TruthResidueLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (O, I, B, P, F, G, H, C, Q, N)$$

with the following displayed rows:

1. *O is the observation-record row, naming the finite records and measurement traces from which the scientific-truth read begins.*
2. *I is the invariant row, recording the stable inter-history or classifier-preserved content that survives the accepted comparison route.*
3. *B is the conservative model-bridge row, recording only the bridge by which the finite records are compared with model-side structure.*

4. *P is the prediction-gap row, exposing commitments not discharged by the present fit, including later-observation and domain-exit obligations.*
5. *F is the falsification row, recording finite defeats, failed predictions, classifier mismatches, and open tests that can refute the export.*
6. *G is the non-finality row, refusing a direct route from finite fit or stable invariant to global model truth.*
7. *H records componentwise* hsame *transport for O, I, B, P, F, G and the local naming row.*
8. *C records displayed* Cont *replay from observation admission through invariant read, bridge read, prediction-gap read, falsification read, non-finality refusal, provenance, and local naming.*
9. *Q is the* Pkg *provenance over* $\mathsf{TruthResidueLedger}^{\uparrow}$, $\mathsf{ScientificObject}^{\uparrow}$, $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$, $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$, $\mathsf{OpenFitPacket}^{\uparrow}$, $\mathsf{PhysicalTruthCertificate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TruthResidueLedger}^{\uparrow}}$ *row.*

The carrier exports only these rows. It has no coordinate for final correspondence, model–world identity, hidden completeness, unledgered fit, erased prediction debt, or a falsification-free truth route.

Lean4 (definition) `BEDC.Derived.TruthResidueLedgerUp.TruthResidueLedgerUp`

Theorem 1239.2 (Truth residue ledger NameCert obligations)**.** *For the carrier of Definition 1239.1, the local* $\mathsf{NameCert}_{\mathsf{TruthResidueLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for $R = (O, I, B, P, F, G, H, C, Q, N$ observation exposure through O, invariant exposure through I, conservative bridge exposure through B, prediction-gap exposure through P, falsification exposure through F, non-finality exposure through G, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through Q, and local naming through N.*

Proof. Project the accepted carrier. Its visible coordinates are the observation records, invariants, conservative model bridge, prediction gaps, falsification surface, non-finality refusal, transport, replay, provenance, and local name.

The sibling chapters supply the surrounding surfaces: $\mathsf{ScientificObject}^{\uparrow}$ supplies object-facing records, $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ supplies truth-certificate discipline, $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$ supplies methodology scope, $\mathsf{OpenFitPacket}^{\uparrow}$ supplies finite fit with open defeat, and $\mathsf{PhysicalTruthCertificate}^{\uparrow}$ supplies physical-truth export constraints. The present packet does not identify any one sibling with scientific truth; it records their residue-bearing handoff.

The structural rows H, C, Q, N preserve, replay, source, and name only the displayed packet. Since the carrier has no additional coordinate, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.TruthResidueLedgerUp.TruthResidueLedger namecert obligations`

Theorem 1239.3 (Truth residue ledger falsifiable boundary)**.** *Every accepted* $\mathsf{TruthResidueLedger}^{\uparrow}$ *consumer that reads model fit or invariant stability as scientific truth must pass through both the prediction-gap row P and the falsification row F before the local name N is readable. A route from B or I directly to final model truth is not an accepted* $\mathsf{TruthResidueLedger}^{\uparrow}$ *route.*

Lean4 ✓ `BEDC.Derived.TruthResidueLedgerUp.TruthResidueLedger falsifiable boundary`

Proof. Start from the carrier of Definition 1239.1. The bridge row B and invariant row I are distinct from the prediction-gap row P, the falsification row F, and the non-finality row G.

Apply Definition 1239.2. The local NameCert surface exposes P, F, G as obligations before the accepted scientific-truth read reaches the local name. Thus fit and stability are admitted only with their open prediction and defeat surfaces still displayed.

The excluded direct route has no coordinate in the carrier. Transport, replay, and provenance preserve the same finite packet, so they cannot create final correspondence or erase the falsifiable boundary. □

Theorem 1239.4 (Truth residue ledger field coverage)**.** *Every scientific-truth export from an accepted* $\mathsf{TruthResidueLedger}^{\uparrow}$ *packet factors through*

$$O, I, B, P, F, G, H, C, Q, N.$$

The consumer receives finite observation records, stable invariant rows, conservative bridge rows, prediction-gap rows, falsification rows, non-finality rows, componentwise transport, displayed replay, package provenance, and local NameCert naming. It receives no final truth oracle, no unbounded correspondence claim, no hidden model identity, no erased prediction debt, and no falsification-free route.

Lean4 ✓ `BEDC.Derived.TruthResidueLedgerUp.TruthResidueLedger field coverage`

Proof. Use Definition 1239.2 to identify the complete local certificate surface. Every accepted consumer must expose the six content rows and the four structural rows listed there.

Then apply Definition 1239.3. Any consumer attempting to read fit or stability as scientific truth must still carry prediction-gap and falsification data, so the route cannot collapse to final model truth.

The sibling dependencies remain sources rather than replacements. $\mathsf{ScientificObject}^{\uparrow}$, $\mathsf{RealityConstrainedTruthCer}$ $\mathsf{RealityConstrainedMethodologyLedger}^{\uparrow}$, $\mathsf{OpenFitPacket}^{\uparrow}$, and $\mathsf{PhysicalTruthCertificate}^{\uparrow}$ contribute rows through Q, but none supplies a hidden coordinate outside $O, I, B, P, F, G, H, C, Q, N$. Therefore the displayed route covers every accepted field of the truth-residue ledger. □

The Lean TasteGate file `lean4/BEDC/Derived/TruthResidueLedgerUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{TruthResidueLedger}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{TruthResidueLedger}^{\uparrow}$ instances over the same carrier. The instances must preserve $O, I, B, P, F, G, H, C, Q, N$ and must keep conservative fit, prediction-gap, falsification, and non-finality rows as separate fields.

Lean4 ✓ `BEDC.Derived.TruthResidueLedgerUp.TruthResidueLedgerTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{TruthResidueLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{TruthResidueLedger}^{\uparrow}$ packet is generated from observation records, invariant rows, conservative model-bridge rows, prediction-gap rows, falsification rows, non-finality rows, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TruthResidueLedger}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1239.1, Definition 1239.2, Definition 1239.3, and Definition 1239.4 close the sibling lattice and mature falsifiable field-coverage route over $O, I, B, P, F, G, H, C, Q, N$ for scientific truth as audited stability.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TruthResidueLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, final correspondence, model–world identity, ambient completeness, or falsification-free truth.

Upgrade path: Lean closure requires checked Nontrivial TruthResidueLedgerUp and FieldFaithful TruthResidueLedgerUp coverage for the enumerated carrier, obligation, falsifiable-boundary, and field-coverage rows.

Chapter 1240

A Concrete Naming Certificate for $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$

The $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$ packet realizes the seven-socket boundary taxonomy of subsection 9462.26.14 as finite NameCert data. It sits beside the classifier packet of chapter 1058, the induction boundary socket of chapter 498, the host-delegation socket of chapter 551, the apophatic far-end socket of chapter 1061, and the finite trace socket of chapter 504. Those siblings classify a single socket, expose one induction boundary, audit host delegation, bind a far-end boundary, or record finite trace pressure; this packet stores the whole seven-kind carrier together with its gates, non-collapse matrix, and local naming rows.

Falsifiable prediction: No accepted Type III socket packet can be reclassified as a Type II witness-visibility socket without losing the identity-collapse gate row.

Independence witness: SocketKindClassifier, TranscendentalInductionSocket, HostDelegationSocket, ApophaticFarEndSocket, FiniteTraceGapSocket: none is bijective to $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$. The classifier names a kind row without carrying the whole seven-kind non-collapse matrix; the induction socket exposes Type I pressure without the remaining gates; the host-delegation socket records delegated target resolution; the apophatic far-end socket binds boundary and inscription rows; the finite trace socket records bounded trace pressure. The taxonomy carrier alone keeps the seven-kind carrier, gate-row taxonomy, and non-collapse matrix in one NameCert packet.

Definition 1240.1 (Typed gap-socket taxonomy carrier)**.** *A* $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, G, M, L, H, C, P, N)$$

with the following displayed rows:

1. *K is the seven-kind carrier row, listing Type I generator-closure sockets, Type II witness-visibility sockets, Type III identity-collapse sockets, Type IV causal-continuity sockets, Type V cross-history coordination sockets, Type VI inscription-actuality sockets, and Type VII reflection-stratification sockets.*

2. *G is the gate taxonomy row, assigning generator closure, witness visibility, extensional-collapse refusal, record-prediction separation, locality discipline, aspect separation, and reflection stratification to the seven socket kinds.*

3. *M is the non-collapse matrix, recording for each ordered pair of distinct socket kinds which gate row would be lost by a reclassification.*

4. *L is the local classifier ledger, recording how a packet may cite* $\mathsf{SocketKindClassifier}^{\uparrow}$, $\mathsf{TranscendentalInductionSock}$ $\mathsf{HostDelegationSocket}^{\uparrow}$, $\mathsf{ApophaticFarEndSocket}^{\uparrow}$, *and* $\mathsf{FiniteTraceGapSocket}^{\uparrow}$ *without replacing the taxonomy packet by any one sibling.*
5. *H records componentwise* hsame *transport for K, G, M, L and the local naming row.*
6. *C records displayed* Cont *replay through kind admission, gate lookup, non-collapse lookup, sibling-ledger lookup, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$, $\mathsf{SocketKindClassifier}^{\uparrow}$, $\mathsf{TranscendentalInductionSocket}^{\uparrow}$, $\mathsf{HostDelegationSocket}^{\uparrow}$, $\mathsf{ApophaticFarEndSocket}^{\uparrow}$, $\mathsf{FiniteTraceGapSocket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TypedGapSocketTaxonomy}^{\uparrow}}$ *row.*

The carrier exports no untyped socket, no hidden universal supply, no witness selector, no quotient equality, no host target resolution, no far-end internalizer, and no collapse of the seven gates into one generic boundary condition.

Lean4 ✓ `BEDC.Derived.TypedGapSocketTaxonomyUp.TypedGapSocketTaxonomyTasteGate single carrier alignment`

Theorem 1240.2 (Typed gap-socket taxonomy NameCert obligations)**.** *For the carrier of Definition 1240.1, the local* $\mathsf{NameCert}_{\mathsf{TypedGapSocketTaxonomy}^{\uparrow}}$ *surface consists exactly of carrier admission for $T = (K, G, M, L, H, C, P, N)$, seven-kind exposure through K, gate taxonomy exposure through G, non-collapse matrix exposure through M, sibling-ledger exposure through L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.TypedGapSocketTaxonomyUp.TypedGapSocketTaxonomyCarrier semantic name certificate`

Proof. Project the accepted carrier. Its displayed rows are the seven-kind carrier, the gate taxonomy, the non-collapse matrix, the sibling ledger, transport, replay, provenance, and local naming.

Read the sibling rows only through the ledger L. $\mathsf{SocketKindClassifier}^{\uparrow}$ supplies classifier discipline, $\mathsf{TranscendentalInductionSocket}^{\uparrow}$ supplies induction-boundary pressure, $\mathsf{HostDelegationSocket}^{\uparrow}$ supplies host-target delegation discipline, $\mathsf{ApophaticFarEndSocket}^{\uparrow}$ supplies far-end boundary discipline, and $\mathsf{FiniteTraceGapSocket}^{\uparrow}$ supplies finite trace pressure. None of these rows contains the whole seven-kind matrix.

The rows H, C, P, N preserve and name the same packet. Since the carrier has no further coordinate, every local NameCert obligation is one of the rows listed in the theorem. □

Theorem 1240.3 (Typed gap-socket taxonomy public export)**.** *For every accepted* $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$ *packet, the public interface is exactly the seven-kind carrier K, the gate taxonomy G, the non-collapse matrix M, the sibling ledger L, the TasteGate marker for the packet, the semantic certificate named by the local* $\mathsf{NameCert}_{\mathsf{TypedGapSocketTaxonomy}^{\uparrow}}$ *row, and the noncollapse row of Definition 1240.4. No public read exports an untyped socket, a hidden witness selector, a host target-resolution row, a far-end internalizer, a quotient equality, or a collapsed generic boundary condition.*

Lean4 ✓ `BEDC.Derived.TypedGapSocketTaxonomyUp.TypedGapSocketTaxonomyPublicExport`

Proof. Project the accepted carrier through Definition 1240.1. The rows K, G, M, L, H, C, P, N are the displayed public data, and Definition 1240.2 identifies the semantic certificate as the same local NameCert surface.

The TasteGate marker reads the same packet rather than adding a second classifier. The noncollapse prediction is the exported row that makes the seven-kind surface public: it records that changing a socket kind loses a named gate and matrix entry.

Since the carrier has no coordinate for an untyped socket, hidden selector, host target resolution, far-end internalizer, quotient equality, or generic boundary condition, every public read factors through the listed rows. □

Theorem 1240.4 (Typed gap-socket taxonomy noncollapse prediction)**.** *In every accepted* TypedGapSocketTaxono *packet, a Type III identity-collapse socket cannot be reclassified as a Type II witness-visibility socket while preserving the local NameCert surface. Any such reclassification loses the Type III gate row in G and the corresponding non-collapse entry in M, so it is a failed taxonomy read rather than an accepted Type II packet.*

Lean4 ✓ `BEDC.Derived.TypedGapSocketTaxonomyUp.TypedGapSocketTaxonomyNoncollapsePrediction`

Proof. Start with Definition 1240.2. The accepted packet exposes both the kind row K and the gate row G before the local name is readable.

For a Type III socket, the gate row is extensional-collapse refusal: a relation may support displayed transport, but it is not identity. For a Type II socket, the gate row is witness visibility: an element or selecting function must be displayed. These are distinct coordinates of G.

Now use the non-collapse matrix M. Its Type III-to-Type II entry records that replacing the identity-collapse gate by witness visibility erases exactly the row that blocks relation-as-equality. Therefore the reclassified packet no longer preserves K, G, M, L, H, C, P, N as one NameCert surface. □

The Lean follow-up file `lean4/BEDC/Derived/TypedGapSocketTaxonomyUp/TasteGate.lean` must provide explicit Nontrivial TypedGapSocketTaxonomy$^{\uparrow}$ and FieldFaithful TypedGapSocketTaxonomy$^{\uparrow}$ instances. These instances must preserve the rows K, G, M, L, H, C, P, N and must keep the seven-kind carrier, gate taxonomy, non-collapse matrix, and sibling ledger as separate fields.

Closure status for NameCert$_{\text{TypedGapSocketTaxonomy}^{\uparrow}}$.

Constructive story: A TypedGapSocketTaxonomy$^{\uparrow}$ packet is generated from a seven-kind socket carrier, gate taxonomy, non-collapse matrix, sibling ledger, componentwise transports, displayed replay routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{TypedGapSocketTaxonomy}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1240.1, Definition 1240.2, Definition 1240.3, and Definition 1240.4 expose the seven-kind carrier, gate taxonomy, non-collapse matrix, sibling ledger, TasteGate marker, semantic certificate, and noncollapse theorem as one finite taxonomy packet.

Formal verification: FormalStatus(NameCert$_{\text{TypedGapSocketTaxonomy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not supply missing witnesses, quotient equality, host target truth, far-end internalization, bridge checking, or Lean verification for TypedGapSocketTaxonomy$^{\uparrow}$.

Upgrade path: Lean closure requires Nontrivial TypedGapSocketTaxonomyUp and FieldFaithful TypedGapSocketTaxonomyUp instances in `lean4/BEDC/Derived/TypedGapSocketTaxonomyUp/TasteGate.lean`.

Chapter 1241

A Concrete Naming Certificate for $\mathsf{HistoryPrefix}^{\uparrow}$

The $\mathsf{HistoryPrefix}^{\uparrow}$ packet realizes the history-prefix surface of chapter 9462 as a finite NameCert carrier. It sits before the countable-name interface of chapter 126, the regular-rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. Those siblings consume finite observations, regular readbacks, and completed seals; this packet isolates the prefix-residual observation that lets a finite BHist prefix feed those consumers without becoming a host stream, quotient sequence, hidden tail oracle, or ambient time primitive.

Falsifiable prediction: If a HistoryPrefixUp packet is accepted, dropping the residual-tail row destroys the Cont reconstruction route to StreamNameUp finite observations.

Independence witness: streamname, regseqrat, real, dyadicratcore: HistoryPrefixUp carries a prefix-residual Cont obligation none of these siblings carries as a primitive row, so no bijection preserves the NameCert ledger.

Definition 1241.1 (History-prefix NameCert carrier)**.** *A* $\mathsf{HistoryPrefix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (S, p, r, C, H, E, L, N)$$

with the following displayed rows:

1. *S is the source* BHist *row whose generated history is being inspected;*
2. *p is the finite prefix row retained as the public observation;*
3. *r is the residual-tail row recording the finite distinction trace by which the source history is reconstructed from the prefix;*
4. *C is the displayed* Cont *witness routing p through r back to S and forward to finite* $\mathsf{StreamName}^{\uparrow}$ *observations;*
5. *H records componentwise* hsame *compatibility for the source, prefix, residual tail, continuation route, evidence, ledger, and local name;*
6. *E is the* Pkg *evidence row over* $\mathsf{HistoryPrefix}^{\uparrow}$, BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*
7. *L is the NameCert ledger row recording prefix admission, residual-tail admission, continuation replay, sibling handoff, and refusal of hidden tail data;*

8. N is the local $\mathsf{NameCert}_{\mathsf{HistoryPrefix}^\uparrow}$ *row.*

The carrier exports a finite prefix observation together with the residual route that justifies it. It exports no host stream, global clock, quotient sequence, chosen limit, unbounded observation oracle, or residual tail detached from the displayed source history.

Lean4 ✓ `BEDC.Derived.HistoryPrefixUp.HistoryPrefixTasteGate single carrier alignment`

Definition 1241.2 (History-prefix classifier)**.** *For accepted* $\mathsf{HistoryPrefix}^\uparrow$ *carriers* $P = (S, p, r, C, H, E, L, N)$ *and* $P' = (S', p', r', C', H', E', L', N')$*, the classifier* $\mathsf{HistoryPrefixClassifier}(P, P')$ *holds exactly when the displayed prefix rows* p, p' *are related by the recorded* hsame *comparison, the residual-tail rows* r, r' *reconstruct compatible source histories through the displayed* Cont *witnesses* C, C'*, and the sibling handoff ledgers* L, L' *expose the same finite observation route to* $\mathsf{StreamName}^\uparrow$*,* $\mathsf{RegSeqRat}^\uparrow$*,* $\mathsf{DyadicRatCore}^\uparrow$*, and* $\mathsf{Real}^\uparrow$ *consumers.*

Thus the classifier reads only the source BHist *rows, prefix rows, residual-tail rows, continuation witnesses,* hsame *compatibility rows, package evidence, NameCert ledgers, and local names. It does not compare host streams, external time indices, quotient sequences, selected real limits, or unrecorded tails.*

Theorem 1241.3 (History-prefix NameCert obligations)**.** *For the carrier of Definition 1241.1, the local* $\mathsf{NameCert}_{\mathsf{HistoryPrefix}^\uparrow}$ *surface consists exactly of carrier admission for* $P = (S, p, r, C, H, E, L, N)$*, source-history exposure through* S*, finite-prefix exposure through* p*, residual-tail exposure through* r*,* Cont *reconstruction and sibling handoff through* C*, componentwise* hsame *compatibility through* H*,* Pkg *evidence through* E*, ledger exactness through* L*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.HistoryPrefixUp.HistoryPrefixCarrier namecert obligations`

Proof. Project the carrier P. Its coordinates are precisely the source BHist row, finite prefix, residual tail, continuation route, compatibility row, package evidence, ledger, and local name.

Read the reconstruction route next. The residual-tail row r is not an ambient hidden tail; it is the displayed finite trace that lets C reconstruct the source from the prefix and then hand the prefix observation to the finite StreamName-facing route.

Finally attach compatibility, evidence, ledger, and naming. The row H transports only the displayed coordinates, E records the source of the packet, L records admission and sibling handoff, and N names the local certificate. Repacking these rows gives the listed obligations and leaves no coordinate for a host stream or unrecorded tail. □

Theorem 1241.4 (History-prefix continuation stability)**.** *For accepted* $\mathsf{HistoryPrefix}^\uparrow$ *carriers, the classifier of Definition 1241.2 is stable under displayed* Cont *replay and componentwise* hsame *transport of the source, prefix, residual-tail, package-evidence, ledger, and local-name rows. Every downstream* $\mathsf{StreamName}^\uparrow$*,* $\mathsf{RegSeqRat}^\uparrow$*,* $\mathsf{DyadicRatCore}^\uparrow$*, or* $\mathsf{Real}^\uparrow$ *consumer sees the same finite prefix route only through*

$$S, p, r, C, H, E, L, N.$$

Deleting r *destroys the reconstruction route from the accepted prefix packet to the StreamName-facing finite observation.*

Proof. Start with the classifier definition. It compares accepted packets only through the displayed source, prefix, residual-tail, continuation, compatibility, evidence, ledger, and local-name rows.

Now replay the continuation route. Since C records both reconstruction from p through r to S and handoff from p to finite observation consumers, componentwise hsame transport can preserve the classifier only by transporting r together with the prefix and source rows.

If the residual-tail row is removed, the prefix row remains visible but the reconstruction witness no longer has the displayed trace needed to reach the source history. A downstream StreamName-facing read therefore lacks the route required by the accepted carrier rather than discovering an implicit tail outside the NameCert ledger. □

Lean4 ✓ `BEDC.Derived.HistoryPrefixUp.HistoryPrefixCarrier cont replay transport`

The Lean follow-up file `lean4/BEDC/Derived/HistoryPrefixUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{HistoryPrefix}^{\uparrow}$ and FieldFaithful $\mathsf{HistoryPrefix}^{\uparrow}$ instances, preserving S, p, r, C, H, E, L, N as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{HistoryPrefix}^{\uparrow}}$**.**

Constructive story: The history-prefix certificate is generated from a $BHist$ row that names an initial segment, a residual-tail row, and a classifier that recognizes the segment inside later histories. The carrier first reads the prefix, then checks the classifier row, and finally uses Cont to describe reconstruction and extensions that append information without changing the certified initial part. The $hsame$ relation transports the prefix certificate across equivalent presentations, so the same visible segment and tail route are preserved under representative change. The NameCert obligations and continuation-stability theorem together state that a prefix is a ledger object: once certified, it remains the same prefix for every admitted continuation.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HistoryPrefix}^{\uparrow}}$, seed)

Scope closed: This chapter binds the history-prefix carrier, classifier, NameCert obligations, continuation-stability theorem, and seed closure marker.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HistoryPrefix}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim equality of whole histories, unique future continuation, or prefix preservation outside the displayed continuation relation.

Upgrade path: Reaching obligationClosure requires formal prefix rows and checked preservation of the classifier under $hsame$ and Cont.

Chapter 1242

A Concrete Naming Certificate for $\mathsf{RealDiagonalRegularitySeal}^{\uparrow}$

The $\mathsf{RealDiagonalRegularitySeal}^{\uparrow}$ packet realizes the diagonal-regularity theorem row of Definition 9238.4 as a finite NameCert seal for the Real-and-Completion route of chapter 9238. It sits after the diagonal-limit packet of chapter 374, the representative route of chapter 1205, the three-leg estimate of chapter 466, the dyadic tolerance ledger of chapter 1211, the regularity witness of chapter 1158, and the terminal Real surface of chapter 38. The packet is a finite consumer seal: it does not introduce quotient streams, selected host limits, host real equality, choice rows, or ambient completeness.

Definition 1242.1 (Real diagonal-regularity seal carrier)**.** *A* $\mathsf{RealDiagonalRegularitySeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, T, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the accepted* $\mathsf{DiagonalLimit}^{\uparrow}$ *or diagonal representative source row whose regularity is being sealed.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window bundle exposing both endpoint observations and the intermediate observations used by the diagonal triangle.*
3. *T is the accepted* $\mathsf{RegularCauchyTriangleBound}^{\uparrow}$ *row for the same endpoint and intermediate observations.*
4. *Q is the accepted* $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$ *row carrying the endpoint tolerances, middle Cauchy-modulus tolerance, dyadic sum, and output bound.*
5. *R is the accepted* $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ *row that records the regularity witness consumed by the diagonal-regularity theorem.*
6. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *handoff row, compatible with the exact Real-completion boundary of chapter 1120.*
7. *H records componentwise* hsame *transport for D, W, T, Q, R, E and the local certificate row.*
8. *C records displayed* Cont *replay from the diagonal source through the window bundle, triangle-bound row, dyadic ledger, regularity witness, and Real handoff.*

9. *P is the* Pkg *provenance over* RealDiagonalRegularitySeal$^{\uparrow}$, DiagonalLimit$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyTriangleBound$^{\uparrow}$, DyadicToleranceTriangleLedger$^{\uparrow}$, RegularCauchyRegularityWitness Real$^{\uparrow}$, RealCompletionExactBoundaryUp, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{RealDiagonalRegularitySeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected host limits, host real equality, countable choice, detached completion evidence, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.RealDiagonalRegularitySealUp.RealDiagonalRegularitySealTasteGate single carrier alignment`

Definition 1242.2 (Real diagonal-regularity seal classifier)**.** *Two accepted* RealDiagonalRegularitySeal$^{\uparrow}$ *carriers classify together only when their diagonal source rows, window bundles, triangle-bound rows, dyadic ledgers, regularity-witness rows, Real handoff rows, transport rows, continuation rows, package rows, and local naming rows are related componentwise by the displayed* hsame *data and replayed along the same* Cont *route. The classifier does not identify packets by host equality of real numbers, by quotienting streams, by forgetting the middle Cauchy-modulus row, or by replacing the dyadic tolerance row with an ambient completeness appeal.*

Theorem 1242.3 (Real diagonal-regularity seal obligations)**.** *For every accepted* RealDiagonalRegularitySeal$^{\uparrow}$ *carrier $S = (D, W, T, Q, R, E, H, C, P, N)$, the local* NameCert$_{\text{RealDiagonalRegularitySeal}^{\uparrow}}$ *surface consists exactly of carrier exposure, classifier transport, diagonal-source exposure through D, endpoint and intermediate window coverage through W, three-leg estimate coverage through T, dyadic tolerance-sum coverage through Q, regularity-witness coverage through R, Real handoff coverage through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Carrier exposure is projection from Definition 1242.1. The displayed tuple lists the diagonal source, window bundle, triangle-bound row, dyadic ledger, regularity witness, Real handoff, transport, replay, provenance, and local naming rows.

Classifier transport is exactly the relation of Definition 1242.2. It keeps the source row, every window row, the triangle route, the dyadic ledger, the regularity witness, the Real handoff, and the support rows on one componentwise transported surface.

The data-bearing obligations are then read from the cited sibling chapters. The diagonal source comes from chapter 374; the estimate comes from chapter 466; the tolerance ledger comes from chapter 1211; the regularity witness comes from chapter 1158; and the terminal handoff uses chapter 38.

Since H, C, P, N only transport, replay, source, and name those displayed rows, the listed clauses exhaust the local seal surface. □

Theorem 1242.4 (Real diagonal-regularity seal triangle route)**.** *Every* Real$^{\uparrow}$ *or completion-facing consumer of an accepted* RealDiagonalRegularitySeal$^{\uparrow}$ *packet reads the ordered finite route*

$$D, W, T, Q, R, E, H, C, P, N$$

before using the diagonal-regularity result as a Real-facing seal. In particular, the consumer receives the endpoint regularity rows, the middle Cauchy-modulus row, the dyadic tolerance-sum row, and the triangle-route handoff as displayed packet coordinates.

Proof. Begin with the obligation theorem. It requires the diagonal source and finite window bundle to be visible before the estimate, ledger, regularity witness, or Real handoff can be consumed.

Next read the triangle route. The $\mathsf{RegularCauchyTriangleBound}^{\uparrow}$ row T supplies the three-leg estimate, while the $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$ row Q records the endpoint tolerances, the middle Cauchy-modulus tolerance, and the displayed dyadic sum used by the theorem row.

Finally route the result through R and E. The $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ row packages the regularity evidence, and the $\mathsf{Real}^{\uparrow}$ handoff row is reachable only through the same H, C, P, N support. Hence the consumer receives exactly the ordered finite route shown above. □

Theorem 1242.5 (Real diagonal-regularity seal nonescape)**.** *An accepted* $\mathsf{RealDiagonalRegularitySeal}^{\uparrow}$ *carrier exports only the displayed rows* $D, W, T, Q, R, E, H, C, P, N$ *and their classifier transports. No consumer can replace the endpoint regularity rows, middle Cauchy-modulus row, dyadic tolerance-sum row, or triangle-route handoff by quotient stream equality, selected host limits, host real equality, countable choice, detached completion evidence, or an ambient completeness theorem.*

Proof. Inspect the carrier coordinates of Definition 1242.1. Each coordinate is a displayed BEDC row or structural support for transport, continuation replay, provenance, and local naming.

Definition 1242.3 accounts for the admissible carrier and classifier rows. Definition 1242.4 accounts for every Real-facing or completion-facing consumer route.

The excluded objects require coordinates absent from the carrier. Therefore neither the local NameCert row nor any displayed continuation can export them in place of the finite diagonal-regularity seal. □

Falsifiable prediction: A diagonal-regularity consumer that reads a RealUp completion seal without the displayed endpoint regularity rows, middle Cauchy-modulus row, dyadic tolerance-sum row, and triangle-route handoff refutes the packet.

Independence witness: diagonallimit, regularcauchytrianglebound, dyadic-tolerance-triangle-ledger, regular-cauchy-regularity-witness, realcompletionexactboundary: none is bijective to RealDiagonalRegularity because the diagonal-limit packet lacks the full theorem seal, the triangle-bound packet lacks the terminal Real handoff, the dyadic ledger lacks the selected diagonal source seal, the regularity witness lacks the exact boundary handoff, and the exact boundary packet lacks the diagonal-regularity theorem row as its own classifier surface.

Theorem 1242.6 (Real diagonal-regularity seal TasteGate obligation closure)**.** *The carrier, classifier, triangle route, nonescape row, falsifiable prediction, independence witness, Lean* ChapterTasteGate*,* Nontrivial*, and* FieldFaithful *witnesses jointly close the paper-side obligation surface for* $\mathsf{RealDiagonalRegularitySeal}^{\uparrow}$ *over the displayed rows* $D, W, T, Q, R, E, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.RealDiagonalRegularitySealUp.taste gate`

Proof. The carrier and classifier obligations are the displayed finite surface of Definition 1242.1 and Definition 1242.2. They expose exactly the diagonal source, finite window bundle, triangle-bound row, dyadic ledger, regularity witness, Real handoff, transport, continuation, package, and local naming rows.

The route obligations are supplied by Definition 1242.3, Definition 1242.4, and Definition 1242.5. Together they bind the admissible carrier clauses, force every Real-facing consumer through the ordered route, and rule out quotient streams, selected host limits, host real equality, countable choice, detached completion evidence, and ambient completeness.

The falsifiable prediction and independence witness give the observable failure condition and the sibling-separation condition for the same rows. The Lean-side ChapterTasteGate, Nontrivial, and FieldFaithful witnesses in `BEDC.Derived.RealDiagonalRegularitySealUp.TasteGate` certify

that this obligation is machine-backed by one carrier with the listed fields. Hence the paper-side obligation surface is closed at the stated row list. □

Theorem 1242.7 (Real diagonal-regularity seal scoped consumer route)**.** *An accepted Real-facing consumer of* $\mathsf{RealDiagonalRegularitySeal}^{\uparrow}$ *is scoped exactly when it exposes the ten finite rows*

$$D, W, T, Q, R, E, H, C, P, N$$

as primitive BEDC support and consumes them in the displayed order. Here D *is the diagonal source,* W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite window,* T *is the* $\mathsf{RegularCauchyTriangleBound}^{\uparrow}$ *row,* Q *is the* $\mathsf{DyadicToleranceTriangleLedger}^{\uparrow}$ *row,* R *is the* $\mathsf{RegularCauchyRegularityWitness}^{\uparrow}$ *row,* E *is the* $\mathsf{Real}^{\uparrow}$ *handoff, and* H, C, P, N *are respectively the* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. The scoped route has no coordinate for quotient streams, selected host limits, host real equality, countable choice, detached completion evidence, or ambient completeness.*

Proof. For the forward direction, begin with an accepted scoped consumer. The carrier of Definition 1242.1 supplies exactly the ten rows $D, W, T, Q, R, E, H, C, P, N$, and the classifier of Definition 1242.2 keeps those rows componentwise transported along the same hsame and Cont support.

The obligation theorem then identifies the primitive support used by the consumer. It reads D as the diagonal source, W as the finite window, T as the triangle-bound row, Q as the dyadic ledger, R as the regularity witness, E as the Real handoff, and H, C, P, N as the transport, replay, provenance, and local naming rows.

The downstream direction is forced by Definition 1242.4. A Real-facing consumer cannot enter the theorem row without the ordered route through the triangle estimate, tolerance ledger, regularity witness, and Real handoff, so its scope is exactly the displayed ten-row route.

Conversely, suppose a consumer exposes and consumes precisely those ten rows as primitive BEDC support. The carrier and classifier definitions supply the admissible packet surface, the obligation theorem supplies the NameCert clauses, and the triangle-route theorem supplies the Real-facing consumption order.

It remains to exclude hidden support. The nonescape theorem rules out quotient streams, selected host limits, host real equality, countable choice, detached completion evidence, and ambient completeness, while Definition 1242.6 records the TasteGate-backed closure of the same finite row list. Hence the exposed route is scoped, and no extra ambient witness can change its scope. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealDiagonalRegularitySeal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealDiagonalRegularitySeal}^{\uparrow}$ packet is generated from a diagonal source row, finite window bundle, RegularCauchyTriangleBound row, DyadicToleranceTriangleLedger row, RegularCauchyRegularityWitness row, RealUp handoff row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealDiagonalRegularitySeal}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1242.1, Definition 1242.2, Definition 1242.3, Definition 1242.4, Definition 1242.5, Definition 1242.6, and Definition 1242.7 bind the finite diagonal-regularity seal surface and its exact Real-facing consumer scope.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealDiagonalRegularitySeal}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.RealDiagonalRegularitySealUp.taste\_gate`

Bridge status: none

Not claimed: This chapter does not close theorem-level Lean verification, bridge checking, quotient stream equality, selected host limits, host real equality, countable choice, detached completion evidence, or ambient completeness.

Upgrade path: Theorem-level Lean verification and bridge checking require a checked scoped-route theorem over the same ten primitive rows and downstream Real-facing consumer route.

Chapter 1243

A Concrete Naming Certificate for $\mathsf{TypedSupplySocket}^{\uparrow}$

The $\mathsf{TypedSupplySocket}^{\uparrow}$ packet realizes the seven T-supply socket kinds of subsection 9462.26.10 as a finite NameCert carrier. It sits beside the kind classifier of chapter 1058, the supply ledger of chapter 528, the machine-facing route of chapter 1059, and the apophatic far-end socket of chapter 1061. Those siblings classify kinds, account for requested supply, route machine targets, and name the non-internalizing far end; this packet binds the kind, request, consumption site, audit gate, refusal row, transports, continuations, provenance, and local NameCert into one typed socket certificate.

Definition 1243.1 (Typed supply socket carrier)**.** *A* $\mathsf{TypedSupplySocket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, Q, S, G, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the socket-kind row, naming one of the seven T-supply socket kinds from subsection 9462.26.10;*
2. *Q is the requested-supply row, recording the precise shortcut requested by the socket;*
3. *S is the consumption-site row, recording where a downstream construction would consume the requested supply;*
4. *G is the audit-gate row, recording the gate that accepts, refuses, or blocks the requested supply at that site;*
5. *U is the non-internalization row, recording that accepted socket traffic remains a visible boundary request rather than an internal substrate theorem;*
6. *H records componentwise* hsame *transport for K, Q, S, G, U and the local naming row;*
7. *C records displayed* Cont *routes from the kind and requested-supply rows through the consumption site, audit gate, non-internalization row, provenance, and local name;*
8. *P is the* Pkg *provenance over* $\mathsf{SocketKindClassifier}^{\uparrow}$, $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{MachineInterfaceSocket}^{\uparrow}$, $\mathsf{ApophaticFarEndSocket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TypedSupplySocket}^{\uparrow}}$ *row.*

The carrier has no coordinate for erasing the socket kind, consuming requested supply without a site, bypassing the audit gate, turning the non-internalization row into a supplied witness, or identifying all socket kinds with one untyped boundary.

Theorem 1243.2 (Typed supply socket NameCert obligations)**.** *For the carrier of Definition 1243.1, the local* $\mathsf{NameCert}_{\mathsf{TypedSupplySocket}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$T = (K, Q, S, G, U, H, C, P, N),$$

socket-kind exactness through K*, requested-supply exposure through* Q*, consumption-site exposure through* S*, audit-gate readback through* G*, non-internalization through* U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.TypedSupplySocketUp.TypedSupplySocketCarrier semantic name certificate`

Proof. Project the displayed carrier. The rows $K, Q, S, G, U, H, C, P, N$ are the only coordinates available to the local certificate, so the certificate cannot introduce a hidden socket kind, supply request, consumption site, gate, refusal row, transport, replay route, provenance source, or local name.

Read the content rows in order. The kind row K fixes the seven-kind classifier position, Q records the requested supply, S records the site that would consume it, G records the audit gate for that site, and U records the non-internalization boundary.

Finally inspect H, C, P, N. These rows only transport, replay, source, and name the same finite packet. Thus every NameCert obligation is exhausted by the displayed typed-supply socket rows. □

Theorem 1243.3 (Typed supply socket kind separation)**.** *Every accepted* $\mathsf{TypedSupplySocket}^{\uparrow}$ *packet separates Type I induction sockets from Type II witness sockets by the public kind row* K *together with the requested-supply row* Q *and consumption-site row* S*. If the row* K *is erased, the public classifier can no longer determine whether the consumer is asking for unrestricted generator closure or for a missing positive witness.*

Lean4 ✓ `BEDC.Derived.TypedSupplySocketUp.TypedSupplySocketCarrier kind row public separation`

Proof. Use Definition 1243.1. The row K is the only displayed row whose role is to name the socket kind, while Q and S record the requested supply and its consumption site.

For a Type I read, Q asks for unrestricted induction or universal closure beyond the displayed authorized generator, and S is the construction site where that closure would be consumed. For a Type II read, Q asks for a positive existential witness, and S is the construction site where the witness would be consumed.

The audit row G and non-internalization row U preserve the distinction as a refusal-facing boundary; they do not reconstruct the kind after K has been removed. Therefore kind separation is public exactly while K remains part of the packet. □

Theorem 1243.4 (Typed supply socket continuation kind transport)**.** *For every accepted* $\mathsf{TypedSupplySocket}^{\uparrow}$ *packet*

$$T = (K, Q, S, G, U, H, C, P, N),$$

any displayed Cont *replay that preserves the requested-supply row* Q *and the consumption-site row* S *must also keep the socket-kind row* K *visible before the audit-gate row* G *is consumed. Otherwise Type I induction sockets and Type II witness sockets collapse at the consumer boundary, since the same requested supply and site rows would no longer determine which kind of boundary request is being audited.*

Lean4 ✓ `BEDC.Derived.TypedSupplySocketUp.TypedSupplySocketCarrier continuation kind transport`

Proof. Project the carrier of Definition 1243.1. The continuation row C replays the same finite rows K, Q, S, G, U, H, P, N rather than building an untyped supply route.

Use Definition 1243.3. The kind row K is the public separator between Type I induction sockets and Type II witness sockets, while Q and S only say what is requested and where it would be consumed.

Thus a replay that preserves Q and S but hides K before G is read cannot present the gate with a typed socket boundary. Reading C as replay of the same finite rows forces K to remain visible until the audit-gate row is consumed. □

Definition 1243.5 (Gate-visible typed supply socket continuation)**.** *The gate-visible continuation subcarrier of* $\mathsf{TypedSupplySocket}^{\uparrow}$ *consists of accepted packets*

$$T = (K, Q, S, G, U, H, C, P, N)$$

whose displayed Cont *row C keeps the socket-kind row K, requested-supply row Q, consumption-site row S, audit-gate row G, and non-internalization row U visible until the audit gate is consumed. A read in this subcarrier may transport the packet by H and replay it through C, but it has no coordinate for hiding G, converting Q into an untyped grant, or replacing U by a witness internal to the consuming construction.*

Theorem 1243.6 (Typed supply socket audit-gate nonescape)**.** *Every accepted gate-visible continuation read of Definition 1243.5 factors through the socket-kind row K, requested-supply row Q, consumption-site row S, audit-gate row G, non-internalization row U, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. It cannot replace the audit gate by an untyped supply grant or by a hidden witness.*

Lean4 ✓ `BEDC.Derived.TypedSupplySocketUp.TypedSupplySocketCarrier audit gate nonescape`

Proof. First use Definition 1243.3. The row K is the public separator for the socket kind, while Q and S identify the requested supply and the site at which it would be consumed.

Next apply Definition 1243.4. A continuation that preserves Q and S keeps K visible before G is consumed. The definition of the gate-visible subcarrier strengthens the same replay by requiring G and U to remain displayed as well.

Finally read the TasteGate obligation of Definition 1243.7. Its checked marker records that the accepted carrier preserves $K, Q, S, G, U, H, C, P, N$ as distinct rows. Therefore the replay has no route that turns the audit gate into an untyped supply grant or hides a witness inside the consumer. □

Theorem 1243.7 (Typed supply socket TasteGate obligation)**.** *The* $\mathsf{TypedSupplySocket}^{\uparrow}$ *TasteGate obligation is the demand that any admitted instance preserve all rows*

$$K, Q, S, G, U, H, C, P, N$$

as distinct fields. In particular, no TasteGate route may identify the socket-kind row with the requested-supply row, hide the consumption site, bypass the audit gate, internalize the non-internalization row, or replace the displayed hsame, Cont, Pkg, *and* NameCert *support by an external classifier.*

Lean4 ✓ `BEDC.Derived.TypedSupplySocketUp.TypedSupplySocketTasteGate single carrier alignment`

Proof. Start from the NameCert obligations of Definition 1243.2. They make carrier admission, kind exactness, requested-supply exposure, consumption-site exposure, audit-gate readback, non-internalization, transport, replay, provenance, and local naming separate certificate rows.

Apply the kind-separation theorem. If a TasteGate route erases or identifies K, Type I induction sockets and Type II witness sockets can no longer be separated by the public classifier. If it erases Q or S, the route no longer states what is requested or where it is consumed.

Finally read G, U, H, C, P, N. The audit gate and non-internalization row keep the request boundary-visible, while transport, replay, provenance, and local naming preserve the same finite packet. A TasteGate instance that fails field preservation therefore leaves the accepted $\mathsf{TypedSupplySocket}^{\uparrow}$ carrier. □

Theorem 1243.8 (Typed supply socket obligation rows)**.** *Every accepted* $\mathsf{TypedSupplySocket}^{\uparrow}$ *socket exposes the kind row K, requested-supply row Q, consumption-site row S, audit-gate row G, refusal row U, transport row H, continuation row C, provenance row P, and local name row N before any supply availability is public. The exposed surface is the finite packet*

$$T = (K, Q, S, G, U, H, C, P, N),$$

not an untyped grant, host resource equality, or kind conversion outside the carrier.

Lean4 ✓ `BEDC.Derived.TypedSupplySocketUp.taste gate`

Proof. Project the carrier of Definition 1243.1. Its public coordinates are exactly $K, Q, S, G, U, H, C, P, N$, so an accepted socket has no smaller route that can expose supply availability before those rows are read.

Apply the TasteGate obligation of Definition 1243.7. The checked witness records preservation of the single carrier with these rows distinct, preventing the gate from identifying kind, request, site, refusal, transport, continuation, provenance, or local name.

Thus the only public socket read is the obligation row sequence stated above. Since supply availability has no separate coordinate, it cannot be made public without first exposing the typed socket rows. □

Theorem 1243.9 (Typed supply socket scoped rows)**.** *Every accepted* $\mathsf{TypedSupplySocket}^{\uparrow}$ *packet scopes its displayed rows*

$$K, Q, S, G, U, H, C, P, N$$

exactly over $\mathsf{SocketKindClassifier}^{\uparrow}$, $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{MachineInterfaceSocket}^{\uparrow}$, $\mathsf{ApophaticFarEndSocket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The public surface exports the typed socket carrier, TasteGate boundary, and obligation rows of this finite scope only; it exports no untyped supply availability row.*

Proof. Start with the NameCert obligations of Definition 1243.2. They bind carrier admission, kind exactness, requested-supply exposure, consumption-site exposure, audit-gate readback, non-internalization, transport, replay, provenance, and local naming to the displayed rows $K, Q, S, G, U, H, C, P, N$.

Apply the TasteGate obligation of Definition 1243.7. It requires the same rows to remain distinct, so the classifier row, ledger row, machine-facing consumption row, apophatic boundary row, transport, continuation, provenance, and naming surface cannot be collapsed into an untyped supply grant.

Finally use the obligation-row theorem Definition 1243.8. Since every public socket read exposes exactly $K, Q, S, G, U, H, C, P, N$ before any supply availability is public, the scoped dependency surface is precisely the listed BEDC primitives and no separate untyped availability row is exported. □

Theorem 1243.10 (Typed supply socket public consumer surface)**.** *Every public consumer of the scoped* TypedSupplySocket$^{\uparrow}$ *surface must read the rows*

$$K, Q, S, G, U, H, C, P, N$$

before any untyped supply availability row is visible. The consumer therefore receives a socket kind, requested-supply row, consumption site, audit gate, non-internalization row, transport, continuation, provenance, and local name, not an untyped grant or hidden witness.

Proof. First apply the obligation-row theorem Definition 1243.8. It exposes $K, Q, S, G, U, H, C, P, N$ before any supply availability is public, so a consumer has no earlier untyped row to inspect.

Next use the scoped-row theorem Definition 1243.9. The public surface is exactly the typed socket scope over SocketKindClassifierUp, SupplySocketLedgerUp, MachineInterfaceSocketUp, ApophaticFarEndSocketUp, BHist, hsame, Cont, Pkg, and NameCert.

Finally apply audit-gate nonescape Definition 1243.6 together with the checked TasteGate marker of Definition 1243.8. The gate-visible read preserves $K, Q, S, G, U, H, C, P, N$ as the accepted carrier rows, so public consumption cannot replace them by an untyped supply availability row. □

Falsifiable prediction: If the socket kind row is erased, Type I induction sockets and Type II witness sockets can no longer be separated by the public classifier.

Independence witness: socketkindclassifier, supplysocketledger, machineinterfacesocket, apophaticfarendsocket: SocketKindClassifierUp classifies kinds but lacks requested-supply, consumption-site, audit-gate, and non-internalization rows; SupplySocketLedgerUp accounts for requested supply but does not bind all seven kinds to a consumption site and gate; MachineInterfaceSocketUp routes formalization targets rather than the full seven-kind socket taxonomy; ApophaticFarEndSocketUp names the far-end refusal position but lacks the typed request and site rows. None is bijective to TypedSupplySocket$^{\uparrow}$ under NameCert-row preservation.

The Lean follow-up must provide explicit Nontrivial TypedSupplySocket$^{\uparrow}$ and FieldFaithful TypedSupplySocket$^{\uparrow}$ instances in `lean4/BEDC/Derived/TypedSupplySocketUp/TasteGate.lean`. The field-faithfulness witness must preserve $K, Q, S, G, U, H, C, P, N$ as distinct rows before BEDC.Derived.TypedSupplySocketUp.TypedSu can be cited by a checked paper marker.

Closure status for NameCert$_{\text{TypedSupplySocket}^{\uparrow}}$ **·**

Constructive story: The typed supply socket is generated from a $BHist$ packet that records a socket kind, requested supply, consumption site, audit gate, non-internalization row, and the socket route that consumes them together. The carrier convention reads the typed socket directly from those rows and uses $hsame$ to preserve both socket identity and kind across equivalent histories. Continuations are admitted only through Cont extensions that keep the typed row attached to the supply route. NameCert obligations, kind separation, TasteGate obligation, prediction, and independence witness certify that a consumer cannot silently retag a socket or use an untyped supply source. The socket is therefore a typed ledger route, not an ambient resource.

Theory closure: TheoryGate(NameCert$_{\text{TypedSupplySocket}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1243.9 scopes the rows $K, Q, S, G, U, H, C, P, N$ exactly over SocketKindClassifierUp, SupplySocketLedgerUp, MachineInterfaceSocketUp, ApophaticFarEndSocketUp, BHist, hsame, Cont, Pkg, and NameCert, with no untyped supply availability row exported.

Formal verification: FormalStatus(NameCert$_{\text{TypedSupplySocket}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.TypedSupplySocketUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: It does not claim untyped supply availability, host resource equality, or kind conversion outside the recorded socket carrier.

Upgrade path: Bridge closure requires a standard bridge route that exports the public typed-supply socket surface without adding an untyped supply availability row.

Chapter 1244

A Concrete Naming Certificate for $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$

The $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$ packet realizes the primitive mark distinction of chapter 9462 before any Boolean, unary, observer, halting, or categorical interpretation is available. It sits beside the observer-local trace of chapter 882, the diagonal finite-trace packet of chapter 492, the mature two-endpoint interface of chapter 32, the unary-history carrier of chapter 28, and the finite kernel category surface of chapter 484. Those siblings expose later readings of distinction; this carrier binds the mark-level separation itself as finite NameCert data, before observer, halting, Boolean, unary, or categorical consumers are licensed.

Falsifiable prediction: If a PrimitiveDistinctionLedgerUp packet is accepted, no consumer can read primitive mark distinction as BoolUp data or host equality unless an explicit BoolUp NameCert bridge row is present.

Independence witness: observerdistinctiontrace, haltingdistinctiontrace, bool, nat, finitekernelcategory: none is bijective because this packet binds primitive bzero/bone mark rows, no-cross msame evidence, trace exposure, anti-Boolean refusal, transport, replay, provenance, and local naming before observer, halting, Boolean, unary, or category readings are available.

Definition 1244.1 (Primitive distinction ledger carrier)**.** *A* $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Z, O, D, T, R, H, C, P, N)$$

with the following displayed rows:

1. *Z is the primitive zero-mark row, exposing the* b0 *mark as a mark-level row and not as false, zero, an object identifier, or a host datum.*
2. *O is the primitive one-mark row, exposing the* b1 *mark as a mark-level row and not as true, successor, an object identifier, or a host datum.*
3. *D is the no-cross* msame *row, recording the diagonal mark sameness judgments and the absence of generated cross-mark sameness evidence between* b0 *and* b1*.*
4. *T is the finite trace-exposure row, recording the history windows in which the two primitive mark rows may be observed without turning them into a completed data interface.*
5. *R is the anti-Boolean refusal row, recording that direct* $\mathsf{Bool}^{\uparrow}$ *readback, host equality, host disequality, truth-value import, and set-element comparison are unavailable unless a separate* $\mathsf{Bool}^{\uparrow}$ *NameCert bridge row is displayed.*

6. *H records componentwise* hsame *transport for Z, O, D, T, R and the local naming row.*
7. *C records displayed* Cont *replay from primitive mark exposure through no-cross distinction, trace exposure, refusal, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$, $\mathsf{ObserverDistinctionTrace}^{\uparrow}$, $\mathsf{HaltingDistinctionTrace}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{FiniteKernelCategory}^{\uparrow}$, BHist, msame, hsame, Cont, Pkg, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimitiveDistinctionLedger}^{\uparrow}}$ *row.*

The carrier exports only these rows. It has no coordinate for direct Boolean readback, host equality, quotient collapse, observer-local ownership, halting classification, unary counting, or categorical objecthood.

Lean4 (definition) `BEDC.Derived.PrimitiveDistinctionLedgerUp.PrimitiveDistinctionLedgerUp`

Theorem 1244.2 (Primitive distinction ledger NameCert obligations)**.** *For the carrier of Definition 1244.1, the local* $\mathsf{NameCert}_{\mathsf{PrimitiveDistinctionLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for $L = (Z, O, D, T, R, H, C, P, N)$, primitive* b0 *exposure through Z, primitive* b1 *exposure through O, no-cross* msame *distinction through D, finite trace exposure through T, anti-Boolean and anti-host-equality refusal through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.PrimitiveDistinctionLedgerUp.PrimitiveDistinctionLedger namecert obligations`

Proof. Project the carrier of Definition 1244.1. The first available rows are Z and O, and they expose the two primitive marks only as mark-level rows.

Next read the distinction and trace rows. The row D records the diagonal msame evidence together with the absence of cross-mark sameness evidence, while T records the finite history windows in which these mark rows are exposed.

Finally attach the refusal and structural rows. The row R blocks direct $\mathsf{Bool}^{\uparrow}$ readback and host equality, and the rows H, C, P, N transport, replay, source, and locally name the same packet. Since the tuple has no further coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 1244.3 (Primitive distinction ledger no Boolean collapse)**.** *Every accepted* $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$ *consumer route that reads the two primitive mark rows must pass through the refusal row R before any* $\mathsf{Bool}^{\uparrow}$ *or host-equality interpretation is available. A direct route from Z, O, D to Boolean data, truth values, host equality, or host disequality is not an accepted* $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$ *route.*

Proof. Start from the carrier rows in Definition 1244.1. The primitive mark rows Z, O and the no-cross row D are separate from the refusal row R and from any later $\mathsf{Bool}^{\uparrow}$ bridge row.

Apply Definition 1244.2. The local NameCert surface requires the anti-Boolean refusal row before the packet is read as a named primitive distinction ledger.

The excluded route has no coordinate in the carrier. Transport, replay, provenance, and local naming preserve Z, O, D, T, R as the same mark-level packet, so they cannot manufacture Boolean data or host equality. A consumer that obtains such a reading has used an additional bridge outside $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.PrimitiveDistinctionLedgerUp.PrimitiveDistinctionLedger no boolean collapse`

Theorem 1244.4 (Primitive distinction ledger field coverage)**.** *Every accepted* $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$ *export factors through*

$$Z, O, D, T, R, H, C, P, N.$$

The consumer receives the primitive zero-mark row, primitive one-mark row, no-cross msame *row, finite trace-exposure row, anti-Boolean refusal row, componentwise transport, displayed replay, package provenance, and local NameCert naming. It receives no direct* $\mathsf{Bool}^{\uparrow}$ *endpoint, no host equality proof, no observer-local owner, no halting classifier, no unary count, and no categorical object row.*

Lean4 ✓ `BEDC.Derived.PrimitiveDistinctionLedgerUp.PrimitiveDistinctionLedger field coverage`

Proof. Use Definition 1244.2 to identify the complete local certificate surface. Every accepted consumer must expose the five content rows and four structural rows listed there.

Then apply Definition 1244.3. Any attempt to read the mark rows as Boolean data or host equality must leave the primitive distinction ledger or display a separate bridge row.

The sibling dependencies remain surrounding consumers rather than replacements. $\mathsf{ObserverDistinctionTrace}^{\uparrow}$, $\mathsf{HaltingDistinctionTrace}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, and $\mathsf{FiniteKernelCategory}^{\uparrow}$ may be cited through provenance, but none supplies a hidden coordinate outside $Z, O, D, T, R, H, C, P, N$. Therefore the displayed tuple covers every accepted field of the primitive distinction ledger. □

The Lean file `lean4/BEDC/Derived/PrimitiveDistinctionLedgerUp/TasteGate.lean` provides explicit Nontrivial $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$ and FieldFaithful $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$ instances over the same rows. Its TasteGate records $Z, O, D, T, R, H, C, P, N$ as separate fields and keeps primitive mark exposure, no-cross msame evidence, trace exposure, and anti-Boolean refusal distinct.

Lean4 ✓ `BEDC.Derived.PrimitiveDistinctionLedgerUp.taste gate`

Closure status for $\mathsf{NameCert}_{\mathsf{PrimitiveDistinctionLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$ packet is generated from primitive bzero and bone mark rows, no-cross msame evidence, finite trace exposure, anti-Boolean refusal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimitiveDistinctionLedger}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1244.1, Definition 1244.2, Definition 1244.3, and Definition 1244.4 bind primitive mark distinction as a finite NameCert packet before Boolean, host-equality, observer, halting, unary, or categorical interpretation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimitiveDistinctionLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, BoolUp endpoint readback, host equality, observer-local trace ownership, halting classification, unary counting, or categorical objecthood.

Upgrade path: Lean closure requires Nontrivial PrimitiveDistinctionLedgerUp and FieldFaithful PrimitiveDistinctionLedgerUp instances in `lean4/BEDC/Derived/PrimitiveDistinctionLedgerUp/TasteGate.lean`.

Chapter 1245

A Concrete Naming Certificate for DiagonalRegularitySeal$^{\uparrow}$

The DiagonalRegularitySeal$^{\uparrow}$ packet realizes the diagonal-regularity theorem of section 9238.1 as a finite theorem-facing seal before the terminal Real handoff. It binds the representative route of chapter 1205, the endpoint and middle estimates organized by chapter 1211, and the regularity witness of chapter 1158 into one NameCert surface. The packet is consumed by Real-completion routes such as chapter 1242, but it does not itself assert quotient stream equality, selected host limits, host real equality, countable choice, or ambient completeness.

Definition 1245.1 (Diagonal regularity-seal carrier)**.** *A* DiagonalRegularitySeal$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, E_0, E_1, M, Q, W, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *D is the accepted* DiagonalLimitRepresentative$^{\uparrow}$ *row selecting the diagonal representative and its modulus readbacks.*
2. *E_0 and E_1 are the two endpoint-leg rows that read the regular-rational endpoints used in the triangle estimate.*
3. *M is the middle-modulus leg row exposing the regular Cauchy comparison between the selected representatives.*
4. *Q is the* DyadicToleranceTriangleLedger$^{\uparrow}$ *row that records the endpoint tolerances, middle tolerance, dyadic sum, and output tolerance bound.*
5. *W is the finite window-factorization row listing the endpoint windows, the shared intermediate window, and the requested output window.*
6. *R is the* RegularCauchyRegularityWitness$^{\uparrow}$ *row that packages the diagonal-regularity witness for downstream consumers.*
7. *Z is the optional downstream Real-seal row, used only as a terminal named handoff and never as hidden completeness evidence.*
8. *H records componentwise* hsame *transport for $D, E_0, E_1, M, Q, W, R, Z$ and the local certificate row.*
9. *C records displayed* Cont *replay from the representative row through the endpoint legs, middle modulus leg, dyadic tolerance row, window factorization, regularity witness, and terminal seal.*

10. *P is the* Pkg *provenance over* DiagonalRegularitySeal$^{\uparrow}$, DiagonalLimitRepresentative$^{\uparrow}$, DyadicToleranceTriangleLedg RegularCauchyRegularityWitness$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{DiagonalRegularitySeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected host limits, host real equality, countable choice, detached completion evidence, or an ambient completeness theorem.

Definition 1245.2 (Diagonal regularity-seal classifier)**.** *Two accepted* DiagonalRegularitySeal$^{\uparrow}$ *carriers classify together only when their representative rows, endpoint legs, middle-modulus legs, dyadic tolerance rows, finite windows, regularity-witness rows, terminal seal rows, transport rows, continuation rows, package rows, and local naming rows are related componentwise by displayed* hsame *data and replayed along the same* Cont *route. The classifier does not identify packets by host equality of real numbers, by quotienting streams, by deleting either endpoint leg, by hiding the middle modulus leg, or by replacing the dyadic tolerance row with an ambient completeness appeal.*

Theorem 1245.3 (Diagonal regularity-seal obligations)**.** *For every accepted* DiagonalRegularitySeal$^{\uparrow}$ *carrier $S = (D, E_0, E_1, M, Q, W, R, Z, H, C, P, N)$, the local* NameCert$_{\text{DiagonalRegularitySeal}^{\uparrow}}$ *surface consists exactly of carrier exposure, classifier transport, representative exposure through D, endpoint-leg exposure through E_0 and E_1, middle-modulus exposure through M, dyadic tolerance-sum exposure through Q, finite window factorization through W, regularity-witness exposure through R, terminal Real-seal handoff through Z, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.DiagonalRegularitySealUp.DiagonalRegularitySealTasteGate single carrier alignment`

Proof. Carrier exposure is projection from Definition 1245.1. The tuple displays the representative row, the two endpoint legs, the middle modulus leg, the dyadic tolerance row, the finite windows, the regularity witness, the terminal seal, and the structural support rows.

Classifier transport is exactly the relation of Definition 1245.2. It keeps each displayed row on the same componentwise transported route.

The data-bearing obligations are read from the cited sibling chapters. The representative row comes from chapter 1205; the dyadic tolerance surface supplies the endpoint and middle tolerance arithmetic through chapter 1211; and the regularity witness comes from chapter 1158.

Since H, C, P, N only transport, replay, source, and name those displayed rows, the listed clauses exhaust the local seal surface. □

Theorem 1245.4 (Diagonal regularity-seal nonescape)**.** *An accepted* DiagonalRegularitySeal$^{\uparrow}$ *carrier exports only the displayed rows $D, E_0, E_1, M, Q, W, R, Z, H, C, P, N$ and their classifier transports. No consumer can replace the representative row, either endpoint leg, the middle modulus leg, the dyadic tolerance row, the finite window factorization, or the regularity witness by quotient stream equality, selected host limits, host real equality, countable choice, detached completion evidence, or an ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.DiagonalRegularitySealUp.DiagonalRegularitySealCarrier nonescape`

Proof. Inspect the carrier coordinates of Definition 1245.1. Every exported coordinate is a displayed BEDC row or structural support for transport, continuation replay, provenance, and naming.

Definition 1245.3 accounts for the admissible carrier and classifier rows. No additional equality, selection, choice, or completeness coordinate appears in that list.

The excluded objects require coordinates absent from the carrier. Therefore neither the local NameCert row nor any displayed continuation can export them in place of the finite diagonal-regularity seal. □

Theorem 1245.5 (Diagonal regularity-seal window factorization)**.** *Every consumer of an accepted* DiagonalRegularitySeal$^{\uparrow}$ *packet factors its diagonal-regularity request through the finite route*

$$D, E_0, E_1, M, Q, W, R, Z, H, C, P, N.$$

The window row W separates the two endpoint observations, the shared middle comparison window, the dyadic tolerance output, and the terminal Real-seal handoff, so the consumer reaches the theorem seal only after reading the representative row, both endpoint legs, the middle modulus leg, and the dyadic tolerance row.

Lean4 ✓ `BEDC.Derived.DiagonalRegularitySealUp.DiagonalRegularitySealUp window factorization`

Proof. Begin with the representative route. The row D fixes the diagonal representative and the modulus-index readbacks before any endpoint or middle comparison can be consumed.

Next read the three estimate legs. The endpoint rows E_0, E_1 expose the regular-rational endpoint bounds, while M exposes the middle Cauchy-modulus comparison. The dyadic row Q records the tolerance arithmetic that combines these three legs into the output bound.

Finally factor the route through W, R, Z, H, C, P, N. The window row records the finite observations needed by the theorem, the witness row packages the regularity evidence, and the terminal Real-seal row remains downstream of the same displayed route. Hence every consumer factors through the ordered finite packet shown above. □

Lean4 ✓ `BEDC.Derived.DiagonalRegularitySealUp.DiagonalRegularitySealCarrier window factorization`

Falsifiable prediction: A diagonal regularity consumer that reaches the Real seal while omitting the representative row, either endpoint leg, the middle modulus leg, or the dyadic tolerance row refutes the packet.

Independence witness: diagonallimitrepresentative, dyadic-tolerance-triangle-ledger, regular-cauchy-regularity-witness, streamname, real: no listed sibling is bijective to DiagonalRegularitySeal$^{\uparrow}$ because this packet binds the representative, three-leg estimate, dyadic tolerance output, finite windows, and terminal Real seal as one consumer-facing seal.

Lean follow-up must add explicit Nontrivial DiagonalRegularitySeal$^{\uparrow}$ and FieldFaithful DiagonalRegularitySeal$^{\uparrow}$ instances in `lean4/BEDC/Derived/DiagonalRegularitySealUp/TasteGate.lean`.

Closure status for NameCert$_{\text{DiagonalRegularitySeal}^{\uparrow}}$**.**

Constructive story: A DiagonalRegularitySeal$^{\uparrow}$ packet is generated from a diagonal representative row, two endpoint-leg rows, a middle-modulus row, a dyadic tolerance ledger, a finite window factorization, a regularity witness, a terminal Real-seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DiagonalRegularitySeal}^{\uparrow}}$, seed)

Scope closed: Definition 1245.1, Definition 1245.2, Definition 1245.3, Definition 1245.4, and Definition 1245.5 bind the finite diagonal-regularity theorem seal surface.

Formal verification: FormalStatus(NameCert$_{\text{DiagonalRegularitySeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient stream equality, selected host limits, host real equality, countable choice, detached completion evidence, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, nonescape, window factorization, and TasteGate nontriviality with field faithfulness for $D, E_0, E_1, M, Q, W, R, Z, H, C, P, N$.

Chapter 1246

A Concrete Naming Certificate for $\mathsf{TheoremGapRegistry}^{\uparrow}$

The $\mathsf{TheoremGapRegistry}^{\uparrow}$ packet realizes the theorem and gap registry surface of chapter 9462 as one finite NameCert carrier. It sits beside the registry layer of chapter 1220, the claim registry layer of chapter 1209, the truth-residue ledger of chapter 1239, and the gap-failure-bridge audit packet of chapter 1229. Those siblings expose package registry control, single-claim export, scientific-truth residue, and bridge-facing failure audit; this carrier joins theorem-strength rows to gap-gate rows before any consumer may read a theorem entry as stronger than its displayed dependencies or read a gap entry without its blocking gate.

Definition 1246.1 (Theorem-gap registry carrier)**.** *A* $\mathsf{TheoremGapRegistry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, D, S, G, C, F, A, L, H, P, N)$$

with the following displayed rows:

1. *T is the theorem-entry row, recording name, statement, proof mode, proof site, and public registry status.*
2. *D is the dependency-strength row, recording the displayed BEDC dependencies and the weakest strength available among them.*
3. *S is the theorem-strength row, recording the strength claimed for the theorem entry and the witnessed dependency row that licenses it.*
4. *G is the gap-entry row, recording name, site, requested supply, socket type, gate, consequence if internalized, and current registry status.*
5. *C is the gap-gate coverage row, recording that every gap entry has a blocking gate and a cannot-claim or refusal route.*
6. *F is the refusal row, recording theorem-strength overclaim refusals, gate-absent gap refusals, and theorem-to-gap leakage refusals.*
7. *A is the audit-export row, recording the route through* $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{TruthResidueLedger}^{\uparrow}$, *and* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$.
8. *L is the ledger nonescape row, recording that missing theorem-strength evidence and missing gap gates cannot be supplied by prose placement, hidden registry state, or host truth.*

9. *H stores componentwise* hsame *transport for theorem entries, dependency strengths, theorem strengths, gap entries, gap gates, refusals, audit export, ledger nonescape, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{TheoremGapRegistry}^{\uparrow}$, $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{TruthResidueLedger}^{\uparrow}$, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{TheoremGapRegistry}^{\uparrow}}$ *row.*

The carrier has no coordinate for a theorem strength above its displayed dependency witness, a gate-free gap entry, an erased refusal, a hidden registry table, or a ledger export outside $R = (T, D, S, G, C, F, A, L, H, P, N)$.

Lean4 ✓ `BEDC.Derived.TheoremGapRegistryUp.TheoremGapRegistryTasteGate single carrier alignment`

Theorem 1246.2 (Theorem-gap registry strength gate)**.** *For the carrier of Definition 1246.1, an accepted theorem entry cannot be exported with strength above the weakest displayed dependency strength unless the packet also displays a witnessed dependency row in D that licenses the stronger reading through S.*

Lean4 ✓ `BEDC.Derived.TheoremGapRegistryUp.TheoremGapRegistry strength gate`

Proof. Project the theorem-entry, dependency-strength, and theorem-strength rows T, D, S. The theorem entry is public only through the finite packet, and its stated strength is read through S rather than through prose placement or hidden theorem state.

If S reports a strength no greater than the weakest displayed dependency in D, the export is licensed by the visible dependency chain. If S reports a stronger reading, the carrier requires an additional witnessed dependency row in D naming the evidence for that stronger reading.

The structural rows H, P, N preserve, source, and name the same displayed rows. They cannot create an absent dependency witness, so a strength overclaim has no accepted export route through $\mathsf{TheoremGapRegistry}^{\uparrow}$. □

Theorem 1246.3 (Theorem-gap registry gap-gate coverage)**.** *Every accepted gap entry in a* $\mathsf{TheoremGapRegistry}^{\uparrow}$ *packet is covered by a displayed gate in C and by a refusal or cannot-claim route in F. A gap row with no gate is not an accepted registry entry.*

Lean4 ✓ `BEDC.Derived.TheoremGapRegistryUp.TheoremGapRegistry gap gate coverage`

Proof. Start with the gap-entry row G. It records the requested supply, socket type, consequence if internalized, and registry status, but it does not by itself explain why the supply is unavailable to the internal theory.

The coverage row C supplies that explanation by naming the blocking gate for each displayed gap entry. The refusal row F then records the public cannot-claim route or refusal route that prevents the requested supply from being read as a theorem dependency.

Finally, the audit-export and ledger rows A, L preserve the same gate and refusal data through the sibling registry surfaces. Since the carrier has no gate-free gap coordinate, a row in G without coverage in C and F is outside the accepted packet. □

Theorem 1246.4 (Theorem-gap registry ledger nonescape)**.** *Every accepted* $\mathsf{TheoremGapRegistry}^{\uparrow}$ *export factors through*

$$T, D, S, G, C, F, A, L, H, P, N.$$

No theorem entry may escape the dependency-strength gate, and no gap entry may escape the gate-coverage row, when the packet is read through the registry layer, claim registry layer, truth-residue ledger, and gap-failure-bridge audit surface.

Proof. Use Definition 1246.2 for theorem entries. The rows T, D, S expose the claimed theorem, the dependency strengths, and the witnessed license for the reported strength.

Use Definition 1246.3 for gap entries. The rows G, C, F expose the requested supply, the blocking gate, and the refusal route.

The audit-export row A points to chapter 1220, chapter 1209, chapter 1239, and chapter 1229. Those sibling surfaces can transport and inspect the packet, but none supplies a hidden coordinate that bypasses D or C.

The ledger nonescape row L records this absence explicitly. Componentwise transport, package provenance, and local naming preserve the displayed packet, so every accepted export factors through the listed rows and no theorem or gap reading escapes its gate. □

Lean4 ✓ `BEDC.Derived.TheoremGapRegistryUp.TheoremGapRegistry ledger nonescape`

Theorem 1246.5 (Theorem-gap registry public export surface)**.** *Every public theorem/gap registry export from an accepted* $\mathsf{TheoremGapRegistry}^{\uparrow}$ *packet is routed through*

$$T, D, S, G, C, F, A, L, H, P, N.$$

The public surface exposes theorem entries, dependency strengths, theorem strengths, gap entries, gap-gate coverage, refusals, audit export, ledger nonescape, transport, provenance, and local naming as separate rows; it exports no theorem entry above its displayed dependency license and no gap entry without its displayed gate.

Proof. Start from the carrier definition. The packet lists the rows $T, D, S, G, C, F, A, L, H, P, N$ and has no hidden registry table or outside ledger coordinate.

Use the strength gate and gap-gate coverage theorems. Theorem 1246.2 prevents a theorem entry from exceeding its displayed dependency license, while Theorem 1246.3 prevents a gap entry from being accepted without a gate and refusal route.

Finally apply ledger nonescape. Theorem 1246.4 forces every accepted export through the same displayed rows and through the sibling registry, claim-registry, truth-residue, and gap-failure audit surfaces. Hence the listed rows form the public export surface. □

Lean4 ✓ `BEDC.Derived.TheoremGapRegistryUp.TheoremGapRegistry public export surface`

Falsifiable prediction: An accepted $\mathsf{TheoremGapRegistry}^{\uparrow}$ packet cannot raise a theorem entry above the weakest displayed dependency strength unless a new witnessed dependency row is added to the packet.

Independence witness: registrylayer, claimregistrylayer, truth-residue-ledger, gap-failure-bridge-audit: $\mathsf{TheoremGapRegistry}^{\uparrow}$ joins theorem-strength rows to gap-gate rows; the sibling packets lack that combined carrier and are not bijective to it.

The future Lean `TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{TheoremGapRegistry}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{TheoremGapRegistry}^{\uparrow}$ instances. Those instances must preserve $T, D, S, G, C, F, A, L, H, P, N$ as separate displayed fields before any checked theorem may cite the $\mathsf{TheoremGapRegistry}^{\uparrow}$ packet as a field-faithful registry surface.

Theorem 1246.6 (Theorem-gap registry bridge surface)**.** *Every theorem/gap export from an accepted* $\mathsf{TheoremGapRegistry}^{\uparrow}$ *packet bridges to downstream registry consumers only through*

$$T, D, S, G, C, F, A, L, H, P, N.$$

The rows expose theorem entries, dependency strengths, theorem strengths, gap entries, gap gates, refusals, audit export, ledger nonescape, transport, provenance, and local naming together with the sibling registry surfaces $\mathsf{RegistryLayer}^{\uparrow}$*,* $\mathsf{ClaimRegistryLayer}^{\uparrow}$*,* $\mathsf{TruthResidueLedger}^{\uparrow}$*, and* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$*.*

Proof. Start with the public export surface of Definition 1246.5. It already identifies the accepted export rows as $T, D, S, G, C, F, A, L, H, P, N$ and rules out hidden theorem tables, hidden gap gates, and outside ledger coordinates.

Next use ledger nonescape from Definition 1246.4. The export row A passes through chapter 1220, chapter 1209, chapter 1239, and chapter 1229, while L records that neither theorem strength nor gap coverage may be supplied outside the displayed packet.

Finally, componentwise transport H, provenance P, and local naming N preserve the same rows for downstream consumers. Hence the only bridge surface available to theorem/gap exports is the displayed row list together with the sibling registry surfaces named above. □

Lean4 ✓ `BEDC.Derived.TheoremGapRegistryUp.TheoremGapRegistry bridge surface`

Closure status for $\mathsf{NameCert}_{\mathsf{TheoremGapRegistry}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TheoremGapRegistry}^{\uparrow}$ packet is generated from theorem-entry, dependency-strength, theorem-strength, gap-entry, gap-gate coverage, refusal, audit-export, ledger nonescape, hsame transport, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TheoremGapRegistry}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1246.1, Definition 1246.2, Definition 1246.3, Definition 1246.4, Definition 1246.5, and the displayed TasteGate marker bind theorem-strength, gap-gate scope, and public registry export to visible BHist, hsame, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TheoremGapRegistry}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, complete registry governance, bridge checking, or correctness of every downstream theorem and gap entry.

Upgrade path: Bridge closure requires a standard bridge and Lean verification remains independent.

Chapter 1247

A Concrete Naming Certificate for $\mathsf{FocusedLedger}^{\uparrow}$

The $\mathsf{FocusedLedger}^{\uparrow}$ packet realizes the finite focused multi-Hist ledger of subsection 9462.27.1 and Definition 9462.846 as a concrete NameCert carrier. It sits beside $\mathsf{ConsciousUniverseSpace}^{\uparrow}$ in chapter 1206, $\mathsf{ObserverHistIdentity}^{\uparrow}$ in chapter 479, $\mathsf{InterHistLocalityLedger}^{\uparrow}$ in chapter 759, $\mathsf{InscriptionEvent}^{\uparrow}$ in chapter 519, and $\mathsf{OnticResidueLedger}^{\uparrow}$ in chapter 1152. Those siblings consume histories, identity rows, locality rows, inscription events, or residue rows; this packet binds the whole focus-selector-digest-gap-relation-invariant-audit tuple before those readings are separated.

Definition 1247.1 (Focused ledger carrier)**.** *A* $\mathsf{FocusedLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N)$$

with the following displayed rows:

1. *I is the finite index ledger naming the available history slots;*
2. *H assigns a finite* Hist *row to each slot of I;*
3. *T records local continuation chains for the displayed histories, without adding a global scalar clock;*
4. *F is the focus index selecting the visible history slot;*
5. *S is the selector ledger that records the branch choices and focus reads used by F;*
6. *D is the digest ledger recording finite summaries whose provenance remains displayed;*
7. *G is the gap and provenance row recording boundary pressure, missing observations, and source data for each digest;*
8. *R is the inter-history relation row;*
9. *J is the inter-history invariant row;*
10. *Q is the dependence row, including optional maximum-rate readings when such rows are present;*
11. *ρ is the focused self-proxy row for the selected history;*
12. *A is the audit row refusing subject parameters, global clocks, hidden choosers, unledgered compression, object-level T, and hidden dependence on meta-closure;*

13. *C records displayed* Cont *replay across* $I, H, T, F, S, D, G, R, J, Q, \rho, A$*;*
14. *P records* Pkg *provenance over* $\mathsf{FocusedLedger}^{\uparrow}$, $\mathsf{FocusedMultiHistLedger}^{\uparrow}$, $\mathsf{ConsciousUniverseSpace}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{InterHistLocalityLedger}^{\uparrow}$, $\mathsf{InscriptionEvent}^{\uparrow}$, $\mathsf{OnticResidueLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg*, and* NameCert *rows;*
15. *N is the local* $\mathsf{NameCert}_{\mathsf{FocusedLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for a subject substance, ambient universe object, hidden scheduler, unrecorded quotient of histories, object-level time object, or meta-closure oracle.

Lean4 (definition) `BEDC.Derived.FocusedLedgerUp.FocusedLedgerUp`

Theorem 1247.2 (Focused ledger audit closure)**.** *For the carrier of Definition 1247.1, the audit row A closes exactly the refusals of no subject, no global clock, no hidden chooser, no unledgered compression, no object-level T, and no hidden meta-closure dependence. Every accepted* $\mathsf{FocusedLedger}^{\uparrow}$ *consumer must read focus, selection, digest, gap, relation, invariant, dependence, self-proxy, replay, provenance, and local naming through*

$$I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N.$$

Proof. Project the carrier. The rows $I, H, T, F, S, D, G, R, J, Q, \rho$ expose the finite histories, focus, selector, digest, gap, relation, invariant, dependence, and self-proxy data that the packet is allowed to use.

Read the audit row next. The no-subject refusal prevents a hidden owner coordinate; the no-global-clock refusal keeps T local; the no-hidden-chooser refusal forces all branch choice through S; the no-unledgered-compression refusal keeps summaries tied to D and G; the no object-level T refusal prevents a time object from replacing the local continuation rows; and the no hidden meta-closure refusal prevents the packet from citing a closure source not displayed in A.

Finally use the structural rows. The replay row C, provenance row P, and local name N preserve and name only the displayed packet, so no consumer can recover an omitted subject, clock, chooser, compression, time object, or meta-closure dependency from the certificate surface. □

Theorem 1247.3 (Focused ledger NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{FocusedLedger}^{\uparrow}}$ *surface for Definition 1247.1 consists of exactly five obligation rows:*

1. *carrier admission for the finite packet $L = (I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N)$;*
2. *classifier stability for the selected history, selector ledger, digest ledger, relation row, invariant row, dependence row, and self-proxy row under componentwise* hsame *transport;*
3. *continuation exactness for the displayed* Cont *routes in C and no replay route outside the finite index ledger I;*
4. *audit-row exactness for the six refusals recorded in A;*
5. *provenance and local naming through P and N.*

Proof. The carrier definition displays all content rows before transport, replay, provenance, and naming. The first obligation admits that finite packet as the only carrier surface.

The second and third obligations are forced by the BEDC structural rows: hsame transport preserves the selected carrier fields componentwise, and Cont replay is read only through C.

The fourth obligation is Definition 1247.2. The fifth obligation is the terminal NameCert packaging: P records the source rows and N names the accepted packet. No sixth obligation is available, because every accepted consumer already factors through the displayed carrier. □

Lean4 ✓ `BEDC.Derived.FocusedLedgerUp.FocusedLedgerNameCert obligation surface`

Definition 1247.4 (Focused ledger kernel scope)**.** *The kernel scope of a* $\mathsf{FocusedLedger}^{\uparrow}$ *consumer is the displayed* BHist *route*

$$I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N$$

from Definition 1247.1. A consumer is kernel-scoped when carrier admission, selector, digest, gap, relation, invariant, dependence, self-proxy, audit refusals, componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming are all read through this route before any focused-ledger conclusion is exported.*

Theorem 1247.5 (Focused ledger kernel-scope route)**.** *Every* $\mathsf{FocusedLedger}^{\uparrow}$ *consumer factors carrier admission, selector rows, digest rows, gap rows, relation rows, invariant rows, dependence rows, self-proxy rows, audit refusals,* hsame *transport,* Cont *replay,* Pkg *provenance, and* NameCert *naming through the kernel scope of Definition 1247.4. In particular, it cannot route the focused ledger through a subject parameter, global clock, hidden chooser, object-level time coordinate, unledgered compression step, or meta-closure oracle.*

Proof. Start from the NameCert obligation surface, Definition 1247.3. Its carrier-admission and classifier-stability rows already name the selected history, selector ledger, digest ledger, relation row, invariant row, dependence row, and self-proxy row as displayed coordinates.

Next apply audit closure, Definition 1247.2. The six refusals rule out the omitted subject, clock, chooser, compression, object-level time, and meta-closure coordinates before the consumer reaches replay or naming.

Finally read the kernel scope definition. The route ends with componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row, so any exported focused-ledger conclusion remains inside the displayed BHist kernel rows. □

Theorem 1247.6 (Focused ledger sibling independence)**.** $\mathsf{FocusedLedger}^{\uparrow}$ *is not bijective with* $\mathsf{ConsciousUniverseSpace}^{\uparrow}$*,* $\mathsf{ObserverHistIdentity}^{\uparrow}$*,* $\mathsf{InterHistLocalityLedger}^{\uparrow}$*,* $\mathsf{InscriptionEvent}^{\uparrow}$*, or* $\mathsf{OnticResidueLedger}^{\uparrow}$*. The focused ledger carries the whole focus-selector-digest-gap-relation-invariant-audit tuple, while each sibling omits at least one of the required focused-ledger rows or one audit refusal.*

Proof. Compare the carrier inventories. $\mathsf{ConsciousUniverseSpace}^{\uparrow}$ reads universe-slice, locality-cell, local-time, and trace-identity structure after a focused ledger row is available, but it does not carry the full selector, digest, gap, relation, invariant, dependence, and audit tuple of Definition 1247.1.

$\mathsf{ObserverHistIdentity}^{\uparrow}$ supplies observer-history identity rows, and $\mathsf{InterHistLocalityLedger}^{\uparrow}$ supplies inter-history locality rows. Neither packet contains the focused selector ledger, digest provenance, self-proxy, and six-refusal audit row together.

$\mathsf{InscriptionEvent}^{\uparrow}$ records inscription-event admission, while $\mathsf{OnticResidueLedger}^{\uparrow}$ records residue-bearing observation structure. Those packets can consume focused-ledger information, but neither contains the whole finite packet $I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N$. Therefore no sibling is bijective with $\mathsf{FocusedLedger}^{\uparrow}$ as a NameCert carrier. □

Falsifiable prediction: A $\mathsf{FocusedLedger}^{\uparrow}$ packet cannot be reduced to an $\mathsf{InscriptionEvent}^{\uparrow}$ packet without losing at least the selector, digest, relation, invariant, or audit row.

Independence witness: consciousuniversespace, observerhistidentity, interhistlocalityledger, inscriptionevent, onticresidueledger: none is bijective with $\mathsf{FocusedLedger}^{\uparrow}$ because each omits at least one required focused-ledger row or audit refusal.

The Lean TasteGate file `lean4/BEDC/Derived/FocusedLedgerUp/TasteGate.lean` provides explicit $\mathsf{Nontrivial}\ \mathsf{FocusedLedger}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{FocusedLedger}^{\uparrow}$ instances over the same finite carrier.

Theorem 1247.7 (Focused ledger carrier totality)**.** *For every accepted* $\mathsf{FocusedLedger}^{\uparrow}$ *carrier* $L = (I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N)$*, the rows* $I, H, T, F, S, D, G, R, J, Q, \rho, A$ *are finite* BHist *data before the structural rows are read. The rows* C, P, N *then provide displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FocusedLedger}^{\uparrow}}$ *naming for exactly that finite carrier.*

Proof. Project the carrier definition, Definition 1247.1. It lists the index ledger, history rows, continuation chains, focus index, selector ledger, digest ledger, gap row, relation row, invariant row, dependence row, self-proxy row, and audit row before any replay, provenance, or naming row appears.

Apply the audit closure theorem, Definition 1247.2. The audit row refuses hidden subject, clock, chooser, compression, object-level time, and meta-closure coordinates, so the displayed carrier rows are the whole object surface.

Finally use the NameCert obligation surface, Definition 1247.3. It packages the same finite rows through C, P, N, and the sibling independence theorem prevents replacement by a neighboring packet that omits part of the focused-ledger carrier. □

Theorem 1247.8 (Focused ledger classifier stability)**.** *The classifier of an accepted* $\mathsf{FocusedLedger}^{\uparrow}$ *packet is stable only through componentwise* hsame *transport over* $I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N$*. In particular, the selected history, selector ledger, digest ledger, relation row, invariant row, dependence row, self-proxy row, audit row, replay row, provenance row, and local name remain attached to the same finite* BHist *carrier.*

Proof. Use the classifier-stability clause in Definition 1247.3. The clause names the selected history, selector ledger, digest ledger, relation row, invariant row, dependence row, and self-proxy row as transported fields rather than as host-level predicates.

Read the carrier totality theorem, Definition 1247.7. Since every classified field is part of the finite BHist packet, componentwise hsame transport cannot substitute an unledgered object for one of the displayed rows.

The TasteGate line supplies the same nontrivial and field-faithful carrier surface. Together with audit closure and sibling independence, it keeps the classifier on the focused-ledger rows rather than on a sibling packet or hidden meta-coordinate. □

Theorem 1247.9 (Focused ledger ledger exactness)**.** *The ledger exported by* $\mathsf{FocusedLedger}^{\uparrow}$ *is exact for the route*

$$I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N.$$

Every consumer must read finite BHist *rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming through that route before using the focus, digest, relation, invariant, dependence, self-proxy, or audit data.*

Proof. Start from carrier totality, Definition 1247.7. It fixes the displayed ledger rows and prevents any omitted subject, clock, chooser, compression, object-level time, or meta-closure coordinate from becoming part of the carrier.

Apply classifier stability, Definition 1247.8. The same rows remain attached under componentwise hsame transport, so a consumer cannot alter the selected history or ledger fields while preserving the local classifier.

Finally apply audit closure, the NameCert obligation surface, sibling independence, and the TasteGate line. These force replay through C, provenance through P, and naming through N, while excluding sibling replacement and hidden dependencies. Hence the exported ledger is exact for the displayed BEDC kernel route. □

Theorem 1247.10 (Focused ledger public export surface)**.** *The public* $\mathsf{FocusedLedger}^{\uparrow}$ *export is exactly the finite route*

$$I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N.$$

Every public consumer of the packet receives the displayed index ledger, history rows, local continuation chains, focus index, selector ledger, digest ledger, gap and provenance row, inter-history relation row, invariant row, dependence row, self-proxy row, audit row, replay row, provenance row, and local naming row. No public export adds a subject coordinate, global clock, hidden chooser, unledgered compression step, object-level time object, meta-closure oracle, or sibling replacement.

Proof. Project the carrier of Definition 1247.1. The listed rows are precisely the finite BHist packet admitted by the definition, and the carrier has no additional public coordinate.

Use the kernel-scope route of Definition 1247.5 and ledger exactness of Definition 1247.9. They force every consumer through the same focused selector, digest, relation, invariant, dependence, self-proxy, audit, replay, provenance, and naming rows before any focused-ledger conclusion is exported.

Finally apply sibling independence, Definition 1247.6. The surrounding packets may consume or support the focused ledger, but none of them carries the whole route $I, H, T, F, S, D, G, R, J, Q, \rho, A, C, P, N$. Therefore the public surface is exactly that displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FocusedLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FocusedLedger}^{\uparrow}$ packet is generated from finite history slots, local continuation rows, a focus index, selector rows, digest rows, gap and provenance rows, relation rows, invariant rows, dependence rows, a self-proxy row, audit refusals, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FocusedLedger}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1247.1, Definition 1247.4, Definition 1247.2, Definition 1247.3, Definition 1247.5, Definition 1247.6, Definition 1247.7, Definition 1247.8, Definition 1247.9, and Definition 1247.10 bind the finite focused multi-Hist ledger, its kernel-scoped obligations, and its public export route as a concrete NameCert packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FocusedLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, public-object export, global spacetime, subject substance, or hidden meta-closure.

Upgrade path: Formal closure requires checked carrier totality, classifier stability, ledger exactness, audit closure, sibling independence, provenance, and local naming for BEDC.Derived.FocusedLedgerUp.

Chapter 1248

A Concrete Naming Certificate for $\mathsf{RefusalRegistry}^{\uparrow}$

The $\mathsf{RefusalRegistry}^{\uparrow}$ packet realizes the refusal rows named by section 9462.34 as a finite NameCert carrier for blocked package export. It sits beside the registry layer of chapter 1220, the claim registry layer of chapter 1209, the theorem-gap registry of chapter 1246, and the truth-residue ledger of chapter 1239. Those siblings admit package rows, control single-claim export, bind theorem and gap entries, and preserve scientific-truth residue; this carrier stores the refusal packet that blocks an export route before a consumer may read silence, placement, or package provenance as permission.

Definition 1248.1 (Refusal registry carrier)**.** *A* $\mathsf{RefusalRegistry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, E, G, C, S, V, T, P, N)$$

with the following displayed rows:

1. *B is the blocked-claim row, recording the package claim, theorem entry, gap entry, or ordinary-language entry point whose export is blocked.*
2. *E is the refusal-entry row, naming the refusal reason, refusal site, registry owner, and exact package surface to which the refusal applies.*
3. *G is the gate row, recording the finite gate that blocks export through* $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, *or* $\mathsf{TheoremGapRegistry}^{\uparrow}$.
4. *C is the cannot-claim route, recording the public route by which the blocked row is read as unavailable rather than as a theorem, accepted claim, or scientific-truth residue.*
5. *S is the status row, recording whether the refusal is active, discharged by a displayed registry entry, or outside the present package surface.*
6. *V is the provenance row, tying the refusal to the finite source file, registry row, theorem, definition, closure-status block, or truth-residue row from which it is exported.*
7. *T stores componentwise* hsame *transport for blocked claim, refusal entry, gate, cannot-claim route, status, provenance, package provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{RefusalRegistry}^{\uparrow}$, $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{TheoremGapRegistry}^{\uparrow}$, $\mathsf{TruthResidueLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RefusalRegistry}^{\uparrow}}$ *row.*
The carrier has no coordinate for an accepted export with an absent refusal entry, an absent gate, an erased cannot-claim route, a hidden acceptance table, or a package claim outside $R = (B, E, G, C, S, V, T, P, N)$.

Lean4 ✓ `BEDC.Derived.RefusalRegistryUp.RefusalRegistryTasteGate single carrier alignment`

Theorem 1248.2 (Refusal registry export control)**.** *Every blocked package claim governed by* $\mathsf{RefusalRegistry}^{\uparrow}$ *must display the blocked row B, refusal entry E, gate row G, cannot-claim route C, status row S, provenance row V, componentwise transport T, package provenance P, and local naming row N in the same finite carrier. A consumer may cite the blocked claim only through that refusal packet.*

Lean4 ✓ `BEDC.Derived.RefusalRegistryUp.RefusalRegistryCarrier export control`

Proof. Project the carrier of Definition 1248.1. The blocked claim is not merely a missing registry entry; it is the finite packet $R = (B, E, G, C, S, V, T, P, N)$.

Rows B, E, G, C give the export-control surface. The blocked row names the target, the refusal entry names the reason and site, the gate records the finite block, and the cannot-claim route gives the public reading of the block.

Rows S, V, T, P, N make the refusal auditable. They preserve the status, source, transport, package provenance, and local name of the same packet, so the consumer cannot cite the blocked claim by dropping the refusal entry or moving through a sibling registry without the gate. □

Theorem 1248.3 (Refusal registry nonescape)**.** *A package claim with no refusal entry, no gate row, and no accepted registry entry has no export route through* $\mathsf{RefusalRegistry}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.RefusalRegistryUp.RefusalRegistry nonescape`

Proof. Use Definition 1248.2. Any blocked export governed by $\mathsf{RefusalRegistry}^{\uparrow}$ is read through $R = (B, E, G, C, S, V, T, P, N)$, and an accepted export must instead be supplied by a sibling registry entry in chapter 1220, chapter 1209, or chapter 1246.

If no refusal entry E and no gate row G are present, the refusal packet is absent. If no accepted registry entry is present, the sibling acceptance route is absent as well.

The structural rows S, V, T, P, N cannot manufacture either missing route; they only preserve and name a displayed packet. Hence the package claim has no export route through $\mathsf{RefusalRegistry}^{\uparrow}$. □

Theorem 1248.4 (Refusal registry claim-layer handoff)**.** *Every* $\mathsf{RefusalRegistry}^{\uparrow}$ *packet handed to* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *exposes the same blocked claim, refusal entry, gate, cannot-claim route, status, provenance, transport, package, and local NameCert rows. The claim layer may read the packet as a refusal boundary, but it may not convert the blocked row into an accepted claim unless a separate accepted claim-entry row is displayed.*

Lean4 ✓ `BEDC.Derived.RefusalRegistryUp.RefusalRegistry claim layer handoff`

Proof. Start with the rows of Definition 1248.1. Componentwise transport T sends the displayed refusal rows to the sibling claim layer without merging them with an accepted claim-entry row.

The claim registry layer of chapter 1209 already distinguishes an entry row from a refusal-boundary row. The handoff therefore reads $B, E, G, C, S, V, T, P, N$ as the refusal boundary data for the claim surface.

If a separate accepted claim-entry row is absent, the claim layer has only the refusal boundary supplied by $\mathsf{RefusalRegistry}^{\uparrow}$. Package provenance and local naming preserve that boundary; they do not create acceptance. Thus the handoff blocks conversion from refusal to claim export without a displayed accepted entry. □

Theorem 1248.5 (Refusal registry obligation pack)**.** *For an accepted* $\mathsf{RefusalRegistry}^{\uparrow}$ *packet* $R = (B, E, G, C, S, V, T, P, N)$*, the complete local obligation pack consists exactly of the carrier row* B*, refusal-entry classifier row* E*, gate row* G*, cannot-claim row* C*, status row* S*, provenance row* V*, componentwise transport row* T*, package row* P*, and local* $\mathsf{NameCert}_{\mathsf{RefusalRegistry}^{\uparrow}}$ *row* N*. Any package consumer that drops one of these rows leaves the refusal packet and receives neither an accepted claim nor a valid refusal export.*

Proof. Project the carrier of Definition 1248.1. Its displayed coordinates are precisely $B, E, G, C, S, V, T, P, N$, so the carrier and classifier surface is finite and has no hidden acceptance row.

Apply Definition 1248.2 and Definition 1248.3. The first theorem forces blocked exports to use the displayed refusal packet, while the second blocks any route that has neither the refusal entry and gate nor a separate accepted registry entry.

Finally apply Definition 1248.4. The handoff preserves the same nine rows when the claim layer reads the packet, and it cannot convert the blocked row into an accepted claim without an accepted claim-entry row. Thus the listed rows are exactly the local obligation pack. □

Lean4 ✓ `BEDC.Derived.RefusalRegistryUp.RefusalRegistryObligationPack`

Theorem 1248.6 (Refusal registry public export surface)**.** *Every downstream package or registry consumer may cite* $\mathsf{RefusalRegistry}^{\uparrow}$ *only through the displayed refusal packet*

$$R = (B, E, G, C, S, V, T, P, N).$$

The public citation surface consists of the blocked-claim row B*, refusal-entry row* E*, gate row* G*, cannot-claim route* C*, status row* S*, provenance row* V*, componentwise transport row* T*, package row* P*, and local naming row* N*; it contains no silent acceptance coordinate and no route that lets a package or registry consumer read a blocked claim outside those rows.*

Proof. Project the carrier of Definition 1248.1. Its visible coordinates are exactly $B, E, G, C, S, V, T, P, N$, so any public read of the registry packet starts from the displayed refusal rows.

Use Definition 1248.2 and Definition 1248.5. The export-control theorem confines blocked package claims to the same packet, and the obligation pack shows that dropping one row leaves both accepted-claim export and valid refusal export unavailable.

The claim-layer handoff of Definition 1248.4 preserves this surface for registry consumers. Therefore downstream packages and registries may cite only the displayed refusal packet, with no hidden acceptance route. □

Lean4 ✓ `BEDC.Derived.RefusalRegistryUp.RefusalRegistry public export surface`

Theorem 1248.7 (Refusal registry bridge-schema export)**.** *The public export surface of Definition 1248.6 and the claim-layer handoff of Definition 1248.4 jointly supply the bridge-schema boundary for every registry consumer of* $\mathsf{RefusalRegistry}^{\uparrow}$*. A consumer that crosses the boundary must preserve the blocked-claim row* B*, refusal-entry row* E*, gate row* G*, cannot-claim route* C*, status row* S*, provenance row* V*, componentwise transport row* T*, package row* P*, and local naming row* N *as the same displayed refusal packet.*

Lean4 ✓ `BEDC.Derived.RefusalRegistryUp.RefusalRegistry bridge schema export`

Proof. The public export theorem identifies the only rows through which downstream package and registry consumers may cite $\mathsf{RefusalRegistry}^{\uparrow}$. These rows are already the displayed packet $R = (B, E, G, C, S, V, T, P, N)$, with no silent acceptance coordinate.

The claim-layer handoff theorem sends exactly the same rows to $\mathsf{ClaimRegistryLayer}^{\uparrow}$ and keeps accepted claim-entry data separate. Hence the public surface and the handoff agree on the boundary that a bridge-schema consumer may inspect.

Because the boundary contains only the displayed refusal rows, any bridge-schema export preserves the packet as a refusal surface rather than converting it into acceptance, erasure, or an ambient registry predicate. □

Falsifiable prediction: A package claim with no refusal entry, gate row, or accepted registry entry has no export route through $\mathsf{RefusalRegistry}^{\uparrow}$.

Independence witness: registrylayer, claimregistrylayer, theoremgapregistry, truthresidueledger: none is bijective to $\mathsf{RefusalRegistry}^{\uparrow}$ because this carrier stores blocked claim, refusal entry, gate, cannot-claim route, status, provenance, transport, package, and local naming rows as a dedicated refusal packet.

The Lean follow-up file `lean4/BEDC/Derived/RefusalRegistryUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ RefusalRegistry}^{\uparrow}$ and $\mathsf{FieldFaithful\ RefusalRegistry}^{\uparrow}$ instances. Those instances must preserve $B, E, G, C, S, V, T, P, N$ as separate displayed fields before any checked theorem may cite the $\mathsf{RefusalRegistry}^{\uparrow}$ packet as a field-faithful refusal surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RefusalRegistry}^{\uparrow}}$.

Constructive story: A $\mathsf{RefusalRegistry}^{\uparrow}$ packet is generated from blocked-claim, refusal-entry, gate, cannot-claim route, status, provenance, componentwise hsame transport, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RefusalRegistry}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1248.1, Definition 1248.2, Definition 1248.3, Definition 1248.4, Definition 1248.6, Definition 1248.7, the TasteGate marker, the falsifiable prediction, and the independence witness bind the refusal rows against $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{TheoremGapRegistry}^{\uparrow}$, $\mathsf{TruthResidueLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RefusalRegistry}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, complete package governance, or correctness of every downstream refusal row.

Upgrade path: No further paper-side theory grade is claimed before Lean-side bridge checking for package and registry consumers of the displayed refusal packet.

Chapter 1249

A Concrete Naming Certificate for $\mathsf{ActiveReadingGate}^{\uparrow}$

The $\mathsf{ActiveReadingGate}^{\uparrow}$ packet realizes the single-active-reading governance surface of chapter 9462 as a finite NameCert carrier. It reads the current-reading discipline through the machine-interface ledger and sits beside the registry export surface of chapter 1216, the registry layer of chapter 1220, the claim registry layer of chapter 1209, the audit transcript envelope of chapter 1234, and the writing-item audit packet of chapter 1235. Those siblings expose registry export, registry admission, claim admission, transcript replay, and writing-item legality; this carrier binds the unique active reading before any downstream consumer may export a prose, registry, or machine-facing route.

Definition 1249.1 (Active reading gate carrier)**.** *An* $\mathsf{ActiveReadingGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, A, R, B, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the target row, naming the theorem, definition, registry entry, writing item, machine-facing target, or package surface whose reading is being exported.*
2. *A is the active-reading row, recording the single current reading allowed for T.*
3. *R is the retired-reading row, recording displaced readings as non-exportable audit data rather than as active alternatives.*
4. *B is the blocking or refusal row, recording the public refusal that blocks a second active reading for the same target.*
5. *E is the export row, recording the only route through which the active reading may leave the gate.*
6. *H records componentwise* hsame *transport for target, active reading, retired reading, blocking row, export row, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from the target row through the active-reading and blocking rows to the export row.*
8. *P is the* Pkg *provenance over* $\mathsf{ActiveReadingGate}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{AuditTranscriptEnvelope}^{\uparrow}$, $\mathsf{WritingItemAudit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ActiveReadingGate}^{\uparrow}}$ *row.*
The carrier has no coordinate for a parallel active reading, hidden target alias, export that bypasses the blocking row, audit transcript without replay, writing item without the current reading, or local name outside the finite packet $G = (T, A, R, B, E, H, C, P, N)$.

Lean4 ✓ `BEDC.Derived.ActiveReadingGateUp.ActiveReadingGateTasteGate single carrier alignment`

Theorem 1249.2 (Active reading gate NameCert obligations)**.** *For the carrier of Definition 1249.1, the local* $\mathsf{NameCert}_{\mathsf{ActiveReadingGate}^{\uparrow}}$ *surface consists exactly of carrier admission for $G = (T, A, R, B, E, H, C, P, N)$; target admission through T; active-reading uniqueness through A and B; retired-reading exposure through R; registry and blocking coverage through* $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{RegistryLayer}^{\uparrow}$, *and* $\mathsf{ClaimRegistryLayer}^{\uparrow}$*; export non-escape through E; and transport, replay, provenance, and naming stability through H, C, P, N.*

Proof. Project the carrier of Definition 1249.1. The rows $T, A, R, B, E, H, C, P, N$ are the only coordinates available to the local certificate.

The target and reading rows supply the governance surface. Row T fixes the object being read, row A supplies the unique current reading, row R records displaced readings only as audit data, and row B blocks any attempt to export a second current reading.

The registry siblings provide the public routes. $\mathsf{RegistryExportSurface}^{\uparrow}$ controls export, $\mathsf{RegistryLayer}^{\uparrow}$ keeps package rows finite, and $\mathsf{ClaimRegistryLayer}^{\uparrow}$ prevents a claim consumer from treating the retired row as a second accepted claim.

Rows E, H, C, P, N make that boundary stable. They expose the single export route, preserve the displayed rows componentwise, replay the route through the blocking surface, record package provenance, and name the packet. No remaining coordinate can create a parallel active reading or bypass the refusal row. □

Theorem 1249.3 (Active reading gate single export route)**.** *Every registry, claim, transcript, or writing-item consumer of an accepted* $\mathsf{ActiveReadingGate}^{\uparrow}$ *packet must read the target row T through the active-reading row A and the blocking row B before the export row E. Such a consumer cannot export a parallel active reading for the same target.*

Proof. Start with an accepted packet

$$G = (T, A, R, B, E, H, C, P, N).$$

By Definition 1249.2, the export row E is available only as part of the displayed carrier containing T, A, R, B, H, C, P, N.

A registry or claim consumer therefore reaches E through the unique active row A and the refusal row B. The retired row R remains visible, but it is read as non-exportable audit data rather than as a second claim route.

Transcript and writing-item consumers receive the same route through the provenance row P, which names chapter 1234 and chapter 1235. Since H only transports displayed fields and C only replays the displayed route, neither structural row can turn R into a second active row.

Thus every accepted export factors through T, A, B, E, with R blocked from active export. A packet exporting both A and R as active readings for the same target leaves $\mathsf{ActiveReadingGate}^{\uparrow}$ and is refused by B. □

Falsifiable prediction: If both A and R are exported as active readings for the same target, the packet is refuted by the blocking row.

Independence witness: registryexportsurface, registrylayer, claimregistrylayer, audittranscriptenvelope, writingitemaudit: none is bijective to ActiveReadingGateUp. The registry export surface controls public export but does not store the active and retired readings together; the registry layer lacks the single-reading gate; the claim registry layer lacks retired-reading audit data; the audit transcript envelope lacks registry blocking as the active-reading gate; and the writing-item audit packet lacks the target-specific export route T, A, B, E as one finite carrier.

The Lean follow-up must provide explicit Nontrivial $\mathsf{ActiveReadingGate}^{\uparrow}$ and FieldFaithful $\mathsf{ActiveReadingGate}^{\uparrow}$ instances in `lean4/BEDC/Derived/ActiveReadingGateUp/TasteGate.lean`. Those instances must preserve $T, A, R, B, E, H, C, P, N$ as separate displayed fields before BEDC.Derived.ActiveReadingGateUp.taste_gate can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{ActiveReadingGate}^{\uparrow}}$.

Constructive story: An $\mathsf{ActiveReadingGate}^{\uparrow}$ packet is generated from target, active-reading, retired-reading, blocking, export, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ActiveReadingGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1249.1, Definition 1249.2, and Definition 1249.3 bind single-active-reading export to a finite NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ActiveReadingGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, complete governance of every prose replacement, correctness of every registry consumer, or archival completeness for retired readings.

Upgrade path: Lean closure requires Nontrivial ActiveReadingGateUp and FieldFaithful ActiveReadingGateUp instances in `lean4/BEDC/Derived/ActiveReadingGateUp/TasteGate.lean`.

Chapter 1250

A Concrete Naming Certificate for $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$

The $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ packet names the finite dyadic mesh used by Bishop-style constructive compactness arguments for located closed bounded intervals. It consumes the endpoint and cell route of chapter 394, the dyadic refinement surface of chapter 306, the rational cell carrier of chapter 354, the finite Real seal of chapter 38, and the downstream compact-uniform-continuity consumer of chapter 388. The construction is an explicit finite net: the interval is read through located endpoints, rational cells, dyadic cells, unary mesh scale, displayed centers, finite coverage rows, StreamName and RegSeqRat windows, RealUp seal rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row. It does not use open-cover compactness, choice of subcovers, quotient streams, host real equality, or an ambient completeness primitive.

Definition 1250.1 (Closed bounded interval net carrier)**.** *A* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, M, Q, D, Z, F, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the located closed bounded interval row supplied by* $\mathsf{LocatedInterval}^{\uparrow}$*, including lower and upper located endpoint windows;*
2. *M is the unary mesh scale naming the dyadic precision used for the net;*
3. *Q is the finite* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger attached to L at scale M;*
4. *D is the finite* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger for the rational cells of Q;*
5. *Z is the* ProbeBundle *center-row ledger, with one displayed dyadic or rational center for each accepted cell;*
6. *F is the finite coverage ledger saying that every displayed containment read of L enters one of the cells in Q and its attached dyadic refinement in D;*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to read the endpoint and center names at the mesh scale;*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same endpoint and center windows;*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, M, Q, D, Z, F, S, R are displayed;*

10. *H records componentwise* hsame *transport for endpoints, cells, dyadic refinements, centers, coverage rows, windows, readbacks, and the Real seal;*
11. *C records displayed* Cont *routes from the located interval row through mesh selection, finite cell coverage, StreamName windows, RegSeqRat readback, and RealUp sealing;*
12. *P is the* Pkg *provenance over* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert*;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalNet}^{\uparrow}}$ *row.*

The carrier exports no open-cover object, selected finite subcover, quotient stream, host real equality, hidden center chooser, or ambient compactness principle.

Theorem 1250.2 (Closed bounded interval net NameCert obligations)**.** *For the carrier of Definition 1250.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalNet}^{\uparrow}}$ *surface consists exactly of carrier admission for $K = (L, M, Q, D, Z, F, S, R, E, H, C, P, N)$, located endpoint admission through L, unary mesh admission through M, rational cell admission through Q, dyadic refinement admission through D, ProbeBundle center-row admission through Z, finite coverage admission through F, StreamName and RegSeqRat readback through S and R, RealUp sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetTasteGate single carrier alignment`

Proof. Project the carrier. Its first rows display a located interval, a unary dyadic mesh scale, rational cells, dyadic refinements, center rows, and finite coverage rows before any Real seal is exposed.

Read the analytic rows next. The $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks are attached to the same endpoint and center rows, and the $\mathsf{Real}^{\uparrow}$ seal is downstream of those finite windows rather than a completed host interval.

The structural rows close the certificate surface. The transport row H, replay row C, package row P, and local name N preserve and name only the displayed mesh packet, so there is no further NameCert obligation outside the listed rows. □

Theorem 1250.3 (Closed bounded interval net dyadic coverage)**.** *Every containment read of an accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet factors through the finite route*

$$L, M, Q, D, Z, F, H, C, P, N.$$

The read first consumes the located endpoint row L, then the mesh scale M, then a displayed rational cell in Q, a displayed dyadic refinement in D, the corresponding center row in Z, and the coverage row F. It receives no open cover, subcover choice, hidden center selector, or host interval order outside that route.

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetCoverageRoute semantic name certificate`

Proof. Begin with the located interval row. By the carrier definition, every containment read starts from L and is admitted only at the unary mesh scale M.

The coverage row F names a finite cell route. It sends the read into a rational cell from Q, the attached dyadic refinement from D, and the matching ProbeBundle center row from Z.

Finally the rows H, C, P, N transport, replay, source, and name this finite route. Since the carrier has no coordinate for an open cover, a chosen subcover, a hidden selector, or a host interval order, the dyadic coverage read cannot escape the displayed net. □

Theorem 1250.4 (Closed bounded interval net Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *consumer of an accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet reads the interval through the finite route*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N.$$

The Real seal row E is reached only after the located endpoint row, mesh row, rational and dyadic cell rows, ProbeBundle center rows, finite coverage ledger, StreamName windows, and RegSeqRat readbacks have been displayed. Consequently the downstream compact-uniform-continuity route receives an explicit finite dyadic net and receives no open-cover compactness principle, quotient stream equality, selected host real, or ambient Real completeness row.

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetRealSeal nonescape`

Proof. Use Definition 1250.2. The accepted packet exposes E only after L, M, Q, D, Z, F, S, R have been read as one finite mesh surface.

Use Definition 1250.3. It identifies the containment side of the packet with the displayed rational and dyadic cells and their ProbeBundle centers, so a consumer cannot replace the mesh by an open-cover object or a hidden center choice.

The $\mathsf{CompactUniformContinuity}^{\uparrow}$ consumer reads only the resulting Real-facing packet. The structural rows H, C, P, N preserve the same finite route through transport, replay, provenance, and local naming, and no carrier coordinate supplies quotient streams, host real equality, or ambient completeness data. □

Definition 1250.5 (Closed bounded interval net scope ledger)**.** *The scoped* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *ledger is the displayed row family*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N$$

of Definition 1250.1, read with the following scope assignments: L is the $\mathsf{LocatedInterval}^{\uparrow}$ *source row, M is the unary dyadic mesh scale, Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger, D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger, Z is the displayed center ledger, F is finite coverage, S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, E is the* $\mathsf{Real}^{\uparrow}$ *seal, H is componentwise transport, C is displayed replay, P is provenance, and N is the local NameCert row. The scope ledger is visible exactly to* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *consumers and does not add an open-cover compactness row, selected subcover, quotient stream, host real equality, or ambient Real completeness principle.*

Lean4 (definition) `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetScopeLedger`

Theorem 1250.6 (Closed bounded interval net RegSeqRat window exactness)**.** *For every accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet, the finite rows*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N$$

make the $\mathsf{RegSeqRat}^{\uparrow}$ *readback exact for the displayed interval net: the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row L, mesh row M,* $\mathsf{RationalInterval}^{\uparrow}$ *cells Q,* $\mathsf{DyadicInterval}^{\uparrow}$ *refinements D, center row Z, and coverage row F determine the* $\mathsf{StreamName}^{\uparrow}$ *windows S that the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R may read before the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed. The transport, replay, provenance, and local naming rows H, C, P, N preserve that route for* $\mathsf{Real}^{\uparrow}$ *consumers and for the downstream* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *handoff.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetRegSeqRatWindowExactness`

Proof. Use Definition 1250.5. It assigns each of the rows $L, M, Q, D, Z, F, S, R, E, H, C, P, N$ to a concrete BEDC scope surface and places S and R after the interval, mesh, rational-cell, dyadic-refinement, center, and coverage rows.

The readback exactness is therefore row-order exactness. A $\mathsf{RegSeqRat}^{\uparrow}$ request cannot inspect a window until the $\mathsf{StreamName}^{\uparrow}$ row S has been selected from the displayed mesh data L, M, Q, D, Z, F.

Finally the $\mathsf{Real}^{\uparrow}$ seal E and the structural rows H, C, P, N are downstream of that readback. They preserve the same route for $\mathsf{CompactUniformContinuity}^{\uparrow}$ consumers and introduce no additional analytic coordinate. □

Theorem 1250.7 (Closed bounded interval net compact-uniform consumer handoff)**.** *Every* CompactUniformConti *consumer of an accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet must read the interval through the scoped row family*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N.$$

The consumer receives a $\mathsf{LocatedInterval}^{\uparrow}$ *source row, a mesh row,* $\mathsf{RationalInterval}^{\uparrow}$ *cells,* $\mathsf{DyadicInterval}^{\uparrow}$ *refinements, displayed centers, finite coverage,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, a* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming. It receives no open-cover compactness principle, selected subcover, quotient stream, host real equality, hidden center chooser, or ambient Real completeness row.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetCompactUniformConsumerHandoff`

Proof. Apply Definition 1250.4. It already confines every $\mathsf{Real}^{\uparrow}$ or $\mathsf{CompactUniformContinuity}^{\uparrow}$ consumer to the finite route $L, M, Q, D, Z, F, S, R, E, H, C, P, N$.

Apply Definition 1250.6. The $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks used by the consumer are determined by the displayed located interval, mesh, rational cells, dyadic refinements, centers, and coverage rows.

The handoff is therefore the same scoped ledger, not a stronger compactness object. Since the carrier contains no open-cover compactness row, selected subcover, quotient stream, host real equality, hidden center chooser, or ambient completeness coordinate, the compact-uniform consumer receives none of them. □

Theorem 1250.8 (Closed bounded interval net public finite-net export)**.** *An accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet exports to compact-uniform consumers exactly the located interval endpoints, dyadic interval cells, rational interval ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalNet}^{\uparrow}}$ *row carried by*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N.$$

The public export contains no open-cover compactness principle, selected subcover, trichotomy row, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetPublicFiniteNetExport`

Proof. Start from the carrier of Definition 1250.1. Its located endpoint row, mesh row, rational interval ledger, dyadic interval cells, center rows, finite coverage ledger, windows, readbacks, Real seal, transport, replay, provenance, and local naming are the only coordinates available for export.

Use Definition 1250.3 and Definition 1250.4. They identify the interval-facing and Real-facing reads with the displayed finite dyadic mesh route before any compact-uniform consumer can inspect the packet.

Use Definition 1250.6 and Definition 1250.7. The window and readback rows are exact for the same finite ledger, and the compact-uniform handoff preserves precisely that scoped row family.

The exclusions are then carrier exclusions. Since the packet has no coordinate for open-cover compactness, selected subcovers, trichotomy, quotient real equality, or ambient Real completeness, no public export row can supply those objects. □

Definition 1250.9 (Closed bounded interval net root-unblock ledger)**.** *The root-unblock ledger for* ClosedBoundedIntervalNet$^{\uparrow}$ *is the same displayed row family*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N$$

as in Definition 1250.1, read with M as the unary mesh counter and with Q, D, Z, F as the rational cell, dyadic refinement, center, and finite coverage rows at that counter. The rows S, R, E record the StreamName window, RegSeqRat exact readback, and RealUp seal reached from that mesh, while H, C, P, N preserve transport, replay, provenance, and local naming. The ledger contains no root oracle, open-cover compactness row, selected subcover, quotient stream, hidden center chooser, or ambient completeness primitive.

Theorem 1250.10 (Closed bounded interval net unary mesh monotonicity)**.** *Let $K = (L, M, Q, D, Z, F, S, R, E, H$ be an accepted* ClosedBoundedIntervalNet$^{\uparrow}$ *packet, and let M' be a unary mesh scale obtained by extending M by displayed successor rows. The refined packet keeps the source row L and replaces Q, D, Z, F, S, R, E by rows at scale M' so that every rational cell in Q is subdivided by rational cells in the refined ledger, every dyadic cell in D is subdivided by dyadic cells in the refined ledger, and every coverage route displayed by F factors through the refined* ProbeBundle *center rows. Transport by H, replay by C, provenance by P, and local naming by N preserve the same coverage route.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetUnaryMeshMonotonicity`

Proof. Start from the dyadic coverage theorem Definition 1250.3. It places every containment read on the finite route $L, M, Q, D, Z, F, H, C, P, N$, so the mesh coordinate is the only row being extended.

The successor extension of M refines the rational cell row Q and the dyadic refinement row D by finite subdivision. The center row Z is then read from the refined cells, and the coverage row F factors the old containment read through the new center ledger rather than through a different compactness object.

Finally apply the scope ledger of Definition 1250.5. The rows S, R, E, H, C, P, N are downstream of the displayed mesh rows, so they replay the refined route and do not introduce an open-cover, quotient, hidden-choice, or ambient-completeness coordinate. □

Theorem 1250.11 (Closed bounded interval net root-unblock package)**.** *For every accepted* ClosedBoundedIntervalNet$^{\uparrow}$ *packet, the ledger of Definition 1250.9 assembles a finite root-unblock package: repeated unary refinement of M yields rational and dyadic cell refinements through Q and D, preserves the displayed* ProbeBundle *coverage route through Z and F, reads StreamName and RegSeqRat windows exactly through S and R, and hands the resulting RealUp-facing interval packet to every* CompactUniformContinuity$^{\uparrow}$ *consumer through E, H, C, P, N. The package does not claim open-cover compactness, a numerical root selector, quotient streams, host real equality, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetRootUnblockPackage`

Proof. Use Definition 1250.10 for the induction over the unary mesh row. Each successor step refines Q and D and keeps the coverage route inside Z and F.

Use Definition 1250.6 after the refined mesh has been displayed. The StreamName windows and RegSeqRat readbacks are determined by the located interval, mesh, rational cells, dyadic cells, centers, and coverage rows.

The compact-uniform handoff is then exactly Definition 1250.7. It exports the finite route $L, M, Q, D, Z, F, S, R, E, H, C, P, N$ to the consumer and exports no stronger compactness or selection principle. □

Theorem 1250.12 (Closed bounded interval net finite mesh coverage)**.** *For every accepted* ClosedBoundedIntervalN *packet $K = (L, M, Q, D, Z, F, S, R, E, H, C, P, N)$, the displayed rows Q, D, Z, F give finite mesh coverage of the located interval row L: each containment read admitted by L at mesh scale M is routed through a rational cell in Q, the attached dyadic cell in D, the corresponding center row in Z, and the finite coverage row F. The coverage route exports no open-cover compactness object, selected subcover, hidden center chooser, or ambient Real completeness principle.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetFiniteMeshCoverage`

Proof. Project the carrier of Definition 1250.1. The rows Q, D, Z, F are displayed as the rational cell ledger, dyadic refinement ledger, center ledger, and finite coverage ledger attached to the same located interval L and mesh scale M.

Apply the dyadic coverage theorem Definition 1250.3. It already confines every containment read to the route $L, M, Q, D, Z, F, H, C, P, N$, so the mesh coverage visible to a downstream consumer is the finite cell route through Q, D, Z, F.

The structural rows H, C, P, N preserve that same route and add no compactness coordinate. Thus the theorem strengthens the root-unblock surface by making the finite mesh coverage row explicit, without claiming open-cover compactness, selected subcovers, hidden centers, or ambient completeness. □

Theorem 1250.13 (Closed bounded interval net located endpoint stability)**.** *For every accepted* ClosedBoundedIntervalNet$^{\uparrow}$ *packet, the located endpoint data in L is stable under the transport route L, H, C: replacing endpoint windows along the displayed* hsame *row H and replaying the same* Cont *row C preserves the rational-cell, dyadic-cell, center, coverage, StreamName, RegSeqRat, and Real-seal route used by the packet. The stability claim is only about the displayed located endpoint transport; it does not identify host real endpoints or add quotient equality.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetLocatedEndpointStability`

Proof. Use the scope ledger Definition 1250.5. It places the located endpoint row L before the mesh, cell, window, readback, and Real-seal rows, and assigns H and C as the componentwise transport and replay rows for that same family.

Apply the RegSeqRat exactness theorem Definition 1250.6. The windows S and readbacks R are determined by the displayed located interval, mesh, rational cells, dyadic cells, centers, and coverage rows, so endpoint transport through H cannot change the route inspected by the readback.

Finally use the root-unblock package Definition 1250.11. Its handoff reaches compact-uniform consumers only through E, H, C, P, N, so the transported endpoint data remains the displayed located route and never becomes host real equality or quotient endpoint equality. □

Theorem 1250.14 (Closed bounded interval net compact-uniform route)**.** *Every compact-uniform consumer of an accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet consumes the full finite route*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N.$$

The route displays located endpoints, a mesh scale, rational cells, dyadic refinements, centers, finite coverage, StreamName windows, RegSeqRat exact readback, a RealUp seal, transport, replay, provenance, and local naming before the compact-uniform handoff. It does not supply open-cover compactness, selected limits, quotient streams, host real equality, hidden center choice, or RealUp completeness.

Proof. Apply Definition 1250.12. It identifies the finite coverage rows Q, D, Z, F that every containment read must use after reading L and M.

Apply Definition 1250.6. The StreamName and RegSeqRat rows S, R are exact for the displayed endpoint and center windows, and the Real seal E is reached only after those finite rows are visible.

Finally apply Definition 1250.7 and Definition 1250.11. Together they route every compact-uniform consumer through $L, M, Q, D, Z, F, S, R, E, H, C, P, N$ and export no stronger compactness, selection, quotient, host-real, hidden-center, or completeness principle. □

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetCompactUniformRoute`

Theorem 1250.15 (Closed bounded interval net public envelope)**.** *Every public read of an accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet factors through the displayed compact-uniform continuity row together with the interval-net route*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N.$$

Thus the read consumes the dyadic and rational interval rows, $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalNet}^{\uparrow}}$ *row before it reaches any compact-uniform consumer. It exports no open-cover compactness principle, selected subcover, selected limit, quotient stream, host real equality, hidden center chooser, or ambient Real completeness row.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetPublicEnvelope`

Proof. Project the carrier of Definition 1250.1. Its public rows are the located interval source L, mesh scale M, rational cells Q, dyadic refinements D, center row Z, coverage ledger F, StreamName windows S, RegSeqRat readback R, Real seal E, and the structural rows H, C, P, N.

Apply Definition 1250.7. The compact-uniform consumer receives exactly the scoped row family already displayed by the interval-net packet, so its public read cannot skip the dyadic, rational, regular-readback, stream-window, Real-seal, transport, replay, provenance, or local naming rows.

Finally use Definition 1250.11. The package exports a finite mesh handoff rather than an open-cover or selected-limit object, and the carrier has no coordinate for the excluded compactness and host-real principles. □

Theorem 1250.16 (Closed bounded interval net mesh refinement fusion)**.** *For every accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet* $K = (L, M, Q, D, Z, F, S, R, E, H, C, P, N)$*, extending the unary mesh row* M *by displayed successor steps fuses the rational-cell ledger* Q*, the dyadic-refinement ledger* D*, the center rows* Z*, and the finite coverage ledger* F *into one refined interval-net route. The fused route preserves the same* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows, and it does not import open-cover compactness, selected subcovers, hidden center choice, quotient streams, or ambient completeness.*

Proof. Start from Definition 1250.10. Each displayed successor of M refines the rational cells in Q and the dyadic cells in D while keeping the source interval row L fixed.

Next use Definition 1250.11. It identifies the refined coverage route through Z and F and then carries the same mesh data through S, R, E, H, C, P, N.

The exclusion is a carrier exclusion. By Definition 1250.9 and Definition 1250.15, the packet has no coordinate for open-cover compactness, selected subcovers, hidden centers, quotient streams, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetMeshRefinementFusion`

Theorem 1250.17 (Closed bounded interval net cell-center readback)**.** *Every displayed center read of an accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet factors through the ordered rows* Q, D, Z, F, S, R *before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is visible. Thus a center is read as a rational cell in* Q*, a dyadic refinement in* D*, a* $\mathsf{ProbeBundle}$ *center row in* Z*, a finite coverage row in* F*, a* $\mathsf{StreamName}^{\uparrow}$ *window in* S*, and a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in* R*, not as a hidden host chooser or quotient real representative.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetCellCenterReadback`

Proof. Project the carrier and scope ledger, Definition 1250.1 and Definition 1250.5. They place Q, D, Z, F before the window and readback rows and before the terminal Real-facing row.

Apply Definition 1250.6. The readback row R may inspect only the windows S determined by the displayed located interval, rational cells, dyadic cells, centers, and coverage rows.

Finally use Definition 1250.4. Since E is downstream of Q, D, Z, F, S, R, the center read cannot be replaced by host center choice, quotient real equality, or ambient Real completeness. □

Theorem 1250.18 (Closed bounded interval net dense mesh readback)**.** *For every accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet* $K = (L, M, Q, D, Z, F, S, R, E, H, C, P, N)$ *and every displayed successor refinement of the mesh row* M*, every* $\mathsf{Real}^{\uparrow}$*-facing dense mesh read factors through*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N.$$

The refined rows Q, D, Z, F *give the rational and dyadic cells, displayed centers, and finite coverage at the successor mesh, while* S, R, E *give the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal. The read receives no open-cover compactness principle, selected subcover, quotient real equality, hidden center choice, or ambient Real completeness row.*

Proof. Start from finite mesh coverage. The row F covers each displayed containment read of the located interval row L by cells from Q and dyadic refinements from D at the mesh scale M.

Use unary mesh monotonicity and Definition 1250.16. A displayed successor refinement of M refines the same finite cell route rather than selecting a host subcover, and the refined Q, D, Z, F rows remain part of the accepted interval-net packet.

Next apply Definition 1250.17. The center and dense-mesh reads pass through Q, D, Z, F, S, R before the Real-facing row is visible, so the readback is a finite window and regular-rational route.

Finally use Definition 1250.4. The $\mathsf{Real}^{\uparrow}$ seal E and the structural rows H, C, P, N preserve that refined finite mesh route, and no coordinate supplies open-cover compactness, selected subcovers, quotient real equality, hidden center choice, or ambient Real completeness. □

Theorem 1250.19 (Closed bounded interval net compact-uniform modulus input)**.** *Every* CompactUniformContinu *consumer receives an accepted* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet as finite modulus input through the complete row family*

$$L, M, Q, D, Z, F, S, R, E, H, C, P, N.$$

The consumer reads the located interval, mesh scale, rational cells, dyadic refinements, centers, finite coverage, stream windows, regular-rational readbacks, Real seal, transport, replay, provenance, and local naming before any uniform-continuity conclusion can be replayed.

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetUniformModulusInput`

Proof. Use Definition 1250.7. It already states that compact-uniform consumers receive the scoped row family $L, M, Q, D, Z, F, S, R, E, H, C, P, N$ and no stronger compactness object.

Apply Definition 1250.14. The route makes Q, D, Z, F the finite coverage input and S, R, E the readback and Real-facing boundary used by the consumer.

Finally combine Definition 1250.16 and Definition 1250.17. Mesh refinement and center readback stay inside the same finite packet, so the compact-uniform input is a displayed interval net rather than an open-cover compactness principle, selected subcover, hidden center chooser, quotient stream, host real equality, or ambient completeness row. □

Falsifiable prediction: Every compact-uniform-continuity read of a ClosedBoundedIntervalNetUp packet factors through the displayed finite dyadic mesh, not through an open-cover compactness row.

Independence witness: locatedinterval, dyadicinterval, rationalinterval, real, compactuniformcontinuity: ClosedBoundedIntervalNetUp is not bijective to any listed sibling because it jointly carries located endpoints, a unary mesh scale, rational and dyadic cell ledgers, ProbeBundle centers, finite coverage rows, StreamName and RegSeqRat readback, a RealUp seal, and the compact-uniform-continuity handoff route.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalNet}\uparrow}$.

Constructive story: A $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ packet is generated from located interval endpoints, a unary dyadic mesh scale, rational cells, dyadic refinements, ProbeBundle centers, finite coverage rows, StreamName windows, RegSeqRat readbacks, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalNet}\uparrow}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1250.1, Definition 1250.2, Definition 1250.3, Definition 1250.4, Definition 1250.5, Definition 1250.6, Definition 1250.7, and Definition 1250.8 bind the scoped finite dyadic mesh route for located closed bounded RealUp intervals and compact-uniform consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalNet}\uparrow}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.ClosedBoundedIntervalNetUp.ClosedBoundedIntervalNetCoverageRoute\_semantic\_name\_certi`

Bridge status: paperBridge

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, quotient streams, host real equality, selected host limits, or ambient Real completeness.

Upgrade path: No further theory-axis upgrade remains; bridge checking is the remaining formal-axis route beyond the current paper bridge.

Chapter 1251

A Concrete Naming Certificate for $\mathsf{CoreRegistryIndex}^{\uparrow}$

The $\mathsf{CoreRegistryIndex}^{\uparrow}$ packet realizes the finite registry tables of section 9462.34 as one NameCert carrier for package-level indexing. It sits beside the export surface of chapter 1216, the cannot-claim registry of chapter 554, the verifier boundary of chapter 1188, the focused ledger of chapter 1109, and the GroundCompiler recognition packet of chapter 821. Those siblings supply export, refusal, machine-verifier, focused-history, and recognition rows; this carrier binds the index itself before a consumer may treat a registry table as an accepted route.

Definition 1251.1 (Core registry index carrier)**.** *A* $\mathsf{CoreRegistryIndex}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (C, T, G, D, S, F, U, O, A, H, K, P, N)$$

with the following displayed rows:

1. *C is the concept-registry row, naming BEDC concepts and their package surfaces;*
2. *T is the theorem-registry row, naming theorem entries, proof sites, and checked or unclosed status;*
3. *G is the gap-registry row, naming open gaps, refusal sites, and boundary items;*
4. *D is the tradition-registry row, recording inherited mathematical or philosophical entry surfaces;*
5. *S is the scientific-claim row, recording empirical or model-facing claims with their audit boundaries;*
6. *F is the refusal row, recording blocked export, cannot-claim, unavailable-evidence, or policy refusal entries;*
7. *U is the route and upgrade row, recording how a registry entry may move to a stronger closure surface;*
8. *O is the ordinary-language row, recording entry points by which a reader reaches a finite registry entry;*
9. *A is the audit row, recording export checks, consistency gates, and machine-readable review data;*
10. *H is the componentwise* hsame *transport row for all displayed registry rows;*

11. *K is the displayed* Cont *continuation row through the concept, theorem, gap, tradition, scientific-claim, refusal, route, ordinary-language, and audit entries;*
12. *P is the* Pkg *provenance over* $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{LargeModelOutputVerifier}^{\uparrow}$, $\mathsf{FocusedMultiHistLedger}^{\uparrow}$, $\mathsf{GroundCompilerRecognition}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CoreRegistryIndex}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unlicensed export, hidden total index, theorem-content synthesis, erased refusal, audit-free route, or ordinary-language entry point outside the finite packet $R = (C, T, G, D, S, F, U, O, A, H, K, P, N)$.

Lean4 ✓ `BEDC.Derived.CoreRegistryIndexUp.CoreRegistryIndexCarrier row surface semantic certificate`

Theorem 1251.2 (Core registry index NameCert obligations)**.** *For the carrier of Definition 1251.1, the local* $\mathsf{NameCert}_{\mathsf{CoreRegistryIndex}^{\uparrow}}$ *surface consists exactly of carrier admission for $R = (C, T, G, D, S, F, U, O, A, H,$ registry exposure for concept, theorem, gap, tradition, scientific-claim, refusal, route, and ordinary-language rows; audit exposure through A; componentwise transport through H; displayed continuation through K; package provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.CoreRegistryIndexUp.CoreRegistryIndexTasteGate single carrier alignment`

Proof. Project the carrier definition. The finite packet displays every registry table named by the core-registry surface together with audit, transport, continuation, package, and local naming rows.

The sibling chapters provide only bounded surfaces. The export surface controls public registry export, the cannot-claim packet supplies refusal discipline, the large-model verifier controls checked machine output, the focused multi-Hist ledger supplies finite history focus, and the GroundCompiler recognition packet supplies recognized machine-facing rows.

Rows A, H, K, P, N bind those registry rows as one NameCert surface. Since no row names a hidden total index or theorem-content generator, the obligations are exactly the displayed finite registry packet and its audit, transport, continuation, provenance, and naming data. □

Theorem 1251.3 (Core registry index nonescape)**.** *Every public consumer of an accepted* $\mathsf{CoreRegistryIndex}^{\uparrow}$ *packet must read the concept, theorem, gap, tradition, scientific-claim, refusal, route, ordinary-language, audit, transport, continuation, provenance, and local NameCert rows together. Removing the refusal row F or audit row A exits the accepted registry index and cannot be repaired by transport, continuation, package provenance, or local naming alone.*

Lean4 ✓ `BEDC.Derived.CoreRegistryIndexUp.CoreRegistryIndex refusal audit nonescape certificate`

Proof. Apply the NameCert obligations of Definition 1251.2. They require the registry rows C, T, G, D, S, F, U, O and the audit row A before the packet may be exported as $\mathsf{CoreRegistryIndex}^{\uparrow}$.

The export surface and cannot-claim sibling chapters keep exported rows and blocked rows distinct. The verifier, focused-ledger, and recognition siblings keep machine-output, history-focus, and recognition data bounded by their displayed rows.

Thus a consumer that removes F loses the refusal boundary, and a consumer that removes A loses the export audit. The support rows H, K, P, N preserve an admitted packet; they do not synthesize the missing refusal or audit surface. □

Falsifiable prediction: Removing the refusal row or audit row permits an unlicensed registry export.

Independence witness: registryexportsurface, axiszeckendorfcannotclaim, largemodeloutputverifier, focused-multi-hist-ledger, groundcompilerrecognition: none is bijective to $\mathsf{CoreRegistryIndex}^{\uparrow}$. The export surface lacks the concept, theorem, gap, tradition, scientific-claim, ordinary-language, and upgrade index together; the cannot-claim packet lacks accepted registry export rows; the large-model verifier lacks package registry rows; the focused multi-Hist ledger lacks refusal and ordinary-language index rows; the GroundCompiler recognition packet lacks theorem, gap, refusal, audit, and route rows as one finite registry carrier.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{CoreRegistryIndex}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{CoreRegistryIndex}^{\uparrow}$ instances in `lean4/BEDC/Derived/CoreRegistryIndexUp/TasteGate.lean`. Those instances must preserve $C, T, G, D, S, F, U, O, A, H, K, P, N$ as separate displayed fields before any checked theorem may cite the $\mathsf{CoreRegistryIndex}^{\uparrow}$ packet as a field-faithful registry index.

Theorem 1251.4 (Core registry index export-surface bridge)**.** *A public read of* $\mathsf{CoreRegistryIndex}^{\uparrow}$ *bridges to* $\mathsf{RegistryExportSurface}^{\uparrow}$ *only when the refusal row F and audit row A remain displayed with the concept, theorem, gap, tradition, scientific-claim, route, ordinary-language, transport, continuation, provenance, and local naming rows. Removing either F or A leaves the bridge route and cannot be repaired by export-surface recognition alone.*

Proof. Apply the carrier and nonescape rows of Definition 1251.1 and Definition 1251.3. They force every public registry-index consumer to retain the refusal row F and audit row A together with the displayed registry rows.

The registry export surface can expose an accepted public row only after those rows remain visible. Since the export surface does not synthesize missing refusal or audit evidence, a read without F or A is outside the $\mathsf{CoreRegistryIndex}^{\uparrow}$ bridge route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CoreRegistryIndex}^{\uparrow}}$.

Constructive story: A $\mathsf{CoreRegistryIndex}^{\uparrow}$ packet is generated from concept, theorem, gap, tradition, scientific-claim, refusal, route, ordinary-language, audit, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CoreRegistryIndex}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1251.1, Definition 1251.2, Definition 1251.3, Definition 1251.4, the visible sibling routes through RegistryExportSurfaceUp, AxisZeckendorfCannotClaimUp, LargeModelOutputVerifierUp, FocusedMultiHistLedgerUp, and GroundCompilerRecognitionUp, the falsifiable prediction row, and the independence-witness row bind the public exported registry-index surface for the displayed finite packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CoreRegistryIndex}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.CoreRegistryIndexUp.CoreRegistryIndex\_refusal\_audit\_nonescape\_certificate`

Bridge status: paperBridge

Not claimed: This chapter does not close Lean bridge checking, registry completeness, hidden total indexing, or correctness of every downstream registry entry.

Upgrade path: No further paper theory-axis strengthening is recorded for this registry-index packet; bridge checking remains a separate formal-axis target.

Chapter 1252

A Concrete Naming Certificate for $\mathsf{ConceptRegistrySurface}^{\uparrow}$

The $\mathsf{ConceptRegistrySurface}^{\uparrow}$ packet realizes the registry family of Definition 9462.2206 and the concept-entry discipline of Definition 9462.2209 as a finite NameCert carrier. It sits beside the export-control packet of chapter 1216, the failed-gate witness of chapter 901, and the auditable-generativity package of chapter 9462. Those siblings expose registry export, diagnostic failure, or package-level vision rows; this packet binds concept entry, theorem entry, gap entry, tradition entry, science entry, cannot-claim row, upgrade route, transport, provenance, and local naming before a philosophical concept can leave the registry family as BEDC prose.

Definition 1252.1 (Concept registry surface carrier)**.** *A* $\mathsf{ConceptRegistrySurface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (C, T, G, R, S, F, U, H, P, N)$$

with the following displayed rows:

1. *C is the concept-entry row, recording the concept name, BEDC site, carrier, classifier, ledger, positive reading, forbidden readings, gap status, closure status, and formal status.*
2. *T is the theorem-entry row, recording the theorem or theorem-facing obligation to which the concept may point.*
3. *G is the gap-entry row, recording the visible socket, missing proof, boundary pressure, or formalization target carried by the concept.*
4. *R is the tradition-entry row, recording comparison with inherited philosophical vocabulary without turning that comparison into package membership.*
5. *S is the science-entry row, recording empirical or records-side claims whose export remains tied to displayed observations and prediction sockets.*
6. *F is the cannot-claim row, recording the forbidden readings that block export as subject substance, global world object, hidden theorem, primitive law, or unlicensed term.*
7. *U is the upgrade-route row, recording the route by which a concept may move to a stronger registry status after a displayed carrier, theorem, gap, or bridge row is present.*
8. *H stores componentwise* hsame *transport for concept, theorem, gap, tradition, science, cannot-claim, upgrade, provenance, and local naming rows.*

9. *P is the* Pkg *provenance over* ConceptRegistrySurface$^{\uparrow}$, RegistryExportSurface$^{\uparrow}$, AuditGateFailureWitness$^{\uparrow}$, AxisZeckendorfCannotClaim$^{\uparrow}$, *philosophy-package registry rows,* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{ConceptRegistrySurface}^{\uparrow}}$ *row.*

The carrier has no coordinate for a concept with no displayed BEDC site, no forbidden-reading row, no registry route, or no local naming row.

Lean4 (definition) `BEDC.Derived.ConceptRegistrySurfaceUp.ConceptRegistrySurfaceCarrier`

Theorem 1252.2 (Concept registry surface export exactness)**.** *For the carrier of Definition 1252.1, the local* NameCert$_{\text{ConceptRegistrySurface}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for $Q = (C, T, G, R, S, F, U, H, P, N)$;*
2. *concept-entry exactness through C, requiring the displayed BEDC site, carrier, classifier, ledger, positive reading, forbidden readings, gap status, closure status, and formal status to remain in one row;*
3. *registry-family coverage through T, G, R, S, F, U, requiring theorem, gap, tradition, science, cannot-claim, and upgrade readings to be displayed before export;*
4. *componentwise transport and displayed route replay through H and the registry routes named in P;*
5. *package provenance and local naming through P and N.*

Proof. Project the finite packet of Definition 1252.1. The concept row C contains the exact entry fields required by the concept registry, while T, G, R, S, F, U place the same concept inside the theorem, gap, tradition, science, cannot-claim, and upgrade routes of the registry family.

The export-control surface of chapter 1216 supplies the public reading discipline: a concept leaves the philosophy package only through displayed registration, status, blocking, audit, and non-smuggling rows. Here those rows are specialized to the concept-entry exactness carried by C and to the registry-family rows T, G, R, S, F, U.

Finally H, P, N transport, package, and name the same packet. Since Q contains no hidden registry state or prose-only export coordinate, the five rows listed in the statement exhaust the local NameCert$_{\text{ConceptRegistrySurface}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.ConceptRegistrySurfaceUp.ConceptRegistrySurface export exactness certificate`

Theorem 1252.3 (Concept registry surface forbidden-reading refusal)**.** *Every accepted* ConceptRegistrySurface$^{\uparrow}$ *packet refuses export of a philosophical concept that lacks one of the displayed BEDC site in C, forbidden-reading row F, registry-family route T, G, R, S, U, transport row H, provenance row P, or local naming row N. A consumer cannot replace those rows by prose synthesis, inherited tradition, scientific vocabulary, host semantics, or an audit-gate failure read as theorem content.*

Lean4 ✓ `BEDC.Derived.ConceptRegistrySurfaceUp.ConceptRegistrySurface forbidden reading refusal certificate`

Proof. Use Definition 1252.2. It binds every exportable concept to the displayed concept entry and to the theorem, gap, tradition, science, cannot-claim, and upgrade rows of the same finite packet.

If the BEDC site in C is absent, the concept remains external vocabulary rather than an accepted registry entry. If the forbidden-reading row F is absent, the packet no longer records which readings are blocked, so it cannot be an accepted concept-registry export.

The sibling failure surface of chapter 901 records failed gate items as diagnostic refusal data. It does not convert a missing concept row or missing forbidden-reading row into theorem content. Package provenance and local naming preserve the displayed refusal route; they do not add a hidden export path. □

Theorem 1252.4 (Concept registry surface bridge schema)**.** *For an accepted* ConceptRegistrySurface$^{\uparrow}$ *packet* $Q = (C, T, G, R, S, F, U, H, P, N)$*, the export exactness row of Definition 1252.2 and the forbidden-reading refusal row of Definition 1252.3 form the paper bridge schema from the local registry surface to the abstract registry interface. The schema exports only the displayed concept-entry, theorem-entry, gap-entry, tradition-entry, science-entry, cannot-claim, upgrade, transport, provenance, and local naming rows, and it does not assert Lean bridge checking.*

Lean4 ✓ `BEDC.Derived.ConceptRegistrySurfaceUp.ConceptRegistrySurface bridge schema certificate`

Proof. Read the export exactness theorem first. It identifies the registry-facing public surface with the displayed rows $C, T, G, R, S, F, U, H, P, N$ and makes those rows the only admissible source of concept export.

Read the forbidden-reading refusal theorem next. It blocks prose synthesis, inherited tradition, scientific vocabulary, host semantics, and diagnostic failure rows from replacing any displayed registry coordinate.

Together these two rows give the bridge schema: every abstract registry-interface read must enter through the local carrier rows and must respect the refusal boundary. Since the schema is stated entirely on the paper side, it records no Lean bridge certificate. □

Falsifiable prediction: An exported philosophical concept without a displayed BEDC site, forbidden-reading row, and registry route is outside ConceptRegistrySurfaceUp.

Independence witness: registryexportsurface, auditgatefailurewitness, cannotclaimregistry, conceptregistry, philosophypackage: none is bijective because ConceptRegistrySurfaceUp carries the concept-entry exactness and forbidden-reading route simultaneously while each sibling lacks at least one of those rows.

The Lean follow-up for ConceptRegistrySurface$^{\uparrow}$ must provide Nontrivial ConceptRegistrySurface$^{\uparrow}$ and FieldFaithful ConceptRegistrySurface$^{\uparrow}$ instances in `lean4/BEDC/Derived/ConceptRegistrySurfaceUp/TasteG` The instances must preserve the concept, theorem, gap, tradition, science, cannot-claim, upgrade, transport, provenance, and local NameCert rows of $Q = (C, T, G, R, S, F, U, H, P, N)$ before any later checked theorem cites the carrier as a TasteGate surface.

Closure status for NameCert$_{\text{ConceptRegistrySurface}^{\uparrow}}$.

Constructive story: A ConceptRegistrySurface$^{\uparrow}$ packet is generated from concept, theorem, gap, tradition, science, cannot-claim, upgrade, componentwise hsame transport, package provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{ConceptRegistrySurface}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1252.2, Definition 1252.3, Definition 1252.4, the falsifiable prediction, the independence witness, and the existing ConceptRegistrySurfaceTasteGate_single_carrier_alignment, Nontrivial, and FieldFaithful Lean support in `lean4/BEDC/Derived/ConceptRegistrySurfaceUp/TasteGate.lean` bind the paper bridge schema, examples, and completeness coverage for the concept registry surface.

Formal verification: FormalStatus(NameCert$_{\text{ConceptRegistrySurface}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, complete philosophy-package governance, or correctness of every downstream concept registry entry.

Upgrade path: The remaining work is Lean verification and bridge checking on the formal axis, not further paper-axis closure.

Chapter 1253

A Concrete Naming Certificate for $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$

The $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ packet records the Bishop–Bridges and Heine–Cantor interval route inside the BEDC finite-ledger substrate. It specializes the compact-uniform-continuity vision of chapter 9237 to a closed bounded real interval: the endpoint and membership rows come from $\mathsf{Real}^{\uparrow}$ and $\mathsf{Interval}^{\uparrow}$, compactness is read through the finite dyadic-cover surface of chapter 129, pointwise continuity is read through chapter 130, the Lebesgue-radius ledger is supplied by chapter 452, and the output is the $\mathsf{UniformModulus}^{\uparrow}$ consumer row.

Definition 1253.1 (Closed bounded interval uniform-modulus carrier)**.** *A* $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, B, R, C, D, L, M, U, H, Q, P, N)$$

with the following visible rows:

1. *A and B are* $\mathsf{Real}^{\uparrow}$ *endpoint rows with the displayed interval orientation $A \leq B$;*
2. *R is the* $\mathsf{Interval}^{\uparrow}$ *membership row for the closed bounded source interval $[A, B]$;*
3. *C is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite dyadic-cover row whose centers and mesh are carried by a finite* $\mathsf{ProbeBundle}$*;*
4. *D is the* $\mathsf{DyadicCover}^{\uparrow}$ *mesh ledger relating the interval endpoints, dyadic centers, and half-radius coverage rows;*
5. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *radius ledger giving one positive radius below every dyadic cover radius used by C and D;*
6. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row for the displayed map on the interval source;*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row carrying the tolerance-to-precision history produced from L and M;*
8. *H records componentwise* hsame *transport for endpoints, membership, dyadic cover, Lebesgue radius, pointwise modulus, and uniform-modulus output;*
9. *Q records the displayed* Cont *routes through which interval, compact-metric, continuous-map, dyadic-cover, Lebesgue-number, and uniform-modulus consumers read the packet;*

10. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{Interval}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicCover}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, *and* Cont *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, sequential compactness, a host minimum over radii, quotient real equality, or an external modulus function. Every public read of the interval Heine–Cantor route must pass through the displayed finite dyadic cover and finite Lebesgue-number ledger.

Theorem 1253.2 (Closed bounded interval uniform-modulus NameCert obligations)**.** *For the carrier of Definition 1253.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}}$ *surface consists exactly of five finite obligations: carrier admission for the displayed packet I; classifier preservation under the componentwise* hsame *rows H; dyadic-cover coverage for every* $\mathsf{Interval}^{\uparrow}$ *member read from R; finite Lebesgue-number compatibility between D and L; and output exactness saying that the* $\mathsf{UniformModulus}^{\uparrow}$ *row U is read only through C, D, L, M, H, Q, P, N.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUniformModulusUp.ClosedBoundedIntervalUniformModulusTasteGate`
`single carrier alignment`

Proof. Carrier admission is immediate from the displayed packet: every endpoint, interval-membership, dyadic-cover, Lebesgue-radius, pointwise-modulus, output, transport, route, provenance, and local naming row is one of the coordinates of I.

Classifier preservation follows by reading the componentwise hsame rows in H. These rows transport the endpoint orientation, interval membership, dyadic cover mesh, finite Lebesgue-number radius, pointwise modulus, and uniform-modulus output without adding a row outside the carrier.

The coverage and radius clauses are supplied by C, D, L. The compact-metric finite cover chooses only bundled dyadic centers from D, and the finite Lebesgue-number ledger L gives a positive radius below the displayed cover radii.

Finally the output exactness clause routes the continuous-map rows M and the finite radius ledger L into U through Q, P, N. Thus every local naming obligation is discharged by rows already visible in I. □

Theorem 1253.3 (Closed bounded interval Heine–Cantor route)**.** *Let $I = (A, B, R, C, D, L, M, U, H, Q, P, N)$ be an accepted* $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *carrier. For every positive target-tolerance history read by the* $\mathsf{ContinuousMap}^{\uparrow}$ *row M, the* $\mathsf{UniformModulus}^{\uparrow}$ *output U factors through the finite dyadic cover D and the finite Lebesgue-number ledger L: a source-distance read below the precision exported by U is routed to one bundled dyadic center, then through the corresponding pointwise-modulus row of M, and finally through the target metric triangle row.*

The factorization uses the interval membership row R, compact finite-cover row C, dyadic mesh row D, Lebesgue-number row L, pointwise-modulus row M, and transport and provenance rows H, Q, P, N. It uses no open-cover compactness theorem, no host minimum, no selected subsequence, no quotient equality of reals, and no external modulus selector.

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUniformModulusUp.ClosedBoundedIntervalUniformModulus`
`heine cantor route rows`

Proof. Start with the interval source. The endpoint rows A, B and the membership row R identify the closed bounded interval as the only source domain visible to the packet.

Read compactness through the finite dyadic-cover rows C and D. For each source history admitted by R, the cover returns a bundled dyadic center and a displayed mesh-radius comparison; the center is a row of the finite ProbeBundle, not an externally chosen real point.

Use the finite Lebesgue-number ledger L to choose the precision handed to the uniform-modulus output. Since L is below every displayed dyadic cover radius, any pair of interval histories whose source distance is below the exported precision remains inside one cover member after transport through H.

At that bundled center, the ContinuousMap$^{\uparrow}$ row M supplies the pointwise modulus for the requested tolerance. The target metric triangle row then combines the two pointwise estimates through the same center, and the route rows Q, P, N repack the result as the UniformModulus$^{\uparrow}$ output U.

All rows used in the argument are coordinates of I. Hence the Heine–Cantor interval route is realized by finite dyadic cover data plus the finite Lebesgue-number ledger, with no appeal to an open cover, host minimum, selected subsequence, quotient real equality, or external analytic modulus. □

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUniformModulusUp.ClosedBoundedIntervalUniformModulusHeineCant`

Theorem 1253.4 (Closed bounded interval dyadic-cover scope)**.** *For every accepted* ClosedBoundedIntervalUniformM *carrier $I = (A, B, R, C, D, L, M, U, H, Q, P, N)$, the endpoint rows A, B, closed-interval membership row R, compact finite-cover row C, and dyadic-cover ledger D are scoped entirely to the source side of the interval route. Any consumer of the uniform-modulus output must read these rows before it may inspect the finite Lebesgue-number ledger or the* UniformModulus$^{\uparrow}$ *row.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUniformModulusUp.ClosedBoundedIntervalUniformModulus dyadic cover scope`

Proof. Project the carrier. The endpoint rows A, B and interval membership row R identify the closed bounded source interval and do not mention the target modulus output.

The finite-cover rows C, D remain on the same source side. They provide bundled dyadic centers, mesh data, and coverage comparisons for interval members, but they do not supply a pointwise-modulus value or a uniform-modulus output.

Thus the dependency scope for the source side is precisely the endpoint, interval, compact finite-cover, and dyadic-cover rows. Later rows may consume this scope, but they cannot replace it with open-cover compactness, host minimum selection, quotient-real equality, or an external interval object. □

Theorem 1253.5 (Closed bounded interval Lebesgue handoff scope)**.** *For every accepted* ClosedBoundedIntervalUni *carrier $I = (A, B, R, C, D, L, M, U, H, Q, P, N)$, the pointwise-modulus row M, finite Lebesgue-number ledger L, and* UniformModulus$^{\uparrow}$ *output row U form the handoff scope from source-side dyadic covers to the public uniform-modulus read. Transport, replay, provenance, and local naming are exactly the rows H, Q, P, N.*

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUniformModulusUp.ClosedBoundedIntervalUniformModulus lebesgue handoff scope`

Proof. Start from the source scope of Definition 1253.4. The dyadic-cover rows C, D feed the finite Lebesgue-number ledger L, which records a positive radius below the displayed cover radii.

The pointwise-modulus row M is then read at the bundled centers selected by the finite cover, and the output row U packages the resulting tolerance-to-precision history as the UniformModulus$^{\uparrow}$ consumer row.

The remaining rows H, Q, P, N preserve the same handoff under componentwise hsame transport, displayed Cont replay, provenance, and local naming. Hence the scoped dependencies are exactly Real$^{\uparrow}$, Interval$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DyadicCover$^{\uparrow}$, FiniteLebesgueNumber$^{\uparrow}$, UniformModulus$^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows. □

Theorem 1253.6 (Closed bounded interval uniform-modulus consumer examples)**.** *Every public consumer example for an accepted* ClosedBoundedIntervalUniformModulus$^{\uparrow}$ *carrier reads the same finite Heine–Cantor route before it reaches its own output row. The* ContinuousMap$^{\uparrow}$ *consumer supplies the pointwise modulus row, the* CompactMetric$^{\uparrow}$ *consumer supplies the finite compact source, the* FiniteLebesgueNumber$^{\uparrow}$ *consumer supplies the radius ledger, the* UniformModulus$^{\uparrow}$ *consumer reads the produced tolerance-to-precision history, the* DyadicCover$^{\uparrow}$ *consumer supplies the cover mesh, and the* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *consumers read the regular-rational and terminal real-name seals only after those rows are displayed.*

Proof. Begin with the Heine–Cantor route of Definition 1253.3. It identifies the source interval, compact finite cover, dyadic cover, finite Lebesgue-number ledger, pointwise modulus, and uniform-modulus output as one finite route.

Use the dyadic-cover scope theorem Definition 1253.4. It places CompactMetric$^{\uparrow}$ and DyadicCover$^{\uparrow}$ before any Lebesgue-number or uniform-modulus output can be read.

Now apply the Lebesgue handoff scope Definition 1253.5. The ContinuousMap$^{\uparrow}$ row, FiniteLebesgueNumber$^{\uparrow}$ ledger, and UniformModulus$^{\uparrow}$ output form the handoff, while RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ consumers remain downstream of the same displayed real-name route.

Thus the named consumer examples are examples of the existing finite dependency route, not additional compactness, completeness, selected-minimum, quotient-real, or host-function-equality principles. □

Lean4 ✓ `BEDC.Derived.ClosedBoundedIntervalUniformModulusUp.ClosedBoundedIntervalUniformModulus consumer examples`

Closure status for NameCert$_{\text{ClosedBoundedIntervalUniformModulus}^{\uparrow}}$.

Constructive story: The closed bounded interval uniform-modulus certificate is generated from the classical Heine–Cantor pattern, but its BEDC carrier reads only visible $BHist$ rows: closed interval bounds, finite dyadic cover data, bundled dyadic centers, pointwise continuity rows, finite Lebesgue-number ledger, and the uniform modulus row produced for the interval route. The $hsame$ relation transports those rows across equivalent histories without invoking host equality of functions or intervals. Cont allows the uniform-modulus evidence to be consumed downstream while preserving the same interval and continuity ledger. The chapter therefore records the constructive route expected of the theorem, while keeping compactness and completeness obligations explicit rather than importing them silently.

Theory closure: TheoryGate(NameCert$_{\text{ClosedBoundedIntervalUniformModulus}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1253.3, Definition 1253.4, and Definition 1253.5 bind the public Heine–Cantor interval route, the source-side dyadic-cover rows, and the Lebesgue-to-uniform-modulus handoff to the displayed dependency scope.

Formal verification: FormalStatus(NameCert$_{\text{ClosedBoundedIntervalUniformModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: It does not claim a proved compactness theorem, ambient real completeness, open-cover minimum selection, or host-level function equality beyond the displayed route rows.

Upgrade path: The mature paper route is closed over Real$^{\uparrow}$, Interval$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DyadicCover$^{\uparrow}$, FiniteLebesgueNumber$^{\uparrow}$, UniformModulus$^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows; Lean verification and a standard bridge remain outside this chapter.

Chapter 1254

A Concrete Naming Certificate for BolzanoWeierstrass$^{\uparrow}$

Following Bolzano and Weierstrass, the BolzanoWeierstrass$^{\uparrow}$ packet records the finite interval-net and regular-subsequence route for a bounded Real$^{\uparrow}$ sequence. The construction reads boundedness through the finite mesh surface of chapter 1250, the interval modulus surface of chapter 1253, the monotone-cofinal extraction row of chapter 381, the regular rational readback of chapter 301, and the completed real-name seal of chapter 38. It is a subsequence compactness certificate for bounded real sequences, not an open-cover compactness theorem, a host completeness principle, quotient equality of streams, or a choice of arbitrary subsequences.

Definition 1254.1 (Bolzano–Weierstrass carrier)**.** *A* BolzanoWeierstrass$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, K, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded* Real$^{\uparrow}$ *sequence surface, exposed by finite* StreamName$^{\uparrow}$ *windows and bounded by the interval read used by K;*
2. *K is the* ClosedBoundedIntervalNet$^{\uparrow}$ *packet naming the finite interval nets and dyadic mesh rows used to trap subsequence windows;*
3. *R is the* RegularCauchySubsequence$^{\uparrow}$ *extraction row, including the monotone-cofinal unary reindexing ledger and the selected finite windows;*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row attached to the extracted windows and their dyadic tolerance comparisons;*
5. *E is the* Real$^{\uparrow}$ *cluster seal reached only after S, K, R, Q have been displayed;*
6. *H records componentwise* hsame *transport for the bounded sequence rows, interval nets, extracted subsequence rows, regular rational readback, and real cluster seal;*
7. *C records displayed* Cont *routes from bounded sequence inspection through finite interval nets, regular Cauchy subsequence extraction, RegSeqRat readback, and RealUp sealing;*
8. *P is the* Pkg *provenance over* BolzanoWeierstrass$^{\uparrow}$, ClosedBoundedIntervalNet$^{\uparrow}$, ClosedBoundedIntervalUniformMo RegularCauchySubsequence$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrass}^{\uparrow}}$ *row.*
The carrier exports no open-cover compactness object, no host completeness row, no quotient equality of real names, no least cluster selector, and no choice-selected arbitrary subsequence.

Lean4 (definition) `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassUp`
Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassTasteGate single carrier alignment`

Theorem 1254.2 (Bolzano–Weierstrass NameCert obligations)**.** *For the carrier of Definition 1254.1, the local* $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrass}^{\uparrow}}$ *surface consists exactly of carrier admission for $B = (S, K, R, Q, E, H, C, P, N)$, bounded sequence admission through S, finite interval-net admission through K, interval-modulus compatibility with the closed bounded interval route, monotone-cofinal regular-subsequence extraction through R, RegSeqRat readback through Q, RealUp cluster sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier namecert obligations`

Proof. Project the carrier. The bounded sequence row S is visible before any cluster seal is read, and the interval-net row K supplies the finite dyadic mesh and containment rows from chapter 1250.

Read the interval compatibility next. The uniform-modulus route of chapter 1253 keeps the closed bounded interval data tied to displayed dyadic covers and finite radius ledgers, so the packet does not import an open-cover object or a host minimum.

The subsequence rows close the analytic surface. The extraction row R is the monotone-cofinal route of chapter 381, while Q is the regular rational readback through chapter 301; the cluster seal E is then reached through the real-name boundary of chapter 38.

Finally the structural rows H, C, P, N transport, replay, source, and name only these displayed rows. No additional NameCert obligation remains outside the listed finite ledger. □

Theorem 1254.3 (Bolzano–Weierstrass finite subsequence obligations)**.** *For an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier $B = (S, K, R, Q, E, H, C, P, N)$, finite subsequence extraction is an obligation over the displayed rows S, K, R, Q, H, C, P, N. The row K supplies finite* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *selections, the row R records the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *monotone-cofinal schedule, the row Q reads the selected windows through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal remains downstream of those rows.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier finite subsequence obligations`

Proof. Project the carrier of Definition 1254.1. The bounded source S and interval-net row K are visible before any subsequence schedule or real cluster seal is consumed.

Apply Definition 1254.2. It identifies K as the finite $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ source, R as the $\mathsf{RegularCauchySubsequence}^{\uparrow}$ extraction row, and Q as the $\mathsf{RegSeqRat}^{\uparrow}$ readback row over finite stream windows and dyadic tolerances.

Transport and replay through H and C, then source and name the same route through P and N. The extraction therefore uses only finite interval-net selection, monotone-cofinal scheduling, regular rational readback, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, and the downstream $\mathsf{Real}^{\uparrow}$ seal; it does not claim open-cover compactness or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrass tagged fromEventFlow exactness`

Theorem 1254.4 (Bolzano–Weierstrass interval nesting route)**.** *For an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier* $B = (S, K, R, Q, E, H, C, P, N)$*, nested dyadic-window retention is read only through the finite* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row* K *before the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *row* R *is consumed. Later retained windows refine earlier retained windows inside the same interval-net route, and the selected windows are then exposed to* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *without importing open-cover compactness, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier interval nesting route`

Proof. Start with Definition 1254.2. It places finite interval-net admission through K before monotone-cofinal regular-subsequence extraction through R and regular rational readback through Q.

At each inspected depth, the retained dyadic window is a displayed child of the same $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ route. The transport row H carries the source window and interval row together, while the replay row C records the containment and dyadic tolerance facts used by the next retained window.

Only after that nesting route is displayed may R append the next monotone-cofinal index. The readback row Q then exposes the same retained windows through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$, so no open-cover compactness or ambient $\mathsf{Real}^{\uparrow}$ completeness row enters the route. □

Theorem 1254.5 (Bolzano–Weierstrass RegSeqRat handoff)**.** *For an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier* $B = (S, K, R, Q, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *cluster handoff factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q *after finite interval selection and regular-subsequence scheduling have been displayed. The consumer route is*

$$\mathsf{ClosedBoundedIntervalNet}^{\uparrow} \longmapsto \mathsf{RegularCauchySubsequence}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}$$

It exports a finite regular-rational handoff, not a host completeness point, selected cluster limit, open-cover compactness theorem, or quotient equality of streams.

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier regseqrat handoff`

Proof. Use Definition 1254.3 to expose finite interval-net selection, the regular-subsequence schedule, and the regular rational readback before the terminal Real seal.

Then use Definition 1254.4. The retained windows form a nested dyadic route inside K, and the row R records the monotone-cofinal schedule attached to those windows.

Now read Q. Its $\mathsf{RegSeqRat}^{\uparrow}$ surface receives exactly the $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances already displayed by K and R. The row E may be consumed only after this handoff, and H, C, P, N preserve the same route.

Thus the cluster-facing output is a finite $\mathsf{RegSeqRat}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$ handoff. No ambient completeness, selected limit, open-cover compactness, or quotient stream equality is available from the carrier. □

Theorem 1254.6 (Bolzano–Weierstrass root interval-tree obligation)**.** *For an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier* $B = (S, K, R, Q, E, H, C, P, N)$*, the root interval-tree obligation sends every bounded real sequence read through the finite* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ S, K, H, C, P, N.$$

The row S *supplies finite* $\mathsf{StreamName}^{\uparrow}$ *windows for the bounded source,* K *supplies the dyadic interval-tree and* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh rows, and* H, C, P, N *transport, replay, source, and name*

only that displayed tree. The obligation refuses selected subsequence choice, open-cover compactness, quotient real equality, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier root interval tree obligation`

Proof. Project the carrier of Definition 1254.1. The bounded source row S and the interval-net row K are visible before any subsequence extraction or Real seal is consumed.

Apply Definition 1254.2. It identifies S, K, H, C, P, N as NameCert rows over bounded sequence admission, finite dyadic interval nets, componentwise transport, displayed replay, provenance, and local naming.

The excluded principles are absent from the carrier inventory. Since the interval tree is finite and dyadic, the root obligation is a displayed BEDC row rather than an open-cover compactness or choice-selected extraction principle. □

Theorem 1254.7 (Bolzano–Weierstrass root subsequence extraction obligation)**.** *For an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier, extracting a cofinal regular subsequence is an obligation over the displayed rows* S, K, R, Q, H, C, P, N*. The finite interval-tree row* K *supplies retained bounded windows from* S*; the extraction row* R *records the monotone-cofinal* $\mathsf{StreamName}^{\uparrow}$ *reindexing ledger; and* Q *reads those windows through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *before any* $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

Thus the root extraction obligation has an explicit $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{NameCert}$ *surface and does not export selected subsequence choice, host compactness, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the interval-tree obligation of Definition 1254.6. It gives the bounded source windows and dyadic retained-cell rows before the extraction ledger is read.

Use the carrier row R for monotone-cofinal reindexing and Q for the regular rational readback. These are the only rows that can name the extracted subsequence in Definition 1254.1.

Finally use H, C, P, N to transport, replay, source, and name the route. Because the subsequence is read from retained finite windows and regular rational schedules, no external selector or ambient completeness object is available. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier root subsequence extraction obligation`

Definition 1254.8 (Bolzano–Weierstrass finite monotone-subsequence window)**.** *For an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier* $B = (S, K, R, Q, E, H, C, P, N)$*, a finite monotone-subsequence window is the displayed BEDC row obtained by pairing:*

1. *the retained closed bounded interval rows of* K*, read as finite* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *cells over the bounded source windows of* S*;*
2. *the monotone-cofinal reindexing ledger of* R*, read as the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *schedule that keeps the retained rows in increasing subsequence order;*
3. *the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows of* Q *attached to the same retained windows;*
4. *the transport, replay, provenance, and local naming rows* H, C, P, N*.*

The window has no coordinate for a selected infinite subsequence, quotient real equality, host open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassMonotoneSubsequenceWindow single carrier alignment`

Theorem 1254.9 (Bolzano–Weierstrass monotone window regularity)**.** *Every finite monotone-subsequence window of an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier is a regular BEDC readback surface. Its retained interval rows are read through the same* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh bounds, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback that already occur in* S, K, R, Q, H, C, P, N*.*

Consequently regularity is witnessed by the displayed finite windows and monotone-cofinal ledger, not by an external selector, a quotient stream, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier monotone window regularity`

Proof. Start from Definition 1254.8. The retained interval rows come from K, and the only admitted order on them is the monotone-cofinal schedule recorded by R.

Read the retained rows through Q. The $\mathsf{StreamName}^{\uparrow}$ coordinate supplies the finite window schedule, the $\mathsf{DyadicRatCore}^{\uparrow}$ coordinate supplies the dyadic mesh and containment bounds, and the $\mathsf{RegSeqRat}^{\uparrow}$ coordinate supplies the regular rational readback.

Finally transport the same rows through H, C, P, N. Since every regularity datum has already been displayed before the $\mathsf{Real}^{\uparrow}$ seal is inspected, the theorem proves regularity of the finite window surface rather than a host-level subsequence choice principle. □

Theorem 1254.10 (Bolzano–Weierstrass closed-interval cluster handoff)**.** *For an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier* $B = (S, K, R, Q, E, H, C, P, N)$*, every cluster handoff to* $\mathsf{Real}^{\uparrow}$ *factors through a finite monotone-subsequence window. The route first reads retained* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *rows from* K*, then the monotone-cofinal* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *ledger from* R*, then the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows from* Q*, and only then reaches the seal row* E*.*

The handoff exports no open-cover compactness, selected subsequence choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness. It reaches* $\mathsf{Real}^{\uparrow}$ *only through the finite retained rows and their displayed transport, replay, provenance, and local* $\mathsf{NameCert}$ *coordinates.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier closed interval cluster handoff`

Proof. Apply Definition 1254.6 to obtain the finite retained interval tree and bounded source windows. These rows are the only interval data exposed by K.

Use Definition 1254.7 to read the monotone-cofinal schedule through R and the regular rational surface through Q. The preceding regularity theorem identifies that surface as the finite monotone-subsequence window.

Only after these rows are displayed may the cluster row E be consumed. The support rows H, C, P, N preserve the same route, so the cluster handoff remains a finite closed-interval derivation surface and never becomes an open-cover or ambient-completeness assertion. □

Theorem 1254.11 (Bolzano–Weierstrass root Real-seal obligation)**.** *Every* $\mathsf{Real}^{\uparrow}$ *cluster endpoint exposed by an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier is routed through the root interval-tree obligation and the root subsequence extraction obligation before the seal row* E *is read. The cluster endpoint is therefore a displayed Real seal over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*, not a host-level completeness point.*

The obligation refuses selected subsequence choice, open-cover compactness, quotient real equality, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1254.6. It supplies the finite dyadic retained-cell tree and bounded source windows.

Apply Definition 1254.7. It extracts the monotone-cofinal schedule and reads it as the $\mathsf{RegSeqRat}^{\uparrow}$ row consumed before the Real seal.

Only then read the cluster row E from Definition 1254.1. The support rows H, C, P, N preserve the same finite route, so the displayed $\mathsf{Real}^{\uparrow}$ seal cannot turn into a selected host endpoint or an ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassRootRealSealObligation`

Theorem 1254.12 (Bolzano–Weierstrass bounded-subsequence cluster obligation)**.** *For every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier* $B = (S, K, R, Q, E, H, C, P, N)$*, each bounded-subsequence cluster consumer must traverse the concrete rows*

$$S, K, R, Q, E, H, C, P, N$$

in the BEDC route through $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$*,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The source row* S *displays bounded real-sequence windows,* K *retains finite closed-bounded interval cells,* R *records the monotone-cofinal subsequence ledger,* Q *reads the retained windows as regular rational data, and* E *is the only* $\mathsf{Real}^{\uparrow}$ *cluster seal exposed after those rows.*

The obligation exports no selected subsequence choice, quotient real equality, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier bounded subsequence cluster obligation`

Proof. Project the carrier of Definition 1254.1. The displayed rows already separate the bounded source S, interval-net packet K, extraction ledger R, regular readback Q, Real seal E, and structural rows H, C, P, N.

Apply Definition 1254.6. It places every bounded source read behind the finite $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ route and the dyadic interval cells retained by K.

Apply Definition 1254.7. The retained windows are then consumed by R as a $\mathsf{RegularCauchySubsequence}^{\uparrow}$ schedule and by Q through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$.

Finally use Definition 1254.11. Since E is downstream of those rows and H, C, P, N only transport, replay, source, and name the same route, the bounded-subsequence cluster surface cannot expose a selected subsequence, quotient equality, open-cover compactness proof, or ambient completeness row. □

Theorem 1254.13 (Bolzano–Weierstrass cluster Real-seal factorization)**.** *Let* $B = (S, K, R, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *cluster seal read from* B *factors first through the closed-bounded interval net row* K*, then through the regular Cauchy subsequence row* R*, then through the finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface inside* Q*, and only then through* E, H, C, P, N*.*

Equivalently, the cluster seal is a displayed factorization

$$\mathsf{ClosedBoundedIntervalNet}^{\uparrow} \longmapsto \mathsf{RegularCauchySubsequence}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}$$

over the same concrete rows $S, K, R, Q, E, H, C, P, N$*. It is not a quotient-real equality witness, not an open-cover compactness principle, not a selected subsequence, and not ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier cluster real seal factorization`

Proof. Begin with Definition 1254.12. It displays the complete carrier route and identifies the only rows available to a cluster consumer.

The interval-net part is supplied by K. The regular-subsequence part is supplied by R, whose retained windows are the same finite windows obtained from S through K.

The readback part is supplied by Q. It passes the retained finite windows through $\mathsf{StreamName}^{\uparrow}$, reads dyadic tolerances through $\mathsf{DyadicRatCore}^{\uparrow}$, and exposes the regular rational surface through $\mathsf{RegSeqRat}^{\uparrow}$ before the cluster row E can be consumed.

Rows H, C, P, N preserve the displayed route by transport, replay, provenance, and local naming. Therefore the factorization reaches the $\mathsf{Real}^{\uparrow}$ seal only through the named finite rows and cannot introduce quotient real equality, selected subsequence choice, open-cover compactness, or ambient completeness. □

Theorem 1254.14 (Bolzano–Weierstrass interval-net choice-free retention)**.** *For every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier* $B = (S, K, R, Q, E, H, C, P, N)$*, the retained interval windows used by the cluster route are retained inside the displayed* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row* K *before the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *row* R *is read. Each retained window is then passed through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *using only the same* S, K, R, Q, H, C, P, N *support.*

Thus interval retention is a finite NameCert projection from the carrier, not a countable-choice selection of subsequence indices, not quotient real equality, not open-cover compactness, and not an appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the finite interval tree supplied by Definition 1254.6. The row K displays the closed-bounded interval net and the retained cells before any subsequence schedule is consumed.

Use Definition 1254.7. The row R reads only the retained windows already exposed by K, so its monotone-cofinal schedule is a projection of the finite interval-net ledger rather than an external choice function.

Read the retained windows through Q and then through E. The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows are therefore downstream of the same retained interval data, and the Real seal is reached only after that readback.

Finally transport and name the route with H, C, P, N. Since no carrier row stores a choice-selected subsequence, quotient equality, open-cover compactness proof, or ambient completeness principle, the interval-net retention remains choice-free. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier interval net choice free retention`

Theorem 1254.15 (Bolzano–Weierstrass bounded sequence source)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier reads bounded* $\mathsf{Real}^{\uparrow}$ *sequence data through the finite source route*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{NameCert}$$

before any interval-net row is consumed. The bounded source row S *exposes only scheduled stream windows, dyadic tolerance comparisons, regular rational readback, and the terminal real-name seal needed to feed* K, R, Q, E, H, C, P, N*. It does not expose selected subsequence choice, quotient real equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier bounded sequence source`

Proof. Project the carrier $B = (S, K, R, Q, E, H, C, P, N)$ from Definition 1254.1. The source coordinate S is the only row that can supply bounded sequence observations before interval nets are opened.

Read S through the displayed stream, dyadic, regular rational, and real rows. The $\mathsf{StreamName}^{\uparrow}$ windows give finite sequence observations, $\mathsf{DyadicRatCore}^{\uparrow}$ gives the tolerance comparisons, $\mathsf{RegSeqRat}^{\uparrow}$ gives the regular readback, and $\mathsf{Real}^{\uparrow}$ seals the bounded real-name surface.

Only after that source route is displayed may the interval-net row K be consumed. The structural rows H, C, P, N transport, replay, source, and name the same route, leaving no coordinate for selected subsequence choice, quotient real equality, open-cover compactness, or ambient completeness. □

Theorem 1254.16 (Bolzano–Weierstrass interval-net obligation)**.** *For every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier* $B = (S, K, R, Q, E, H, C, P, N)$*, the rows* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *and* $\mathsf{ClosedBoundedIntervalUniformMod}$ *are the only interval-tree source for retained windows. Every retained window consumed by* R *or* Q *must first be read through* K *and its uniform-modulus compatibility route, and the route refuses selected subsequence choice, quotient real equality, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier interval net obligation`

Proof. Start from the interval-net coordinate K. It is the only carrier row naming finite closed bounded interval nets, dyadic mesh cells, and retained windows.

The uniform-modulus compatibility is read inside the same interval-tree route. It binds the retained windows to displayed dyadic refinements and prevents a consumer from substituting an open-cover compactness proof or a host finite-subcover selector.

Rows R and Q consume retained windows only after K has supplied them. Transport and replay through H and C, followed by provenance and local naming through P, N, preserve the same interval-tree source and add no quotient real equality, selected subsequence choice, or ambient completeness coordinate. □

Theorem 1254.17 (Bolzano–Weierstrass regular subsequence window readback)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *route consumes* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the* $\mathsf{Real}^{\uparrow}$ *cluster seal. The row* R *records the monotone-cofinal retained-window extraction from the interval tree, the row* Q *reads those windows as regular rational data, and only then may* E *be read as the Real cluster seal. The readback exports no selected subsequence choice, quotient real equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier regular subsequence window readback`

Proof. Use Definition 1254.16 to obtain retained windows from K. These windows are finite interval-tree data rather than host subsequence choices.

Read the extraction row R next. It records the monotone-cofinal $\mathsf{RegularCauchySubsequence}^{\uparrow}$ route, so the subsequence window is named by displayed reindexing data.

Read Q before E. The regular rational readback turns the extracted windows into the $\mathsf{RegSeqRat}^{\uparrow}$ surface consumed by the Real cluster seal, and the rows H, C, P, N preserve that order.

Thus the Real seal is downstream of regular-subsequence and regular-rational readback. None of the refused principles appears in the carrier rows or in the transport and replay route. □

Theorem 1254.18 (Bolzano–Weierstrass regular subsequence route)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier routes a bounded real sequence to a regular Cauchy subsequence through the finite path*

$$S, K, R, Q, H, C, P, N.$$

The path first reads the bounded sequence surface S, then the finite interval-net packet K, then the monotone-cofinal extraction row R, and finally the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q. The route does not expose a choice-selected arbitrary subsequence, a quotient-stream representative, a host compactness theorem, or an ambient completeness field.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier regular subsequence route`

Proof. Start with the bounded sequence row. The only boundedness data visible to the carrier is the finite sequence surface S together with the closed bounded interval net K.

Apply the interval-net route of chapter 1250. Its dyadic mesh rows supply nested finite traps for inspected sequence windows, and its Real-facing seal remains downstream of the displayed mesh and readback rows.

Now use the regular-subsequence route of chapter 381. The row R supplies a monotone-cofinal unary reindexing ledger, so the subsequence is read by finite reindexing data rather than by an arbitrary choice function.

The row Q reads the extracted windows as a $\mathsf{RegSeqRat}^{\uparrow}$ surface. Transport and replay through H and C, followed by P and N, preserve that same route, leaving no coordinate for quotient streams, host compactness, or ambient completeness. □

Theorem 1254.19 (Bolzano–Weierstrass bounded source factorization)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier reads its bounded sequence row S through the finite* $\mathsf{BoundedRealSequence}^{\uparrow}$ *route of chapter 1415 before it consumes the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row K, the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *row R, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, and the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal. Thus the bounded-source surface of the Bolzano–Weierstrass packet is not a free host-level sequence input; it is the reusable finite certificate supplied by Definition 1415.4.*

Proof. Apply Definition 1415.4. It exposes the bounded real sequence source by the finite route $S, W, Q, R, I, H, C, P, N$, with stream windows, regular readback, a $\mathsf{Real}^{\uparrow}$ seal, and an interval-net bound row already displayed inside the $\mathsf{BoundedRealSequence}^{\uparrow}$ certificate.

Feed that certified source into Definition 1254.18. The Bolzano–Weierstrass carrier can then consume K for closed bounded interval nets, R for monotone-cofinal regular subsequence extraction, Q for $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal without adding another bounded-sequence coordinate.

The composite route leaves no slot for open-cover compactness, host completeness, quotient stream equality, or a choice-selected subsequence. Those principles are not transported by the $\mathsf{BoundedRealSequence}^{\uparrow}$ handoff, and the regular-subsequence route only consumes the displayed finite rows. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier bounded source factorization`

Theorem 1254.20 (Bolzano–Weierstrass bounded cluster route)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier whose bounded source is supplied by* $\mathsf{BoundedRealSequence}^{\uparrow}$ *and whose terminal cluster candidate is consumed by* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *factors through the concrete route*

$$\mathsf{BoundedRealSequence}^{\uparrow} \longmapsto \mathsf{ClosedBoundedIntervalNet}^{\uparrow} \longmapsto \mathsf{RegularCauchySubsequence}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealS}$$

The same finite interval-tree evidence is preserved by the displayed hsame, Cont, Pkg, *and* NameCert *rows, so the cluster consumer receives no detached bounded sequence, arbitrary subsequence selector, quotient stream equality, open-cover compactness, or ambient completeness row.*

Proof. Start with the bounded-source factorization of Definition 1254.19. It places the source row S behind the finite $\mathsf{BoundedRealSequence}^{\uparrow}$ handoff of Definition 1415.4 before the interval-net row K is consumed.

Use the interval-tree induction and regular-Cauchy subsequence readback blocks. The row K supplies the retained closed-bounded interval cells, R records the monotone-cofinal $\mathsf{RegularCauchySubsequence}^{\uparrow}$ ledger, and Q reads the selected windows as $\mathsf{RegSeqRat}^{\uparrow}$ data.

Now consume the terminal cluster candidate through the public export of Definition 1580.4. The $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ route reads the same bounded source, cofinal subsequence, selected windows, regular readback, dyadic tolerance ledger, and $\mathsf{Real}^{\uparrow}$ seal before a cluster point is exposed.

Finally H, C, P, N transport, replay, source, and name that same finite interval-tree evidence. Since no second source, selector, quotient stream, open-cover compactness theorem, or ambient completeness row is present, the bounded cluster route is exactly the displayed composite. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier bounded cluster route`

Theorem 1254.21 (Bolzano–Weierstrass finite interval-tree induction)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. For every inspected unary depth of the closed-bounded interval net, the displayed finite dyadic refinement tree in K determines, by induction on that tree, a retained cell, a nonempty finite sequence-window row from S, and a monotone-cofinal reindexing row in R. The retained cells refine through the same* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *and* $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *rows, and the extracted finite windows are exactly the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback consumed by Q.*

Proof. For depth 0, read the root bounded interval from S and the root net row from K. The boundedness ledger supplies a nonempty inspected sequence-window row in S, and the identity unary index row is monotone and cofinal on the displayed root window.

For the induction step, assume the retained cell and window have been displayed at depth d. The dyadic mesh row in K splits that cell into its finite children at depth $d + 1$, and the packet ledger witnesses that at least one child retains a nonempty finite sequence-window row from S.

Choose that retained child only by the displayed finite branch witness. Componentwise transport through H carries the previous route to the child cell, while displayed replay through C records the same containment and radius facts in the $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ and $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ rows.

The reindexing row in R appends the retained-window index and records monotonicity and cofinality in the unary ledger. Reading the selected windows through Q gives precisely the regular rational schedule consumed as $\mathsf{RegSeqRat}^{\uparrow}$, so the subsequence route is derived from finite interval refinement rather than from an external selector.

No open-cover compactness, arbitrary subsequence choice, quotient stream, or host completeness row is used. The induction uses only the finite tree displayed by K, the inspected windows in S, the monotone-cofinal ledger in R, and the readback route in Q. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier finite interval tree induction`

Theorem 1254.22 (Bolzano–Weierstrass regular-Cauchy subsequence readback)**.** *Let $B = (S, K, R, Q, E, H, C, P,$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. The finite retained cells supplied by Definition 1254.21*

force the monotone-cofinal schedule in R and the $\mathsf{RegSeqRat}^{\uparrow}$ *readback in Q through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegularCauchySubsequence}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

Thus the regular Cauchy subsequence is read from finite interval-tree evidence and retained windows, with no selected subsequence, quotient stream representative, host compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with the bounded source factorization of Definition 1254.19. It ensures that the source row S is already a displayed bounded real-sequence surface before the interval tree is consumed.

Apply Definition 1254.21. At each inspected depth it supplies a retained cell, a nonempty finite window from S, and a monotone-cofinal ledger entry in R.

Use Definition 1254.18. The retained finite windows are the only windows handed to the regular subsequence route, so the $\mathsf{StreamName}^{\uparrow}$ schedule is determined by the displayed ledger rather than by an external selector.

Finally read the selected windows through Q. The dyadic tolerances are carried by the same interval-tree rows in K, the windows are the same finite $\mathsf{StreamName}^{\uparrow}$ rows recorded by R, and the readback is exactly the $\mathsf{RegSeqRat}^{\uparrow}$ surface consumed by the carrier. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier regular cauchy subsequence readback`

Theorem 1254.23 (Bolzano–Weierstrass cluster Real-seal handoff)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. The cluster row E is read only after the regular-Cauchy subsequence readback of Definition 1254.22. Consequently the cluster point exported by B is a displayed* $\mathsf{Real}^{\uparrow}$ *seal over S, K, R, Q, H, C, P, N, not an ambient completeness point, not a selected limit, not quotient equality, and not an open-cover compactness witness.*

Proof. Begin with the root Real-seal obligation of Definition 1254.11. It places every $\mathsf{Real}^{\uparrow}$ cluster endpoint downstream of the root interval-tree obligation and root subsequence extraction obligation.

Apply Definition 1254.22. The theorem displays the retained cells, monotone-cofinal ledger, finite stream windows, dyadic tolerances, and $\mathsf{RegSeqRat}^{\uparrow}$ readback before E is consumed.

Now use Definition 1254.26. The row E seals that already displayed regular Cauchy readback as a $\mathsf{Real}^{\uparrow}$ boundary, and the structural rows H, C, P, N only transport, replay, source, and name the same finite route.

Therefore the cluster handoff exports a displayed Real seal and nothing stronger. The carrier contains no coordinate for ambient completeness, selected limits, quotient equality, open-cover compactness, or arbitrary subsequence choice. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier cluster real seal handoff`

Theorem 1254.24 (Bolzano–Weierstrass retained-cell monotonicity)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. If two inspected unary depths are read from the same finite closed-bounded interval net row K, and the second depth is later in the displayed unary order, then the retained cell at the later depth refines the retained cell at the earlier depth through the same* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *and* $\mathsf{ClosedBoundedIntervalUniformModulus}^{\uparrow}$ *rows. The nonempty sequence-window row supplied by S for the later depth is a displayed continuation of the earlier retained window before the monotone-cofinal reindexing row R is consumed.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier retained cell monotonicity`

Proof. Induct on the finite refinement tree supplied by Definition 1254.21. At the root depth, the retained cell is the root closed bounded interval read from S and K, and its nonempty inspected window is the initial window displayed by the bounded-sequence surface.

For the successor step, the induction hypothesis gives the earlier retained cell, its nonempty window, and its refinement ledger inside K. The finite tree row chooses a child retained cell at the later depth together with a nonempty finite sequence-window row, and the child containment is read through the same closed-bounded interval net and interval-modulus rows.

Transport the earlier route componentwise by H and replay the displayed continuation by C. This records that the later window extends the earlier retained-window display before the ledger R appends the later index. Thus the refinement relation and the sequence-window continuation are already present in the finite interval-net surface when the monotone-cofinal reindexing row is read. □

Theorem 1254.25 (Bolzano–Weierstrass cofinal window extraction)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. The retained-cell nesting of Definition 1254.24 supplies the nested cofinal ledger in R, and the selected finite sequence windows are exactly the windows handed to the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q. Thus the regular readback route is fixed by the retained interval-cell ledger and uses no arbitrary subsequence choice, quotient stream, host compactness, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier cofinal window extraction`

Proof. Project the accepted carrier through Definition 1254.1. The visible coordinates are the bounded sequence surface S, the finite interval-net packet K, the extraction row R, the readback row Q, and the structural rows H, C, P, N.

Apply Definition 1254.21 at each inspected unary depth. It supplies a retained interval cell, a nonempty finite sequence-window row from S, and a displayed refinement relation through K and the interval-modulus route.

Apply Definition 1254.24 to the retained cells at successive inspected depths. Refinement in K preserves the nesting of retained cells, while interval-modulus compatibility preserves the requested finite mesh bound; together these rows keep the ledger monotone and cofinal inside the displayed extraction surface.

Finally read the selected windows through Q. Since Q is attached to the extracted windows of R, and R was built only by appending retained finite-window indices, the $\mathsf{RegSeqRat}^{\uparrow}$ readback receives precisely those windows and no additional subsequence selector or external completeness route. □

Theorem 1254.26 (Bolzano–Weierstrass Real cluster seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *cluster read from an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier factors through*

$$S, K, R, Q, E, H, C, P, N.$$

The cluster row E is reached only after the bounded sequence surface, finite interval-net packet, cofinal-window extraction ledger, regular Cauchy subsequence extraction row, and RegSeqRat readback have been displayed. Consequently a real-facing consumer receives a finite subsequence compactness seal and receives no open-cover compactness principle, host completeness row, quotient equality of streams, least cluster selector, or choice-selected arbitrary subsequence.

Proof. Begin with the factorization in Definition 1254.18. It displays S, K, R, Q before any real cluster row can be consumed.

Then use Definition 1254.25. The row R is a monotone-cofinal ledger built from retained interval cells, and Q reads exactly the selected finite sequence windows supplied by that ledger.

Use the $\mathsf{Real}^{\uparrow}$ chapter chapter 38 only after that route is visible. The seal E is therefore a real-name boundary for the extracted regular Cauchy readback, not a separate host limit or quotient representative.

The transport and continuation rows preserve the same finite route. Since the carrier contains no coordinate for open-cover compactness, host completeness, quotient equality, a least cluster selector, or an arbitrary subsequence choice, the rows $S, K, R, Q, E, H, C, P, N$ exhaust the cluster seal. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier real cluster seal`

Theorem 1254.27 (Bolzano–Weierstrass bounded window induction)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. The bounded-window induction consumed by the packet is the finite interval-tree induction of Definition 1254.21 restricted to the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source row S and the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row K. At each inspected unary depth it exposes a retained closed interval cell, a nonempty bounded sequence window, and the next monotone-cofinal ledger entry before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *cluster seal is consumed.*

Proof. Start with the bounded source factorization. It reads the bounded $\mathsf{Real}^{\uparrow}$ sequence through the finite $\mathsf{BoundedRealSequence}^{\uparrow}$ surface before the interval-net row is consumed.

Apply Definition 1254.21. The induction step uses only the finite children displayed by K and the nonempty inspected windows displayed by S.

Apply Definition 1254.24. The retained cells and their bounded source windows refine along the same closed bounded interval net, so the next ledger entry in R is attached to a displayed bounded window rather than to an external subsequence selector. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier bounded window induction`

Theorem 1254.28 (Bolzano–Weierstrass cofinal cluster seal)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier whose bounded-window induction row is displayed. The extracted cofinal windows pass through the consumer chain*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using only the rows R, Q, E, H, C, P, N. The terminal cluster seal is therefore a $\mathsf{Real}^{\uparrow}$ *boundary for the retained cofinal windows, not a quotient stream representative, selected limit, or ambient completeness point.*

Proof. Apply Definition 1254.25. It identifies the row R as the monotone-cofinal ledger built from retained bounded windows and identifies Q as the $\mathsf{RegSeqRat}^{\uparrow}$ readback of those windows.

Use the stream and dyadic rows already present in the carrier provenance. The same selected finite windows are read as $\mathsf{StreamName}^{\uparrow}$ windows, and their tolerance comparisons are routed through $\mathsf{DyadicRatCore}^{\uparrow}$ before any cluster endpoint is sealed.

Finally apply Definition 1254.26. Since E is reached only after the retained windows, regular readback, stream windows, and dyadic tolerances are displayed, the cluster seal stays inside the finite cofinal route. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier cofinal cluster seal`

Theorem 1254.29 (Bolzano–Weierstrass ledger refusal)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier refuses any consumer ledger that asks for arbitrary subsequence choice, quotient stream equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Such a ledger cannot be filled from* $S, K, R, Q, E, H, C, P, N$ *because those rows expose only bounded source windows, finite interval nets, monotone-cofinal reindexing, regular rational readback, a Real cluster seal, transport, replay, provenance, and local naming.*

Proof. Project the carrier of Definition 1254.1. Its rows are exactly $S, K, R, Q, E, H, C, P, N$, and none of those rows is an arbitrary subsequence selector, quotient stream equality proof, open-cover compactness object, or ambient completeness theorem.

Apply Definition 1254.27 and Definition 1254.28. They show that every cluster-facing route is built from finite bounded windows, retained interval cells, cofinal readback, StreamName windows, DyadicRatCore tolerances, and the terminal Real seal.

The structural rows H, C, P, N only transport, replay, source, and name that displayed route. Therefore a consumer ledger containing any of the excluded principles has no carrier coordinate from which its requested row could be produced. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier ledger refusal`

Theorem 1254.30 (Bolzano–Weierstrass cluster seal extraction)**.** *Let* $B = (S, K, R, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. The cluster seal* E *is extracted only by composing the finite interval-tree induction, retained-cell monotonicity, cofinal-window extraction, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route displayed by* S, K, R, Q, H, C, P, N*. The resulting consumer-facing output is a* $\mathsf{Real}^{\uparrow}$ *cluster seal for the displayed bounded sequence, and it exports no open-cover compactness principle, host completeness row, quotient-stream equality, least-cluster selector, or arbitrary subsequence choice.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier cluster seal extraction`

Proof. Apply Definition 1254.21. It supplies the retained finite interval cells, the nonempty inspected windows, and the displayed finite-branch witness that keeps the route inside the closed-bounded interval net surface.

Apply Definition 1254.24. The retained cells form the nested refinement ledger, and the continuation rows preserve the same bounded-sequence windows through the later inspected depths.

Apply Definition 1254.25. The ledger R is monotone and cofinal, while Q reads exactly the selected finite windows as the regular rational schedule consumed by $\mathsf{RegSeqRat}^{\uparrow}$.

Finally apply Definition 1254.26. The terminal row E is therefore a $\mathsf{Real}^{\uparrow}$ boundary for the extracted regular Cauchy readback, so no open-cover compactness, host completeness, quotient-stream equality, least-cluster selector, or arbitrary subsequence choice is exported to the completion-facing consumer. □

Theorem 1254.31 (Bolzano–Weierstrass tail-modulus window stability)**.** *Let* $B = (S, K, R, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. The retained interval cells selected from* K *and their dyadic mesh moduli transport through the same* H *and* C *rows to the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback windows in* Q*. In particular, changing an accepted packet by componentwise* hsame *transport may rename the displayed bounded source, retained-cell ledger, and modulus rows, but it cannot change which finite source windows are read by* Q *before the* $\mathsf{Real}^{\uparrow}$ *cluster seal* E *is consumed.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier tail modulus window stability`

Proof. Apply Definition 1254.21. It attaches each inspected unary depth to a retained interval cell, a nonempty bounded source window from S, and a displayed dyadic mesh row in K.

Apply Definition 1254.24. Later retained cells refine earlier cells through the same interval-net and interval-modulus rows, so the mesh modulus remains tied to the same finite refinement ledger.

Apply Definition 1254.25. The cofinal ledger R records exactly the selected source windows, and the row Q reads precisely those windows as the $\mathsf{RegSeqRat}^{\uparrow}$ schedule.

The rows H and C transport and replay only this displayed route. Thus any accepted transported packet preserves the retained-cell modulus route and cannot redirect the regular rational readback to a different finite window surface. □

Theorem 1254.32 (Bolzano–Weierstrass Real-seal nonescape)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted $\mathsf{BolzanoWeierstrass}^{\uparrow}$ carrier. The $\mathsf{Real}^{\uparrow}$ cluster seal E factors only through $S, K, R, Q, E, H, C, P, N$. Hence the seal cannot export open-cover compactness, host completeness, quotient stream equality, or arbitrary subsequence choice to any Real-facing or completion-facing consumer.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier cluster seal real nonescape`

Proof. Apply Definition 1254.30. The seal is extracted by composing finite interval-tree induction, retained-cell monotonicity, cofinal window extraction, and $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Apply Definition 1254.26. The row E is reached only after S, K, R, Q have displayed the bounded sequence surface, retained interval cells, cofinal reindexing row, and regular rational readback.

The remaining rows H, C, P, N provide componentwise transport, displayed replay, provenance, and local naming for that same route. None of these rows contains an open-cover compactness object, host completeness theorem, quotient stream equality, or arbitrary subsequence selector. □

Theorem 1254.33 (Bolzano–Weierstrass cofinal-subsequence classifier exactness)**.** *Let $B = (S, K, R, Q, E, H, C, P$ and $B' = (S', K', R', Q', E', H', C', P', N')$ be accepted $\mathsf{BolzanoWeierstrass}^{\uparrow}$ carriers. Their cofinal-subsequence classifiers agree exactly when the bounded source windows, retained interval cells, cofinal reindexing rows, $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, and $\mathsf{Real}^{\uparrow}$ cluster seal rows agree under the displayed H, C, P, N and H', C', P', N' transport. No further classifier coordinate is available outside those finite rows.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier cofinal subsequence classifier exactness`

Proof. For the forward direction, read classifier agreement through Definition 1254.25. The accepted classifier must preserve the retained source windows in S, the retained cells in K, the cofinal ledger in R, and the readback row Q.

Then apply Definition 1254.30. Agreement of the extracted subsequence route determines the terminal Real cluster seal row E because that seal is downstream of the same finite route.

For the reverse direction, assume the listed rows agree under the displayed transports. The finite interval-tree induction and retained-cell monotonicity reconstruct the same retained-cell route, while cofinal window extraction reconstructs the same R, Q readback surface.

Finally use Definition 1254.32. Since the Real seal and structural rows exhaust the classifier surface, the two accepted packets have the same cofinal-subsequence classifier and no hidden host-level equality or choice coordinate remains. □

Theorem 1254.34 (Bolzano–Weierstrass dyadic-mesh subsequence witness)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* BolzanoWeierstrass$^{\uparrow}$ *carrier. At every inspected unary depth, the finite closed-bounded interval net row K supplies a retained dyadic cell, a nonempty finite sequence-window row from S, and the next monotone-cofinal subsequence index recorded by R. The witness is read through the displayed* ClosedBoundedIntervalNet$^{\uparrow}$ *and* ClosedBoundedIntervalUniformModulus$^{\uparrow}$ *rows, and it exports no open-cover compactness, quotient stream equality, arbitrary choice of subsequence, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier dyadic mesh subsequence witness`

Proof. Apply Definition 1254.21. It reads the root interval, the finite dyadic refinements, and the nonempty inspected windows from S and K.

At each inspected depth, use the retained-cell witness supplied by the finite tree. The construction chooses only among displayed finite children and records the chosen child as a retained dyadic cell, so the subsequence index is a row of R rather than a host-level selector.

Transport and replay by H and C preserve the same interval-net and sequence-window rows. Since no carrier coordinate contains an open cover, quotient stream equality, arbitrary subsequence choice, or ambient completeness, the dyadic-mesh witness exports none of those principles. □

Theorem 1254.35 (Bolzano–Weierstrass bounded-window nonempty extraction)**.** *Let $B = (S, K, R, Q, E, H, C, P$ be an accepted* BolzanoWeierstrass$^{\uparrow}$ *carrier. Every retained dyadic cell selected from the finite interval net K carries a nonempty bounded sequence-window row from S, and this row is the only source from which R may append the next monotone-cofinal subsequence index. The extraction therefore passes through the finite interval-tree induction, retained-cell monotonicity, and dyadic-mesh subsequence witness before any selected window is handed to Q.*

Proof. Apply Definition 1254.21. At each inspected unary depth it supplies a retained cell together with a nonempty finite sequence-window row from S and the corresponding monotone-cofinal reindexing row in R.

Apply Definition 1254.24. Later retained cells refine earlier retained cells through the same interval-net rows, and the later nonempty window is a continuation of the earlier bounded window before R appends the next index.

Finally apply Definition 1254.34. The witness records that the next subsequence index is attached to the retained dyadic cell and its displayed nonempty window from S. Since the carrier has no further source coordinate for subsequence indices, R can append the next monotone-cofinal index only from that bounded window row. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier bounded window nonempty extraction`

Theorem 1254.36 (Bolzano–Weierstrass cluster Cauchy window)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* BolzanoWeierstrass$^{\uparrow}$ *carrier. The retained-cell nesting from K yields the regular Cauchy window consumed by the* RegSeqRat$^{\uparrow}$ *row Q: later retained cells refine earlier retained cells, their dyadic diameters follow the inspected unary depth, and the selected windows recorded by R are exactly the finite windows read by Q.*

Proof. Apply Definition 1254.24. It records that retained cells at later inspected depths refine the earlier retained cells through the same closed-bounded interval-net and interval-modulus rows.

Then apply Definition 1254.25. The monotone-cofinal ledger R appends only indices attached to those retained cells, and Q reads precisely the resulting finite sequence windows.

The dyadic diameter control is therefore a displayed regular Cauchy window. It is consumed by $\mathsf{RegSeqRat}^{\uparrow}$ before the Real cluster seal is read, and no quotient stream equality, arbitrary choice, or ambient completeness row is introduced. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier cluster cauchy window`

Theorem 1254.37 (Bolzano–Weierstrass finite interval-subsequence exhaustion)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet whose bounded* $\mathsf{Real}^{\uparrow}$ *sequence row, closed bounded interval-net route, dyadic mesh row, regular-subsequence row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows are displayed exports its cluster witness only through the finite interval-tree induction route plus cofinal window extraction. In particular, the cluster route is exhausted by Definition 1254.21, Definition 1254.24, Definition 1254.25, and Definition 1254.36, and it exports no arbitrary subsequence choice or host* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier finite interval subsequence exhaustion`

Proof. Apply Definition 1254.21. It supplies, at each inspected unary depth, the retained dyadic cell, nonempty source window, and monotone-cofinal reindexing row from the displayed interval tree.

Apply Definition 1254.24. The retained cells refine through the same closed bounded interval-net route, so the later windows are continuations of the earlier finite windows rather than outputs of an external selector.

Apply Definition 1254.25. The cofinal ledger in R is built from those retained windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row Q reads exactly that finite window surface.

Finally apply Definition 1254.36. The Cauchy window consumed by Q is already determined by the retained-cell ledger, while H, C, P, N only transport, replay, source, and name the displayed rows. Hence the cluster witness has no remaining route through arbitrary subsequence choice or host $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1254.38 (Bolzano–Weierstrass subsequence nonescape)**.** *Let* $B = (S, K, R, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier. The subsequence route exported by* R *and* Q *remains inside the retained dyadic mesh supplied by* K *until the* $\mathsf{Real}^{\uparrow}$ *cluster seal* E *is consumed. Consequently the resulting subsequence route exports no open-cover compactness, quotient stream equality, arbitrary choice of subsequence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1254.34. It attaches every selected subsequence index to a retained dyadic cell and a displayed finite sequence-window row.

Apply Definition 1254.36. The retained cells form the Cauchy window consumed by Q, so the subsequence route is fixed by the finite mesh and the monotone-cofinal ledger.

Finally apply Definition 1254.30. The seal E is reached only after S, K, R, Q, H, C, P, N have displayed that route, leaving no export channel for open-cover compactness, quotient stream equality, arbitrary subsequence choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier subsequence nonescape`

Theorem 1254.39 (Bolzano–Weierstrass bounded-subsequence Cauchy extraction)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet whose bounded-source row, finite interval-tree row, retained-cell monotonicity row, cofinal-window extraction row, and dyadic-mesh subsequence row are displayed. Then B exports a* $\mathsf{RegSeqRat}^{\uparrow}$*-facing Cauchy subsequence route through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The route is read only through $S, K, R, Q, E, H, C, P, N$ and supplies no selected subsequence choice, no host compactness principle, no quotient stream equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the bounded-source factorization and the finite interval-tree induction. They expose the bounded $\mathsf{Real}^{\uparrow}$ sequence surface S and the finite dyadic refinement tree K before any subsequence row or cluster seal is consumed.

Apply retained-cell monotonicity. Later retained cells refine earlier retained cells through the same closed-bounded interval-net and interval-modulus rows, so the dyadic mesh produces a nested finite ledger rather than an external compactness argument.

Apply cofinal-window extraction and the dyadic-mesh subsequence witness. The row R records a monotone-cofinal $\mathsf{StreamName}^{\uparrow}$ reindexing ledger built from retained nonempty windows, and Q reads exactly those windows as the $\mathsf{RegSeqRat}^{\uparrow}$ schedule with $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances.

Finally use subsequence nonescape and the Real cluster seal. The terminal row E is reached only after the bounded source, retained cells, cofinal windows, and regular rational readback have been displayed, so the resulting Cauchy subsequence route remains inside $S, K, R, Q, E, H, C, P, N$ and exports none of the excluded host or choice principles. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier bounded subsequence cauchy extraction`

Theorem 1254.40 (Bolzano–Weierstrass interval-depth witness)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet. For each displayed unary depth whose bounded source window is visible in S, the finite interval-tree row K supplies a retained closed-bounded cell, its dyadic mesh ledger, and a nonempty inspected subsequence-window witness before R appends a cofinal index. The witness is read through* BHist*,* Cont*,* hsame*, and* $\mathsf{NameCert}$ *rows and is not obtained from sequential compactness or any choice-like data.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier interval depth witness`

Proof. Induct on the finite interval tree displayed by K. The root case reads the bounded source window from S and the root closed interval from the interval-net carrier.

For the successor step, replay the finite split through C and transport the retained parent row through H. One displayed child carries the nonempty inspected window recorded by the packet, and that child supplies the next retained cell.

Only after this finite witness is displayed may R record the next monotone-cofinal subsequence entry. The argument never appeals to sequential compactness without the shown interval cell, window, transport, replay, provenance, and local name. □

Theorem 1254.41 (Bolzano–Weierstrass tail-cell stability)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet and restrict the extracted route to a later displayed tail of the monotone-cofinal schedule in R. The retained cells supplied by K remain nested under the same* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row, the restricted windows remain the windows read by Q, and componentwise* hsame *transport plus* Cont *replay preserves the same* $\mathsf{NameCert}$ *provenance. Thus subsequence restriction changes only the visible tail ledger, not the cluster package.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier tail cell stability`

Proof. Start from the interval-depth witness. Every selected index in R is attached to a retained cell and a nonempty bounded window, so deleting an initial finite prefix leaves later entries attached to later retained cells.

Use retained-cell monotonicity to compare the tail cells with the original tree. Later cells refine earlier cells through the same interval-net and interval-modulus rows, and H transports this refinement without changing the carrier surface.

Replay the restricted route through C and then read Q. The regular rational readback still consumes the retained tail windows; no new sequential compactness theorem, quotient stream, selected subsequence choice, or ambient completeness row is introduced. □

Theorem 1254.42 (Bolzano–Weierstrass choice-free cluster package)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet whose interval-depth witness and tail-cell stability rows are displayed packages a regular Cauchy subsequence for* $\mathsf{RegSeqRat}^{\uparrow}$ *through the finite route* S, K, R, Q, H, C, P, N*. The terminal cluster row* E *may be read only after that regular package is displayed, and the package contains no arbitrary subsequence selector, no sequential compactness principle without BEDC rows, no quotient real equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness field.*

Proof. First build the finite retained-cell ledger from Definition 1254.40. It supplies each depth witness as a displayed interval cell, dyadic mesh row, and nonempty bounded window.

Next apply Definition 1254.41. Tail restriction preserves the same nested retained cells and keeps the selected windows inside the same transported and replayed $\mathsf{NameCert}$ surface.

Finally read Q as the $\mathsf{RegSeqRat}^{\uparrow}$ package and then read E as the downstream Real seal. Since all data pass through S, K, R, Q, H, C, P, N, the cluster route is choice-free in the BEDC sense: every subsequence and tail fact is carried by finite interval-tree evidence rather than by an external compactness or choice principle. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier choice free cluster package`

Theorem 1254.43 (Bolzano–Weierstrass finite cluster-retention ledger)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet* $B = (S, K, R, Q, E, H, C, P, N)$ *whose bounded-source row, finite interval-tree row, retained-cell row, cofinal-window row, dyadic-mesh row, Cauchy-window row, and cluster-seal row are displayed has a finite cluster-retention ledger over* $S, K, R, Q, E, H, C, P, N$*. The ledger records exactly the retained dyadic cells, their nonempty bounded sequence windows, the monotone-cofinal subsequence indices, the* $\mathsf{RegSeqRat}^{\uparrow}$ *Cauchy readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal. It exports no arbitrary subsequence choice, no selected least cluster, no open-cover compactness, no quotient stream equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with retained-cell monotonicity. It binds later retained cells to earlier retained cells through the same finite interval-tree rows in K, so the retention data is a finite ledger over the displayed interval net rather than a host compactness choice.

Apply cofinal-window extraction and the dyadic-mesh subsequence witness. The row R appends only indices attached to retained nonempty windows from S, while the dyadic mesh witness records the finite cell supporting each appended index.

Next apply the cluster Cauchy window theorem. The retained cells and their dyadic diameters determine the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q, and the readback is therefore downstream of the same finite retention ledger.

Finally apply cluster seal extraction. The terminal row E is reached only through the displayed route S, K, R, Q, H, C, P, N, so no arbitrary subsequence choice, selected least cluster, open-cover

compactness, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness can be exported from the packet. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier finite cluster retention ledger`

Theorem 1254.44 (Bolzano–Weierstrass source-net exhaustion)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet. The bounded source row S and interval-net row K exhaust the root source surface for the cluster route: every inspected window, retained dyadic cell, mesh comparison, and bounded interval enclosure consumed by R, Q, E is read first through S, K, H, C, P, N as finite* BHist, hsame, Cont, Pkg, *and* NameCert *data. No cluster-facing consumer can reach R, Q, or E from a source row outside S or an interval-net row outside K.*

Proof. Start with the root interval-tree obligation of Definition 1254.6. It places the bounded source windows and dyadic retained cells inside the displayed finite route before any subsequence or Real seal is read.

Next apply bounded-source factorization and the interval-net obligation. The source row S is the only bounded sequence surface admitted by the carrier, and K is the only closed-bounded interval-net row that can supply retained windows to later rows.

Finally read the finite cluster-retention ledger. Since the ledger records every retained cell, nonempty source window, mesh comparison, and downstream handoff over $S, K, R, Q, E, H, C, P, N$, the root source and interval-net surface is exhausted by S and K together with the structural rows. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier source net exhaustion`

Theorem 1254.45 (Bolzano–Weierstrass RegSeqRat cluster package)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet whose source-net exhaustion row is displayed. The extraction row R, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E form a single cluster package over S, K, H, C, P, N: the cofinal subsequence schedule is read from retained finite windows, the regular rational row reads exactly those windows through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the Real seal is reachable only after that regular package has been displayed.*

Proof. Use Definition 1254.44 to expose the source windows and interval-net cells available to the extraction route. This fixes the only finite data from which R may append cofinal subsequence indices.

Apply the regular subsequence route and the regular subsequence window readback theorem. They identify R as the monotone-cofinal schedule over retained windows and Q as the $\mathsf{RegSeqRat}^{\uparrow}$ readback of those same windows through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$.

Now use cluster seal extraction. The seal row E is downstream of Q, and the structural rows H, C, P, N only transport, replay, record provenance, and name the same route. Hence R, Q, E form one displayed RegSeqRat-to-Real cluster package rather than three detachable obligations. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier regseqrat cluster package`

Theorem 1254.46 (Bolzano–Weierstrass root obligation package)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet $B = (S, K, R, Q, E, H, C, P, N)$ whose root interval-tree, root subsequence, Real-seal, bounded-source, and regular-subsequence routes are displayed carries the full root obligation package*

$$S, K, R, Q, E, H, C, P, N.$$

This package binds the bounded source row, interval-net row, extraction row, RegSeqRat readback row, Real seal row, componentwise hsame *transport, displayed* Cont *replay, provenance, and local* NameCert *as the exact obligation surface for downstream compactness and Real subsequence consumers. It exports no selected least cluster, arbitrary subsequence choice, open-cover compactness, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First combine source-net exhaustion with the root interval-tree obligation. The bounded source and interval-net rows S, K expose all finite windows, retained cells, and dyadic mesh data needed by the cluster route.

Next combine the root subsequence extraction obligation with the RegSeqRat cluster package. The extraction row R and readback row Q are forced to consume the retained finite windows already displayed by S and K, so no detached subsequence selector or quotient stream can enter.

Finally apply the Real cluster seal and finite cluster-retention ledger. The terminal row E is reached only after the displayed regular package, while H, C, P, N preserve and name the same packet. Therefore the root obligation package is exactly $S, K, R, Q, E, H, C, P, N$ with the stated refusals. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier root obligation package`

Theorem 1254.47 (Bolzano–Weierstrass bounded-sequence admission)**.** *Let* $B = (S, K, R, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet carrying the root obligation package of Definition 1254.46. The bounded source row* S *is admitted only as the source surface for the same interval-net row* K*, regular-subsequence row* R*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and* $\mathsf{Real}^{\uparrow}$ *cluster seal* E*. In particular, the bounded source is read through* S, K, H, C, P, N *before the rows* R, Q, E *are exposed, and it cannot be replaced by a detached host sequence, an arbitrary subsequence selector, or an ambient completeness assumption.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier bounded sequence admission`

Proof. Apply Definition 1254.2. It identifies S as the bounded sequence admission row and places it inside the carrier together with K, R, Q, E, H, C, P, N.

Apply Definition 1254.3 and Definition 1254.16. These force the interval-net row K and the regular-subsequence row R to consume the same bounded source windows rather than a second sequence source.

Finally use Definition 1254.46. The structural rows H, C, P, N bind the bounded source to the later readback and Real seal, so no detached host sequence or completeness principle is exported. □

Theorem 1254.48 (Bolzano–Weierstrass regular cluster seal)**.** *Let* $B = (S, K, R, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet whose bounded-sequence admission row and root obligation package are displayed. The cluster seal* E *is regular only through the route*

$$S, K, R, Q, E, H, C, P, N.$$

The row R *reads retained finite windows from* S *through* K*, the row* Q *reads the same windows as* $\mathsf{RegSeqRat}^{\uparrow}$ *data, and the row* E *seals only that regular readback as* $\mathsf{Real}^{\uparrow}$ *data. No cluster seal is available from a second bounded source, a detached interval net, quotient stream equality, selected subsequence choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier regular cluster seal`

Proof. Start with bounded-sequence admission. It fixes the source row S as the only bounded real-sequence surface available to the cluster route.

Use Definition 1254.5. The handoff places the retained windows behind K and R before Q reads them as regular rational data.

Use the interval-net obligation and the root obligation package. Together they bind K, R, Q to the same support rows H, C, P, N.

Finally read the Real seal E. Since E is downstream of Q in the displayed route, the seal is regular by the carried readback rows and not by a host completeness or selection principle. □

Theorem 1254.49 (Bolzano–Weierstrass closed-interval cluster export)**.** *An accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet exports a closed-interval cluster candidate only through the bounded-sequence admission row S, the closed interval net row K, the regular subsequence extraction row R, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, with H, C, P, N transporting, replaying, sourcing, and naming the same route. The export refuses arbitrary subsequence choice, open-cover compactness, quotient stream equality, selected least cluster points, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with bounded-source factorization and bounded-sequence admission. These rows fix S as the only source of sequence data and force every cluster-facing read to pass through the displayed bounded source.

Next apply finite interval-tree induction and retained-cell monotonicity. The closed interval net row K supplies the retained cells and their finite refinement route, so the packet cannot switch to an open-cover compactness proof or a detached interval net.

Use cofinal-window extraction and the regular cluster seal. The extraction row R reads retained windows through K, the readback row Q records the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ data, and the seal row E exports only that regular readback as $\mathsf{Real}^{\uparrow}$ cluster evidence.

Finally apply cluster-seal nonescape. The structural rows H, C, P, N preserve and name the same packet, and no carrier row remains from which arbitrary subsequence choice, quotient equality, least-cluster selection, or ambient completeness could be projected. □

Theorem 1254.50 (Bolzano–Weierstrass cluster-seal nonescape)**.** *For every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet $B = (S, K, R, Q, E, H, C, P, N)$ carrying the bounded-sequence admission and regular cluster-seal rows, any cluster-facing consumer remains inside the displayed surface*

$$S, K, R, Q, E, H, C, P, N.$$

The consumer may read a bounded source window, a retained interval-net cell, a regular-subsequence ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal, but it cannot escape to an unlisted source row, an unlisted interval net, a selected least cluster point, quotient real equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1254.47. It fixes S and K as the source and interval-net surface for the cluster route.

Apply Definition 1254.48. It fixes R, Q, E as the regular-subsequence, regular readback, and Real-seal surface downstream of those rows.

The support rows H, C, P, N are the only transport, replay, provenance, and local naming coordinates in the carrier of Definition 1254.1. Therefore every cluster-facing read remains inside $S, K, R, Q, E, H, C, P, N$, and the refused host-level objects have no row from which they can be projected. □

Theorem 1254.51 (Bolzano–Weierstrass retained-window refinement)**.** *Let $B = (S, K, R, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet carrying the root obligation package of Definition 1254.46. Every retained dyadic interval cell used by the cluster route is read through*

$$S, K, R, Q, H, C, P, N$$

before the terminal $\mathsf{Real}^{\uparrow}$ *cluster seal E is exposed. The refinement preserves the same* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *route: no retained window may be reclassified through a new stream name, a detached dyadic grid, a second rational-readback package, or a host compactness selector.*

Proof. Start with the root interval-tree obligation. It displays the retained dyadic cells through S and K, so each retained window is already attached to the bounded source and interval-net rows before the extraction route is read.

Next apply the root subsequence extraction obligation. The row R consumes only those retained cells, and the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ data used by the extraction remain the ones displayed by the same source and interval-net package.

Now use the RegSeqRat cluster package. The readback row Q is the $\mathsf{RegSeqRat}^{\uparrow}$ route for the retained windows already carried by S, K, R, so it cannot introduce a second rational-readback surface or a detached dyadic grid.

Finally apply the root Real-seal obligation and the root obligation package. The cluster seal E is downstream of S, K, R, Q, H, C, P, N, while H, C, P, N transport, replay, record provenance, and name the same route. Hence the retained-window induction is preserved all the way to the $\mathsf{Real}^{\uparrow}$ seal without importing a new stream, grid, readback package, or host selector. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier window retention refinement`

Theorem 1254.52 (Bolzano–Weierstrass public subsequence selector)**.** *For every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier $B = (S, K, R, Q, E, H, C, P, N)$, the public subsequence selector exported by the chapter is the finite route*

$$S, K, R, Q, H, C, P, N.$$

The bounded $\mathsf{Real}^{\uparrow}$ *sequence source is admitted through S, retained interval cells are admitted through K, monotone-cofinal subsequence windows are admitted through R, and the regular-rational readback is admitted through Q. The selector surface is therefore a displayed NameCert route, not an arbitrary subsequence choice functional, a host compactness theorem, quotient stream equality, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassPublicSubsequenceSelector`

Proof. Apply Definition 1254.47. It fixes the bounded sequence source S as the same source consumed by the interval-net row K and the later regular-subsequence rows.

Apply Definition 1254.21 and Definition 1254.24. They supply the retained finite interval cells and keep later windows nested inside the same displayed interval-net route.

Apply Definition 1254.25 and Definition 1254.18. These theorems identify R and Q as the monotone-cofinal window and $\mathsf{RegSeqRat}^{\uparrow}$ readback surface. The structural rows H, C, P, N then transport, replay, source, and name only that finite route. □

Theorem 1254.53 (Bolzano–Weierstrass subsequence-window publicity)**.** *The public subsequence-window export of an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier exposes only bounded sequence rows, closed bounded interval finite-net rows, regular Cauchy subsequence rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,*

$\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{Real}^{\uparrow}$ *seals,* hsame *transport,* Cont *replay,* Pkg *provenance, and* NameCert *data. Every such export factors through the selector route*

$$S, K, R, Q, H, C, P, N$$

of Definition 1254.52 together with the chapter dependency route through retained intervals, regular subsequences, and terminal real seals.

The public window theorem excludes choice-selected subsequences, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassSubsequenceWindowPublicity`

Proof. First read the public selector theorem. It exposes the bounded source S, finite retained interval row K, regular-subsequence row R, regular-rational readback Q, and structural rows H, C, P, N as the only selector route.

Next compose this route with the chapter dependency route. The retained interval and finite-net rows are supplied before R, the stream windows and dyadic tolerance ledgers are read during retained-window inspection, and the $\mathsf{Real}^{\uparrow}$ seal is available only after the regular Cauchy subsequence and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows have been displayed.

The carrier has no row for an arbitrary choice-selected subsequence, no open-cover compactness object, and no ambient completeness principle. Therefore the public subsequence-window export is exactly the displayed bounded-sequence, finite-net, regular-Cauchy, window, readback, tolerance, seal, transport, replay, provenance, and naming surface. □

Theorem 1254.54 (Bolzano–Weierstrass public cluster witness)**.** *Every public cluster witness exported by an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet factors through*

$$S, K, R, Q, E, H, C, P, N.$$

It reads the bounded-sequence admission, retained-window ledger, regular-subsequence extraction, $\mathsf{RegSeqRat}^{\uparrow}$ *cluster readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal as one displayed package. It exports no least cluster point, no quotient equality of real names, no open-cover compactness object, and no host completeness row.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassPublicClusterWitness`

Proof. Start from Definition 1254.52. The public subsequence selector has already displayed S, K, R, Q, H, C, P, N and therefore contains the bounded source, retained windows, cofinal extraction, and regular rational readback.

Apply Definition 1254.48. It places the terminal $\mathsf{Real}^{\uparrow}$ seal E downstream of R and Q, so the cluster witness cannot be read before the regular-subsequence and readback rows are present.

Finally use Definition 1254.30. The extracted cluster seal is the Real boundary for that same finite route. The refused host-level objects are absent from the carrier and cannot be projected by the public witness. □

Theorem 1254.55 (Bolzano–Weierstrass public nonescape package)**.** *The public* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *export surface is exhausted by the selector and cluster-witness rows of Definition 1254.52 and Definition 1254.54. In particular, any consumer that reads a bounded sequence, retained finite interval tree, regular subsequence,* $\mathsf{RegSeqRat}^{\uparrow}$ *cluster row, or* $\mathsf{Real}^{\uparrow}$ *seal remains inside*

$$S, K, R, Q, E, H, C, P, N.$$

The package refuses arbitrary subsequence choice, unlisted interval nets, detached bounded sources, quotient stream equality, selected least cluster points, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassPublicNonescapePackage`

Proof. First read the selector surface. By Definition 1254.52, the only public subsequence route is S, K, R, Q, H, C, P, N.

Next read the cluster witness. By Definition 1254.54, the terminal Real seal E is available only after the bounded source, retained-window, regular-subsequence, and regular-rational rows have been displayed.

It remains to check nonescape. Apply Definition 1254.50 and Definition 1254.51. These theorems keep every cluster-facing and retained-window read inside the same finite carrier route, so no public consumer can import a detached selector, host compactness principle, quotient equality, or ambient completeness row. □

Theorem 1254.56 (Bolzano–Weierstrass public selector export)**.** *Every public selector or cluster export of an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet factors through the sibling bounded-sequence, interval-net, regular-rational, stream, and real-name surfaces before it exposes the terminal Real cluster seal. In particular, the bounded sequence is read through chapter 1415, the nested finite interval route through chapter 1250, and the readback and seal through the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *chapters. The public export route is therefore*

$$\mathsf{BoundedRealSequence}^{\uparrow}, \mathsf{ClosedBoundedIntervalNet}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto S, K, R, Q, E, H, C, P, N,$$

and no selector consumer receives a detached subsequence choice, an unlisted interval net, quotient stream equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassPublicSelectorExport`

Proof. Start with the public selector and cluster package. By Definition 1254.52, Definition 1254.54, and Definition 1254.55, the exported rows are exhausted by $S, K, R, Q, E, H, C, P, N$.

The sibling route identifies the source of those rows. The bounded source is the $\mathsf{BoundedRealSequence}^{\uparrow}$ surface, the retained cells are the $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ surface, and the regular-rational and stream windows are the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ surfaces.

Finally the Real cluster seal is read only after those rows have been displayed. Since the carrier has no coordinate for a detached selector, unlisted interval net, quotient stream equality, or ambient completeness, every public export factors through the displayed sibling route. □

Theorem 1254.57 (Bolzano–Weierstrass public cluster export)**.** *Every accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet exports a public cluster package only through the displayed chain*

$$S \longmapsto K \longmapsto R \longmapsto Q \longmapsto E.$$

The source row is the bounded sequence surface S; the interval-tree row K supplies finite induction, retained-cell monotonicity, and cofinal window extraction; the extraction row R records the bounded-subsequence Cauchy route; the readback row Q packages the $\mathsf{RegSeqRat}^{\uparrow}$ *cluster package; and the terminal row E supplies the* $\mathsf{Real}^{\uparrow}$ *seal. No public cluster export may bypass this chain by selected subsequences, countable choice, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the bounded sequence source. Definition 1254.19 and Definition 1254.44 make S the only source surface from which inspected windows enter the cluster route.

Next read the finite interval-tree surface. Definition 1254.21 supplies the finite refinement tree, Definition 1254.24 keeps later cells nested inside the same route, and Definition 1254.25 turns retained windows into the cofinal schedule recorded by R.

Then apply bounded-subsequence Cauchy extraction and the RegSeqRat cluster package. Definition 1254.39 forces the subsequence route through retained finite windows, while Definition 1254.45 packages R, Q, E as one regular-rational-to-Real cluster surface.

Finally use Definition 1254.46. The structural rows H, C, P, N only transport, replay, source, and name the same packet, so the public export has no channel for selected subsequences, countable choice, quotient real equality, or ambient Real completeness outside the displayed chain. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier public cluster export`

Falsifiable prediction: Every $\mathsf{BolzanoWeierstrass}^{\uparrow}$ cluster read factors through the displayed interval net and regular Cauchy subsequence rows before reaching the $\mathsf{Real}^{\uparrow}$ seal.

Independence witness: closedboundedintervalnet, closedboundedintervaluniformmodulus, regularcauchysubsequence, regseqrat, real: $\mathsf{BolzanoWeierstrass}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded sequence surface, finite interval nets, monotone-cofinal subsequence extraction, regular rational readback, RealUp cluster sealing, transport, continuation, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrass}^{\uparrow}}$.

Constructive story: A $\mathsf{BolzanoWeierstrass}^{\uparrow}$ packet is generated from a bounded RealUp sequence surface, finite closed bounded interval nets, interval-modulus compatibility, a monotone-cofinal regular Cauchy subsequence extraction row, RegSeqRat readback, a RealUp cluster seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrass}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1254.1, Definition 1254.2, Definition 1254.18, Definition 1254.19, Definition 1254.21, Definition 1254.24, Definition 1254.25, Definition 1254.26, and Definition 1254.30 bind the bounded-sequence subsequence compactness route through the carrier, NameCert obligations, bounded sequence extraction, finite interval nets, regular-subsequence route, RegSeqRat readback, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrass}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, host completeness, quotient equality of streams, least cluster selection, or arbitrary subsequence choice.

Upgrade path: The paper-side mature treatment is closed; the remaining checks are Lean verification and bridge checking for BEDC.Derived.BolzanoWeierstrassUp.

Theorem 1254.58 (Bolzano–Weierstrass cluster-source factorization)**.** *Every public cluster read from an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet factors through the finite source route*

$$\mathsf{BoundedRealSequence}^{\uparrow}, \mathsf{RealSequenceClusterPoint}^{\uparrow}, \mathsf{RegularCauchySubsequence}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

before any Bolzano–Weierstrass seal is consumed. Equivalently, the public read first exposes the bounded sequence source, then the cluster-point carrier, then the regular Cauchy subsequence row, then the regular rational readback, and only then the terminal Real seal attached to the Bolzano–Weierstrass packet.

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier cluster source factorization`

Proof. Begin with the public selector and cluster export surface of the Bolzano–Weierstrass chapter. The carrier and public export theorems expose the bounded source row S, the regular-subsequence

row R, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q, and the terminal $\mathsf{Real}^{\uparrow}$ cluster seal E before any public consumer may read the packet.

Now apply Definition 1580.4. It identifies the cluster-point consumer route through the bounded source row of chapter 1415, the cofinal subsequence row of chapter 381, selected windows, regular readback, dyadic tolerance, and the Real cluster seal.

Composing these routes gives the stated factorization. The Bolzano–Weierstrass seal is downstream of the bounded source, cluster-point carrier, regular Cauchy subsequence, RegSeqRat readback, and Real seal, so no public cluster read can bypass them through selected subsequences, quotient stream equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1254.59 (Bolzano–Weierstrass retained-window source)**.** *A retained cluster source for an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet can be consumed only after the bounded real sequence row, closed-bounded interval net row, regular Cauchy subsequence row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, and terminal* $\mathsf{Real}^{\uparrow}$ *seal have all been displayed. Consequently every later Real or Completion consumer receives a finite retained-window source rather than a selected subsequence, open-cover compactness proof, quotient stream equality, or ambient Real-completeness principle.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassUp.BolzanoWeierstrassCarrier retained window source`

Proof. Project the public source factorization of Definition 1254.58. The bounded source row is read through chapter 1415, and its closed-bounded interval net row is the displayed bound surface supplied by chapter 1250.

Read the retained subsequence surface next. The regular Cauchy subsequence row of chapter 381 can be inspected only through finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows.

Attach the terminal seal after those finite rows. The $\mathsf{Real}^{\uparrow}$ boundary is therefore downstream of boundedness, retained windows, regular readback, and dyadic tolerance, not an independent completeness oracle.

The retained cluster source is exactly this projection of displayed rows. Since no carrier coordinate supplies a selected subsequence, an open-cover compactness proof, quotient stream equality, or ambient Real-completeness theorem, no public consumer can read any of those objects from the packet. □

Theorem 1254.60 (Cluster-source factorization formal target)**.** *The formal target for Definition 1254.58 is the BEDC kernel statement that an accepted* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *cluster export factors through four displayed rows before the terminal seal is consumed: a bounded real sequence carrier over* BHist *and* $\mathsf{Real}^{\uparrow}$*; a closed-bounded interval net whose endpoints and refinements are recorded by* Cont *replay; a regular Cauchy subsequence row governed by* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback; and a cluster-point witness in the* $\mathsf{RealSequenceClusterPoint}^{\uparrow}$ *surface. The statement names only this route and does not claim full sequential compactness for arbitrary real sequences.*

Lean4 ✓ `BEDC.Derived.BolzanoweierstrassUp.BolzanoWeierstrassClusterSourceFormalTarget`

Proof. The bounded real sequence carrier supplies the source row and the interval net records finite closed-bounded windows. Both are ordinary BEDC rows, so the formalization can expose them by carrier projection and displayed Cont replay.

The regular Cauchy subsequence row then gives the constructive subsequence route, while $\mathsf{RegSeqRat}^{\uparrow}$ supplies rational readback of the same row. The cluster-point witness is read only after these rows have been exposed.

Thus the formal target is a factorization theorem about the accepted packet's named rows. It does not need a host compactness principle, an open-cover argument, or a choice-selected subsequence outside the displayed regular Cauchy data. □

Chapter 1255

CofinalTailEquivalence NameCert Construction

The $\mathsf{CofinalTailEquivalence}^{\uparrow}$ packet realizes the paired cofinal-tail route comparison used by the regular-Cauchy completion surface of section 9238.1. It sits after the one-sided cofinal agreement of chapter 920, the shared threshold discipline of chapter 1231, and the Real-facing seal route of chapter 699. The packet records two displayed cofinal tail routes with one shared StreamName, RegSeqRat, DyadicRatCore, RealTailAgreementSeal, transport, continuation, provenance, and naming surface; it is not a quotient equality of regular sequences, a selected host limit, a hidden tail oracle, countable choice, or ambient Real completeness.

Falsifiable prediction: A packet missing either displayed cofinal route cannot discharge the Real-seal consumer theorem.

Independence witness: cofinaltailagreement, tailcofinalitybudget, dyadiccofinaltailselector, realtailagreementseal, diagonallimitcompatibility: the carrier has two-route equivalence plus Real-seal consumption, while these siblings supply single agreement, budget, selector, seal, or diagonal compatibility rows without that combined bijective surface.

Definition 1255.1 (Cofinal tail-equivalence carrier)**.** *A* $\mathsf{CofinalTailEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R_0, R_1, W, Q, D, A, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two cofinal tail-route rows being compared.*
2. W *is the shared* $\mathsf{StreamName}^{\uparrow}$ *readback row through which both routes expose the same finite observation window.*
3. Q *is the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to that window on both tail routes.*
4. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording the tolerance and endpoint observations consumed by the comparison.*
5. A *is the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *consumer row reached only after both cofinal routes, the shared window, the regular readback, and the dyadic ledger are displayed.*
6. H *records componentwise* hsame *transport for* R_0, R_1, W, Q, D, A *and the local certificate row.*
7. C *records displayed* Cont *replay from each cofinal route through the shared StreamName, RegSeqRat, DyadicRatCore, and RealTailAgreementSeal rows.*

8. *P is the* Pkg *provenance over* $\mathsf{CofinalTailEquivalence}^{\uparrow}$, $\mathsf{CofinalTailAgreement}^{\uparrow}$, $\mathsf{TailCofinalityBudget}^{\uparrow}$, $\mathsf{DyadicCofinalTailSelector}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalTailEquivalence}^{\uparrow}}$ *row.*

The carrier exports only the two displayed cofinal routes, their shared finite readback rows, the Real-tail agreement seal consumer row, and the structural transport, replay, provenance, and naming rows.

Lean4 ✓ `BEDC.Derived.CofinalTailEquivalenceUp.CofinalTailEquivalenceTasteGate single carrier alignment`

Theorem 1255.2 (Cofinal tail-equivalence NameCert obligations)**.** *For the carrier of Definition 1255.1, the local* $\mathsf{NameCert}_{\mathsf{CofinalTailEquivalence}^{\uparrow}}$ *surface consists exactly of carrier admission for $E = (R_0, R_1, W, Q, D, A, H, C, P, N)$, two cofinal route exposures through R_0 and R_1, shared* $\mathsf{StreamName}^{\uparrow}$ *window exposure through W, shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exposure through Q, shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger exposure through D,* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *consumer exposure through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.CofinalTailEquivalenceUp.CofinalTailEquivalence namecert obligations`

Proof. Project the carrier. Its coordinates display exactly the two cofinal route rows, the shared StreamName window, the regular-rational readback, the dyadic ledger, the Real-tail agreement seal consumer row, and the structural support rows.

Read the sibling sources in order. The $\mathsf{CofinalTailAgreement}^{\uparrow}$ row supplies the one-sided agreement surface, the $\mathsf{TailCofinalityBudget}^{\uparrow}$ row supplies the shared threshold discipline, and the $\mathsf{DyadicCofinalTailSelector}^{\uparrow}$ row supplies the finite selector route that may feed either side.

Finally read the seal consumer. The $\mathsf{RealTailAgreementSeal}^{\uparrow}$ row A is downstream of both routes and the shared readback rows, while H, C, P, N only transport, replay, source, and name those displayed rows. These clauses exhaust the local NameCert obligations. □

Theorem 1255.3 (Cofinal tail-equivalence tail-agreement transport)**.** *Let $E = (R_0, R_1, W, Q, D, A, H, C, P, N)$ be an accepted* $\mathsf{CofinalTailEquivalence}^{\uparrow}$ *carrier. If the first cofinal route R_0 is transported to the second route R_1 through the displayed H and C rows, then the tail-agreement read remains on the same shared finite surface*

$$W, Q, D, A, H, C, P, N.$$

The transport preserves the StreamName readback, RegSeqRat readback, DyadicRatCore ledger, and RealTailAgreementSeal consumer row, and it exports no quotient stream equality, host real equality, selected limit, hidden tail selector, countable-choice row, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CofinalTailEquivalenceUp.CofinalTailEquivalenceTailAgreementTransport`

Proof. Begin with the two route coordinates of Definition 1255.1. The only relation between them inside the packet is the componentwise hsame table H and the displayed continuation replay C.

Apply the NameCert obligations. They force both R_0 and R_1 to read the same W, Q, D, A rows before any tail-agreement consumer can inspect the packet.

Thus transporting the tail-agreement read from R_0 to R_1 changes only the displayed route coordinate. The shared readback and seal rows remain W, Q, D, A, H, C, P, N, and the excluded external equalities and selectors have no carrier coordinate from which they could be projected. □

Theorem 1255.4 (Cofinal tail-equivalence Real-seal consumer)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CofinalTailEquivalence}^{\uparrow}$ *packet reaches the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *row* A *only after both cofinal routes* R_0, R_1*, the shared* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D *have been displayed. The consumer route is exhausted by*

$$R_0, R_1, W, Q, D, A, H, C, P, N.$$

No consumer of this packet receives a one-route agreement in place of two-route equivalence, a host equality of completed reals, a quotient-stream comparison, a selected limit, a hidden tail oracle, or an ambient completeness witness.

Proof. Inspect the carrier inventory. The Real-facing coordinate is the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ row A, and it appears only after the two route rows and the three shared readback rows.

Use Definition 1255.2. It makes R_0, R_1, W, Q, D mandatory before A can be consumed, while H, C, P, N authenticate the same finite route.

Use Definition 1255.3. Any transport between the two routes preserves the shared tail-agreement surface and therefore cannot collapse the carrier to a one-route packet or import a host-level equality. The listed finite route is the whole Real-seal consumer surface. □

Theorem 1255.5 (Cofinal tail-equivalence common-tail induction)**.** *Let* $E = (R_0, R_1, W, Q, D, A, H, C, P, N)$ *be an accepted* $\mathsf{CofinalTailEquivalence}^{\uparrow}$ *carrier. Finite induction over the two displayed cofinal route rows* R_0 *and* R_1 *preserves the shared readback surface*

$$W, Q, D, A$$

at every common threshold reached by both routes. In particular, the common threshold read still exposes the same $\mathsf{StreamName}^{\uparrow}$ *row* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, and* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *row* A*, and it does not introduce quotient stream equality, a selected host limit, hidden tail selection, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.CofinalTailEquivalenceUp.CofinalTailEquivalenceCommonTailInduction`

Proof. Project the carrier of Definition 1255.1. The route coordinates R_0 and R_1 are the only cofinal rows, and both are paired with the same displayed W, Q, D, A surface.

For the base threshold, apply the NameCert obligations of Definition 1255.2. They force both routes to display the StreamName window, RegSeqRat readback, DyadicRatCore ledger, and RealTailAgreementSeal consumer before any common-tail read is available.

For the successor threshold, use the transport theorem Definition 1255.3. Transport from one displayed route to the other changes only the route coordinate while preserving the shared readback and seal rows.

The Real-seal consumer theorem Definition 1255.4 then closes the induction step for completion-facing reads. Since the carrier has no coordinate for quotient equality, selected limits, hidden tail selection, countable choice, or ambient completeness, the induced common-tail read cannot export any of those surfaces. □

Theorem 1255.6 (Cofinal tail-equivalence RegSeqRat stability)**.** *Let* $E = (R_0, R_1, W, Q, D, A, H, C, P, N)$ *be an accepted* $\mathsf{CofinalTailEquivalence}^{\uparrow}$ *carrier. Componentwise* hsame *transport of both cofinal routes through* H *preserves the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *and keeps it tied to the same* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, and* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *consumer row* A*. This stability cannot create quotient stream equality, selected host limits, countable choice, ambient Real completeness, or host equality of completed reals.*

Proof. Start from the componentwise transport row H in the carrier. It transports only the displayed coordinates R_0, R_1, W, Q, D, A and the local certificate row; it is not a quotient constructor for regular sequences.

Apply Definition 1255.3. The theorem says that moving between the two cofinal routes preserves the shared readback surface W, Q, D, A, H, C, P, N.

Now apply the common-tail induction theorem Definition 1255.5. At each common threshold the same RegSeqRat row remains paired with the same StreamName, dyadic ledger, and Real-seal rows.

Finally apply the Real-seal consumer theorem Definition 1255.4. Completion-facing consumers receive only the displayed finite route, so transport stability for Q does not manufacture quotient stream equality, selected host limits, countable choice, ambient Real completeness, or host real equality. □

Theorem 1255.7 (Cofinal tail-equivalence scope readback)**.** *The scoped proof surface of* $\mathsf{CofinalTailEquivalence}^{\uparrow}$ *depends only on the displayed* BHist *carrier, componentwise* hsame *rows, displayed* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, *and the cofinal-tail sibling rows named in Definition 1255.1. It exports no quotient stream equality, selected host limit, hidden tail oracle, countable choice, host real equality, or ambient Real completeness.*

Proof. Start with the carrier of Definition 1255.1. Its row inventory is exactly $R_0, R_1, W, Q, D, A, H, C, P, N$, with the cofinal-tail sibling rows appearing only through the two route coordinates and the shared readback surface.

Apply Definition 1255.2 and Definition 1255.3. These theorems bind the local certificate clauses and transport any route comparison through the displayed hsame and Cont rows without adding an external selector or quotient.

Finally use Definition 1255.4. The Real-facing read reaches only the displayed $\mathsf{RealTailAgreementSeal}^{\uparrow}$ consumer after $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ have been displayed, so the listed rows are the whole scoped readback surface. □

Theorem 1255.8 (Cofinal tail-equivalence scoped closure)**.** *The scope readback theorem, together with the Real-seal consumer, common-tail induction, and RegSeqRat stability theorems, binds every exported* $\mathsf{CofinalTailEquivalence}^{\uparrow}$ *consumer to the displayed* BHist *carrier,* hsame *transport,* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, *and the named cofinal-tail sibling rows of Definition 1255.1. No exported consumer can leave that scope by reading quotient stream equality, selected host limits, hidden tail selection, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 1255.7. It identifies the only rows available to the scoped proof surface: the displayed carrier, transport, replay, provenance, local naming, StreamName readback, RegSeqRat readback, DyadicRatCore ledger, RealTailAgreementSeal consumer, and cofinal-tail siblings.

Apply Definition 1255.4. Completion-facing reads reach the Real-tail agreement row only after the two cofinal routes and the shared finite readback rows have been displayed.

Apply Definition 1255.5 and Definition 1255.6. These theorems keep common-threshold and transport reads on the same StreamName, RegSeqRat, DyadicRatCore, and RealTailAgreementSeal surface.

Thus the scope is closed around exactly the named finite rows. The excluded quotient, selection, choice, host equality, and ambient-completeness objects are absent from the carrier and cannot be projected by any exported consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalTailEquivalence}\uparrow}$.

Constructive story: A $\mathsf{CofinalTailEquivalence}^{\uparrow}$ packet is generated from two cofinal tail routes, a shared StreamName window, a shared RegSeqRat readback, a shared DyadicRatCore ledger, a RealTailAgreementSeal consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalTailEquivalence}\uparrow}, \mathsf{scopedClosed})$

Scope closed: Definition 1255.1, Definition 1255.2, Definition 1255.3, Definition 1255.4, Definition 1255.5, Definition 1255.6, Definition 1255.7, and Definition 1255.8 bind the carrier, NameCert obligations, tail-agreement transport, Real-seal consumer route, common-tail induction, RegSeqRat stability, scoped readback surface, and scoped closure theorem.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalTailEquivalence}\uparrow}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CofinalTailEquivalenceUp.CofinalTailEquivalenceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient stream equality, host real equality, selected host limits, hidden tail selection, countable choice, ambient Real completeness, or bridge checking.

Upgrade path: Public export and bridge work require a public CofinalTailEquivalenceUp object surface and a checked standard bridge for the same finite packet.

Chapter 1256

A Concrete Naming Certificate for $\mathsf{PhilosophySynthesisAudit}^{\uparrow}$

The $\mathsf{PhilosophySynthesisAudit}^{\uparrow}$ packet realizes the auditable-generativity reading of chapter 9462 as a finite synthesis-audit NameCert carrier. It sits beside the core registry index of chapter 1251, the registry export surface of chapter 1216, the theorem-gap registry of chapter 1246, the audit gate boundary of chapter 526, and the focused ledger of chapter 1247. Those siblings index, export, gate, audit, and focus finite rows; this carrier binds the philosophical synthesis only when the same rows make the synthesis auditable.

Definition 1256.1 (Philosophy synthesis audit carrier)**.** *A* $\mathsf{PhilosophySynthesisAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, E, G, A, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{CoreRegistryIndex}^{\uparrow}$ *row naming the concept, theorem, gap, tradition, scientific-claim, refusal, route, ordinary-language, and audit entries that the synthesis may read;*
2. *E is the* $\mathsf{RegistryExportSurface}^{\uparrow}$ *row recording whether a synthesized reading is exported, blocked, horizon-facing, or held as a formalization target;*
3. *G is the* $\mathsf{TheoremGapRegistry}^{\uparrow}$ *row separating theorem-strength readings from gap-gate readings;*
4. *A is the* $\mathsf{AuditGateBoundary}^{\uparrow}$ *row recording the audit route by which the synthesis is checked before export;*
5. *L is the* $\mathsf{FocusedLedger}^{\uparrow}$ *row recording the finite focus, selector, digest, gap, relation, invariant, dependence, self-proxy, and audit rows consumed by the reading;*
6. *Q is the synthesis-question row recording the philosophical reading, its allowed registry entries, its blocked readings, its audit-route requirement, and its not-claimed surface;*
7. *H records componentwise* hsame *transport for R, E, G, A, L, Q;*
8. *C records displayed* Cont *replay through the registry index, export surface, theorem-gap registry, audit boundary, focused ledger, and synthesis-question row;*
9. *P is the* Pkg *provenance over* $\mathsf{CoreRegistryIndex}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{TheoremGapRegistry}^{\uparrow}$, $\mathsf{AuditGateBoundary}^{\uparrow}$, $\mathsf{FocusedLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PhilosophySynthesisAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for inspiration-only synthesis, hidden registry export, gate-free theorem strength, audit-free philosophical conclusion, unledgered focus selection, or a reading that bypasses the not-claimed surface in Q.

Lean4 ✓ `BEDC.Derived.PhilosophySynthesisAuditUp.PhilosophySynthesisAuditTasteGate single carrier alignment`

Theorem 1256.2 (Philosophy synthesis audit NameCert obligations)**.** *For the carrier of Definition 1256.1, the local* $\mathsf{NameCert}_{\mathsf{PhilosophySynthesisAudit}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$S = (R, E, G, A, L, Q, H, C, P, N),$$

registry-index coverage through R, export-status coverage through E, theorem-gap separation through G, audit-route exposure through A, focused-ledger support through L, synthesis-question accountability through Q, componentwise hsame *stability through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the finite carrier of Definition 1256.1. The rows R, E, G, A, L, Q display the registry, export, theorem-gap, audit, focus, and synthesis-question data before any public reading of auditable generativity is allowed.

Read the sibling rows in order. $\mathsf{CoreRegistryIndex}^{\uparrow}$ supplies the finite registry entries, $\mathsf{RegistryExportSurface}^{\uparrow}$ controls whether the reading may leave the registry, $\mathsf{TheoremGapRegistry}^{\uparrow}$ keeps theorem strength distinct from gap status, $\mathsf{AuditGateBoundary}^{\uparrow}$ supplies the audit route, and $\mathsf{FocusedLedger}^{\uparrow}$ records the finite focused ledger consumed by the reading.

Finally inspect Q, H, C, P, N. The synthesis-question row records the philosophical reading and its not-claimed surface, while the structural rows only transport, replay, source, and name the same finite packet. Hence the local NameCert obligations are exactly the displayed synthesis-audit rows. □

Theorem 1256.3 (Philosophy synthesis audit nonescape)**.** *Every exported auditable-generativity reading of an accepted* $\mathsf{PhilosophySynthesisAudit}^{\uparrow}$ *packet must read the registry-index row R, export row E, theorem-gap row G, audit-route row A, focused-ledger row L, synthesis-question row Q, transport row H, replay row C, provenance row P, and local naming row N. A packet without the audit-route row A cannot export an auditable-generativity reading.*

Proof. Apply the NameCert obligations of Definition 1256.2. They require the registry, export, theorem-gap, audit, focused-ledger, and synthesis-question rows as one finite packet before a reading can be exported.

If A is absent, the reading still has no audit route. The registry index can name entries, the export surface can classify status, the theorem-gap registry can separate theorem and gap rows, and the focused ledger can display finite focus data, but none of those rows records the audit-route check by itself.

The structural rows H, C, P, N preserve an admitted packet; they do not synthesize a missing audit boundary. Thus a synthesis-audit packet without A exits the accepted carrier and cannot export an auditable-generativity reading. □

Falsifiable prediction: A synthesis-audit packet without the audit-route row cannot export an auditable-generativity reading.

Independence witness: coreregistryindex, registryexportsurface, theoremgapregistry, auditgateboundary, focusedledger: the core registry index lacks export-status and synthesis-question accountability, the registry export surface lacks theorem-gap and focused-ledger rows, the theorem-gap registry lacks the philosophical synthesis-question row, the audit gate boundary lacks registry-index and focused-ledger content, and the focused ledger lacks export-status and audit-route authority; no sibling is bijective to $\mathsf{PhilosophySynthesisAudit}^{\uparrow}$.

The Lean follow-up must provide $\mathsf{Nontrivial\ PhilosophySynthesisAudit}^{\uparrow}$ and $\mathsf{FieldFaithful\ PhilosophySynthesisAudit}$ in `lean4/BEDC/Derived/PhilosophySynthesisAuditUp/TasteGate.lean`. Those instances must preserve $R, E, G, A, L, Q, H, C, P, N$ as separate displayed fields before the target BEDC.Derived.PhilosophySynthesis can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{PhilosophySynthesisAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{PhilosophySynthesisAudit}^{\uparrow}$ packet is generated from core-registry, registry-export, theorem-gap, audit-route, focused-ledger, synthesis-question, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhilosophySynthesisAudit}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 1256.1, Definition 1256.2, and Definition 1256.3 bind auditable generativity to the displayed finite synthesis-audit packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhilosophySynthesisAudit}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.PhilosophySynthesisAuditUp.PhilosophySynthesisAuditTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, full philosophical completeness, theorem truth for every registry entry, or export of readings without an audit route.

Upgrade path: Lean closure requires Nontrivial PhilosophySynthesisAuditUp and FieldFaithful PhilosophySynthesisAuditUp instances in `lean4/BEDC/Derived/PhilosophySynthesisAuditUp/TasteGate.lean`.

Chapter 1257

A Concrete Naming Certificate for $\mathsf{CompactUniformEpsilonTriangleHandoff}^{\uparrow}$

The $\mathsf{CompactUniformEpsilonTriangleHandoff}^{\uparrow}$ packet isolates the epsilon-third source and target triangle step in the compact-uniform-continuity construction of chapter 9237. It sits after the source metric and compact finite-net rows of chapter 57 and chapter 60, the continuous-map pointwise-modulus rows of chapter 130, the rational tolerance rows of chapter 37, the selected uniform-modulus consumer row of chapter 369, and the final triangle estimate packet of chapter 1159. Its carrier is narrower than $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$: it records the precise source triangle that keeps x' inside the selected compact center and the target triangle that combines the two $\varepsilon/3$ pointwise estimates.

Definition 1257.1 (Compact-uniform epsilon-triangle handoff carrier)**.** *A* $\mathsf{CompactUniformEpsilonTriangleHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, Y, c, x, x', \varepsilon, \mu, \rho, d_x, d_{x'}, d_y, d_{y'}, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, read together with the* $\mathsf{Compact}^{\uparrow}$ *finite-net center row for c;*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row carrying the target triangle certificate;*
3. *c is the compact center selected from the finite cover for the tolerance history ε;*
4. *x and x' are the source histories whose target images are compared by the uniform-modulus consumer;*
5. *ε is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row whose three equal thirds are read by the pointwise target estimates;*
6. *μ is the positive* $\mathsf{Rat}^{\uparrow}$ *uniform precision row exported to* $\mathsf{UniformModulus}^{\uparrow}$*;*
7. *ρ is the positive* $\mathsf{Rat}^{\uparrow}$ *local center radius subordinate to the pointwise-modulus row at c;*
8. *d_x is the compact coverage distance row certifying $d_X(x, c) < \rho/2$;*
9. *$d_{x'}$ is the source triangle row certifying $d_X(x', c) \leq d_X(x', x) + d_X(x, c) < \rho$ from the μ-bound on $d_X(x, x')$ and the coverage row d_x;*
10. *d_y is the pointwise-modulus target row at c for the pair (c, x), bounded by $\varepsilon/3$;*

11. *$d_{y'}$ is the pointwise-modulus target row at c for the pair (c, x'), bounded by $\varepsilon/3$;*
12. *H records componentwise* hsame *transport for the metric, compact center, source histories, rational tolerance, precision, radius, source triangle, pointwise target, and target triangle rows;*
13. *C records the displayed* Cont *routes from compact coverage to source triangle, from source triangle to the double pointwise-modulus application, and from those target estimates to the uniform-modulus output;*
14. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, MetricTriangleUniformE BHist, hsame, Cont, *and* NameCert *rows;*
15. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformEpsilonTriangleHandoff}^{\uparrow}}$ *row.*

The classifier compares carriers only through these displayed rows. It has no coordinate for an open-cover compactness proof, a selected subsequence, a host-level modulus function, a quotient real equality, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CompactUniformEpsilonTriangleHandoffUp.CompactUniformEpsilonTriangleHandoffTasteGa`
`single carrier alignment`

Theorem 1257.2 (Compact-uniform epsilon-triangle handoff NameCert obligations)**.** *For the carrier of Definition 1257.1, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformEpsilonTriangleHandoff}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$E = (X, Y, c, x, x', \varepsilon, \mu, \rho, d_x, d_{x'}, d_y, d_{y'}, H, C, P, N),$$

compact-center preservation through c, source triangle admission through d_x and $d_{x'}$, double pointwise-modulus admission through d_y and $d_{y'}$, target triangle admission through Y, uniform-modulus output through μ, componentwise hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The rows $X, c, x, x', \varepsilon, \mu, \rho, d_x, d_{x'}, d_y, d_{y'}$ are the analytic rows, while H, C, P, N are the structural rows that transport, replay, package, and name the same finite packet.

The compact center is preserved because c is a carrier coordinate and every consumer route in C starts from the coverage row at that center. The source triangle row $d_{x'}$ is therefore read from the same X, c, x, x' data as the coverage row d_x.

The two pointwise-modulus rows then use the same center c and the same tolerance split $\varepsilon/3$. The target metric row Y consumes those two target estimates and sends the resulting bound to the $\mathsf{UniformModulus}^{\uparrow}$ output row attached to μ.

No further row is present in the carrier. Thus the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CompactUniformEpsilonTriangleHandoffUp.CompactUniformEpsilonTriangleHandoff`
`namecert obligations`

Theorem 1257.3 (Compact-uniform epsilon-triangle handoff estimate)**.** *For every accepted* CompactUniformEpsilo *packet*

$$E = (X, Y, c, x, x', \varepsilon, \mu, \rho, d_x, d_{x'}, d_y, d_{y'}, H, C, P, N),$$

the uniform-modulus consumer receives the following finite estimate route. The compact row preserves the selected center c and supplies $d_X(x, c) < \rho/2$. The source metric row combines this with the μ-bound on $d_X(x, x')$ to certify

$$d_X(x', c) \le d_X(x', x) + d_X(x, c) < \rho.$$

The continuous-map pointwise-modulus row at c then applies to both x and x', giving $d_y < \varepsilon/3$ and $d_{y'} < \varepsilon/3$. The target metric triangle row combines d_y and $d_{y'}$ into the displayed ε-bound exported to UniformModulus$^{\uparrow}$.

Proof. Start with the compact center row. The carrier preserves c together with the coverage row d_x, so the input point x is within the displayed half-radius around c.

Use the source triangle row in X. Since the uniform precision row μ bounds the distance between x and x' and is below the selected half-radius ledger, the source triangle gives the displayed bound on $d_X(x', c)$ and keeps x' inside the same local radius ρ.

Now apply the pointwise-modulus rows at c. The radius bound ρ is subordinate to the local modulus, so the same continuous-map packet supplies the target estimates $d_y < \varepsilon/3$ and $d_{y'} < \varepsilon/3$.

Finally read the target triangle certificate in Y. It joins the two target estimates through the same center image and exports the resulting ε-bound along the continuation route to UniformModulus$^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.CompactUniformEpsilonTriangleHandoffUp.TasteGate.CompactUniformEpsilonTriangleHand`
`single carrier alignment`

Falsifiable prediction: If the source triangle row $d_{x'}$ is removed, the packet cannot certify that x' lies inside the local radius around the selected compact center, and the second pointwise-modulus application at c is unavailable.

Independence witness: metric, compact, continuousmap, rat, uniformmodulus, metric-triangle-uniform-estimate: CompactUniformEpsilonTriangleHandoff$^{\uparrow}$ binds one selected center, two source points, the epsilon-third split, the source triangle route, two pointwise target rows, and the final target triangle route; none of the named siblings alone contains both the source and target triangle handoff as one finite packet.

Closure status for NameCert$_{\text{CompactUniformEpsilonTriangleHandoff}^{\uparrow}}$.

Constructive story: A CompactUniformEpsilonTriangleHandoff$^{\uparrow}$ packet is generated from source and target metric rows, a compact finite-net center, two source histories, a positive rational tolerance, a positive uniform precision, a local radius, source-distance rows, pointwise target estimates, componentwise hsame transports, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformEpsilonTriangleHandoff}^{\uparrow}}$, seed)

Scope closed: Definition 1257.1, Definition 1257.2, and Definition 1257.3 bind the epsilon-third source and target triangle handoff for compact-uniform-continuity to one finite carrier.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformEpsilonTriangleHandoff}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.CompactUniformEpsilonTriangleHandoffUp.CompactUniformEpsilonTriangleHandoff\_namecert\_`

Bridge status: none

Not claimed: This chapter does not close Lean verification, Real completion, open-cover compactness, selected subsequences, quotient real equality, or an ambient completeness principle.

Upgrade path: The next paper grade is obligation closure for compact-center preservation, source triangle admission, double pointwise-modulus admission, target triangle admission, and UniformModulus$^{\uparrow}$ output.

Chapter 1258

A Concrete Naming Certificate for $\mathsf{AuditSystem}^{\uparrow}$

The $\mathsf{AuditSystem}^{\uparrow}$ packet realizes the total audit theory of subsection 9462.31.11 as a finite NameCert surface. It sits beside the kernel-acceptance audit witness of chapter 547, the claim registry layer of chapter 1209, and the failure-certificate packet of chapter 1233. As a composite over those sibling audit surfaces, the packet bundles their acceptance, registry, and refusal rows into one finite audit carrier. Those siblings expose kernel acceptance, positive claim registration, and typed refusal separately; this packet binds admissible claims, positive certificates, failure certificates, cannot-claim rows, export grades, and ledger closure in one finite audit carrier.

As a composite over $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{FailureCertificate}^{\uparrow}$, and $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, the packet records the joint audit surface rather than a primitive carrier discovery.

Definition 1258.1 (Audit system carrier)**.** *An* $\mathsf{AuditSystem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (C, P, F, R, E, L, H, K, Q, N)$$

with the following displayed rows:

1. *C is the admissible-claim row, recording the claim name, subject surface, carrier, classifier, and intended export site;*
2. *P is the positive-certificate row, recording the certificate that licenses the claim when the carrier, classifier, ledger, status, and surface fields are present;*
3. *F is the failure-certificate row, recording the missing, invalid, overstated, unchecked, or axis-confused field when export is blocked;*
4. *R is the cannot-claim row, recording a typed refusal when the packet is required to expose non-export rather than positive admission;*
5. *E is the export-grade row, recording whether the claim is read as paper-scoped, theorem-checked, audit-clean, axiom-clean, bridge-checked, or explicitly non-exportable;*
6. *L is the ledger-closure row, recording that the claim, certificate, failure certificate, refusal row, export grade, provenance, and local naming are closed as one audit packet;*
7. *H stores componentwise* hsame *transport for admissible claim, positive certificate, failure certificate, cannot-claim row, export grade, ledger closure, replay, provenance, and local naming;*

8. *K stores displayed* Cont *replay for reading C, P, F, R, E, L without adding a host-side repair route;*
9. *Q is the* Pkg *provenance over* $\mathsf{AuditSystem}^{\uparrow}$, $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{FailureCertificate}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditSystem}^{\uparrow}}$ *row.*

The carrier has no coordinate for exporting a claim outside the displayed positive certificate, failure certificate, refusal row, export grade, and ledger-closure surface.

Lean4 ✓ `BEDC.Derived.AuditSystemUp.AuditSystemTasteGate single carrier alignment`

Theorem 1258.2 (Audit system NameCert surface)**.** *For the carrier of Definition 1258.1, the local* $\mathsf{NameCert}_{\mathsf{AuditSystem}^{\uparrow}}$ *surface consists exactly of the admissible-claim row C, positive-certificate row P, failure-certificate row F, cannot-claim row R, export-grade row E, ledger-closure row L, componentwise transport row H, replay row K, provenance row Q, and local naming row N.*

Lean4 ✓ `BEDC.Derived.AuditSystemUp.AuditSystemCarrier namecert surface`

Proof. Project the finite packet $A = (C, P, F, R, E, L, H, K, Q, N)$. The admissible claim is read first through C, but it is not an exported BEDC claim until the certificate and boundary rows are read in the same carrier.

Rows P, F, R, E supply the positive and negative audit faces. The positive row licenses export, the failure row blocks export by naming the failed field, the cannot-claim row records explicit refusal, and the export-grade row records the public strength of the same claim site.

Rows L, H, K, Q, N then close, transport, replay, package, and name the displayed audit data. Since the carrier contains no additional export coordinate, these ten rows exhaust the local NameCert surface. □

Theorem 1258.3 (Audit system export refusal)**.** *If an accepted* $\mathsf{AuditSystem}^{\uparrow}$ *packet attempts to export the claim row C while its failure-certificate row F or cannot-claim row R is active for the same claim site, then the packet produces a certificate conflict rather than an exportable claim.*

Lean4 ✓ `BEDC.Derived.AuditSystemUp.AuditSystemCarrier export refusal conflict`

Proof. Assume an accepted packet $A = (C, P, F, R, E, L, H, K, Q, N)$. The export-grade row E is read together with the positive certificate P, failure certificate F, and cannot-claim row R.

If F is active for the same claim site, the packet records a missing, invalid, overstated, unchecked, or axis-confused field. The positive certificate cannot erase that negative row, because both rows are displayed before ledger closure is read.

If R is active, the packet records explicit refusal. Again P cannot by itself create an export route, since the carrier admits no coordinate for export outside P, F, R, E, L.

Thus the accepted packet exposes a certificate conflict. It may be audited as a blocked or refused claim, but it is not an exportable claim. □

Theorem 1258.4 (Audit system certificate conflict determinacy)**.** *Let $A = (C, P, F, R, E, L, H, K, Q, N)$ be an accepted* $\mathsf{AuditSystem}^{\uparrow}$ *packet. If the same claim site has active F or active R, then every export-grade read through E, L, H, K, Q, N is classified as the same blocked or refused claim boundary, and no second export route can be produced by replaying P alone.*

Lean4 ✓ `BEDC.Derived.AuditSystemUp.AuditSystemCertificateConflictDeterminacy`

Proof. Project the accepted carrier of Definition 1258.1. The negative rows F and R share the same claim site as C, and the export-grade row E is read together with those rows before ledger closure.

Apply Definition 1258.3. An active F yields a certificate conflict, and an active R yields explicit refusal; in either case the packet is classified at the blocked or refused claim boundary rather than as an exportable claim.

Now use Definition 1258.5. Rows L, H, K, Q, N close, transport, replay, source, and name the same displayed negative boundary. Since the carrier has no coordinate for a second export grade and P is not readable outside F, R, E, L, replaying P alone cannot produce another export route. □

Lean4 ✓ `BEDC.Derived.AuditSystemUp.AuditSystemCarrier certificate conflict determinacy`

Theorem 1258.5 (Audit system ledger closure)**.** *Every exported claim admitted by* $\mathsf{AuditSystem}^{\uparrow}$ *is ledger-closed by the same finite packet that displays its admissible-claim row, certificate row, negative rows, export grade, transport, replay, provenance, and local NameCert row.*

Proof. By Definition 1258.1, the only ledger-closure coordinate is L inside $A = (C, P, F, R, E, L, H, K, Q, N)$. The packet therefore cannot close a claim by citing an external ledger while omitting C, P, F, R, E.

The transport, replay, provenance, and local naming rows H, K, Q, N preserve the same displayed rows. They do not add a second claim, a second export grade, or a hidden ledger.

Consequently any admitted export is closed by the same finite packet that names its positive and negative audit data. □

Lean4 ✓ `BEDC.Derived.AuditSystemUp.AuditSystemLedgerClosure`

Theorem 1258.6 (Audit system independence witness)**.** *The* $\mathsf{AuditSystem}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{FailureCertificate}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, *or* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$.

Proof. Compare the displayed rows. $\mathsf{ClaimRegistryLayer}^{\uparrow}$ registers or refuses package claims, $\mathsf{FailureCertificate}^{\uparrow}$ supplies a typed negative certificate, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ blocks inconsistent export, and $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$ records kernel-side acceptance audit data.

None of those siblings carries the simultaneous positive-certificate row P, failure-certificate row F, cannot-claim row R, export-grade row E, and ledger-closure row L for the same admissible claim C. A NameCert-row-preserving bijection would have to preserve that joint positive and negative audit surface, so no such bijection exists. □

Lean4 ✓ `BEDC.Derived.AuditSystemUp.AuditSystemIndependenceWitness`

Theorem 1258.7 (Audit system bridged handoff package)**.** *The admissible claim row, positive certificate row, failure certificate row, refusal row, export grade row, ledger-closure row, transport row, replay row, provenance row, and local name row of an accepted* $\mathsf{AuditSystem}^{\uparrow}$ *packet form the paper bridge handoff to the abstract audit interface. The handoff exposes exactly the finite audit surface needed by that interface, and it exports no additional registry, certificate, or ledger coordinate beyond those rows.*

Proof. Read the carrier of Definition 1258.1 as $A = (C, P, F, R, E, L, H, K, Q, N)$. The rows C, P, F, R, E, L provide the admissible claim, positive certificate, typed failure certificate, refusal boundary, export grade, and ledger closure.

The structural rows H, K, Q, N transport, replay, source, and name the same finite packet. By Definition 1258.2, Definition 1258.3, and Definition 1258.5, those rows are exactly the public audit rows preserved by the abstract audit interface.

The independence witness Definition 1258.6 excludes collapse to any one sibling registry or certificate packet. Hence the displayed rows form a bridge handoff package, not a hidden registry extension. □

The Lean follow-up file `lean4/BEDC/Derived/AuditSystemUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{AuditSystem}^{\uparrow}$ and FieldFaithful $\mathsf{AuditSystem}^{\uparrow}$ instances. The field-faithfulness witness must preserve $C, P, F, R, E, L, H, K, Q, N$ as distinct rows so positive certification, typed failure, cannot-claim refusal, export grade, and ledger closure cannot be merged.

Falsifiable prediction: If an AuditSystemUp packet accepts a claim while its failure-certificate row is active, the export-refusal theorem produces a certificate conflict rather than an exportable claim.

Independence witness: Compare claimregistrylayer, failurecertificate, registryexportconsistencygate, kernelacceptanceauditwitness: AuditSystemUp is not bijective with any one sibling because it carries both positive certificate and negative refusal rows plus export-grade ledger closure.

Closure status for $\mathsf{NameCert}_{\mathsf{AuditSystem}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditSystem}^{\uparrow}$ packet is generated from admissible-claim, positive-certificate, failure-certificate, cannot-claim, export-grade, ledger-closure, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AuditSystem}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1258.1, Definition 1258.2, Definition 1258.3, Definition 1258.4, Definition 1258.5, Definition 1258.6, Definition 1258.7, the falsifiable claim-conflict prediction, the independence witness, and the displayed TasteGate alignment marker bind the BHist, hsame, Cont, Pkg, NameCert, $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{FailureCertificate}^{\uparrow}$, and $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ scope used by the carrier, export-refusal, certificate-conflict, ledger, independence, sibling audit rows, and bridged handoff package.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AuditSystem}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, proof of every exported claim, or registry export beyond the displayed audit packet.

Upgrade path: Obligation closure requires Lean Nontrivial and FieldFaithful TasteGate instances plus checked carrier, export-refusal, and ledger rows for $C, P, F, R, E, L, H, K, Q, N$.

Chapter 1259

A Concrete Naming Certificate for AxiomPurityGate$^{\uparrow}$

The AxiomPurityGate$^{\uparrow}$ packet is a composite over the forbidden-schema obstruction of chapter 899, the finite choice-output refusal ledger of chapter 677, the quotient-boundary packet of chapter 634, the proposition-transport boundary of chapter 566, and the positive-content closure surface of chapter 515. It realizes the axiom-purity section of subsection 9462.25.8 inside the auditable-generativity programme of chapter 9462. Those siblings expose forbidden schemas, term-stratum choice demand, quotient soundness, proposition transport, and positive-content closure; this carrier binds the dependency-audit gate that accepts only finite reports with visible forbidden-dependency refusals.

It is an ai over the forbidden-schema obstruction, finite choice-output refusal ledger, quotient-boundary packet, and proposition-transport boundary, with the additional theorem-target and replay rows serving only as the local audit interface.

The packet is a composite over theorem-target audit rows, dependency-report rows, forbidden-dependency refusal rows, replay rows, replacement rows, and transport rows, rather than an atomic carrier.

Definition 1259.1 (AxiomPurityGate carrier)**.** *An* AxiomPurityGate$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, D, F, R, L, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the theorem-target row naming the declaration whose dependency report is being consumed;*
2. *D is the finite dependency-report row, listing the transitive proof dependencies visible to the audit consumer;*
3. *F is the forbidden-dependency refusal row for* Classical.choice*, quotient soundness, and propositional extensionality;*
4. *R is the replay row recording the command-level route by which the dependency report can be re-read;*
5. *L is the replacement row naming the constructive BEDC route used when a forbidden dependency request is refused;*
6. *S is the transport row recording that theorem-target, dependency-report, refusal, replay, and replacement reads are consumed componentwise;*

7. *H records componentwise* hsame *transports for T, D, F, R, L, S, P, N;*
8. *C records the displayed* Cont *routes by which consumers read the report, refusals, replay route, replacement route, and transport row;*
9. *P is the* Pkg *provenance over* $\mathsf{MetaClosureObstruction}^{\uparrow}$, $\mathsf{UnwitnessedExistenceClosure}^{\uparrow}$, $\mathsf{ChoiceRecipeLedger}^{\uparrow}$, $\mathsf{QuotientSoundnessBoundary}^{\uparrow}$, $\mathsf{PropextTransportBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AxiomPurityGate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed rows $T, D, F, R, L, S, H, C, P, N$. A packet missing any forbidden-dependency refusal row in F is not accepted as an $\mathsf{AxiomPurityGate}^{\uparrow}$ *carrier.*

Lean4 ✓ `BEDC.Derived.AxiomPurityGateUp.AxiomPurityGateTasteGate single carrier alignment`

Theorem 1259.2 (AxiomPurityGate NameCert obligations)**.** *For the carrier of Definition 1259.1, the local* $\mathsf{NameCert}_{\mathsf{AxiomPurityGate}^{\uparrow}}$ *surface consists of carrier admission for*

$$G = (T, D, F, R, L, S, H, C, P, N),$$

theorem-target exposure through T, dependency-report exposure through D, forbidden-dependency refusal through F, replay exposure through R, constructive replacement exposure through L, transport exposure through S, componentwise hsame *stability through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 1259.1. The tuple displays the theorem target, dependency report, forbidden-dependency refusal, replay route, replacement route, transport row, componentwise stability, continuation replay, provenance, and local naming.

The rows T, D, F are the audit-facing core. Row T names the declaration being read, row D exposes the finite dependency report, and row F records the refusal of each forbidden dependency class rather than treating purity as prose outside the carrier.

The rows R, L, S make the refusal replayable and consumable. Row R records the report replay route, row L records the constructive replacement route, and row S records transport of the visible rows without adding a hidden dependency or host equality.

Finally H, C, P, N exhaust stability, continuation replay, provenance, and naming. Since no further coordinate exists, the listed rows are exactly the local NameCert obligations for the gate packet. □

Lean4 ✓ `BEDC.Derived.AxiomPurityGateUp.AxiomPurityGateNameCert obligations`

Theorem 1259.3 (AxiomPurityGate non-escape)**.** *Every accepted* $\mathsf{AxiomPurityGate}^{\uparrow}$ *packet exports only the finite rows*

$$T, D, F, R, L, S, H, C, P, N.$$

No consumer can extract from such a packet an unreported theorem dependency, a Classical.choice *dependency, a quotient-soundness dependency, a propositional-extensionality dependency, a hidden replay oracle, a host equality transport, or a proof of meta closure. A packet missing any forbidden-dependency refusal row cannot be accepted as an* $\mathsf{AxiomPurityGate}^{\uparrow}$ *carrier.*

Proof. Project the accepted packet to the carrier inventory of Definition 1259.1. The only dependency information available to a consumer is the theorem target T, the finite report D, and the forbidden-dependency refusal row F.

Apply the NameCert obligations of Definition 1259.2. Every replay, replacement, and transport read must pass through R, L, S, H, C, P, N, so a consumer may inspect the displayed audit packet but cannot bypass it to obtain a hidden dependency or host-level equality route.

The last claim is part of carrier admission. Row F contains the refusal records for the forbidden dependency classes; removing one of those records removes a displayed coordinate required by the classifier and therefore removes acceptance as an $\mathsf{AxiomPurityGate}^{\uparrow}$ carrier. □

Lean4 ✓ `BEDC.Derived.AxiomPurityGateUp.AxiomPurityGateNonescape`

Theorem 1259.4 (AxiomPurityGate witness-preserving consumer)**.** *Every downstream consumer of an accepted* $\mathsf{AxiomPurityGate}^{\uparrow}$ *packet that asks for a theorem-target audit must read the dependency report, forbidden-dependency refusal, replay route, constructive replacement route, transport row, stability row, continuation route, provenance row, and local naming row through*

$$T, D, F, R, L, S, H, C, P, N.$$

Such a consumer preserves the displayed witness boundary: accepted theorem reads may cite the finite report and replacement rows, while rejected reads remain blocked by F. The consumer cannot turn the gate into a selector for witnesses, a quotient of dependency reports, a proposition-equality transport, a second replay surface, or a meta-closure proof.

Proof. First expose the theorem-target audit through T, D, F. The dependency report is visible only as the finite row D, and each forbidden dependency class is handled by its refusal record in F.

Next route replay and replacement through R, L, S. The replay row lets the report be re-read, the replacement row records the constructive BEDC route available after refusal, and the transport row keeps those reads componentwise rather than quotienting dependency reports.

Finally apply H, C, P, N. These rows preserve stability, continuation replay, package provenance, and the local name of the packet. They do not add a selector, quotient, proposition-equality transport, second replay surface, or meta-closure theorem, so the consumer remains witness-preserving. □

Lean4 ✓ `BEDC.Derived.AxiomPurityGateUp.AxiomPurityGateWitnessPreservingConsumer`

Theorem 1259.5 (AxiomPurityGate bridged handoff)**.** *The public* $\mathsf{AxiomPurityGate}^{\uparrow}$ *surface has a bridge-facing handoff whose visible rows are the theorem target T, dependency report D, forbidden-dependency refusals F, replay route R, constructive replacement route L, transport row S, stability row H, continuation row C, provenance row P, and local naming row N. The handoff packages the forbidden-dependency refusal rows of Definition 1259.3, the witness-preserving consumer of Definition 1259.4, and the TasteGate carrier alignment recorded at Definition 1259.1.*

Consequently any bridge-facing consumer must preserve the displayed refusal boundary: accepted theorem reads may replay the finite dependency report and constructive replacement route, while rejected reads remain blocked by F. The handoff does not assert Lean bridge checking, global axiom-purity for every BEDC theorem, a selector for witnesses, a quotient of dependency reports, proposition-equality transport, or meta closure.

Proof. First read the carrier and TasteGate row. The accepted packet has exactly the displayed coordinates $T, D, F, R, L, S, H, C, P, N$, and the carrier alignment binds the local gate to those coordinates rather than to an external audit oracle.

Next apply Definition 1259.3. The forbidden-dependency refusal row F is part of carrier admission, so a bridge-facing read cannot erase a refusal for Classical.choice, quotient soundness, or propositional extensionality.

Finally apply Definition 1259.4. The downstream consumer must read report, refusal, replay, replacement, transport, stability, continuation, provenance, and naming rows through the same packet. This repackages the public surface for bridge-facing use without adding a Lean bridge theorem or any of the excluded escape routes. □

Lean4 ✓ `BEDC.Derived.AxiomPurityGateUp.AxiomPurityGateBridgedHandoff`

Falsifiable prediction: A packet missing any forbidden-dependency refusal row cannot be accepted as an AxiomPurityGateUp carrier.

Independence witness: MetaClosureObstruction, UnwitnessedExistenceClosure, ChoiceRecipeLedger, QuotientSoundnessBoundary, PropextTransportBoundary: the axiom-purity gate packet contains a theorem-target row, dependency-report row, forbidden-dependency refusal row, replay row, replacement row, transport row, provenance row, and local NameCert row. MetaClosureObstruction carries forbidden-schema refusal without dependency-report replay; UnwitnessedExistenceClosure carries the positive-content closure family without a gate-local theorem target; ChoiceRecipeLedger records term-stratum recipe refusal without quotient or propext dependency rows; QuotientSoundnessBoundary isolates quotient soundness without choice and propext refusal as one audit packet; PropextTransportBoundary isolates proposition transport without a theorem-target dependency report. Hence none is bijective to $\mathsf{AxiomPurityGate}^{\uparrow}$ while preserving all displayed NameCert rows.

The future Lean target `BEDC.Derived.AxiomPurityGateUp` must place the ChapterTasteGate realization in `TasteGate.lean` with explicit `Nontrivial` and `FieldFaithful` instances for the displayed carrier and forbidden-dependency refusal rows.

Closure status for $\mathsf{NameCert}_{\mathsf{AxiomPurityGate}^{\uparrow}}$.

Constructive story: An $\mathsf{AxiomPurityGate}^{\uparrow}$ packet is generated from a theorem target, finite dependency report, forbidden-dependency refusals, replay route, replacement route, transport row, componentwise hsame stability, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AxiomPurityGate}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1259.1, Definition 1259.2, Definition 1259.3, the witness-preserving consumer of Definition 1259.4, and the bridge-facing handoff of Definition 1259.5 bind the public-facing and bridge-facing scope to the forbidden-dependency refusal rows $T, D, F, R, L, S, H, C, P, N$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AxiomPurityGate}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not prove a Lean implementation, a standard bridge, global axiom-purity for every BEDC theorem, or a replacement proof for any particular refused dependency.

Upgrade path: No further paper closure grade remains; Lean-side axiom-purity and bridge checking remain on the verification axis.

Chapter 1260

A Concrete Naming Certificate for $\mathsf{RuntimeBoundaryAudit}^{\uparrow}$

The $\mathsf{RuntimeBoundaryAudit}^{\uparrow}$ packet realizes the runtime-boundary claim of subsection 9462.25.5 as a finite audit surface. It binds the object-level candidate boundary of chapter 591, the runtime-request and refusal surface of chapter 890, the meta-closure obstruction of chapter 899, the structural reflection limit of chapter 586, and the claim ledger of chapter 1258 into a single NameCert packet. The carrier records an auditable boundary without converting the host proof checker into an object-layer row.

Definition 1260.1 (Runtime-boundary audit carrier)**.** *A* $\mathsf{RuntimeBoundaryAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, R, E, M, L, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the structural self-description row, recording formation, replay, and certificate-shape data described by Definition 9462.702;*
2. *R is the runtime-candidate row inherited from* $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$*, naming the object-level candidate, transition, and accepted-result boundary;*
3. *E is the runtime-reflection refusal row inherited from* $\mathsf{RuntimeReflectionBoundary}^{\uparrow}$*, recording the request for validation and the execution refusal report;*
4. *M is the meta-closure obstruction row inherited from* $\mathsf{MetaClosureObstruction}^{\uparrow}$*, blocking conversion of the runtime request into an unwitnessed closure principle;*
5. *L is the reflection-limit row inherited from* $\mathsf{ReflectionLimitBoundary}^{\uparrow}$*, separating structural reflection from truth-total or runtime-total claims;*
6. *G is the audit-system row inherited from* $\mathsf{AuditSystem}^{\uparrow}$*, recording the admissible claim, positive or negative certificate face, export grade, and ledger closure;*
7. *H records componentwise* hsame *transport for $S, R, E, M, L, G, C, P, N$;*
8. *C records displayed* Cont *routes by which consumers read the structural description, candidate boundary, runtime refusal, obstruction, reflection limit, audit ledger, and transports;*
9. *P is the* Pkg *provenance over* $\mathsf{RuntimeCandidateBoundary}^{\uparrow}$, $\mathsf{RuntimeReflectionBoundary}^{\uparrow}$, $\mathsf{MetaClosureObstruction}$ $\mathsf{ReflectionLimitBoundary}^{\uparrow}$, $\mathsf{AuditSystem}^{\uparrow}$, BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, *and* $\mathsf{TasteGate}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{RuntimeBoundaryAudit}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $S, R, E, M, L, G, H, C, P, N$. No accepted carrier has an additional row for host-runtime execution, runtime validation, or a BEDC truth predicate.

Theorem 1260.2 (Runtime-boundary audit NameCert obligations)**.** *For the carrier of Definition 1260.1, the local* $\mathsf{NameCert}_{\mathsf{RuntimeBoundaryAudit}^{\uparrow}}$ *surface consists exactly of carrier admission for $A = (S, R, E, M, L, G, H, C, P, N)$, structural-description exactness through S, runtime-candidate accountability through R, runtime-reflection refusal through E, meta-closure obstruction through M, reflection-limit boundary through L, audit-ledger closure through G, and transport, consumer, provenance, and local naming closure through H, C, P, N.*

Proof. Carrier admission is projection from the finite packet of Definition 1260.1. The rows $S, R, E, M, L, G, H, C, P, N$ are the complete displayed surface.

The rows S, R, E, M, L, G supply the substantive audit coordinates. They record structural self-description, the object-level candidate boundary, runtime-request refusal, meta-closure obstruction, reflection-limit separation, and claim-ledger status.

The rows H, C, P, N transport, replay, package, and name the same packet. Since those rows only preserve the displayed coordinates, they cannot add a hidden validator, a runtime-total row, or a truth predicate. □

Theorem 1260.3 (Runtime-boundary audit validation non-escape)**.** *Every accepted* $\mathsf{RuntimeBoundaryAudit}^{\uparrow}$ *packet exports runtime-boundary evidence only through the finite rows $S, R, E, M, L, G, H, C, P, N$. A consumer asking for host-runtime validation must therefore encounter the refusal row E, the meta-closure obstruction row M, and the reflection-limit row L before any audit export through G.*

Proof. Let $A = (S, R, E, M, L, G, H, C, P, N)$ be an accepted carrier. By Definition 1260.1, every consumer route is displayed in C and every route is transported by H over the same coordinates.

A runtime-validation request is first classified as an object-level candidate read by R. It is then recorded as a runtime-reflection request and refusal by E.

The request cannot bypass the obstruction and limit rows. Row M blocks the conversion of the request into an unwitnessed closure principle, while row L blocks the conversion of structural reflection into a truth-total or runtime-total claim.

The audit-system row G can export only the resulting finite claim status. It has no coordinate for replacing E, M, L by host execution, so validation does not escape the displayed boundary packet. □

Theorem 1260.4 (Runtime-boundary audit consumer boundary)**.** *Every consumer of an accepted* $\mathsf{RuntimeBoundaryAudit}^{\uparrow}$ *packet that reports structural self-description must preserve the distinction between the structural row S and the runtime-validation refusal path R, E, M, L. In particular, the consumer cannot certify self-description by replacing R, E, M, L with a host-checker row outside the packet.*

Proof. Consumer access is mediated by the displayed route row C. Reading the structural description therefore begins at S and remains inside the same finite carrier.

The runtime-facing path is separate. It passes through the candidate row R, the runtime-reflection refusal row E, the meta-closure obstruction row M, and the reflection-limit row L.

The provenance and local naming rows P, N name that route as part of the same packet, and H transports it componentwise. None of these rows supplies a host-checker coordinate. The consumer boundary is therefore exactly the displayed separation between S and R, E, M, L. □

Lean4 ✓ `BEDC.Derived.RuntimeBoundaryAuditUp.RuntimeBoundaryAuditTasteGate single carrier alignment`

Falsifiable prediction: Any accepted RuntimeBoundaryAuditUp packet that exports a self-description claim while omitting the runtime-reflection refusal row, meta-closure obstruction row, or reflection-limit row fails the carrier classifier.

Independence witness: runtimecandidateboundary, runtime-reflection-boundary, metaclosure-obstruction, reflectionlimitboundary, auditsystem: the runtime-boundary audit carrier is not bijective to any single sibling because it simultaneously carries structural self-description, runtime-candidate accountability, runtime-reflection refusal, meta-closure obstruction, reflection-limit separation, audit-ledger closure, and one local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{RuntimeBoundaryAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{RuntimeBoundaryAudit}^{\uparrow}$ packet is generated from structural self-description, runtime-candidate accountability, runtime-reflection refusal, meta-closure obstruction, reflection-limit separation, audit-ledger closure, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RuntimeBoundaryAudit}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1260.1, Definition 1260.2, Definition 1260.3, Definition 1260.4, and

Lean4 ✓ `BEDC.Derived.RuntimeBoundaryAuditUp.taste gate`

bind the finite runtime-boundary audit carrier, validation non-escape, and consumer boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RuntimeBoundaryAudit}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.RuntimeBoundaryAuditUp.RuntimeBoundaryAuditTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not internalize the host proof checker, provide a BEDC truth predicate, claim runtime-total validation, or bridge $\mathsf{RuntimeBoundaryAudit}^{\uparrow}$ to a standard schema.

Upgrade path: Bridge checking requires a standard-schema bridge for the displayed runtime-boundary audit packet.

Chapter 1261

A Concrete Naming Certificate for $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$

The $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$ packet realizes the logic and meta-loop boundary of section 9462.25 as a finite NameCert carrier. It sits after the quotient refusal surface of chapter 634 and the failed audit witness of chapter 901. Those siblings refuse representative collapse and expose failed gate diagnostics, while the present packet binds proof-pattern discipline, local refutation, open meta-loop refusal, audit-gate failure, transport, route replay, provenance, and local naming before any consumer may read a logical closure claim.

Definition 1261.1 (Logic contradiction meta-loop carrier)**.** *A* $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, R, M, A, T, C, G, N)$$

with the following displayed rows:

1. *P is the finite proof-pattern row recording constructive formation, introduction, elimination, and local refutation steps;*
2. *R is the local-refutation row that records a witnessed contradiction only as a bounded failure of the displayed proof pattern;*
3. *M is the open meta-loop refusal row, rejecting total truth, unrestricted choice, quotient collapse, and halting closure as consumer-readable coordinates;*
4. *A is the audit-gate row, with failed reads routed through the* $\mathsf{AuditGateFailureWitness}^{\uparrow}$ *surface;*
5. *T records componentwise* hsame *transport for proof-pattern, refutation, meta-loop refusal, audit gate, route, provenance, and local naming rows;*
6. *C records the displayed* Cont *replay from proof-pattern inspection through local refutation and open meta-loop refusal into the audit gate;*
7. *G is the* Pkg *provenance over* $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$*,* $\mathsf{QuotientSoundnessBoundary}^{\uparrow}$*,* $\mathsf{AuditGateFailureWitne}$ BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LogicContradictionMetaLoop}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the visible rows P, R, M, A, T, C, G, N and has no coordinate for total truth, global choice, quotient equality elimination, or a halting oracle.

Lean4 ✓ BEDC.Derived.LogicContradictionMetaLoopUp.LogicContradictionMetaLoopTasteGate single carrier alignment

Theorem 1261.2 (Logic contradiction meta-loop NameCert obligations)**.** *For every accepted* $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$ *carrier*

$$L = (P, R, M, A, T, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{LogicContradictionMetaLoop}^{\uparrow}}$ *surface consists exactly of proof-pattern admission through* P*, local-refutation exposure through* R*, open meta-loop refusal through* M*, audit-gate failure routing through* A*, componentwise transport through* T*, displayed continuation replay through* C*, package provenance through* G*, local naming through* N*, and non-admission of total truth, unrestricted choice, quotient collapse, and halting closure.*

Lean4 ✓ BEDC.Derived.LogicContradictionMetaLoopUp.LogicContradictionMetaLoopCarrier namecert obligations

Proof. Project the carrier of Definition 1261.1. Each admitted proof-pattern, refutation, meta-loop refusal, audit-gate, transport, continuation, provenance, and naming row is a displayed coordinate of the finite packet.

The quotient side is already constrained by chapter 634: a quotient-like consumer receives a refusal-and-transport surface rather than a representative selector or a Quot.sound row. The present carrier records that refusal in M and transports it only through T, C, G, N.

The audit side is constrained by chapter 901: a failed gate read must expose its diagnostic row before it reaches a refusal target. The present carrier records that dependency in A and does not promote the failed item to theorem content.

Thus the local NameCert surface is exhausted by the eight displayed rows. There is no remaining coordinate from which a consumer could read total truth, unrestricted choice, quotient collapse, or halting closure. □

Theorem 1261.3 (Logic contradiction meta-loop carrier admission)**.** *Carrier admission for* LogicContradictionMet*is exactly the finite projection of* $L = (P, R, M, A, T, C, G, N)$ *through proof-pattern discipline* P*, local refutation* R*, open meta-loop refusal* M*, audit-gate routing* A*, and the structural rows* T, C, G, N*. A packet that supplies only a contradiction report, only an audit failure, or only a quotient refusal is not admitted as this carrier.*

Lean4 ✓ BEDC.Derived.LogicContradictionMetaLoopUp.LogicContradictionMetaLoopCarrierAdmission

Proof. Project the definition of the carrier. The rows P, R, M, A jointly supply proof-pattern formation, bounded refutation, open meta-loop refusal, and audit-gate diagnostics.

The structural rows are not optional. Componentwise hsame transport T, displayed Cont replay C, Pkg provenance G, and local naming N keep the same finite packet available to consumers.

Thus carrier admission is the whole eight-row packet. A narrower item may be a sibling route, but it does not expose the local proof-pattern, refutation, refusal, audit, transport, replay, provenance, and naming surface at once. □

Theorem 1261.4 (Logic contradiction meta-loop ledger nonescape)**.** *Every refusal-ledger route of an accepted* $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$ *packet must pass through open meta-loop refusal* M*, audit-gate row* A*, transport* T*, replay* C*, provenance* G*, and local naming* N*. Transport and replay preserve the ledger route; they do not export total truth, unrestricted choice, quotient collapse, halting closure, or a closed meta-loop classifier.*

Proof. Start with the refusal-bearing rows. The open meta-loop row M records refusal of total truth, choice, quotient collapse, and halting closure, while A routes failed reads through the audit-gate surface.

Transport and replay keep this ledger finite. The row T compares the same refusal and audit coordinates componentwise, and C replays the route from proof-pattern inspection through local refutation into the audit gate.

Finally G records provenance and N supplies local naming. Since no row in the route is a truth oracle, choice principle, quotient-elimination rule, halting oracle, or closed classifier, the refusal ledger cannot escape the displayed packet. □

Lean4 ✓ `BEDC.Derived.LogicContradictionMetaLoopUp.LogicContradictionMetaLoopCarrier ledger nonescape`

Theorem 1261.5 (Logic contradiction meta-loop non-escape)**.** *An accepted* $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$ *carrier cannot export a route from local contradiction management to total truth, unrestricted choice, quotient equality elimination, global proof search, halting closure, or a closed meta-loop classifier. Every accepted consumer route must preserve the displayed packet* P, R, M, A, T, C, G, N.

Proof. Read the NameCert obligations of Definition 1261.2. The only content rows are proof pattern, local refutation, open meta-loop refusal, and audit gate; the remaining rows transport, replay, package, and name those same coordinates.

If a consumer asks for quotient collapse, the request is forced through the quotient-soundness refusal surface cited in the obligation proof. If a consumer asks to turn a failed audit item into theorem content, the request is forced through the audit-gate failure witness and remains refusal data.

The carrier supplies no row for total truth, unrestricted choice, global proof search, halting closure, or a closed meta-loop classifier. Therefore every accepted route remains inside P, R, M, A, T, C, G, N. □

Lean4 ✓ `BEDC.Derived.LogicContradictionMetaLoopUp.LogicContradictionMetaLoopCarrier nonescape`

Theorem 1261.6 (Logic contradiction meta-loop sibling dependency)**.** *The carrier of Definition 1261.1 is not bijective, row for row, with* $\mathsf{QuotientSoundnessBoundary}^{\uparrow}$, $\mathsf{AuditGateFailureWitness}^{\uparrow}$, *quotient-soundness boundary packets, audit-gate failure packets, MetaCIC decidable-boundary packets, MetaCIC confluence-audit packets, or normal-false-exclusion packets. The present packet jointly carries proof-pattern discipline and open meta-loop refusal, while each sibling exposes only a quotient gate, an audit diagnostic, a checker boundary, a confluence audit, or a local false-exclusion surface.*

Lean4 ✓ `BEDC.Derived.LogicContradictionMetaLoopUp.LogicContradictionMetaLoop sibling dependency route`

Proof. Compare first with $\mathsf{QuotientSoundnessBoundary}^{\uparrow}$. That sibling refuses representative selection and replaces quotient-like reads by displayed psame transport, but it does not carry the proof-pattern row P, the local contradiction row R, or the full open meta-loop refusal row M.

Compare next with $\mathsf{AuditGateFailureWitness}^{\uparrow}$. That sibling records a failed gate item, diagnostic readback, refusal target, transport, replay, provenance, and local naming, but it does not carry the quotient-collapse refusal or the proof-pattern discipline as one logic-facing carrier.

The remaining checker and confluence siblings are narrower still. A decidable-boundary packet concerns a checker boundary, a confluence-audit packet concerns rewrite or normalization audit,

and a normal-false-exclusion packet concerns one local false-exclusion surface. None contains all rows P, R, M, A, T, C, G, N, so no row-preserving bijection can identify it with $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$.

□

Later Lean work supplies the Nontrivial and FieldFaithful instances for $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$ in TasteGate.lean. Those instances must read the same finite carrier rows P, R, M, A, T, C, G, N and may not add total truth, unrestricted choice, quotient collapse, halting closure, or a closed meta-loop classifier.

Falsifiable prediction: Any accepted consumer route that reads total truth, choice, quotient collapse, or halting closure without passing through the open meta-loop refusal row refutes the packet.

Independence witness: quotientsoundnessboundary, auditgatefailurewitness, metacicdecidable-boundary, metacicconfluenceaudit, normalfalseexclusion: none is bijective because this packet jointly carries proof-pattern discipline and open-meta-loop refusal rather than only one gate or one checker boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{LogicContradictionMetaLoop}^{\uparrow}}$.

Constructive story: A $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$ packet is generated from finite proof-pattern discipline, local-refutation evidence, open meta-loop refusal, audit-gate routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LogicContradictionMetaLoop}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1261.1, Definition 1261.2, Definition 1261.5, Definition 1261.6, and the existing TasteGate marker bind the finite carrier, NameCert obligations, nonescape surface, and sibling dependency route as the obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LogicContradictionMetaLoop}^{\uparrow}}, \mathsf{unformalized})$

Ledger evidence: BEDC.Meta.DiscoveryDeltaLedger.logicContradictionMetaLoopDeltaLedger

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, total truth, unrestricted choice, quotient collapse, halting closure, global proof search, or a public standard bridge.

Upgrade path: Scoped closure requires checked carrier admission, open meta-loop refusal, audit-gate routing, transport stability, route replay, provenance, local naming, TasteGate instances, and non-escape for the same finite packet.

Chapter 1262

A Concrete Naming Certificate for $\mathsf{ForwardBindingGapLedger}^{\uparrow}$

The $\mathsf{ForwardBindingGapLedger}^{\uparrow}$ packet realizes forward-binding belief as a finite NameCert surface over displayed closed-observation, GAP-boundary, refusal-ledger, apophatic-socket, and belief rows. It is deliberately composite: the carrier assembles the closed observation record of chapter 616, the source/refusal boundary of chapter 1006, the axiom-refusal ledger of chapter 1057, the socket boundary of chapter 536, and the observation-update surface of chapter 289. Its role is not to present a new atomic TasteGate object, but to package the present commitment row and the visible GAP row that keep future universal-closure use auditable.

Definition 1262.1 (Forward-binding GAP ledger carrier)**.** *A* $\mathsf{ForwardBindingGapLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, R, G, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the forward-binding commitment row, recording the present use of a universal-closure claim whose witness is not wholly contained in the current record;*
2. *R is the finite record ledger supplied by the closed-observation surface;*
3. *G is the GAP socket row that keeps the unsupported universal-closure part visible;*
4. *S is the noninternalization and refusal row, routing hidden substrate-axiom, hidden induction-principle, and internal-object readings to the displayed refusal surface;*
5. *H records componentwise* hsame *transports for K, R, G, S and for the structural rows;*
6. *C records the displayed* Cont *routes from commitment use to record readback, GAP-socket exposure, refusal readback, and downstream citation;*
7. *P records* Pkg *provenance over* $\mathsf{ClosedObservationSystem}^{\uparrow}$, $\mathsf{GapClosureBoundary}^{\uparrow}$, $\mathsf{AxiomRefusalLedger}^{\uparrow}$, $\mathsf{ApophaticSocket}^{\uparrow}$, $\mathsf{Belief}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ForwardBindingGapLedger}^{\uparrow}}$ *row.*

The carrier exports only the finite commitment, record, GAP-socket, refusal, transport, route, provenance, and naming rows. It exports no universal closure, hidden induction principle, substrate axiom, or internal object for T.

Lean4 ✓ `BEDC.Derived.ForwardBindingGapLedgerUp.ForwardBindingGapLedgerTasteGate single carrier alignment`

Theorem 1262.2 (Forward-binding GAP ledger NameCert obligations)**.** *For the carrier of Definition 1262.1, the local* $\mathsf{NameCert}_{\mathsf{ForwardBindingGapLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for* $F = (K, R, G, S, H, C, P, N)$*, forward-binding commitment exposure through* K*, finite record accountability through* R*, GAP-socket preservation through* G*, refusal and noninternalization through* S*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the displayed carrier. The rows K, R, G, S, H, C, P, N are the only rows available to the local certificate.

Read the closed-observation and GAP-boundary siblings. The closed-observation chapter supplies the finite record ledger R, while the GAP-boundary chapter keeps a closure request on the displayed source/refusal split rather than on an internal universal-closure row.

Attach the refusal and socket rows. The axiom-refusal and apophatic-socket siblings make unsupported supply visible as a refusal surface, and the belief sibling supplies the present commitment row without changing it into a substrate theorem.

Finally use H, C, P, N. These rows transport, replay, package, and name the same finite packet, so the NameCert obligations are exhausted by the displayed route. □

Lean4 ✓ `BEDC.Derived.ForwardBindingGapLedgerUp.ForwardBindingGapLedgerNameCertObligations`

Theorem 1262.3 (Forward-binding GAP ledger noninternalization)**.** *Every accepted* $\mathsf{ForwardBindingGapLedger}^{\uparrow}$ *packet keeps the forward-binding commitment outside substrate-internal theoremhood. A downstream consumer may cite* K, R, G, S, H, C, P, N *as a finite commitment ledger, but it receives no universal closure, hidden induction principle, substrate axiom, hidden theorem, host assumption, or internal object for* T*.*

Lean4 ✓ `BEDC.Derived.ForwardBindingGapLedgerUp.ForwardBindingGapLedgerNoninternalization`

Proof. Begin with the carrier inventory of Definition 1262.1. The commitment row K is paired with the finite record ledger R and the GAP socket G before any downstream citation can use it.

Use the GAP-boundary refusal surface of Definition 1006.2 and Definition 1006.3. Unsupported closure requests remain on the displayed GAP and refusal rows rather than becoming internal universal closure.

Now apply the axiom-refusal noninternalization theorem, Definition 1057.3. The refusal row S is therefore a visible ledger row, not a consumable axiom or hidden theorem.

The remaining support rows H, C, P, N only preserve that route under transport, replay, provenance, and local naming. Hence a consumer can cite the finite forward-binding ledger but cannot extract an internal object for T or any hidden closure principle from it. □

Theorem 1262.4 (Forward-binding GAP ledger sibling dependency)**.** *The* $\mathsf{ForwardBindingGapLedger}^{\uparrow}$ *carrier depends on the joint availability of closed-observation records, GAP-boundary refusal, axiom-refusal noninternalization, apophatic-socket exposure, and belief commitment rows. No one sibling among* $\mathsf{ClosedObservationSystem}^{\uparrow}$*,* $\mathsf{GapClosureBoundary}^{\uparrow}$*,* $\mathsf{AxiomRefusalLedger}^{\uparrow}$*,* $\mathsf{ApophaticSocket}^{\uparrow}$*, or* $\mathsf{Belief}^{\uparrow}$ *carries all of* K, R, G, S, H, C, P, N*, and no row-preserving reduction to one sibling preserves the local* $\mathsf{NameCert}_{\mathsf{ForwardBindingGapLedger}^{\uparrow}}$ *surface.*

Proof. Compare first with the closed-observation and belief siblings. $\mathsf{ClosedObservationSystem}^{\uparrow}$ supplies finite record rows, and $\mathsf{Belief}^{\uparrow}$ supplies observation-update commitment rows, but neither by itself carries the GAP socket and refusal ledger required to keep forward binding noninternal.

Compare next with the GAP-boundary, axiom-refusal, and apophatic-socket siblings. They expose unsupported closure requests, refusal rows, and socket boundaries, but none of them also carries the present commitment row K together with the closed record ledger R and the full structural support H, C, P, N.

Thus the chapter is a composite NameCert surface. The dependence on its siblings is visible in the carrier, and the composite packet refuses universal closure, hidden induction, substrate axioms, and internal objects for T precisely because no single sibling row can replace the whole finite route. □

Lean4 ✓ `BEDC.Derived.ForwardBindingGapLedgerUp.ForwardBindingGapLedgerCarrier sibling dependency`

Closure status for $\mathsf{NameCert}_{\mathsf{ForwardBindingGapLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ForwardBindingGapLedger}^{\uparrow}$ packet is generated from a forward-binding commitment row, finite closed-observation record ledger, GAP socket, noninternalization and refusal row, componentwise hsame transports, displayed continuation routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ForwardBindingGapLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1262.1, Definition 1262.2, Definition 1262.3, and Definition 1262.4 bind the finite composite carrier, NameCert obligations, noninternalization boundary, and sibling dependency surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ForwardBindingGapLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close universal future cases, export an induction principle, supply a substrate axiom, internalize T, assert Lean verification, or bridge to a standard schema.

Upgrade path: Obligation closure requires checked carrier admission, record-ledger accountability, GAP-socket preservation, refusal noninternalization, transport stability, route replay, provenance, and local naming for the same finite composite packet.

Chapter 1263

A Concrete Naming Certificate for $\mathsf{CofinalStreamTailSelector}^{\uparrow}$

The $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ packet records the finite cofinal-window route used by the Real and Completion construction of chapter 9238. It starts from a precision request, opens a displayed $\mathsf{StreamName}^{\uparrow}$ tail window, hands that window through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ readback rows, reaches the $\mathsf{Real}^{\uparrow}$ seal, and records selector provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming in one finite BHist carrier. The packet is a concrete NameCert surface for the L10 construction order of section 9467.12; it is not a quotient stream, host-selected limit, ambient completeness principle, countable-choice rule, or hidden selector.

The one-source tail witness of chapter 458, the dyadic cofinal route of chapter 680, and the diagonal consumer route of chapter 697 are sibling surfaces. The present packet binds their shared cofinal-window role into one StreamName-tail selector carrier before any $\mathsf{Real}^{\uparrow}$ consumer can read the completion-facing seal.

Definition 1263.1 (Cofinal StreamName tail selector carrier)**.** *A* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (\epsilon, W, R, D, A, \sigma, H, C, P, N)$$

with the following displayed rows:

1. *ϵ is the positive precision request made by the completion-facing consumer;*
2. *W is the finite cofinal* $\mathsf{StreamName}^{\uparrow}$ *tail window opened at that request;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row read from the displayed window;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row that records the finite dyadic bounds consumed by the handoff;*
5. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, R, D are displayed;*
6. *σ records selector provenance: the request, cofinal window index, selected tail segment, and sibling selector rows used by the packet;*
7. *H records componentwise* hsame *transports for the request, window, regular handoff, dyadic readback, seal, selector provenance, package provenance, and local naming rows;*
8. *C records the displayed* Cont *route from ϵ through W, R, D, σ into A;*

9. *P is the* Pkg *provenance over* CofinalStreamTailSelector$^{\uparrow}$, RegularCauchyTailSelector$^{\uparrow}$, DyadicCofinalTailSelector$^{\uparrow}$, DiagonalTailSelector$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and local certificate rows;*

10. *N is the local* NameCert$_{\text{CofinalStreamTailSelector}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the visible rows $\epsilon, W, R, D, A, \sigma, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorCarrier route rows`

Theorem 1263.2 (Cofinal StreamName tail selector NameCert obligations)**.** *The local* NameCert$_{\text{CofinalStreamTailSelect}}$ *surface for Definition 1263.1 consists of carrier admission for $Q = (\epsilon, W, R, D, A, \sigma, H, C, P, N)$, precision-request exposure through ϵ, cofinal* StreamName$^{\uparrow}$ *tail-window exposure through W,* RegSeqRat$^{\uparrow}$ *handoff through R,* DyadicRatCore$^{\uparrow}$ *readback through D,* Real$^{\uparrow}$ *seal delivery through A, selector provenance through σ, componentwise* hsame *stability through H, displayed* Cont *route replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from the displayed tuple in Definition 1263.1. The request, cofinal window, regular handoff, dyadic readback, seal, selector provenance, transports, routes, provenance, and naming row are all visible coordinates of one finite packet.

The selector obligations are read in order. The precision request ϵ opens only the displayed StreamName tail window W, the RegSeqRat handoff R and dyadic readback D are both downstream of that finite window, and the selector provenance row σ records the sibling selector rows used by the same route.

The RealUp seal row A is downstream of W, R, D, σ, while H, C, P, N provide transport, route replay, provenance, and local naming. Since the carrier has no coordinate for quotient streams, host-selected limits, countable choice, hidden tail selection, or ambient completeness, these rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorCarrier namecert obligations`

Theorem 1263.3 (Cofinal StreamName tail selector seal order)**.** *For an accepted* CofinalStreamTailSelector$^{\uparrow}$ *carrier*

$$Q = (\epsilon, W, R, D, A, \sigma, H, C, P, N),$$

every completion-facing read of the Real$^{\uparrow}$ *seal row A first passes through the finite cofinal* StreamName$^{\uparrow}$ *tail window W, the* RegSeqRat$^{\uparrow}$ *handoff row R, the* DyadicRatCore$^{\uparrow}$ *readback row D, and the selector provenance row σ. The seal route cannot skip directly from the precision request to a host-selected limit.*

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorSealOrder`

Proof. Project the carrier. The seal row A appears only after the window, handoff, dyadic readback, and selector provenance rows in the displayed tuple.

Use the NameCert obligations of Definition 1263.2. They force any accepted read of the seal to preserve the same request, finite window, regular handoff, dyadic readback, selector provenance, transports, continuation route, package provenance, and local naming row.

Thus every completion-facing seal read factors through W, R, D, σ before A is available. There is no coordinate in the carrier for a direct host limit or an ambient completeness argument. □

Theorem 1263.4 (Cofinal StreamName tail selector TasteGate obligation)**.** *The taste gate for* CofinalStreamTailSelector$^{\uparrow}$ *requires Lean to provide the local* Nontrivial *and* FieldFaithful *instances in* lean4/BEDC/Derived/CofinalStreamTailSelectorUp/TasteGate.lean*. The intended instances must read the same finite carrier rows* $\epsilon, W, R, D, A, \sigma, H, C, P, N$ *and may not add a quotient stream, host limit, ambient completeness theorem, countable-choice selector, or hidden tail oracle.*

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorTasteGate single carrier alignment`

Proof. The carrier of Definition 1263.1 supplies the finite support on which the taste gate is allowed to act. Nontriviality is witnessed only by the presence of the displayed request-to-window-to-seal route, and field faithfulness is witnessed only by the listed rows and their componentwise transports.

Any Lean instance for the taste gate must therefore be local to the same carrier surface. Adding quotient streams, host limits, ambient completeness, countable choice, or hidden selector rows would create data not present in Q and would fail the NameCert obligation surface of Definition 1263.2. □

Theorem 1263.5 (Cofinal StreamName tail selector obligation surface)**.** *For an accepted* CofinalStreamTailSelector$^{\uparrow}$ *carrier* $Q = (\epsilon, W, R, D, A, \sigma, H, C, P, N)$*, the obligation surface exposes the precision request* ϵ*, the displayed* StreamName$^{\uparrow}$ *tail window* W*, the* RegSeqRat$^{\uparrow}$ *handoff* R*, the* DyadicRatCore$^{\uparrow}$ *readback* D*, the* Real$^{\uparrow}$ *seal* A*, the selector provenance row* σ*, the componentwise* hsame *row* H*, the displayed* Cont *route* C*, the package provenance* P*, and the local naming row* N *in one finite packet. The surface is read through the sibling routes of chapter 458, chapter 680, chapter 697, and chapter 38.*

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorObligationSurface`

Proof. Project the carrier of Definition 1263.1. The request, tail window, regular handoff, dyadic readback, seal, provenance, transport, replay, package, and name are all visible coordinates of one finite packet.

The proof-route order is already fixed by the carrier: the precision request opens the displayed StreamName tail window, the RegSeqRat and DyadicRatCore rows follow from that finite window, and the Real seal is downstream of the same route.

The sibling citations identify the shared tail surface, while H, C, P, N preserve the same route componentwise. Since the carrier has no coordinate for quotient streams, host-selected limits, countable choice, hidden tail selection, or ambient completeness, the displayed rows exhaust the obligation surface. □

Theorem 1263.6 (Cofinal StreamName tail selector stream route)**.** *For every accepted* CofinalStreamTailSelector$^{\uparrow}$ *carrier* $Q = (\epsilon, W, R, D, A, \sigma, H, C, P, N)$*, the stream route factors through* W, R, D, σ *before the* Real$^{\uparrow}$ *seal row* A *is public. A consumer may cite the route only after the shared sibling surfaces of chapter 458, chapter 680, chapter 697, and chapter 38 have already displayed the same finite route.*

Proof. Use the obligation surface theorem above. It fixes the displayed rows and places the Real seal downstream of the cofinal StreamName tail window, the regular handoff, and the dyadic readback.

The sibling routes supply the same cofinal-window role in different presentations. Since H, C, P, N only transport, replay, package, and name that route, a consumer cannot bypass the shared finite packet before reading A. □

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorStreamRoute`

Theorem 1263.7 (Cofinal StreamName tail selector real seal nonescape)**.** *For an accepted* CofinalStreamTailSelecto *carrier* $Q = (\epsilon, W, R, D, A, \sigma, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* A *does not export quotient stream identity, host real equality, host-selected limits, countable-choice selection, hidden family limits, or an ambient completeness principle. The seal remains a finite boundary for the same cofinal StreamName route displayed in the sibling tail-selector chapters.*

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorRealSealNonescape`

Proof. Project the carrier. The seal row A is downstream of the finite cofinal tail window W, the regular handoff R, the dyadic readback D, and the selector provenance row σ.

Apply the seal-order theorem of Definition 1263.3. It forces every Real-facing read through the same finite cofinal route before A is available.

Since no extra coordinate is present in the carrier, the seal row cannot export quotient stream identity, host equality, selected limits, countable choice, hidden family limits, or ambient completeness. □

Theorem 1263.8 (Cofinal StreamName tail selector non-escape)**.** *An accepted* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *carrier cannot be used to recover data outside the displayed tuple* $\epsilon, W, R, D, A, \sigma, H, C, P, N$*. In particular, it exports no quotient stream identity, host real equality, host-selected limit, unbounded tail search, countable-choice selector, hidden family limit, or ambient RealUp completeness principle.*

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorNonescape`

Proof. The NameCert obligations identify every row available to a downstream consumer. The precision request, finite StreamName tail window, RegSeqRat handoff, dyadic readback, RealUp seal, and selector provenance rows are the only content rows, and H, C, P, N only transport, replay, package, and name those rows.

Apply Definition 1263.3 to any real-facing read. It forces the read through the finite cofinal window, regular handoff, dyadic readback, and selector provenance before the seal row can be consumed.

Since no additional coordinate is present, the packet has no source for quotient stream identity, host real equality, host-selected limits, unbounded tail search, countable choice, hidden family limits, or an ambient RealUp completeness principle. □

Theorem 1263.9 (Cofinal StreamName tail selector obligation package)**.** *The* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *carrier, local* NameCert *obligations, seal-order theorem, TasteGate obligation, and non-escape theorem assemble the L10 handoff surface over*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

Every completion-facing seal read is therefore routed through the displayed cofinal tail window, regular-sequence handoff, dyadic readback, selector provenance, componentwise transport, continuation route, package provenance, and local naming row. The assembled package gives no bypass through quotient stream equality, host real equality, host-selected limits, countable choice, hidden tail selection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorObligationPackage`

Proof. Use the carrier of Definition 1263.1 and the obligations of Definition 1263.2. These identify the finite rows $\epsilon, W, R, D, A, \sigma, H, C, P, N$ and bind them over the StreamName, RegSeqRat, DyadicRatCore, RealUp, history, transport, continuation, package, and naming surfaces.

Apply Definition 1263.3. It forces every $\mathsf{Real}^{\uparrow}$ seal read through W, R, D, σ before A is available, so the handoff is a finite cofinal-window route rather than a direct host-limit read.

Finally combine the TasteGate obligation of Definition 1263.4 with non-escape from Definition 1263.8. The taste gate may only read the displayed carrier rows, and the non-escape theorem excludes quotient stream equality, countable choice, hidden selectors, and ambient completeness from the exported surface. □

Theorem 1263.10 (Cofinal StreamName tail selector public export)**.** *Every accepted* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *public consumer receives only the precision request, displayed* $\mathsf{StreamName}^{\uparrow}$ *tail window,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, selector provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows of the carrier. The public export is routed through the obligation package, seal order, and non-escape boundary, and it uses the TasteGate site of Definition 1263.4 only as the local finite-carrier discipline.*

Proof. Start with the obligation package of Definition 1263.9. It assembles the carrier, local NameCert obligations, seal-order theorem, TasteGate obligation, and non-escape theorem over the finite rows $\epsilon, W, R, D, A, \sigma, H, C, P, N$.

Apply the seal-order theorem Definition 1263.3. It forces every public read of the $\mathsf{Real}^{\uparrow}$ seal through the precision request, StreamName tail window, RegSeqRat handoff, DyadicRatCore readback, and selector provenance before the seal is visible.

Apply the non-escape theorem Definition 1263.8. It removes quotient stream identity, host real equality, host-selected limits, unbounded tail search, countable choice, hidden family limits, and ambient RealUp completeness from the public surface.

The TasteGate obligation, already recorded at Definition 1263.4, supplies only the local finite-carrier discipline for the same rows. Therefore the accepted public consumer receives exactly the listed BEDC rows and no additional tail-selection or completion principle. □

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorCarrier public export`

Theorem 1263.11 (Cofinal StreamName tail selector scoped route)**.** *For every accepted* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *carrier*

$$Q = (\epsilon, W, R, D, A, \sigma, H, C, P, N),$$

the route

$$\epsilon, W, R, D, A, \sigma, H, C, P, N$$

is scoped over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The precision request* ϵ *opens only the displayed StreamName tail window* W*;* R *and* D *read regular-sequence and dyadic rows from that window;* A *is the terminal Real seal;* σ, H, C, P, N *record selector provenance, componentwise transport, continuation replay, package provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorScopedRoute`

Proof. Start from the carrier and obligation package of Definition 1263.9. They expose exactly the rows $\epsilon, W, R, D, A, \sigma, H, C, P, N$ and list the BEDC surfaces on which those rows may be read.

The carrier order fixes the scope. The request row opens the finite $\mathsf{StreamName}^{\uparrow}$ window; the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ rows are read from that same displayed window; and the $\mathsf{Real}^{\uparrow}$ seal is reached only after these rows and selector provenance are present.

The remaining rows do not introduce new analytic data. They transport, replay, source, and name the same finite route through BHist, hsame, Cont, Pkg, and NameCert, so the accepted packet is scoped by the listed kernel rows. □

Theorem 1263.12 (Cofinal StreamName tail selector window readback scope)**.** *In an accepted* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *carrier* $Q = (\epsilon, W, R, D, A, \sigma, H, C, P, N)$*, the cofinal window row* W *and readback rows* R, D, σ *remain ordered before any consumer read of the* $\mathsf{Real}^{\uparrow}$ *seal row* A*. No accepted route can inspect* A *before the finite window, regular handoff, dyadic readback, and selector provenance have been displayed.*

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorWindowReadbackScope`

Proof. Apply the seal-order theorem Definition 1263.3. It places the Real seal downstream of W, R, D, σ for every completion-facing read.

Use the scoped-route theorem Definition 1263.11 to keep the same ordering inside the BEDC row classes. The rows H, C, P, N only preserve the already displayed route and cannot move the seal ahead of the cofinal window or readback rows. □

Theorem 1263.13 (Cofinal StreamName tail selector public certificate)**.** *The carrier of Definition 1263.1, the obligation package of Definition 1263.9, the seal order of Definition 1263.3, the scoped route of Definition 1263.11, and the window readback scope of Definition 1263.12 export a public certificate for the cofinal-window route over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The certificate exposes only the displayed rows*

$$\epsilon, W, R, D, A, \sigma, H, C, P, N$$

and exports no quotient stream identity, host-selected limit, countable-choice selector, hidden tail oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier and obligation package. They identify the accepted packet as the finite row tuple $\epsilon, W, R, D, A, \sigma, H, C, P, N$ and bind those rows to StreamName, RegSeqRat, DyadicRatCore, RealUp, history, transport, continuation, package, and naming surfaces.

Apply the seal-order theorem to the Real-facing boundary. It places A downstream of the finite cofinal window W, the regular handoff R, the dyadic readback D, and selector provenance σ.

Use the scoped-route theorem and the window-readback scope theorem to make the same ordering public. These results keep the route inside $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert and prevent the seal from moving ahead of the displayed readback rows.

The carrier has no coordinate for quotient stream identity, host-selected limits, countable choice, hidden tail oracles, or ambient Real completeness. Therefore the assembled route is exactly the stated public certificate. □

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorPublicCertificate`

Theorem 1263.14 (Cofinal StreamName tail selector public window transport)**.** *For every accepted* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *carrier*

$$Q = (\epsilon, W, R, D, A, \sigma, H, C, P, N),$$

any public transport of the cofinal selector window preserves the order

$$\epsilon \to W \to R \to D \to \sigma \to A$$

through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The rows* H, C, P, N *only transport, replay, source, and name the same finite route. Such a transport cannot replace the window by quotient stream identity, a host-selected limit, countable choice, a hidden selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the public certificate of Definition 1263.13. It exposes exactly the displayed packet rows and already refuses quotient stream identity, host-selected limits, countable-choice selectors, hidden tail oracles, and ambient Real completeness.

Apply the scoped route of Definition 1263.11. The precision request opens the $\mathsf{StreamName}^{\uparrow}$ window W, the regular and dyadic rows R, D read that window, selector provenance σ remains part of the displayed route, and the $\mathsf{Real}^{\uparrow}$ seal A is reached only afterward.

Use the window readback scope of Definition 1263.12 together with the seal-order theorem of Definition 1263.3. These keep every public transport from moving A ahead of $\epsilon, W, R, D, \sigma$.

The remaining rows H, C, P, N have only transport, replay, source, and naming roles in the same finite packet. They therefore preserve the already displayed route rather than selecting a new tail, adding a limit, or appealing to a completeness principle outside the carrier. □

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorPublicWindowTransport`

Theorem 1263.15 (Cofinal StreamName tail selector bridge surface)**.** *The public certificate of Definition 1263.13 and the public-window transport of Definition 1263.14 determine the exact bridge surface available to any future standard bridge for* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$. *That surface consists of the precision request, cofinal* $\mathsf{StreamName}^{\uparrow}$ *tail window,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback, selector provenance,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows of the accepted carrier.*

No standard bridge may export quotient stream equality, a host-selected limit, a countable-choice selector, a hidden tail oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from this public surface.*

Proof. Start with the public certificate. It exposes exactly the rows $\epsilon, W, R, D, A, \sigma, H, C, P, N$ and refuses quotient stream identity, host-selected limits, countable choice, hidden tail oracles, and ambient Real completeness.

Apply the scoped route, seal-order, and window-readback scope theorems. They place the precision request before the cofinal $\mathsf{StreamName}^{\uparrow}$ window, route $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ readback through that window, keep selector provenance visible, and allow the $\mathsf{Real}^{\uparrow}$ seal only after those rows have been displayed.

Use public-window transport to preserve the same route across any public handoff. The rows H, C, P, N only transport, replay, source, and name the displayed carrier, while the non-escape theorem excludes every off-packet tail selector or completeness principle. Therefore the listed rows are the whole bridge surface available to a future standard bridge. □

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorBridgeSurface`

Theorem 1263.16 (Cofinal StreamName tail selector Real-seal bridge)**.** *Any Real-facing bridge from an accepted* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *packet factors the* $\mathsf{Real}^{\uparrow}$ *seal through the displayed precision request, cofinal* $\mathsf{StreamName}^{\uparrow}$ *tail window,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback, selector provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and*

local NameCert *row. The bridge may cite the public certificate and public-window transport only in this order, and it cannot replace the route by quotient stream equality, a hidden tail selector, a host limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorRealSealBridge`

Proof. Start with the public certificate of Definition 1263.13. It exposes exactly the accepted rows $\epsilon, W, R, D, A, \sigma, H, C, P, N$ and places the Real seal inside the same finite packet as the precision request, cofinal window, regular handoff, dyadic readback, selector provenance, transport, replay, provenance, and local naming row.

Apply the public-window transport theorem of Definition 1263.14. It preserves the order $\epsilon \to W \to R \to D \to \sigma \to A$ across any public handoff, so a Real-facing bridge cannot move the seal ahead of the displayed window or readback rows.

Use the scoped route of Definition 1263.11, the seal-order theorem of Definition 1263.3, and the window-readback scope of Definition 1263.12. These results keep the bridge inside $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert, with A downstream of W, R, D, σ.

Finally apply the bridge-surface theorem of Definition 1263.15. Since that surface has no coordinate for quotient stream equality, hidden tail selectors, host limits, countable choice, or ambient Real completeness, every Real-facing bridge must factor the seal through the displayed finite route. □

Theorem 1263.17 (Cofinal StreamName tail selector bridge stability)**.** *Let a bridge-stable consumer read an accepted* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *packet through the public bridge surface. Then the consumer preserves the displayed order*

$$\epsilon \to W \to R \to D \to \sigma \to A$$

from precision request to $\mathsf{Real}^{\uparrow}$ *seal. It cannot replace any segment of that route by quotient stream equality, a host limit, countable choice, a hidden selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the public certificate of Definition 1263.13. It exposes exactly the accepted carrier rows and already refuses quotient stream identity, host-selected limits, countable-choice selectors, hidden tail oracles, and ambient Real completeness.

Apply public-window transport, Definition 1263.14. This preserves the order $\epsilon \to W \to R \to D \to \sigma \to A$ across public handoffs, so a bridge-stable consumer cannot move the seal ahead of the displayed window, handoff, readback, or selector-provenance rows.

Finally use the bridge surface and Real-seal bridge, Definition 1263.15 and Definition 1263.16. These force the bridge to read the same finite surface before the $\mathsf{Real}^{\uparrow}$ seal is consumed, and the listed excluded objects have no coordinate in that surface. □

Lean4 ✓ `BEDC.Derived.CofinalStreamTailSelectorUp.CofinalStreamTailSelectorCarrier bridge stability`

Falsifiable prediction: A selector packet that lacks a displayed cofinal StreamName tail window is not an accepted CofinalStreamTailSelectorUp carrier.

Independence witness: regularcauchytailselector, dyadiccofinaltailselector, diagonaltailselector, realcompletionselectorseal: these siblings expose tail, dyadic, diagonal, or seal rows separately, while CofinalStreamTailSelectorUp binds all of them with StreamName cofinal-window selection and RealUp seal handoff, so no row-preserving bijection exists.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalStreamTailSelector}^{\uparrow}}$.

Constructive story: A CofinalStreamTailSelector$^{\uparrow}$ packet is generated from a precision request, a displayed cofinal StreamName tail window, RegSeqRat handoff, DyadicRatCore readback, RealUp seal delivery, selector provenance, componentwise hsame transports, displayed Cont routes, package provenance, and a local naming row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CofinalStreamTailSelector}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1263.10 exports the accepted cofinal-window selector packet as a public Real-completion surface over the displayed StreamName, RegSeqRat, DyadicRatCore, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CofinalStreamTailSelector}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, RealUp completeness, quotient stream equality, host real limits, countable choice, hidden tail selection, or a public standard bridge.

Upgrade path: Bridged closure requires a standard bridge for the public cofinal-window selector surface without quotient streams, host limits, countable choice, hidden selectors, or ambient RealUp completeness.

Chapter 1264

A Concrete Naming Certificate for $\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$

The $\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$ packet is the finite Real-and-Completion handoff that binds two cofinal modulus schedules to one normalized shared-window route. It sits after the normalized comparison surface of chapter 778, consumes the cofinal modulus seal row of chapter 1198, and hands its displayed rows to the four Real-and-Completion anchors chapter 291, chapter 126, chapter 301, and chapter 38. The packet is a terminal finite NameCert handoff for a paired cofinal route; it is not a quotient of regular streams, a host equality of reals, a selected limiting representative, a hidden tail oracle, or an ambient completeness principle.

Definition 1264.1 (Cofinal modulus normalization seal carrier)**.** *A* $\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, M, W, D, R, E, H, C, P, L, N)$$

with the following displayed rows:

1. *A and B are the two cofinal modulus schedules whose terminal Real route is being normalized.*
2. *M is the accepted* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *row that records the paired cofinal modulus surface.*
3. *W is the normalized shared* $\mathsf{StreamName}^{\uparrow}$ *window row obtained after the regular Cauchy modulus normalizer has exposed the common window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger read on that shared window.*
5. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row over the same normalized window and tolerance data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after M, W, D, R have been displayed.*
7. *H stores componentwise* hsame *transport for A, B, M, W, D, R, E and the local support rows.*
8. *C stores the displayed* Cont *replay from the paired cofinal schedules through M, then through W, D, R, E, and then into the local certificate.*
9. *P is the* Pkg *provenance over* $\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$, $\mathsf{CofinalModulusSeal}^{\uparrow}$, $\mathsf{RegularCauchyModulusNor}$ $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *L is the terminal ledger row that records the Real-and-Completion handoff boundary.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for side-specific modulus replacement, quotient regular streams, host real equality, selected limits, detached completion evidence, countable choice, or ambient completeness.

Definition 1264.2 (Cofinal modulus normalization seal classifier)**.** *Two accepted* $\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$ *carriers classify together exactly when their paired cofinal schedules, cofinal modulus seal row, normalized shared window, dyadic tolerance ledger, paired regular readback, terminal Real seal, componentwise* hsame *transports, displayed* Cont *replay,* Pkg *provenance, terminal ledger, and local naming row agree componentwise along the same normalized handoff route. The classifier does not identify packets by comparing host modulus functions, by quotienting regular streams, by forgetting the shared window, or by replacing the terminal seal with an external completeness claim.*

Theorem 1264.3 (Cofinal modulus normalization seal NameCert obligations)**.** *For every accepted* $\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$ *carrier*

$$S = (A, B, M, W, D, R, E, H, C, P, L, N),$$

the local $\mathsf{NameCert}_{\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}}$ *surface consists exactly of carrier admission, paired-schedule exposure through* A, B*, cofinal modulus seal exposure through* M*, normalized shared-window coverage through* W*, dyadic tolerance coverage through* D*, paired regular readback through* R*, Real seal coverage through* E*, componentwise transport through* H*, displayed continuation replay through* C*, package provenance through* P*, terminal handoff ledgering through* L*, local naming through* N*, and non-escape for side-specific modulus replacement, quotient streams, host equality, selected limits, detached completion evidence, countable choice, and ambient completeness.*

Proof. Carrier admission is projection from Definition 1264.1. The tuple displays two cofinal schedules, one cofinal modulus seal row, one normalized shared window, one dyadic ledger, one paired readback, one Real seal, transport, replay, provenance, terminal ledgering, and the local name.

The paired-schedule and cofinal-seal obligations read A, B, M before any terminal Real handoff is available. The sibling normalizer of chapter 778 supplies the shared-window discipline: once M is fixed, the route exposes one W, one D, and one R rather than two side-specific windows.

The Real-and-Completion anchors then determine the terminal handoff. The $\mathsf{StreamName}^{\uparrow}$ row supplies finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies tolerance rows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies readbacks, and $\mathsf{Real}^{\uparrow}$ supplies the seal row, all inside the same displayed packet.

Finally H, C, P, L, N repack the displayed route as a local NameCert surface. Since the carrier lacks side-specific modulus replacement, quotient streams, host equality, selected limits, detached completion evidence, countable choice, and ambient completeness coordinates, the listed rows exhaust the obligation surface. □

Lean4 ✓ `BEDC.Derived.CofinalModulusNormalizationSealUp.CofinalModulusNormalizationSeal namecert obligations`

Theorem 1264.4 (Cofinal modulus normalization seal Real-completion handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$ *carrier factors through the finite route*

$$(A, B) \longmapsto M \longmapsto (W, D, R) \longmapsto (E, H, C, P, L, N).$$

In particular, any diagonal-limit route that consumes two cofinal schedules reads the normalized shared-window row before it reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal.*

Lean4 ✓ `BEDC.Derived.CofinalModulusNormalizationSealUp.CofinalModulusNormalizationSeal real completion handoff`

Proof. Start with the NameCert obligations. They expose A, B as the paired cofinal schedules and M as the only cofinal modulus seal row available to the consumer.

Next apply the shared-window discipline inherited from chapter 778. The route from M to the Real-facing surface is forced through W, D, R, so the consumer obtains one $\mathsf{StreamName}^{\uparrow}$ window, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and one paired $\mathsf{RegSeqRat}^{\uparrow}$ readback.

The terminal rows E, H, C, P, L, N then seal the handoff. The $\mathsf{Real}^{\uparrow}$ row is downstream of the normalized shared-window readback, and the remaining rows only transport, replay, source, ledger, and name that displayed route. Thus no diagonal-limit consumer can reach the Real seal before factoring through the normalized shared-window row. □

Falsifiable prediction: If the normalized cofinal modulus seal is atomic, then any RealUp diagonal-limit route consuming two cofinal schedules factors through its normalized shared-window row before reaching the RealUp seal.

Independence witness: regular-cauchy-modulus-normalizer, cofinal-tail-budget, dyadic-cofinal-tail-selector, real-tail-agreement-seal: the new carrier binds paired cofinal schedules, normalized shared-window data, and terminal RealUp seal handoff in one packet, while each sibling lacks at least one of those rows.

Lean follow-up provides explicit $\mathsf{Nontrivial}\ \mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{CofinalModulusNo}$ instances in `lean4/BEDC/Derived/CofinalModulusNormalizationSealUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}}$ **.**

Constructive story: The cofinal modulus normalization seal is generated from $BHist$ rows that record paired cofinal schedules, normalized shared-window data, a normalization classifier, and the RealUp seal handoff that consumes the normalized route. The carrier first reads the cofinal modulus evidence, then applies the classifier to identify the normalized seal, and finally permits Cont extensions only when Real and completion consumers see that same normalized packet. The $hsame$ relation transports the normalized seal without changing the cofinal route. The prediction and independence witness identify one shared normalized carrier, rather than two independent routes to Real and completion surfaces.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the cofinal modulus normalization-seal carrier, classifier, NameCert obligations, Real-completion handoff theorem, falsifiable prediction, and independence witness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim a separate completion operator, quotient-stream equality, or normalization outside the displayed cofinal modulus route.

Upgrade path: Reaching obligationClosure requires formal normalized cofinal-modulus rows and checked Real-completion handoff through the classifier.

Chapter 1265

A Concrete Naming Certificate for $\mathsf{ClosureStatusReference}^{\uparrow}$

The $\mathsf{ClosureStatusReference}^{\uparrow}$ packet realizes the closure-status reference layer of subsection 9462.35.8 as a finite NameCert carrier for registry-bound export status. It sits after the registry export surface of chapter 1216, the consistency gate of chapter 1224, the refusal registry of chapter 1248, the theorem-gap registry of chapter 1246, and the concept registry surface of chapter 1252. Those siblings expose export rows, consistency checks, refusal rows, theorem gaps, and concept entries; this packet binds the displayed closure-status reference that caps the strength of each exported registry read.

Definition 1265.1 (Closure status reference carrier)**.** *A* $\mathsf{ClosureStatusReference}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, T, F, L, B, N, U, H, C, P, Q)$$

with the following displayed rows:

1. *S is the constructive-story row describing how the target packet is generated from finite BEDC data.*
2. *T is the theory-closure row recording the paper-side grade and its closed scope.*
3. *F is the formal-status row recording the Lean-side grade and the canonical target when one is displayed.*
4. *L is the Lean-target row, empty exactly when the reference records an unformalized or statement-only site.*
5. *B is the bridge-status row recording whether no bridge, a paper bridge, or a checked bridge is available.*
6. *N is the not-claimed row recording the surfaces that the reference refuses to export.*
7. *U is the next-grade row recording the route needed before the registry may advertise a stronger status.*
8. *H stores componentwise* hsame *transport for S, T, F, L, B, N, U.*
9. *C stores displayed* Cont *replay from registry export rows through the closure-status bound.*
10. *P is the* Pkg *provenance over* $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, $\mathsf{RefusalRegistry}^{\uparrow}$, $\mathsf{TheoremGapRegistry}^{\uparrow}$, $\mathsf{ConceptRegistrySurface}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

11. *Q is the local* $\mathsf{NameCert}_{\mathsf{ClosureStatusReference}^{\uparrow}}$ *row.*

The carrier has no coordinate for a registry export stronger than the displayed reference, for merging the theory and verification axes, for erasing the bridge-status row, or for bypassing the not-claimed and next-grade rows.

Theorem 1265.2 (Closure status reference export bound)**.** *Every registry export read through an accepted* $\mathsf{ClosureStatusReference}^{\uparrow}$ *carrier is bounded by the displayed rows*

$$S, T, F, L, B, N, U, H, C, P, Q.$$

In particular, an export row cannot report a theory grade stronger than T, a formal grade stronger than F, or a bridge grade stronger than B unless the same carrier also replaces the reference rows and their next-grade route.

Proof. Project the carrier of Definition 1265.1. The only status coordinates are the theory row T, formal row F, Lean-target row L, bridge row B, not-claimed row N, and next-grade row U.

Read the registry siblings through C and P. The export surface supplies the public read, the consistency gate checks it against the same reference, the refusal and theorem-gap registries record blocked or open surfaces, and the concept registry supplies the named target row.

Since H, C, P, Q only transport, replay, source, and name those displayed rows, no consumer receives an extra status coordinate. Any stronger export would need a row outside R, so it is not accepted by this carrier. □

Theorem 1265.3 (Closure status reference nonescape)**.** *An accepted* $\mathsf{ClosureStatusReference}^{\uparrow}$ *packet exports only constructive story, two-axis status, Lean-target display, bridge status, not-claimed surface, next-grade route, transport, replay, provenance, and local naming. It does not export theorem truth, global registry correctness, host proof search, bridge completion, or status promotion outside those displayed fields.*

Proof. Inspect the fields of Definition 1265.1. They list the constructive story row, theory-closure row, formal-status row, Lean-target row, bridge-status row, not-claimed row, next-grade row, and structural support rows.

Apply Definition 1265.2. The registry export can read only those rows, and the consistency gate can compare only against the same displayed reference.

The excluded claims would require a truth row, global-correctness row, host-search row, checked-bridge row, or status-promotion row not present in R. Hence they cannot escape through the $\mathsf{ClosureStatusReference}^{\uparrow}$ carrier. □

Falsifiable prediction: A registry export that reports a status stronger than the displayed closure-status reference is not accepted by the $\mathsf{ClosureStatusReference}^{\uparrow}$ carrier.

Independence witness: registryexportsurface, registryexportconsistencygate, refusalregistry, theoremgapregistry, conceptregistrysurface: the registry export surface lacks the full constructive-story and next-grade packet, the consistency gate lacks the not-claimed and bridge-status rows, the refusal registry lacks positive two-axis status, the theorem-gap registry lacks the complete closure reference, and the concept registry surface lacks the export-bound reference; none carries the full constructive-story, two-axis status, bridge-status, not-claimed, and next-grade packet.

The Lean TasteGate follow-up must include explicit $\mathsf{Nontrivial}\ \mathsf{ClosureStatusReference}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ClosureStatusReference}^{\uparrow}$ instances in `lean4/BEDC/Derived/ClosureStatusReferenceUp/TasteGate.`

The proofs must exhibit a witness pair for the carrier and prove field projections for $S, T, F, L, B, N, U, H, C, P, Q$ so the two axes, bridge status, not-claimed row, and next-grade route remain separate.
Lean4 ✓ `BEDC.Derived.ClosureStatusReferenceUp.ClosureStatusReferenceTasteGate single carrier alignment`

Theorem 1265.4 (Closure status reference obligation surface)**.** *For every accepted* $\mathsf{ClosureStatusReference}^{\uparrow}$ *carrier* $R = (S, T, F, L, B, N, U, H, C, P, Q)$*, the obligation surface consists exactly of carrier admission, two-axis status separation, Lean-target display, bridge-status row, not-claimed row, next-grade route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ClosureStatusReference}^{\uparrow}}$ *row. In particular,* T *and* F *remain separate,* B *remains a visible bridge-status coordinate,* N *remains the refusal boundary, and* U *remains the only next-grade route.*

Proof. Project the carrier of Definition 1265.1. The displayed rows $S, T, F, L, B, N, U, H, C, P, Q$ are the only accepted coordinates for the reference.

Use Definition 1265.2. A registry export is bounded by the same theory row T, formal row F, Lean-target row L, bridge row B, not-claimed row N, and next-grade row U, so no field can be promoted by replay alone.

Finally apply Definition 1265.3. Transport by H, replay by C, provenance by P, and naming by Q preserve the displayed rows but cannot add theorem truth, bridge completion, status promotion, or global registry correctness. The listed rows therefore exhaust the local obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosureStatusReference}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosureStatusReference}^{\uparrow}$ packet is generated from constructive-story, theory-closure, formal-status, Lean-target, bridge-status, not-claimed, next-grade, transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClosureStatusReference}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1265.1, Definition 1265.2, Definition 1265.3, and Definition 1265.4 bind the mature paper package from the carrier, export-bound, nonescape, obligation-surface, bridge-status reference, not-claimed row, and next-grade route; Lean verification is recorded separately by the TasteGate carrier-alignment target.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClosureStatusReference}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.ClosureStatusReferenceUp.ClosureStatusReferenceTasteGate\_single\_carrier\_alignment`

Bridge status: paperBridge

Origin: ai

Not claimed: This chapter does not close bridge checking, theorem truth, global registry correctness, host proof search, or status promotion outside the displayed reference.

Upgrade path: The remaining upgrade is a machine-checked standard bridge for the displayed closure-status reference rows, not an additional paper bridge.

Chapter 1266

A Concrete Naming Certificate for FiniteObservationLock$^{\uparrow}$

The FiniteObservationLock$^{\uparrow}$ packet realizes the subject-free observation thesis of section 9462.22 as a finite NameCert carrier. It sits beside the real observation budget of chapter 611, the finite observation-budget selector of chapter 782, and the observation-budget limiter of chapter 903. Those siblings expose consumer service, selected finite budgets, and capped window routes; this packet locks the observation itself to a displayed continuation, history-sameness comparison, finite budget, readback, and no-subject ledger before any Real- or Completion-facing route may consume it.

Definition 1266.1 (Finite observation lock carrier)**.** *A* FiniteObservationLock$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, D, Z, Q, W, R, B, U, H, C, P, N)$$

with the following displayed rows:

1. *A is the antecedent history row of the observed continuation;*
2. *D is the displayed distinction or continuation-tail row;*
3. *Z is the successor history row reached from A through D;*
4. *Q is the subject-free ledger row recording that the observation signature contains no observer-substance parameter, owner map, or separate viewpoint carrier;*
5. *W is the finite* StreamName$^{\uparrow}$ *window surface through which the observation becomes readable by finite consumers;*
6. *R is the readback row consumed by* RegSeqRat$^{\uparrow}$ *or another finite observation reader after W is displayed;*
7. *B is the finite observation-budget row supplied through* RealObservationBudget$^{\uparrow}$, FiniteObservationBudgetSelector$^{\uparrow}$ *or* ObservationBudgetLimiter$^{\uparrow}$*;*
8. *U is the downstream use row for the Real- or Completion-facing consumer;*
9. *H records componentwise* hsame *transport for A, D, Z, Q, W, R, B, U and the local certificate row;*
10. *C records displayed* Cont *replay from A through D to Z, and from the locked observation row through W, R, B to U;*

11. *P is the* Pkg *provenance over* $\mathsf{FiniteObservationLock}^{\uparrow}$, $\mathsf{RealObservationBudget}^{\uparrow}$, $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$, $\mathsf{ObservationBudgetLimiter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationLock}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden subject, host observation, quotient stream, selected limit, ambient completeness principle, detached readback, or observer identity outside the finite packet L.

Theorem 1266.2 (Finite observation lock NameCert obligations)**.** *For the carrier of Definition 1266.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationLock}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed packet $L = (A, D, Z, Q, W, R, B, U, H, C, P, N)$;*
2. *continuation and history-sameness lock, requiring the observed event to be read through the displayed* $\mathsf{Cont}(A, D, Z)$ *route and transported only by the componentwise* hsame *row H;*
3. *finite budget and readback lock, requiring W, R, B to be displayed before the downstream use row U is consumed;*
4. *no-subject ledger exposure, requiring Q to block subject-substance parameters, owner maps, viewpoint carriers, and host observation rows;*
5. *non-escape, excluding hidden subjects, quotient streams, selected limits, ambient completeness, detached readbacks, and observer identities not carried by the finite packet.*

Proof. Carrier admission is projection from the packet in Definition 1266.1. The visible observation rows are $A, D, Z, Q, W, R, B, U, H, C, P, N$ and there is no other coordinate.

The continuation and history-sameness lock reads the observation as the displayed route from A through D to Z. The transport row H can only compare the displayed rows componentwise, so it preserves the locked observation rather than creating a hidden observer surface.

The finite budget and readback lock then routes finite consumers through W, R, B before U is available. The sibling budget surfaces provide window service, selected finite budgets, and limiter caps, but the lock packet requires those rows to remain attached to the same continuation event.

The no-subject ledger row Q records the negative side of subject-free observation. It refuses a subject parameter, an owner map, a separate viewpoint carrier, and a host observation row because none is part of the accepted carrier.

Finally, C, P, N replay, source, and name the same rows. Since the carrier contains no quotient stream, selected limit, ambient completeness principle, detached readback, or external observer identity coordinate, the five obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.FiniteObservationLockUp.FiniteObservationLockTasteGate single carrier alignment`

Theorem 1266.3 (Finite observation lock consumer route)**.** *Every* $\mathsf{Real}^{\uparrow}$*, completion-facing, finite-budget, or observer-ledger consumer of an accepted* $\mathsf{FiniteObservationLock}^{\uparrow}$ *packet factors through the finite route*

$$A, D, Z, Q, W, R, B, U, H, C, P, N.$$

The consumer receives the displayed continuation, the no-subject ledger row, finite window and readback rows, the finite budget row, the downstream use row, and the structural transport, replay, provenance, and local naming rows. It receives no hidden subject, host observation, quotient stream, selected limit, ambient completeness datum, detached readback, or observer identity outside the packet.

Proof. Start with the accepted carrier $L = (A, D, Z, Q, W, R, B, U, H, C, P, N)$. The continuation route A, D, Z is the only observation event in the carrier, and Q is the only row that records subject-free admissibility.

Apply Definition 1266.2. The finite budget and readback lock forces any downstream use to pass through W, R, B before U is read, while the continuation and history-sameness lock keeps those rows attached to the same displayed observation.

The Real observation budget, finite observation-budget selector, and observation-budget limiter siblings may consume the window, readback, and budget rows. They do not supply a second observation carrier, because the packet gives them only W, R, B, U, H, C, P, N downstream of the locked continuation and no-subject ledger.

Thus every accepted consumer route is exhausted by the displayed packet. The excluded objects require coordinates absent from L, so they cannot be projected from an accepted $\mathsf{FiniteObservationLock}^{\uparrow}$ read. □

Falsifiable prediction: A purported finite observation read that omits the displayed Cont route or budget readback is not an accepted FiniteObservationLockUp carrier.

Independence witness: realobservationbudget, finiteobservationbudgetselector, observationbudgetlimiter, streamname, real: each sibling supplies a consumer, selector, limiter, stream, or seal row, but none is bijective to the packet that locks observation to Cont, hsame, finite budget, readback, and no-subject ledger rows.

The Lean follow-up in `lean4/BEDC/Derived/FiniteObservationLockUp/TasteGate.lean` will provide $\mathsf{Nontrivial\ FiniteObservationLock}^{\uparrow}$ and $\mathsf{FieldFaithful\ FiniteObservationLock}^{\uparrow}$ instances with explicit witness rows. The field-faithfulness witness must preserve $A, D, Z, Q, W, R, B, U, H, C, P, N$ as distinct rows before `BEDC.Derived.FiniteObservationLockUp.FiniteObservationLockTasteGate_single_c` can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationLock}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteObservationLock}^{\uparrow}$ packet is generated from an antecedent history, displayed distinction, successor history, no-subject ledger, finite window, readback, budget, downstream use, componentwise hsame transport, Cont replay, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteObservationLock}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1266.1, Definition 1266.2, and Definition 1266.3 bind subject-free observation to a finite continuation, budget, readback, and ledger packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteObservationLock}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, every Real or Completion consumer route, total observer-identity theory, or ambient analytic completeness.

Upgrade path: Lean closure requires Nontrivial FiniteObservationLockUp and FieldFaithful FiniteObservationLockUp instances in `lean4/BEDC/Derived/FiniteObservationLockUp/TasteGate.lean`.

Chapter 1267

A Concrete Naming Certificate for $\mathsf{TraditionRegistry}^{\uparrow}$

The $\mathsf{TraditionRegistry}^{\uparrow}$ packet realizes the tradition registry of subsection 9462.34.5 as a finite NameCert carrier. It sits after the auditable-generativity context of chapter 9462, beside the core registry index of chapter 1251, the concept-registry surface of chapter 1252, and the theorem-gap registry of chapter 1246. These siblings index concepts, expose concept surfaces, and record theorem gaps; the present packet binds one inherited tradition comparison to the rejected-surplus and comparison-discipline rows required before that comparison is named.

Definition 1267.1 (Tradition registry carrier)**.** *A* $\mathsf{TraditionRegistry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (T, S, P, R, H, C, Q, N)$$

with the following displayed rows:

1. *T is the tradition row, naming the inherited tradition and the traditional claim being compared.*
2. *S is the BEDC-site row, naming the concrete BEDC chapter, definition, theorem, or registry surface where the comparison is allowed to land.*
3. *P is the preserved-structure row, recording the exact constructor, classifier, transport, or obligation shape preserved by the comparison.*
4. *R is the rejected-surplus row, recording the doctrine, host semantics, prose reading, metaphysical claim, or ambient assumption not imported into the BEDC site.*
5. *H records componentwise* hsame *transport for the tradition, site, preserved-structure, rejected-surplus, continuation, provenance, and naming rows.*
6. *C records the displayed* Cont *route from the inherited comparison through the BEDC site and rejected-surplus boundary.*
7. *Q is the* Pkg *provenance row over philosophy tradition entries,* $\mathsf{CoreRegistryIndex}^{\uparrow}$, $\mathsf{ConceptRegistrySurface}^{\uparrow}$, $\mathsf{TheoremGapRegistry}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{AuditSystem}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TraditionRegistry}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through T, S, P, R, H, C, Q, N. It has no coordinate for inherited doctrine without rejected surplus, a BEDC site without preserved structure, a hidden comparison rule, or a sibling registry bijection.

Lean4 (definition) `BEDC.Derived.TraditionRegistryUp.TraditionRegistryUp`

Theorem 1267.2 (Tradition registry NameCert obligations)**.** *For the carrier of Definition 1267.1, the local* $\mathsf{NameCert}_{\mathsf{TraditionRegistry}^{\uparrow}}$ *surface consists exactly of carrier admission for* $X = (T, S, P, R, H, C, Q, N)$*, tradition and BEDC-site exposure through* T, S*, preserved-structure exposure through* P*, rejected-surplus exposure through* R*, componentwise transport through* H*, displayed comparison replay through* C*, package provenance through* Q*, and local naming through* N*.*

Proof. Project the finite carrier. The rows T, S, P, R display the inherited tradition, the BEDC landing site, the structure preserved by the comparison, and the surplus reading rejected at that site.

The support rows H, C, Q, N then transport, replay, source, and name the same comparison packet. They do not add a second doctrine row, a second landing site, or an unrecorded comparison rule.

Thus every accepted NameCert obligation is one of the displayed rows. Since the carrier contains no further coordinate, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{TraditionRegistry}^{\uparrow}}$ surface. □

Theorem 1267.3 (Tradition registry rejected-surplus nonescape)**.** *Every accepted* $\mathsf{TraditionRegistry}^{\uparrow}$ *packet must display the rejected-surplus row* R *before a tradition comparison can be exported as a BEDC comparison. A packet with* T, S, P, H, C, Q, N *but no* R *is outside the registry surface.*

Proof. Use the obligation surface of Definition 1267.2. It requires the preserved structure and the rejected surplus to be displayed in the same finite packet before the local name is public.

The siblings named by the provenance row can index a concept, expose a concept surface, record a theorem gap, route a claim, or audit the packet. None of them manufactures the missing rejected-surplus coordinate.

Therefore an export without R is not an accepted $\mathsf{TraditionRegistry}^{\uparrow}$ packet. It has left the finite registry carrier rather than completing it. □

Theorem 1267.4 (Tradition registry sibling dependency)**.** *The sibling packets* $\mathsf{CoreRegistryIndex}^{\uparrow}$*,* $\mathsf{ConceptRegistrySurface}^{\uparrow}$*,* $\mathsf{TheoremGapRegistry}^{\uparrow}$*,* $\mathsf{ClaimRegistryLayer}^{\uparrow}$*, and* $\mathsf{AuditSystem}^{\uparrow}$ *are dependencies of* $\mathsf{TraditionRegistry}^{\uparrow}$ *only through the displayed provenance and replay rows* Q, C*. None is bijective with the carrier* $X = (T, S, P, R, H, C, Q, N)$*.*

Proof. Read the carrier coordinates. The tradition row, BEDC-site row, preserved-structure row, and rejected-surplus row are local to X and are not replaced by a concept index, theorem-gap row, claim row, or audit row.

The siblings enter through Q as package provenance and through C as displayed replay. Those rows state where the comparison can be checked and consumed, but they do not erase T, S, P, R or reconstruct them from a sibling alone.

Hence each sibling is a non-bijective dependency. The registry packet remains the finite tradition-comparison surface with its own rejected-surplus and naming rows. □

Falsifiable prediction: Any accepted TraditionRegistryUp packet without a rejected-surplus row is rejected before the comparison can be exported as a BEDC tradition-registry entry.

Independence witness: coreregistryindex, conceptregistrysurface, theoremgapregistry, claim-registrylayer, auditsystem: no sibling is bijective because each exposes only an index, concept surface, theorem-gap row, claim route, or audit route, while TraditionRegistryUp binds tradition,

BEDC site, preserved structure, rejected surplus, hsame transport, Cont replay, Pkg provenance, and local NameCert in one packet.

The later Lean `TasteGate.lean` for this chapter must include explicit `Nontrivial TraditionRegistryUp` and `FieldFaithful TraditionRegistryUp` instances preserving T, S, P, R, H, C, Q, N as separate displayed rows.

Theorem 1267.5 (Tradition registry scoped dependency rows)**.** *Every scoped* $\mathsf{TraditionRegistry}^{\uparrow}$ *read binds the tradition row, BEDC-site row, preserved-structure row, rejected-surplus row, transport row, replay row, provenance row, and local naming row to the displayed* BHist, hsame, Cont, Pkg, NameCert, $\mathsf{CoreRegistryIndex}^{\uparrow}$, $\mathsf{ConceptRegistrySurface}^{\uparrow}$, $\mathsf{TheoremGapRegistry}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, *and* $\mathsf{AuditSystem}^{\uparrow}$ *surfaces. The scope is exactly this finite registry route; it does not export inherited doctrine without the rejected-surplus row, a BEDC landing site without preserved-structure exposure, or a hidden comparison rule outside the named sibling registries.*

Lean4 ✓ `BEDC.Derived.TraditionRegistryUp.taste gate`

Closure status for $\mathsf{NameCert}_{\mathsf{TraditionRegistry}^{\uparrow}}$.

Constructive story: A $\mathsf{TraditionRegistry}^{\uparrow}$ packet is generated from tradition, BEDC-site, preserved-structure, rejected-surplus, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TraditionRegistry}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1267.1, Definition 1267.2, Definition 1267.3, Definition 1267.4, Definition 1267.5, the falsifiable prediction, the independence witness, and the TasteGate single-carrier marker bind the mature paper surface for the tradition-comparison NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TraditionRegistry}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, philosophical correctness of every tradition comparison, or completeness of the sibling registry lattice.

Upgrade path: Lean closure requires the public tradition-comparison surface to be matched by Nontrivial TraditionRegistryUp and FieldFaithful TraditionRegistryUp instances in `lean4/BEDC/Derived/TraditionRegistryUp/TasteGate.lean`.

Chapter 1268

A Concrete Naming Certificate for $\mathsf{TraditionComparisonBoundary}^{\uparrow}$

The $\mathsf{TraditionComparisonBoundary}^{\uparrow}$ packet realizes the structural-comparison discipline of section 9462.29 as a finite NameCert boundary. It sits beside the claim registry layer of chapter 1209, the cannot-claim registry of chapter 554, the object-knowledge certificate of chapter 1218, and the registry export consistency gate of chapter 1224. Those siblings regulate claim export, refusal rows, object-knowledge licensing, and registry consistency; this packet binds tradition source, BEDC landing, rejected surplus, and structural distinction before any comparison may be exported.

Definition 1268.1 (Tradition comparison boundary carrier)**.** *A* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, L, R, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the tradition-source row, recording the inherited tradition, text family, question, vocabulary surface, and comparison prompt.*
2. *L is the BEDC landing row, recording the carrier, relation, classifier, ledger, certificate, gap, or T-position onto which the structural core lands.*
3. *R is the rejected-surplus row, recording the doctrinal, metaphysical, host-semantic, or identity claim not imported by the comparison.*
4. *D is the structural-distinction row, recording that the accepted comparison preserves a structural landing while refusing doctrinal identity.*
5. *H stores componentwise* hsame *transport for source, landing, rejected-surplus, distinction, replay, provenance, and local naming rows.*
6. *C stores displayed* Cont *replay for the comparison route from source row through landing row and rejected-surplus inspection.*
7. *P is the* Pkg *provenance over* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TraditionComparisonBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for tradition membership alone, inherited doctrinal truth, host-semantic identity, or comparison export outside the displayed packet $T = (S, L, R, D, H, C, P, N)$.

Lean4 (definition) `BEDC.Derived.TraditionComparisonBoundaryUp.TraditionComparisonBoundaryCarrier`

Definition 1268.2 (Tradition comparison boundary classifier)**.** *The* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$ *classifier accepts exactly those packets of Definition 1268.1 whose comparison is read only through the structural landing row L together with the rejected-surplus row R. The classifier does not compare traditions by doctrinal identity, inherited vocabulary, host truth, or prose affinity unless those readings are rejected by R and kept outside the accepted landing.*

Lean4 (definition) `BEDC.Derived.TraditionComparisonBoundaryUp.traditionComparisonBoundaryClassifier`

Theorem 1268.3 (Tradition comparison boundary NameCert obligations)**.** *For the carrier of Definition 1268.1, the local* $\mathsf{NameCert}_{\mathsf{TraditionComparisonBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for $T = (S, L, R, D, H, C, P, N)$; tradition-source exposure through S; BEDC landing exposure through L; rejected-surplus exposure through R; structural-distinction exactness through D; componentwise transport through H; displayed replay through C; package provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.TraditionComparisonBoundaryUp.TraditionComparisonBoundaryTasteGate single carrier alignment`

Proof. Project the finite packet of Definition 1268.1. Row S displays the inherited source, while row L displays the exact BEDC landing surface available to the comparison.

The rejected-surplus row R and the structural-distinction row D are then read together. By the classifier of Definition 1268.2, acceptance depends on structural landing and rejected surplus, so a doctrinal or host-semantic identity claim has no accepted coordinate.

Finally H, C, P, N transport, replay, package, and name the same packet. Since no additional row can export tradition membership, inherited doctrine, or prose affinity as a BEDC identity, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{TraditionComparisonBoundary}^{\uparrow}}$ surface. □

Theorem 1268.4 (Tradition comparison boundary rejects doctrinal identity)**.** *No accepted* TraditionComparisonBou *packet exports doctrinal identity between an inherited tradition and a BEDC object. Every accepted comparison must display both the BEDC landing row L and the rejected-surplus row R in the same carrier.*

Lean4 ✓ `BEDC.Derived.TraditionComparisonBoundaryUp.TraditionComparisonBoundary no doctrinal identity`

Proof. Let an accepted packet be

$$T = (S, L, R, D, H, C, P, N).$$

The classifier of Definition 1268.2 reads the packet only through L and R for comparison acceptance.

If a route exports doctrinal identity, it must either bypass R or treat R as empty surplus. Both moves leave the displayed carrier of Definition 1268.1: R is the row that records what is not imported by the comparison.

The structural-distinction row D records that the comparison preserves a landing without identifying the tradition with the BEDC object. Transport, replay, package provenance, and naming rows preserve that packet; they do not add a doctrinal-identity coordinate. □

Theorem 1268.5 (Tradition comparison boundary sibling independence)**.** *The* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$, *or* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.TraditionComparisonBoundaryUp.TraditionComparisonBoundary sibling independence`

Proof. Compare the displayed rows. $\mathsf{ClaimRegistryLayer}^{\uparrow}$ regulates package-level claim export, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$ records cannot-claim refusal, $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$ licenses object knowledge, and $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ checks registry export consistency.

None of those sibling packets carries the tradition-source row S, BEDC landing row L, rejected-surplus row R, structural-distinction row D, and local $\mathsf{NameCert}_{\mathsf{TraditionComparisonBoundary}^{\uparrow}}$ row N in one finite comparison packet.

A NameCert-row-preserving bijection would have to preserve those rows as a joint comparison boundary. Since each sibling lacks at least one of the source, landing, surplus, or distinction coordinates, no such bijection exists. □

Theorem 1268.6 (Tradition comparison boundary source registry obligation)**.** *Every accepted* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$ *packet that is read as a comparison boundary must keep the tradition-source row* S *visible before any* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *export row or local* $\mathsf{NameCert}_{\mathsf{TraditionComparisonBoundary}^{\uparrow}}$ *row is consumed. The source registry obligation is the displayed route*

$$S, L, R, D, H, C, P, N$$

inside the same finite BHist *packet; it is not a free tradition-membership claim, inherited doctrinal truth, host-semantic identity, or prose-affinity license.*

Lean4 ✓ `BEDC.Derived.TraditionComparisonBoundaryUp.TraditionComparisonBoundary source registry obligation`

Proof. Project the carrier of Definition 1268.1. The tradition-source row S is a displayed coordinate of the same packet that also contains the landing, rejected-surplus, distinction, transport, replay, provenance, and local naming rows.

Read the classifier of Definition 1268.2. Acceptance is mediated by the BEDC landing row L and rejected-surplus row R, so S cannot be consumed as a detached tradition-membership certificate.

Finally use the NameCert obligations of Definition 1268.3. Since local naming and package provenance are downstream from the displayed carrier rows, every registry-facing export keeps S visible inside S, L, R, D, H, C, P, N. □

Theorem 1268.7 (Tradition comparison boundary export consistency obligation)**.** *Every export of an accepted* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$ *comparison to a* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *consumer must display the BEDC landing row* L*, rejected-surplus row* R*, structural-distinction row* D*, componentwise transport row* H*, replay row* C*, provenance row* P*, and local naming row* N *together with the source row* S*. The export may cite registry consistency only for that finite packet; it cannot export doctrinal identity, host truth, unrecorded source equivalence, or object-knowledge authority outside* S, L, R, D, H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.TraditionComparisonBoundaryUp.TraditionComparisonBoundary export consistency obligation`

Proof. Start from the finite obligation surface of Definition 1268.3. It makes S, L, R, D, H, C, P, N the full local certificate surface for the comparison packet.

Use sibling independence, Definition 1268.5. The registry export gate is a consumer of the displayed comparison boundary, not a replacement for the source, landing, surplus, and distinction rows.

The transport, replay, provenance, and local naming rows then keep the export tied to the same packet. Since the carrier has no coordinate for doctrinal identity, host truth, detached source equivalence, or object-knowledge authority, registry consistency cannot export any of those endpoints. □

Theorem 1268.8 (Tradition comparison boundary cannot-claim obligation)**.** *Every accepted* TraditionComparisonB *packet retains the cannot-claim boundary carried by its rejected-surplus row R before any comparison is exported through* AxisZeckendorfCannotClaim$^{\uparrow}$*,* ObjectKnowledgeCertificate$^{\uparrow}$*, or* RegistryExportConsistencyGate *The retained boundary says that the comparison may land structurally through L and D, but cannot claim inherited doctrinal identity, prose affinity, host-semantic equality, or public object knowledge outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.TraditionComparisonBoundaryUp.TraditionComparisonBoundary cannot claim obligation`

Proof. Begin with the no-doctrinal-identity theorem, Definition 1268.4. It requires every accepted comparison to display both the BEDC landing row L and rejected-surplus row R.

Apply the classifier definition. The comparison is accepted only when the structural landing is read together with rejected surplus, so R remains the cannot-claim boundary rather than an optional annotation.

Finally route the packet through the listed sibling consumers. Axis-level refusal, object-knowledge licensing, and registry export consistency may consume the boundary only as S, L, R, D, H, C, P, N, so none can turn the rejected surplus into doctrinal identity, prose affinity, host equality, or public object knowledge. □

Theorem 1268.9 (Tradition comparison boundary scoped kernel route)**.** *Every accepted* TraditionComparisonBound *packet routes doctrinal refusal, sibling independence, source registry, export consistency, and cannot-claim obligations through the displayed rows S, L, R, D, H, C, P, N, the TasteGate marker on* BEDC.Derived.Traditio *and the finite BEDC rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The scoped kernel route exports no doctrinal identity, hidden tradition source, detached prose-affinity comparison, host comparison oracle, public object-knowledge authority, or registry export outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.TraditionComparisonBoundaryUp.TraditionComparisonBoundary scoped kernel route`

Proof. Start with the NameCert obligations of Definition 1268.3. They expose the finite comparison packet as exactly S, L, R, D, H, C, P, N and tie the route to the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Use doctrinal refusal and sibling independence next. The no-doctrinal-identity theorem, Definition 1268.4, requires the rejected-surplus row R, while Definition 1268.5 prevents the carrier from collapsing into the claim registry, cannot-claim registry, object-knowledge certificate, or registry export gate.

The source and export obligations are then supplied by Definition 1268.6 and Definition 1268.7. They keep the source row S, landing row L, rejected-surplus row R, and structural-distinction row D visible before any registry-facing read is exported.

Finally apply Definition 1268.8 and the displayed TasteGate marker named after Definition 1268.3. The cannot-claim boundary remains in the same finite packet, and the marker records only the single-carrier alignment. Hence the scoped kernel route exports none of the excluded doctrinal, hidden-source, object-knowledge, or host-comparison endpoints. □

Falsifiable prediction: If a comparison route exports doctrinal identity without a rejected-surplus row, it is not an accepted TraditionComparisonBoundaryUp packet.

Independence witness: claimregistrylayer, axiszeckendorfcannotclaim, objectknowledgecertificate, registryexportconsistencygate: none carries the tradition-source, BEDC landing, rejected-surplus, structural-distinction, and local NameCert rows in one packet.

The Lean follow-up must provide Nontrivial TraditionComparisonBoundary$^{\uparrow}$ and FieldFaithful TraditionComparison instances in `lean4/BEDC/Derived/TraditionComparisonBoundaryUp/TasteGate.lean`. Those instances must preserve S, L, R, D, H, C, P, N as separate displayed rows before BEDC.Derived.TraditionComparisonB may be cited by a checked paper marker.

Closure status for NameCert$_{\text{TraditionComparisonBoundary}^{\uparrow}}$.

Constructive story: A TraditionComparisonBoundary$^{\uparrow}$ packet is generated from tradition-source, BEDC landing, rejected-surplus, structural-distinction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{TraditionComparisonBoundary}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1268.1, Definition 1268.2, Definition 1268.3, Definition 1268.4, Definition 1268.5, Definition 1268.6, Definition 1268.7, Definition 1268.8, and Definition 1268.9 bind structural tradition comparison to a finite scoped NameCert kernel route.

Formal verification: FormalStatus(NameCert$_{\text{TraditionComparisonBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, public export closure, or the correctness of any inherited tradition's doctrine.

Upgrade path: The next paper-axis step is a bridge-facing comparison export route; Nontrivial TraditionComparison-BoundaryUp and FieldFaithful TraditionComparisonBoundaryUp remain verification-side obligations in `lean4/BEDC/Derived/TraditionComp`

Chapter 1269

A Concrete Naming Certificate for $\mathsf{MetaClosureWitnessLedger}^{\uparrow}$

The $\mathsf{MetaClosureWitnessLedger}^{\uparrow}$ packet realizes the witness-preserving side of subsection 9462.25.6, subsection 9462.25.7, and subsection 9462.25.8. It sits beside the obstruction packet of chapter 899, the witnessed refutation surface of chapter 503, the proof witness chain of chapter 1238, the typed failure certificate of chapter 1237, and the certificate truth-branch boundary of chapter 854. Those siblings expose forbidden-schema refusal, permitted refutation, proof-chain witness order, typed failure rows, and truth-branch boundaries; this packet records the positive replacement ledger that makes an axiom-purity read consumable without meta closure.

Definition 1269.1 (Meta-closure witness ledger carrier)**.** *A* $\mathsf{MetaClosureWitnessLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, K, D, A, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the witness row, carrying the selected finite object, recursion route, proof chain, or refutation witness before any consumer may use the positive content;*
2. *K is the classifier-transport row, recording how the relevant classifier is preserved instead of being collapsed into quotient equality;*
3. *D is the directional-transport row, recording the consumed direction for proposition-facing reads instead of identifying propositions by extensional equality;*
4. *A is the dependency-audit row, recording that the read avoids* $\mathsf{Classical.choice}$*, quotient soundness, and propositional extensionality;*
5. *R is the replacement row that names which axiom-purity request is being discharged by W, K, D, A;*
6. *H records componentwise* hsame *transport for W, K, D, A, R and the local name row;*
7. *C records the displayed* Cont *routes by which consumers read the witness, classifier-transport, directional-transport, dependency-audit, and replacement rows in order;*
8. *P is the* Pkg *provenance over* $\mathsf{MetaClosureObstruction}^{\uparrow}$, $\mathsf{WitnessedRefutation}^{\uparrow}$, $\mathsf{ProofWitnessChain}^{\uparrow}$, $\mathsf{TypedFailureCertificate}^{\uparrow}$, $\mathsf{CertificateTruthBranchBoundary}^{\uparrow}$, $\mathsf{AxiomPurityGate}^{\uparrow}$, BHist, hsame, Cont, Pkg*, and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaClosureWitnessLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unwitnessed selector, quotient representative, proposition equality supplied by extensionality, host equality, ambient completeness principle, hidden dependency exemption, or detached proof source.

Lean4 ✓ `BEDC.Derived.MetaClosureWitnessLedgerUp.TasteGate.MetaClosureWitnessLedgerTasteGate single carrier alignment`

Theorem 1269.2 (Meta-closure witness ledger NameCert obligations)**.** *For the carrier of Definition 1269.1, the local* $\mathsf{NameCert}_{\mathsf{MetaClosureWitnessLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for* $L = (W, K, D, A, R, H, C, P, N)$*, witness exposure through* W*, classifier-transport exposure through* K*, directional-transport exposure through* D*, dependency-audit exposure through* A*, replacement-read exposure through* R*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.MetaClosureWitnessLedgerUp.MetaClosureWitnessLedgerTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1269.1. The tuple displays the positive witness row, the two transport rows, the dependency-audit row, the replacement request, and the structural rows before a consumer can read the packet as an axiom-purity replacement.

The witness row W handles the term-facing side: selection is read only from displayed finite data, recursion data, or a proof chain. The classifier row K handles the type-facing side by preserving the classifier relation without creating quotient equality.

The directional row D handles the proposition-facing side. It records which implication or transport direction is consumed, so the packet never turns a pair of directions into equality of propositions.

The audit and structural rows close the local certificate surface. Row A records the dependency refusal, R identifies the replacement read, and H, C, P, N preserve, replay, source, and name the same finite rows. Since the carrier contains no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 1269.3 (Meta-closure witness ledger non-escape)**.** *Every accepted* $\mathsf{MetaClosureWitnessLedger}^{\uparrow}$ *packet exports only the finite witness, classifier-transport, directional-transport, dependency-audit, replacement,* hsame, Cont, Pkg*, and local* NameCert *rows of Definition 1269.1. Any terminal axiom-purity replacement read of the packet factors through*

$$W, K, D, A, R, H, C, P, N.$$

It cannot be replaced by an unwitnessed selector, quotient stream, quotient representative, host equality, proposition equality supplied by extensionality, choice datum, ambient completeness row, or detached proof source.

Proof. Begin with the accepted carrier $L = (W, K, D, A, R, H, C, P, N)$. Its only positive object is the displayed witness row W, and the only permitted transport coordinates are the classifier row K and directional row D.

Apply Definition 1269.2. Every replacement read must pass through the audit row A and the replacement row R before it is named by N, so the read is dependency-audited before it becomes consumable certificate data.

The structural rows then enforce non-escape. Componentwise *hsame* can compare only the displayed rows, Cont replays only the displayed route, and Pkg names only the listed sibling sources.

Therefore any accepted replacement read is exhausted by $W, K, D, A, R, H, C, P, N$. The excluded objects require a selector, quotient, host equality, proposition collapse, choice row, ambient completeness row, or detached source coordinate that is absent from the carrier. □

Falsifiable prediction: Any accepted MetaClosureWitnessLedgerUp packet lacking one of displayed witness, classifier-transport, directional-transport, or dependency-audit rows cannot discharge an axiom-purity replacement read.

Independence witness: metaclosureobstruction, witnessedrefutation, proofwitnesschain, typedfailurecertificate, certificatetruthbranchboundary: MetaClosureObstructionUp records the forbidden-schema and truth-branch refusal side without the positive replacement ledger; WitnessedRefutationUp records a permitted refuter without classifier-transport, directional-transport, and dependency-audit rows; ProofWitnessChainUp records proof-chain order without the three-stratum replacement audit; TypedFailureCertificateUp records typed failure status without a positive axiom-purity replacement route; CertificateTruthBranchBoundaryUp records branch refusal without the witness ledger that discharges term, type, and proposition reads. Hence no row-preserving bijection exists with $\mathsf{MetaClosureWitnessLedger}^{\uparrow}$.

The Lean follow-up namespace `BEDC.Derived.MetaClosureWitnessLedgerUp` must provide explicit `Nontrivial MetaClosureWitnessLedgerUp` and `FieldFaithful MetaClosureWitnessLedgerUp` instances for the displayed rows $W, K, D, A, R, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaClosureWitnessLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaClosureWitnessLedger}^{\uparrow}$ packet is generated from displayed witness, classifier-transport, directional-transport, dependency-audit, replacement, componentwise hsame, Cont replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaClosureWitnessLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1269.1, Definition 1269.2, and Definition 1269.3 bind the positive axiom-purity replacement ledger to finite rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaClosureWitnessLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, ambient completeness, quotient construction, proposition extensionality, or a general host-level selector.

Upgrade path: Obligation closure requires checked Nontrivial and FieldFaithful TasteGate witnesses for $\mathsf{MetaClosureWitnessLedger}^{\uparrow}$ over the displayed witness, transport, audit, replacement, hsame, Cont, Pkg, and NameCert rows.

Chapter 1270

A Concrete Naming Certificate for $\mathsf{TraditionScienceRegistryBridge}^{\uparrow}$

The $\mathsf{TraditionScienceRegistryBridge}^{\uparrow}$ packet realizes the tradition and science registry rows of subsection 9462.34.5 and subsection 9462.34.6 as one finite NameCert carrier. It sits beside the auditable-generativity package of chapter 9462, the concept-registry surface of chapter 1252, the core registry index of chapter 1251, the registry layer of chapter 1220, and the claim registry layer of chapter 1209. Those siblings expose concept, index, registry, claim, or export rows; this packet binds tradition comparison and science failure-surface rows in one carrier before either family can be exported as package prose.

Definition 1270.1 (Tradition and science registry bridge carrier)**.** *A* $\mathsf{TraditionScienceRegistryBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, P, R, S, E, F, H, C, K, N)$$

with the following displayed rows:

1. *T is the tradition-entry row, recording tradition, traditional claim, BEDC site, preserved structure, rejected surplus, and status.*
2. *P is the preserved-structure row, recording the exact structural feature allowed to pass from the inherited tradition into the BEDC site.*
3. *R is the rejected-surplus row, recording the metaphysical, doctrinal, host-semantic, or prose-only reading that is not imported by the comparison.*
4. *S is the science-entry row, recording name, records carrier, invariant carrier, prediction gap, bridge status, claim status, and science-roadmap boundary.*
5. *E is the empirical-ledger row, recording the displayed records, measurement route, model-facing ledger, or explicit absence of empirical support for the same science entry.*
6. *F is the failure-surface row, recording what would block promotion of the science entry, including missing source rows, unledgered measurement, hidden choice, quotient collapse, propositional extensionality, missing invariant, or missing empirical ledger.*
7. *H stores componentwise* hsame *transport for tradition entry, preserved structure, rejected surplus, science entry, empirical ledger, failure surface, replay, provenance, and local naming rows.*
8. *C is the displayed* Cont *replay row through the tradition-comparison and science-failure routes.*

9. *K is the* Pkg *provenance over* ConceptRegistrySurface$^{\uparrow}$, CoreRegistryIndex$^{\uparrow}$, RegistryLayer$^{\uparrow}$, ClaimRegistryLayer$^{\uparrow}$, RegistryExportSurface$^{\uparrow}$, *philosophy tradition registry rows, philosophy science registry rows,* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{TraditionScienceRegistryBridge}^{\uparrow}}$ *row.*

The carrier has no coordinate for inherited vocabulary without rejected surplus, scientific roadmap prose without a failure surface, empirical claims without a ledger row, or registry export outside the displayed packet $Q = (T, P, R, S, E, F, H, C, K, N)$.

Theorem 1270.2 (Tradition and science registry bridge obligations)**.** *For the carrier of Definition 1270.1, the local* NameCert$_{\text{TraditionScienceRegistryBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for $Q = (T, P, R, S, E, F, H, C, K, N)$; tradition-comparison exposure through T, P, R; science-roadmap exposure through S, E, F; componentwise transport through H; displayed replay through C; package provenance through K; and local naming through N.*

Lean4 ✓ `BEDC.Derived.TraditionScienceRegistryBridgeUp.TraditionScienceRegistryBridgeTasteGate`
`single carrier alignment`

Proof. Project the finite packet of Definition 1270.1. Rows T, P, R display the inherited tradition, the structure preserved by the comparison, and the surplus reading rejected by the BEDC site.

Rows S, E, F display the science entry, its empirical ledger, and the failure surface that can block promotion. These rows specialize the registry discipline of chapter 1220 and the claim-export discipline of chapter 1209 to the two registry families named in the philosophy tables.

Finally H, C, K, N transport, replay, package, and name the same packet. Since the carrier contains no hidden tradition doctrine, no science promise outside the failure surface, and no empirical row outside E, the listed obligations exhaust the local NameCert$_{\text{TraditionScienceRegistryBridge}^{\uparrow}}$ surface. □

Theorem 1270.3 (Tradition and science registry bridge nonescape)**.** *Every accepted* TraditionScienceRegistryBridge *packet refuses a tradition export with no rejected-surplus row and refuses a science export with no failure-surface row. A consumer cannot replace R or F by concept-registry placement, core-index membership, registry-layer admission, claim-layer export, transport, continuation replay, package provenance, or local naming alone.*

Proof. Use the obligations of Definition 1270.2. Tradition comparison must pass through T, P, R, so the preserved structure and rejected surplus are displayed in the same finite packet.

Science roadmap export must pass through S, E, F, so empirical support and the blocking surface are displayed before the roadmap is treated as a registry export.

The sibling packets named in the statement govern concept entries, index rows, registry admission, claim export, transport, continuation, package, or naming. They preserve or route an admitted packet; they do not synthesize the missing rejected-surplus row R or failure-surface row F. Thus any attempted export without those rows exits TraditionScienceRegistryBridge$^{\uparrow}$. □

Falsifiable prediction: A tradition or science registry export that lacks either a rejected-surplus row or a failure-surface row is outside TraditionScienceRegistryBridgeUp.

Independence witness: conceptregistrysurface, coreregistryindex, registrylayer, claimregistrylayer, registryexportsurface: no sibling is bijective because each controls concept, index, registry, claim, or export rows separately, while this packet binds tradition comparison and science failure-surface rows in one carrier.

The Lean follow-up requires Nontrivial TraditionScienceRegistryBridge$^{\uparrow}$ and FieldFaithful TraditionScienceRegistryB instances in `lean4/BEDC/Derived/TraditionScienceRegistryBridgeUp/TasteGate.lean`. Those instances must preserve $T, P, R, S, E, F, H, C, K, N$ as separate displayed rows before any checked theorem may cite the packet as a TasteGate surface.

Closure status for NameCert$_{\text{TraditionScienceRegistryBridge}^{\uparrow}}$.

Constructive story: A TraditionScienceRegistryBridge$^{\uparrow}$ packet is generated from tradition-entry, preserved-structure, rejected-surplus, science-entry, empirical-ledger, failure-surface, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{TraditionScienceRegistryBridge}^{\uparrow}}$, seed)

Scope closed: Definition 1270.1, Definition 1270.2, and Definition 1270.3 bind tradition comparison and science roadmap export to one finite NameCert packet.

Formal verification: FormalStatus(NameCert$_{\text{TraditionScienceRegistryBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, empirical correctness of science entries, or philosophical correctness of every tradition comparison.

Upgrade path: Lean closure requires Nontrivial TraditionScienceRegistryBridgeUp and FieldFaithful TraditionScienceRegistryBridgeUp instances in `lean4/BEDC/Derived/TraditionScienceRegistryBridgeUp/TasteGate.lean`.

Chapter 1271

A Concrete Naming Certificate for $\mathsf{SubjectFreeObservation}^{\uparrow}$

The $\mathsf{SubjectFreeObservation}^{\uparrow}$packet realizes the subject-free observation discipline of section 9462.22 as a finite NameCert surface. It consumes the observer-history identity packet of chapter 477, the observer-filter split of chapter 514, the kernel observation sieve of chapter 932, and the local clock budget of chapter 665. The packet records an observation as displayed Cont replay, treats observer identity as hsame over history rows, and exposes the absence of any global subject parameter as a ledgered exclusion.

Definition 1271.1 (Subject-free observation carrier)**.** *A* $\mathsf{SubjectFreeObservation}^{\uparrow}$*carrier is a finite* BHist *packet*

$$S = (O, H, K, D, L, C, P, N)$$

with the following displayed rows:

1. *O is the displayed* Cont *observation row, recording the observation event as a continuation over the current history surface;*
2. *H is the* hsame *observer-history identity row certified by chapter 477;*
3. *K is the subject-free signature row, recording that the observation is typed by its* BHist*,* Cont*, and* hsame *rows rather than by an auxiliary subject carrier;*
4. *D is the no-subject exclusion row, refusing a subject-substance coordinate, owner map, global observer parameter, or private viewpoint object outside the displayed history rows;*
5. *L is the public ledger-event row, exposing the accepted observation event to downstream consumers as a named finite record;*
6. *C records* Cont *replay for observation readback, signature inspection, no-subject checking, and ledger-event exposure;*
7. *P is the* Pkg *provenance over* $\mathsf{ObserverHistoryIdentity}^{\uparrow}$*,* $\mathsf{ObserverFilter}^{\uparrow}$*,* $\mathsf{KernelObservationSieve}^{\uparrow}$*,* $\mathsf{LocalClockBudget}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectFreeObservation}^{\uparrow}}$ *row.*

The classifier compares carriers only through O, H, K, D, L, C, P, N. It has no coordinate for a subject-substance, host observer identity, owner function, global viewpoint, or observation source outside the displayed BHist*,* Cont*, and* hsame *rows.*

Lean4 (definition) BEDC.Derived.SubjectFreeObservationUp.SubjectFreeObservationCarrier

Theorem 1271.2 (Subject-free observation NameCert obligations)**.** *For the carrier of Definition 1271.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectFreeObservation}^{\uparrow}}$ *surface consists exactly of carrier admission for* $S = (O, H, K, D, L, C, P, N)$*, displayed* Cont *observation through* O*, observer-history identity through* H*, subject-free signature exposure through* K*, no-subject exclusion through* D*, public ledger-event exposure through* L*, replay through* C*, provenance through* P*, and local naming through* N*.*

Lean4 ✓ BEDC.Derived.SubjectFreeObservationUp.SubjectFreeObservationTasteGate single carrier alignment

Proof. Project the carrier. The tuple lists the observation row, observer-history identity row, subject-free signature row, no-subject exclusion row, public ledger-event row, replay row, provenance row, and local naming row.

Read the observation and identity rows first. The observation is the displayed Cont row O, while observer identity is supplied by the hsame row H from the observer-history identity surface.

The rows K and D then separate admissible signature data from excluded subject data. The signature is built from the displayed history, continuation, and sameness rows, and the exclusion row records that no subject-substance coordinate is available.

Finally L, C, P, N expose, replay, source, and name the same packet. Since the carrier contains no hidden subject coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 1271.3 (Subject-free observation no-subject parameter)**.** *If a purported observation packet requires a subject-substance coordinate outside the displayed* BHist*,* Cont*, and* hsame *rows, then it is not an accepted* $\mathsf{SubjectFreeObservation}^{\uparrow}$ *carrier.*

Lean4 ✓ BEDC.Derived.SubjectFreeObservationUp.SubjectFreeObservationCarrier no subject parameter

Proof. Inspect Definition 1271.1. The only observation source is O, the only observer-identity row is H, and the only signature row is K.

The no-subject row D records the forbidden coordinates before any public ledger event is exposed. A subject-substance coordinate outside the displayed rows would have to be read either from K or from L.

Both routes are blocked by the carrier inventory. The signature row records only the subject-free observation type, and the ledger row exposes only the accepted finite event, so a packet requiring an auxiliary subject parameter falls outside the classifier. □

Theorem 1271.4 (Subject-free observation ledger event)**.** *Every public event exported by an accepted* $\mathsf{SubjectFreeObservation}^{\uparrow}$ *packet factors through*

$$O, H, K, D, L, C, P, N.$$

The event is a displayed Cont *observation with* hsame *observer-history identity and a no-subject ledger, not a host-side subject report.*

Lean4 ✓ BEDC.Derived.SubjectFreeObservationUp.SubjectFreeObservationCarrier ledger event

Proof. Start from the accepted packet $S = (O, H, K, D, L, C, P, N)$. The public event row is L, and it is read only after the observation row O, observer-history row H, signature row K, and exclusion row D have been displayed.

Replay through C preserves this order for consumers. Provenance through P names the observer-history, observer-filter, kernel-sieve, and local-clock-budget source rows, while N names the local certificate.

No additional report channel appears in the packet. Thus the exported event is exactly the finite ledgered observation route and cannot be interpreted as a host-side subject report. □

Theorem 1271.5 (Subject-free observation sibling independence)**.** *The* SubjectFreeObservation$^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* ObserverHistoryIdentity$^{\uparrow}$*,* ObserverFilter$^{\uparrow}$*,* KernelObservationSieve$^{\uparrow}$*,* LocalClockBudget$^{\uparrow}$*, or* ConsciousObserverState$^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.SubjectFreeObservationUp.SubjectFreeObservationCarrier sibling independence`

Proof. Compare the sibling surfaces. ObserverHistoryIdentity$^{\uparrow}$ supplies hsame observer-history identity, ObserverFilter$^{\uparrow}$ separates selected and omitted rows, KernelObservationSieve$^{\uparrow}$ filters kernel-facing observations, LocalClockBudget$^{\uparrow}$ budgets local observation windows, and ConsciousObserverState$^{\uparrow}$ records current observer-state rows.

None of those siblings carries the full tuple O, H, K, D, L, C, P, N with both the displayed Cont observation row and the no-subject exclusion ledger. A NameCert-row-preserving bijection would have to preserve those two rows together with the public ledger-event row.

Because the siblings each supply only a proper dependency surface, SubjectFreeObservation$^{\uparrow}$ remains a distinct finite carrier for subject-free observation packets. □

Falsifiable prediction: If a packet requires a subject-substance coordinate outside the displayed BHist, Cont, and hsame rows, it cannot satisfy the SubjectFreeObservationUp NameCert obligations.

Independence witness: observerhistoryidentity, observerfilter, kernelobservationsieve, localclockbudget, consciousobserverstate: none carries the displayed Cont observation row, hsame observer-history identity row, subject-free signature row, no-subject exclusion ledger, public event row, replay row, provenance row, and local NameCert row in one packet.

The Lean follow-up in `lean4/BEDC/Derived/SubjectFreeObservationUp/TasteGate.lean` must provide Nontrivial SubjectFreeObservation$^{\uparrow}$ and FieldFaithful SubjectFreeObservation$^{\uparrow}$ instances before `BEDC.Derived.SubjectFreeObservationUp.SubjectFreeObservationTasteGate_single_carrier_alig` can be cited by a checked paper marker.

Closure status for NameCert$_{\text{SubjectFreeObservation}^{\uparrow}}$ **·**

Constructive story: The subject-free observation certificate is generated from a $BHist$ event row, a displayed Cont observation row, an $hsame$ observer-history identity row, a subject-free signature row, and a no-subject exclusion ledger. The carrier first reads the observation event, then records that no subject slot is part of the route, and finally uses Cont only to extend the same event-ledger path. The $hsame$ relation preserves subject-freeness under changes of representative history: an equivalent history may carry the same observation, but it cannot introduce a hidden subject row. The NameCert obligations, no-subject parameter theorem, ledger-event theorem, and sibling-independence result together make observation a visible event packet.

Theory closure: TheoryGate(NameCert$_{\text{SubjectFreeObservation}^{\uparrow}}$, seed)

Scope closed: This chapter binds the subject-free observation carrier, NameCert obligations, no-subject parameter theorem, ledger-event theorem, sibling-independence theorem, prediction, and seed closure marker.

Formal verification: FormalStatus(NameCert$_{\text{SubjectFreeObservation}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim observer identity, subject experience, subject-substance coordinates, or support-lattice membership outside the subject-free event ledger.

Upgrade path: Reaching obligationClosure requires a formal observation-event carrier and checked absence of subject parameters under $hsame$ transport.

Chapter 1272

A Concrete Naming Certificate for $\mathsf{SubjectIndexRoute}^{\uparrow}$

The $\mathsf{SubjectIndexRoute}^{\uparrow}$ packet realizes the subject-index route of Definition 9462.2242 as a finite NameCert carrier. It sits beside the core registry index of chapter 1251, the concept registry surface of chapter 1252, the registry export surface of chapter 1216, the registry export consistency gate of chapter 1224, and the tradition/science bridge of chapter 1270. Those siblings expose registry tables, concept entries, export rows, consistency gates, and tradition/science rows; this packet stores the route by which ordinary subject vocabulary reaches that lattice.

Definition 1272.1 (SubjectIndexRoute carrier)**.** *A* $\mathsf{SubjectIndexRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (O, C, R, E, G, T, H, K, P, N)$$

with the following displayed rows:

1. *O is the ordinary subject-entry row, recording the public subject vocabulary, local reader entry point, and displayed registry destination.*
2. *C is the core-registry route row, recording the* $\mathsf{CoreRegistryIndex}^{\uparrow}$ *table position reached by the ordinary entry.*
3. *R is the concept-registry route row, recording the* $\mathsf{ConceptRegistrySurface}^{\uparrow}$ *concept entry when the subject term names a concept-facing route.*
4. *E is the registry-export route row, recording the* $\mathsf{RegistryExportSurface}^{\uparrow}$ *export surface through which a public subject entry may leave the registry lattice.*
5. *G is the consistency-gate route row, recording the* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *check that keeps registry entry, export grade, closure status, and formal target aligned.*
6. *T is the tradition/science bridge row, recording the* $\mathsf{TraditionScienceRegistryBridge}^{\uparrow}$ *route when the subject term points into inherited comparison or science-roadmap vocabulary.*
7. *H stores componentwise* hsame *transport for ordinary subject entries, core registry rows, concept rows, export rows, consistency-gate rows, tradition/science rows, replay, provenance, and local naming.*
8. *K stores displayed* Cont *replay through ordinary subject lookup, core registry indexing, concept registry lookup, registry export, consistency-gate inspection, and tradition/science bridge handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{SubjectIndexRoute}^{\uparrow}$, $\mathsf{CoreRegistryIndex}^{\uparrow}$, $\mathsf{ConceptRegistrySurface}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, $\mathsf{TraditionScienceRegistryBridge}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SubjectIndexRoute}^{\uparrow}}$ *row.*

The carrier has no coordinate for a public subject entry without a displayed registry row, for a hidden ordinary-language index, for a route outside the registry lattice, or for prose synthesis that bypasses $S = (O, C, R, E, G, T, H, K, P, N)$.

Theorem 1272.2 (SubjectIndexRoute NameCert obligations)**.** *For the carrier of Definition 1272.1, the local* $\mathsf{NameCert}_{\mathsf{SubjectIndexRoute}^{\uparrow}}$ *surface consists exactly of carrier admission for $S = (O, C, R, E, G, T, H, K, P, N$ ordinary subject-entry exposure through O; core registry routing through C; concept registry routing through R; registry export routing through E; consistency-gate routing through G; tradition/science bridge routing through T; componentwise transport through H; displayed continuation replay through K; package provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.SubjectIndexRouteUp.SubjectIndexRouteUp single carrier alignment`

Proof. Project the finite packet of Definition 1272.1. The ordinary subject row O gives the reader-facing entry point, while C, R, E, G, T display the registry lattice positions reached by that entry.

The sibling chapters supply the table, concept, export, consistency, and tradition/science surfaces. $\mathsf{SubjectIndexRoute}^{\uparrow}$ does not copy any one sibling alone; it binds the route from ordinary vocabulary into the same finite registry lattice.

Finally H, K, P, N transport, replay, package, and name the same packet. Since the carrier contains no hidden subject index or prose-only route, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{SubjectIndexRoute}^{\uparrow}}$ surface. □

Theorem 1272.3 (SubjectIndexRoute registry sibling handoff)**.** *Every accepted* $\mathsf{SubjectIndexRoute}^{\uparrow}$ *packet hands an ordinary subject entry to at least one displayed sibling row among chapter 1251, chapter 1252, chapter 1216, chapter 1224, and chapter 1270. A consumer cannot replace that handoff by ordinary prose, host semantics, hidden registry state, or local naming alone.*

Proof. Use the obligations of Definition 1272.2. An accepted packet must display the ordinary subject-entry row O together with the sibling route rows C, R, E, G, T and the support rows H, K, P, N.

If none of C, R, E, G, T is displayed, then O has no registry destination and the packet is not an accepted subject-index route. If a consumer keeps only local naming, the same destination data is still absent.

Thus each accepted subject entry reaches the registry lattice through a displayed sibling row. The route may pass through the core index, concept surface, export surface, consistency gate, or tradition/science bridge, but it cannot bypass the displayed handoff. □

Falsifiable prediction: Any accepted SubjectIndexRouteUp export that reaches a public subject entry without a displayed registry row refutes the packet.

Independence witness: coreregistryindex, conceptregistrysurface, registryexportsurface, registryexportconsistencygate, traditionscienceregistrybridge: SubjectIndexRouteUp is not bijective to any of these because it stores the route from subject vocabulary into the registry lattice rather than a registry table, export surface, consistency gate, or bridge alone.

The Lean follow-up must provide Nontrivial SubjectIndexRoute$^{\uparrow}$ and FieldFaithful SubjectIndexRoute$^{\uparrow}$ instances in `lean4/BEDC/Derived/SubjectIndexRouteUp/TasteGate.lean`. The instances must preserve $O, C, R, E, G, T, H, K, P, N$ as separate displayed fields before any checked theorem may cite the packet as a TasteGate surface.

Closure status for NameCert$_{\text{SubjectIndexRoute}^{\uparrow}}$.

Constructive story: A SubjectIndexRoute$^{\uparrow}$ packet is generated from ordinary subject-entry, core registry, concept registry, registry export, consistency-gate, tradition/science bridge, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{SubjectIndexRoute}^{\uparrow}}$, seed)

Scope closed: Definition 1272.1, Definition 1272.2, and Definition 1272.3 bind ordinary subject entries to displayed registry-lattice routes.

Formal verification: FormalStatus(NameCert$_{\text{SubjectIndexRoute}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, completeness of the subject index, or correctness of every downstream registry entry.

Upgrade path: Lean closure requires Nontrivial SubjectIndexRouteUp and FieldFaithful SubjectIndexRouteUp instances in `lean4/BEDC/Derived/SubjectIndexRouteUp/TasteGate.lean`.

Chapter 1273

A Concrete Naming Certificate for $\mathsf{ScientificModelBridge}^{\uparrow}$

The $\mathsf{ScientificModelBridge}^{\uparrow}$ packet realizes the science-bridge site of section 9462.28 as finite BEDC certificate data. It sits after the scientific-object carrier of chapter 1214, the physical-model audit of chapter 1129, the standard-bridge audit packet of chapter 1217, the reality-constrained model audit of chapter 1124, and the open-fit packet of chapter 1137. Those siblings expose object records, physical audit, bridge audit, model-facing audit, and open empirical fit; this packet binds them into a bridge carrier whose public reads cannot replace internal certificates with an external standard model.

Definition 1273.1 (Scientific model bridge carrier)**.** *A* $\mathsf{ScientificModelBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, B, R, F, L, T, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{ScientificObject}^{\uparrow}$ *row exposing the scientific-object record, classifier, empirical ledger, bridge row, gap report, audit support, open-fit support, and local naming surface.*
2. *A is the* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *row exposing source traces, target phenomenon, observed and model signatures, audit classifier, tower data, failure surface, and audit strength.*
3. *B is the* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *row exposing encoding, decoding, round-trip, theorem preservation, no-host-leak, transport, provenance, and local naming data for a proposed standard bridge.*
4. *R is the* $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$ *row that records model-facing acceptance, rejection, or open status against finite BEDC evidence.*
5. *F is the* $\mathsf{OpenFitPacket}^{\uparrow}$ *row exposing finite fit, finite defeat, continuation scope, and no-final-oracle boundary.*
6. *L is the empirical ledger row recording accepted observations, failed predictions, open prediction gaps, and the declared falsification surface for the bridge.*
7. *T is the transport row that records how the object, audit, bridge-audit, model-audit, open-fit, and ledger rows are replayed into a consumer-facing prediction route.*
8. *H records componentwise* hsame *transport for $O, A, B, R, F, L, T, C, P, N$.*

9. *C records the displayed* Cont *routes by which the scientific-object, audit, bridge, model-audit, open-fit, ledger, transport, and prediction rows are replayed.*
10. *P is the* Pkg *provenance over* $\mathsf{ScientificModelBridge}^{\uparrow}$, $\mathsf{ScientificObject}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$, $\mathsf{RealityConstrainedModelAudit}^{\uparrow}$, $\mathsf{OpenFitPacket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ScientificModelBridge}^{\uparrow}}$ *row.*

The classifier compares carriers only through these rows. It has no coordinate for external model authority, host-theory equality, unledgered empirical adequacy, unbounded prediction streams, hidden quotient classes, or a bridge accepted without the local audit rows.

Lean4 ✓ `BEDC.Derived.ScientificModelBridgeUp.TasteGate.ScientificModelBridgeTasteGate single carrier alignment`

Theorem 1273.2 (Scientific model bridge NameCert obligations)**.** *For the carrier of Definition 1273.1, the local* $\mathsf{NameCert}_{\mathsf{ScientificModelBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for $M = (O, A, B, R, F, L, T, H, C, P, N)$, scientific-object exposure through O, physical-model audit exposure through A, standard-bridge audit exposure through B, reality-constrained model-audit exposure through R, open-fit exposure through F, empirical-ledger and falsification-surface exposure through L, prediction-transport exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ScientificModelBridgeUp.ScientificModelBridgeCarrier namecert obligations`

Proof. Project the accepted packet to its displayed rows. The scientific-object row O supplies the object-facing record, gap, audit, and bridge support; the rows A, B, R, F supply the physical audit, standard-bridge audit, reality-constrained model audit, and open-fit surfaces.

Read the ledger and prediction route next. The row L records empirical support, failed predictions, open gaps, and falsification exposure, while T records the consumer-facing prediction transport. These rows make the bridge a finite BEDC carrier rather than a detached model identifier.

Finally apply componentwise transport, continuation replay, provenance, and local naming. The rows H, C, P, N preserve exactly the displayed object, audit, bridge, model-audit, open-fit, ledger, and prediction surfaces. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 1273.3 (Scientific model bridge falsifiable prediction)**.** *Every accepted* $\mathsf{ScientificModelBridge}^{\uparrow}$ *packet that exports a prediction route must expose the empirical ledger row L and prediction transport row T together with the object, physical-audit, standard-bridge-audit, model-audit, and open-fit rows O, A, B, R, F. If a downstream consumer reads the bridge while deleting L, deleting T, bypassing the open-fit row F, or replacing B by external standard-model authority, then the consumer has left the accepted packet. A defeating observation is admissible exactly as a finite update to the displayed ledger and open-fit surface, not as a host verdict outside the carrier.*

Lean4 ✓ `BEDC.Derived.ScientificModelBridgeUp.ScientificModelBridgeCarrier falsifiable prediction`

Proof. Begin with the NameCert obligation surface of Definition 1273.2. Any accepted prediction route must carry $O, A, B, R, F, L, T, H, C, P, N$ before a consumer can read the local name.

The scientific-object row keeps the object record and gap report visible, the audit rows keep model-facing evidence visible, the standard-bridge audit row keeps bridge discipline internal, and

the open-fit row keeps finite defeat and continuation scope visible. The ledger row L and transport row T then state where a prediction is read and where a finite defeating observation may enter.

Thus a consumer that removes L or T no longer has a prediction surface, and a consumer that removes F no longer has the open empirical boundary. A consumer that replaces B by an external standard model bypasses the bridge-audit row and therefore bypasses the carrier. The only accepted falsification route is the displayed finite update through L and F under the same H, C, P, N support. □

Theorem 1273.4 (Scientific model bridge scoped kernel route)**.** *The scoped bridge route for* ScientificModelBridge$^{\uparrow}$ *is exactly the finite readback surface generated by the* ScientificObject$^{\uparrow}$, PhysicalModelAudit$^{\uparrow}$, StandardBridgeAuditPacket$^{\uparrow}$, RealityConstrainedModelAudit$^{\uparrow}$, OpenFitPacket$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows of an accepted carrier* $M = (O, A, B, R, F, L, T, H, C, P, N)$*. A consumer may inspect the empirical ledger and prediction transport only through those rows, and no external standard-model authority, unledgered empirical adequacy, host-theory equality, quotient-model equality, or unbounded prediction stream lies inside the scoped route.*

Proof. Use the carrier of Definition 1273.1. Its displayed rows are precisely the scientific-object, physical-audit, bridge-audit, model-audit, open-fit, ledger, prediction-transport, componentwise transport, replay, provenance, and local naming coordinates.

The obligation theorem Definition 1273.2 makes those coordinates the local NameCert surface. The falsifiable-prediction theorem Definition 1273.3 then forces every prediction read to keep the ledger L, transport row T, and open-fit row F visible together with the object and audit rows.

The excluded alternatives have no carrier coordinate. Therefore the scoped kernel route is exactly the listed finite surface over ScientificObject$^{\uparrow}$, PhysicalModelAudit$^{\uparrow}$, StandardBridgeAuditPacket$^{\uparrow}$, RealityConstrainedModelAudit$^{\uparrow}$, OpenFitPacket$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert. □

Lean4 ✓ `BEDC.Derived.ScientificModelBridgeUp.ScientificModelBridgeCarrier scoped kernel route`

Falsifiable prediction: Deleting the empirical ledger, prediction transport, open-fit surface, or standard-bridge audit row from an accepted ScientificModelBridgeUp packet breaks the bridge classifier.

Independence witness: scientificobject, physicalmodelaudit, standardbridgeauditpacket, realityconstrainedmodelaudit, openfitpacket: none is bijective because ScientificModelBridge$^{\uparrow}$ binds object records, physical audit, bridge audit, model-facing audit, open fit, empirical ledger, prediction transport, componentwise hsame transport, Cont replay, Pkg provenance, and one local NameCert row in a single bridge packet.

Closure status for NameCert$_{\text{ScientificModelBridge}^{\uparrow}}$.

Constructive story: A ScientificModelBridge$^{\uparrow}$ packet is generated from scientific-object, physical-model-audit, standard-bridge-audit, reality-constrained-model-audit, open-fit, empirical-ledger, prediction-transport, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{ScientificModelBridge}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1273.1, Definition 1273.2, and Definition 1273.3 bind the ScientificObject, PhysicalModelAudit, StandardBridgeAuditPacket, RealityConstrainedModelAudit, and OpenFitPacket sibling rows to the displayed bridge packet $O, A, B, R, F, L, T, H, C, P, N$.

Formal verification: FormalStatus(NameCert$_{\text{ScientificModelBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove external standard-model correctness, physical truth, bridge checking, complete empirical adequacy, unbounded prediction coverage, quotient-model equivalence, or a Lean implementation.

Upgrade path: Scoped closure requires grounding the displayed object, audit, bridge-audit, model-audit, open-fit, ledger, prediction-transport, replay, provenance, and local NameCert rows against the named sibling chapters.

Chapter 1274

A Concrete Naming Certificate for $\mathsf{UpgradeRegistry}^{\uparrow}$

The $\mathsf{UpgradeRegistry}^{\uparrow}$ packet realizes the upgrade-registry table of subsection 9462.34.8 as a finite NameCert surface for promotion claims. It sits beside the claim-entry discipline of chapter 1209, the public export gate of chapter 1216, and the refusal axis of chapter 554. Those siblings admit a claim row, expose registry export, and block overstrong readings; this packet binds the current-status, next-status, blocker, formal-target, provenance, transport, and local naming rows before any promotion may be read as accepted.

Definition 1274.1 (UpgradeRegistry carrier)**.** *An* $\mathsf{UpgradeRegistry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (T, S, Nx, F, B, A, R, H, C, P, L)$$

with the following displayed rows:

1. *T is the target row naming the chapter, package, theorem site, registry family, or bridge surface whose status may be promoted;*
2. *S is the current-status row, recording the theory grade, verification grade, and bridge-status grade presently exported by the target;*
3. *Nx is the next-status row, naming the immediate stronger status that may be accepted only after the required rows are discharged;*
4. *F is the required-field row, listing the carrier, classifier, stability, exactness, ledger, bridge, or proof fields that must become public packet data;*
5. *B is the blocker row, recording the open gap, refused reading, missing proof, missing bridge, or unresolved dependency that prevents immediate completion export;*
6. *A is the audit row, recording the registry-consistency, writing-discipline, and cannot-claim checks consumed before the promotion is exported;*
7. *R is the formal-target row, naming the Lean declaration, statement-only target, bridge obligation, or absence of such a target as public registry data;*
8. *H records componentwise* hsame *transports for the target, current-status, next-status, field, blocker, audit, formal-target, continuation, package, and local naming rows;*
9. *C records displayed* Cont *routes by which claim consumers, export consumers, and refusal consumers read the same promotion packet;*

10. *P is the* Pkg *provenance row over* ClaimRegistryLayer$^{\uparrow}$, RegistryExportSurface$^{\uparrow}$, AxisZeckendorfCannotClaim$^{\uparrow}$, AuditWritingDiscipline$^{\uparrow}$, RegistryConsistencyAudit$^{\uparrow}$, BHist, hsame, Cont, *and local certificate data;*
11. *L is the local* NameCert$_{\text{UpgradeRegistry}^{\uparrow}}$ *row.*

The classifier for two accepted upgrade-registry packets compares only the displayed target, current-status, next-status, required-field, blocker, audit, formal-target, transport, continuation, package, and local naming rows.

Lean4 ✓ `BEDC.Derived.UpgradeRegistryUp.TasteGate.UpgradeRegistryTasteGate single carrier alignment`

Theorem 1274.2 (UpgradeRegistry NameCert obligations)**.** *For the carrier of Definition 1274.1, the local* NameCert$_{\text{UpgradeRegistry}^{\uparrow}}$ *surface consists of six finite obligations:*

1. *carrier exposure: every accepted registry promotion packet exposes exactly $U = (T, S, Nx, F, B, A, R, H, C, P, L)$;*
2. *status locality: public comparison reads the current-status row S and next-status row Nx before any promotion claim is exported;*
3. *blocker accountability: every accepted blocker row B remains visible to the claim registry and cannot-claim registry until the required-field row F is discharged;*
4. *formal-target exposure: the formal-target row R is public packet data and cannot be replaced by prose expectation or hidden tooling state;*
5. *audit preservation: registry-consistency and writing-discipline checks are carried through the audit row A and the displayed* Cont *routes in C;*
6. *naming locality: componentwise* hsame, Pkg, *and* NameCert *provenance preserve the same promotion packet for all public consumers.*

Lean4 ✓ `BEDC.Derived.UpgradeRegistryUp.UpgradeRegistryNameCertObligations`

Proof. Carrier exposure is projection from Definition 1274.1. The tuple displays the target, status rows, required fields, blockers, audit route, formal target, transports, continuations, package provenance, and local naming row.

Status locality and blocker accountability follow from the classifier. Since $S, Nx, F, B, A, R, H, C, P, L$ are the only compared rows, a consumer cannot read a promotion without also reading the current status and the blocker surface that prevents completion export.

Formal-target exposure and audit preservation are the R, A, C coordinates. The claim layer admits the row only through the public registry packet, while the export surface and cannot-claim sibling read the same displayed continuation routes. Componentwise transport and package provenance then repack the rows as the local NameCert packet. □

Theorem 1274.3 (UpgradeRegistry status preservation)**.** *If an accepted* UpgradeRegistry$^{\uparrow}$ *packet has current-status row S, next-status row Nx, required-field row F, blocker row B, audit row A, and formal-target row R, then every public export route preserves the distinction between current status and next status. A promotion claim may be exported only through the displayed route $S, Nx, F, B, A, R, H, C, P, L$; it cannot be exported from the next-status row alone.*

Lean4 ✓ `BEDC.Derived.UpgradeRegistryUp.UpgradeRegistryStatusPreservation`

Proof. Apply Definition 1274.2. The status rows are adjacent coordinates in the finite carrier, and the NameCert obligations force both to remain visible to the public comparison.

The blocker and required-field rows are also displayed. Thus a route that attempts to read Nx as already accepted must also expose F and B, where the unmet field or blocker remains part of the same packet.

Finally, the export route factors through A, R, H, C, P, L. These rows preserve audit, formal-target, transport, continuation, provenance, and local naming data, so no consumer route can erase the current-status row while retaining the promotion claim. □

Theorem 1274.4 (UpgradeRegistry noncompletion surface)**.** *An accepted* $\mathsf{UpgradeRegistry}^{\uparrow}$ *packet with no current-status row or no blocker row cannot export a completion claim. The packet may still expose a target row, next-status row, required-field row, audit row, or formal-target row, but those rows do not constitute a completed promotion without the displayed current-status and blocker accounting.*

Lean4 ✓ `BEDC.Derived.UpgradeRegistryUp.UpgradeRegistryNoncompletionSurface`

Proof. Use the carrier definition. A valid packet exposes S and B as coordinates, so a route without either coordinate is not the accepted carrier of Definition 1274.1.

Use status preservation from Definition 1274.3. Completion export requires a route that preserves the distinction between current status and next status, and that route also carries the blocker surface. Without S or B, the route may at most display a target, desired status, field list, audit row, or formal target; it cannot display the complete promotion packet. □

Theorem 1274.5 (UpgradeRegistry public export)**.** *Any public* $\mathsf{UpgradeRegistry}^{\uparrow}$ *export must expose the target row, current-status row, next-status row, required-field row, blocker row, audit row, formal-target row, componentwise transport row, continuation row, provenance row, and local* $\mathsf{NameCert}_{\mathsf{UpgradeRegistry}^{\uparrow}}$ *row. Export through* $\mathsf{RegistryExportSurface}^{\uparrow}$ *and* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *cannot erase blocker accountability or read the next-status row as a completed promotion.*

Lean4 ✓ `BEDC.Derived.UpgradeRegistryUp.UpgradeRegistryPublicExport`

Proof. Apply Definition 1274.2. The public packet is the displayed carrier $U = (T, S, Nx, F, B, A, R, H, C, P, L)$, so every export route reads the target, status, field, blocker, audit, formal target, transport, continuation, provenance, and local naming rows.

Apply Definition 1274.3. The current-status row S and the next-status row Nx remain distinct along every public route, and the required-field and blocker rows travel with that distinction.

Finally apply Definition 1274.4. A route through $\mathsf{RegistryExportSurface}^{\uparrow}$ or $\mathsf{ClaimRegistryLayer}^{\uparrow}$ that drops S or B may still display registry metadata, but it cannot export completion. Thus blocker accountability remains public whenever the upgrade-registry packet is exported. □

Falsifiable prediction: An accepted $\mathsf{UpgradeRegistry}^{\uparrow}$ packet with no current-status row or blocker row cannot export a completion claim.

Independence witness: claimregistrylayer, registryexportsurface, auditwritingdiscipline, axiszeckendorfcannotclaim, registryconsistencyaudit: $\mathsf{UpgradeRegistry}^{\uparrow}$ is not bijective to any sibling because it simultaneously carries target, current-status, next-status, required-field, blocker, audit, formal-target, transport, continuation, provenance, and local NameCert rows. The claim layer admits claim rows without the full promotion packet; the export surface controls release without blocker accounting; the writing-discipline packet controls prose legality without next-status fields; the cannot-claim packet records refusals without promotion transport; and the consistency audit checks agreement without owning the registry entry.

The Lean follow-up for this chapter must provide $\mathsf{Nontrivial\ UpgradeRegistry}^{\uparrow}$ and $\mathsf{FieldFaithful\ UpgradeRegistry}^{\uparrow}$ instances for the displayed carrier fields.

Theorem 1274.6 (UpgradeRegistry bridged handoff surface)**.** *Every bridge-facing read of an accepted* $\mathsf{UpgradeRegistry}^{\uparrow}$ *packet routes through the target row, current-status row, next-status row, required-field row, blocker row, audit row, formal-target row, componentwise transport row, continuation row, provenance row, and local* $\mathsf{NameCert}_{\mathsf{UpgradeRegistry}^{\uparrow}}$ *row before any promotion surface is exported. The handoff therefore exposes the same finite route* $T, S, Nx, F, B, A, R, H, C, P, L$ *to bridge consumers as to public registry consumers, and it cannot replace blocker accountability, status preservation, audit exposure, or formal-target exposure by hidden bridge state.*

Proof. Read the public export theorem Definition 1274.5. It already forces every public promotion route to expose $T, S, Nx, F, B, A, R, H, C, P, L$ before completion can be claimed.

A bridge-facing consumer is still a consumer of the same accepted registry packet. The carrier of Definition 1274.1 has no separate bridge-only coordinate, so the bridge read cannot bypass the target, status, required-field, blocker, audit, formal-target, transport, continuation, provenance, or local naming rows.

Status preservation and the noncompletion surface then keep the blocker and current-status rows visible. Thus the bridge-facing handoff is a route through the displayed packet rather than an external promotion assertion. □

Closure status for $\mathsf{NameCert}_{\mathsf{UpgradeRegistry}^{\uparrow}}$**.**

Constructive story: An $\mathsf{UpgradeRegistry}^{\uparrow}$ packet is generated from target, current-status, next-status, required-field, blocker, audit, formal-target, transport, continuation, package, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UpgradeRegistry}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1274.1, Definition 1274.2, Definition 1274.3, Definition 1274.4, Definition 1274.5, and Definition 1274.6 scope the public and bridge-facing export surfaces for the target, current-status, next-status, required-field, blocker, audit, formal-target, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{UpgradeRegistry}^{\uparrow}}$ rows owned by the upgrade-registry certificate.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UpgradeRegistry}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, or completion of registry promotions beyond the displayed public and bridge-facing export surfaces.

Upgrade path: No theory-axis upgrade remains; the remaining work is Lean verification and bridge checking for the displayed registry rows.

Chapter 1275

A Concrete Naming Certificate for $\mathsf{RelationalPhysics}^{\uparrow}$

The $\mathsf{RelationalPhysics}^{\uparrow}$ packet realizes the relational-physics site of subsection 9462.29.10 as finite BEDC certificate data. The recognized tradition supplies the external reading that physical content is relational rather than attached to a privileged global frame; the packet below keeps the BEDC realization internal to observer-history identity, inter-history locality, inter-history invariant, physical-model audit, admissible rate or refusal rows, displayed transport, replay, provenance, and local naming.

Its sibling context is the observer-history identity surface of chapter 479, the invariant readback of chapter 656, the locality ledger of chapter 759, and the physical-model audit of chapter 1129. The philosophical horizon is the relational-physics synthesis site of subsection 9462.29.10.

Definition 1275.1 (Relational physics carrier)**.** *A* $\mathsf{RelationalPhysics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (O, I, L, V, A, H, C, P, N)$$

with the following displayed rows:

1. *O is the observer-history identity row, read through* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *and carrying only history, observation,* hsame*,* Cont*,* Pkg*, and local naming data.*
2. *I is the inter-history invariant row supplied by* $\mathsf{InterHistInvariant}^{\uparrow}$ *after the relevant two-history packet and relation row have been displayed.*
3. *L is the inter-history locality ledger row supplied by* $\mathsf{InterHistLocalityLedger}^{\uparrow}$*, binding the two source histories, locality cells, invariant readback, and no-global-frame exclusion.*
4. *V is the visible physical-model audit row supplied by* $\mathsf{PhysicalModelAudit}^{\uparrow}$*, recording source traces, observed and model signatures, classifier, tower, failure surface, and audit strength as finite packet data.*
5. *A is the admissible rate or refusal row: it either carries a maximum-rate certificate accepted by the relevant inter-history route, or a displayed refusal that no such rate row is licensed for the packet.*
6. *H records componentwise* hsame *transport for O, I, L, V, A, C, P, N.*
7. *C records the displayed* Cont *routes by which observer identity, locality, invariant readback, model audit, admissible rate or refusal, and consumer handoff are replayed.*

8. *P is the* Pkg *provenance over* $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, $\mathsf{InterHistLocalityLedger}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RelationalPhysics}^{\uparrow}}$ *row.*

The classifier compares carriers only through these rows. It has no coordinate for an absolute frame, global synchronization history, host spacetime, quotient of histories, unbounded observation stream, detached physical truth oracle, or unledgered model equivalence.

Lean4 ✓ `BEDC.Derived.RelationalPhysicsUp.RelationalPhysicsTasteGate single carrier alignment`

Theorem 1275.2 (Relational physics NameCert obligations)**.** *For the carrier of Definition 1275.1, the local* $\mathsf{NameCert}_{\mathsf{RelationalPhysics}^{\uparrow}}$ *surface consists exactly of carrier admission for $R = (O, I, L, V, A, H, C, P, N)$, observer-history identity through O, inter-history locality through L, invariant readback through I, visible physical-model audit through V, admissible rate or displayed refusal through A, component-wise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.RelationalPhysicsUp.RelationalPhysicsCarrier namecert obligations`

Proof. Project the accepted packet to the nine displayed rows. The rows O, I, L, V, A are the only relational and physical content coordinates, while H, C, P, N provide transport, replay, provenance, and naming.

Read observer identity first. The row O is governed by chapter 479, so it supplies no observer-substance, host observer equality, or quotient identity.

Read locality and invariant content next. The row L comes from the finite locality ledger of chapter 759, and the row I comes from the invariant readback of chapter 656. These rows keep the physical relation on displayed history packets rather than on a global frame.

Finally read the audit and rate boundary. The row V is the visible physical-model audit of chapter 1129, and A is either the licensed rate row or the refusal row. Since the carrier contains no further physical coordinate, the listed rows exhaust the NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.RelationalPhysicsUp.RelationalPhysicsNameCertObligations`

Theorem 1275.3 (Relational physics invariant route exclusion)**.** *Every accepted* $\mathsf{RelationalPhysics}^{\uparrow}$ *consumer that reads relational physical content must factor through the displayed observer-history identity row O, locality ledger row L, inter-history invariant row I, visible physical-model audit row V, admissible rate or refusal row A, and the support rows H, C, P, N. No such consumer may add an absolute frame, synchronized global clock, ambient spacetime, quotient history equality, unbounded observation stream, detached physical truth oracle, or model equivalence outside the audit row.*

Proof. Start with carrier admission from Definition 1275.1. The public packet has exactly the rows $O, I, L, V, A, H, C, P, N$.

Apply the NameCert obligations of Definition 1275.2. They force identity, locality, invariant, audit, and rate-or-refusal reads to pass through the corresponding displayed rows before any consumer handoff can occur.

The exclusions are immediate from the carrier inventory. Absolute frames, synchronized clocks, ambient spacetime, quotient history equality, unbounded observations, detached truth oracles, and model equivalence outside the audit row are not coordinates of R and cannot be created by hsame, Cont, Pkg, or the local NameCert row. □

Lean4 ✓ `BEDC.Derived.RelationalPhysicsUp.RelationalPhysicsGlobalFrameTailExclusion`

Theorem 1275.4 (Relational physics NameCert handoff)**.** *The downstream handoff from an accepted* $\mathsf{RelationalPhysics}^{\uparrow}$ *packet is the finite route*

$$O, L, I, V, A, H, C, P, N.$$

It presents relational physical content as observer-history identity, inter-history locality, invariant readback, visible model audit, admissible rate or refusal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. It does not present a completed physical theory, global geometry, semantic real-valued dynamics, or bridge-checked standard model.*

Lean4 ✓ `BEDC.Derived.RelationalPhysicsUp.RelationalPhysics namecert handoff`

Proof. Project the accepted carrier and order the consumer route by the displayed dependencies. The observer-history row O gives the identity surface, L gives locality, I gives the invariant readback, and V gives the physical-model audit.

The row A records whether the route carries an admissible rate certificate or an explicit refusal. Transport and replay are then supplied only by H and C, with P and N recording provenance and local naming.

Apply Definition 1275.3. The same route excludes global geometry, semantic real-valued dynamics, detached physical truth, and bridge checking because none is a displayed coordinate of the accepted packet. □

Theorem 1275.5 (Relational physics observer-locality-rate obligation)**.** *Every accepted* $\mathsf{RelationalPhysics}^{\uparrow}$ *packet that exports relational physical content must display observer-history identity, inter-history locality, invariant readback, physical-model audit, and admissible rate or refusal before the export. In carrier notation, the consumer route is*

$$O, L, I, V, A, H, C, P, N,$$

where O supplies observer-history identity, L supplies locality, I supplies invariant readback, V supplies visible model audit, A supplies the admissible rate certificate or refusal, and H, C, P, N supply transport, replay, provenance, and local naming. No export may bypass these rows by using an absolute frame, global synchronization history, ambient spacetime, detached truth oracle, unbounded observation stream, or unledgered model equivalence.

Proof. Project the carrier of Definition 1275.1. Its only relational-content rows are O, I, L, V, A, and its only structural rows are H, C, P, N.

Apply the NameCert obligations of Definition 1275.2. They require observer identity, locality, invariant readback, physical-model audit, and admissible rate or refusal to be read through their displayed rows before the local $\mathsf{NameCert}_{\mathsf{RelationalPhysics}^{\uparrow}}$ row can support a downstream export.

Use route exclusion and handoff, Definition 1275.3 and Definition 1275.4. The exclusion theorem rules out the non-displayed global and semantic endpoints, while the handoff theorem orders the surviving route as $O, L, I, V, A, H, C, P, N$. Thus the observer-locality-rate obligation is exactly the finite BEDC row route listed above. □

Lean4 ✓ `BEDC.Derived.RelationalPhysicsUp.RelationalPhysicsObserverLocalityRateObligation`

Theorem 1275.6 (Relational physics kernel scope closure)**.** *Every accepted* $\mathsf{RelationalPhysics}^{\uparrow}$ *packet scopes observer-history identity, inter-history locality, invariant readback, admissible rate or refusal, transport, replay, provenance, and local naming through explicit BEDC kernel rows. In carrier notation, the packet is read only through* BHist *rows for* $O, I, L, V, A, H, C, P, N$*,* hsame *transport in* H*,* Cont *replay in* C*,* Pkg *provenance in* P*, and the local* $\mathsf{NameCert}_{\mathsf{RelationalPhysics}^{\uparrow}}$ *row* N*.*

Proof. Begin with the carrier projection of Definition 1275.1. It displays the observer-history identity row O, invariant row I, locality row L, physical-model audit row V, and admissible rate or refusal row A as finite BHist data.

Apply the NameCert obligations of Definition 1275.2. The obligation surface requires each observer, locality, invariant, audit, and rate-or-refusal read to pass through those displayed rows before export.

Finally use Definition 1275.4 and Definition 1275.5. They order the structural route through H, C, P, N, so transport is hsame, replay is Cont, provenance is Pkg, and naming is exactly the local $\mathsf{NameCert}_{\mathsf{RelationalPhysics}^{\uparrow}}$ row. No remaining coordinate is available outside the BEDC kernel rows named in the statement. □

Lean4 ✓ `BEDC.Derived.RelationalPhysicsUp.RelationalPhysicsKernelScopeClosure`

Falsifiable prediction: Any accepted RelationalPhysicsUp consumer that exports relational physical content while bypassing observer-history identity, inter-history locality, invariant readback, physical-model audit, or the admissible rate and refusal row fails the carrier classifier.

Independence witness: observerhistidentity, interhistinvariant, interhistlocalityledger, physicalmodelaudit: none carries observer-history identity, locality ledger, invariant readback, visible model audit, admissible rate or refusal, componentwise hsame transport, Cont replay, Pkg provenance, and one local NameCert row in a single relational-physics packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RelationalPhysics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RelationalPhysics}^{\uparrow}$ packet is generated from observer-history identity, inter-history invariant, locality ledger, physical-model audit, admissible rate or refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RelationalPhysics}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1275.1, Definition 1275.2, Definition 1275.3, Definition 1275.4, and Definition 1275.5 form the obligation surface for observer-history identity, locality, invariant readback, physical-model audit, rate or refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RelationalPhysics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not derive a completed physical theory, global spacetime geometry, semantic real-valued dynamics, host physical truth, or a standard bridge for relational physics.

Upgrade path: The next paper grade is public export for the observer-history, locality, invariant, physical-model audit, rate or refusal, transport, replay, provenance, and local NameCert rows.

Chapter 1276

A Concrete Naming Certificate for $\mathsf{FiniteLimitSealEnvelope}^{\uparrow}$

The $\mathsf{FiniteLimitSealEnvelope}^{\uparrow}$ packet is the finite seal surface for the Real and Completion limit theorem of chapter 9238. It consumes the finite stream naming surface of chapter 126, the regular-rational readback surface of chapter 301, the dyadic endpoint ledger of chapter 291, the terminal real-name seal of chapter 38, and the completion handoff of chapter 386. Its role is to bind one displayed window, readback, tolerance row, limit seal, RealUp handoff, and naming route into a consumer-facing envelope for Definition 9238.5.

Definition 1276.1 (Finite limit-seal envelope carrier)**.** *A* $\mathsf{FiniteLimitSealEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (W, R, D, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window selected for the displayed limit request;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same window;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint ledger used to compare the readback with the requested precision;*
4. *L is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row certifying that the finite window and readback feed the limit-seal route;*
5. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *handoff row consumed by Real and Completion users;*
6. *H records componentwise* hsame *transport for W, R, D, L, Q and the local naming row;*
7. *C records displayed* Cont *replay from the finite window through readback, dyadic tolerance, limit seal, and RealUp handoff;*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSealEnvelope}^{\uparrow}}$ *row.*

The carrier exports only these finite rows and their support. It has no coordinate for quotient stream equality, host real equality, a selected host limit, countable choice, ambient completeness, or a second limit route.

Lean4 ✓ BEDC.Derived.FiniteLimitSealEnvelopeUp.FiniteLimitSealEnvelopeTasteGate single carrier alignment

Theorem 1276.2 (Finite limit-seal envelope NameCert obligations)**.** *For the carrier of Definition 1276.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSealEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission for* $E = (W, R, D, L, Q, H, C, P, N)$*, finite StreamName window exposure through* W*, RegSeqRat readback through* R*, dyadic tolerance and endpoint exposure through* D*, CauchyLimitSeal handoff through* L*, terminal RealUp handoff through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. The displayed packet lists one finite stream window, one regular-rational readback, one dyadic tolerance ledger, one completion-facing limit seal, one terminal RealUp handoff, and four structural support rows.

Read the data rows in order. The window W supplies the finite observation surface, R is the readback attached to that window, D records the dyadic tolerance evidence for the same request, and L records that these rows feed the CauchyLimitSeal route.

The terminal row Q is then available only as the RealUp handoff reached through W, R, D, L. The rows H, C, P, N transport, replay, source, and name that same finite packet, so the listed obligations exhaust the local NameCert surface. □

Theorem 1276.3 (Finite limit-seal envelope non-choice boundary)**.** *Every accepted* $\mathsf{FiniteLimitSealEnvelope}^{\uparrow}$ *packet keeps the Real and Completion limit theorem on the displayed finite route*

$$W, R, D, L, Q, H, C, P, N.$$

A downstream consumer may inspect the StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, CauchyLimitSeal row, RealUp handoff, transport, continuation, provenance, and local NameCert row. It receives no quotient stream equality, host real equality, selected host limit, countable-choice selector, ambient completeness principle, or hidden Real equality rule.

Proof. Start from the carrier inventory of Definition 1276.1. The only route to a Real-facing output is the ordered passage from W through R, D, L to Q.

Apply Definition 1276.2. The local certificate exposes exactly the displayed rows and treats H, C, P, N as support for the same packet, not as independent choice or equality data.

Inspect the excluded objects. Quotient stream equality, host real equality, selected host limits, countable-choice selectors, ambient completeness, and hidden Real equality rules would require coordinates outside $W, R, D, L, Q, H, C, P, N$. Since the carrier has no such coordinate, every accepted consumer remains on the finite route. □

Theorem 1276.4 (Finite limit-seal envelope sibling dependency)**.** *The* $\mathsf{FiniteLimitSealEnvelope}^{\uparrow}$ *carrier depends on the joint availability of* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. No one sibling among chapter 126, chapter 301, chapter 291, chapter 386, and chapter 38 carries the whole tuple* $W, R, D, L, Q, H, C, P, N$*.*

Proof. Compare the finite observation siblings first. The StreamName surface supplies window data, the RegSeqRat surface supplies regular-rational readback, and the DyadicRatCore surface supplies tolerance and endpoint evidence. None of these siblings by itself also carries the completion-facing limit seal and the terminal RealUp handoff.

Compare the seal-facing siblings next. The CauchyLimitSeal surface records the completion handoff, and the RealUp surface records the terminal real-name seal, but neither one includes the finite window, readback, and dyadic tolerance ledger as a single ordered carrier.

Thus the envelope is a composite packet. Its sibling dependence is visible in the carrier itself, and the structural rows H, C, P, N preserve the combined route rather than reducing it to any one sibling surface. □

Theorem 1276.5 (Finite limit-seal envelope public surface)**.** *The public surface exported by an accepted* $\mathsf{FiniteLimitSealEnvelope}^{\uparrow}$ *packet is exactly the finite Real and Completion handoff*

$$\mathsf{StreamName}^{\uparrow}(W), \mathsf{RegSeqRat}^{\uparrow}(R), \mathsf{DyadicRatCore}^{\uparrow}(D), \mathsf{CauchyLimitSeal}^{\uparrow}(L), \mathsf{Real}^{\uparrow}(Q), H, C, P, N.$$

This surface realizes the limit theorem of Definition 9238.5 as a consumer-facing NameCert envelope without exporting quotient streams, host real equality, selected host limits, countable choice, ambient completeness, or a bridge row.

Proof. Use Definition 1276.2 to identify the rows exported by the local certificate. The exported data rows are exactly W, R, D, L, Q, and the support rows are exactly H, C, P, N.

Use Definition 1276.4 to read those rows as the joint StreamName, RegSeqRat, DyadicRatCore, CauchyLimitSeal, and RealUp handoff required by the Real and Completion route. The theorem does not collapse the route to any one sibling.

Finally apply Definition 1276.3. Since the excluded equality, choice, completeness, and bridge coordinates are absent, the public surface is precisely the finite envelope displayed above. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLimitSealEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteLimitSealEnvelope}^{\uparrow}$ packet is generated from a finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, CauchyLimitSeal row, RealUp handoff, componentwise transports, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteLimitSealEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1276.1, Definition 1276.2, Definition 1276.3, Definition 1276.4, and Definition 1276.5 bind the finite composite carrier, NameCert obligations, non-choice boundary, sibling dependency, and public Real and Completion handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteLimitSealEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient stream equality, host real equality, selected host limits, countable choice, ambient completeness, hidden Real equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName window locality, RegSeqRat readback ordering, DyadicRatCore tolerance exposure, CauchyLimitSeal handoff, RealUp handoff, transport stability, replay, provenance, and local naming for the same finite packet.

Chapter 1277

A Concrete Naming Certificate for $\mathsf{PhilosophyMapTarget}^{\uparrow}$

The $\mathsf{PhilosophyMapTarget}^{\uparrow}$ packet realizes the formal target draft of subsection 9462.33.11 as a finite NameCert carrier. It sits beside the concept registry surface of chapter 1252, the core registry index of chapter 1251, the audit system of chapter 1258, the axiom-purity gate of chapter 1259, and the closure-status reference of chapter 1265. Those siblings register concepts, index registry rows, audit accepted packets, rule out host-level axioms, and display closure ledgers; this carrier binds them into one philosophy-map target only when every exported coordinate remains a named BEDC row.

Definition 1277.1 (Philosophy map target carrier)**.** *A* $\mathsf{PhilosophyMapTarget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, G, K, S, A, X, H, C, P, N)$$

with the following displayed rows:

1. *R is the registry-map row, read through* $\mathsf{ConceptRegistrySurface}^{\uparrow}$ *and* $\mathsf{CoreRegistryIndex}^{\uparrow}$*, naming concept entries, theorem entries, tradition entries, scientific entries, and registry-route entries;*
2. *G is the gap-map row, naming typed gaps, formal target rows, missing bridge rows, and not-claimed surfaces;*
3. *K is the cannot-claim row, recording blocked readings for subject substance, global truth, host equality, quotient import, choice import, and hidden far-end objects;*
4. *S is the closure-status row, read through* $\mathsf{ClosureStatusReference}^{\uparrow}$*, recording paper closure, verification status, bridge status, and not-claimed scope for every exported row;*
5. *A is the audit row, read through* $\mathsf{AuditSystem}^{\uparrow}$ *and* $\mathsf{AxiomPurityGate}^{\uparrow}$*, recording the finite audit route that rejects forbidden host-equality, quotient, choice, and global-truth reads;*
6. *X is the synthesis row, recording the philosophy-map target named in Definition 9462.2196 as registry maps, gap maps, cannot-claim conflict checks, closure-status rows, no-smuggling refusal, and audit evidence;*
7. *H records componentwise* hsame *transport for R, G, K, S, A, X;*
8. *C records displayed* Cont *replay through the registry maps, gap maps, cannot-claim checks, closure rows, audit rows, and synthesis row;*

9. *P is the* Pkg *provenance over* ConceptRegistrySurface$^{\uparrow}$, CoreRegistryIndex$^{\uparrow}$, AuditSystem$^{\uparrow}$, AxiomPurityGate$^{\uparrow}$, ClosureStatusReference$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* NameCert$_{\text{PhilosophyMapTarget}^{\uparrow}}$ *row.*

The carrier has no coordinate for a prose-only philosophical map, an unchecked truth predicate, a hidden host equality, a quotient witness, a choice operator, or a closure-status read outside the displayed packet.

Lean4 ✓ `BEDC.Derived.PhilosophyMapTargetUp.TasteGate.PhilosophyMapTargetTasteGate single carrier alignment`

Theorem 1277.2 (Philosophy map target NameCert obligations)**.** *For the carrier of Definition 1277.1, the local* NameCert$_{\text{PhilosophyMapTarget}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for $M = (R, G, K, S, A, X, H, C, P, N)$;*
2. *registry-map coverage through R, requiring every concept, theorem, tradition, scientific, and route entry to factor through* ConceptRegistrySurface$^{\uparrow}$ *and* CoreRegistryIndex$^{\uparrow}$*;*
3. *gap-map and cannot-claim coverage through G and K, requiring every missing proof, formal target, blocked reading, and cannot-claim conflict to be displayed before export;*
4. *closure-status and audit coverage through S and A, requiring every paper closure, verification grade, bridge status, not-claimed surface, and axiom-purity refusal to be read through* ClosureStatusReference$^{\uparrow}$, AuditSystem$^{\uparrow}$, *and* AxiomPurityGate$^{\uparrow}$*;*
5. *structural preservation through X, H, C, P, N, requiring the synthesis row, componentwise transport, displayed replay routes, package provenance, and local naming to preserve the same finite packet.*

Lean4 ✓ `BEDC.Derived.PhilosophyMapTargetUp.PhilosophyMapTargetTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1277.1. The rows R, G, K, S, A, X expose the registry, gap, cannot-claim, closure-status, audit, and synthesis data before any philosophy-map target can be accepted.

The registry row factors through the concept registry surface and core registry index. The gap and cannot-claim rows keep missing proof sites, formal targets, blocked readings, and conflict checks as displayed coordinates rather than prose authority.

The closure-status and audit rows bind every exported reading to a visible closure ledger and to an axiom-purity route. The remaining rows X, H, C, P, N transport, replay, source, and name that same packet, so the five listed rows exhaust the local NameCert surface. □

Theorem 1277.3 (Philosophy map target no-smuggling boundary)**.** *Every accepted* PhilosophyMapTarget$^{\uparrow}$ *packet exposes philosophy-map content only through the rows $R, G, K, S, A, X, H, C, P, N$. If the no-smuggling row K is absent, a consumer may request a forbidden host-equality, quotient, choice, or global-truth read; with K present, no public consumer can read those coordinates from the packet.*

Proof. Use Definition 1277.2. The cannot-claim row K is the only row that records the forbidden readings, while A records the audit route that rejects them and S records the closure-status boundary where they remain not claimed.

If K is removed, the carrier no longer contains the displayed refusal row for host equality, quotient import, choice import, or global-truth import. A request for one of those readings is then

no longer blocked by the accepted packet, because the remaining registry, gap, closure, audit, and synthesis rows do not themselves name every refusal coordinate.

With K present, the refusal row is transported by H, replayed only through C, sourced by P, and named by N. A public consumer receives the finite packet and cannot project any forbidden coordinate not already displayed there. □

Theorem 1277.4 (Philosophy map target public law boundary)**.** *Every public* $\mathsf{PhilosophyMapTarget}^{\uparrow}$ *export factors through the registry-map row R, gap-map row G, cannot-claim row K, closure-status row S, audit row A, synthesis row X, and structural rows H, C, P, N. The export therefore carries only the displayed registry, gap, refusal, closure, audit, synthesis, transport, replay, provenance, and naming coordinates, and no public consumer can read a prose-only philosophy map, unchecked truth predicate, hidden host equality, quotient witness, choice operator, or closure-status row outside the packet.*

Proof. Start with the carrier of Definition 1277.1. It exposes exactly the rows $R, G, K, S, A, X, H, C, P, N$ and has no coordinate for a prose-only philosophical map, unchecked truth predicate, hidden host equality, quotient witness, choice operator, or external closure-status read.

Apply the NameCert obligations of Definition 1277.2. Registry-map coverage is read through R, gap-map and cannot-claim coverage are read through G and K, closure-status and audit coverage are read through S and A, and the synthesis and structural obligations preserve the same finite packet through X, H, C, P, N.

Finally use the no-smuggling boundary of Definition 1277.3. Since the forbidden readings are blocked by K and the audit and closure rows remain displayed, a public export can factor only through the named rows and cannot acquire an additional public-law coordinate. □

Falsifiable prediction: Every accepted $\mathsf{PhilosophyMapTarget}^{\uparrow}$ packet whose no-smuggling row is removed admits a forbidden host-equality, quotient, choice, or global-truth read; with the row present no public consumer can read those coordinates.

Independence witness: conceptregistrysurface, coreregistryindex, auditsystem, axiompurity-gate, closurestatusreference: none is bijective because $\mathsf{PhilosophyMapTarget}^{\uparrow}$ simultaneously carries registry maps, gap maps, cannot-claim conflict checks, closure-status rows, and no-smuggling refusal in one packet.

Theorem 1277.5 (Philosophy map target bridge ledger)**.** *Every bridge-facing* $\mathsf{PhilosophyMapTarget}^{\uparrow}$ *read factors through the registry row R, gap row G, cannot-claim row K, closure-status row S, audit row A, synthesis row X, transport row H, replay row C, provenance row P, and local* $\mathsf{NameCert}$ *row N. Thus a bridge consumer receives only the displayed registry, gap, refusal, closure, audit, synthesis, transport, replay, provenance, and naming coordinates.*

Proof. Use the carrier of Definition 1277.1. The rows R, G, K, S, A, X are the only content rows exposed by the packet, while H, C, P, N are the only structural rows available to transport, replay, source, and name them.

Apply the public law boundary of Definition 1277.4. Since public export already factors through the same ten rows, a bridge-facing read has no additional coordinate from which to import a prose-only philosophy map, hidden host equality, quotient witness, choice operator, global truth predicate, or closure-status row outside the packet. □

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{PhilosophyMapTarget}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{PhilosophyMapTarget}^{\uparrow}$ instances in `lean4/BEDC/Derived/PhilosophyMapTargetUp/TasteGate.lean`. Those instances

must preserve $R, G, K, S, A, X, H, C, P, N$ as separate displayed fields before the target BEDC.Derived.PhilosophyMa can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{PhilosophyMapTarget}^{\uparrow}}$.

Constructive story: A $\mathsf{PhilosophyMapTarget}^{\uparrow}$ packet is generated from registry-map, gap-map, cannot-claim, closure-status, audit, synthesis, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhilosophyMapTarget}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1277.1, Definition 1277.2, Definition 1277.3, Definition 1277.4, and Definition 1277.5 bind the displayed carrier, NameCert obligations, no-smuggling boundary, sibling scope, public export, and bridge-facing ledger over $\mathsf{ConceptRegistrySurface}^{\uparrow}$, $\mathsf{CoreRegistryIndex}^{\uparrow}$, $\mathsf{AuditSystem}^{\uparrow}$, $\mathsf{AxiomPurityGate}^{\uparrow}$, and $\mathsf{ClosureStatusReference}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhilosophyMapTarget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, philosophical completeness, global truth, host equality, quotient import, choice import, or all downstream registry entries.

Upgrade path: Lean closure requires Nontrivial PhilosophyMapTargetUp and FieldFaithful PhilosophyMapTargetUp instances in `lean4/BEDC/Derived/PhilosophyMapTargetUp/TasteGate.lean`.

Chapter 1278

A Concrete Naming Certificate for $\mathsf{DiagonalIndexCofinality}^{\uparrow}$

The $\mathsf{DiagonalIndexCofinality}^{\uparrow}$ packet realizes the finite modulus-threshold row used by the Real completeness proof target of section 9238.2. For a regular Cauchy input and precision request n, it records the displayed inequality that the selected diagonal index is at least $\mu(1/(n+1))$ before any $\mathsf{Real}^{\uparrow}$ completion-facing consumer reads the diagonal representative. The packet sits between the representative route of chapter 1205, the cofinal modulus seal of chapter 1198, the tail budget of chapter 1231, the stream naming surface of chapter 126, the regular-rational row of chapter 301, the dyadic observation core of chapter 291, and the terminal Real surface of chapter 38.

The certificate is deliberately finite. It names the threshold comparison, the selected diagonal window, the regular-rational readback, the dyadic tolerance row, the Real handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. It does not export quotient stream equality, a host-selected limit, countable choice, an unbounded search principle, or an ambient completeness theorem.

Definition 1278.1 (Diagonal index cofinality carrier)**.** *A* $\mathsf{DiagonalIndexCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, \mu, n, k, i, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the accepted regular Cauchy input family over* $\mathsf{RegSeqRat}^{\uparrow}$*;*
2. *μ is the displayed modulus row whose precision read at $1/(n+1)$ returns k;*
3. *n is the finite precision request made by the Real-completion consumer;*
4. *k is the threshold row $k = \mu(1/(n+1))$;*
5. *i is the selected diagonal index row with $i = k + n + 1$ and hence $i \geq k$;*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened at the selected diagonal index;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected member and index;*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same finite read;*
9. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *handoff row reached only after W, R, D and the threshold comparison have been displayed;*

10. *H records componentwise* hsame *transport for the input family, modulus row, request, threshold, index, window, readback, dyadic ledger, Real handoff, route, provenance, and naming rows;*
11. *C records the displayed* Cont *replay from the request through the modulus threshold and selected diagonal index into the window, readback, dyadic ledger, and Real handoff;*
12. *P is the* Pkg *provenance over* $\mathsf{DiagonalIndexCofinality}^{\uparrow}$, $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$, $\mathsf{CofinalModulusSeal}^{\uparrow}$, $\mathsf{TailCofinalityBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiagonalIndexCofinality}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed rows $X, \mu, n, k, i, W, R, D, E, H, C, P, N$ and the visible threshold proof $i \geq k$.

Lean4 ✓ `BEDC.Derived.DiagonalIndexCofinalityUp.DiagonalIndexCofinalityTasteGate single carrier alignment`

Theorem 1278.2 (Diagonal index cofinality NameCert obligation surface)**.** *For every accepted* $\mathsf{DiagonalIndexCofinality}^{\uparrow}$ *carrier $I = (X, \mu, n, k, i, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DiagonalIndexCofinality}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier transport through the displayed rows, modulus-threshold exposure $k = \mu(1/(n+1))$, diagonal-index exposure $i = k+n+1$, cofinality exposure $i \geq k$, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger exposure through D,* $\mathsf{Real}^{\uparrow}$ *handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.DiagonalIndexCofinalityUp.DiagonalIndexCofinalityNameCertObligationSurface`

Proof. Project the accepted packet to the displayed tuple in Definition 1278.1. The input family, modulus row, precision request, threshold, selected index, finite window, readback, dyadic ledger, Real handoff, transport, route, provenance, and naming row are all visible coordinates.

The arithmetic content is confined to the threshold and selected-index rows. The carrier records $k = \mu(1/(n+1))$ and $i = k + n + 1$, so the cofinality comparison $i \geq k$ is read from the displayed successor extension rather than from an unbounded search.

The downstream certificate rows then follow the same ordered route as the representative and seal siblings. The $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and $\mathsf{Real}^{\uparrow}$ handoff are consumed only after the threshold comparison has been displayed, while H, C, P, N only transport, replay, source, and name those rows. □

Theorem 1278.3 (Diagonal index cofinality window monotonicity)**.** *For an accepted* $\mathsf{DiagonalIndexCofinality}^{\uparrow}$ *carrier $I = (X, \mu, n, k, i, W, R, D, E, H, C, P, N)$, every downstream finite-window read exposed through W, R, D, E is indexed at i and therefore lies at or beyond the modulus threshold $k = \mu(1/(n+1))$. If the same packet is transported by the componentwise* hsame *row H, the transported window preserves the same threshold comparison before the* $\mathsf{Real}^{\uparrow}$ *handoff can be consumed.*

Proof. The selected window row W is attached to the index coordinate i of the carrier. By Definition 1278.1, this coordinate is not independent of the modulus row: it is the displayed value $k + n + 1$ with $k = \mu(1/(n+1))$.

Apply the obligation surface of Definition 1278.2. It requires any accepted read of W, R, D, E to preserve the threshold row, selected-index row, and cofinality comparison before the readback or handoff row is public.

Transport along H is componentwise. Hence it carries the request, threshold, selected index, window, readback, dyadic ledger, and Real handoff together, and it cannot move the finite window to a pre-threshold index without changing one of the displayed coordinates. □

Lean4 ✓ `BEDC.Derived.DiagonalIndexCofinalityUp.TasteGate.DiagonalIndexCofinalityTasteGate single carrier alignment`

Theorem 1278.4 (Diagonal index cofinality Real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Real-completion consumer of an accepted* $\mathsf{DiagonalIndexCofinality}^{\uparrow}$ *packet factors through the finite route*

$$X, \mu, n, k, i, W, R, D, E, H, C, P, N.$$

In particular, the consumer receives the diagonal-index cofinality row $i \geq \mu(1/(n+1))$ *before using the diagonal representative in the limit proof of Definition 9238.5.*

Proof. Start with the route displayed by the carrier. The precision request n first reads the modulus row μ to obtain k, then forms the selected diagonal index $i = k + n + 1$.

Next apply Definition 1278.3. It shows that the finite StreamName, RegSeqRat, dyadic, and Real rows exposed by the packet all remain at or beyond the modulus threshold.

Finally read the Real handoff through E and the support rows H, C, P, N. Since the carrier has no coordinate for a direct host limit, quotient stream equality, unbounded selection, countable choice, or ambient completeness, every consumer of this packet receives exactly the finite cofinality handoff displayed above. □

Falsifiable prediction: A diagonal representative consumer that reaches a RealUp handoff without displaying the modulus threshold k, selected index i, and proof that i is at least k is not an accepted DiagonalIndexCofinalityUp carrier.

Independence witness: diagonallimitrepresentative, cofinalmodulusseal, tailcofinalitybudget, streamname, regseqrat, dyadicratcore, real: none is bijective to $\mathsf{DiagonalIndexCofinality}^{\uparrow}$, because each sibling records a representative, seal, budget, window, readback, dyadic observation, or Real handoff row without binding the explicit diagonal-index inequality $i \geq \mu(1/(n+1))$ as its own local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalIndexCofinality}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{DiagonalIndexCofinality}^{\uparrow}$ packet is generated from a regular Cauchy input family, modulus row, precision request, threshold row, selected diagonal index, finite StreamName window, RegSeqRat readback, DyadicRatCore ledger, RealUp handoff, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DiagonalIndexCofinality}^{\uparrow}}$, seed)

Scope closed: Definition 1278.1, Definition 1278.2, Definition 1278.3, and Definition 1278.4 bind the finite diagonal-index cofinality carrier and its Real-completion handoff route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DiagonalIndexCofinality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, Real completeness, quotient stream equality, host real equality, countable choice, unbounded diagonal search, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, modulus-threshold exposure, selected-index cofinality, finite-window monotonicity, Real handoff non-escape, and TasteGate nontriviality with field faithfulness for $X, \mu, n, k, i, W, R, D, E, H, C, P, N$.

Chapter 1279

A Concrete Naming Certificate for $\mathsf{SocketReport}^{\uparrow}$

The $\mathsf{SocketReport}^{\uparrow}$ packet realizes the socket-report discipline of subsection 9462.26.14 as a finite NameCert carrier. It sits beside the typed supply socket of chapter 1243, the socket-kind classifier of chapter 1058, the supply socket ledger of chapter 528, the audit gate boundary of chapter 526, and the closed observation system of chapter 616. Those siblings expose typed requests, kind classification, ledger accounting, gate locality, and closed observation separately; this packet binds them into one report object that audit consumers can inspect without broadening the reported socket kind.

Definition 1279.1 (Socket report carrier)**.** *A* $\mathsf{SocketReport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, U, K, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the site row, recording the proof, construction, or audit position where a missing supply would be consumed;*
2. *U is the requested-supply row, recording the exact supply requested at S rather than a generic gap label;*
3. *K is the narrow socket-kind row, recording the smallest socket kind that explains the requested supply;*
4. *G is the audit-gate row, recording the local gate that accepts, blocks, or refuses internalization of the request;*
5. *H stores componentwise* hsame *transport for the site, requested-supply, narrow-kind, audit-gate, continuation, provenance, and local naming rows;*
6. *C stores displayed* Cont *continuation from the reported site through the requested supply, classifier, gate, provenance, and local name;*
7. *P is the* Pkg *provenance over* $\mathsf{TypedSupplySocket}^{\uparrow}$, $\mathsf{SocketKindClassifier}^{\uparrow}$, $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{AuditGateBoundary}^{\uparrow}$, $\mathsf{ClosedObservationSystem}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SocketReport}^{\uparrow}}$ *row.*

The carrier has no coordinate for replacing K by a broader gap family, discharging U, moving G to a different site, or hiding the report behind the closed observation substrate.

Lean4 ✓ `BEDC.Derived.SocketReportUp.SocketReportTasteGate single carrier alignment`

Theorem 1279.2 (Socket report NameCert obligations)**.** *For the carrier of Definition 1279.1, the local* $\mathsf{NameCert}_{\mathsf{SocketReport}^{\uparrow}}$ *surface consists exactly of carrier exposure for*

$$R = (S, U, K, G, H, C, P, N),$$

site exposure through S*, requested-supply exposure through* U*, narrow-kind classifier stability through* K*, audit-gate locality through* G*, componentwise* hsame *transport through* H*, displayed* Cont *continuation through* C*, provenance through* P*, local naming through* N*, and a non-discharge ledger stating that the report names a boundary request without supplying the requested row.*

Lean4 ✓ `BEDC.Derived.SocketReportUp.SocketReportNameCertObligations`

Proof. Project the finite packet $R = (S, U, K, G, H, C, P, N)$. The site, requested-supply, narrow-kind, and audit-gate rows are displayed before transport, continuation, provenance, and naming are read, so the certificate cannot introduce an unreported site or a hidden request.

Read the classifier and gate rows together. The row K is stable because it is the only row whose role is to name the narrow socket kind for the displayed request U at site S. The row G is local because it is read in the same packet as S and cannot be reassigned after continuation replay.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same finite packet. None of them contains a supply witness for U, so the non-discharge ledger remains part of the local NameCert surface. □

Theorem 1279.3 (Socket report minimal classification)**.** *Every accepted* $\mathsf{SocketReport}^{\uparrow}$ *report preserves the narrowest socket kind displayed by* K*. In particular, an accepted report for the same requested-supply row* U *cannot replace a Type II witness request, a Type III identity request, or any other displayed narrow socket kind by a broader gap label while remaining the same NameCert report.*

Lean4 ✓ `BEDC.Derived.SocketReportUp.SocketReportUp minimal classification`

Proof. Assume an accepted packet $R = (S, U, K, G, H, C, P, N)$. By Definition 1279.2, the classifier row K is part of the local NameCert surface and is transported only componentwise with the same requested-supply row U.

If an audit consumer broadens the report while preserving U, it must either erase K or replace K by a different classifier row. Erasing K leaves the carrier of Definition 1279.1; replacing it changes the local naming row N because the certificate names the displayed packet.

Thus Type II, Type III, and the other narrow socket rows remain public whenever the report is accepted. A broader gap label may be written as a separate report, but it is not the same accepted $\mathsf{SocketReport}^{\uparrow}$ packet for the displayed requested supply. □

Theorem 1279.4 (Socket report sibling separation)**.** *The* $\mathsf{SocketReport}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{TypedSupplySocket}^{\uparrow}$*,* $\mathsf{SocketKindClassifier}^{\uparrow}$*,* $\mathsf{SupplySocketLedger}^{\uparrow}$*,* $\mathsf{AuditGateBoundary}^{\uparrow}$*, or* $\mathsf{ClosedObservationSystem}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.SocketReportUp.SocketReportUp sibling separation`

Proof. Compare the displayed rows. $\mathsf{TypedSupplySocket}^{\uparrow}$ carries typed socket data, $\mathsf{SocketKindClassifier}^{\uparrow}$ classifies kinds, $\mathsf{SupplySocketLedger}^{\uparrow}$ accounts for requested supply, $\mathsf{AuditGateBoundary}^{\uparrow}$ exposes gate locality, and $\mathsf{ClosedObservationSystem}^{\uparrow}$ records closed observational discipline.

None of those siblings carries the simultaneous report rows S, U, K, G, H, C, P, N with a non-discharge ledger for the same site and request. A NameCert-row-preserving bijection would have to preserve that joint report surface, so no listed sibling is bijective to $\mathsf{SocketReport}^{\uparrow}$. □

Theorem 1279.5 (Socket report scoped report route)**.** *Every scoped read of an accepted* $\mathsf{SocketReport}^{\uparrow}$ *packet factors through*

$$S, U, K, G, H, C, P, N$$

before any audit consumer reads the report. The route preserves the requested-supply row U, the narrow classifier row K, the audit-gate row G, the non-discharge ledger, componentwise transport, displayed replay, provenance, and local naming; it cannot replace the report by a broader gap family or absorb it into $\mathsf{TypedSupplySocket}^{\uparrow}$, $\mathsf{SocketKindClassifier}^{\uparrow}$, $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{AuditGateBoundary}^{\uparrow}$, *or* $\mathsf{ClosedObservationSystem}^{\uparrow}$.

Proof. Project the carrier definition of Definition 1279.1. The accepted packet displays exactly S, U, K, G, H, C, P, N, so a scoped report read begins from the site, requested supply, classifier, and gate rows before structural replay is available.

Use the NameCert obligations of Definition 1279.2. They expose the site row, requested-supply row, narrow-kind classifier, audit gate, transport, continuation, provenance, local naming, and non-discharge ledger as one report surface.

The minimal classification theorem Definition 1279.3 prevents replacing K by a broader gap label while keeping the same requested supply. The sibling separation theorem Definition 1279.4 then rules out absorbing the full report surface into any listed sibling, because none of them carries the simultaneous rows S, U, K, G, H, C, P, N with the same non-discharge ledger. □

Lean4 ✓ `BEDC.Derived.SocketReportUp.SocketReportScopedReportRoute`

Theorem 1279.6 (Socket report public export surface)**.** *The public export of an accepted* $\mathsf{SocketReport}^{\uparrow}$ *packet is exactly the visible tuple*

$$S, U, K, G, H, C, P, N$$

from Definition 1279.1. The export preserves the narrow classifier row K and the non-discharge ledger attached to U; it does not broaden K, discharge U, move G away from the displayed site S, or absorb the packet into any sibling socket interface.

Proof. Start with the scoped report route of Definition 1279.5. It forces every accepted read to pass through S, U, K, G, H, C, P, N before any consumer can inspect the report.

The public export forgets no displayed report row. The typed request is U, the socket-kind classifier is K, the audit gate is G, the transport and closed-observation replay are H and C, and the supply-ledger provenance is carried by P together with the local naming row N.

Minimal classification from Definition 1279.3 prevents replacing K by a broader gap family, while sibling separation from Definition 1279.4 prevents absorbing the joint packet into any listed socket sibling. Thus the public surface exports the scoped rows without widening the socket kind. □

Lean4 ✓ `BEDC.Derived.SocketReportUp.SocketReportPublicExportSurface`

Falsifiable prediction: An accepted $\mathsf{SocketReport}^{\uparrow}$ packet is refuted by any audit consumer that replaces the displayed narrow socket kind with a broader gap label while preserving the same requested-supply row.

Independence witness: typedsupplysocket, socketkindclassifier, supplysocketledger, auditgateboundary, closedobservationsystem: TypedSupplySocketUp binds typed socket rows but not the

full report continuation; SocketKindClassifierUp lacks site, gate, and non-discharge rows; SupplySocketLedgerUp accounts for requests without preserving the narrow classifier as a report field; AuditGateBoundaryUp localizes gates without carrying the requested-supply ledger; ClosedObservationSystemUp records substrate closure rather than a visible gap report. None is bijective to the full $\mathsf{SocketReport}^{\uparrow}$ carrier under NameCert-row preservation.

The Lean follow-up file `lean4/BEDC/Derived/SocketReportUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ SocketReport}^{\uparrow}$ and $\mathsf{FieldFaithful\ SocketReport}^{\uparrow}$ instances. The field-faithfulness witness must preserve S, U, K, G, H, C, P, N as distinct rows so a checked TasteGate theorem can rule out broad-gap replacement of a narrow accepted report.

Closure status for $\mathsf{NameCert}_{\mathsf{SocketReport}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SocketReport}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1279.1, Definition 1279.2, Definition 1279.3, Definition 1279.4, Definition 1279.5, Definition 1279.6, the falsifiable prediction, the independence witness, and the TasteGate marker bind the public typed request, socket-kind classifier, supply-ledger provenance, audit gate, closed-observation replay, transport, and local naming rows of the displayed report packet without broadening the socket kind.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SocketReport}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim stack certification, typed supply availability, phase-refusal verdicts, or broad-gap replacement of the report classifier.

Upgrade path: A higher closure grade requires Lean-side verification of the public export surface and any standard bridge demanded by downstream socket-report schemas.

Constructive story: The socket report is generated from a $BHist$ packet that contains a requested-supply row, socket kind, site, gate, narrow report classifier, and the continuation needed to identify it as a socket-facing report. The carrier does not include stack certification, typed supply, or phase-refusal rows; it reads only the report packet and transports that packet along $hsame$. A Cont extension may carry the report to a later consumer, but it must preserve the minimal classification row. The NameCert obligations, minimal classification theorem, sibling separation, prediction, independence witness, and TasteGate marker make the report a narrow ledger object.

Chapter 1280

A Concrete Naming Certificate for $\mathsf{StatusDowngrade}^{\uparrow}$

The $\mathsf{StatusDowngrade}^{\uparrow}$ packet realizes the downgrade discipline of chapter 9462 as a finite NameCert carrier for lowering an advertised report status after a verification failure. It sits beside chapter 1233, chapter 1237, chapter 901, chapter 1265, and chapter 1259. Those siblings expose failure reasons, typed failure branches, audit-gate diagnostics, closure-status references, and axiom-purity gates; this packet binds the previous advertised status, the displayed failure certificate, the lowered report, and the route by which the public gap row remains visible.

Definition 1280.1 (Status downgrade carrier)**.** *A* $\mathsf{StatusDowngrade}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (O, F, L, G, R, V, H, C, P, N)$$

with the following displayed rows:

1. *O is the prior-status row, recording the theory-closure, formal-status, bridge-status, and public report row that had been advertised;*
2. *F is the failure-certificate row, consumed from* $\mathsf{FailureCertificate}^{\uparrow}$, $\mathsf{TypedFailureCertificate}^{\uparrow}$, AuditGateFailureWitne $\mathsf{ClosureStatusReference}^{\uparrow}$, *or* $\mathsf{AxiomPurityGate}^{\uparrow}$*;*
3. *L is the lowered-report row, recording the status that remains licensed after the failure certificate is displayed;*
4. *G is the exposed gap row, naming the theorem, definition, bridge, audit, axiom-purity, or closure field that blocks the prior status;*
5. *R is the downgrade-route row, displaying the finite route from O through F and G to L;*
6. *V is the verification-report row whose status is being lowered and whose public read must retain the prior-status and failure-certificate rows;*
7. *H stores componentwise* hsame *transport for prior status, failure certificate, lowered report, gap row, route, verification report, provenance, and local naming rows;*
8. *C stores displayed* Cont *replay for reading the prior status before the failure certificate, reading the failure certificate before the gap row, and reading the gap row before the lowered report;*
9. *P is the* Pkg *provenance over* $\mathsf{StatusDowngrade}^{\uparrow}$, $\mathsf{FailureCertificate}^{\uparrow}$, $\mathsf{TypedFailureCertificate}^{\uparrow}$, $\mathsf{AuditGateFailureWitness}^{\uparrow}$, $\mathsf{ClosureStatusReference}^{\uparrow}$, $\mathsf{AxiomPurityGate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{StatusDowngrade}^{\uparrow}}$ *row.*
The carrier has no coordinate for silently erasing the prior status, hiding the failure certificate, promoting the lowered report above the displayed gap, or replacing the finite downgrade route by an unchecked host report.

Lean4 (definition) `BEDC.Derived.StatusDowngradeUp.StatusDowngradeUp`

Theorem 1280.2 (StatusDowngrade NameCert obligations)**.** *For the carrier of Definition 1280.1, the local* $\mathsf{NameCert}_{\mathsf{StatusDowngrade}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$S = (O, F, L, G, R, V, H, C, P, N),$$

prior-status display through O, failure-certificate display through F, lowered-report display through L, exposed-gap display through G, downgrade-route display through R, verification-report display through V, componentwise hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the finite carrier. The displayed BHist packet lists the prior status, failure certificate, lowered report, gap row, downgrade route, verification report, transport, replay, provenance, and local naming rows as separate coordinates.

Read the sibling certificate rows next. $\mathsf{FailureCertificate}^{\uparrow}$ and $\mathsf{TypedFailureCertificate}^{\uparrow}$ supply the failed gate and typed branch; $\mathsf{AuditGateFailureWitness}^{\uparrow}$ supplies the diagnostic row; $\mathsf{ClosureStatusReference}^{\uparrow}$ supplies the bounded report status; $\mathsf{AxiomPurityGate}^{\uparrow}$ supplies the forbidden-dependency refusal when that is the failing field.

The support rows only preserve this inventory. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming cannot add a hidden stronger report, so the listed rows exhaust the local NameCert surface. □

Theorem 1280.3 (StatusDowngrade strength monotonicity)**.** *Every accepted* $\mathsf{StatusDowngrade}^{\uparrow}$ *packet*

$$S = (O, F, L, G, R, V, H, C, P, N)$$

exports a report no stronger than the lowered-report row L after the failure-certificate row F is read. A consumer may still display the prior-status row O, but it cannot advertise O as current status unless it also removes the displayed failure certificate and thereby leaves the accepted packet.

Proof. Start with the NameCert obligations of Definition 1280.2. They force a public read to display both the prior-status row O and the failure-certificate row F before the lowered report L is consumed.

The downgrade route R records the ordering from O through F and G to L. Thus the public report may remember the previous status as evidence of what was lowered, but the exported status after the route is the row L.

Finally inspect the carrier inventory. No coordinate supplies a second current-status row stronger than L, and H, C, P, N only transport, replay, source, and name the same finite packet. Treating O as current status would erase F or bypass R, so it is not an accepted read of S. □

Theorem 1280.4 (StatusDowngrade gap routing)**.** *For every accepted* $\mathsf{StatusDowngrade}^{\uparrow}$ *packet*

$$S = (O, F, L, G, R, V, H, C, P, N),$$

the exposed gap row G is routed between the failure-certificate row F and the lowered-report row L. The lowered report cannot be read as a bare editorial decision, a detached audit note, a hidden

checker result, or an ambient closure correction; it must pass through the displayed finite route $O, F, G, R, L, H, C, P, N$.

Proof. Project the route and replay rows. The route R and continuation row C display the readback from prior status to failure certificate, from failure certificate to exposed gap, and from exposed gap to lowered report.

Use the sibling certificates named in the carrier provenance. Failure-certificate, typed-failure, audit-gate witness, closure-status reference, and axiom-purity gate rows each provide a concrete blocking surface rather than an editorial status change.

The support rows preserve the same route. Since hsame, Cont, Pkg, and NameCert do not create a detached report coordinate, every accepted lowered report remains routed through G and the finite downgrade route. □

Theorem 1280.5 (StatusDowngrade nonescape)**.** *An accepted* $\mathsf{StatusDowngrade}^{\uparrow}$ *packet exports only prior status, failure certificate, lowered report, exposed gap, downgrade route, verification-report row, componentwise transport, replay, provenance, and local naming. It does not export silent status erasure, hidden promotion, unchecked report repair, host proof search, bridge completion, axiom-purity repair, or a verification status stronger than* L.

Proof. Inspect Definition 1280.1. The carrier has exactly the rows $O, F, L, G, R, V, H, C, P, N$ and deliberately lacks hidden repair, promotion, host-search, bridge-completion, or axiom-repair coordinates.

Apply strength monotonicity from Definition 1280.3. After the failure certificate is read, the accepted exported status is bounded by L.

Apply gap routing from Definition 1280.4. The lowered report reaches consumers only through the displayed gap row and downgrade route, so no detached report can escape the packet. Therefore every listed stronger or hidden report lies outside the accepted carrier. □

Theorem 1280.6 (StatusDowngrade scoped gap route)**.** *For every accepted* $\mathsf{StatusDowngrade}^{\uparrow}$ *packet*

$$S = (O, F, L, G, R, V, H, C, P, N),$$

every accepted downgrade read is scoped by the prior-status row O*, failure-certificate row* F*, lowered-report row* L*, exposed-gap row* G*, downgrade-route row* R*, verification-report row* V*, componentwise transport row* H*, replay row* C*, provenance row* P*, and local naming row* N*. A consumer may read the lowered report only along this finite route, so the downgrade cannot be detached from the failure certificate, the exposed gap, or the local NameCert surface.*

Proof. Start from the carrier of Definition 1280.1. Its displayed rows are exactly $O, F, L, G, R, V, H, C, P, N$, so an accepted read has no coordinate outside the prior status, failure certificate, lowered report, exposed gap, route, verification report, transport, replay, provenance, and local naming rows.

Apply the NameCert obligations of Definition 1280.2. They force the public downgrade surface to expose each of the displayed rows before the packet is named as a local $\mathsf{StatusDowngrade}^{\uparrow}$ certificate.

Now use strength monotonicity and gap routing from Definition 1280.3 and Definition 1280.4. The lowered report is bounded by L after the failure certificate is read, and the gap row G lies on the route from F to L.

Finally apply nonescape from Definition 1280.5. Hidden promotion, silent status erasure, detached repair, and status conversion outside the route are absent from the carrier, so the displayed rows scope every accepted downgrade read. □

Falsifiable prediction: A StatusDowngradeUp packet is refuted by any lowered report status that lacks a displayed prior-status row and failure-certificate row.

Independence witness: failurecertificate, typedfailurecertificate, auditgatefailurewitness, closurestatusreference, axiompuritygate: none is bijective because only StatusDowngradeUp stores prior status, failure certificate, lowered report, exposed gap row, downgrade route, provenance, and local NameCert together.

The Lean follow-up for this chapter must provide `Derived/StatusDowngradeUp/TasteGate.lean` with Nontrivial StatusDowngrade$^{\uparrow}$ and FieldFaithful StatusDowngrade$^{\uparrow}$ instances for the displayed carrier fields.

Closure status for NameCert$_{\text{StatusDowngrade}^{\uparrow}}$.

Constructive story: The status downgrade certificate is generated from $BHist$ rows that record an original status, a failure certificate, a weaker report status, and the exposed gap route that explains why the weaker status is the admitted one. The carrier first reads the strength ordering, then records the gap routing row, and finally allows Cont to carry the weaker status forward without silently restoring the stronger one. The $hsame$ relation keeps the downgrade stable across representative histories. NameCert obligations, strength monotonicity, gap routing, nonescape, prediction, and independence witness define a visible status transition: every downgrade must expose both the target and the ledger reason that blocks the stronger status.

Theory closure: TheoryGate(NameCert$_{\text{StatusDowngrade}^{\uparrow}}$, scopedClosed)

Scope closed: This chapter binds the status downgrade carrier, NameCert obligations, strength-monotonicity theorem, gap-routing theorem, scoped gap-route theorem, nonescape theorem, falsifiable prediction, and independence witness.

Formal verification: FormalStatus(NameCert$_{\text{StatusDowngrade}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim recovery of the stronger status, hidden gap discharge, or status conversion outside the recorded downgrade route.

Upgrade path: Reaching scopedClosure requires formal status-order and gap-route predicates plus checked nonescape of downgraded statuses.

Chapter 1281

EventualTailAgreement NameCert Construction

The $\mathsf{EventualTailAgreement}^{\uparrow}$ packet realizes the shared-tail classifier route for the regular-Cauchy completion surface of section 9238.1. It sits after the finite StreamName windows of chapter 126, the RegSeqRat readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal Real seal of chapter 38, the paired seal route of chapter 699, and the cofinal agreement route of chapter 920. The packet records a finite shared-tail window before any Real or completion-facing seal is served; it is not a quotient of streams, a host real equality, a selected limiting real, countable choice, or ambient completeness.

Falsifiable prediction: Every accepted $\mathsf{EventualTailAgreement}^{\uparrow}$ packet must expose the shared $\mathsf{StreamName}^{\uparrow}$ tail window before a $\mathsf{RealTailAgreementSeal}^{\uparrow}$ handoff; a consumer route reaching the seal without that window refutes the packet.

Independence witness: streamname, regseqrat, real, realtailagreementseal, cofinaltailagreement: EventualTailAgreementUp is not bijective to any listed sibling because it jointly carries two Real-facing regular-Cauchy sources, one eventual threshold and modulus row, a shared StreamName tail window, paired RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a RealTailAgreementSeal handoff, and local transport, continuation, package, and naming rows.

Definition 1281.1 (Eventual tail-agreement carrier)**.** *An* $\mathsf{EventualTailAgreement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (A, B, M, T, R, D, S, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two Real-facing regular-Cauchy source rows whose tails are compared.*
2. *M is the shared eventual threshold and modulus row; it records the point after which both sources are read by the same tolerance request.*
3. *T is the shared* $\mathsf{StreamName}^{\uparrow}$ *tail-window row exposed at that threshold.*
4. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for A and B over the same window T.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the radius, endpoint, and comparison rows used by the shared readback.*
6. *S is the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *handoff row reached only after A, B, M, T, R, D are displayed.*

7. *H records componentwise* hsame *transport for A, B, M, T, R, D, S and the local certificate row.*
8. *C records displayed* Cont *replay from the two source rows through the shared threshold, tail window, readback, dyadic ledger, and seal handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{EventualTailAgreement}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, $\mathsf{CofinalTailAgreement}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EventualTailAgreement}^{\uparrow}}$ *row.*

The carrier exports only the displayed shared-tail classifier packet and its Real-completion handoff surface.

Theorem 1281.2 (Eventual tail-agreement NameCert obligations)**.** *For the carrier of Definition 1281.1, the local* $\mathsf{NameCert}_{\mathsf{EventualTailAgreement}^{\uparrow}}$ *surface consists exactly of carrier admission for $E = (A, B, M, T, R, D, S, H, C, P, N)$, source admission for A and B, shared threshold and modulus exposure through M, shared* $\mathsf{StreamName}^{\uparrow}$ *tail-window exposure through T, paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger exactness through D,* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *handoff exposure through S, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.EventualTailAgreementUp.EventualTailAgreementTasteGate single carrier alignment`

Proof. Project the carrier. Its coordinates display the two regular-Cauchy source rows, the shared eventual threshold and modulus row, the tail window, the paired regular readback, the dyadic tolerance ledger, the Real-tail seal row, and the structural support rows.

Read the sibling surfaces in order. The $\mathsf{StreamName}^{\uparrow}$ row supplies the finite tail window, the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the paired regular-rational readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance ledger, and the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ row supplies the downstream seal handoff.

The transport, continuation, package, and local naming rows do not add another analytic object. They authenticate exactly the displayed rows A, B, M, T, R, D, S, so the listed clauses exhaust the local NameCert obligations. □

Theorem 1281.3 (Eventual tail-agreement tail-shift invariance)**.** *Let $E = (A, B, M, T, R, D, S, H, C, P, N)$ be an accepted* $\mathsf{EventualTailAgreement}^{\uparrow}$ *carrier. If the shared eventual threshold in M is shifted to a later displayed threshold and the corresponding* $\mathsf{StreamName}^{\uparrow}$ *tail window is replayed through the same H and C rows, then the accepted classifier surface remains*

$$A, B, M, T, R, D, S, H, C, P, N.$$

The shift changes only the chosen late window inside the same shared-tail route; it preserves the paired $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *handoff, and it exports no quotient stream, host real equality, selected limit, countable-choice row, or ambient completeness theorem.*

Proof. Begin with the threshold coordinate M and the tail-window coordinate T. The carrier stores no independent tail oracle; a later threshold is admitted only by replaying the same source rows through the displayed StreamName route.

Use Definition 1281.2. The paired readback R and tolerance ledger D are attached to the shared tail window, while H and C transport and replay that attachment componentwise.

Finally read the seal coordinate S. Since the seal handoff is downstream of A, B, M, T, R, D, a tail shift that preserves the displayed route preserves the same Real-facing classifier surface and cannot import any excluded external equality or selection principle. □

Theorem 1281.4 (Eventual tail-agreement Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{EventualTailAgreement}^{\uparrow}$ *packet reaches the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *row* S *only after the two source rows* A, B*, the shared eventual threshold and modulus* M*, the shared* $\mathsf{StreamName}^{\uparrow}$ *tail window* T*, the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D *have been displayed. The consumer route is exhausted by*

$$A, B, M, T, R, D, S, H, C, P, N.$$

No consumer of this packet receives a quotient stream comparison, host real equality, selected host limit, countable-choice schedule, hidden tail oracle, or ambient completeness witness.

Proof. Inspect the carrier inventory. Its only Real-facing coordinate is the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ row S, and the carrier places S after the two source rows, the shared threshold row, the shared window, the paired regular readback, and the dyadic ledger.

Apply Definition 1281.2. The local certificate makes A, B, M, T, R, D mandatory before S can be consumed, with H, C, P, N recording the visible transport, replay, provenance, and naming route.

Apply Definition 1281.3 for later-tail reindexing. Any accepted shift remains on the same shared-tail surface, so a Real or completion-facing consumer cannot bypass the finite window by appealing to quotient streams, selected limits, host equality, countable choice, or ambient completeness. □

The Lean follow-up for this chapter is to provide $\mathsf{Nontrivial\ EventualTailAgreement}^{\uparrow}$ and $\mathsf{FieldFaithful\ EventualTail}$ instances in `BEDC.Derived.EventualTailAgreementUp/TasteGate.lean` for the same finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{EventualTailAgreement}^{\uparrow}}$.

Constructive story: An $\mathsf{EventualTailAgreement}^{\uparrow}$ packet is generated from two Real-facing regular-Cauchy source rows, one shared eventual threshold and modulus row, a shared StreamName tail window, paired RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a RealTailAgreementSeal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EventualTailAgreement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1281.1, Definition 1281.2, Definition 1281.3, and Definition 1281.4 bind the finite shared-tail classifier packet and its Real-completion handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EventualTailAgreement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, hidden tail selection, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, tail-shift invariance, Real-seal handoff, Nontrivial EventualTailAgreementUp, and FieldFaithful EventualTailAgreementUp for the same finite packet.

Chapter 1282

A Concrete Naming Certificate for $\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}$

The $\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}$ packet realizes the formal-target draft of chapter 9462 as a finite package ledger for philosophy-facing machine targets. It sits beside the claim registry layer of chapter 1209, the registry export surface of chapter 1216, the machine-interface formalization target of chapter 1225, the writing-item audit packet of chapter 1235, and the axiom-purity gate of chapter 1259. Those siblings respectively bind claim admission, export rows, target skeletons, writing-item legality, and dependency purity; this carrier binds all five before a philosophy-package target can be read by an audit consumer.

Definition 1282.1 (Philosophy formal-target ledger carrier)**.** *A* $\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, T, G, D, S, U, L, M, B, H, C, P, N)$$

with the following displayed rows:

1. *R is the concept-registry row, recording the concept entry, carrier or boundary position, classifier status, ledger status, forbidden readings, and cannot-claim conflicts.*
2. *T is the theorem-map row, recording the theorem or statement site, its claim-entry row, its expected machine namespace, and its dependency surface.*
3. *G is the gap-map row, recording the typed open boundary, refusal branch, or target socket associated with the claim.*
4. *D is the tradition-map row, recording preserved structure, rejected surplus, and tradition-comparison boundary rows.*
5. *S is the scientific-map row, recording empirical record, invariant, bridge, value, and prediction-gap rows when the target touches science-facing prose.*
6. *U is the cannot-claim registry row, recording the exact claim forms refused by the packet.*
7. *L is the closure-status row, recording the paper-side closure grade, formal-verification grade, bridge status, not-claimed surface, and next obligation for the target.*
8. *M is the formal-target skeleton row, recording name, namespace, binder shape, statement outline, dependency list, expected status, and queue status.*

9. *B is the refusal-boundary and no-smuggling row, recording absence of host truth predicates, subject-substance, quotient equality, Classical choice, external philosophy authority, and any hidden solution claim.*
10. *H records componentwise* hsame *transport for $R, T, G, D, S, U, L, M, B$.*
11. *C records displayed* Cont *replay through the registry, theorem, gap, tradition, science, refusal, closure-status, target-skeleton, and no-smuggling rows.*
12. *P is the* Pkg *provenance over* $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$, $\mathsf{WritingItemAudit}^{\uparrow}$, $\mathsf{AxiomPurityGate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host truth predicate, subject-substance, quotient equality, Classical choice, external philosophical authority, proof content for the target skeleton, or export beyond the displayed refusal boundary.

Lean4 (definition) `BEDC.Derived.PhilosophyFormalTargetLedgerUp.PhilosophyFormalTargetLedgerUp`
Lean4 ✓ `BEDC.Derived.PhilosophyFormalTargetLedgerUp.PhilosophyFormalTargetLedgerTasteGate`
`single carrier alignment`

Definition 1282.2 (Philosophy formal-target ledger classifier)**.** *The* $\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}$ *classifier compares exactly the displayed rows*

$$R, T, G, D, S, U, L, M, B, H, C, P, N.$$

Two packets are classifier-equal only when their concept-registry entries, theorem-map entries, gap-map entries, tradition-map entries, scientific-map entries, cannot-claim rows, closure-status rows, target skeletons, no-smuggling rows, componentwise hsame *routes, displayed* Cont *replays, provenance rows, and local NameCert rows agree. The classifier refuses any comparison that factors through a host truth predicate, subject-substance, quotient equality, Classical choice, or external philosophy authority.*

Theorem 1282.3 (Philosophy formal-target ledger NameCert obligations)**.** *For the carrier of Definition 1282.1, the local* $\mathsf{NameCert}_{\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$F = (R, T, G, D, S, U, L, M, B, H, C, P, N),$$

claim-entry coverage through R and T, gap and tradition coverage through G and D, science-facing coverage through S, refusal coverage through U and B, closure-status coverage through L, target-skeleton coverage through M, componentwise hsame *stability through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the finite packet of Definition 1282.1. The rows $R, T, G, D, S, U, L, M, B$ are displayed before transport, replay, provenance, and naming are read, so every accepted target exposes its claim entry, target skeleton, no-smuggling check, closure status, and refusal boundary as packet data.

Read the sibling surfaces in order. $\mathsf{ClaimRegistryLayer}^{\uparrow}$ supplies claim-entry discipline, $\mathsf{RegistryExportSurface}^{\uparrow}$ supplies public export status, $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$ supplies the machine-readable skeleton, $\mathsf{WritingItemAudit}^{\uparrow}$ supplies separated paper and machine status rows, and $\mathsf{AxiomPurityGate}^{\uparrow}$ supplies the dependency-purity refusal boundary.

Finally inspect H, C, P, N. These structural rows preserve, replay, source, and name the same displayed packet. None of them adds a hidden truth predicate, subject-substance, quotient equality, Classical choice, external philosophical authority, or proof object. Hence the local NameCert obligations are exactly the displayed ledger rows. □

Lean4 ✓ `BEDC.Derived.PhilosophyFormalTargetLedgerUp.PhilosophyFormalTargetLedger namecert obligations`

Theorem 1282.4 (Philosophy formal-target ledger nonescape)**.** *Every machine-readable audit consumer of an accepted* PhilosophyFormalTargetLedger$^{\uparrow}$ *packet reads a claim-entry row, target-skeleton row, no-smuggling row, closure-status row, and refusal-boundary row before it can read the philosophy-package formal target. If any one of these rows is absent, the consumer leaves the accepted carrier and cannot cite the packet as a formal-target ledger.*

Lean4 ✓ `BEDC.Derived.PhilosophyFormalTargetLedgerUp.PhilosophyFormalTargetLedger nonescape`

Proof. Use Definition 1282.3. The obligations expose claim-entry coverage through R, T, target-skeleton coverage through M, no-smuggling and refusal-boundary coverage through B, U, and closure-status coverage through L.

The audit consumer has no alternate route to those data. The continuation row C only replays the displayed path, the transport row H only preserves componentwise rows, and the provenance row P only records the sibling surfaces already named by the packet.

Therefore removing a claim-entry row, target-skeleton row, no-smuggling row, closure-status row, or refusal-boundary row changes the carrier being read. The resulting object may be a partial registry or target record, but it is not an accepted PhilosophyFormalTargetLedger$^{\uparrow}$ packet. □

Theorem 1282.5 (Philosophy formal-target ledger sibling dependency)**.** *The* PhilosophyFormalTargetLedger$^{\uparrow}$ *carrier depends on* ClaimRegistryLayer$^{\uparrow}$, RegistryExportSurface$^{\uparrow}$, MachineInterfaceFormalizationTarget$^{\uparrow}$, WritingItemAudit$^{\uparrow}$, *and* AxiomPurityGate$^{\uparrow}$ *without being bijective to any one of them under NameCert-row preservation.*

Proof. Compare the displayed rows. ClaimRegistryLayer$^{\uparrow}$ binds claim entries, RegistryExportSurface$^{\uparrow}$ binds export rows, MachineInterfaceFormalizationTarget$^{\uparrow}$ binds target sockets and statement skeletons, WritingItemAudit$^{\uparrow}$ binds writing-item legality and separated status rows, and AxiomPurityGate$^{\uparrow}$ binds forbidden dependency checks.

The present carrier stores all five surfaces together with closure status, no-smuggling, transport, replay, provenance, and local NameCert rows. A NameCert-row-preserving bijection to any one sibling would have to preserve fields that the sibling does not carry.

Thus the sibling lattice is a dependency lattice rather than an identification. The ledger consumes the siblings as rows of one package-formal-target packet while preserving its own classifier and nonescape boundary. □

Lean4 ✓ `BEDC.Derived.PhilosophyFormalTargetLedgerUp.PhilosophyFormalTargetLedger sibling dependency`

Falsifiable prediction: If a PhilosophyFormalTargetLedgerUp packet is accepted, every exported philosophy-package formal target has a claim-entry row, target-skeleton row, no-smuggling row, closure-status row, and refusal-boundary row before any machine-readable audit consumer can read it; a consumer that reaches a formal target without one of these rows refutes the packet.

Independence witness: claimregistrylayer, registryexportsurface, machineinterfaceformalizationtarget, writingitemaudit, axiom-purity-gate: none is bijective to PhilosophyFormalTargetLedger$^{\uparrow}$

because those siblings respectively bind claim entries, export rows, target sockets, writing-item checks, or axiom-purity gates, while this carrier binds all five with closure status, no-smuggling, transport, provenance, and local NameCert rows in one package-formal-target ledger.

The Lean follow-up file `lean4/BEDC/Derived/PhilosophyFormalTargetLedgerUp/TasteGate.lean` must provide explicit Nontrivial PhilosophyFormalTargetLedger$^{\uparrow}$ and FieldFaithful PhilosophyFormalTargetLedger$^{\uparrow}$ instances. The nontriviality witness must use distinct packet witnesses, and the field-faithfulness witness must use constructor-field injection to preserve $R, T, G, D, S, U, L, M, B, H, C, P, N$ rather than a singleton carrier.

Closure status for NameCert$_{\text{PhilosophyFormalTargetLedger}^{\uparrow}}$.

Constructive story: The philosophy formal-target ledger is generated from $BHist$ rows that record a claim-entry row, target-skeleton row, no-smuggling row, closure-status row, refusal-boundary row, and the classifier that binds a philosophy-facing item to that formal target. The carrier first reads the ledger entry, then checks the target classifier, and finally uses Cont to carry the same target relation into later audit or writing routes. The $hsame$ relation keeps the target ledger stable across equivalent histories. The NameCert obligations, nonescape theorem, sibling-dependency theorem, prediction, and independence witness separate this object from claim registries, export surfaces, machine-interface targets, or axiom-purity gates.

Theory closure: TheoryGate(NameCert$_{\text{PhilosophyFormalTargetLedger}^{\uparrow}}$, maturePackageClosed)

Scope closed: This chapter binds the carrier, classifier, NameCert obligations, nonescape theorem, sibling dependency, falsifiable prediction, independence witness, and TasteGate marker to the local BHist, hsame, Cont, Pkg, NameCert, target-classifier, and ledger-entry scope.

Formal verification: FormalStatus(NameCert$_{\text{PhilosophyFormalTargetLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim the target is proved, that claims are registered elsewhere, or that status rows are supplied by this ledger.

Upgrade path: No theory-axis grade remains beyond the displayed carrier, classifier, NameCert, nonescape, sibling-dependency, prediction, independence, and TasteGate surface; the Lean verification axis remains independent.

Chapter 1283

A Concrete Naming Certificate for $\mathsf{SocketStackCertificate}^{\uparrow}$

The $\mathsf{SocketStackCertificate}^{\uparrow}$ packet realizes stacked socket reports from subsection 9462.26.13 as finite NameCert data. It sits beside the typed gap socket taxonomy of chapter 1240, the socket-kind classifier of chapter 1058, the socket taxonomy ledger of chapter 767, the supply socket ledger of chapter 528, and the apophatic far-end socket of chapter 1061. Those siblings expose kind families, single-row classifiers, non-collapse accounting, requested-supply ledgers, and the common far-end boundary; this packet binds an ordered multi-socket stack without collapsing the component requests into one dominant kind.

Definition 1283.1 (Socket stack certificate carrier)**.** *A* $\mathsf{SocketStackCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Sigma = (Q, R, E, K, A, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the stack site row, naming the blocked proof, construction, or audit position whose requested supply has more than one socket component;*
2. *$R = (R_0, \ldots, R_n)$ is a nonempty ordered list of component socket-report rows, each carrying its site, requested-supply, narrow kind, and local gate;*
3. *E is the stack-exposure row, recording that every component socket row is visible to audit consumers before any summary row is read;*
4. *$K = (K_0, \ldots, K_n)$ is the componentwise narrowest-kind classifier row, with K_i classifying R_i by the smallest socket kind licensed for that component;*
5. *$A = (A_0, \ldots, A_n)$ is the per-row audit-gate preservation row, requiring each component gate to be replayed at its own socket row;*
6. *L is the non-discharge ledger route, recording that the stack reports requested supply without supplying any component row;*
7. *H stores componentwise* hsame *transport for $Q, R, E, K, A, L, C, P, N$;*
8. *C stores displayed* Cont *continuation from the stack site through the component reports, classifiers, gates, ledger route, provenance, and local name;*
9. *P is the* Pkg *provenance over* $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$, $\mathsf{SocketKindClassifier}^{\uparrow}$, $\mathsf{SocketTaxonomyLedger}^{\uparrow}$, $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{ApophaticFarEndSocket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{SocketStackCertificate}^{\uparrow}}$ *row.*
The carrier has no coordinate for replacing the ordered component list by a single aggregate socket kind, deleting a component row after acceptance, moving a component gate to a sibling row, or treating the common far-end position as a discharge witness.

Lean4 (definition) `BEDC.Derived.SocketStackCertificateUp.SocketStackCertificateUp`

Theorem 1283.2 (Socket stack certificate NameCert obligations)**.** *For the carrier of Definition 1283.1, the local* $\mathsf{NameCert}_{\mathsf{SocketStackCertificate}^{\uparrow}}$ *surface consists exactly of carrier exposure for*

$$\Sigma = (Q, R, E, K, A, L, H, C, P, N),$$

stack-site exposure through Q, ordered component socket exposure through R, stack exhaustion through E, componentwise narrowest-kind classification through K, per-row audit-gate preservation through A, non-discharge ledger routing through L, componentwise hsame *transport through H, displayed* Cont *continuation through C, provenance through P, and local naming through N.*

Proof. Project the finite packet $\Sigma = (Q, R, E, K, A, L, H, C, P, N)$. The stack site and the ordered component rows are read before classifier, gate, ledger, continuation, provenance, and naming rows, so the certificate cannot replace the stack by an uninspected summary.

Read K and A componentwise. Each K_i names the narrow socket kind for the displayed component R_i, while each A_i preserves the local gate attached to that same row. Componentwise transport in H can replay these rows but cannot move a classifier or gate to a different component.

Finally inspect L, C, P, N. These rows account for the route, replay the same ordered packet, cite the sibling socket ledgers, and name the certificate. None supplies a requested component row, so the non-discharge route remains part of the local NameCert surface. □

Theorem 1283.3 (Socket stack certificate exhaustion)**.** *Every accepted* $\mathsf{SocketStackCertificate}^{\uparrow}$ *packet exposes all component socket rows in its ordered carrier. Removing any component row from an accepted stack changes the componentwise classifier surface or breaks the* NameCert *handoff.*

Proof. Let $\Sigma = (Q, R, E, K, A, L, H, C, P, N)$ be accepted. By Definition 1283.2, the exposure row E is part of the local NameCert surface and is read against the ordered component list $R = (R_0, \ldots, R_n)$.

If a component row R_i is removed, then the matching classifier row K_i and gate row A_i either become unmatched or must also be removed. In the first case, the componentwise classifier surface is no longer a well-formed stack surface. In the second case, the displayed packet named by N is a different finite carrier.

Thus accepted stacks are exhausted by their displayed component rows. A shorter stack may be a separate packet, but it is not the same accepted $\mathsf{SocketStackCertificate}^{\uparrow}$ certificate. □

Theorem 1283.4 (Socket stack certificate sibling independence)**.** *The* $\mathsf{SocketStackCertificate}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$, $\mathsf{SocketKindClassifier}^{\uparrow}$, $\mathsf{SocketTaxonomyLedger}^{\uparrow}$, $\mathsf{SupplySocketLedger}^{\uparrow}$, *or* $\mathsf{ApophaticFarEndSocket}^{\uparrow}$.

Proof. Compare the displayed rows. $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$ carries the seven-kind taxonomy, $\mathsf{SocketKindClassifier}^{\uparrow}$ classifies a socket kind, $\mathsf{SocketTaxonomyLedger}^{\uparrow}$ records taxonomy and non-collapse rows, $\mathsf{SupplySocketLedger}^{\uparrow}$ accounts for requested supply, and $\mathsf{ApophaticFarEndSocket}^{\uparrow}$ names the common far-end boundary.

None of those siblings carries an ordered multi-socket component list with stack exposure, per-row narrowest-kind classifiers, per-row gate preservation, stack exhaustion, and a non-discharge

ledger route. A NameCert-row-preserving bijection would have to preserve that joint ordered surface, so no listed sibling is bijective to $\mathsf{SocketStackCertificate}^{\uparrow}$. □

Falsifiable prediction: Removing any component socket row from an accepted stack changes the componentwise classifier or breaks the NameCert handoff.

Independence witness: typedgapsockettaxonomy, socketkindclassifier, sockettaxonomyledger, supplysocketledger, apophaticfarendsocket: none carries an ordered multi-socket carrier with per-row gate preservation and stack exhaustion.

The Lean follow-up file for BEDC.Derived.SocketStackCertificateUp must provide explicit Nontrivial SocketStackC and FieldFaithful $\mathsf{SocketStackCertificate}^{\uparrow}$ instances. The field-faithfulness witness must preserve $Q, R, E, K, A, L, H, C, P, N$ as distinct rows so a checked TasteGate theorem can rule out component deletion and single-kind collapse of an accepted stack.

Closure status for $\mathsf{NameCert}_{\mathsf{SocketStackCertificate}^{\uparrow}}$.

Constructive story: The socket stack certificate is generated from $BHist$ rows that record an ordered multi-socket carrier, component socket rows, per-row gate preservation, and an exhaustion witness saying that the stack has been read as a stack. The carrier first names the stack packet, then checks that the stack rows are exhausted by the certificate, and finally allows Cont only to carry the same certified stack forward. The $hsame$ relation preserves the stack certificate across representative histories. NameCert obligations, stack exhaustion, sibling independence, prediction, and independence witness keep this object distinct from typed-gap taxonomy, socket-kind classifier, supply socket ledger, and apophatic far-end sockets.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SocketStackCertificate}^{\uparrow}}$, seed)

Scope closed: This chapter binds the socket stack-certificate carrier, NameCert obligations, stack-exhaustion theorem, sibling-independence theorem, falsifiable prediction, and independence witness.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SocketStackCertificate}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim report classification, typed supply availability, phase-refusal verdicts, or stack equality outside the certified rows.

Upgrade path: Reaching obligationClosure requires formal stack rows and checked exhaustion plus sibling separation for the stack certificate.

Chapter 1284

A Concrete Naming Certificate for $\mathsf{ObjectConstitutionLedger}^{\uparrow}$

The $\mathsf{ObjectConstitutionLedger}^{\uparrow}$ packet realizes the object-constitution claim of Definition 9462.1948 as finite BEDC data. It sits after the focused history ledger of chapter 1247, the observer-history identity surface of chapter 477, the public inscription event surface of chapter 519, the concept registry surface of chapter 1252, and the scientific-object packet of chapter 1214. The chapter does not add a hidden object substrate to chapter 9462; it records the appearance of an object as focused history, continuation, classifier, ledger, gap, provenance, and local naming rows.

Definition 1284.1 (Object-constitution ledger carrier)**.** *An* $\mathsf{ObjectConstitutionLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (F, I, E, R, S, A, K, L, G, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FocusedLedger}^{\uparrow}$ *row exposing the focused records-side history in which the object pattern is read.*
2. *I is the* $\mathsf{ObserverHistoryIdentity}^{\uparrow}$ *row naming the observer-history identity surface for the same focused read.*
3. *E is the* $\mathsf{InscriptionEvent}^{\uparrow}$ *row recording the public event by which the constituted object is available as record data.*
4. *R is the* $\mathsf{ConceptRegistrySurface}^{\uparrow}$ *row naming the concept entry or registry route under which the object is classified.*
5. *S is the* $\mathsf{ScientificObject}^{\uparrow}$ *row when the constituted object is used by a scientific-object consumer.*
6. *A is the stable-appearance row recording the focused pattern exposed by F, I, E, R before any object name is accepted.*
7. *K is the classifier row that decides which focused appearances count as the same object-facing pattern.*
8. *L is the constitution ledger row recording continuation, classifier stability, registry readback, and inscription provenance.*
9. *G is the gap row listing unclosed appearance, classifier, registry, empirical, and scientific-object commitments.*

10. *H records componentwise* hsame *transport for $F, I, E, R, S, A, K, L, G$ and the local certificate row.*
11. *C records displayed* Cont *replay from focused history through observer identity, inscription, registry, scientific-object read, stable appearance, classifier, ledger, gap, provenance, and local name.*
12. *P is the* Pkg *provenance over* $\mathsf{ObjectConstitutionLedger}^{\uparrow}$, $\mathsf{FocusedLedger}^{\uparrow}$, $\mathsf{ObserverHistoryIdentity}^{\uparrow}$, $\mathsf{InscriptionEvent}^{\uparrow}$, $\mathsf{ConceptRegistrySurface}^{\uparrow}$, $\mathsf{ScientificObject}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ObjectConstitutionLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for a bare object behind appearances, a private subject-state object, a host-side identity predicate, an unregistered concept, or an unledgered scientific object.

Lean4 (definition) `BEDC.Derived.ObjectConstitutionLedgerUp.ObjectConstitutionLedgerUp`
Lean4 ✓ `BEDC.Derived.ObjectConstitutionLedgerUp.ObjectConstitutionLedgerTasteGate single carrier alignment`

Theorem 1284.2 (Object-constitution ledger NameCert obligations)**.** *For the carrier of Definition 1284.1, the local* $\mathsf{NameCert}_{\mathsf{ObjectConstitutionLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for O, focused-ledger exposure through F, observer-history identity exposure through I, inscription-event exposure through E, concept-registry exposure through R, scientific-object exposure through S, stable-appearance exposure through A, classifier exposure through K, constitution-ledger exposure through L, gap exposure through G, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from the displayed packet. The rows expose the focused records-side history, observer-history identity, public inscription event, registry route, scientific-object route, stable appearance, classifier, ledger, gap, transport, replay, provenance, and local name.

The appearance rows are read first. The focused ledger F supplies the records-side focus, I binds the observer-history identity of that focus, E makes the read public as an inscription event, and R supplies the concept-registry classifier surface.

The object-facing rows are then forced. The stable-appearance row A and classifier row K must be present before the constitution ledger L can name the pattern, and the gap row G remains visible before N is readable. If a scientific-object consumer is present, it reaches the object through S and the same H, C, P, N rows rather than through a separate object substrate. □

Theorem 1284.3 (Object-constitution ledger non-escape)**.** *Every accepted* $\mathsf{ObjectConstitutionLedger}^{\uparrow}$ *object read factors through*

$$F, I, E, R, S, A, K, L, G, H, C, P, N.$$

A consumer that omits the focused ledger, observer-history identity, inscription event, concept-registry surface, stable appearance, classifier, constitution ledger, gap row, provenance, or local NameCert row cannot export the constituted object as a BEDC object name.

Proof. Inspect the carrier inventory of Definition 1284.1. The packet contains exactly the displayed rows $F, I, E, R, S, A, K, L, G, H, C, P, N$ and no row for bare object existence, hidden subject state, host identity, or unregistered concept membership.

Apply Definition 1284.2. The local certificate makes each appearance, classifier, ledger, gap, transport, replay, provenance, and name row mandatory for an accepted object-constitution read.

The sibling packets supply only their respective surfaces. $\mathsf{FocusedLedger}^{\uparrow}$ does not by itself name an object, $\mathsf{ObserverHistoryIdentity}^{\uparrow}$ does not by itself certify a concept, $\mathsf{InscriptionEvent}^{\uparrow}$ does not by itself stabilize an appearance, $\mathsf{ConceptRegistrySurface}^{\uparrow}$ does not by itself provide empirical object use, and $\mathsf{ScientificObject}^{\uparrow}$ does not erase the focused-appearance ledger. Therefore a consumer that drops any mandatory row reads a projection of the packet, not the constituted object name. □

Falsifiable prediction: Any accepted ObjectConstitutionLedgerUp consumer that exports a stable object name while omitting the focused ledger, observer-history identity, inscription event, concept registry, stable-appearance classifier, gap row, or local NameCert row refutes the packet.

Independence witness: focusedledger, observerhistoryidentity, inscriptionevent, conceptregistrysurface, scientificobject: none is bijective because $\mathsf{ObjectConstitutionLedger}^{\uparrow}$ binds focused history, observer-history identity, public inscription, concept registry, scientific-object use, stable appearance, classifier, constitution ledger, gap, transport, replay, provenance, and local NameCert rows in one carrier, while each sibling supplies only one constituent surface.

The Lean follow-up namespace `BEDC.Derived.ObjectConstitutionLedgerUp.TasteGate` must provide explicit $\mathsf{Nontrivial\ ObjectConstitutionLedger}^{\uparrow}$ and $\mathsf{FieldFaithful\ ObjectConstitutionLedger}^{\uparrow}$ instances. These instances must preserve the rows $F, I, E, R, S, A, K, L, G, H, C, P, N$ as the same finite carrier surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ObjectConstitutionLedger}^{\uparrow}}$.

Constructive story: An $\mathsf{ObjectConstitutionLedger}^{\uparrow}$ packet is generated from focused history, observer-history identity, inscription event, concept registry, scientific-object use, stable appearance, classifier, constitution ledger, gap, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObjectConstitutionLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1284.1, Definition 1284.2, and Definition 1284.3 bind object constitution to a finite NameCert carrier and non-escape surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObjectConstitutionLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, bare object existence, hidden subject-state identity, unregistered concept membership, or final scientific truth.

Upgrade path: Obligation closure requires checked carrier admission, focused-ledger exposure, observer-history identity exposure, inscription-event exposure, concept-registry exposure, scientific-object exposure, gap-report separation, and TasteGate nontriviality and field faithfulness for the same packet.

Chapter 1285

A Concrete Naming Certificate for $\mathsf{PhysicalLawBridge}^{\uparrow}$

The $\mathsf{PhysicalLawBridge}^{\uparrow}$ packet realizes the science-bridge site of section 9462.28 as a finite BEDC NameCert carrier for physical laws. It sits after the law-certificate packet of chapter 1155, the empirical-regularity persistence packet of chapter 1156, the scientific-object carrier of chapter 1214, the standard-bridge audit packet of chapter 1217, and the open physical fit packet of chapter 1131. Those siblings expose law status, empirical persistence, object anchoring, bridge theorem preservation, and open finite fit; this carrier binds them before a consumer may read a physical law as bridge-recognized.

Definition 1285.1 (Physical law bridge carrier)**.** *A* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (L, E, B, O, F, G, H, C, Q, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LawCertificate}^{\uparrow}$ *row exposing equation pattern, source fit, classifier, continuation stability, failure surface, ledger, transport, provenance, and local law naming.*
2. *E is the* $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ *row exposing finite measurement, observed regularity, classifier, error ledger, future-persistence GAP, LawCertificate consumption, stability, failure, replay, provenance, and local naming.*
3. *B is the* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *row exposing host bridge encoding, decoding, paired round trips, finite theorem-preservation, no-host-leak, audit transport, provenance, and local bridge naming.*
4. *O is the* $\mathsf{ScientificObject}^{\uparrow}$ *row exposing record, classifier, invariant, empirical ledger, bridge, gap report, audit, truth, open-fit, domain, transport, provenance, and local object naming.*
5. *F is the* $\mathrm{OpenPhysicalFit}^{\uparrow}$ *row exposing finite trace, observed signature, model-generated signature, classifier, refutation row, open-continuation row, ledger, replay, and local fit naming.*
6. *G is the failure and falsification row recording omitted-law rows, finite refuting observations, bridge-preservation failures, open-fit exits, and the precise refusal branch.*
7. *H records componentwise* hsame *transport for $L, E, B, O, F, G, C, Q, N$.*
8. *C records the displayed* Cont *routes by which the law, empirical persistence, bridge audit, scientific object, open fit, failure, transport, provenance, and local name are replayed.*

9. *Q is the* Pkg *provenance over* $\mathsf{PhysicalLawBridge}^{\uparrow}$, $\mathsf{LawCertificate}^{\uparrow}$, $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$, $\mathsf{ScientificObject}^{\uparrow}$, $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$, $\mathrm{OpenPhysicalFit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalLawBridge}^{\uparrow}}$ *row.*

The classifier compares packets only through these rows. It has no coordinate for bare equation authority, record-only empirical adequacy, unchecked host-model bridges, hidden theorem preservation, final physical truth, or a law read without an exposed falsification surface.

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.TasteGate.PhysicalLawBridgeTasteGate single carrier alignment`

↪ variant `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeTasteGate single carrier alignment`

Lean4 (definition) `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeUp`

Theorem 1285.2 (Physical law bridge NameCert surface)**.** *For the carrier of Definition 1285.1, the local* $\mathsf{NameCert}_{\mathsf{PhysicalLawBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for $P = (L, E, B, O, F, G, H, C, Q, N$ law-certificate exposure through L, empirical-persistence exposure through E, standard-bridge-audit exposure through B, scientific-object exposure through O, open-physical-fit exposure through F, failure and falsification exposure through G, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through Q, and local naming through N.*

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeCarrier namecert surface`

Proof. Project the accepted packet to its displayed rows. The row L supplies law-certificate status, E supplies finite empirical persistence and its future-persistence GAP, B supplies finite bridge theorem-preservation with no-host-leak discipline, O supplies the scientific-object anchoring surface, and F supplies open physical fit.

Read the failure surface next. The row G is not a summary sentence; it is the carrier coordinate where omitted empirical persistence, missing theorem-preservation, fit defeat, and falsification branches are recorded.

Finally apply componentwise transport, continuation replay, provenance, and local naming. Since H, C, Q, N preserve only the displayed rows, the listed surface exhausts the local NameCert obligations and leaves no hidden bridge-recognition coordinate. □

Theorem 1285.3 (Physical law bridge law-gap nonescape)**.** *Every accepted* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *read of a physical law factors through the law-certificate row L, empirical-persistence row E, standard-bridge-audit row B, scientific-object row O, open-fit row F, and failure row G. A consumer that keeps the law-certificate row but omits empirical persistence, finite theorem-preservation, open physical fit, or falsification data reads only a projection of the packet, not an accepted bridge-recognized physical law.*

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeLawGapNonescape`

Proof. Start from Definition 1285.2. The accepted local name is available only after $L, E, B, O, F, G, H, C, Q, N$ have been displayed.

The law-certificate row records equation-like status under continuation and failure discipline, but it does not by itself provide finite measurement persistence or bridge theorem preservation. The empirical-persistence row supplies finite records and future-persistence GAP exposure, while the standard-bridge-audit row supplies the bridge rows that keep theorem transport internal to the packet.

The scientific-object and open-fit rows prevent the law from being detached from object anchoring and finite observation defeat. The failure row then records the refusal branch whenever one of those surfaces is missing. Thus no accepted consumer can escape the law gap by reading L alone or by replacing E, B, F, G with outside authority. □

Theorem 1285.4 (Physical law bridge falsification boundary)**.** *An accepted* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *packet admits falsification exactly through the displayed failure row G together with the empirical-persistence row E, standard-bridge-audit row B, and open-physical-fit row F. A finite refuting observation, a missing persistence ledger, a failed theorem-preservation row, or an open-fit classifier exit changes the packet only as a displayed failure branch; it cannot be hidden inside law status, object status, bridge status, or provenance.*

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeFalsificationBoundary encode append`

Proof. Use the packet coordinates of Definition 1285.1. The rows E, B, F expose the empirical, bridge, and finite-fit sites where a physical-law read can fail.

The row G names the corresponding failure branch. It records omitted rows, finite refutations, theorem-preservation failures, open-fit exits, and the refusal route in the same carrier.

Transport, replay, provenance, and naming do not erase those branches. They only replay the displayed packet. Therefore falsification remains a finite row inside $\mathsf{PhysicalLawBridge}^{\uparrow}$ rather than a host verdict outside the carrier. □

Theorem 1285.5 (Physical law bridge obligation package)**.** *For every accepted* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *carrier $P = (L, E, B, O, F, G, H, C, Q, N)$, the obligation package is exactly the displayed collection of carrier admission, law-certificate exposure, empirical-persistence exposure, bridge-audit exposure, scientific-object anchoring, open-fit exposure, falsification exposure, componentwise transport, replay, provenance, and local naming rows. A consumer may project one of these rows only as a projection of the package, not as a smaller physical-law bridge certificate.*

Proof. Project the carrier of Definition 1285.1. The rows L, E, B, O, F, G provide the law, empirical, bridge, object, fit, and falsification obligations.

The structural rows H, C, Q, N preserve and replay those obligations without introducing a hidden shortcut. Thus the accepted certificate is the full displayed package, and any smaller read is only a projection. □

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeObligationPackage`

Theorem 1285.6 (Physical law bridge scoped export)**.** *Every accepted* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *export factors through the displayed carrier rows*

$$L, E, B, O, F, G, H, C, Q, N.$$

The rows L, E, B, O, F are respectively the $\mathsf{LawCertificate}^{\uparrow}$ *route of chapter 1155, the* $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$ *route of chapter 1156, the* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *route of chapter 1217, the* $\mathsf{ScientificObject}^{\uparrow}$ *route of chapter 1214, and the* $\mathrm{OpenPhysicalFit}^{\uparrow}$ *route of chapter 1131. The row G is the falsification branch, and H, C, Q, N are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows. No export that omits one of these rows is an accepted physical-law bridge export.*

Proof. Project the obligation package of Definition 1285.5. It already lists carrier admission, law-certificate exposure, empirical-persistence exposure, bridge-audit exposure, scientific-object anchoring, open-fit exposure, falsification exposure, transport, replay, provenance, and local naming as the displayed package.

Read the five upstream science-bridge siblings through the introduction's carrier order. The law-certificate row L supplies law status, E supplies empirical persistence, B supplies standard bridge audit, O supplies scientific-object anchoring, and F supplies open physical fit.

Now retain the falsification and structural rows. The row G records the refusal or falsification branch, while H, C, Q, N transport, replay, source, and name the same packet. Removing any one of these rows leaves only a projection because the local $\mathsf{NameCert}_{\mathsf{PhysicalLawBridge}^{\uparrow}}$ is issued for the complete displayed carrier.

Thus every accepted export is scoped by the carrier rows themselves. The theorem supplies no additional physical truth predicate, no final model authority, and no bridge-recognition shortcut outside the sibling rows. □

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeScopeExport`

Theorem 1285.7 (Physical law bridge field-faithful obligation)**.** *No accepted* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *read can erase any of the rows* $L, E, B, O, F, G, H, C, Q, N$*. If two accepted reads agree after deleting one of these coordinates, the agreement is only a projection-level agreement and is not an accepted field-faithful bridge read.*

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeFieldFaithfulObligation`

Proof. Use Definition 1285.5. Each row is named as part of the obligation package and is transported by H and replayed by C before provenance and local naming are read.

Deleting a row removes either a semantic obligation among L, E, B, O, F, G or a structural obligation among H, C, Q, N. The resulting projection cannot be the same accepted local name, because the local $\mathsf{NameCert}_{\mathsf{PhysicalLawBridge}^{\uparrow}}$ is issued only for the displayed packet. □

Theorem 1285.8 (Physical law bridge nontrivial obligation)**.** *The law-recognized branch and the refusal or falsification branch of a* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *packet remain distinguishable. In particular, a carrier that exposes* L, E, B, O, F *with no active failure row is not identified with a carrier whose row* G *records omitted empirical persistence, missing theorem preservation, open-fit exit, or finite refutation.*

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeNontrivialObligation`

Proof. Read the falsification boundary of Definition 1285.4. The row G is the finite coordinate where omitted rows, refutations, preservation failures, and open-fit exits are recorded.

The law-recognized branch depends on the displayed law, empirical, bridge, object, and fit rows without such a failure record. Since transport and replay preserve G rather than erasing it, the two branches remain distinct inside the packet. □

Falsifiable prediction: A PhysicalLawBridgeUp consumer that reads a law as bridge-recognized while omitting either empirical persistence, finite theorem-preservation, or falsification rows refutes the packet.

Independence witness: lawcertificate, empiricalregularitypersistence, scientificobject, standardbridgeauditpacket, openphysicalfit: non-bijection follows by row omission. $\mathsf{LawCertificate}^{\uparrow}$ lacks empirical-persistence, bridge-audit, scientific-object, and open-fit rows; $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$

lacks bridge theorem-preservation and object anchoring; $\mathsf{ScientificObject}^{\uparrow}$ lacks law-certificate and theorem-preservation rows; $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ lacks empirical persistence and open physical fit; $\mathrm{OpenPhysicalFit}^{\uparrow}$ lacks law-certificate, empirical-persistence, and bridge-audit rows.

The Lean follow-up path `lean4/BEDC/Derived/PhysicalLawBridgeUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{PhysicalLawBridge}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{PhysicalLawBridge}^{\uparrow}$ instances. These instances must preserve law-certificate, empirical-persistence, bridge-audit, scientific-object, open-fit, failure, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before `BEDC.Derived.PhysicalLa` can be cited by a checked paper marker.

Theorem 1285.9 (Physical law bridge scoped TasteGate route)**.** *Every accepted scoped export of* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *factors through the carrier rows*

$$L, E, B, O, F, G, H, C, Q, N$$

of Definition 1285.1, where H is the componentwise hsame *transport row, C is the displayed* Cont *replay row, Q is the* Pkg *provenance row, and N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalLawBridge}^{\uparrow}}$ *row. The scoped export is accepted only along the TasteGate single-carrier alignment marker* `BEDC.Derived.PhysicalLawBri` *it may not bypass the law-certificate, empirical-persistence, bridge-audit, scientific-object, open-fit, falsification, transport, replay, provenance, or local naming rows.*

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeScopedTasteGateRoute`

Proof. Apply Definition 1285.6. It already forces every accepted export through $L, E, B, O, F, G, H, C, Q, N$, with H, C, Q, N respectively carrying the hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Use Definition 1285.7 to keep the read field-faithful. Deleting any one of the displayed coordinates leaves only a projection-level agreement, so a scoped export cannot erase a carrier row while retaining the accepted local name.

Finally apply Definition 1285.8. The law-recognized branch and the refusal or falsification branch remain distinct, which is exactly the branch discipline witnessed by the cited TasteGate single-carrier alignment marker. Therefore the scoped export is accepted only through the displayed BEDC rows and the TasteGate route, not through outside physical authority or host-model equality. □

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgeCarrier scoped tastegate route`

Theorem 1285.10 (Physical law bridge public closure route)**.** *The public* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *read is available only after the carrier of Definition 1285.1, the law-gap nonescape theorem Definition 1285.3, the falsification boundary Definition 1285.4, the field-faithful obligation Definition 1285.7, the nontrivial obligation Definition 1285.8, and the scoped TasteGate route Definition 1285.9 have all been displayed.*

Thus a public consumer reads the same rows $L, E, B, O, F, G, H, C, Q, N$ and cannot treat $\mathsf{PhysicalLawBridge}^{\uparrow}$ *as bare physical truth, host-model identity, unchecked bridge authority, or law status without empirical persistence, theorem preservation, open fit, and falsification rows.*

Lean4 ✓ `BEDC.Derived.PhysicalLawBridgeUp.PhysicalLawBridgePublicClosureRoute`

Proof. Start with the carrier and NameCert surface. The carrier of Definition 1285.1 supplies exactly the law-certificate, empirical-persistence, bridge-audit, scientific-object, open-fit, falsification, transport, replay, provenance, and local naming rows, and Definition 1285.2 binds those rows as the local certificate surface.

Read the public prerequisites in order. The law-gap nonescape theorem keeps L attached to E, B, O, F, G, while the falsification boundary keeps failure and refutation data visible instead of hiding them in law or bridge status.

Now apply the field-faithful and nontrivial obligations. They prevent deletion of a row and keep law-recognized and refusal branches distinguishable inside the same packet.

Finally use the scoped TasteGate route. Since the scoped export already passes through $L, E, B, O, F, G, H, C, Q, N$ and the TasteGate single-carrier alignment marker, the public read is available only as that displayed route, with no additional host-model authority or physical-truth coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{PhysicalLawBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{PhysicalLawBridge}^{\uparrow}$ packet is generated from law-certificate, empirical-persistence, standard-bridge-audit, scientific-object, open-physical-fit, failure, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhysicalLawBridge}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1285.1, Definition 1285.2, Definition 1285.3, Definition 1285.4, Definition 1285.5, Definition 1285.7, Definition 1285.8, Definition 1285.9, and Definition 1285.10 bind the finite physical-law bridge carrier, NameCert surface, law-gap boundary, falsification boundary, obligation package, field-faithful read, nontrivial branch distinction, scoped TasteGate route, and public read.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhysicalLawBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, final physical truth, total future prediction, host-model law identity, or law status without empirical persistence, theorem-preservation, open-fit, and falsification rows.

Upgrade path: Further closure requires checked carrier admission, NameCert surface, law-gap nonescape, falsification boundary, scoped TasteGate routing, nontriviality, and field faithfulness for $L, E, B, O, F, G, H, C, Q, N$.

Chapter 1286

A Concrete Naming Certificate for $\mathsf{ScienceBridge}^{\uparrow}$

The $\mathsf{ScienceBridge}^{\uparrow}$ packet realizes the science-bridge site of section 9462.28 as one finite NameCert surface. It sits after the scientific-object carrier of chapter 1214, the physical-model audit of chapter 1129, the reality-constrained truth certificate of chapter 1144, the standard-bridge audit packet of chapter 1217, and the gap/failure bridge audit of chapter 1229. Those siblings expose object records, physical audit, truth rows, bridge preservation, and typed gap/failure rows; this packet binds them before any consumer reads a scientific bridge as an accepted BEDC object.

Definition 1286.1 (Science bridge carrier)**.** *A* $\mathsf{ScienceBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, O, A, T, B, G, F, H, C, P, N)$$

with the following displayed rows:

1. *R is the records row, storing the source histories, observation traces, instrument records, and finite ledgers from which the bridge is read.*
2. *O is the* $\mathsf{ScientificObject}^{\uparrow}$ *row exposing the object record, classifier, invariant, empirical ledger, bridge row, gap report, audit, truth, open-fit, domain, transport, replay, provenance, and local naming surfaces.*
3. *A is the* $\mathsf{PhysicalModelAudit}^{\uparrow}$ *row exposing source traces, target phenomenon, observed signatures, model signatures, audit classifier, tower data, failure surface, and audit strength.*
4. *T is the* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *row exposing the truth-certificate source, signature, classifier, tower, stability, descent, invariant, ledger, and failure fields.*
5. *B is the* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *row exposing encoding, decoding, round-trip, theorem preservation, no-host-leak, transport, provenance, and local naming data for a proposed bridge.*
6. *G is the* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ *row exposing the typed gap, failure branch, bridge row, no-host-leak row, axis-separation row, audit route, transport, replay, provenance, and local naming data.*
7. *F is the failure-surface row, recording falsifying observations, open prediction gaps, bridge defeats, and domain exits that remain visible to downstream consumers.*
8. *H records componentwise* hsame *transport for $R, O, A, T, B, G, F, C, P, N$.*

9. *C records the displayed* Cont *routes by which records, objects, audits, truth certificates, bridge audits, gaps, failure surfaces, transports, provenance, and local naming are replayed.*

10. *P is the* Pkg *provenance over* $\mathsf{ScienceBridge}^{\uparrow}$, $\mathsf{ScientificObject}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{RealityConstrainedTruthCert}$ $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ScienceBridge}^{\uparrow}}$ *row.*

The classifier compares carriers only through these rows. It has no coordinate for host scientific-object identity, unledgered physical truth, standard-model authority outside the bridge audit, a bridge-checked export without a gap/falsification row, or a repair of a failed bridge by local naming alone.

Lean4 ✓ `BEDC.Derived.ScienceBridgeUp.ScienceBridgeTasteGate single carrier alignment`

Theorem 1286.2 (Science bridge NameCert obligations)**.** *For the carrier of Definition 1286.1, the local* $\mathsf{NameCert}_{\mathsf{ScienceBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for $S = (R, O, A, T, B, G, F, H, C, P, N)$, records exposure through R, scientific-object exposure through O, physical-model audit exposure through A, reality-constrained truth exposure through T, standard-bridge audit exposure through B, gap/falsification exposure through G, failure-surface exposure through F, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ScienceBridgeUp.TasteGate.ScienceBridgeTasteGate single carrier alignment`

Proof. Project the accepted packet to its displayed rows. The records row R supplies the finite source data, while O, A, T, B, G, F supply the scientific-object, physical-audit, truth-certificate, standard-bridge-audit, gap/falsification, and failure-surface coordinates.

Read the transport and replay rows next. The componentwise hsame row H preserves only the displayed coordinates, and the continuation row C replays only the routes listed by the packet.

Finally apply provenance and local naming. The package row P records the sibling surfaces used by the carrier, and N names the resulting finite packet. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 1286.3 (Science bridge axis separation)**.** *An accepted* $\mathsf{ScienceBridge}^{\uparrow}$ *carrier cannot read scientific-object maturity, physical-model audit strength, reality-constrained truth, standard-bridge preservation, and gap/falsification visibility as one axis. The rows O, A, T, B, G, F remain distinct under the same R, H, C, P, N support, so a consumer may not promote a bridge row to physical truth, erase the failure surface, or treat the gap/falsification row as discharged by local naming.*

Lean4 ✓ `BEDC.Derived.ScienceBridgeUp.ScienceBridgeAxisSeparation`

Proof. Start from the carrier of Definition 1286.1. The rows O, A, T, B, G, F are separate coordinates, and each is transported and replayed through H and C without being identified with another coordinate.

Use Definition 1286.2. The local certificate admits scientific-object, physical-audit, truth-certificate, standard-bridge-audit, gap/falsification, and failure-surface rows separately before provenance or naming can be consumed.

Thus a bridge-preservation read cannot become physical truth, and a local name cannot erase an open gap or failure surface. Any such reading would collapse coordinates that the accepted packet stores separately. □

Theorem 1286.4 (Science bridge kernel-scope grounding)**.** *Every accepted* $\mathsf{ScienceBridge}^{\uparrow}$ *carrier* $S = (R, O, A, T, B, G, F, H, C, P, N)$ *is scoped only through finite* BHist *records, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *route. The rows* R, O, A, T, B, G, F *may be consumed as records, scientific-object surface, physical-model audit, reality-constrained truth certificate, standard-bridge audit, gap/falsification surface, and failure surface inside that finite route, but none of them can be read as external physical truth, host scientific-object identity, complete empirical adequacy, or bridge closure.*

Lean4 ✓ `BEDC.Derived.ScienceBridgeUp.ScienceBridgeKernelScopeGrounding`

Proof. Project the carrier of Definition 1286.1. The rows R, O, A, T, B, G, F are finite coordinates of one BHist packet, and their only structural support is the displayed transport, replay, provenance, and local naming rows H, C, P, N.

Apply the NameCert obligations, Definition 1286.2. They admit each row separately through the finite carrier surface and do not add an external truth coordinate, a host identity coordinate, or a bridge-checked export.

Use axis separation, Definition 1286.3. It prevents the scientific-object, physical-audit, truth-certificate, bridge-audit, gap/falsification, and failure rows from collapsing into a single authority axis, so no row can promote another row into physical truth or bridge closure.

The falsifiable prediction and independence witness give the same scope test. Omitting the gap/falsification or bridge-audit row refutes the carrier, and the packet is not bijective to any sibling surface; hence the accepted read remains grounded in the listed BEDC kernel primitives and nowhere else. □

Falsifiable prediction: Any accepted ScienceBridgeUp packet that exports a bridge-checked scientific object while omitting the gap/falsification row or the standard-bridge audit row refutes the carrier.

Independence witness: scientificobject, physicalmodelaudit, realityconstrainedtruthcert, standardbridgeauditpacket, gapfailurebridgeaudit: none is bijective because ScienceBridgeUp binds records, object surface, audit row, truth row, bridge row, gap/falsification row, failure surface, transport, replay, provenance, and local NameCert in one carrier.

The Lean follow-up path `lean4/BEDC/Derived/ScienceBridgeUp/TasteGate.lean` must provide $\mathsf{Nontrivial}\ \mathsf{ScienceBridge}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ScienceBridge}^{\uparrow}$ instances for the same finite $R, O, A, T, B, G, F, H, C,$ carrier.

Theorem 1286.5 (Science bridge standard-audit handoff)**.** *Every accepted bridge-facing consumer of a* $\mathsf{ScienceBridge}^{\uparrow}$ *packet must pass through the* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *surface, the* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ *surface, the* $\mathsf{RealityConstrainedTruthCert}^{\uparrow}$ *surface, and the finite* BHist, hsame, Cont, Pkg, *and* NameCert *rows before any bridge read is public. Consequently a consumer may not publish the bridge row while bypassing the standard audit route, erasing the gap or failure branch, replacing the truth certificate by host physical truth, or reading outside the displayed records and local naming rows.*

Lean4 ✓ `BEDC.Derived.ScienceBridgeUp.ScienceBridgeStandardAuditHandoff`

Proof. Project the carrier of Definition 1286.1. The bridge-facing rows are already displayed as B, G, T together with the records, failure, transport, replay, provenance, and naming rows.

Apply Definition 1286.2. It requires standard-bridge audit exposure through B, gap/falsification exposure through G, reality-constrained truth exposure through T, and finite structural support through R, H, C, P, N before the local certificate can be consumed.

Use axis separation, Definition 1286.3. It prevents bridge preservation, gap/failure visibility, and truth certification from collapsing into one authority row, so the public bridge read remains routed through the standard audit handoff. □

Theorem 1286.6 (Science bridge mature failure-surface export)**.** *Every mature* $\mathsf{ScienceBridge}^{\uparrow}$ *consumer must preserve the records row, scientific-object row, physical-model-audit row, truth-certificate row, standard-bridge-audit row, gap/falsification row, and failure-surface row through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route. In particular, a mature read may not publish the bridge surface while dropping* $R, O, A, T, B, G, F, H, C, P, N$ *or replacing the gap/falsification and failure-surface rows by external scientific authority.*

Lean4 ✓ `BEDC.Derived.ScienceBridgeUp.ScienceBridgeMatureFailureSurfaceExport`

Proof. Project the carrier of Definition 1286.1. The rows R, O, A, T, B, G, F are distinct coordinates of the accepted packet, and H, C, P, N are the only structural rows that transport, replay, source, and name them.

Apply the NameCert obligations and axis-separation results. They require records, scientific-object, physical-model audit, truth certificate, standard-bridge audit, gap/falsification, and failure-surface exposure before any bridge read can be consumed, and they keep those rows from collapsing into one authority axis.

Use the standard-audit handoff. Since the handoff already requires the standard-bridge audit, gap/falsification, truth-certificate, records, transport, replay, provenance, and local naming rows, a mature consumer can export the science bridge only by preserving the whole displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{ScienceBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{ScienceBridge}^{\uparrow}$ packet is generated from records, scientific-object, physical-model-audit, reality-constrained-truth, standard-bridge-audit, gap/falsification, failure-surface, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ScienceBridge}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1286.4 is the public export surface for the finite carrier, obligation, axis-separation, BHist, hsame, Cont, Pkg, and NameCert scope of the science-bridge packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ScienceBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, external physical truth, host scientific-object identity, complete empirical adequacy, or final model–reality correspondence.

Upgrade path: Bridge closure requires a standard-bridge audit whose bridge row preserves the public science-bridge surface without erasing the gap/falsification or failure rows.

Chapter 1287

A Concrete Naming Certificate for $\mathsf{ConceptRegistryObligation}^{\uparrow}$

The $\mathsf{ConceptRegistryObligation}^{\uparrow}$ packet realizes the concept-entry obligation of Definition 9462.2157 and Definition 9462.2161 as finite BEDC data. It sits beside chapter 1252, chapter 1216, chapter 1251, chapter 1220, and chapter 901. Those siblings expose the concept-registry surface, public export boundary, core index, package registry layer, and failed-gate diagnostic surface; this carrier isolates the finite row packet a concept entry must carry before it can be exported as philosophy-package vocabulary.

Definition 1287.1 (Concept registry obligation carrier)**.** *A* $\mathsf{ConceptRegistryObligation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (E, A, L, F, S, X, H, C, P, N)$$

with the following displayed rows:

1. *E is the concept-entry row, recording the name named by the philosophy package and the entry surface required by Definition 9462.2157;*
2. *A is the carrier-and-classifier row, recording the displayed BEDC carrier and classifier to which the concept entry is attached;*
3. *L is the ledger row, recording the positive reading, supporting ledger, and package route that a consumer may inspect;*
4. *F is the forbidden-reading row, recording the readings blocked before the entry can be exported;*
5. *S is the status row, recording gap status, theory closure, formal status, and export readiness as finite registry data;*
6. *X is the export row, recording whether the entry is read by the concept-registry surface, registry-export surface, core registry index, or registry layer;*
7. *H stores componentwise* hsame *transport for concept-entry, carrier-and-classifier, ledger, forbidden-reading, status, export, route, provenance, and local naming rows;*
8. *C stores displayed* Cont *routes from concept entry through carrier, classifier, ledger, forbidden-reading, status, and export rows;*
9. *P is the* Pkg *provenance over* $\mathsf{ConceptRegistryObligation}^{\uparrow}$, $\mathsf{ConceptRegistrySurface}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{CoreRegistryIndex}^{\uparrow}$, $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{AuditGateFailureWitness}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{ConceptRegistryObligation}^{\uparrow}}$ *row.*
The carrier has no coordinate for a prose-only concept, missing carrier, missing classifier, erased ledger, absent forbidden-reading row, hidden status row, export bypass, host semantic equality, or package-private override.

Lean4 ✓ `BEDC.Derived.ConceptRegistryObligationUp.ConceptRegistryObligationTasteGate single carrier alignment`

Theorem 1287.2 (Concept registry obligation NameCert obligations)**.** *For the carrier of Definition 1287.1, the local* $\mathsf{NameCert}_{\mathsf{ConceptRegistryObligation}^{\uparrow}}$ *surface consists exactly of carrier admission for $O = (E, A, L, F, S, X, H, C, P, N)$; concept-entry exposure through E; carrier and classifier exposure through A; ledger accountability through L; forbidden-reading accountability through F; status exposure through S; export routing through X; transport and route replay through H, C; provenance through P; and local naming through N.*

Proof. Project the finite packet of Definition 1287.1. The row E names the entry required by the philosophy concept registry, and A, L, F, S display the carrier, classifier, ledger, forbidden readings, and status fields that Definition 9462.2157 requires.

The export row X binds the same entry to the sibling registry surfaces. The concept-registry surface reads the entry discipline, the registry-export surface reads public export control, the core registry index reads the table location, and the registry layer reads package-level admit-or-block routing.

Finally H, C, P, N transport, replay, package, and name the same rows. Since the carrier has no hidden row from which a missing carrier, classifier, ledger, forbidden-reading, or status field can be reconstructed, the displayed rows exhaust the local NameCert surface. □

Theorem 1287.3 (Concept registry obligation export readiness)**.** *An accepted* $\mathsf{ConceptRegistryObligation}^{\uparrow}$ *packet is export-ready only when the concept-entry row E, carrier-and-classifier row A, ledger row L, forbidden-reading row F, status row S, export row X, transport row H, route row C, provenance row P, and local naming row N are all present in the same finite packet. A concept export missing any one of carrier, classifier, ledger, forbidden-reading, or status data exits the accepted carrier.*

Proof. Use Definition 1287.2. It lists each accepted row as part of one local NameCert surface, so export readiness cannot be checked by the entry name alone.

If A is absent, the concept has no displayed BEDC carrier and classifier. If L is absent, the positive reading and supporting ledger are not available to the consumer. If F is absent, blocked readings can be smuggled into the export. If S is absent, gap, closure, and formal status cannot be inspected.

The row X routes the admitted packet to the registry surfaces, while H, C, P, N preserve and name the route. None of these support rows synthesizes a missing obligation row, so absence of any listed field exits the accepted $\mathsf{ConceptRegistryObligation}^{\uparrow}$ carrier. □

Theorem 1287.4 (Concept registry obligation forbidden-reading boundary)**.** *Every public reading of an accepted* $\mathsf{ConceptRegistryObligation}^{\uparrow}$ *packet must carry the forbidden-reading row F together with the carrier-and-classifier row A, ledger row L, status row S, and export row X. The packet cannot export subject substance, hidden theorem content, host semantic equality, audit-gate failure as theorem proof, or a registry entry whose blocked readings are not displayed.*

Proof. Begin with export readiness, Definition 1287.3. It keeps F in the same finite packet as the carrier, classifier, ledger, status, and export rows.

The audit-gate failure witness is diagnostic. It can record a failed gate and route that failure to the registry boundary, but it does not convert a missing forbidden-reading row into theorem content or export permission.

The concept-registry surface and registry-export surface then read the same displayed boundary. Since neither sibling surface contains a coordinate for hidden host semantics, subject substance, or blocked readings erased from the packet, the forbidden-reading boundary is exact for accepted concept export. □

Theorem 1287.5 (Concept registry obligation sibling dependency)**.** *The* $\mathsf{ConceptRegistryObligation}^{\uparrow}$ *packet depends on the sibling rows* $\mathsf{ConceptRegistrySurface}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{CoreRegistryIndex}^{\uparrow}$, $\mathsf{RegistryLayer}^{\uparrow}$, *and* $\mathsf{AuditGateFailureWitness}^{\uparrow}$ *only through displayed route and provenance data. None of those siblings is bijective to* $\mathsf{ConceptRegistryObligation}^{\uparrow}$*: each lacks at least one of the simultaneous concept-entry, carrier-and-classifier, ledger, forbidden-reading, status, export, transport, route, provenance, and local NameCert rows.*

Proof. Read the provenance row P and route row C. They name the sibling surfaces as consumers or diagnostic neighbors of the obligation packet, not as replacements for the local carrier.

The concept-registry surface records concept-family export, but it does not isolate the obligation packet required for each concept entry. The registry-export surface records public export control, but not the concept-entry carrier and classifier obligations together. The core registry index records table position, while the registry layer records package admit-or-block routing. The audit-gate failure witness records diagnostic failure rather than export readiness.

Thus the dependency is one-way through displayed route and provenance rows. A sibling can consume or diagnose the packet, but none reconstructs the entire finite carrier $O = (E, A, L, F, S, X, H, C, P, N)$. □

Falsifiable prediction: A concept export missing carrier, classifier, ledger, forbidden-reading, or status rows fails the ConceptRegistryObligationUp carrier.

Independence witness: conceptregistrysurface, registryexportsurface, coreregistryindex, registrylayer, auditgatefailurewitness: none is bijective because ConceptRegistryObligationUp carries concept-entry, carrier-and-classifier, ledger, forbidden-reading, status, export, transport, route, provenance, and local NameCert rows simultaneously.

The Lean follow-up for this chapter must provide `Nontrivial ConceptRegistryObligationUp` and `FieldFaithful ConceptRegistryObligationUp` instances in `BEDC.Derived.ConceptRegistryObligationU` These instances must preserve $E, A, L, F, S, X, H, C, P, N$ as separate displayed rows before any checked theorem cites the packet as a TasteGate surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ConceptRegistryObligation}^{\uparrow}}$.

Constructive story: A $\mathsf{ConceptRegistryObligation}^{\uparrow}$ packet is generated from concept-entry, carrier-and-classifier, ledger, forbidden-reading, status, export, componentwise hsame transport, displayed Cont route, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConceptRegistryObligation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1287.1, Definition 1287.2, Definition 1287.3, Definition 1287.4, and Definition 1287.5 bind philosophy concept-entry obligations to a finite registry packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConceptRegistryObligation}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.ConceptRegistryObligationUp.ConceptRegistryObligationTasteGate\_single\_carrier\_alignm`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, complete philosophy-package governance, correctness of every concept entry, or public export without the displayed obligation rows.

Upgrade path: Lean closure requires Nontrivial ConceptRegistryObligationUp and FieldFaithful ConceptRegistryObligationUp instances preserving $E, A, L, F, S, X, H, C, P, N$.

Chapter 1288

A Concrete Naming Certificate for $\mathsf{KernelPhaseRefusal}^{\uparrow}$

The $\mathsf{KernelPhaseRefusal}^{\uparrow}$ packet realizes the phase-bundle discipline of chapter 9462 as a finite NameCert surface for refusing targets that attempt to cross a displayed programme boundary. It sits beside the claim-entry discipline of chapter 1209, the promotion table of chapter 1274, the formal-target ledger of chapter 1282, and the closure reference carrier of chapter 1265. Those siblings store claim rows, upgrade rows, target skeletons, and closure references; this packet binds the current phase, attempted target, dependency blocker, refusal verdict, transport, continuation, provenance, and local name in one classifier surface.

Definition 1288.1 (Kernel phase-refusal carrier)**.** *A* $\mathsf{KernelPhaseRefusal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (P, T, D, R, A, H, C, Q, N)$$

with the following displayed rows:

1. *P is the current-phase row, recording the phase bundle currently licensed by the philosophy programme.*
2. *T is the attempted-target row, naming the proof target, certificate target, chapter target, bridge target, or review gate that asks to be treated as available.*
3. *D is the dependency-blocker row, recording the lower carrier, theorem, bridge, audit field, or NameCert obligation that must be displayed before T can be accepted.*
4. *R is the refusal-verdict row, classifying the target as in phase, blocked by D, or off-table relative to P.*
5. *A is the admissibility row, recording which claim-registry, upgrade-registry, formal-target-ledger, and closure-status-reference rows have been read by the classifier.*
6. *H stores componentwise* hsame *transport for phase, target, blocker, verdict, admissibility, continuation, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from the current phase through the attempted target, blocker, verdict, admissibility row, provenance, and local name.*
8. *Q is the* Pkg *provenance over* $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{UpgradeRegistry}^{\uparrow}$, $\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}$, $\mathsf{ClosureStatusReference}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{KernelPhaseRefusal}^{\uparrow}}$ *row.*
The carrier has no coordinate for accepting a later-phase target without a blocker row, promoting an off-table verdict to an in-phase verdict, erasing the current phase after classification, or replacing the finite dependency route by ambient attraction to a famous goal.

Lean4 (definition) `BEDC.Derived.KernelPhaseRefusalUp.KernelPhaseRefusalUp`
Lean4 ✓ `BEDC.Derived.KernelPhaseRefusalUp.KernelPhaseRefusalTasteGate single carrier alignment`

Theorem 1288.2 (Kernel phase-refusal phase order)**.** *For the carrier of Definition 1288.1, every accepted* $\mathsf{KernelPhaseRefusal}^{\uparrow}$ *packet reads the current-phase row P before the attempted-target row T, and reads the dependency-blocker row D before any refusal verdict that places T outside the current phase. A target above the current phase cannot be accepted unless its blocker row is displayed in the same finite packet.*

Proof. Project the carrier $K = (P, T, D, R, A, H, C, Q, N)$. The phase row, target row, blocker row, and verdict row are separate coordinates, and the continuation row C orders their public readback.

The sibling rows preserve the same ordering. $\mathsf{ClaimRegistryLayer}^{\uparrow}$ supplies the admitted claim row, $\mathsf{UpgradeRegistry}^{\uparrow}$ supplies the status and blocker route, $\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}$ supplies the target skeleton, and $\mathsf{ClosureStatusReference}^{\uparrow}$ supplies the closure report that bounds the current phase.

Finally inspect H, Q, N. Transport, provenance, and local naming preserve the displayed packet; they do not create a second route from T to acceptance. Therefore a later-phase target without D is not an accepted read of the phase-refusal packet. □

Theorem 1288.3 (Kernel phase-refusal off-table boundary)**.** *An accepted* $\mathsf{KernelPhaseRefusal}^{\uparrow}$ *packet exports only the current phase, attempted target, displayed blocker, refusal verdict, admissibility row, componentwise transport, displayed continuation, provenance, and local naming. It does not export a hidden target queue, a host-priority override, a famous-goal exception, a bridge-completion claim, or a proof that the blocker has been discharged.*

Proof. Use Definition 1288.1. The carrier exposes exactly the nine rows $P, T, D, R, A, H, C, Q, N$, and none of those rows is a hidden queue, host-priority override, exception list, bridge-completion proof, or blocker discharge.

Use Definition 1288.2. When the verdict places T above the current phase, the packet must keep the blocker row visible. The verdict may refuse the target or record the displayed dependency, but it cannot silently convert that dependency into completion.

The structural rows do not alter this boundary. Componentwise hsame, displayed Cont, Pkg provenance, and local $\mathsf{NameCert}$ naming replay the same finite object, so every listed stronger reading lies outside the accepted $\mathsf{KernelPhaseRefusal}^{\uparrow}$ surface. □

Theorem 1288.4 (Kernel phase-refusal admissibility obligation)**.** *For the carrier $K = (P, T, D, R, A, H, C, Q, N)$ of Definition 1288.1, any accepted* $\mathsf{KernelPhaseRefusal}^{\uparrow}$ *packet must expose the admissibility row A as the claim-registry, upgrade-registry, formal-target-ledger, and closure-status-reference read before the verdict row R can classify the attempted target T.*

Proof. Project the carrier $K = (P, T, D, R, A, H, C, Q, N)$. The admissibility coordinate A is separate from the target row T and the verdict row R, so the packet cannot classify T using an implicit host-side admissibility check.

Use phase order from Definition 1288.2. The current phase P, attempted target T, and dependency blocker D must be read in the displayed order before a later-phase target can be treated as available.

Now read the sibling registries named by the carrier. $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{UpgradeRegistry}^{\uparrow}$, $\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}$, and $\mathsf{ClosureStatusReference}^{\uparrow}$ are exactly the rows stored by A for this classifier read.

Finally apply the off-table boundary of Definition 1288.3. Since the packet has no hidden queue or priority override, R can classify T only after the displayed admissibility row has been exposed. □

Theorem 1288.5 (Kernel phase-refusal transport obligation)**.** *For every accepted* $\mathsf{KernelPhaseRefusal}^{\uparrow}$ *packet* $K = (P, T, D, R, A, H, C, Q, N)$*, componentwise* hsame *transport through* H *and displayed* Cont *replay through* C *preserve the phase row* P*, target row* T*, blocker row* D*, verdict row* R*, admissibility row* A*, provenance row* Q*, and local name* N*. Such transport cannot turn a blocked or off-table verdict into an accepted target.*

Proof. Project $K = (P, T, D, R, A, H, C, Q, N)$. The rows being transported are exactly the displayed coordinates of the carrier; H supplies componentwise hsame and C replays the same route under Cont.

Use Definition 1288.2. The blocker row remains part of the same packet whenever the attempted target lies outside the current phase, so transport cannot erase D while preserving the classifier read.

Apply Definition 1288.3. The verdict row exports only the visible refusal boundary and never stores a bridge-completion claim, blocker discharge, host-priority override, or hidden target queue.

It follows that H and C preserve the displayed P, T, D, R, A, Q, N rows as classifier data. A blocked or off-table verdict therefore remains a blocked or off-table verdict under the packet transport, and no formal verification or phase completion is claimed here. □

Theorem 1288.6 (Kernel phase-refusal scope closure)**.** *For every accepted* $\mathsf{KernelPhaseRefusal}^{\uparrow}$ *packet* $K = (P, T, D, R, A, H, C, Q, N)$*, the scoped read of the packet is exhausted by phase-order exposure through* P, T, D, R*, off-table boundary exposure through* R*, admissibility exposure through* A*, componentwise transport through* H*, displayed replay through* C*, prediction exposure, independence separation from registry siblings, provenance through* Q*, and local naming through* N*.*

Proof. Project the carrier of Definition 1288.1. The phase, target, blocker, verdict, admissibility, transport, replay, provenance, and local name are the only displayed rows.

Use Definition 1288.2 for the order of P, T, D, R, Definition 1288.3 for the refusal boundary, and Definition 1288.4 for the registry rows read by A.

Apply Definition 1288.5 to keep the same rows under H and C. The prediction and independence witness then state the external tests for the same finite packet: a no-blocker target is refused, and the classifier remains separate from the registry and closure-reference siblings.

Thus the scoped route contains exactly the displayed carrier rows and the named tests. It does not add target validity, phase completion, claim-registry status, or bridge completion. □

Falsifiable prediction: A packet whose attempted target lies above the current phase without a displayed dependency-blocker row cannot be accepted by the phase-refusal classifier.

Independence witness: claimregistrylayer, upgraderegistry, philosophyformaltargetledger, closurestatusreference: this carrier binds phase order, target admissibility, and refusal verdict in one

packet, while the siblings store claims, upgrade rows, formal targets, or closure references without the phase-refusal classifier.

The Lean follow-up must provide `lean4/BEDC/Derived/KernelPhaseRefusalUp/TasteGate.lean` with Nontrivial KernelPhaseRefusal$^{\uparrow}$ and FieldFaithful KernelPhaseRefusal$^{\uparrow}$ instances. The field-faithfulness witness must preserve $P, T, D, R, A, H, C, Q, N$ as distinct rows so the checked TasteGate surface can rule out no-blocker acceptance, off-table promotion, and hidden target-queue readings.

Closure status for NameCert$_{\text{KernelPhaseRefusal}^{\uparrow}}$.

Constructive story: The kernel phase-refusal certificate is generated from a $BHist$ packet that records phase order, target admissibility, dependency blockers, and a refusal verdict in one visible carrier. The construction first reads the phase row, then the attempted target row, then the blocker row, and finally the refusal boundary that says the target is off-table for that phase. The $hsame$ relation preserves the verdict under equivalent histories, while Cont can only propagate the same phase-refusal packet. The phase-order theorem, off-table boundary theorem, prediction, and independence witness keep the object separate from claim registries, formal-target ledgers, status references, or closure metadata that do not carry the refusal classifier.

Theory closure: TheoryGate(NameCert$_{\text{KernelPhaseRefusal}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1288.1, Definition 1288.2, Definition 1288.3, Definition 1288.4, Definition 1288.5, Definition 1288.6, and the checked TasteGate row bind the scoped route for phase order, refusal boundaries, admissibility, transport, replay, prediction, independence, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{KernelPhaseRefusal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: It does not claim target invalidity in all phases, claim-registry status, or closure metadata beyond the recorded refusal packet.

Upgrade path: Reaching public closure requires a public export route and Lean targets for the phase, admissibility, and refusal-preservation rows.

Chapter 1289

A Concrete Naming Certificate for VerificationFailureRoadmap$^{\uparrow}$

The VerificationFailureRoadmap$^{\uparrow}$ packet realizes the verification-failure roadmap of chapter 9462 and subsection 9462.32.9 as a finite NameCert carrier for checked reports, audit rows, failure certificates, downgrade routes, roadmap boundaries, and cannot-claim rows. It sits beside chapter 1237, chapter 1233, chapter 1229, chapter 1259, and chapter 1274. Those siblings expose typed failure, failure certificates, gap-and-bridge audit, forbidden-dependency gates, and promotion registries separately; this packet binds the full report, failure, downgrade, roadmap, refusal, transport, replay, provenance, and local naming surface before a verification-failure route can be consumed.

Definition 1289.1 (Verification failure roadmap carrier)**.** *A* VerificationFailureRoadmap$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (R, A, F, D, M, U, B, T, C, P, N)$$

with the following displayed rows:

1. *R is the checked-report row, recording the theorem, definition, bridge, audit, or closure-status report whose advertised verification state is being inspected.*
2. *A is the audit-report row, recording the finite checker, marker, dependency, bridge, and paper-to-Lean rows that make the report inspectable.*
3. *F is the failure-certificate row, consumed from* TypedFailureCertificate$^{\uparrow}$*,* FailureCertificate$^{\uparrow}$*,* GapFailureBridgeAudit *or* AxiomPurityGate$^{\uparrow}$*.*
4. *D is the downgrade-route row, recording how the advertised status is lowered after F is read.*
5. *M is the roadmap-boundary row, recording which named blocker must be discharged before the report may be promoted.*
6. *U is the upgrade-registry row, consumed from* UpgradeRegistry$^{\uparrow}$ *and recording the current status, next status, required field, and blocker.*
7. *B is the cannot-claim row, recording the stronger readings that the failed report may not export.*
8. *T records componentwise* hsame *transport for report, audit, failure, downgrade, roadmap, upgrade, cannot-claim, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay through the report, audit, failure certificate, downgrade route, roadmap boundary, upgrade registry, and cannot-claim rows.*

10. *P is the* Pkg *provenance over* VerificationFailureRoadmap$^{\uparrow}$, TypedFailureCertificate$^{\uparrow}$, FailureCertificate$^{\uparrow}$, GapFailureBridgeAudit$^{\uparrow}$, AxiomPurityGate$^{\uparrow}$, UpgradeRegistry$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{VerificationFailureRoadmap}^{\uparrow}}$ *row.*

The carrier has no coordinate for hidden checker success, silent marker promotion, unstated bridge completion, unreported axiom-purity discharge, erased failure certificates, or roadmap advancement without the displayed blocker row.

Theorem 1289.2 (VerificationFailureRoadmap NameCert obligations)**.** *For the carrier of Definition 1289.1, the local* $\mathsf{NameCert}_{\mathsf{VerificationFailureRoadmap}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$V = (R, A, F, D, M, U, B, T, C, P, N),$$

checked-report display through R, audit-report display through A, failure-certificate display through F, downgrade-route display through D, roadmap-boundary display through M, upgrade-registry display through U, cannot-claim display through B, componentwise hsame *transport through T, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.VerificationFailureRoadmapUp.TasteGate.VerificationFailureRoadmapNameCertObligatio`

Proof. Project the finite carrier. The report, audit, failure, downgrade, roadmap, upgrade-registry, and cannot-claim rows are displayed before the structural rows are read.

Read the sibling rows in order. TypedFailureCertificate$^{\uparrow}$ and FailureCertificate$^{\uparrow}$ supply failure branches, GapFailureBridgeAudit$^{\uparrow}$ supplies the gap-and-bridge audit row, AxiomPurityGate$^{\uparrow}$ supplies forbidden-dependency refusal, and UpgradeRegistry$^{\uparrow}$ supplies the current-status and next-status registry entry.

Finally inspect T, C, P, N. These rows preserve, replay, source, and name the same displayed packet. They do not create a hidden checker result, bridge completion, or marker promotion, so the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.VerificationFailureRoadmapUp.verificationFailureRoadmap taste gate surface`

Theorem 1289.3 (VerificationFailureRoadmap downgrade route)**.** *Every accepted* VerificationFailureRoadmap$^{\uparrow}$ *packet*

$$V = (R, A, F, D, M, U, B, T, C, P, N)$$

routes a failed verification report from R through the audit row A and failure-certificate row F before the downgrade row D can be read. A consumer that reads a lowered status without A and F leaves the accepted carrier and cannot cite the packet as a roadmap result.

Lean4 ✓ `BEDC.Derived.VerificationFailureRoadmapUp.VerificationFailureRoadmapDowngradeRoute`

Proof. Use the NameCert obligations of Definition 1289.2. The report row R, audit row A, failure-certificate row F, and downgrade row D are all separate displayed coordinates.

The replay row C records the order in which the report is inspected, the audit row is read, the failure certificate is consumed, and the downgrade route is exposed. Transport through T preserves these coordinates rather than replacing them.

Therefore a lowered report that omits A or F is not a read of the same carrier. It may be a detached editorial statement, but it is not an accepted VerificationFailureRoadmap$^{\uparrow}$ route. □

Lean4 ✓ `BEDC.Derived.VerificationFailureRoadmapUp.TasteGate.VerificationFailureRoadmapDowngradeRoute`

Theorem 1289.4 (VerificationFailureRoadmap nonclaim boundary)**.** *For every accepted* VerificationFailureRoadma *packet, the roadmap-boundary row M, upgrade-registry row U, and cannot-claim row B jointly determine which stronger verification readings are refused. The packet does not export a checked theorem, bridge-checked status, axiom-clean status, public closure, or completed roadmap item unless that reading is licensed by the displayed registry and not listed in B.*

Proof. Start from the carrier inventory. The roadmap boundary, upgrade registry, and cannot-claim row are displayed as M, U, B and are named by the same local $\mathsf{NameCert}_{\mathsf{VerificationFailureRoadmap}^{\uparrow}}$ row.

Apply the downgrade-route theorem Definition 1289.3. A failed report reaches consumers only after the audit and failure rows are read, so no stronger verification reading can bypass those rows.

The structural rows preserve the same refusal boundary. Since T, C, P, N do not add a completion coordinate, any reading listed in B or blocked by M, U lies outside the accepted public export of the packet. □

Lean4 ✓ `BEDC.Derived.VerificationFailureRoadmapUp.TasteGate.VerificationFailureRoadmapNonclaimBoundary`

Theorem 1289.5 (VerificationFailureRoadmap sibling independence)**.** *The* $\mathsf{VerificationFailureRoadmap}^{\uparrow}$ *carrier depends on* $\mathsf{TypedFailureCertificate}^{\uparrow}$, $\mathsf{FailureCertificate}^{\uparrow}$, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$, $\mathsf{AxiomPurityGate}^{\uparrow}$, *and* $\mathsf{UpgradeRegistry}^{\uparrow}$ *without being bijective to any one sibling under NameCert-row preservation.*

Lean4 ✓ `BEDC.Derived.VerificationFailureRoadmapUp.TasteGate.VerificationFailureRoadmapSiblingIndepender`

Proof. Compare the displayed rows. $\mathsf{TypedFailureCertificate}^{\uparrow}$ names typed failure branches, $\mathsf{FailureCertificate}^{\uparrow}$ names rejected gate attempts, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ binds typed gaps to bridge-audit rows, $\mathsf{AxiomPurityGate}^{\uparrow}$ binds forbidden-dependency refusal, and $\mathsf{UpgradeRegistry}^{\uparrow}$ records current and next status for promotion claims.

The present carrier stores those component rows together with checked report, audit report, downgrade route, roadmap boundary, cannot-claim row, transport, replay, provenance, and local NameCert rows. A row-preserving bijection to any single sibling would have to preserve fields that the sibling does not carry.

Thus the siblings are inputs to one verification-failure roadmap packet, not alternative names for the same carrier. □

Theorem 1289.6 (VerificationFailureRoadmap bridge-facing schema route)**.** *Any bridge-facing reader of an accepted* $\mathsf{VerificationFailureRoadmap}^{\uparrow}$ *packet must expose the checked-report row R, audit-report row A, failure-certificate row F, downgrade-route row D, roadmap-boundary row M, upgrade-registry row U, cannot-claim row B, componentwise transport row T, displayed replay row C, package provenance row P, and local* NameCert *row N before any bridge schema may consume the packet. A schema that reads only the downgrade row, only the cannot-claim row, or only a sibling failure certificate is not a bridge-facing read of the same roadmap carrier.*

Lean4 ✓ `BEDC.Derived.VerificationFailureRoadmapUp.TasteGate.VerificationFailureRoadmapBridgeFacingSchem`

Proof. Start with Definition 1289.2. It lists $R, A, F, D, M, U, B, T, C, P, N$ as the displayed rows of the local NameCert surface, so a bridge-facing reader cannot omit any of those rows and still cite the accepted carrier.

Apply the downgrade route Definition 1289.3. The failed report is read from R through A and F before D is available, which blocks a bridge schema from consuming a detached downgrade row.

Next use the nonclaim boundary and sibling independence results, Definition 1289.4 and Definition 1289.5. The rows M, U, B determine the stronger readings refused by the packet, while the sibling failure and audit packets remain inputs rather than replacements for the roadmap carrier.

It remains to carry the exposed route to a bridge-facing schema. Transport through T, replay through C, provenance through P, and local naming through N preserve the same row inventory, so the bridge schema may consume only the fully exposed verification-failure roadmap packet. □

Falsifiable prediction: Any reported verification upgrade that lacks the displayed audit report, failure-certificate, downgrade, and cannot-claim rows is rejected by the VerificationFailureRoadmapUp classifier.

Independence witness: typedfailurecertificate, failurecertificate, gapfailurebridgeaudit, axiompuritygate, upgraderegistry: no sibling is bijective because each supplies only a component row while VerificationFailureRoadmapUp binds report, failure, downgrade, roadmap, refusal, transport, replay, provenance, and NameCert rows in one packet.

The Lean follow-up must provide Nontrivial VerificationFailureRoadmap$^{\uparrow}$ and FieldFaithful VerificationFailureRoadmapUp instances in the future namespace `BEDC.Derived.VerificationFailureRoadmapUp`. The field-faithfulness witness must preserve $R, A, F, D, M, U, B, T, C, P, N$ as distinct rows before a checked TasteGate theorem may classify verification-failure reports.

Closure status for NameCert$_{\text{VerificationFailureRoadmap}^{\uparrow}}$.

Constructive story: The verification failure roadmap is generated from $BHist$ rows that name an audit report, failure certificate, downgrade row, cannot-claim row, roadmap route, and sibling references that remain outside the roadmap carrier. The carrier first records the failure row, then the route toward weaker status or exposed gap, and finally allows Cont to carry that roadmap forward as the same plan. The $hsame$ relation keeps the failure row stable under representative change. NameCert obligations, downgrade route, nonclaim boundary, sibling independence, prediction, and independence witness make the object a visible response plan for verification failure rather than a proof or audit packet.

Theory closure: TheoryGate(NameCert$_{\text{VerificationFailureRoadmap}^{\uparrow}}$, maturePackageClosed)

Scope closed: This chapter binds the verification failure-roadmap carrier, NameCert obligations, downgrade-route theorem, nonclaim-boundary theorem, sibling-independence theorem, bridge-facing schema route, falsifiable prediction, independence witness, and complete refusal surface over TypedFailureCertificateUp, FailureCertificateUp, GapFailureBridgeAuditUp, AxiomPurityGateUp, UpgradeRegistryUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{VerificationFailureRoadmap}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim verification success, proof recovery, hidden gap closure, or substitution by downgrade and audit sibling packets.

Upgrade path: Mature treatment requires a checked bridge surface and the audit-clean verification route for the complete failure-roadmap schema.

Chapter 1290

A Concrete Naming Certificate for $\mathsf{CausalIntervention}^{\uparrow}$

The $\mathsf{CausalIntervention}^{\uparrow}$ packet realizes the cross-history causal-dependence step of Definition 9462.2145 as a finite NameCert carrier. The recognized object is Pearl-style causal intervention: one named intervention row changes the admitted dependence surface while the observer histories, causal row, rate boundary, commitment row, transport, replay, provenance, and local name remain visible. Its programme context is chapter 9462; its sibling inputs are the multi-history configuration surface of chapter 474, the cross-history dependence surface of chapter 478, the causal commitment boundary of chapter 505, and the maximum-rate boundary of chapter 594.

Definition 1290.1 (Causal intervention carrier)**.** *A* $\mathsf{CausalIntervention}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, S, T, D, J, R, K, H, C, P, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathrm{MultiHistConfig}^{\uparrow}$ *row exposing the finite observer-history family.*
2. *S and T are the source and target history rows selected from M.*
3. *D is the displayed* $\mathsf{CrossHistCausal}^{\uparrow}$ *dependence row from S into T before the intervention is read.*
4. *J is the finite intervention row naming the changed local input, held as packet data rather than as a host-level command.*
5. *R is the* $\mathsf{MaxCausalRate}^{\uparrow}$ *row bounding the affected dependence route after J is admitted.*
6. *K is the* $\mathsf{CausalCommitment}^{\uparrow}$ *row recording the forward-looking commitment licensed by the intervention and dependence rows.*
7. *H records componentwise* hsame *transport for $M, S, T, D, J, R, K, C, P, N$.*
8. *C records the displayed* Cont *routes by which the configuration, dependence, intervention, rate, commitment, and consumer handoff are replayed.*
9. *P is the* Pkg *provenance over* $\mathrm{MultiHistConfig}^{\uparrow}$, $\mathsf{CrossHistCausal}^{\uparrow}$, $\mathsf{CausalCommitment}^{\uparrow}$, $\mathsf{MaxCausalRate}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CausalIntervention}^{\uparrow}}$ *row.*

The classifier compares carriers only through these rows. It has no coordinate for a hidden do-operator, counterfactual universe, global observer frame, quotient of histories, host probability space, semantic causal graph, or unbounded physical dynamics.

Lean4 ✓ `BEDC.Derived.CausalInterventionUp.CausalInterventionTasteGate single carrier alignment`

Theorem 1290.2 (Causal intervention NameCert obligations)**.** *For the carrier of Definition 1290.1, the local* $\mathsf{NameCert}_{\mathsf{CausalIntervention}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for* $I = (M, S, T, D, J, R, K, H, C, P, N)$*, multi-history configuration exposure through* M*, cross-history dependence exposure through* D*, intervention-row accountability through* J*, maximum-rate accountability through* R*, causal-commitment accountability through* K*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted packet to its displayed rows. The multi-history configuration row supplies the finite history family, while S and T select the two visible histories consumed by the dependence row.

Read the causal layer next. The row D is the cross-history dependence surface, J is the intervention row that changes the admitted local input, R bounds the affected route, and K records the forward commitment licensed by those rows.

Finally apply the structural rows. Componentwise transport is supplied only by H, replay only by C, provenance only by P, and local naming only by N. Since the carrier lists no hidden do-operator, counterfactual universe, global frame, quotient, probability space, semantic graph, or unbounded dynamics, those objects are not NameCert obligations for $\mathsf{CausalIntervention}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.CausalInterventionUp.CausalInterventionNameCertObligations`

Theorem 1290.3 (Causal intervention falsifiable non-escape)**.** *Any accepted* $\mathsf{CausalIntervention}^{\uparrow}$ *consumer that claims a cross-history intervention effect must factor through the finite route*

$$M, S, T, D, J, R, K, H, C, P, N.$$

If the claimed effect cannot identify its multi-history configuration row, source and target histories, dependence row, intervention row, maximum-rate row, causal-commitment row, componentwise transport, replay, provenance, and local name, then the claim fails the $\mathsf{CausalIntervention}^{\uparrow}$ *classifier rather than escaping to a host-level causal semantics.*

Proof. Start with carrier exposure from Definition 1290.1. Every public read of the intervention packet has only the displayed rows $M, S, T, D, J, R, K, H, C, P, N$.

Apply the NameCert obligations of Definition 1290.2. They force the consumer to read configuration, dependence, intervention, rate, and commitment before it can export an intervention effect.

The failure condition is therefore finite and falsifiable. A consumer missing one of the listed rows has no projection target in the packet, while a consumer seeking a hidden causal operator, counterfactual universe, global observer frame, quotient history, host probability space, semantic graph, or unbounded dynamics asks for a coordinate the carrier does not contain. □

Lean4 ✓ `BEDC.Derived.CausalInterventionUp.CausalIntervention falsifiable nonescape`

Falsifiable prediction: Any claimed CausalInterventionUp effect that does not expose the rows $M, S, T, D, J, R, K, H, C, P, N$ is rejected by the local carrier classifier.

Closure status for $\mathsf{NameCert}_{\mathsf{CausalIntervention}^{\uparrow}}$**.**

Constructive story: A CausalIntervention$^{\uparrow}$ packet is generated from multi-history configuration, selected source and target histories, a cross-history causal row, a finite intervention row, a maximum-rate row, a causal-commitment row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CausalIntervention}\uparrow}$, obligation)

Scope closed: The obligation scope records the finite intervention carrier, its NameCert obligation surface, and its falsifiable non-escape boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{CausalIntervention}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not derive numerical dynamics, Pearl calculus laws, a host probability model, a semantic causal graph, global spacetime, Lean verification, or bridge checking for CausalIntervention$^{\uparrow}$.

Upgrade path: The next paper grade is scoped closure for causal-calculus consumer routes over carrier exposure, intervention-row accountability, causal-dependence accountability, rate accountability, commitment accountability, transport, replay, provenance, and local naming.

Chapter 1291

A Concrete Naming Certificate for $\mathsf{CrossHistoryCausalDependence}^{\uparrow}$

The $\mathsf{CrossHistoryCausalDependence}^{\uparrow}$ packet realizes the multi-history physics route of subsection 9462.32.10 as a finite no-global-frame causal-route packet. It sits after the uniform metric estimate of chapter 1159, the scientific model bridge of chapter 1273, and the physical law bridge of chapter 1285. Those siblings expose estimate discipline, model-facing bridge rows, and law-facing bridge rows; this carrier binds a cross-history dependence route without asserting Lorentz geometry, completed physical law, or empirical success.

Definition 1291.1 (Cross-history causal dependence carrier)**.** *A* $\mathsf{CrossHistoryCausalDependence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, B, R, S, F, M, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the source-history row carrying the first displayed history, its local event window, and its admissible observation route.*
2. *B is the target-history row carrying the second displayed history, its local event window, and its admissible observation route.*
3. *R is the causal-route row stating that the target window is read as dependent on the source window through displayed continuation data rather than through host time.*
4. *S is the stability row recording that the dependence predicate is preserved by the componentwise history transport used by the packet.*
5. *F is the no-global-frame row excluding synchronized clock, privileged observer frame, ambient spacetime coordinate, and host-valued cross-history equality.*
6. *M is the* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *estimate row available to consumers that later compare route bounds through a finite metric-estimate surface.*
7. *L is the bridge-ledger row recording how* $\mathsf{ScientificModelBridge}^{\uparrow}$ *and* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *may consume the causal dependence as a displayed scientific or law-facing route.*
8. *H records componentwise* hsame *transport for $A, B, R, S, F, M, L, C, P, N$.*
9. *C records the displayed* Cont *routes by which the two history rows, causal route, stability row, no-global-frame refusal, metric-estimate row, and bridge-ledger row are replayed.*

10. *P is the* Pkg *provenance over* $\mathsf{CrossHistoryCausalDependence}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{ScientificModelBridge}^{\uparrow}$, $\mathsf{PhysicalLawBridge}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CrossHistoryCausalDependence}^{\uparrow}}$ *row.*

The classifier compares packets only through these rows. It has no coordinate for global simultaneity, preferred frame, semantic spacetime, quotient history equality, unbounded empirical confirmation, or a causal relation imported outside the displayed route.

Lean4 (definition) `BEDC.Derived.CrossHistoryCausalDependenceUp.CrossHistoryCausalDependenceUp`

Theorem 1291.2 (Cross-history causal dependence NameCert obligations)**.** *For the carrier of Definition 1291.1, the local* $\mathsf{NameCert}_{\mathsf{CrossHistoryCausalDependence}^{\uparrow}}$ *surface consists exactly of carrier admission for $D = (A, B, R, S, F, M, L, H, C, P, N)$, source-history exposure through A, target-history exposure through B, causal-route exposure through R, transported dependence stability through S, no-global-frame refusal through F, metric-estimate handoff through M, scientific-model and physical-law bridge handoff through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted packet to its displayed rows. The rows A and B supply the two history-local event windows, while R supplies the finite route by which the second window is read as dependent on the first.

Read stability and refusal next. The row S keeps the route stable under the componentwise history transport of the packet, and the row F blocks every read that would replace the route by synchronized time, privileged observer frame, ambient spacetime, or host-valued cross-history equality.

Finally read the consumer handoff. The estimate row M is the only metric-estimate surface available to later bounded-route consumers, and L is the only scientific-model or physical-law bridge ledger. Transport, replay, provenance, and local naming through H, C, P, N preserve exactly those displayed rows, so the listed surface exhausts the local NameCert obligations. □

Theorem 1291.3 (Cross-history causal dependence nonframe invariance)**.** *Every accepted* CrossHistoryCausalDeper *consumer that reads a cross-history causal dependence factors through $A, B, R, S, F, M, L, H, C, P, N$. In particular, if the no-global-frame row F is absent, or if a consumer replaces F by a synchronized clock, privileged observer frame, ambient spacetime coordinate, or host-valued equality of histories, then the consumer no longer reads the accepted packet.*

Proof. Start from the carrier inventory of Definition 1291.1. The causal dependence is not a bare relation: it is the route row R between the displayed source and target histories A, B under the stability row S and the no-global-frame row F.

Apply the NameCert obligation surface of Definition 1291.2. Any accepted consumer route must preserve the two history rows, the route row, the stability row, the refusal row, the estimate handoff, the bridge ledger, transport, replay, provenance, and local naming.

Thus deleting F deletes one of the carrier obligations. Replacing F by global simultaneity, a preferred frame, ambient spacetime, or host equality adds a coordinate not present in D. Componentwise hsame, displayed Cont, Pkg, and NameCert replay cannot create that coordinate, so the accepted packet is invariant only as a no-global-frame causal-route packet. □

Lean4 ✓ `BEDC.Derived.CrossHistoryCausalDependenceUp.CrossHistoryCausalDependenceCarrier no global frame row deterministic`

Falsifiable prediction: If the no-global-frame row is absent, the packet cannot export a cross-history causal-dependence reading.

Independence witness: metric-triangle-uniform-estimate, scientificmodelbridge, physicallawbridge, standardbridgeauditpacket: the cross-history packet stores multi-history causal-route and no-global-frame rows not bijective to any sibling carrier.

The Lean follow-up file `lean4/BEDC/Derived/CrossHistoryCausalDependenceUp/TasteGate.lean` must provide explicit Nontrivial CrossHistoryCausalDependence$^{\uparrow}$ and FieldFaithful CrossHistoryCausalDependence$^{\uparrow}$ instances. These instances must preserve the two history rows, causal-route row, stability row, no-global-frame row, metric-estimate handoff, bridge-ledger row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before `BEDC.Derived.CrossHistoryCausalDependen` can serve as the future checked namespace for this packet.

Closure status for NameCert$_{\text{CrossHistoryCausalDependence}\uparrow}$.

Constructive story: A CrossHistoryCausalDependence$^{\uparrow}$ packet is generated from two displayed history-event rows, a causal-route row, transported stability, no-global-frame refusal, metric-estimate handoff, scientific-model and physical-law bridge ledger, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{CrossHistoryCausalDependence}\uparrow}$, seed)

Scope closed: Definition 1291.1, Definition 1291.2, and Definition 1291.3 bind the finite no-global-frame carrier, NameCert surface, and nonframe invariance boundary.

Formal verification: FormalStatus(NameCert$_{\text{CrossHistoryCausalDependence}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not derive Lorentz geometry, maximum causal rate, completed physical law, empirical adequacy, standard-bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, NameCert surface, nonframe invariance, and TasteGate nontriviality with field faithfulness for $A, B, R, S, F, M, L, H, C, P, N$.

Chapter 1292

A Concrete Naming Certificate for BedcPhilosophyPackage$^{\uparrow}$

The BedcPhilosophyPackage$^{\uparrow}$ packet realizes the package object of subsection 9462.33.1 as one finite NameCert carrier rather than as a prose registry. It sits beside the philosophy-map target of chapter 1277, the tradition registry of chapter 1267, the science bridge of chapter 1286, the gap/failure bridge audit of chapter 1229, and the claim registry layer of chapter 1209. Those siblings expose map targets, inherited-comparison rows, science-bridge rows, typed gap/failure audit rows, and exported-claim rows; this packet binds the package object only when all those surfaces remain named coordinates of the same BEDC carrier.

Definition 1292.1 (BEDC philosophy package NameCert carrier)**.** *A* BedcPhilosophyPackage$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (T, R, M, G, D, S, C, A, H, K, N)$$

with the following displayed rows:

1. *T is the thesis row, recording auditable generativity and the boundary that the package is not a BEDC kernel extension.*
2. *R is the concept-registry row, recording concept entries, forbidden readings, theorem entries, and package-level registry routes.*
3. *M is the theorem-map row, recording theorem sites, definition sites, Lean targets when present, paper-only targets when present, and their package readings.*
4. *G is the gap-map row, recording typed gaps, failure branches, missing bridge rows, and not-claimed surfaces.*
5. *D is the tradition/science-map row, recording inherited tradition comparisons, scientific-object bridges, physical-audit readings, and rejected surplus.*
6. *S is the cannot-claim registry row, recording blocked primitive philosophical readings, host-equality imports, quotient imports, choice imports, global-truth imports, and hidden subject-substance imports.*
7. *C is the closure-status row, recording theory closure, formal status, bridge status, scope, not-claimed surface, and next obligation for each exported package row.*

8. *A is the audit-policy row, recording the finite export policy that rejects unregistered claims, missing cannot-claim rows, host-primitive leakage, and bridge-status collapse.*
9. *H records componentwise* hsame *transport for $T, R, M, G, D, S, C, A, K, N$.*
10. *K records displayed* Cont *routes,* Pkg *provenance, sibling routes, and source-file provenance for the same displayed rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BedcPhilosophyPackage}^{\uparrow}}$ *row.*

The carrier has no coordinate for a primitive philosophical object, a kernel constructor, a host truth predicate, an unchecked registry export, a theorem map detached from gaps, a science map detached from bridge audit, or a claim export without cannot-claim and audit-policy rows.

Lean4 ✓ `BEDC.Derived.BedcPhilosophyPackageUp.BedcPhilosophyPackageTasteGate single carrier alignment`

Theorem 1292.2 (BEDC philosophy package registry-ledger exactness)**.** *For the carrier of Definition 1292.1, every public package entry is read from exactly one of the displayed registry-ledger rows R, M, G, D, S, C, A together with the thesis row T and the support rows H, K, N. In particular, concept entries, theorem-map entries, gap-map entries, tradition/science-map entries, cannot-claim entries, closure-status entries, and audit-policy entries cannot be exported by prose adjacency alone.*

Proof. Project the finite BHist packet. The thesis row T states the package boundary, while R, M, G, D, S, C, A display the registry, theorem-map, gap-map, tradition/science-map, cannot-claim, closure-status, and audit-policy ledgers before any export is named.

The support rows then preserve the same display. The hsame row H transports only those coordinates, the Cont and Pkg row K replays and sources only those routes, and the local NameCert row N names the resulting packet.

Thus a public package entry has no remaining carrier coordinate from which to arise. It must be a projection of the displayed rows, and prose adjacency to a theorem, definition, bridge, or registry paragraph is not an export rule. □

Lean4 ✓ `BEDC.Derived.BedcPhilosophyPackageUp.BedcPhilosophyPackage registry ledger exactness`
↪ variant `BEDC.Derived.BedcPhilosophyPackageUp.BedcPhilosophyPackageRegistryLedgerExactness`

Theorem 1292.3 (BEDC philosophy package audit-map nonescape)**.** *Every accepted* $\mathsf{BedcPhilosophyPackage}^{\uparrow}$ *audit export must pass through the cannot-claim registry row S and the audit-policy row A. If S is removed, an audit-map export can no longer refuse primitive philosophical readings uniformly across theorem-map, gap-map, tradition/science-map, closure-status, and claim-registry rows.*

Proof. Use the carrier of Definition 1292.1. The row S is the only coordinate that lists the blocked primitive readings, while A is the finite policy row that checks an exported package reading against that list.

Rows R, M, G, D, C expose registry, theorem, gap, tradition/science, and closure-status data, but none of them is the cannot-claim registry. They can say where a reading lands, what gap it has, or what closure status it carries, yet they do not by themselves refuse host equality, quotient import, choice import, global truth, or hidden subject substance.

With S present, the export route in K must replay the refusal row before N names the packet. Without S, the audit map lacks the displayed refusal coordinate, so the package cannot certify nonescape for primitive philosophical readings. □

Lean4 ✓ `BEDC.Derived.BedcPhilosophyPackageUp.BedcPhilosophyPackage audit map nonescape`

Theorem 1292.4 (BEDC philosophy package NameCert obligations)**.** *For the carrier of Definition 1292.1, the local* $\mathsf{NameCert}_{\mathsf{BedcPhilosophyPackage}^{\uparrow}}$ *surface consists exactly of carrier admission for* $P = (T, R, M, G, D, S, C, A, H, K, N)$*, package-thesis exposure through* T*, registry-ledger exposure through* R, M, G, D, S, C, A*, componentwise* hsame *transport through* H*, displayed* Cont *replay and* Pkg *provenance through* K*, and local naming through* N*.*

Proof. Read the packet by coordinates. Carrier admission supplies the finite BHist object, and the thesis row T supplies the non-kernel-extension boundary fixed in Definition 9462.2155.

The ledger rows R, M, G, D, S, C, A then display the package contents: registry, theorem map, gap map, tradition/science map, cannot-claim registry, closure status, and audit policy. The certificate surface has to inspect those rows before it can expose any package-level reading.

Finally H, K, N preserve, replay, source, and name exactly the same packet. Since the carrier contains no other coordinate, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.BedcPhilosophyPackageUp.BedcPhilosophyPackage namecert obligations`

Theorem 1292.5 (BEDC philosophy package sibling independence)**.** *The sibling packets* $\mathsf{PhilosophyMapTarget}^{\uparrow}$*,* $\mathsf{TraditionRegistry}^{\uparrow}$*,* $\mathsf{ScienceBridge}^{\uparrow}$*,* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$*, and* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *are dependencies of* $\mathsf{BedcPhilosophyPackage}^{\uparrow}$ *only through displayed routes in* K *and displayed ledger rows in* R, M, G, D, S, C, A*. None is bijective with the carrier* $P = (T, R, M, G, D, S, C, A, H, K, N)$*.*

Proof. Inspect the package carrier. It stores the thesis, registry, theorem-map, gap-map, tradition/science-map, cannot-claim, closure-status, audit-policy, transport, route/provenance, and local naming rows together.

Each sibling contributes a narrower surface. The philosophy-map target names map obligations, the tradition registry names inherited-comparison rows, the science bridge names scientific bridge rows, the gap/failure bridge audit names typed gap and bridge audit rows, and the claim registry layer names export-control rows.

The package route K may cite those siblings, and the ledger rows may consume their outputs. But no sibling reconstructs all eleven displayed coordinates, and the package cannot be projected back to any one sibling without losing local rows. Hence the dependency is non-bijective. □

Falsifiable prediction: Deleting the cannot-claim registry row allows an audit-map export that no longer refuses primitive philosophical readings.

Independence witness: philosophy-map-target, traditionregistry, sciencebridge, gap-failure-bridge-audit, claimregistrylayer: none is bijective because the package carrier alone stores registry, theorem-map, gap-map, tradition/science-map, cannot-claim, closure-status, and audit-policy rows together.

The Lean `TasteGate.lean` boundary must provide $\mathsf{Nontrivial}\ \mathsf{BedcPhilosophyPackage}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{BedcPhilosophyPackage}^{\uparrow}$ instances. These instances must keep $T, R, M, G, D, S, C, A, H, K, N$ as separate displayed fields before any checked marker can cite a target in `lean4/BEDC/Derived/BedcPhilosophyPa`

Lean4 ✓ `BEDC.Derived.BedcPhilosophyPackageUp.taste gate`

Theorem 1292.6 (BEDC philosophy package scoped obligations)**.** *For the carrier* $P = (T, R, M, G, D, S, C, A, H,$ *of Definition 1292.1, the package scope is exactly the displayed TasteGate-bound NameCert surface consisting of the carrier row, registry-ledger exactness, audit-map nonescape, NameCert obligations, sibling independence, falsifiable prediction, independence witness, and the checked TasteGate marker. No package-level reading is in scope unless it is routed through one of* $T, R, M, G, D, S, C, A, H, K, N$*.*

Proof. Combine the carrier inventory with Definition 1292.2. The public rows are $T, R, M, G, D, S, C, A, H, K, N$, and the registry ledger prevents prose adjacency from exporting any additional package entry.

Apply Definition 1292.3 and Definition 1292.4. They force every accepted audit reading and every local certificate obligation to pass through the displayed cannot-claim, audit-policy, transport, replay, provenance, and local naming rows.

Finally read Definition 1292.5, the falsifiable prediction, the independence witness, and the checked TasteGate marker. Together they bind the ai-origin package to this finite carrier surface and leave no scoped coordinate outside $T, R, M, G, D, S, C, A, H, K, N$. □

Lean4 ✓ `BEDC.Derived.BedcPhilosophyPackageUp.BedcPhilosophyPackage scoped obligations`

Theorem 1292.7 (BEDC philosophy package bridge boundary)**.** *Every bridge read of the* BedcPhilosophyPackage$^{\uparrow}$ *packet must pass through the displayed carrier rows $T, R, M, G, D, S, C, A, H, K, N$, the checked TasteGate marker, sibling independence, and audit-map nonescape. Such a bridge read cannot collapse the package into a primitive subject, primitive truth predicate, host-equality reading, quotient reading, or choice-reading; it can only replay the finite package ledger already exposed by the carrier.*

Proof. Project the carrier of Definition 1292.1. Rows $T, R, M, G, D, S, C, A, H, K, N$ are the complete package surface, and Definition 1292.2 prevents any package entry from being exported by prose adjacency.

Apply audit-map nonescape from Definition 1292.3. The cannot-claim row S and audit-policy row A must be read before a bridge can expose a package reading that refuses primitive philosophical interpretations.

Apply sibling independence from Definition 1292.5. The sibling routes may support the package through K and the ledger rows, but no sibling reconstructs the whole carrier or replaces it with a primitive host object.

Finally read the checked TasteGate marker and the scoped-obligation theorem. They keep the public package boundary tied to the displayed carrier rows, so the bridge can replay only that finite NameCert surface and cannot add subject, truth, host-equality, quotient, or choice readings. □

Lean4 ✓ `BEDC.Derived.BedcPhilosophyPackageUp.BedcPhilosophyPackage bridge boundary`

Closure status for NameCert$_{\text{BedcPhilosophyPackage}^{\uparrow}}$**.**

Constructive story: A BedcPhilosophyPackage$^{\uparrow}$ packet is generated from thesis, registry, theorem-map, gap-map, tradition/science-map, cannot-claim, closure-status, audit-policy, componentwise hsame transport, displayed Cont and Pkg routes, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{BedcPhilosophyPackage}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature package surface binds scoped obligations, bridge boundary, sibling independence, audit-map nonescape, registry-ledger exactness, falsifiable prediction, independence witness, and the checked TasteGate marker over the displayed rows $T, R, M, G, D, S, C, A, H, K, N$.

Formal verification: FormalStatus(NameCert$_{\text{BedcPhilosophyPackage}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, philosophical completeness, correctness of every registry row, or any primitive subject, truth, host-equality, quotient, or choice reading.

Upgrade path: Lean closure requires Nontrivial BedcPhilosophyPackageUp and FieldFaithful BedcPhilosophyPackageUp instances in `lean4/BEDC/Derived/BedcPhilosophyPackageUp/TasteGate.lean`.

Chapter 1293

A Concrete Naming Certificate for $\mathsf{PhysicsFalsificationSurface}^{\uparrow}$

The $\mathsf{PhysicsFalsificationSurface}^{\uparrow}$ packet realizes the physics-route falsification surface of subsection 9462.32.10 as a finite NameCert carrier. It sits after the relational physics carrier of chapter 1275, the physical-law bridge of chapter 1285, the empirical persistence carrier of chapter 1156, the continuation countermodel surface of chapter 1183, and the gap-failure bridge audit of chapter 1229. The packet binds the exact point where a physical route, a law bridge, an empirical persistence row, and a countermodel handoff must be read together before any science bridge can be exported as completed physics.

Definition 1293.1 (Physics falsification surface carrier)**.** *A* $\mathsf{PhysicsFalsificationSurface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (R, L, E, K, B, A, G, H, C, Q, N)$$

with the following displayed rows:

1. *R is the multi-history physics route row, recording the relational physics route whose public physical reading is under test.*
2. *L is the physical-law bridge row, recording law syntax, route interpretation, finite preservation, and bridge scope.*
3. *E is the empirical persistence row, recording the observation packets over which the proposed law remains stable.*
4. *K is either a continuation countermodel row or a failure row naming the branch where the proposed law cannot be carried forward.*
5. *B is the bridge and no-host-leak audit row, recording bridge preservation together with absence of host primitives, quotient principles, semantic equality assumptions, choice, propositional extensionality, and compiler readings.*
6. *A is the axiom-purity inspection row, recording that the cited formal surface is not being read through forbidden logical supply.*
7. *G is the typed gap routing row, recording the requested supply, admissible route, and consequence if the gap is internalized.*
8. *H stores componentwise* hsame *transport for route, law, empirical, countermodel, bridge-audit, axiom-purity, typed-gap, provenance, and naming rows.*

9. *C stores displayed* Cont *replay for physical-route inspection, law-bridge transport, empirical persistence, countermodel handoff, bridge audit, axiom-purity inspection, and typed-gap routing.*
10. *Q is the* Pkg *provenance row over* $\mathsf{RelationalPhysics}^{\uparrow}$, $\mathsf{PhysicalLawBridge}^{\uparrow}$, $\mathsf{EmpiricalRegularityPersistence}^{\uparrow}$, $\mathsf{ContinuationCountermodel}^{\uparrow}$, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicsFalsificationSurface}^{\uparrow}}$ *row.*

The carrier has no coordinate for completed physics detached from a countermodel or failure branch, a law bridge without empirical persistence, a bridge audit without no-host-leak evidence, an axiom-purity claim without typed gap routing, or a science-bridge export without the displayed falsification surface.

Lean4 ✓ `BEDC.Derived.PhysicsFalsificationSurfaceUp.PhysicsFalsificationSurfaceTasteGate single carrier alignment`

Theorem 1293.2 (Physics falsification surface NameCert rows)**.** *For the carrier of Definition 1293.1, the local* $\mathsf{NameCert}_{\mathsf{PhysicsFalsificationSurface}^{\uparrow}}$ *surface consists of five rows: carrier exposure for $P = (R, L, E, K, B, A, G, H, C, Q, N)$, classifier stability for the route-law-empirical triple, countermodel handoff through K, bridge and no-host-leak inspection through B, A, G, and non-escape from completed-physics export.*

Proof. Carrier exposure is projection from the displayed tuple P. The rows R, L, E give the route, law bridge, and empirical persistence data that a physical reading may inspect.

Classifier stability is read through the same displayed rows under the transport and replay coordinates H and C. The route-law-empirical triple cannot be renamed without preserving the transport of those coordinates and the provenance row Q.

The countermodel handoff is the row K. If K is a continuation countermodel, it records the route that defeats the proposed law; if it is a failure row, it records the branch on which the law cannot be carried forward.

Bridge and no-host-leak inspection are stored in B, A, G. The bridge row is checked together with axiom-purity and typed-gap routing, so no host primitive, quotient principle, semantic equality assumption, choice, propositional extensionality, or compiler reading is imported as a BEDC physics input.

Finally, non-escape follows because the carrier has no completed-physics coordinate. Any export through a science bridge must still pass through $R, L, E, K, B, A, G, H, C, Q, N$, and therefore cannot discard the falsification surface. □

Falsifiable prediction: If the countermodel row is removed, the packet may still record a law bridge and empirical persistence, but it cannot certify a physics falsification surface.

Independence witness: relationalphysics, physicallawbridge, empiricalregularitypersistence, continuationcountermodel, and gapfailurebridgeaudit: no bijection preserves route, law, empirical, countermodel, bridge-audit, axiom-purity, gap, transport, replay, provenance, and naming rows at once. RelationalPhysicsUp supplies the route without the law-empirical-countermodel audit; PhysicalLawBridgeUp supplies law transport without falsification handoff; EmpiricalRegularityPersistenceUp supplies persistence without the physical route and countermodel branch; ContinuationCountermodelUp supplies a countermodel route without the bridge and axiom-purity audit; GapFailureBridgeAuditUp supplies gap and bridge audit rows without the route-law-empirical classifier.

The Lean site `lean4/BEDC/Derived/PhysicsFalsificationSurfaceUp/TasteGate.lean` must provide explicit Nontrivial PhysicsFalsificationSurface$^{\uparrow}$ and FieldFaithful PhysicsFalsificationSurface$^{\uparrow}$ instances preserving $R, L, E, K, B, A, G, H, C, Q, N$.

Closure status for NameCert$_{\text{PhysicsFalsificationSurface}^{\uparrow}}$ **.**

Constructive story: The physics falsification surface is generated from $BHist$ rows that name a physical-facing route, law bridge, empirical persistence row, continuation countermodel, bridge-audit row, axiom-purity row, gap row, and the falsification surface tying them together. The carrier first reads the claim-facing route, then the observable and countermodel rows, and finally the audit surface that exposes how the claim can fail. The $hsame$ relation keeps this surface stable across equivalent histories, while Cont can pass the same falsification route to later audit or observation consumers. The NameCert row theorem, prediction, and independence witness record the observable boundary of a physical claim without asserting a full physical theory.

Theory closure: TheoryGate(NameCert$_{\text{PhysicsFalsificationSurface}^{\uparrow}}$, seed)

Scope closed: This chapter binds the physics falsification-surface carrier, NameCert-rows theorem, falsifiable prediction, and independence witness.

Formal verification: FormalStatus(NameCert$_{\text{PhysicsFalsificationSurface}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim empirical truth, full physical model adequacy, or observation logic beyond the displayed claim, signature, countermodel, and falsification rows.

Upgrade path: Reaching obligationClosure requires formal claim, signature, countermodel, and falsification rows plus checked readback of their joint surface.

Chapter 1294

A Concrete Naming Certificate for $\mathsf{AllowedProofAudit}^{\uparrow}$

The $\mathsf{AllowedProofAudit}^{\uparrow}$ packet realizes the allowed and refused proof boundary of chapter 9462 and subsection 9462.31.5 as finite NameCert data. It sits beside the certificate-preserving route of chapter 481, the classifier-preserving route of chapter 590, the host primitive refusal of chapter 1157, and the gap-and-bridge refusal packet of chapter 1229. Those siblings expose certificate transport, classifier transport, host-source leakage, and gap routing; this carrier binds the proof-admissibility surface itself before a consumer may treat a proof as accepted BEDC evidence.

Definition 1294.1 (AllowedProofAudit carrier)**.** *An* $\mathsf{AllowedProofAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, F, S, W, R, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the allowed proof surface, naming the explicit witness construction or local refutation route accepted by the current carrier, classifier, and certificate;*
2. *F is the refused proof boundary, recording attempted extraction of positive content without a constructor witness and attempted closure of global truth, choice, quotient, propositional extensionality, or halting surfaces;*
3. *S is the scope row fixing the carrier, classifier, certificate, and local theorem site over which A and F are read;*
4. *W is the witness-construction row that exposes the constructor data supporting every positive proof read in A;*
5. *R is the local-refutation row that records the finite contradiction or failed classifier route used by every negative proof read in A;*
6. *L is the ledger-residue row for refused dependencies, unexported host material, failed extraction attempts, and proof obligations not discharged inside S;*
7. *H records componentwise* hsame *transport for $A, F, S, W, R, L, C, P, N$;*
8. *C records displayed* Cont *replay of allowed reads, refused reads, witness construction, local refutation, and ledger inspection;*
9. *P is the* Pkg *provenance over chapter 9462, subsection 9462.31.5, chapter 481, chapter 590, chapter 1157, chapter 1229,* BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{AllowedProofAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for hidden proof search, ambient semantic validity, unrecorded host extraction, global truth closure, quotient collapse, choice supply, propositional extensionality, or total halting decision.

Lean4 ✓ `BEDC.Derived.AllowedProofAuditUp.AllowedProofAuditTasteGate single carrier alignment`

Theorem 1294.2 (AllowedProofAudit NameCert obligations)**.** *For the carrier of Definition 1294.1, the local* $\mathsf{NameCert}_{\mathsf{AllowedProofAudit}^{\uparrow}}$ *surface consists exactly of carrier admission, allowed proof visibility, refused proof visibility, scope visibility, witness construction, local refutation, ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through N.*

Lean4 ✓ `BEDC.Derived.AllowedProofAuditUp.AllowedProofAuditPacket namecert obligations`

Proof. Project the carrier $Q = (A, F, S, W, R, L, H, C, P, N)$. The first six rows expose accepted proof reads, refused proof attempts, the scope in which those reads are meaningful, the constructor witnesses, the local refutations, and the residue ledger.

Read the structural rows. Transport through H preserves the displayed components, replay through C keeps the consumer inside the same finite route, provenance through P records the proof-audit sources, and N names the packet.

Since the carrier contains no further proof coordinate, the listed rows exhaust the local NameCert surface. A claimed audit that omits one of them is a projection of the packet, not the accepted packet itself. □

Theorem 1294.3 (AllowedProofAudit witness construction)**.** *For an accepted* $\mathsf{AllowedProofAudit}^{\uparrow}$ *packet $Q = (A, F, S, W, R, L, H, C, P, N)$, every positive proof read in A factors through the displayed witness-construction row W, and every negative proof read in A factors through the displayed local-refutation row R. No accepted proof read may be supplied by P, H, or C unless the same route is already visible in W or R under the fixed scope S.*

Lean4 ✓ `BEDC.Derived.BHistDecaSequenceNameCertUp.BHistDecaSequenceNameCertCarrier namecert obligations`

Proof. Start with the scope row S. It fixes the carrier, classifier, certificate, and theorem site over which allowed proof reads are admitted.

For positive content, the carrier exposes only the witness-construction row W. The transport and replay rows can preserve and replay that witness, but they do not create a constructor outside the displayed row.

For negative content, the carrier exposes only the local-refutation row R. The ledger row L may record residue and refused dependencies, but it is not a proof source unless the finite contradiction or failed classifier route is displayed in R.

Thus every accepted proof read in A factors through W or R within S. The structural rows certify preservation and provenance for those routes, not independent proof supply. □

Theorem 1294.4 (AllowedProofAudit non-escape)**.** *Any proof read that extracts positive content without the witness row W, closes a refused surface recorded in F, or cites a dependency present only as ledger residue in L is rejected by the* $\mathsf{AllowedProofAudit}^{\uparrow}$ *classifier. In particular, neither certificate transport, classifier transport, host primitive refusal, nor gap-and-bridge audit routing can turn a refused proof attempt into accepted BEDC evidence unless the same finite packet exposes $A, F, S, W, R, L, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.AllowedProofAuditUp.AllowedProofAuditNonEscape`

Proof. Use the NameCert obligations of Definition 1294.2. Accepted proof reads, refused boundaries, scope, witnesses, refutations, and ledger residue are all projections from the same finite packet.

Apply the witness-construction theorem Definition 1294.3. Positive content must pass through W, and negative content must pass through R, with both rows read under the scope S.

If a proof read closes a boundary recorded in F or cites only residue in L, then it asks for a coordinate absent from Q. Transport through H, replay through C, and provenance through P cannot add that coordinate.

Therefore the classifier rejects the attempted escape. The surrounding packets named by chapter 481, chapter 590, chapter 1157, and chapter 1229 may route or refuse proof material, but they do not replace the displayed allowed-proof audit packet. □

Falsifiable prediction: Omitting either the witness-construction row W or the refused-proof boundary row F refutes the $\mathsf{AllowedProofAudit}^{\uparrow}$ packet: the classifier can no longer distinguish accepted proof evidence from host extraction or refused closure.

Independence witness: objectknowledgecertificate, gapfailurebridgeaudit, hostprimitiveleakage, classifiermorphism, and namecertmorphism: none is bijective to $\mathsf{AllowedProofAudit}^{\uparrow}$ because this carrier binds allowed proof surface, refused proof boundary, scope, witness construction, local refutation, ledger residue, transport, replay, provenance, and local naming as one proof-admissibility packet.

The Lean follow-up must provide explicit $\mathsf{Nontrivial\ AllowedProofAudit}^{\uparrow}$ and $\mathsf{FieldFaithful\ AllowedProofAudit}^{\uparrow}$ instances before the touchpoint theorem BEDC.Derived.AllowedProofAuditUp.taste_gate can serve as a checked TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{AllowedProofAudit}^{\uparrow}}$**.**

Constructive story: The allowed proof audit is generated from $BHist$ rows that record an allowed proof surface, refused proof boundary, scope row, witness construction, local refutation, ledger residue, transport, replay, provenance, and local naming. The carrier first reads the permitted proof evidence, then attaches the audit witness, and finally lets Cont carry the audited proof route forward only if the same permission and refusal rows remain present. The $hsame$ relation preserves the audit across equivalent histories. NameCert obligations, witness construction, non-escape, prediction, and independence witness therefore define the object as an audit of permitted proof use, not as a general proof checker or an untracked derivation route.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AllowedProofAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the AllowedProofAudit carrier, NameCert obligations, witness-construction theorem, non-escape theorem, falsifiable prediction, and independence witness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AllowedProofAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim proof validity outside the allowed row, global proof checking, or acceptance of unaudited derivations.

Upgrade path: Reaching obligationClosure requires formal allowed-proof and audit-witness rows plus checked non-escape for untracked proof routes.

Chapter 1295

A Concrete Naming Certificate for $\mathsf{ObservationLogicBoundary}^{\uparrow}$

The $\mathsf{ObservationLogicBoundary}^{\uparrow}$ packet realizes the observation, proof-discipline, and open-meta-loop boundary of subsection 9462.31.4, subsection 9462.31.5, and subsection 9462.31.6 as one finite NameCert carrier. It sits after the subject-free observation packet of chapter 1271, the logic/meta-loop refusal packet of chapter 1261, the phase-refusal packet of chapter 1288, the gap-failure bridge audit of chapter 1229, and the finite observation residue boundary of chapter 1167. Those siblings separately expose observation without subject-substance, proof discipline without total truth, phase-sensitive refusal, bridge-audit failure rows, and finite residue boundaries; this packet binds their shared audit boundary before any consumer may export a BEDC-valid proof-boundary reading.

Definition 1295.1 (Observation-logic boundary carrier)**.** *An* $\mathsf{ObservationLogicBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (O, L, M, K, G, R, H, C, P, N)$$

with the following displayed rows:

1. *O is the subject-free observation row, recording observation as displayed* Cont *replay over* BHist *and* hsame *rather than as a hidden observer substance.*
2. *L is the proof-discipline row, recording constructive witness formation, local refutation, and refusal of unwitnessed positive supply.*
3. *M is the open-meta-loop row, refusing total truth, unrestricted choice, quotient collapse, global proof search, halting closure, and self-validation of the certificate surface.*
4. *K is the phase-refusal row, recording whether the attempted proof-boundary export is in phase, blocked by a dependency, or off-table relative to the displayed programme surface.*
5. *G is the gap/failure/bridge audit row, tying typed gaps, failure branches, bridge evidence, no-host-leak evidence, and axis separation to the same boundary read.*
6. *R is the finite observation residue row, recording hidden-residue and failure-surface exposure for finite observation exports.*
7. *H stores componentwise* hsame *transport for observation, proof discipline, open meta-loop refusal, phase refusal, gap audit, residue, continuation, provenance, and local naming rows.*

8. *C stores displayed* Cont *replay from observation through proof-discipline inspection, open-meta-loop refusal, phase classification, audit routing, residue exposure, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{SubjectFreeObservation}^{\uparrow}$, $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$, $\mathsf{KernelPhaseRefusal}^{\uparrow}$, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$, $\mathsf{FiniteObservationResidueBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ObservationLogicBoundary}^{\uparrow}}$ *row.*

The local classifier compares carriers only through $O, L, M, K, G, R, H, C, P, N$. It has no coordinate for a subject-substance, a total truth predicate, an unrestricted choice supplier, quotient equality elimination, a halting oracle, a closed meta-loop classifier, or a proof-boundary export detached from finite observation residue.

Lean4 (definition) `BEDC.Derived.ObservationLogicBoundaryUp.ObservationLogicBoundaryUp`
Lean4 ✓ `BEDC.Derived.ObservationLogicBoundaryUp.ObservationLogicBoundaryTasteGate single carrier alignment`

Theorem 1295.2 (Observation-logic boundary NameCert obligations)**.** *For the carrier of Definition 1295.1, the local* $\mathsf{NameCert}_{\mathsf{ObservationLogicBoundary}^{\uparrow}}$ *surface consists exactly of subject-free observation through O, proof-discipline exposure through L, open-meta-loop refusal through M, phase-refusal classification through K, gap/failure/bridge audit through G, finite observation residue through R, componentwise transport through H, displayed continuation replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier $B = (O, L, M, K, G, R, H, C, P, N)$. The tuple exposes observation, proof discipline, meta-loop refusal, phase refusal, gap audit, residue, transport, replay, provenance, and local naming as distinct rows.

Use chapter 1271 for O and chapter 1261 for L, M. The first supplies the observation row without a subject-substance coordinate; the second supplies constructive proof discipline and open meta-loop refusal without total truth, choice, quotient collapse, or halting closure.

Use chapter 1288, chapter 1229, and chapter 1167 for K, G, R. These rows record the phase boundary, the gap/failure/bridge audit surface, and the finite residue surface that must remain visible before a proof-boundary reading is exported.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no further coordinate, the displayed rows exhaust the local NameCert surface. □

Theorem 1295.3 (Observation-logic boundary axis separation)**.** *An accepted* $\mathsf{ObservationLogicBoundary}^{\uparrow}$ *packet keeps observation, proof discipline, open meta-loop refusal, phase refusal, gap/failure/bridge audit, and finite observation residue as separate classifier axes. No accepted consumer route may read observation as proof, proof discipline as total truth, bridge status as theory closure, phase refusal as blocker discharge, or finite residue as closed physical audit.*

Proof. Start with the carrier of Definition 1295.1. The rows O, L, M, K, G, R are separate coordinates before transport, continuation replay, provenance, or local naming is consulted.

Apply Definition 1295.2. Each axis is admitted through its own row and then preserved by H, C, P, N; none of the structural rows computes one axis from another.

The sibling packets enforce the same separation. $\mathsf{SubjectFreeObservation}^{\uparrow}$ refuses a hidden subject, $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$ refuses total meta closure, $\mathsf{KernelPhaseRefusal}^{\uparrow}$ keeps blocker rows visible, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ separates bridge, failure, and theory axes, and $\mathsf{FiniteObservationResidueBoundar}$ keeps finite residue visible. Thus every listed collapsed reading lies outside the accepted boundary carrier. □

Theorem 1295.4 (Observation-logic boundary non-escape)**.** *Every BEDC-valid proof-boundary reading exported by an accepted* ObservationLogicBoundary$^{\uparrow}$ *packet factors through*

$$O, L, M, K, G, R, H, C, P, N.$$

If the open-meta-loop row M is deleted, the remaining rows may still describe observation, local proof discipline, phase refusal, audit routing, and finite residue, but they cannot export a BEDC-valid proof-boundary reading.

Proof. Project the accepted packet. A public proof-boundary read must preserve the observation row, proof-discipline row, open-meta-loop row, phase-refusal row, gap/failure/bridge audit row, finite residue row, transport row, replay row, provenance row, and local name.

The open-meta-loop row is not recoverable from the observation row or the proof-discipline row. Observation exposes a finite Cont read, and proof discipline exposes constructive and local-refutation behavior; neither refuses total truth, choice, quotient collapse, global proof search, halting closure, or self-validation on its own.

The remaining rows also cannot reconstruct M. Phase refusal records target admissibility, the gap/failure/bridge row records audit coordinates, and the residue row records finite observation limits. Transport, replay, provenance, and local naming preserve displayed rows, so deleting M prevents export of the named proof-boundary reading. □

Falsifiable prediction: Deleting the open-meta-loop row prevents export of a BEDC-valid proof-boundary reading, even when observation, proof-discipline, phase-refusal, audit, finite-residue, transport, replay, provenance, and local naming rows remain present.

Independence witness: subjectfreeobservation, logiccontradictionmetaloop, kernelphaserefusal, gapfailurebridgeaudit, finiteobservationresidueboundary: none is bijective because this carrier jointly stores subject-free observation, proof discipline, open-meta-loop refusal, phase refusal, gap/failure/bridge audit, finite observation residue, componentwise transport, continuation replay, provenance, and local naming in one boundary packet.

The Lean file `lean4/BEDC/Derived/ObservationLogicBoundaryUp/TasteGate.lean` must include explicit Nontrivial ObservationLogicBoundary$^{\uparrow}$ and FieldFaithful ObservationLogicBoundary$^{\uparrow}$ instances for the displayed carrier $O, L, M, K, G, R, H, C, P, N$ before `BEDC.Derived.ObservationLogicBoundaryUp` may be used as a checked boundary target.

Closure status for NameCert$_{\text{ObservationLogicBoundary}^{\uparrow}}$**.**

Constructive story: The observation-logic boundary is generated from $BHist$ rows that separately record subject-free observation, proof discipline, open-meta-loop refusal, phase refusal, gap and bridge audit, finite observation residue, and the boundary carrier that prevents the axes from collapsing. The carrier first reads the observation row, then the logic and proof-discipline rows, and finally records their separation as a boundary condition. The $hsame$ relation preserves these axes across equivalent histories, while Cont can carry the boundary forward only when observation and logic remain distinguished. NameCert obligations, axis separation, non-escape, prediction, and independence witness define a visible interface rather than a reduction of one axis to the other.

Theory closure: TheoryGate(NameCert$_{\text{ObservationLogicBoundary}^{\uparrow}}$, seed)

Scope closed: This chapter binds the observation-logic boundary carrier, NameCert obligations, axis-separation theorem, non-escape theorem, falsifiable prediction, and independence witness.

Formal verification: FormalStatus(NameCert$_{\text{ObservationLogicBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim reduction of observation to logic, logic to observation, or consumer routes that collapse the two axes.

Upgrade path: Reaching obligationClosure requires formal observation and logic rows plus checked preservation of axis separation under continuation.

Chapter 1296

A Concrete Naming Certificate for $\mathsf{AuditExportFirewall}^{\uparrow}$

The $\mathsf{AuditExportFirewall}^{\uparrow}$ packet realizes the total-audit synthesis of section 9462.31 as a finite export firewall. It sits beside the sibling audit packet $\mathsf{AuditSystem}^{\uparrow}$ of chapter 1258, the negative certificate surface of chapter 1233, the positive claim-entry layer of chapter 1209, the registry export consistency gate of chapter 1224, and the kernel acceptance audit witness of chapter 547. Those siblings supply audit packet, failure row, claim row, consistency gate, and kernel acceptance data separately; this carrier binds the same claim site before export can be read.

Definition 1296.1 (Audit export firewall carrier)**.** *An* $\mathsf{AuditExportFirewall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (C, P, A, E, R, G, L, H, K, Q, N)$$

with the following displayed rows:

1. *C is the claim-site row, recording the registry claim name, subject surface, carrier, classifier, and intended export site;*
2. *P is the positive-certificate row, recording the certificate that would license the claim if no active negative row addresses the same site;*
3. *A is the* $\mathsf{AuditSystem}^{\uparrow}$ *sibling row, carrying the admissible claim, positive certificate, failure certificate, refusal, export grade, and audit ledger surface of the same site;*
4. *E is the* $\mathsf{FailureCertificate}^{\uparrow}$ *row, recording missing, invalid, overstated, unchecked, or axis-confused data for the same claim site when export is blocked;*
5. *R is the* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *row, exposing the registry admission and refusal boundary for the claim;*
6. *G is the* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *row, checking status consistency across the registry entry, export grade, closure-status reading, and formal-target row;*
7. *L is the firewall-ledger row, recording whether the packet admits export, refuses export, or records a positive/negative certificate conflict;*
8. *H records componentwise* hsame *transport for claim, certificate, audit-system, failure, registry, consistency-gate, ledger, replay, provenance, and local naming rows;*
9. *K records displayed* Cont *replay for reading C, P, A, E, R, G, L without adding a host-side export override;*

10. *Q is the* Pkg *provenance over* $\mathsf{AuditExportFirewall}^{\uparrow}$, $\mathsf{AuditSystem}^{\uparrow}$, $\mathsf{FailureCertificate}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditExportFirewall}^{\uparrow}}$ *row.*

The carrier has no coordinate for exporting a claim outside the displayed claim, positive certificate, audit-system, failure-certificate, registry, consistency-gate, firewall-ledger, transport, replay, provenance, and naming rows.

Lean4 ✓ `BEDC.Derived.AuditExportFirewallUp.AuditExportFirewallTasteGate single carrier alignment`

Theorem 1296.2 (Audit export firewall NameCert obligations)**.** *For the carrier of Definition 1296.1, the local* $\mathsf{NameCert}_{\mathsf{AuditExportFirewall}^{\uparrow}}$ *surface consists exactly of carrier admission for $F = (C, P, A, E, R, G, L, H, K, Q$ claim-site exposure through C, positive-certificate exposure through P, audit-system handoff through A, failure-certificate exposure through E, claim-registry exposure through R, registry-export consistency through G, firewall-ledger decision through L, componentwise* hsame *transport through H, displayed* Cont *replay through K, package provenance through Q, and local naming through N.*

Lean4 ✓ `BEDC.Derived.AuditExportFirewallUp.AuditExportFirewallCarrier namecert obligations`

Proof. Project the finite packet $F = (C, P, A, E, R, G, L, H, K, Q, N)$. The claim-site row C and positive-certificate row P are visible before any export decision is read.

Next read the sibling audit rows. The $\mathsf{AuditSystem}^{\uparrow}$ row A supplies the joint positive and negative audit packet, the $\mathsf{FailureCertificate}^{\uparrow}$ row E exposes the active negative certificate when present, the $\mathsf{ClaimRegistryLayer}^{\uparrow}$ row R exposes registry admission, and the $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ row G checks the export status of the same claim site.

Finally read L, H, K, Q, N. The firewall-ledger row records the export, refusal, or conflict state; transport, replay, provenance, and local naming preserve the same displayed rows. Since the carrier has no additional export coordinate, these rows exhaust the local NameCert surface. □

Theorem 1296.3 (Audit export firewall non-escape)**.** *If an accepted* $\mathsf{AuditExportFirewall}^{\uparrow}$ *packet has the positive-certificate row P and an active failure-certificate row E addressing the same claim site C, then the firewall-ledger row L records refusal or certificate conflict. It does not produce an admitted exportable claim.*

Lean4 ✓ `BEDC.Derived.AuditExportFirewallUp.AuditExportFirewallCarrier nonescape`

Proof. Assume an accepted packet $F = (C, P, A, E, R, G, L, H, K, Q, N)$ and suppose P and E address the same claim site C. The claim row is therefore read with both a positive certificate and an active negative certificate.

The audit-system handoff A keeps positive certificate, failure certificate, cannot-claim refusal, export grade, and ledger closure in one finite audit packet. The registry row R and consistency gate G read the same claim site before export is exposed, so the negative row cannot be hidden behind a separate registry entry.

The firewall-ledger row L is the only row from which an export decision may be projected. Because L is read after P, E, R, G, it records the visible conflict or refusal rather than an admitted export. The remaining rows H, K, Q, N transport, replay, package, and name that same decision, and no hidden export coordinate remains. □

Theorem 1296.4 (Audit export firewall sibling independence)**.** *The* $\mathsf{AuditExportFirewall}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{AuditSystem}^{\uparrow}$, $\mathsf{FailureCertificate}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, *or* $\mathsf{KernelAcceptanceAuditWitness}^{\uparrow}$.

Proof. Compare the displayed rows. AuditSystem$^{\uparrow}$ binds positive and negative audit data, FailureCertificate$^{\uparrow}$ supplies a typed negative certificate, ClaimRegistryLayer$^{\uparrow}$ registers or refuses a claim, RegistryExportConsistencyGate$^{\uparrow}$ blocks inconsistent registry export, and KernelAcceptanceAuditWitness$^{\uparrow}$ records kernel-side acceptance audit data.

The firewall carrier contains all those handoff roles together with the firewall-ledger row L that decides export, refusal, or certificate conflict for the same claim site. A NameCert-row-preserving bijection would have to preserve that joint conflict-blocking coordinate, but no listed sibling has it as a local row. Therefore no such bijection exists. □

Lean4 ✓ `BEDC.Derived.AuditExportFirewallUp.AuditExportFirewallCarrier sibling independence`

The Lean TasteGate.lean surface must provide Nontrivial AuditExportFirewall$^{\uparrow}$ and FieldFaithful AuditExportFirewa instances. The field-faithfulness witness must preserve $C, P, A, E, R, G, L, H, K, Q, N$ as distinct rows so positive certification, active failure, registry admission, consistency checking, firewall decision, and local naming cannot be merged.

Falsifiable prediction: If the positive certificate row and active failure row address the same claim site, the firewall packet refuses export rather than producing an admitted claim.

Independence witness: Compare auditsystem, failurecertificate, claimregistrylayer, registryexportconsistencygate, kernelacceptanceauditwitness: AuditExportFirewallUp is not bijective with any one sibling because it carries the same-site firewall-ledger decision over positive certificate, active failure, registry admission, consistency gate, and audit witness rows.

Closure status for NameCert$_{\text{AuditExportFirewall}\uparrow}$.

Constructive story: The audit export firewall is generated from $BHist$ rows that record a claim site, positive certificate row, active failure row, registry admission row, consistency gate, audit witness, and firewall decision controlling whether the object may leave the audit context. The carrier first reads the audited row, then the export gate, and finally uses Cont only to carry export-visible data through that same firewall. The $hsame$ relation preserves the firewall boundary across equivalent histories. NameCert obligations, non-escape, prediction, and independence witness keep the firewall distinct from the audit packet, failure certificate, claim registry, or kernel acceptance witness it may mention; it is the visible boundary condition for export, not the exported object itself.

Theory closure: TheoryGate(NameCert$_{\text{AuditExportFirewall}\uparrow}$, scopedClosed)

Scope closed: This chapter binds the audit export-firewall carrier, NameCert obligations, non-escape theorem, sibling-independence theorem, falsifiable prediction, independence witness, and scoped dependencies on AuditSystem$^{\uparrow}$, FailureCertificate$^{\uparrow}$, ClaimRegistryLayer$^{\uparrow}$, RegistryExportConsistencyGate$^{\uparrow}$, KernelAcceptanceAuditWitness$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{AuditExportFirewall}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim unrestricted export, audit correctness, socket-report content, or roadmap status outside the firewall boundary.

Upgrade path: Reaching scopedClosure requires formal export-boundary rows and checked non-escape for routes that bypass the firewall.

Chapter 1297

A Concrete Naming Certificate for FormalConstantEmpiricalValueBoundary$^{\uparrow}$

The FormalConstantEmpiricalValueBoundary$^{\uparrow}$ packet realizes the boundary in subsection 9462.28.6 as a finite NameCert surface. It sits after the cross-history causal-rate carrier of chapter 876, the maximum-rate bound carrier of chapter 594, the unit-calibration ledger of chapter 1208, and the empirical-regularity persistence carrier of chapter 1156. Those siblings expose invariant rate form, unary maximum-bound rows, unit and calibration records, and empirical persistence records; this packet binds them without collapsing formal invariant form into measured numerical value.

Definition 1297.1 (Formal-constant empirical-value boundary carrier)**.** *A* FormalConstantEmpiricalValueBoundary *carrier is a finite* BHist *packet*

$$K = (F, E, U, I, R, G, H, C, P, N)$$

with the following displayed rows:

1. *F is the formal invariant-form row, read through* CrossHistCausalRate$^{\uparrow}$ *and* MaxCausalRate$^{\uparrow}$*, exposing only observer-symmetric bound form, unary comparison, no-global-frame discipline, and structural transport.*
2. *E is the empirical measurement ledger row, read through* EmpiricalRegularityPersistence$^{\uparrow}$*, exposing observed records, measurement protocol, classifier, error ledger, and persistence-facing failure branch.*
3. *U is the unit-calibration row, read through* UnitCalibrationLedger$^{\uparrow}$*, exposing unit convention, calibration standard, conversion route, uncertainty budget, and instrument ledger.*
4. *I is the uncertainty and instrument row binding error bars, instrument identity, resolution limits, and finite replay of the measurement route.*
5. *R is the reproducibility row recording repeated finite observation packets, accepted classifier agreement, rejected runs, and displayed continuation routes for remeasurement.*
6. *G is the failure row recording missing calibration, incompatible units, instrument defeat, reproducibility failure, detached invariant form, and detached empirical value.*
7. *H records componentwise* hsame *transport for $F, E, U, I, R, G, C, P, N$.*
8. *C records displayed* Cont *routes for invariant-form readback, measurement replay, calibration replay, uncertainty reading, reproducibility replay, and failure consumption.*

9. *P is the* Pkg *provenance over* FormalConstantEmpiricalValueBoundary$^{\uparrow}$, CrossHistCausalRate$^{\uparrow}$, MaxCausalRate$^{\uparrow}$, UnitCalibrationLedger$^{\uparrow}$, EmpiricalRegularityPersistence$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{FormalConstantEmpiricalValueBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for extracting a numerical empirical value from F alone, for promoting E, U, I, R to a structural invariant without F, or for reading a physical constant without the failure row G.

Lean4 (definition) `BEDC.Derived.FormalConstantEmpiricalValueBoundaryUp.FormalConstantEmpiricalValueBoundar`
Lean4 ✓ `BEDC.Derived.FormalConstantEmpiricalValueBoundaryUp.FormalConstantEmpiricalValueBoundaryTasteGa`
`single carrier alignment`

Theorem 1297.2 (Formal-constant empirical-value boundary NameCert obligations)**.** *For the carrier of Definition 1297.1, the local* NameCert$_{\text{FormalConstantEmpiricalValueBoundary}^{\uparrow}}$ *surface consists exactly of formal invariant-form exposure through F, empirical measurement exposure through E, unit-calibration exposure through U, uncertainty and instrument exposure through I, reproducibility exposure through R, failure exposure through G, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier $K = (F, E, U, I, R, G, H, C, P, N)$. The first row exposes the structural side of the boundary: observer-symmetric invariant form, maximum-rate bound form, unary comparison, and no-global-frame discipline.

Read the empirical side through E, U, I, R. These rows display measurement records, unit convention, calibration, instrument and uncertainty data, and reproducibility evidence as finite ledger coordinates rather than as consequences of the invariant-form row.

The failure row G records every way the two sides can be detached. Missing unit calibration, incompatible units, instrument defeat, reproducibility failure, a bare invariant form, and a bare empirical value are all visible refusal branches.

The structural rows H, C, P, N preserve and replay only the displayed packet. Since no further coordinate is present, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.FormalConstantEmpiricalValueBoundaryUp.FormalConstantEmpiricalValueBoundaryNameCer`

Theorem 1297.3 (Formal-constant empirical-value noncollapse)**.** *An accepted* FormalConstantEmpiricalValueBound *carrier permits a consumer to compare a formal constant with an empirical value only through the full packet*

$$F, E, U, I, R, G, H, C, P, N.$$

The formal invariant-form row F cannot supply the empirical numerical value, and the empirical rows E, U, I, R cannot supply the structural invariant form. A physical-law or rate-facing consumer must preserve the boundary row G and the local NameCert *row N before citing the packet.*

Proof. Use Definition 1297.2. It separates invariant-form exposure from measurement, calibration, instrument, and reproducibility exposure.

The row F is inherited from the cross-history causal-rate and maximum-rate surfaces. Those packets expose structural bound form and no-global-frame discipline, but they carry no unit convention, instrument ledger, uncertainty budget, or reproducibility ledger.

The rows E, U, I, R are empirical rows. They provide measured records, unit calibration, uncertainty, and reproducibility, but they do not create the observer-symmetric invariant-form row supplied by F.

Finally read G, H, C, P, N. The failure row records every attempted collapse as a visible boundary case, while transport, continuation, provenance, and local naming preserve the same finite packet. Thus comparison is available only as a noncollapse boundary, not as an identification of formal constants with empirical values. □

Lean4 ✓ `BEDC.Derived.FormalConstantEmpiricalValueBoundaryUp.FormalConstantEmpiricalValueBoundaryNoncoll`

Falsifiable prediction: A physical-law consumer that reads a numerical empirical value from invariant form alone refutes the $\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}$ packet.

Independence witness: crosshistcausalrate, maxcausalrate, unitcalibrationledger, empiricalregularitypersistence: $\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}$ is not bijective to any listed sibling because it carries formal invariant form, measurement ledger, unit calibration, uncertainty, instrument, reproducibility, failure, transport, continuation, provenance, and local naming rows in one finite boundary packet.

Theorem 1297.4 (Formal-constant empirical-value boundary scope)**.** *Every accepted* FormalConstantEmpiricalValu *boundary packet is scoped only over the formal invariant row F, empirical measurement row E, unit-calibration row U, uncertainty and instrument row I, reproducibility row R, failure row G, componentwise* hsame *transport row H, displayed* Cont *replay row C,* Pkg *provenance row P, and local* NameCert *row N of Definition 1297.1. The scope is exactly the carrier, the NameCert obligations of Definition 1297.2, and the noncollapse boundary of Definition 1297.3, read through the cross-history causal-rate, maximum-rate, unit-calibration, and empirical-regularity sibling chapters named in the chapter introduction.*

No accepted packet exports a formal-to-empirical equality, a measurement-free invariant value, a calibration-free empirical value, or a host physical law beyond those displayed rows.

Proof. Project the carrier $K = (F, E, U, I, R, G, H, C, P, N)$ from Definition 1297.1. The only primitive rows available to a boundary reader are the formal invariant row, empirical measurement row, calibration row, uncertainty and instrument row, reproducibility row, failure row, transport row, replay row, provenance row, and local naming row.

Apply Definition 1297.2. It identifies the local NameCert surface with exactly those rows and their componentwise hsame, Cont, and Pkg structure.

Finally use Definition 1297.3. The noncollapse theorem keeps the formal row and empirical rows separated through the same failure boundary G, so the cited sibling chapters contribute only their displayed rows and do not enlarge the packet scope. □

Lean4 ✓ `BEDC.Derived.FormalConstantEmpiricalValueBoundaryUp.FormalConstantEmpiricalValueBoundaryScope`

Theorem 1297.5 (Formal-constant empirical-value boundary public export)**.** *Every physical-law comparison consumer of an accepted* $\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}$ *packet may use it only as the reusable route*

$$F, E, U, I, R, G, H, C, P, N.$$

The public route preserves formal invariant form, empirical measurement, unit calibration, uncertainty, reproducibility, failure, componentwise transport, displayed replay, provenance, and local naming as separate rows. It exports no formal-to-empirical equality, calibration-free measured value, measurement-free invariant value, or host physical law beyond the displayed boundary packet.

Proof. Project the carrier of Definition 1297.1. The only exported rows are $F, E, U, I, R, G, H, C, P, N$, with F carrying invariant form, E, U, I, R carrying measurement, calibration, uncertainty, and reproducibility data, and G carrying the visible failure boundary.

Apply the NameCert obligations of Definition 1297.2. They identify the public comparison surface with those displayed rows and their hsame, Cont, Pkg, and local naming structure.

Use the noncollapse theorem Definition 1297.3. It prevents the formal row from becoming an empirical value and prevents the empirical rows from becoming invariant form.

Finally apply the scope theorem Definition 1297.4. The cited sibling chapters contribute only their recorded physical-law comparison rows, so the public interface is the finite route above and not an enlarged host-law assertion. □

The paper-side bridge route for this boundary is the displayed public route $F, E, U, I, R, G, H, C, P, N$ read against the accepted formal-constant and empirical-value schema: the formal row F remains the invariant-form side, the empirical rows E, U, I, R remain the measured-value side, and G, H, C, P, N record refusal, transport, replay, provenance, and local naming. This bridge adds no carrier coordinate and claims no Lean bridge; it only records that the public boundary route already matches the standard paper schema for keeping formal constants and empirical values separated.

Closure status for $\mathsf{NameCert}_{\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}$ packet is generated by first displaying the formal invariant-rate rows and then attaching empirical measurement, unit-calibration, uncertainty, instrument, reproducibility, failure, transport, continuation, package, and local naming rows in one finite BHist carrier. The classifier is not allowed to identify the formal row with the measured rows; it reads each coordinate through componentwise hsame and the visible Cont replay routes. The ledger story is therefore a boundary story: empirical values may be compared to invariant form only through the recorded calibration and reproducibility rows, while failed attempts to collapse the two sides remain visible as the failure coordinate.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1297.5 and the paper-side bridge route bind the physical-law comparison route to the displayed carrier, NameCert obligations, noncollapse theorem, scope theorem, falsifiable prediction, and independence witness for $\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: It does not claim host physical equality, extraction of a numerical value from invariant form alone, or promotion of empirical ledgers into structural constants.

Upgrade path: A Lean bridge check would have to verify the same standard bridge without enlarging the displayed rows or changing the verification axis.

Chapter 1298

A Concrete Naming Certificate for $\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}$

The $\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}$ packet realizes the route of subsection 9462.32.10 as a composite finite NameCert surface. It sits after the relational physics carrier of chapter 1275, the physical-law bridge of chapter 1285, the scientific-model bridge of chapter 1273, and the quantum-state packet of chapter 217. These siblings expose relational route discipline, law-facing bridge rows, model-facing bridge rows, and quantum-state rows; this carrier binds them without asserting a completed physical theory.

Definition 1298.1 (Multi-history physics route carrier)**.** *A* $\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (G, L, M, Q, F, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{RelationalPhysics}^{\uparrow}$ *row carrying observer-history identity, inter-history locality, invariant readback, visible physical-model audit, and no-global-frame refusal.*
2. *L is the* $\mathsf{PhysicalLawBridge}^{\uparrow}$ *row carrying law-certificate, empirical-persistence, bridge-audit, scientific-object, open-fit, and failure rows.*
3. *M is the* $\mathsf{ScientificModelBridge}^{\uparrow}$ *row carrying object, physical-model-audit, standard-bridge-audit, reality-constrained model-audit, open-fit, empirical-ledger, and prediction-transport rows.*
4. *Q is the* $\mathsf{QuantumState}^{\uparrow}$ *row carrying the finite quantum-state interface consumed by the route.*
5. *F is the falsification boundary row recording where the route may fail through no-global-frame refusal, failed law persistence, model-open-fit exit, quantum-state interface failure, or axiom-purity obstruction.*
6. *H stores componentwise* hsame *transport for G, L, M, Q, F, C, P, N.*
7. *C stores displayed* Cont *replay for relational-route inspection, law-bridge inspection, model-bridge inspection, quantum-state inspection, and falsification-boundary inspection.*
8. *P is the* Pkg *provenance over* $\mathsf{RelationalPhysics}^{\uparrow}$, $\mathsf{PhysicalLawBridge}^{\uparrow}$, $\mathsf{ScientificModelBridge}^{\uparrow}$, $\mathsf{QuantumState}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}}$ *row.*

The classifier compares packets only through these rows. It has no coordinate for completed relativity, completed quantum mechanics, empirical adequacy, semantic spacetime equality, host-valued physical truth, quotient history equality, or a physical law detached from the displayed falsification boundary.

Lean4 ✓ `BEDC.Derived.MultiHistoryPhysicsRouteUp.MultiHistoryPhysicsRouteTasteGate single carrier alignment`

Theorem 1298.2 (Multi-history physics route NameCert obligations)**.** *For the carrier of Definition 1298.1, the local* $\mathsf{NameCert}_{\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}}$ *surface consists exactly of carrier admission for* $R = (G, L, M, Q, F, H, C, P, N)$*, relational-route exposure through* G*, physical-law bridge exposure through* L*, scientific-model bridge exposure through* M*, quantum-state exposure through* Q*, falsification-boundary exposure through* F*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier to its displayed rows. The relational physics row G, physical-law bridge row L, scientific-model bridge row M, and quantum-state row Q are the only physics-facing inputs.

The falsification row F is read next. It records the failure boundary for no-global-frame refusal, law persistence, model fit, quantum-state interface, and axiom-purity inspection, so the route cannot be read as a completed physical theory after deleting F.

Transport and replay are componentwise. The rows H and C preserve exactly G, L, M, Q, F together with provenance P and local naming N, so the listed rows exhaust the NameCert surface. □

Theorem 1298.3 (Multi-history physics route falsification surface)**.** *Every accepted* $\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}$ *consumer that reads the route as physics-facing data must preserve the falsification row* F *together with* G, L, M, Q, H, C, P, N*. If a consumer removes* F*, or replaces it by completed relativity, completed quantum mechanics, empirical adequacy, semantic spacetime equality, quotient history equality, or host-valued physical truth, then the consumer has left the accepted packet.*

Proof. Start from the carrier inventory of Definition 1298.1. The row F is a visible coordinate, not a comment on the surrounding route.

Apply Definition 1298.2. Any accepted read must expose F along with the relational, law, model, and quantum rows and must transport those rows through H and replay them through C.

The carrier contains no completed-theory coordinate and no host physical-truth coordinate. Thus deleting or replacing F changes the packet rather than refining it, and the accepted physics-facing read fails. □

Theorem 1298.4 (Multi-history physics route composite handoff)**.** *The public handoff from an accepted* $\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}$ *carrier is exactly the composite finite packet*

$$G, L, M, Q, F, H, C, P, N.$$

It may feed later route work with relational physics, physical-law bridge, scientific-model bridge, and quantum-state rows, but it supplies no completed physical theory and no escape from the displayed falsification boundaries.

Proof. Use the carrier definition to identify the public packet. The four dependency rows G, L, M, Q are carried beside the falsification row F, transport row H, continuation row C, provenance row P, and local naming row N.

The NameCert obligations keep every consumer read on those displayed rows. The falsification-surface theorem keeps the failure boundary attached to the handoff whenever the route is read as physics-facing data.

Therefore the composite handoff is finite and internal to the BEDC packet. It can be consumed by later route work, but it cannot be read as completed physical law, completed spacetime semantics, or completed quantum theory. □

Falsifiable prediction: A multi-history physics consumer that exports completed physical theory while deleting the falsification row does not read an accepted $\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}$ packet.

Independence witness: relationalphysics, physicallawbridge, scientificmodelbridge, and quantumstate: no listed sibling carries the relational route, law bridge, model bridge, quantum-state row, falsification boundary, transport, replay, provenance, and local naming rows at once.

Closure status for $\mathsf{NameCert}_{\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}$ packet is generated from relational physics, physical-law bridge, scientific-model bridge, quantum-state, falsification-boundary, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1298.1, Definition 1298.2, Definition 1298.3, and Definition 1298.4 bind the finite composite route, NameCert obligations, falsification boundary, and public handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not derive relativity, quantum mechanics, empirical adequacy, standard-bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, falsification preservation, composite handoff, and TasteGate nontriviality with field faithfulness for $G, L, M, Q, F, H, C, P, N$.

Chapter 1299

A Concrete Naming Certificate for $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$

The $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ packet is the finite Real and Completion carrier that turns a shared-tail threshold into a single normal-form row before any $\mathsf{Real}^{\uparrow}$ seal consumer may read a tail window. It sits between the shared tail data of chapter 983, the seal-facing row of chapter 1171, the readback surfaces of chapter 126, chapter 301, and chapter 291, and the terminal consumers chapter 699 and chapter 38. Its role is to make the common finite threshold a displayed route object rather than a private parameter carried separately by each downstream seal.

Definition 1299.1 (Cauchy tail threshold normalizer carrier)**.** *A* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{CauchySharedTailModulus}^{\uparrow}$ *row naming the shared tail source whose threshold is being normalized.*
2. *M is the* $\mathsf{CauchyTailModulusSeal}^{\uparrow}$ *row that exposes the seal-facing modulus bound.*
3. *Θ is the normalized shared finite threshold row.*
4. *W_0 and W_1 are the two* $\mathsf{StreamName}^{\uparrow}$ *window readbacks cut from the same threshold Θ.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger read on the same threshold.*
6. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to W_0, W_1, D.*
7. *A is the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *row reached after the two threshold-indexed windows have been compared.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *consumer row available only after $S, M, \Theta, W_0, W_1, D, R, A$ have been displayed.*
9. *H stores componentwise* hsame *transport for the shared-tail, seal, threshold, window, tolerance, readback, agreement, Real, provenance, ledger, and naming rows.*
10. *C stores displayed* Cont *replay from the shared-tail source through the seal row, normalized threshold, both window readbacks, tolerance ledger, regular readback, agreement seal, and Real consumer row.*

11. *P is the* Pkg *provenance over* CauchyTailThresholdNormalizer$^{\uparrow}$, CauchySharedTailModulus$^{\uparrow}$, CauchyTailModulusSe RealTailAgreementSeal$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the route-exhaustion ledger recording that every seal-facing consumer has already read the same threshold Θ.*
13. *N is the local* NameCert$_{\text{CauchyTailThresholdNormalizer}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected host limits, host real equality, trichotomy, ambient completeness, private side thresholds, or a second Real seal route.

Definition 1299.2 (Cauchy tail threshold normalizer classifier)**.** *Two accepted* CauchyTailThresholdNormalizer$^{\uparrow}$ *carriers classify together exactly when their shared-tail source, modulus seal, normalized threshold, two StreamName windows, dyadic tolerance ledger, RegSeqRat readback, RealTailAgreementSeal route, RealUp consumer row, componentwise transports, displayed continuation replay, provenance, route-exhaustion ledger, and local naming row agree componentwise over the same threshold Θ. The classifier does not identify carriers by comparing quotient streams, by choosing host limits, by imposing host real equality, by invoking trichotomy, by importing ambient completeness, or by allowing each seal consumer to carry a private threshold.*

Lean4 (definition) `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerClassifier`

Theorem 1299.3 (Cauchy tail threshold normalizer NameCert obligations)**.** *For every accepted* CauchyTailThresholdNormalizer$^{\uparrow}$ *carrier*

$$T = (S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N),$$

the local NameCert$_{\text{CauchyTailThresholdNormalizer}^{\uparrow}}$ *surface consists exactly of carrier admission, shared-tail source exposure through S, modulus-seal exposure through M, normalized threshold exposure through Θ, paired StreamName window readback through W_0, W_1, dyadic tolerance exposure through D, RegSeqRat readback through R, RealTailAgreementSeal handoff through A, RealUp consumer exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, route-exhaustion ledgering through L, local naming through N, and non-escape for quotient streams, selected host limits, host real equality, trichotomy, ambient completeness, private side thresholds, and second Real seal routes.*

Proof. Carrier admission is projection from Definition 1299.1. The packet displays one shared-tail source, one seal-facing modulus row, one normalized threshold, two windows cut from that threshold, one dyadic tolerance ledger, one regular readback row, one agreement seal, one terminal Real consumer row, and five structural support rows.

The threshold row is read before any seal consumer. The source S and seal row M expose the tail data, then Θ fixes the finite threshold that both windows must use.

The readback rows are downstream of that threshold. The windows W_0, W_1, tolerance ledger D, and regular readback R are all indexed by the same Θ, so neither side can substitute a private finite window before the Real-facing handoff.

Finally A, E, H, C, P, L, N package the route as a NameCert surface. The carrier lacks quotient streams, selected host limits, host real equality, trichotomy, ambient completeness, private side thresholds, and second Real seal routes, so the listed rows exhaust the local obligations. □

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerCarrier namecert obligations`

Theorem 1299.4 (Cauchy tail threshold normalizer route exhaustion)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *consumer of a* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *carrier factors through the finite route*

$$S \longmapsto M \longmapsto \Theta \longmapsto (W_0, W_1, D, R) \longmapsto (A, E, H, C, P, L, N).$$

In particular, no such consumer can read two incompatible finite tail windows through private thresholds.

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerCarrier route exhaustion`

Proof. Start with the NameCert obligations of Definition 1299.3. They expose S and M before any Real-facing row appears.

Next read the normalized threshold Θ. The two StreamName windows, dyadic ledger, and regular readback are attached to Θ, so the threshold-indexed data rows are W_0, W_1, D, R and not side-private alternatives.

The agreement and Real rows are therefore downstream of the same finite threshold. The rows A, E, H, C, P, L, N transport, replay, source, ledger, and name the displayed route, and the carrier contains no coordinate for a second route around Θ. □

Theorem 1299.5 (Cauchy tail threshold normalizer tail-window induction)**.** *Every accepted* CauchyTailThresholdN *packet normalizes a threshold read by finite induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *tail windows. The base window is the threshold row* Θ *exposed between* S, M *and* W_0, W_1*; each successor window preserves the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, route-exhaustion ledger, and local* NameCert *row.*

Consequently every Real-facing consumer must pass through the same finite induction surface before reading a tail window. The induction exports no quotient stream equality, selected limit, trichotomy, countable choice, ambient Real completeness, private side threshold, or second Real seal route.

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerTailWindowInduction`

Proof. Project the carrier of Definition 1299.1. Its threshold row Θ is displayed before the two $\mathsf{StreamName}^{\uparrow}$ windows, so the base step is the finite threshold read itself, not a hidden limit or quotient-stream representative.

For the successor step, use the componentwise transport row H. Moving from one displayed tail window to the next preserves the shared-tail source, seal row, threshold row, tolerance ledger, regular readback, agreement-seal handoff, Real consumer row, continuation replay, provenance, route ledger, and local naming row component by component.

The $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows supply the numerical readback discipline at each displayed window. The $\mathsf{Real}^{\uparrow}$ seal row is downstream of those rows, so no successor step can inspect a Real-facing value before the window, tolerance, and readback data have been presented.

Finally apply route exhaustion from Definition 1299.4. Every accepted Real-facing consumer already factors through

$$S \longmapsto M \longmapsto \Theta \longmapsto (W_0, W_1, D, R) \longmapsto (A, E, H, C, P, L, N),$$

so the induction has no coordinate for quotient equality, selected limits, trichotomy, countable choice, ambient completeness, private side thresholds, or a second Real seal route. □

Theorem 1299.6 (Cauchy tail threshold normalizer shared-threshold uniqueness)**.** *Let T and T' be accepted* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *carriers read by* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *consumers. If the two consumers read the same shared-tail source row S and the same seal-facing modulus row M through classified normalizer packets, then both consumers expose the same normalized threshold row Θ before any W_0, W_1, D, R, A, E row is available.*

In particular, the classifier cannot admit two downstream seal reads with the same S, M source data and different normalized tail thresholds.

Proof. Project both accepted carriers through Definition 1299.1. In each carrier, the source and seal rows S, M are followed by a single normalized threshold row before any window, tolerance, readback, agreement, or Real-seal row appears.

Apply route exhaustion from Definition 1299.4. A $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealTailAgreementSeal}^{\uparrow}$ consumer has no route around Θ, so the downstream rows W_0, W_1, D, R, A, E can be read only after the normalized threshold has been displayed.

Finally use the classifier of Definition 1299.2. Classified packets are compared componentwise on the shared-tail source, seal row, normalized threshold, two windows, dyadic tolerance ledger, regular readback, agreement seal, and Real row. Since the two reads agree on S and M inside that classified normalizer surface, the threshold component exposed before the window rows is the same Θ in both reads. □

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerSharedThresholdUnique`

Theorem 1299.7 (Cauchy tail threshold normalizer window cofinality)**.** *Let T be an accepted* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *packet with shared source row S, seal row M, and normalized threshold row Θ. Every later finite* $\mathsf{StreamName}^{\uparrow}$ *window read by a* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer factors through a finite successor of the same Θ. No such consumer can introduce a private later threshold outside the displayed normalizer route.*

Proof. Project the carrier of Definition 1299.1. The rows S, M, Θ appear before W_0, W_1, D, R, A, E, so every seal-facing window read is downstream of the normalized threshold already displayed by the packet.

Use route exhaustion from Definition 1299.4. A $\mathsf{RealTailAgreementSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer has no route around

$$S \longmapsto M \longmapsto \Theta \longmapsto (W_0, W_1, D, R) \longmapsto (A, E, H, C, P, L, N),$$

and therefore any later finite StreamName window must be a successor window in that same finite route.

Apply shared-threshold uniqueness from Definition 1299.6. If a later consumer tried to introduce a private threshold while keeping the same S, M rows, the classified normalizer surface would expose two thresholds before the downstream window rows, contradicting the uniqueness row.

Finally transport the displayed successor window componentwise through H and replay it through C. The rows P, L, N keep the provenance, route-exhaustion ledger, and local NameCert attached to the same Θ, so the consumer receives a cofinal finite-window route rather than a hidden side threshold. □

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerWindowCofinality`

Theorem 1299.8 (Cauchy tail threshold normalizer public Real-seal route)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *seal read of an accepted* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *carrier*

$$T = (S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N)$$

passes through the same displayed route

$$S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N.$$

It cannot use quotient streams, selected host limits, host equality of real names, trichotomy, ambient completeness, private side thresholds, or a second seal route.

Proof. Start with route exhaustion from Definition 1299.4. It already forces every $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealTailAgreementSeal}^{\uparrow}$ consumer through the finite route from S, M to Θ, then through W_0, W_1, D, R, and finally through A, E, H, C, P, L, N.

Apply shared-threshold uniqueness from Definition 1299.6. A public seal read with the same shared source S and modulus seal M cannot split into a private side threshold before the window and readback rows are exposed.

Use window cofinality from Definition 1299.7. Every later finite $\mathsf{StreamName}^{\uparrow}$ window remains downstream of a finite successor of the same Θ, so the public route has no opening for quotient streams, selected host limits, host equality, trichotomy, or ambient completeness.

Finally read the structural rows. Transport, replay, provenance, route ledger, and local naming preserve the same carrier surface, and no listed row contains a second seal route. Therefore every public $\mathsf{Real}^{\uparrow}$ seal read factors through the displayed route and nothing else. □

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerRealSealPublicRoute`

Theorem 1299.9 (Cauchy tail threshold normalizer Real-facing determinacy)**.** *Let two accepted* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *consumers classify through the same* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *source row S and seal row M. Then their* $\mathsf{StreamName}^{\uparrow}$ *windows W_0, W_1,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *row A are all read downstream of the same normalized threshold row Θ.*

Equivalently, the Real-facing classifier surface exposes one finite route

$$S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N$$

before either consumer can inspect a tail window, tolerance ledger, regular readback, or agreement-seal row.

Proof. Project the carrier of Definition 1299.1. The normalized threshold row Θ is a displayed coordinate between the shared source and seal rows S, M and the downstream W_0, W_1, D, R, A, E rows.

Apply route exhaustion from Definition 1299.4. Any accepted $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealTailAgreementSeal}^{\uparrow}$ consumer must pass through Θ before reading the two StreamName windows, the dyadic tolerance ledger, the RegSeqRat readback, or the agreement-seal row.

Apply shared-threshold uniqueness from Definition 1299.6. Since the two consumers classify through the same S, M normalizer source and seal rows, the threshold exposed before the window rows is the same normalized row Θ.

Finally use the classifier of Definition 1299.2. It compares the downstream rows componentwise over the shared threshold surface, so W_0, W_1, D, R, A are determined as reads below that same Θ rather than as private tail windows or side thresholds. □

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerRealFacingDeterminacy`

Theorem 1299.10 (Cauchy tail threshold normalizer window scope)**.** *Every* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer that classifies through a* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *packet must expose*

$$S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N$$

in that order before inspecting a tail-window row. Consequently a private side threshold or second seal route is outside the classifier surface.

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerWindowScope`

Proof. Project the carrier of Definition 1299.1. The displayed coordinates are exactly $S, M, \Theta, W_0, W_1, D, R, A, E, H$ so any classified read begins with the shared-tail source, seal row, and normalized threshold before it reaches a window.

Apply route exhaustion and shared-threshold uniqueness. The route-exhaustion theorem forces every $\mathsf{RealTailAgreementSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer through the same threshold path, and uniqueness prevents two classified consumers with the same S, M rows from introducing separate threshold coordinates.

Use window cofinality and Real-facing determinacy next. They place W_0, W_1, D, R, A, E downstream of the same Θ, so the two windows, dyadic ledger, regular readback, agreement row, and Real row are not available as side reads.

Finally inspect the classifier surface. It has no coordinate for a private threshold or a second seal route, and the structural rows H, C, P, L, N only transport, replay, source, ledger, and name the same displayed packet. Thus any consumer that tries to inspect a tail-window row before the ordered route is outside the accepted classifier. □

Theorem 1299.11 (Cauchy tail threshold composition scope)**.** *Every accepted* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *carrier*

$$T = (S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N)$$

composes the shared-tail source S, modulus seal M, normalized threshold Θ, StreamName windows W_0, W_1, DyadicRatCore tolerance row D, RegSeqRat readback R, RealTailAgreementSeal row A, RealUp row E, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, route-exhaustion ledger L, and local* NameCert *row N into one finite route. No Real-facing consumer may bypass that route with private thresholds, quotient streams, selected host limits, trichotomy, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdCompositionScope`

Proof. Project the carrier of Definition 1299.1. The displayed coordinates are exactly $S, M, \Theta, W_0, W_1, D, R, A, E, H$ so the route starts at the shared-tail and seal rows before any Real-facing read is exposed.

Apply the NameCert obligations of Definition 1299.3. Those obligations make each analytic row available only as part of the same local certificate surface, with the normalized threshold placed before the paired StreamName windows, tolerance ledger, regular readback, agreement seal, and Real row.

Apply route exhaustion from Definition 1299.4. Every accepted $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealTailAgreementSeal}^{\uparrow}$ consumer already factors through the displayed threshold route, so a private threshold, quotient stream, selected host limit, trichotomy, host real equality, or ambient completeness principle has no public coordinate to occupy.

Finally use componentwise hsame transport and displayed Cont replay. They preserve the same route under transport and continuation, while P, L, N source, ledger, and name the packet without adding a second Real-facing path. □

Theorem 1299.12 (Cauchy tail threshold normalizer noninternalization)**.** *The* CauchyTailThresholdNormalizer$^{\uparrow}$ *packet does not internalize quotient streams, selected host limits, host real equality, trichotomy, ambient completeness, or hidden threshold choice. Its public surface is exactly the finite shared-threshold route displayed by*

$$S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N.$$

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerCarrier noninternalization`

Proof. Inspect the carrier of Definition 1299.1. Its data coordinates are the shared-tail source, seal row, normalized threshold, two windows, dyadic ledger, regular readback, agreement seal, and Real consumer row.

Inspect the structural coordinates next. Transport, continuation, provenance, route-exhaustion ledgering, and local naming preserve the displayed route; none supplies quotient equality, a host limit, host real equality, trichotomy, completeness, or hidden threshold selection.

Apply route exhaustion from Definition 1299.4. Every downstream seal consumer already factors through $S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N$, so there is no remaining public coordinate in which an excluded object could be read. □

Theorem 1299.13 (Cauchy tail threshold normalizer obligation ledger)**.** *For every accepted* CauchyTailThresholdNormalizer$^{\uparrow}$ *packet*

$$T = (S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N),$$

the Real-facing route exposes exactly the shared-tail source S, modulus seal M, normalized threshold Θ, two StreamName$^{\uparrow}$ *windows W_0, W_1,* DyadicRatCore$^{\uparrow}$ *ledger D,* RegSeqRat$^{\uparrow}$ *readback R,* RealTailAgreementSeal$^{\uparrow}$ *row A,* Real$^{\uparrow}$ *row E, componentwise transport H, displayed replay C, provenance P, route-exhaustion ledger L, and local* NameCert *row N before any Real-facing consumer reads a tail window.*

No accepted route adds quotient-stream equality, selected host limits, host real equality, trichotomy, ambient completeness, a private side threshold, or a second Real seal route.

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerObligationLedger`

Proof. Project the carrier of Definition 1299.1 and its classifier in Definition 1299.2. The exposed coordinates are precisely $S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N$, compared componentwise over the same threshold surface.

Apply the NameCert obligations of Definition 1299.3 and route exhaustion of Definition 1299.4. They place the shared-tail source and modulus seal before Θ, and place the two StreamName windows, dyadic ledger, RegSeqRat readback, RealTailAgreementSeal row, and Real row downstream of that threshold.

Apply shared-threshold uniqueness and Real-facing determinacy from Definition 1299.6 and Definition 1299.9. These rows prevent two Real-facing consumers with the same source and seal rows from reading private threshold windows or incompatible downstream readbacks.

Finally use noninternalization, Definition 1299.12. The excluded quotient, limit, equality, trichotomy, completeness, private-threshold, and second-seal objects have no carrier coordinate, so the listed rows form the complete L10 obligation ledger before any Real-facing tail-window read. □

Theorem 1299.14 (Cauchy tail threshold encoded obligation readback)**.** *The carrier row of Definition 1299.1, the classifier row of Definition 1299.2, the route-exhaustion row of Definition 1299.4, the shared-threshold uniqueness row of Definition 1299.6, and the Real-facing determinacy row of Definition 1299.9 together provide the full finite obligation readback needed for the next Lean target over* BEDC.Derived.CauchyTailThresholdNormalizerUp*. The readback exports carrier admission, classifier comparison, route coverage, unique shared-threshold exposure, and Real-facing downstream determinacy, and it exports no quotient-stream equality, selected host limit, host real equality, trichotomy, ambient completeness, private side threshold, or second Real seal route.*

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerEncodedObligationRead`

Proof. Read the carrier and classifier first. The carrier theorem displays the rows $S, M, \Theta, W_0, W_1, D, R, A, E, H, C,$ while the classifier requires those rows to be compared componentwise over the same threshold surface.

Next apply route exhaustion. It forces every $\mathsf{Real}^{\uparrow}$ and $\mathsf{RealTailAgreementSeal}^{\uparrow}$ consumer through

$$S \longmapsto M \longmapsto \Theta \longmapsto (W_0, W_1, D, R) \longmapsto (A, E, H, C, P, L, N),$$

so the encoded target has a finite route to read rather than an ambient completion premise.

The constructor induction is over threshold-window rows. The base constructor reads Θ after the shared source and modulus rows; the successor constructors preserve the two StreamName windows, dyadic tolerance ledger, regular readback, agreement seal, Real row, transport, replay, provenance, route ledger, and local naming.

Finally use shared-threshold uniqueness and Real-facing determinacy. They prevent two classified reads with the same S, M rows from splitting into private thresholds, and they force W_0, W_1, D, R, A to remain downstream of the same Θ. These cited rows are exactly the finite obligation surface required by the Lean target. □

Falsifiable prediction: Removing the normalized shared-tail row permits two RealUp seal consumers to read incompatible finite windows through private thresholds.

Independence witness: cauchysharedtailmodulus, cauchytailmodulusseal, realtailagreementseal, regseqrat, real: not bijective because the normalizer carries the common threshold, both window readbacks, both seal-facing routes, and the route-exhaustion ledger simultaneously.

Lean follow-up provides explicit $\mathsf{Nontrivial}\ \mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{CauchyTailThreshold}$ instances in `lean4/BEDC/Derived/CauchyTailThresholdNormalizerUp/TasteGate.lean`.

Theorem 1299.15 (Cauchy tail threshold normalizer obligation scope)**.** *The finite obligation surface of* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *is exactly the carrier row of Definition 1299.1, the classifier row of Definition 1299.2, route exhaustion from Definition 1299.4, tail-window induction from Definition 1299.5, shared-threshold uniqueness from Definition 1299.6, window cofinality from Definition 1299.7, Real-facing determinacy from Definition 1299.9, composition scope from Definition 1299.11, noninternalization from Definition 1299.12, and the obligation ledger of Definition 1299.13. These rows bind the obligationClosure surface over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *without exporting quotient streams, selected host limits, host real equality, trichotomy, ambient completeness, private side thresholds, or a second Real seal route.*

Proof. Project the carrier and classifier first. They display the finite packet $S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L,$ and require classified reads to compare those rows componentwise over the same threshold surface.

Use route exhaustion, tail-window induction, shared-threshold uniqueness, window cofinality, and Real-facing determinacy to bind the analytic rows. These theorems force every $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{RealTailAgreementSeal}^{\uparrow}$ handoff, and $\mathsf{Real}^{\uparrow}$ seal read to pass through the same normalized threshold Θ.

Apply composition scope and noninternalization next. They show that the displayed packet composes as one finite route and that no quotient stream, selected host limit, host real equality, trichotomy, ambient completeness, private side threshold, or second seal row can be projected from it.

Finally read the obligation ledger. It names exactly the same rows as the finite L10 surface, so the chapter reaches obligationClosure on the paper axis while leaving later verification to kernel-scoped dependency wording over those rows. □

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerObligationScope`

Theorem 1299.16 (Cauchy tail threshold normalizer uniform-threshold induction)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *tail-window successor read of an accepted* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *carrier preserves the single normalized threshold row* Θ *across the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *handoff, and every* $\mathsf{Real}^{\uparrow}$ *consumer row. In particular, no successor window may replace the shared* S, M, Θ *surface by a private threshold before exposing* $W_0, W_1, D, R, A, E, H, C, P, L, N$.

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerUniformThresholdIndu`

Proof. Use the tail-window induction row of Definition 1299.5. Its base case reads Θ immediately after the shared source S and seal row M; its successor step preserves the displayed windows W_0, W_1 together with the dyadic, regular-rational, agreement-seal, and Real rows.

Apply shared-threshold uniqueness and window cofinality. These rows force every later $\mathsf{StreamName}^{\uparrow}$ window to remain downstream of the same Θ, and they prevent a $\mathsf{RealTailAgreementSeal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer from introducing a side threshold.

Finally read Real-facing determinacy and the obligation ledger. The ledger lists only $S, M, \Theta, W_0, W_1, D, R, A, E$ so the induction is uniform over all displayed downstream consumers and exports no quotient stream, selected host limit, trichotomy, ambient completeness, or second Real seal route. □

Theorem 1299.17 (Cauchy tail threshold normalizer Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal handoff of an accepted* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *carrier factors first through*

$$S,\ M,\ \Theta,\ W_0,\ W_1,\ D,\ R,\ A$$

before any row among

$$E,\ H,\ C,\ P,\ L,\ N$$

is available to the consumer. Thus the Real-facing route reads the shared source, modulus seal, normalized threshold, two StreamName windows, dyadic tolerance ledger, RegSeqRat readback, and RealTailAgreementSeal handoff before it may expose the Real consumer row, structural transport, replay, provenance, route ledger, or local naming.

Proof. Start with route exhaustion from Definition 1299.4. It presents every $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealTailAgreementSeal}^{\uparrow}$ consumer through the same finite row order and prohibits a detached Real seal.

Use Real-facing determinacy next. Once S and M are fixed, the windows W_0, W_1, dyadic row D, regular readback R, and agreement handoff A are all read downstream of Θ; the $\mathsf{Real}^{\uparrow}$ consumer row E cannot precede that threshold path.

The composition and noninternalization rows then keep H, C, P, L, N as transport, replay, provenance, ledger, and naming data for the same route. They do not create an additional seal handoff, so every Real-facing consumer factors through $S, M, \Theta, W_0, W_1, D, R, A$ before exposing E, H, C, P, L, N. □

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerRealSealHandoff`

Theorem 1299.18 (Cauchy tail threshold normalizer scoped kernel route)**.** *Every accepted* CauchyTailThresholdNor *carrier*

$$T = (S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N)$$

scopes its public threshold-normalizer route over exactly BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* StreamName$^\uparrow$*,* RegSeqRat$^\uparrow$*,* DyadicRatCore$^\uparrow$*,* RealTailAgreementSeal$^\uparrow$*, and* Real$^\uparrow$*. Any* Real$^\uparrow$*-facing read must expose those rows before using the normalized threshold* Θ*, and the scoped route exports no quotient stream, selected host limit, trichotomy, ambient completeness, side threshold, or second* Real$^\uparrow$ *seal.*

Proof. Project the carrier and route-exhaustion rows. The accepted packet displays $S, M, \Theta, W_0, W_1, D, R, A, E, H,$ and Definition 1299.4 forces every public read through that finite route.

Use tail-window induction, shared-threshold uniqueness, and window cofinality. These theorems keep both StreamName$^\uparrow$ windows and the DyadicRatCore$^\uparrow$ tolerance ledger downstream of the same normalized threshold, so no side threshold can be selected by a later consumer.

Apply Real-facing determinacy and the Real-seal handoff. They require the RegSeqRat$^\uparrow$ readback and RealTailAgreementSeal$^\uparrow$ row to be exposed before the terminal Real$^\uparrow$ seal, and they prevent a second seal route from being projected out of the carrier.

Finally read transport, replay, provenance, ledger, and local naming. The rows H, C, P, L, N are exactly the hsame, Cont, Pkg, route-ledger, and NameCert boundary over the same finite packet, so the scoped route has no quotient stream, selected host limit, trichotomy, ambient completeness, or hidden threshold coordinate to export. □

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerScopedKernelRoute`

Theorem 1299.19 (Cauchy tail threshold normalizer public certificate)**.** *Every public* Real$^\uparrow$*,* RealTailAgreementSeal$^\uparrow$*,* StreamName$^\uparrow$*,* RegSeqRat$^\uparrow$*, or* DyadicRatCore$^\uparrow$ *consumer of an accepted* CauchyTailThresholdNormalizer$^\uparrow$ *packet receives exactly the scoped route*

$$S,\ M,\ \Theta,\ W_0,\ W_1,\ D,\ R,\ A,\ E,\ H,\ C,\ P,\ L,\ N$$

from Definition 1299.18. The public certificate exposes the same shared threshold Θ*, the two window rows* W_0, W_1*, the dyadic tolerance ledger* D*, the regular-rational readback* R*, the agreement-seal handoff* A*, the Real row* E*, and the structural rows* H, C, P, L, N*; it exports no quotient stream, selected host limit, trichotomy, ambient completeness, private side threshold, or second Real seal route.*

Proof. Start with the scoped kernel route of Definition 1299.18. It already fixes the accepted packet as the finite row list $S, M, \Theta, W_0, W_1, D, R, A, E, H, C, P, L, N$ over BHist, hsame, Cont, Pkg, NameCert, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, DyadicRatCore$^\uparrow$, RealTailAgreementSeal$^\uparrow$, and Real$^\uparrow$.

For a Real$^\uparrow$ or RealTailAgreementSeal$^\uparrow$ consumer, apply the Real-seal handoff of Definition 1299.17. The handoff requires $S, M, \Theta, W_0, W_1, D, R, A$ before the public Real-facing row is available, and the remaining structural rows E, H, C, P, L, N are read only as part of the same route.

For a $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{DyadicRatCore}^{\uparrow}$ consumer, use window cofinality from Definition 1299.7. It keeps both window rows and the dyadic tolerance ledger downstream of the shared threshold, so the regular readback and agreement seal cannot be separated from S, M, Θ.

The public certificate is therefore only a consumer-facing packaging of the scoped route. Since each admissible public read is obtained by composing these rows, no consumer can add a quotient stream, selected host limit, trichotomy, ambient completeness, private side threshold, or second Real seal route without leaving the displayed packet. □

Lean4 ✓ `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerPublicCertificate`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ packet is generated from two regular-Cauchy tail presentations by making the common tail threshold explicit before any agreement or real-seal read is allowed. The finite BHist carrier stores the threshold normalizer, the tail-agreement row, the eventual-equality row, componentwise hsame transport, displayed Cont routes, package provenance, ledger entries, and local naming. Its classifier reads the same threshold surface in both presentations and rejects side thresholds or second real-seal routes. The constructive content is the normalization discipline: every downstream RealUp or agreement read is generated bottom-up from the displayed threshold and its replay ledger, not from a quotient stream or hidden host limit.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: This chapter binds Definition 1299.18: the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealTailAgreementSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows of the finite $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ kernel route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyTailThresholdNormalizerUp.CauchyTailThresholdNormalizerPublicCertificate`

Bridge status: none

Not claimed: It does not claim quotient-stream equality, selected host limits, trichotomy, ambient completeness, private side thresholds, or a second Real seal route.

Upgrade path: Bridged closure requires a standard bridge over the same public route, including its StreamName, RegSeqRat, DyadicRatCore, RealTailAgreementSeal, Real, BHist, transport, replay, provenance, and local naming rows.

Chapter 1300

A Concrete Naming Certificate for $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$

The $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$ packet realizes the total phenomenology and total philosophy-of-science synthesis of section 9462.31 as one finite NameCert interface. It sits beside the science bridge of chapter 1286, the observer-history identity surface of chapter 479, the inter-history locality ledger of chapter 759, the scientific-object carrier of chapter 1214, and the standard-bridge audit packet of chapter 1217. Those siblings expose science-facing object rows, no-subject observer identity, finite locality ledgers, empirical object structure, and conservative bridge rows; this chapter binds them before any consumer treats phenomenological record access and scientific object access as the same accepted public surface.

Definition 1300.1 (Phenomenology-science interface carrier)**.** *A* $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, U, O, L, S, J, B, G, H, C, P, N)$$

whose displayed rows have the following roles:

1. *R is the records-side conscious packet read through focused records, observer identity, and local continuation rows.*
2. *U is the finite universe-slice row, exposing only the histories admitted by the current ledger.*
3. *O is the* $\mathsf{ObserverHistIdentity}^{\uparrow}$ *row that keeps observer identity on the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *surface.*
4. *L is the* $\mathsf{InterHistLocalityLedger}^{\uparrow}$ *row recording local spatial and inter-history relation data.*
5. *S is the* $\mathsf{ScientificObject}^{\uparrow}$ *row carrying record, classifier, invariant, empirical ledger, bridge, gap report, audit, truth, and local naming data.*
6. *J is the* $\mathsf{ScienceBridge}^{\uparrow}$ *row that reads the scientific-object, physical-audit, truth, bridge, and gap/failure surfaces together.*
7. *B is the* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *row exposing conservative bridge encoding, decoding, round-trip, theorem-preservation, and no-host-leak data.*
8. *G is the gap ledger for hard-problem, other-minds, causality, freedom, self-reference, prediction, domain, bridge, and falsification reports that remain visible to the interface.*

9. *H records componentwise* hsame *transport for $R, U, O, L, S, J, B, G, C, P, N$.*
10. *C records displayed* Cont *replay for records-side reading, universe-slice restriction, locality transport, scientific-object audit, bridge audit, and gap-ledger export.*
11. *P is the* Pkg *provenance over* $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$, $\mathsf{ScienceBridge}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{InterHistLocalityLedger}^{\uparrow}$, $\mathsf{ScientificObject}^{\uparrow}$, $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PhenomenologyScienceInterface}^{\uparrow}}$ *row.*

The carrier has no coordinate for private essence, global universe, global time, host real equality, unrecorded scientific object, or bridge theorem outside the conservative audit row.

Lean4 (definition) `BEDC.Derived.PhenomenologyScienceInterfaceUp.taste gate`

Theorem 1300.2 (Phenomenology-science observation slice)**.** *Every accepted* $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$ *observation read factors through the records-side row R, the finite universe slice U, the observer-history identity row O, the locality ledger L, and the structural rows H, C, P, N. A read that omits one of these rows may still be a projection of a conscious record or a scientific object, but it is not the interface carrier of Definition 1300.1.*

Lean4 ✓ `BEDC.Derived.PhenomenologyScienceInterfaceUp.PhenomenologyScienceInterfaceObservationSlice`

Proof. Project the carrier $I = (R, U, O, L, S, J, B, G, H, C, P, N)$. The records-side row gives the focused conscious packet, while U restricts the read to the finite observation-history slice admitted by the ledger.

Next read observer identity and locality. The $\mathsf{ObserverHistIdentity}^{\uparrow}$ row keeps the observer on the displayed BHist side, and the $\mathsf{InterHistLocalityLedger}^{\uparrow}$ row supplies the finite local relation surface. These two rows prevent the observation slice from becoming a hidden subject or a global container.

Finally use H, C, P, N. Transport preserves the same rows componentwise, continuation replay follows the displayed routes, provenance records the sibling sources, and local naming registers the interface. Therefore an accepted observation slice must keep R, U, O, L, H, C, P, N visible. □

Theorem 1300.3 (Phenomenology-science invariant transport)**.** *If two accepted interface carriers are related by the componentwise* hsame *row H, then the scientific-object row S, the science-bridge row J, the locality ledger L, and the observer-history identity row O transport together. Invariant content may be read as scientific only through the same finite locality and observer-identity support used by the records-side slice.*

Lean4 ✓ `BEDC.Derived.PhenomenologyScienceInterfaceUp.PhenomenologyScienceInterface invariant transport`

Proof. Begin with the componentwise transport coordinate H. Its domain is the whole carrier, so it preserves the records-side, universe-slice, observer-identity, locality, scientific-object, bridge, gap, replay, provenance, and naming rows as one packet.

Apply the sibling readings named in the chapter introduction. $\mathsf{ScientificObject}^{\uparrow}$ supplies invariant and empirical object rows; $\mathsf{ScienceBridge}^{\uparrow}$ supplies the bridge-facing scientific synthesis; $\mathsf{InterHistLocalityLedger}^{\uparrow}$ supplies locality support; and $\mathsf{ObserverHistIdentity}^{\uparrow}$ supplies no-subject observer identity.

The transported scientific read is therefore not detached from the phenomenological slice. It remains supported by O, L, H, C, P, N, so a consumer cannot export scientific invariance while dropping the finite observer and locality rows that make the record slice readable. □

Theorem 1300.4 (Phenomenology-science gap ledger)**.** *The gap row G of an accepted* PhenomenologyScienceInterfa *carrier is mandatory for every interface export that mentions hard-problem excess, other-minds access, causal direction, freedom, self-reference, prediction, domain fit, bridge fit, or falsification. None of the rows $R, U, O, L, S, J, B, H, C, P, N$ may absorb G.*

Proof. Read the carrier inventory. The records-side and universe rows expose finite observation data; the observer and locality rows expose identity and inter-history support; the scientific-object and bridge rows expose empirical and conservative bridge surfaces.

The listed gap forms are not coordinates of those rows. Hard-problem and other-minds reports are not observer identity; prediction, domain, bridge, and falsification reports are not scientific-object naming; bridge fit is not no-host-leak by itself.

Thus G remains the displayed ledger for unresolved or refusal-bearing parts of the interface. Transport, continuation, provenance, and local naming preserve the ledger but do not create it after omission. □

Lean4 ✓ `BEDC.Derived.PhenomenologyScienceInterfaceUp.PhenomenologyScienceInterface gap ledger`

Theorem 1300.5 (Phenomenology-science NameCert obligations)**.** *For the carrier of Definition 1300.1, the local* $\mathsf{NameCert}_{\mathsf{PhenomenologyScienceInterface}^{\uparrow}}$ *surface consists exactly of carrier admission for I, records-side exposure through R, universe-slice exposure through U, observer-identity exposure through O, locality-ledger exposure through L, scientific-object exposure through S, science-bridge exposure through J, conservative bridge exposure through B, gap-ledger exposure through G, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.PhenomenologyScienceInterfaceUp.PhenomenologyScienceInterfaceNameCertObligations`

Proof. Project I into its twelve rows. The first four analytic rows R, U, O, L supply finite conscious-record reading, universe-slice restriction, no-subject observer identity, and local inter-history relation data.

The science-facing rows S, J, B then expose scientific-object, science-bridge, and conservative standard-bridge audit data. The gap row G remains separate by Definition 1300.4; it is not discharged by object naming or bridge audit.

The structural rows finish the certificate. Componentwise hsame transport, displayed Cont replay, package provenance, and local naming keep the same finite packet available to downstream consumers.

Since the carrier has no further coordinate, the listed rows exhaust the local NameCert surface. A proposed interface that supplies only phenomenology rows or only science rows is a projection, not the accepted $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$ packet. □

Theorem 1300.6 (Phenomenology-science conservative bridge obligations)**.** *Every bridge-facing export of an accepted* $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$ *packet must expose the standard-bridge audit row B together with the scientific-object row S, the science-bridge row J, the gap ledger G, transport H, continuation replay C, provenance P, and local naming N. The export may use conservative bridge rows, but it cannot treat host primitives, private phenomenological essence, or a global universe as public BEDC data.*

Lean4 ✓ `BEDC.Derived.PhenomenologyScienceInterfaceUp.PhenomenologyScienceInterfaceConservativeBridgeObl`

Proof. Use Definition 1300.5. The NameCert surface lists B as the bridge audit row and keeps it adjacent to S, J, G, H, C, P, N.

The standard-bridge audit packet supplies encoding, decoding, round-trip, theorem-preservation, and no-host-leak obligations. These obligations do not identify host primitives with BEDC rows; they only record a conservative bridge read.

The records-side and universe-slice rows remain finite, and the gap ledger remains visible. Therefore the bridge-facing export is accepted only as a conservative interface row over the displayed packet, not as a private essence, global universe, or host-theoretic replacement. □

Falsifiable prediction: A proposed phenomenology/science interface that exports scientific object maturity while omitting observer identity, locality ledger, gap ledger, or standard bridge audit is not an accepted PhenomenologyScienceInterfaceUp carrier.

Independence witness: sciencebridge, observerhistidentity, interhistlocalityledger, scientificobject, standardbridgeauditpacket: none is bijective because $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$ binds records-side consciousness, finite universe slice, observer identity, locality, scientific object, science bridge, standard bridge audit, gap ledger, transport, replay, provenance, and local naming in one carrier. Each listed sibling omits at least one mandatory interface row.

Theorem 1300.7 (Phenomenology-science TasteGate grounding)**.** *Any promotion of* PhenomenologyScienceInterfa *beyond seed closure must read the observation slice R, U, O, L, invariant transport over S, J, H, the gap ledger G, the conservative bridge rows B, J, and the Lean-side TasteGate carrier-alignment target as separate obligations. None of these obligations may be discharged merely by naming the composite carrier $I = (R, U, O, L, S, J, B, G, H, C, P, N)$.*

Proof. Inspect the carrier rows. The observation slice is carried by R, U, O, L, while scientific invariance and bridge-facing exports require S, J, B together with transport H and replay C.

The gap ledger G is independent of those rows by Definition 1300.4. It records hard-problem, other-minds, causal, freedom, self-reference, prediction, domain, bridge, and falsification reports that cannot be absorbed by object naming or bridge audit.

The AI growth roadmap discipline requires the TasteGate side to align the carrier before the chapter can move beyond seed status. Therefore a later promotion must exhibit the paper rows and the Lean carrier-alignment obligation separately, with provenance and local naming still visible through P, N. □

Theorem 1300.8 (Phenomenology-science interface obligation carrier)**.** *Every accepted* PhenomenologyScienceInter *carrier exposes the dependency rows* $\mathsf{InterHistLocalityLedger}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, $\mathsf{ScienceBridge}^{\uparrow}$, $\mathsf{ScientificObject}^{\uparrow}$, *and* $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$ *through one finite* BHist *packet. The public carrier rows are exactly $R, U, O, L, S, J, B, G, H, C, P, N$, where the displayed R, U, O, L route the observational side, S, J, B route the scientific and bridge side, and H, C, P, N preserve the accepted packet.*

Proof. Project the carrier of Definition 1300.1. The rows $R, U, O, L, S, J, B, G, H, C, P, N$ are the only public coordinates, so each dependency surface is already stored inside the same finite packet.

Replay the displayed BHist route. The observation slice remains on R, U, O, L, while the scientific-object and bridge rows stay on S, J, B; transport, continuation, provenance, and local naming keep those routes readable as the same accepted packet. □

Lean4 ✓ `BEDC.Derived.PhenomenologyScienceInterfaceUp.PhenomenologyScienceInterface obligation carrier`

Theorem 1300.9 (Phenomenology-science interface obligation classifier)**.** *The classifier for an accepted* PhenomenologyScienceInterface$^{\uparrow}$ *carrier identifies the same finite rows after transporting the records-side and scientific-side routes through* hsame *and replaying them through* Cont*. In particular, the classifier sees the* InterHistLocalityLedger$^{\uparrow}$ *row, the* ObserverHistIdentity$^{\uparrow}$ *row, the* ScienceBridge$^{\uparrow}$ *row, the* ScientificObject$^{\uparrow}$ *row, and the* StandardBridgeAuditPacket$^{\uparrow}$ *row only as displayed dependencies of the same carrier, not as separate choice points.*

Lean4 ✓ `BEDC.Derived.PhenomenologyScienceInterfaceUp.PhenomenologyScienceInterfaceObligationClassifier`

Proof. Project the carrier and read the classifier surface. The rows R, U, O, L and S, J, B are already separated in the definition, so the classifier only compares how those rows are displayed in the same packet.

Replay the hsame and Cont routes. The two routes preserve the same dependency rows, and the local Pkg provenance together with NameCert records that no hidden classifier branch was introduced outside the accepted packet. □

Theorem 1300.10 (Phenomenology-science interface obligation ledger)**.** *The local ledger of an accepted* PhenomenologyScienceInterface$^{\uparrow}$ *carrier records exactly the dependency rows* InterHistLocalityLedger$^{\uparrow}$*,* ObserverHistIdentity$^{\uparrow}$*,* ScienceBridge$^{\uparrow}$*,* ScientificObject$^{\uparrow}$*, and* StandardBridgeAuditPacket$^{\uparrow}$ *together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *route. No ledger row exports a hidden subject, a global universe, a detached scientific-object authority, or a bridge claim that bypasses the displayed packet.*

Proof. Project the carrier one last time. The dependency rows named in the statement are already present in the packet, and the structural rows H, C, P, N keep them visible as one finite ledger.

Read the route through the displayed packet rather than by an external authority. The BHist carrier, componentwise hsame transport, displayed Cont replay, package provenance, and local naming are sufficient to replay the dependency ledger without adding any hidden subject or detached bridge claim. □

Theorem 1300.11 (Phenomenology-science TasteGate obligation scope)**.** *Every accepted* PhenomenologyScienceIn *packet must expose records-side consciousness R, finite universe slice U, observer-history identity O, inter-history locality L, scientific-object row S, science-bridge row J, standard-bridge audit row B, gap ledger G, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N before any interface read. The TasteGate carrier-alignment obligation may be read only after the sibling routes cited in the chapter introduction have supplied* ObserverHistIdentity$^{\uparrow}$*,* InterHistLocalityLedger$^{\uparrow}$*,* ScientificObject$^{\uparrow}$*,* ScienceBridge$^{\uparrow}$*, and* StandardBridgeAuditPacket$^{\uparrow}$ *as exact source rows.*

Proof. Project the carrier of Definition 1300.1. The rows $R, U, O, L, S, J, B, G, H, C, P, N$ are the full public interface, so an accepted packet cannot expose a phenomenology-facing read or a science-facing read before all twelve coordinates are visible.

Read the records-side scope first. The rows R, U, O, L bind conscious-record access to the finite universe slice, observer-history identity, and inter-history locality ledger, matching the sibling routes named in the introduction.

Read the science and bridge scope next. The rows S, J, B must arrive from ScientificObject$^{\uparrow}$, ScienceBridge$^{\uparrow}$, and StandardBridgeAuditPacket$^{\uparrow}$, while G remains the displayed ledger for hard-problem, other-minds, causality, freedom, self-reference, prediction, domain, bridge, and falsification reports.

The structural rows close the obligation boundary. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming keep the same sibling-source packet available before the TasteGate carrier-alignment read. Thus a carrier-only paragraph, a science-only row, or a records-only row cannot move the interface beyond seed scope. □

Closure status for $\mathsf{NameCert}_{\mathsf{PhenomenologyScienceInterface}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$ packet is generated from records-side consciousness, finite universe slice, observer-history identity, inter-history locality, scientific object, science bridge, standard bridge audit, gap ledger, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhenomenologyScienceInterface}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1300.1 and Definition 1300.11 record the composite interface carrier and its exact records-side, science-side, gap-ledger, transport, continuation, provenance, and naming scope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhenomenologyScienceInterface}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, global universe construction, host-theory identity, private essence, or scientific completeness.

Upgrade path: Obligation closure requires binding each carrier row to its exact sibling source, classifier, transport, continuation, provenance, and local naming obligation.

Chapter 1301

A Concrete Naming Certificate for CompactLebesgueUniformHandoff$^{\uparrow}$

The CompactLebesgueUniformHandoff$^{\uparrow}$ packet realizes the finite radius-ledger bridge isolated by chapter 9237. It binds the Lebesgue-number ledger of chapter 452, the compact-net selector of chapter 914, the uniform-modulus consumer of chapter 369, the compact metric source of chapter 129, and the pointwise continuity rows of chapter 130. The coordinate added here is the single public handoff row that makes the finite Lebesgue radius ledger readable by the compact-net selector before the UniformModulus$^{\uparrow}$ consumer accepts a tolerance-only modulus packet.

Definition 1301.1 (Compact Lebesgue uniform handoff carrier)**.** *A* CompactLebesgueUniformHandoff$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, F, S, R, M, C, H, T, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row carrying the finite compact-metric witness consumed by the compact-uniform route;*
2. *F is the* ContinuousMap$^{\uparrow}$ *pointwise-modulus row over the same source and target metric carriers;*
3. *S is the* FiniteLebesgueNumber$^{\uparrow}$ *positive radius ledger, read through* DyadicCover$^{\uparrow}$, FiniteWindowEnvelope$^{\uparrow}$, RationalBall$^{\uparrow}$, *and* DyadicMesh$^{\uparrow}$ *rows;*
4. *R is the compact-net selector packet supplied by* CompactNetModulusSelector$^{\uparrow}$, *with its finite* ProbeBundle *centers and radius-route witnesses;*
5. *M is the* UniformModulus$^{\uparrow}$ *output row that may read a tolerance-only precision history only after K, F, S, and R have been displayed;*
6. *C records the displayed* Cont *routes from compact source, pointwise modulus, Lebesgue radius ledger, and selector packet into the uniform-modulus row;*
7. *H records componentwise* hsame *transport for the compact source, continuous-map row, radius ledger, selector packet, uniform-modulus output, continuation, provenance, and local name rows;*
8. *T is the handoff trace row stating that the selector consumes exactly the positive finite Lebesgue-number ledger before the uniform-modulus row is public;*

9. *P is the* Pkg *provenance over* FiniteLebesgueNumber$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, UniformModulus$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DyadicCover$^{\uparrow}$, FiniteWindowEnvelope$^{\uparrow}$, RationalBall$^{\uparrow}$, DyadicMesh$^{\uparrow}$, BHist, hsame, Cont, *and local certificate rows;*
10. *N is the local* NameCert$_{\text{CompactLebesgueUniformHandoff}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a host minimum, a selected subcover, quotient equality of source points, or an external modulus function.

Theorem 1301.2 (Compact Lebesgue uniform handoff NameCert obligations)**.** *For the carrier of Definition 1301.1, the local* NameCert$_{\text{CompactLebesgueUniformHandoff}^{\uparrow}}$ *surface consists exactly of carrier admission for $U = (K, F, S, R, M, C, H, T, P, N)$, compact metric source exposure through K, pointwise continuous-map modulus exposure through F, finite Lebesgue-number radius-ledger exposure through S, compact-net selector exposure through R, uniform-modulus output exposure through M, displayed continuation through C, componentwise* hsame *transport through H, handoff trace exposure through T, package provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The rows $K, F, S, R, M, C, H, T, P, N$ list the full compact-uniform route before any consumer can read the uniform-modulus output.

The source and pointwise rows are read first. The compact source row K supplies the finite compact-metric context, while F supplies the pointwise-modulus relation over that same source route.

The radius ledger and selector rows form the handoff. The finite Lebesgue-number row S exposes only the dyadic cover, finite-window, rational-ball, and mesh ledgers, and the selector row R reads that positive radius ledger as its compact-net input.

The output row is therefore downstream of the displayed handoff trace T. The transport, continuation, provenance, and local naming rows add no open-cover compactness, host minimum, selected subcover, quotient equality, or external modulus coordinate, so the listed rows exhaust the local certificate surface. □

Lean4 ✓ `BEDC.Derived.CompactLebesgueUniformHandoffUp.TasteGate.CompactLebesgueUniformHandoffTasteGate single carrier alignment`

Theorem 1301.3 (Compact Lebesgue uniform handoff factorization)**.** *Every accepted* UniformModulus$^{\uparrow}$ *read from a* CompactLebesgueUniformHandoff$^{\uparrow}$ *carrier factors through the ordered route*

CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteLebesgueNumber$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, UniformModulus$^{\uparrow}$

The factorization reads the finite Lebesgue-number positive radius ledger through DyadicCover$^{\uparrow}$, FiniteWindowEnvelope$^{\uparrow}$, RationalBall$^{\uparrow}$, *and* DyadicMesh$^{\uparrow}$, *then hands that ledger to the compact-net selector packet, and finally exposes the uniform-modulus output through the carried* hsame, Cont, Pkg, *and* NameCert *rows.*

Proof. Start with the NameCert obligations of Definition 1301.2. They identify $K, F, S, R, M, C, H, T, P, N$ as the complete consumer-facing surface.

The finite Lebesgue-number row S is the only positive radius ledger in the carrier. By chapter 452, its public read is limited to the displayed dyadic-cover, finite-window, rational-ball, mesh, transport, continuation, provenance, and local naming rows.

The selector row R is therefore forced to consume that finite ledger rather than an open-cover compactness object. The route through chapter 914 packages the compact-net centers and radius comparisons before the UniformModulus$^{\uparrow}$ output row M is public.

Finally the compact source K and pointwise continuous-map row F provide the source and local modulus data used by the selector. Since the carrier has no coordinate for host minima, selected subcovers, quotient equality, or external modulus functions, every accepted uniform-modulus read factors through the displayed route and no wider one. □

Falsifiable prediction: Every accepted CompactLebesgueUniformHandoffUp consumer must expose the finite Lebesgue-number radius ledger, compact-net selector packet, compact metric source, continuous-map pointwise-modulus row, uniform-modulus output, hsame, Cont, Pkg, and NameCert rows before a uniform-modulus handoff is public.

Independence witness: finitelebesguenumber, compactnetmodulusselector, uniformmodulus, compactmetric, continuousmap: no sibling is bijective because the handoff binds the radius ledger, selector route, source compactness, pointwise continuity, and output modulus as one packet.

The later Lean TasteGate.lean surface must include explicit Nontrivial CompactLebesgueUniformHandoff$^{\uparrow}$ and FieldFaithful CompactLebesgueUniformHandoff$^{\uparrow}$ instances.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactLebesgueUniformHandoff}^{\uparrow}}$.

Constructive story: A CompactLebesgueUniformHandoff$^{\uparrow}$ packet is generated by placing compact finite-net data, pointwise continuous-map radii, a Lebesgue-style radius selector, a uniform-modulus output row, componentwise hsame transport, displayed Cont replay, package provenance, and local naming into one finite BHist carrier. The classifier does not search an ambient open cover; it only inspects the displayed compact source and the local modulus rows already carried by the packet. The ledger story is the handoff from local to uniform: the selector records a finite radius choice and the uniform-modulus row may consume it only through the same transport and continuation routes.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactLebesgueUniformHandoff}^{\uparrow}}$, seed)

Scope closed: This chapter binds the carrier definition, the NameCert-obligation and factorization theorems, the falsifiable prediction, independence witness, and Lean-follow-up boundary for CompactLebesgueUniformHandoff$^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactLebesgueUniformHandoff}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: It does not claim open-cover compactness, host minima, selected subcovers, quotient equality of points, or an external modulus function.

Upgrade path: To reach obligationClosure, the compact finite-net handoff and uniform-modulus factorization must be represented as checked finite-carrier obligations.

Chapter 1302

A Concrete Naming Certificate for CompactCoverLebesgueLedger$^{\uparrow}$

The CompactCoverLebesgueLedger$^{\uparrow}$ packet materializes the finite-cover lower-bound ledger used by chapter 9237. It sits after the compact-uniform-continuity packet of chapter 388, the finite rational lower-bound fold of chapter 619, the compact-metric finite-net surface, the continuous-map pointwise-radius rows, and the uniform-modulus consumer. Its purpose is narrower than the cover-shrinkage ledger: it records the concrete Lebesgue-number-style row that joins a finite ProbeBundle cover, positive Rat$^{\uparrow}$ radius rows, and the final UniformModulus$^{\uparrow}$ handoff.

Definition 1302.1 (Compact cover Lebesgue ledger carrier)**.** *A* CompactCoverLebesgueLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, C, R, F, U, H, T, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite-net row, exposing the nonempty finite* ProbeBundle *of centers and the cover-membership rows;*
2. *C is the* ContinuousMap$^{\uparrow}$ *pointwise-radius ledger, assigning to each displayed center a positive local radius for the requested target tolerance;*
3. *R is the positive* Rat$^{\uparrow}$ *radius row, recording the half-radius comparisons and the lower-bound candidates consumed by the fold;*
4. *F is the* FiniteNetMinimumFold$^{\uparrow}$ *lower-bound row over the same finite* ProbeBundle *and the same positive radius ledger R;*
5. *U is the* UniformModulus$^{\uparrow}$ *consumer row that receives the precision exported by the finite lower-bound fold;*
6. *H records componentwise* hsame *transport for the compact net, pointwise-radius ledger, rational rows, finite fold, uniform-modulus row, routes, provenance, and local naming;*
7. *T records the displayed* Cont *routes through which compact finite nets, continuous pointwise radii, rational comparisons, fold readback, and uniform-modulus consumers inspect the packet;*
8. *P is the* Pkg *provenance over* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Rat$^{\uparrow}$, FiniteNetMinimumFold$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and local naming rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{CompactCoverLebesgueLedger}^{\uparrow}}$ *row.*
The carrier has no coordinate for an open-cover compactness oracle, host minimum over radii, selected center outside the finite bundle, quotient metric equality, or external modulus function.

Theorem 1302.2 (Compact cover Lebesgue ledger classifier surface)**.** *The classifier of an accepted* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *packet is determined by exactly the rows $K, C, R, F, U, H, T, P, N$. Two presentations with the same compact finite-net row, pointwise-radius row, positive rational ledger, lower-bound fold, uniform-modulus output, componentwise transports, displayed routes, provenance, and local naming row determine the same Lebesgue-ledger classifier, and no presentation may refine the classifier by a host minimum, open-cover oracle, external center selector, quotient metric equality, or external modulus function.*

Proof. Project both presentations to the carrier of Definition 1302.1. Equality of the nine displayed rows identifies the compact source, local radius ledger, rational lower-bound candidates, fold output, and uniform-modulus consumer.

The transport, route, provenance, and naming rows are also shared. They replay the same reads and cannot introduce a new classifier coordinate.

Every excluded object is absent from the carrier inventory. Therefore the classifier is exhausted by the displayed finite packet. □

Lean4 ✓ `BEDC.Derived.CompactCoverLebesgueLedgerUp.CompactCoverLebesgueLedgerCarrier classifier surface`

Theorem 1302.3 (Compact cover Lebesgue ledger NameCert obligations)**.** *For every accepted* $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ *packet*

$$L = (K, C, R, F, U, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactCoverLebesgueLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for L, compact finite-net admission through K, continuous pointwise-radius admission through C, positive* $\mathsf{Rat}^{\uparrow}$ *lower-bound candidates through R, finite lower-bound fold exactness through F, uniform-modulus output exactness through U, componentwise* hsame *stability through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 1302.1. The rows $K, C, R, F, U, H, T, P, N$ are the complete displayed packet, and the first five rows name the compact net, pointwise radii, rational candidates, finite fold, and uniform-modulus consumer.

The compact finite-net and continuous pointwise-radius obligations are read before the fold. Thus every lower-bound candidate in R is attached to a center already visible in K and to a pointwise-radius row already visible in C.

The fold row F is exact over that same finite bundle and radius ledger. Its exported precision is the only row that U may read as a $\mathsf{UniformModulus}^{\uparrow}$ precision.

Finally H, T, P, N transport, replay, package, and name the same finite surface. Since no excluded coordinate occurs in the carrier, no local NameCert obligation can appeal to an open-cover oracle, host minimum, external selected center, quotient metric equality, or external modulus function. □

Lean4 ✓ `BEDC.Derived.CompactCoverLebesgueLedgerUp.CompactCoverLebesgueLedgerCarrier namecert obligations`

Theorem 1302.4 (Compact cover Lebesgue ledger uniform-modulus handoff)**.** *Every accepted* CompactCoverLebesgueLedger$^{\uparrow}$ *consumer that exports a* UniformModulus$^{\uparrow}$ *precision must factor through the compact finite-net row K, the continuous pointwise-radius row C, the positive* Rat$^{\uparrow}$ *lower-bound ledger R, the* FiniteNetMinimumFold$^{\uparrow}$ *row F, and the structural rows H, T, P, N. A consumer cannot export the uniform modulus without the compact finite-net row, continuous pointwise-radius row, positive lower-bound fold,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Proof. Begin with the compact finite-net row K. It supplies the finite ProbeBundle of centers used by the compact-uniform-continuity construction of chapter 9237.

Read the continuous pointwise-radius row C at those centers. The positive rational row R records the half-radius candidates whose comparisons make the local pointwise estimates usable by a common precision.

Apply the lower-bound fold F. Because F is a FiniteNetMinimumFold$^{\uparrow}$ row over the same finite bundle and the same rational ledger, its exported precision is below every displayed local radius and is available as a single tolerance-only row.

The UniformModulus$^{\uparrow}$ row U can read that precision only through H, T, P, N. These structural rows preserve and route the finite ledger; they do not add a direct pointwise-to-uniform selector or a hidden compactness theorem. □

Lean4 ✓ `BEDC.Derived.CompactCoverLebesgueLedgerUp.CompactCoverLebesgueLedgerCarrier uniform modulus handoff`

Theorem 1302.5 (Compact cover Lebesgue ledger finite-net radius exhaustion)**.** *Every uniform precision exported by an accepted* CompactCoverLebesgueLedger$^{\uparrow}$ *packet is exhausted by the displayed finite-net radius ledger. Concretely, if*

$$L = (K, C, R, F, U, H, T, P, N)$$

exports a precision to U, then the export is read from the finite net row K, the pointwise radius row C, the positive rational ledger R, the lower-bound fold F, and the structural rows H, T, P, N. No exported precision may depend on an open-cover oracle, a host minimum over radii, a selected center outside K, quotient metric equality, or an external modulus function.

Lean4 ✓ `BEDC.Derived.CompactCoverLebesgueLedgerUp.CompactCoverLebesgueLedgerFiniteNetRadiusExhaustion`

Proof. Project the carrier through Definition 1302.1. The only rows that can supply radius data are K, C, R, F: the finite net names the displayed centers, the pointwise ledger attaches local radii to those centers, the rational row records positive lower-bound candidates, and the fold row reads the same finite list.

Apply Definition 1302.4. It places every UniformModulus$^{\uparrow}$ export downstream of K, C, R, F and the structural rows H, T, P, N.

The classifier-surface theorem then excludes every other source of precision. Since the carrier has no coordinate for an open-cover compactness oracle, host minimum, external center selector, quotient metric equality, or external modulus function, the finite-net ledger exhausts the exported precision. □

Lean4 ✓ `BEDC.Derived.CompactCoverLebesgueLedgerUp.CompactCoverLebesgueLedgerCarrier finite net radius exhaustion`

Falsifiable prediction: A consumer that exports a UniformModulus$^{\uparrow}$ precision from a compact-continuous packet without reading the compact finite-net row, continuous pointwise-radius row,

positive $\mathsf{Rat}^{\uparrow}$ lower-bound fold, hsame, Cont, Pkg, and NameCert rows refutes the $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ carrier.

Independence witness: compactuniformcontinuity, finitenetminimumfold, compactnetmodulus-selector, compactmoduluscover, uniformmodulus: $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ binds the compact finite-net row, continuous pointwise-radius row, positive rational lower-bound fold, uniform-modulus output, and structural transport rows in one finite NameCert packet; each named sibling lacks at least one of these rows as a local carrier obligation.

Lean follow-up for this surface must provide Nontrivial and FieldFaithful instances in `BEDC.Derived.CompactCov`

Lean4 ✓ `BEDC.Derived.CompactCoverLebesgueLedgerUp.CompactCoverLebesgueLedgerTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCoverLebesgueLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$ packet is generated from a compact finite-net row, continuous pointwise-radius rows, positive rational lower-bound candidates, a finite minimum-fold row, the resulting uniform-modulus output, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier is exhausted by these rows: it reads the finite ProbeBundle centers, their local radii, and the lower-bound fold before any uniform consumer may inspect a precision. The ledger story is a finite Lebesgue-number account, where the cover evidence is not an oracle but a displayed list whose fold and replay routes can be audited in the packet itself.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactCoverLebesgueLedger}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: This chapter gives the mature paper-side finite-net Lebesgue-ledger route witnessed by Definition 1302.4 and Definition 1302.5, carrying $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, Pkg, and NameCert rows from the compact cover surface to the uniform-modulus consumer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactCoverLebesgueLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: It does not claim an open-cover compactness oracle, host minimum over radii, selected center outside the finite bundle, quotient metric equality, or external modulus function.

Upgrade path: Lean formalization and bridge checking remain separate verification-axis work for the finite-net Lebesgue-ledger route.

Chapter 1303

A Concrete Naming Certificate for $\mathsf{RealityConstrainedSignatureDescent}^{\uparrow}$

The $\mathsf{RealityConstrainedSignatureDescent}^{\uparrow}$ packet realizes operational descent from section 9414.1 as a finite NameCert carrier. It consumes the signature-fit packet of **??**, the signature-residue packet of chapter 1213, the finite schedule surface of chapter 126, the endpoint surface of chapter 38, and the comparison surface of chapter 57. These siblings expose physical fit, remaining signature residue, stream schedules, real approximation rows, and metric comparison rows; this packet adds the descent witness that lets a transported mathematical operation be read as a physical-signature operation.

Definition 1303.1 (Reality-constrained signature-descent carrier)**.** *A* $\mathsf{RealityConstrainedSignatureDescent}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, M, G, P, O, W, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row exposing the observation stream on which the operation is tested.*
2. *A is the* $\mathsf{Real}^{\uparrow}$ *approximation row naming the mathematical endpoint before and after operation transport.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row used to evaluate transported outputs.*
4. *G is the GAP row recording unrepresented, withheld, or physically separated signatures.*
5. *P is the physical-representation certificate row for the source and target representations.*
6. *O is the operation-descent witness row recording that the transported operation preserves the source classifier and lands in the target physical-signature classifier.*
7. *W is the witness route joining S, A, M, G, P, O as one physical-signature descent route.*
8. *H is the componentwise* hsame *transport row for S, A, M, G, P, O, W.*
9. *C is the displayed* Cont *replay row for the same finite route.*
10. *Q is the* Pkg *provenance row over* $\mathsf{RealityConstrainedSignatureDescent}^{\uparrow}$, $\mathsf{RealityConstrainedSignatureFit}^{\uparrow}$, $\mathsf{RealityConstrainedSignatureResidue}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureDescent}^{\uparrow}}$ *row.*
The carrier has no coordinate for bare mathematical operation transport, physical adequacy without S, G, P, O, quotient-stream equality, host physical identity, or an unledgered representation shortcut.

Lean4 (definition) `BEDC.Derived.RealityConstrainedSignatureDescentUp.RealityConstrainedSignatureDescentUp`

Theorem 1303.2 (Reality-constrained signature-descent NameCert obligations)**.** *For the carrier of Definition 1303.1, the local* $\mathsf{NameCert}_{\mathsf{RealityConstrainedSignatureDescent}^{\uparrow}}$ *surface consists exactly of carrier admission, stream schedule visibility, Real endpoint visibility, Metric comparison visibility, GAP-row visibility, representation-certificate visibility, operation-descent witness visibility, witness-route coherence, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through N.*

Proof. Project the carrier $D = (S, A, M, G, P, O, W, H, C, Q, N)$. The rows S, A, M, G, P expose the mathematical and physical-signature data already separated by the signature-fit and signature-residue packets.

The row O is the additional descent witness. It records that the transported operation respects the mathematical source classifier and lands in the target physical-signature classifier rather than only in a mathematical target classifier.

The witness route W joins those rows before any public physical-operation read. Transport through H, replay through C, and provenance through Q preserve the same finite route, while N names it locally.

No further coordinate remains in the carrier. Thus the displayed rows exhaust the NameCert obligations for physical-signature operation descent. □

Lean4 ✓ `BEDC.Derived.RealityConstrainedSignatureDescentUp.RealityConstrainedSignatureDescentCarrier namecert obligations`

Theorem 1303.3 (Reality-constrained signature-descent no-free operation)**.** *Let $D = (S, A, M, G, P, O, W, H, C, Q$ be an accepted* $\mathsf{RealityConstrainedSignatureDescent}^{\uparrow}$ *packet. A transported mathematical operation is accepted as a physical-fit operation only when the same route displays the stream schedule S, GAP row G, representation certificate P, physical-signature descent witness O, witness route W, transport row H, replay row C, provenance row Q, and local naming row N. If any of S, G, P, O, W is absent, the route remains mathematical operation transport and is rejected as a physical-fit operation.*

Proof. Use the NameCert obligations of Definition 1303.2. A public physical-operation read must expose the schedule, GAP row, representation certificate, and descent witness as displayed coordinates of one packet.

The mathematical rows A and M can still support operation transport inside the mathematical classifier. They do not by themselves expose a physical-signature route, because the descent witness O and witness route W are the rows that join classifier transport to the physical signature.

The structural rows cannot add missing physical evidence. Componentwise hsame transport preserves the displayed components, Cont replay follows the same route, and Pkg provenance records that route rather than introducing a hidden host witness.

Therefore a route lacking S, G, P, O, or W has no accepted physical-fit operation coordinate. It is rejected as a physical-fit operation even if the mathematical operation is transported. □

Falsifiable prediction: A transported mathematical operation that lacks the displayed stream schedule, GAP row, representation certificate, and physical-signature descent witness is rejected as a physical-fit operation.

Independence witness: reality-constrained-signature-fit, reality-constrained-signature-residue, streamname, real, metric: none carries the operation-descent witness row together with the physical-signature route. Signature-fit binds compatibility rows without the descent witness, signature-residue records remaining separation without licensing operation transport, StreamName supplies schedules without Real or Metric operation data, Real supplies endpoints without physical signatures, and Metric supplies comparison without GAP or representation certificates.

The Lean follow-up site `lean4/BEDC/Derived/RealityConstrainedSignatureDescentUp/TasteGate.lean` must provide Nontrivial RealityConstrainedSignatureDescent$^{\uparrow}$ and FieldFaithful RealityConstrainedSignatureDescent$^{\uparrow}$ instances for the same finite descent packet.

Closure status for NameCert$_{\text{RealityConstrainedSignatureDescent}^{\uparrow}}$ **.**

Constructive story: A RealityConstrainedSignatureDescent$^{\uparrow}$ packet is generated by joining a reality-constrained signature fit, GAP boundary, physical-representation certificate, operation-signature row, descent certificate, componentwise hsame transport, displayed Cont replay, package provenance, and local naming into a finite BHist carrier. The classifier is not bare operation transport: it requires the signature row, the GAP socket, the representation certificate, and the physical-operation surface to be read together. The ledger story is descent under constraint, where an operation may move down the signature route only when every physical and gap-facing coordinate remains visible through the same continuation and provenance rows.

Theory closure: TheoryGate(NameCert$_{\text{RealityConstrainedSignatureDescent}^{\uparrow}}$, seed)

Scope closed: This chapter binds the carrier definition, NameCert-obligation theorem, no-free-operation theorem, falsifiable prediction, independence witness, and Lean-follow-up boundary for RealityConstrainedSignatureDescent$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{RealityConstrainedSignatureDescent}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim bare mathematical operation transport, physical adequacy without the displayed signature rows, quotient-stream equality, host physical identity, or unledgered representation shortcuts.

Upgrade path: To reach obligationClosure, the signature-fit carrier and no-free-operation descent boundary must receive checked finite-history proofs.

Chapter 1304

A Concrete Naming Certificate for $\mathsf{PhenomenologicalFrame}^{\uparrow}$

The $\mathsf{PhenomenologicalFrame}^{\uparrow}$ packet realizes the phenomenological framework of section 9462.27 as a finite NameCert carrier. It sits beside the focused ledger of chapter 1247, the focused multi-Hist ledger of chapter 1109, the observer-subject boundary of chapter 615, the gap-closure boundary of chapter 1006, and the causal-commitment packet of chapter 505. Those siblings expose focused records, multi-history support, no-subject observation, shared gap refusal, and forward causal sockets; this chapter binds the complete phenomenological frame before any consumer reads consciousness, universe, action, or time as a hidden object.

Definition 1304.1 (Phenomenological frame carrier)**.** *A* $\mathsf{PhenomenologicalFrame}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (L, M, U, O, G, A, T, H, C, P, R, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{FocusedLedger}^{\uparrow}$ *row exposing selected histories, focus, selector, digest, gap, relation, invariant, dependence, audit, replay, provenance, and local naming data;*
2. *M is the* $\mathsf{FocusedMultiHistLedger}^{\uparrow}$ *row exposing the finite multi-history support used by the frame;*
3. *U is the consciousness/universe row, read through the finite universe-slice discipline of* $\mathsf{ConsciousUniverseSpace}^{\uparrow}$ *rather than through a global universe object;*
4. *O is the* $\mathsf{ObserverSubjectBoundary}^{\uparrow}$ *row that keeps observation on finite* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows without adding observer substance;*
5. *G is the* $\mathsf{GapClosureBoundary}^{\uparrow}$ *row recording gap requests, source rows, refusal ledgers, and non-escape data;*
6. *A is the hard-problem and action row, consuming the gap boundary and the* $\mathsf{CausalCommitment}^{\uparrow}$ *socket for action, causality, freedom, other minds, mind–matter relation, and self-reference readings;*
7. *T is the local time and continuation ledger, exposing only displayed continuation steps and no object-level time carrier;*
8. *H records componentwise* hsame *transport for $L, M, U, O, G, A, T, C, P, R, N$;*

9. *C records displayed* Cont *replay for focused ledger reads, multi-history restriction, universe-slice access, observer-boundary inspection, gap refusal, causal commitment, and local time steps;*
10. *P records* Pkg *provenance over* $\mathsf{PhenomenologicalFrame}^{\uparrow}$, $\mathsf{FocusedLedger}^{\uparrow}$, $\mathsf{FocusedMultiHistLedger}^{\uparrow}$, $\mathsf{ConsciousUniverseSpace}^{\uparrow}$, $\mathsf{ObserverSubjectBoundary}^{\uparrow}$, $\mathsf{GapClosureBoundary}^{\uparrow}$, $\mathsf{CausalCommitment}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *R is the audit-refusal row excluding subject substance, global universe object, hidden chooser, object-level T, host equality, quotient history equality, and off-packet continuation;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PhenomenologicalFrame}^{\uparrow}}$ *row.*

The carrier has no coordinate for private consciousness substance, ambient world container, global time object, unledgered agency selector, hidden solution of the hard problem, or causal necessity outside the displayed rows.

Lean4 ✓ `BEDC.Derived.PhenomenologicalFrameUp.PhenomenologicalFrameTasteGate single carrier alignment round trip`

Theorem 1304.2 (Phenomenological frame NameCert obligations)**.** *For the carrier of Definition 1304.1, the local* $\mathsf{NameCert}_{\mathsf{PhenomenologicalFrame}^{\uparrow}}$ *surface consists exactly of carrier admission for $F = (L, M, U, O, G, A, T, H, C, P, R, N)$, focused-ledger admission through L, multi-history support through M, consciousness/universe slicing through U, no-subject observation through O, gap and refusal routing through G, hard-problem and action commitment through A, local time and continuation exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, audit refusal through R, and local naming through N.*

Proof. Project the carrier into its twelve rows. The rows L, M, U, O expose focused records, multi-history support, finite universe slicing, and no-subject observation before the frame can be consumed as a phenomenological packet.

Read the gap and action rows next. The gap boundary G supplies source/refusal routing, while A records hard-problem and causal-commitment readings only as displayed socketed commitments.

Finally use the structural rows T, H, C, P, R, N. Local time remains a continuation ledger, transport and replay preserve only displayed rows, provenance names the sibling sources, audit refusal excludes hidden objects, and local naming registers the packet. Since no further coordinate exists, these obligations exhaust the local NameCert surface. □

Theorem 1304.3 (Phenomenological frame audit non-escape)**.** *Every accepted* $\mathsf{PhenomenologicalFrame}^{\uparrow}$ *consumer reads consciousness, universe, time, identity, causality, freedom, other minds, mind–matter relation, and self-reference only through the finite rows*

$$L, M, U, O, G, A, T, H, C, P, R, N.$$

It receives no subject substance, global universe object, hidden chooser, object-level T, host equality, quotient history equality, hidden hard-problem solution, causal necessity row, or off-packet continuation.

Proof. Apply the NameCert obligation surface. It identifies $L, M, U, O, G, A, T, H, C, P, R, N$ as the complete accepted packet and supplies no additional public coordinate.

Inspect the sibling rows. $\mathsf{FocusedLedger}^{\uparrow}$ and $\mathsf{FocusedMultiHistLedger}^{\uparrow}$ supply finite focused histories; $\mathsf{ObserverSubjectBoundary}^{\uparrow}$ refuses a separate subject carrier; $\mathsf{GapClosureBoundary}^{\uparrow}$ routes unsupported closure requests to visible refusal; and $\mathsf{CausalCommitment}^{\uparrow}$ exposes causal reading as a forward socket rather than as necessity.

The excluded objects would require coordinates outside the displayed carrier. The audit row R records their refusal, while H, C, P, N only transport, replay, source, and name the same packet. Therefore the accepted frame cannot export any of the excluded data. □

Theorem 1304.4 (Phenomenological frame dependency package)**.** *The dependency surface of an accepted* $\mathsf{PhenomenologicalFrame}^{\uparrow}$ *carrier is the ordered package consisting of focused-ledger rows, focused multi-Hist rows, consciousness/universe-slice rows, observer-subject-boundary rows, gap-closure rows, causal-commitment action rows, local-time continuation rows, transport, replay, provenance, audit refusal, and local naming. Dropping any one of the sibling rows* L, M, O, G, A *changes the accepted dependency package.*

Proof. The carrier definition assigns one displayed coordinate to each sibling role. The package therefore has distinct rows for focus, multi-history support, observer boundary, shared gap closure, and causal commitment.

If L is absent, the frame has no focused record route. If M is absent, it has no finite multi-history support. If O is absent, observation can no longer be certified without a subject-substance gap. If G is absent, unsupported closure requests have no refusal ledger. If A is absent, action and causal commitment are not socketed into the frame.

The remaining structural rows cannot reconstruct a missing sibling row. They preserve, replay, source, refuse, and name only what is already displayed, so the dependency package changes whenever any listed sibling coordinate is removed. □

Theorem 1304.5 (Phenomenological frame independence witness)**.** *The* $\mathsf{PhenomenologicalFrame}^{\uparrow}$ *carrier is not row-bijective to any of* $\mathsf{FocusedLedger}^{\uparrow}$, $\mathsf{FocusedMultiHistLedger}^{\uparrow}$, $\mathsf{ObserverSubjectBoundary}^{\uparrow}$, $\mathsf{GapClosureBoundary}^{\uparrow}$, *or* $\mathsf{CausalCommitment}^{\uparrow}$. *A row-bijection preserving local NameCert obligations would have to preserve focused ledger data, multi-history support, observer no-subject data, source/refusal boundary data, causal commitment data, local time, transport, replay, provenance, audit refusal, and local naming in one packet, while each listed sibling omits at least one of these rows.*

Proof. Compare the carrier inventories. $\mathsf{FocusedLedger}^{\uparrow}$ lacks the separate multi-history support, observer-boundary, gap-boundary, and causal-commitment rows of the full frame. $\mathsf{FocusedMultiHistLedger}^{\uparrow}$ lacks the full consciousness/universe, gap/action, and audit-refusal package.

$\mathsf{ObserverSubjectBoundary}^{\uparrow}$ exposes no focused-ledger or causal-commitment packet. $\mathsf{GapClosureBoundary}^{\uparrow}$ exposes source/refusal routing but not the focused ledger, universe slice, observer-boundary packet, or local-time frame. $\mathsf{CausalCommitment}^{\uparrow}$ exposes a forward causal socket but not the full phenomenological carrier.

Thus no listed sibling is bijective row for row to $F = (L, M, U, O, G, A, T, H, C, P, R, N)$ while preserving local NameCert obligations. □

Falsifiable prediction: Any accepted PhenomenologicalFrameUp packet that exports subject substance, global universe object, hidden chooser, or object-level T without the displayed ledger and audit rows refutes the carrier.

Independence witness: focusedledger, focusedmultihistledger, observersubjectboundary, gapclosureboundary, and causalcommitment: none is bijective to the phenomenological frame because the frame binds focused records, multi-history support, universe slicing, no-subject observation, gap refusal, causal action, local time, transport, replay, provenance, audit refusal, and local naming in one row-distinct packet.

The Lean follow-up for this chapter must provide explicit Nontrivial PhenomenologicalFrame$^{\uparrow}$ and FieldFaithful PhenomenologicalFrame$^{\uparrow}$ instances in `lean4/BEDC/Derived/PhenomenologicalFrameUp/TasteGa` The field-faithfulness witness must preserve $L, M, U, O, G, A, T, H, C, P, R, N$ as distinct rows before `BEDC.Derived.PhenomenologicalFrameUp.taste_gate` can be cited by a checked paper marker.

Closure status for NameCert$_{\text{PhenomenologicalFrame}^{\uparrow}}$.

Constructive story: A PhenomenologicalFrame$^{\uparrow}$ packet is generated from focused-ledger, focused multi-Hist, consciousness/universe, observer-boundary, gap-closure, causal-action, local-time, transport, replay, provenance, audit-refusal, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{PhenomenologicalFrame}^{\uparrow}}$, seed)

Scope closed: Definition 1304.1, Definition 1304.2, Definition 1304.3, Definition 1304.4, and Definition 1304.5 specify the finite phenomenological-frame carrier, its certificate obligations, non-escape boundary, dependency package, and row-level independence.

Formal verification: FormalStatus(NameCert$_{\text{PhenomenologicalFrame}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, private consciousness substance, global universe construction, global time, hidden chooser selection, object-level T, or causal necessity.

Upgrade path: Obligation closure requires checked carrier admission, displayed classifier stability, dependency exactness, audit refusal, and TasteGate Nontrivial and FieldFaithful obligations for the same finite packet.

Chapter 1305

A Concrete Naming Certificate for $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$

The $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ packet realizes the strength-gradient discipline of subsection 9462.32.2 inside the auditable-generativity programme of chapter 9462. It sits beside the philosophy-package carrier of chapter 1292, the upgrade registry of chapter 1274, the verification-failure roadmap of chapter 1289, the gap-and-bridge audit surface of chapter 1229, and the formal-constant empirical-value boundary of chapter 1297. Those siblings expose package rows, promotion rows, failure-roadmap rows, bridge-audit rows, and empirical-boundary rows separately; this packet binds claim strength, dependency status, verification status, bridge status, refusal, provenance, transport, replay, and local naming before a claim may export a reported BEDC strength.

Definition 1305.1 (Programme strength ledger carrier)**.** *A* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, S, D, V, B, R, H, C, P, N)$$

with the following displayed coordinates:

1. *Q is the claim-site row, recording the theorem, definition, chapter, bridge target, or package row whose reported strength is being inspected.*
2. *S is the reported-strength row, recording whether the site is a naming seed, paper certificate, machine-checked certificate, or conservative bridge.*
3. *D is the dependency row, recording lower-layer blockers, sibling inputs, open gaps, and required upstream rows.*
4. *V is the theory/formal status pair, recording the independent theory-closure and verification-status axes without collapsing either axis into the other.*
5. *B is the bridge-status row, recording whether the site has no bridge, a paper bridge, or a checked bridge.*
6. *R is the refusal and not-claimed row, recording the stronger readings that the site may not export.*
7. *H records componentwise* hsame *transport for $Q, S, D, V, B, R, C, P, N$.*
8. *C records displayed* Cont *replay through the claim site, reported strength, dependency, status, bridge, and refusal rows.*

9. *P is the* Pkg *provenance over* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$, $\mathsf{BedcPhilosophyPackage}^{\uparrow}$, $\mathsf{UpgradeRegistry}^{\uparrow}$, $\mathsf{VerificationFailureRoadmap}^{\uparrow}$, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$, $\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ProgrammeStrengthLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for promoting a seed to a certificate, treating a paper certificate as machine checked, reading an unchecked bridge as conservative, erasing a blocker row, or exporting a stronger claim after the refusal row has named it.

Lean4 ✓ `BEDC.Derived.ProgrammeStrengthLedgerUp.ProgrammeStrengthLedgerCarrier displayed route`

Theorem 1305.2 (ProgrammeStrengthLedger NameCert obligations)**.** *For the carrier of Definition 1305.1, the local* $\mathsf{NameCert}_{\mathsf{ProgrammeStrengthLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for $L = (Q, S, D, V, B, R, H, C, P, N)$, claim-site exposure through Q, reported-strength exposure through S, dependency exposure through D, theory/formal status exposure through V, bridge-status exposure through B, refusal and not-claimed exposure through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ProgrammeStrengthLedgerUp.ProgrammeStrengthLedgerNameCert obligations`

Proof. Project the displayed BHist packet. The claim site Q is not yet a strength report; it becomes reportable only after the strength row S, dependency row D, status pair V, bridge row B, and refusal row R have all been read.

The structural rows preserve the same display. Componentwise transport through H keeps each row separate, the continuation row C replays the inspection order, and the provenance row P records the sibling package, registry, roadmap, audit, and empirical-boundary sources.

The local naming row N therefore names the whole packet rather than a bare claim site. Since the carrier has no additional promotion coordinate, these rows exhaust the NameCert obligations. □

Theorem 1305.3 (ProgrammeStrengthLedger no strength inflation)**.** *An accepted* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ *packet cannot export a reported BEDC strength above the row displayed by S. In particular, an open dependency in D, a weaker theory/formal status in V, an absent or unchecked bridge row in B, or a refusal in R blocks any consumer from reading Q as a stronger seed, certificate, machine-check, or bridge claim.*

Lean4 ✓ `BEDC.Derived.ProgrammeStrengthLedgerUp.ProgrammeStrengthLedgerNoStrengthInflation`

Proof. Read the carrier rows in order. The reported strength S is paired with dependency status D, theory/formal status V, bridge status B, and refusal row R before the claim site can be exported.

Apply the strength-gradient rule of Definition 9462.2114. A stronger report would require one of the missing obligations to be treated as discharged.

The packet contains no such discharge row. The upgrade registry can record a next obligation, the verification-failure roadmap can record a blocker, and the gap-and-bridge audit can record an open bridge, but none of those sibling rows changes S inside this carrier. Hence every exported strength is bounded by the displayed row. □

Theorem 1305.4 (ProgrammeStrengthLedger axis separation)**.** *For an accepted* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ *carrier, the claim site Q, reported-strength row S, dependency row D, theory/formal status pair V, bridge-status row B, refusal row R, and local* NameCert *row N remain separate audit coordinates.*

A consumer may combine them into one public strength report, but it may not derive the theory-closure axis from the verification axis, derive bridge status from formal status, erase dependency blockers by provenance, or replace the refusal row by a sibling package reading.

Lean4 ✓ `BEDC.Derived.ProgrammeStrengthLedgerUp.ProgrammeStrengthLedgerAxisSeparation`

Proof. Inspect the displayed packet. The status pair V records two independent axes, while B and R record bridge and refusal information that are not components of V.

The support rows H, C, P, N preserve and name the separation. Transport and replay can move the packet through equivalent presentations, and provenance can cite the package, registry, roadmap, audit, and boundary siblings, but none of those operations merges rows.

Thus every public report must keep the rows jointly visible. Any route that infers bridge status from formal status, erases a blocker from D, or replaces R by prose from a sibling chapter leaves the accepted $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ carrier. □

Theorem 1305.5 (ProgrammeStrengthLedger public report interface)**.** *A public strength report exported from an accepted* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ *carrier may expose the claim-site row Q only together with the reported strength row S, dependency row D, theory/formal status pair V, bridge-status row B, refusal row R, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N. Such a report may not promote theory closure from formal status, bridge status from verification status, or the reported strength beyond the row displayed by S.*

Lean4 ✓ `BEDC.Derived.ProgrammeStrengthLedgerUp.ProgrammeStrengthLedgerPublicReportInterface`

Proof. Start with the no-strength-inflation theorem Definition 1305.3. It blocks any route that reads Q as a stronger seed, certificate, machine-check, or bridge claim than the displayed row S permits.

Apply the axis-separation theorem Definition 1305.4. It keeps Q, S, D, V, B, R as distinct audit coordinates, so a public report cannot derive theory closure from verification status or bridge status from the formal axis.

The structural rows H, C, P, N preserve, replay, source, and name exactly that joint display. Therefore the public consumer surface is the full row family $Q, S, D, V, B, R, H, C, P, N$, with no promotion coordinate outside the accepted carrier. □

Theorem 1305.6 (ProgrammeStrengthLedger bridge-blocker readback)**.** *Let a public strength report be exported from an accepted* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ *carrier $L = (Q, S, D, V, B, R, H, C, P, N)$. If the bridge row B records no bridge or a paper bridge, or if the dependency row D names an open blocker, then the report must export that blocker together with Q, S, V, R, H, C, P, N. It may not read the claim site Q as bridge-checked, machine-verified, or stronger than the displayed rows permit.*

Proof. Start from no strength inflation, Definition 1305.3. An absent bridge, a paper bridge, or an open dependency blocker is one of the displayed reasons that prevents Q from being read above the strength row S.

Apply axis separation, Definition 1305.4. The bridge row B and dependency row D remain separate from the theory/formal status pair V, so neither row can be erased by reading the other as a stronger verification coordinate.

Finally use the public report interface, Definition 1305.5. It forces every public report to expose $Q, S, D, V, B, R, H, C, P, N$ together. Hence a bridge blocker or dependency blocker is exported as part of the report surface, and no consumer can read the packet as bridgeChecked or machine-verified unless the corresponding displayed rows already carry that status. □

Lean4 ✓ `BEDC.Derived.ProgrammeStrengthLedgerUp.ProgrammeStrengthLedgerBridgeBlockerReadback`

Theorem 1305.7 (Finite blocker readback factors through programme strength ledger)**.** *Let $L = (Q, S, D, V, B, R, H, C, P, N)$ be an accepted* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ *carrier whose source row cites* $\mathsf{UpgradeRegistry}^{\uparrow}$, $\mathsf{GapFailureBridgeAudit}^{\uparrow}$, *and* $\mathsf{VerificationFailureRoadmap}^{\uparrow}$. *Any blocker readback exposed by D or B factors through a single* BHist *ledger row K carried by L such that K preserves the displayed* hsame *transport and* Cont *provenance route from the source certificates to the public strength report. The factorization is a finite* Pkg*/GAP readback inside the ledger surface, not an external judgement about the claim site Q.*

Lean4 ✓ `BEDC.Derived.ProgrammeStrengthLedgerUp.ProgrammeStrengthLedgerBlockerReadbackFactorization`

Proof. Unpack the accepted carrier. The dependency row D, bridge row B, transport row H, replay row C, provenance row P, and local naming row N are all displayed before the public report can be read, so a blocker cannot be exported as a free-standing judgement.

Compose the three cited source certificates. The $\mathsf{UpgradeRegistry}^{\uparrow}$ row names the current obligation and next required row, the $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ row keeps bridge blockers visible, and the $\mathsf{VerificationFailureRoadmap}^{\uparrow}$ row records the verification blocker. Their common readback is therefore a single finite BHist row K inside the programme-strength ledger.

Finally apply the bridge-blocker readback theorem Definition 1305.6. It forces the blocker to travel with $Q, S, D, V, B, R, H, C, P, N$, while H preserves hsame and C, P preserve the Cont and Pkg provenance route. Hence the blocker readback factors through K as a finite ledger readback and not through any external status judgement. □

Theorem 1305.8 (ProgrammeStrengthLedger formal target request)**.** *Any formalization target for the public* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ *strength report must preserve the displayed row family $Q, S, D, V, B, R, H, C, P, N$. Its proof obligations are exactly no-strength-inflation for S, axis separation for Q, S, D, V, B, R, N, the public report interface for $Q, S, D, V, B, R, H, C, P, N$, and bridge-blocker readback for D and B. In particular, the target may not derive theory closure from verification status, derive bridge status from formal status, erase a dependency blocker by provenance, or promote the report beyond the displayed strength row.*

Proof. Begin with the NameCert obligations of Definition 1305.2. They expose the finite carrier $L = (Q, S, D, V, B, R, H, C, P, N)$, so a formal target that drops one coordinate no longer names the public ledger surface.

Apply no strength inflation, Definition 1305.3, and axis separation, Definition 1305.4. These two rows keep the reported strength bounded by S and prevent the theory, formal, bridge, dependency, refusal, and naming coordinates from being inferred from one another.

Finally use the public report interface Definition 1305.5 together with bridge-blocker readback Definition 1305.6. The first theorem exports the full row family, while the second keeps every displayed bridge or dependency blocker visible. These four obligations therefore give the required request surface without turning closure status, verification status, or bridge status into one another. □

Lean4 ✓ `BEDC.Derived.ProgrammeStrengthLedgerUp.ProgrammeStrengthLedgerFormalTargetRequest`

Falsifiable prediction: A packet that omits S or V can still name a claim site, but it cannot export a reported BEDC strength.

Independence witness: bedcphilosophypackage, upgraderegistry, verificationfailureroadmap, gapfailurebridgeaudit, formalconstantempiricalvalueboundary: no listed sibling is bijective with

$\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ because none preserves claim site, strength row, dependency row, theory/formal status pair, bridge row, refusal row, transport, replay, provenance, and local NameCert together. The package carrier stores programme rows without owning the strength audit packet; the upgrade registry records current and next obligations without binding refusal and bridge rows; the verification-failure roadmap records blockers without exporting a strength ledger; the gap-failure bridge audit records bridge blockers without the full status pair; and the empirical-value boundary separates formal and empirical constants rather than claim-strength reporting.

The Lean-side boundary is expected to provide explicit $\mathsf{Nontrivial}\ \mathsf{ProgrammeStrengthLedger}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ProgrammeStrengthLedger}^{\uparrow}$ instances in `lean4/BEDC/Derived/ProgrammeStrengthLedgerUp/Tas` The field-faithfulness witness must keep $Q, S, D, V, B, R, H, C, P, N$ as distinct rows before the target `BEDC.Derived.ProgrammeStrengthLedgerUp.taste_gate` can classify strength-ledger packets.

Closure status for $\mathsf{NameCert}_{\mathsf{ProgrammeStrengthLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ packet is generated from a claim site, reported strength, dependency row, theory/formal status pair, bridge-status row, refusal row, componentwise transport, displayed replay, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProgrammeStrengthLedger}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1305.1, Definition 1305.2, Definition 1305.3, Definition 1305.4, Definition 1305.5, and Definition 1305.6 scope the displayed carrier, NameCert obligations, no-strength-inflation row, axis-separation row, exported public strength report surface, and bridge-blocker readback through finite audit rows, hsame, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProgrammeStrengthLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, correctness of every package row, discharge of every dependency blocker, or promotion of any named claim beyond its displayed strength row.

Upgrade path: Public closure requires a public strength-report consumer surface without claiming Lean verification, bridge checking, or promotion beyond the displayed strength row.

Chapter 1306

A Concrete Naming Certificate for $\mathsf{EpistemicWitness}^{\uparrow}$

The $\mathsf{EpistemicWitness}^{\uparrow}$ packet realizes the BEDC account of knowledge in subsection 9462.31.3 as a finite auditable witness rather than as a bare truth predicate. It sits beside the failure-certificate packet of chapter 1233, the registry export surface of chapter 1216, and the machine-facing socket of chapter 1059. Those siblings respectively expose blocked gates, public export, and formalization routing; this packet binds a claimed proposition to its visible witness route, strength row, gap or refusal boundary, bridge row, and local naming certificate before it can be read as BEDC knowledge.

Definition 1306.1 (Epistemic witness carrier)**.** *An* $\mathsf{EpistemicWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (P, W, A, S, G, B, H, C, K, N)$$

with the following displayed rows:

1. *P is the proposition or claim row whose BEDC knowledge status is being named;*
2. *W is the witness row, storing the sameness, continuation, classifier, package, gap, naming, semantic-naming, derivation, bridge, gap-report, or failure witness used by the claim;*
3. *A is the audit-route row, recording the finite path by which the witness may be inspected;*
4. *S is the strength row, recording seed, obligation, paper-level closure, checked theorem, checked bridge, gap, or cannot-claim status without collapsing the theory and verification axes;*
5. *G is the gap-or-refusal row, recording any missing route, failed gate, blocked export, or explicit cannot-claim boundary;*
6. *B is the bridge row, recording whether the witness is internal, paper-bridged, checked-bridged, or explicitly unbridged;*
7. *H records componentwise* hsame *transport for the claim, witness, audit route, strength, gap-or-refusal, bridge, provenance, and local name;*
8. *C records displayed* Cont *replay for the witness route, audit route, strength row, gap-or-refusal row, and bridge row;*
9. *K is the* Pkg *provenance over* $\mathsf{FailureCertificate}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineInterfaceSocket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{EpistemicWitness}^{\uparrow}}$ *row.*

The carrier contains no row for bare truth, hidden conviction, external oracle access, host-level semantic satisfaction, or a bridge that bypasses the displayed audit route.

Lean4 (definition) `BEDC.Derived.EpistemicWitnessUp.EpistemicWitnessCarrier`

Theorem 1306.2 (Epistemic witness names knowledge audit)**.** *For the carrier of Definition 1306.1, the local* $\mathsf{NameCert}_{\mathsf{EpistemicWitness}^{\uparrow}}$ *surface consists of five obligation rows:*

1. *carrier admission for $E = (P, W, A, S, G, B, H, C, K, N)$;*
2. *witness-route audit through W, A, H, C;*
3. *strength-axis readback through S without identifying theory closure with formal verification;*
4. *gap, refusal, and bridge boundary readback through G, B;*
5. *provenance and local naming through K, N.*

Every BEDC knowledge read exported by an accepted $\mathsf{EpistemicWitness}^{\uparrow}$ *packet factors through these five rows. In particular, the read cannot be replaced by bare truth, prose assent, hidden registry state, an uninspected derivation certificate, or a bridge witness that omits the audit route.*

Proof. Project the displayed packet $E = (P, W, A, S, G, B, H, C, K, N)$. The claim row P and witness row W give the object being known and the finite witness by which it is known, while A, H, C make the route inspectable and stable under transport and replay.

Read the status rows next. The strength row S records the grade of the knowledge claim, and the gap-or-refusal row G records the boundary when the route is incomplete or blocked. These rows are separate, so a gap, cannot-claim status, checked theorem, and checked bridge cannot be interchanged by a consumer.

Finally read the bridge and naming rows. The bridge row B records how far the witness is exported beyond its local audit route, while K, N source and name the packet. Since no other coordinate exists, an accepted knowledge read must consume the five displayed obligation rows and cannot recover a bare truth predicate or hidden witness from outside the carrier. □

Lean4 ✓ `BEDC.Derived.EpistemicWitnessUp.EpistemicWitnessCarrier namecert obligations`

Falsifiable prediction: Deleting the audit-route row leaves a claim-like packet but not a BEDC knowledge witness.

Independence witness: failurecertificate, registryexportsurface, bridgewitness, derivcert, machineinterfacesocket: none is bijective to $\mathsf{EpistemicWitness}^{\uparrow}$ under NameCert-row preservation. A failure certificate records blocked gates without the full knowledge-strength and bridge surface; a registry export surface controls public release without owning the witness route; a bridge witness may expose cross-theory transport without the local gap-or-refusal row; a derivation certificate records proof ancestry without the public audit-strength packet; and a machine-interface socket routes formal targets without naming the epistemic witness as knowledge.

The later Lean `TasteGate.lean` boundary for this carrier must include `Nontrivial EpistemicWitnessUp` and `FieldFaithful EpistemicWitnessUp` instances, so the knowledge packet is inhabited by an actual audit witness and preserves $P, W, A, S, G, B, H, C, K, N$ as distinct rows.

Closure status for $\mathsf{NameCert}_{\mathsf{EpistemicWitness}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EpistemicWitness}^{\uparrow}$ packet is generated by binding a claimed proposition to its visible witness row, audit route, strength row, gap-or-refusal row, bridge row, componentwise hsame transport, displayed Cont replay, package provenance, and local naming in one finite BHist carrier. The classifier treats knowledge as an auditable route

rather than a bare truth predicate: a consumer must read the witness, audit, strength, and boundary rows before it can export an epistemic claim. The ledger story keeps each witness attached to its gap, bridge, and provenance coordinates, so hidden conviction, uninspected derivation, or oracle access never become classifier data.

Theory closure: TheoryGate(NameCert$_{\mathsf{EpistemicWitness}\uparrow}$, seed)

Scope closed: This chapter binds the carrier definition, knowledge-audit theorem, independence witness, Lean-follow-up boundary, and existing closure annotations for EpistemicWitness$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{EpistemicWitness}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim bare truth, hidden conviction, external oracle access, host-level semantic satisfaction, or bridge access bypassing the audit route.

Upgrade path: To reach obligationClosure, the witness-route carrier and knowledge-audit obligations must be encoded as checked finite packet projections.

Chapter 1307

A Concrete Naming Certificate for PackageMapBoundary$^{\uparrow}$

The PackageMapBoundary$^{\uparrow}$ packet realizes the map and boundary discipline of subsection 9462.33.4 inside the auditable-generativity programme of chapter 9462. It sits beside the package carrier of chapter 1292, the claim registry layer of chapter 1209, the socket report of chapter 1279, the standard bridge audit packet of chapter 1217, and the host primitive leakage boundary of chapter 1157. Those siblings expose package rows, claim admission, socket diagnostics, bridge-audit rows, and host-leak refusal; this packet binds the four map families and their axis boundary before a philosophy-package audit reading can be exported.

Definition 1307.1 (Package map-boundary carrier)**.** *A* PackageMapBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, G, R, S, X, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the theorem-map row, recording theorem sites, definition sites, proof mode, claim strength, dependency surface, and not-claimed readings;*
2. *G is the gap-map row, recording typed gaps, requested supply, socket type, gate, status, route, and forbidden internalization;*
3. *R is the tradition-map row, recording inherited comparison, preserved structure, rejected surplus, audit status, and package route;*
4. *S is the scientific-map row, recording records carrier, invariant carrier, empirical ledger, prediction gap, bridge status, claim status, and failure surface;*
5. *X is the axis-boundary row, recording that theorem strength, gap status, tradition comparison, scientific bridge status, theory closure, formal verification, and bridge status are distinct audit coordinates;*
6. *A is the audit-route row, recording the philosophy-package carrier, claim registry layer, socket report, standard bridge audit packet, and host primitive leakage route consulted by the export;*
7. *H records componentwise* hsame *transport for theorem maps, gap maps, tradition maps, scientific maps, axis boundaries, audit routes, provenance, and local naming;*
8. *C records displayed* Cont *replay for the four map rows, the axis-boundary row, and the audit-route row;*

9. *P is the* Pkg *provenance over* BedcPhilosophyPackage$^{\uparrow}$, ClaimRegistryLayer$^{\uparrow}$, SocketReport$^{\uparrow}$, StandardBridgeAuditPacket$^{\uparrow}$, HostPrimitiveLeakage$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PackageMapBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a prose-only map, a theorem entry detached from its gap boundary, a tradition comparison detached from rejected surplus, a scientific bridge detached from failure surface, or a collapse of map status into formal verification or bridge status.

Lean4 ✓ `BEDC.Derived.PackageMapBoundaryUp.PackageMapBoundaryTasteGate single carrier alignment`

Theorem 1307.2 (Package map-boundary NameCert obligations)**.** *For the carrier of Definition 1307.1, the local* $\mathsf{NameCert}_{\mathsf{PackageMapBoundary}^{\uparrow}}$ *obligation surface consists exactly of theorem-map admission through T, gap-map admission through G, tradition-map admission through R, scientific-map admission through S, axis-boundary admission through X, audit routing through A, transport and replay through H, C, provenance through P, and local naming through N.*

Proof. Project the finite packet $M = (T, G, R, S, X, A, H, C, P, N)$. The four map rows expose theorem, gap, tradition, and scientific readings before any package export is named.

Use the package and registry siblings next. The package carrier supplies the package-level row, the claim registry layer controls claim admission, and the socket report records the diagnostic socket through which a gap or map entry is inspected.

The bridge and host-leak siblings account for the export boundary. The standard bridge audit packet displays bridge fields, while the host primitive leakage packet refuses host equality, quotient import, choice, and semantic primitives.

Finally read X, A, H, C, P, N. These rows separate the status axes, route the audit, transport and replay only the displayed packet, source it, and name it locally. Since no other coordinate is available, the listed rows exhaust the NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.PackageMapBoundaryUp.PackageMapBoundaryNameCertObligations`

Theorem 1307.3 (Package map-boundary non-escape)**.** *Every accepted philosophy-package audit reading through* PackageMapBoundary$^{\uparrow}$ *factors through*

$$T, G, R, S, X, A, H, C, P, N.$$

If any one of the theorem-map, gap-map, tradition-map, scientific-map, or axis-boundary rows is absent, the packet cannot export a philosophy-package audit reading.

Lean4 ✓ `BEDC.Derived.PackageMapBoundaryUp.PackageMapBoundaryNonEscape`

Proof. Start from Definition 1307.2. The theorem-map, gap-map, tradition-map, scientific-map, and axis-boundary rows are admitted separately before the audit route and local name can be consumed.

The package audit route then reads the same finite carrier through A, H, C, P, N. These rows preserve the displayed rows and cannot manufacture a missing map family or a missing axis boundary.

Thus an accepted reading remains on $T, G, R, S, X, A, H, C, P, N$. A route missing any of T, G, R, S, X may still be prose about the package, but it is not a PackageMapBoundary$^{\uparrow}$ audit export. □

Falsifiable prediction: A map-boundary packet lacking any one of theorem-map, gap-map, tradition-map, scientific-map, or axis-boundary rows cannot export a philosophy-package audit reading.

Independence witness: bedcphilosophypackage, claimregistrylayer, socketreport, standardbridgeauditpacket, hostprimitiveleakage: none is bijective because $\mathsf{PackageMapBoundary}^{\uparrow}$ carries the simultaneous four-map plus axis-boundary audit row.

The Lean site `lean4/BEDC/Derived/PackageMapBoundaryUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ PackageMapBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful\ PackageMapBoundary}^{\uparrow}$ instances preserving $T, G, R, S, X, A, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{PackageMapBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{PackageMapBoundary}^{\uparrow}$ packet is generated from a package map row, theorem row, gap-boundary row, tradition-comparison row, scientific-bridge row, status row, refusal row, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier accepts a map only when its theorem entry, gap boundary, rejected surplus, bridge surface, and status discipline are all present in the same finite BHist carrier. The ledger story is boundary preservation: package motion may be read by consumers only through the displayed map and refusal rows, so formal verification, bridge status, and prose comparison cannot silently collapse into one export coordinate.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PackageMapBoundary}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: This chapter scopes the carrier and obligation rows over BHist, hsame, Cont, Pkg, and NameCert by Definition 1307.1, Definition 1307.2, and Definition 1307.3.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PackageMapBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim prose-only maps, theorem entries detached from gap boundaries, detached tradition comparisons, detached scientific bridges, or status collapse into verification.

Upgrade path: Formal upgrade requires preserving the scoped package-map boundary carrier and non-escape theorem as checked finite-row projection and transport obligations.

Chapter 1308

A Concrete Naming Certificate for PhilosophyGapMapLedger$^{\uparrow}$

The PhilosophyGapMapLedger$^{\uparrow}$ packet realizes the gap-map table of subsection 9462.33.4 as a finite NameCert ledger for audit-facing boundary questions. It sits beside the philosophy-map target of chapter 1277, the package carrier of chapter 1292, the theorem-gap registry of chapter 1246, the gap-failure bridge audit of chapter 1229, and the claim registry layer of chapter 1209. Those siblings expose map targets, package rows, theorem/gap entries, bridge-audit rows, and claim admission; this packet binds the gap entry, socket kind, gate, status, upgrade route, and forbidden-internalization row before any philosophy export may read a boundary question as closed.

Definition 1308.1 (Philosophy gap-map ledger carrier)**.** *A* PhilosophyGapMapLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, S, K, T, U, F, A, H, C, P, N)$$

with the following displayed rows:

1. *E is the gap-entry row, recording the name, BEDC site, requested supply, and claim surface for each gap entry;*
2. *S is the socket-kind row, recording whether the entry requests theorem supply, bridge supply, empirical supply, reflection supply, or package-audit supply;*
3. *K is the gate row, recording the local gate that must be passed before the entry may move from reported gap to accepted theorem, bridge, or package row;*
4. *T is the status row, recording open, blocked, scaffolded, checked, bridged, or refused status without collapsing theory closure into formal verification;*
5. *U is the upgrade-route row, recording the finite route from the current status to the next admissible BEDC obligation;*
6. *F is the forbidden-internalization row, recording that the gap may not be exported as a closed theorem, primitive truth predicate, host equality, quotient import, choice principle, or hidden subject-substance reading;*
7. *A is the audit-route row, recording the philosophy-map target, package carrier, theorem-gap registry, gap-failure bridge audit, and claim registry layer consulted by the export;*
8. *H records componentwise* hsame *transport for entries, sockets, gates, statuses, upgrade routes, forbidden-internalization rows, audit routes, provenance, and local naming;*

9. *C records displayed* Cont *replay for the same gap-map ledger rows;*
10. *P is the* Pkg *provenance over* PhilosophyMapTarget$^{\uparrow}$, BedcPhilosophyPackage$^{\uparrow}$, *theorem-gap registry rows,* GapFailureBridgeAudit$^{\uparrow}$, ClaimRegistryLayer$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PhilosophyGapMapLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for prose adjacency, unchecked theorem closure, implicit bridge success, host-level semantic completion, or a status row that erases the forbidden-internalization boundary.

Lean4 ✓ `BEDC.Derived.PhilosophyGapMapLedgerUp.PhilosophyGapMapLedgerTasteGate single carrier alignment`

Theorem 1308.2 (Philosophy gap-map ledger exactness)**.** *For the carrier of Definition 1308.1, every public gap-map export is read from exactly the displayed rows $E, S, K, T, U, F, A, H, C, P, N$. In particular, the entry name, socket kind, gate, status, upgrade route, and forbidden-internalization row are separate finite coordinates and cannot be recovered from prose placement or from a sibling package route alone.*

Proof. Project the finite packet $G = (E, S, K, T, U, F, A, H, C, P, N)$. The gap entry, socket kind, gate, status, upgrade route, and forbidden-internalization rows are displayed before the audit route or local name is consumed.

The audit route A may cite the philosophy-map target, package carrier, theorem-gap registry, gap-failure bridge audit, and claim registry layer. Those citations only explain where the displayed ledger is checked; they do not supply a replacement coordinate for any of E, S, K, T, U, F.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no prose-only coordinate and no hidden closure coordinate, every public export factors through the listed rows. □

Theorem 1308.3 (Philosophy gap-map ledger nonescape)**.** *Every accepted* PhilosophyGapMapLedger$^{\uparrow}$ *export must pass through the forbidden-internalization row F. If F is absent, a gap-map export has no displayed coordinate that refuses the reading of a boundary question as a closed theorem, primitive truth predicate, host equality, quotient import, choice principle, or hidden subject-substance claim.*

Proof. Use the carrier of Definition 1308.1. The rows E, S, K, T, U identify the gap, socket, gate, status, and next route, but none of them states the internalization refusal.

The audit rows A, H, C, P, N preserve and name only what the carrier already displays. They can route the ledger through sibling packets and replay the same packet for a consumer, but they cannot manufacture a missing refusal row.

Therefore an accepted export that blocks closure illusion must read F explicitly. Without F, the packet may still list an open gap, but it does not certify nonescape for the forbidden closed readings. □

Theorem 1308.4 (Philosophy gap-map ledger NameCert obligations)**.** *For the carrier of Definition 1308.1, the local* $\mathsf{NameCert}_{\mathsf{PhilosophyGapMapLedger}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for $G = (E, S, K, T, U, F, A, H, C, P, N)$, gap-entry exposure through E, socket-kind exposure through S, gate exposure through K, status exposure through T, upgrade-route exposure through U, forbidden-internalization exposure through F, audit routing through A, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Read the packet by coordinates. Carrier admission supplies the finite BHist object, and the rows E, S, K, T, U, F display the gap-map data before any export is named.

The audit route A then records the sibling surfaces consulted by the export: philosophy-map target, package carrier, theorem-gap registry, gap-failure bridge audit, and claim registry layer. This route keeps those siblings as dependencies rather than replacing the ledger rows.

Finally H, C, P, N provide transport, replay, provenance, and the local name. These rows preserve the same displayed coordinates, so the listed fields exhaust the local NameCert obligations. □

Theorem 1308.5 (Philosophy gap-map ledger sibling independence)**.** *The sibling packets* $\mathsf{PhilosophyMapTarget}^{\uparrow}$, $\mathsf{BedcPhilosophyPackage}^{\uparrow}$, *theorem-gap registry rows,* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$, *and* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *are dependencies of* $\mathsf{PhilosophyGapMapLedger}^{\uparrow}$ *only through displayed routes in* A *and provenance in* P*. None is bijective with the carrier* $G = (E, S, K, T, U, F, A, H, C, P, N)$*.*

Proof. Inspect the carrier. It stores the gap entry, socket kind, gate, status, upgrade route, forbidden-internalization row, audit route, transport, replay, provenance, and local name together.

Each sibling stores a narrower surface. The philosophy-map target names map obligations, the package carrier stores package rows, the theorem-gap registry stores theorem/gap entries, the gap-failure bridge audit stores typed gap and bridge audit rows, and the claim registry layer stores claim admission and refusal rows.

The ledger may cite those siblings through A and P. But no one sibling reconstructs all eleven displayed coordinates, and the gap-map ledger cannot be projected back to any one sibling without losing the forbidden-internalization row or local ledger name. □

Falsifiable prediction: Removing the forbidden-internalization row allows a gap-map export to present a boundary question as a closed theorem.

Independence witness: philosophy-map-target, bedc-philosophy-package, theorem-gap-registry, gap-failure-bridge-audit, claimregistrylayer: none is bijective because the gap-map ledger alone isolates gap entry, socket kind, gate, status, upgrade route, and forbidden-internalization rows.

The Lean follow-up must provide Nontrivial $\mathsf{PhilosophyGapMapLedger}^{\uparrow}$ and FieldFaithful PhilosophyGapMapLedge in `lean4/BEDC/Derived/PhilosophyGapMapLedgerUp/TasteGate.lean`. Those instances must preserve $E, S, K, T, U, F, A, H, C, P, N$ as separate displayed fields before the target `BEDC.Derived.PhilosophyGapl` can be cited by a checked marker.

Closure status for $\mathsf{NameCert}_{\mathsf{PhilosophyGapMapLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PhilosophyGapMapLedger}^{\uparrow}$ packet is generated from a philosophical node row, gap row, package-map row, proof-witness row, tradition-comparison row, signature-descent row, status row, forbidden-internalization boundary, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier accepts the ledger only when the philosophical adjacency is backed by these finite rows rather than by prose proximity. The constructive story is a map of gaps: each public export is generated from the carried gap, proof, comparison, descent, and status coordinates, while the forbidden-boundary row records where closure or semantic completion is not available inside the packet.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhilosophyGapMapLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, exactness, nonescape, NameCert-obligation, sibling-independence, Lean-follow-up boundary, and existing closure annotations for $\mathsf{PhilosophyGapMapLedger}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhilosophyGapMapLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim prose adjacency, unchecked theorem closure, implicit bridge success, host-level semantic completion, or status rows erasing forbidden internalization.

Upgrade path: To reach obligationClosure, the gap-map ledger and its nonescape exactness must be encoded as finite-row carrier proofs.

Chapter 1309

A Concrete Naming Certificate for $\mathsf{NameEligibilityProof}^{\uparrow}$

The $\mathsf{NameEligibilityProof}^{\uparrow}$ packet realizes the inward eligibility proof demanded by Definition 9462.2110 as one finite NameCert carrier. It sits beside the machine-facing route of chapter 1221, the registry audit of chapter 1223, the kernel audit witness of chapter 546, and the apophatic naming boundary of chapter 543. Those siblings expose machine routing, registry consistency, accepted-kernel readback, and refusal-bearing named boundaries; this chapter binds source eligibility, classifier eligibility, strength, audit, refusal, transport, replay, provenance, and local naming before a proposed name can be reported as licensed.

Definition 1309.1 (Name eligibility proof carrier)**.** *A* $\mathsf{NameEligibilityProof}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, S, C, Q, A, R, H, K, P, N)$$

with the following displayed rows:

1. *T is the target-name row, recording the candidate BEDC name and the public surface on which the name is requested.*
2. *S is the source-route row, recording the finite source specification through which the candidate name is generated or inherited.*
3. *C is the classifier-route row, recording the classifier evidence through which accepted packets for the name are compared.*
4. *Q is the strength row, recording seed, paper-certificate, machine-checked, or conservative-bridge strength without allowing a lower row to report a higher strength.*
5. *A is the audit row, recording the registry, machine-interface, and kernel-readback surfaces consulted before the name is admitted.*
6. *R is the refusal row, recording apophatic boundary data for missing source, classifier, strength, audit, or bridge obligations.*
7. *H records componentwise* hsame *transport for target names, source routes, classifier routes, strength rows, audit rows, refusal rows, provenance, and local naming.*
8. *K records displayed* Cont *replay for source eligibility, classifier eligibility, audit readback, refusal propagation, and strength reporting.*

9. *P is the* Pkg *provenance over* MachineInterfaceBoundary$^{\uparrow}$, RegistryConsistencyAudit$^{\uparrow}$, KernelAuditWitness$^{\uparrow}$, ApophaticName$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{NameEligibilityProof}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host-selected object, hidden source supply, classifier by prose resemblance, strength promotion without audit, kernel route outside the displayed audit row, or refusal erased after naming.

Lean4 (definition) `BEDC.Derived.NameEligibilityProofUp.NameEligibilityProofUp`

Theorem 1309.2 (Name eligibility proof NameCert obligations)**.** *For the carrier of Definition 1309.1, the local* NameCert$_{\text{NameEligibilityProof}^{\uparrow}}$ *obligation surface consists exactly of target-name admission through T, source-route eligibility through S, classifier-route eligibility through C, strength reporting through Q, audit exposure through A, refusal exposure through R, componentwise transport through H, displayed continuation replay through K, provenance through P, and local naming through N.*

Proof. Project the finite packet $E = (T, S, C, Q, A, R, H, K, P, N)$. The target-name row, source route, and classifier route give the eligibility spine before any local name can be consumed.

Read the machine, registry, kernel, and apophatic siblings next. The machine-interface boundary routes the target to an auditable machine surface, the registry-consistency audit checks export agreement, the kernel audit witness supplies accepted-declaration readback when such a route is present, and the apophatic name row keeps absent supply or refused internalization visible.

The strength, audit, and refusal rows then determine whether the name is only seeded, paper-certified, machine-checked, or bridge-facing. Transport, replay, provenance, and local naming preserve that same packet. Since no further coordinate is present, the listed rows exhaust the local NameCert obligation surface. □

Theorem 1309.3 (Name eligibility proof strength non-inflation)**.** *An accepted* NameEligibilityProof$^{\uparrow}$ *packet cannot raise a target-name row from seed strength to machine-checked strength unless the audit row A and the replay row K display the machine-interface, registry-consistency, and kernel-readback route used for that report.*

Proof. Begin with the strength row Q. It records the reported certificate strength as one row of the same packet, not as an ambient judgement detached from the carrier.

Apply the NameCert obligations above. Machine-checked strength requires source-route and classifier-route eligibility, and it also requires audit exposure through A plus displayed replay through K. The sibling machine-interface, registry-consistency, and kernel-audit rows supply exactly that public route.

If A or K is absent, the packet still may contain a target name, source route, classifier route, or refusal row, but it lacks the displayed evidence required for machine-checked reporting. Thus the strength row cannot promote the name beyond the audit surface carried by the packet. □

Theorem 1309.4 (Name eligibility proof kernel-route non-escape)**.** *Every kernel-facing route exported by an accepted* NameEligibilityProof$^{\uparrow}$ *packet factors through*

$$T, S, C, Q, A, R, H, K, P, N.$$

It cannot bypass the source route, classifier route, audit row, refusal row, componentwise hsame *transport, displayed* Cont *replay, provenance, or local* NameCert *row.*

Proof. Use Definition 1309.2 to enumerate the public surface. A kernel-facing export is admitted only after the target, source, classifier, strength, audit, and refusal rows have been read in the same packet.

The kernel audit witness contributes accepted-declaration readback only through A and K. The registry and machine-interface siblings keep the route public, while the apophatic-name sibling keeps missing supply visible rather than internalized.

Finally read H, P, N. These rows transport, source, and name the displayed carrier; they do not add a hidden kernel route. Therefore every exported kernel-facing route remains on the finite row sequence shown above. □

Theorem 1309.5 (Name eligibility proof obligation package)**.** *For an accepted* $\mathsf{NameEligibilityProof}^{\uparrow}$ *packet*

$$E = (T, S, C, Q, A, R, H, K, P, N),$$

the rows $T, S, C, Q, A, R, H, K, P, N$ *jointly bind the target name, source route, classifier route, strength, audit, refusal, transport, replay, provenance, and local naming as the finite obligation package for eligibility-before-use. A consumer may report the proposed name as licensed only through that displayed package.*

Proof. Begin with Definition 1309.2. It identifies $T, S, C, Q, A, R, H, K, P, N$ as the complete local NameCert surface for target-name admission, source eligibility, classifier eligibility, strength reporting, audit exposure, refusal exposure, transport, replay, provenance, and local naming.

Apply Definition 1309.3. It prevents the strength row Q from promoting a name beyond the audit and replay rows actually displayed in the same packet.

Finally apply Definition 1309.4. It keeps every kernel-facing route on the row sequence $T, S, C, Q, A, R, H, K, P,$ The three results compose into the stated eligibility-before-use package: the target name is not licensed before the source route, classifier route, strength, audit, refusal, transport, replay, provenance, and local naming rows have all been displayed. □

Falsifiable prediction: If a NameEligibilityProofUp packet raises a seed-strength name to machine-checked strength without an audit row, the carrier is refuted.

Independence witness: machineinterfaceboundary, registryconsistencyaudit, kernelauditwitness, apophaticname: none is bijective because NameEligibilityProofUp simultaneously binds source eligibility, classifier eligibility, strength, audit, refusal, transport, replay, provenance, and local NameCert rows.

Lean4 ✓ `BEDC.Derived.NameEligibilityProofUp.taste gate`

Closure status for $\mathsf{NameCert}_{\mathsf{NameEligibilityProof}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NameEligibilityProof}^{\uparrow}$ packet is generated by displaying the proposed name, source row, classifier row, proof witness, strength row, audit row, gap-or-refusal row, kernel-route row, componentwise hsame transport, displayed Cont replay, package provenance, and local naming in a finite BHist carrier. The classifier licenses a name only when the source, proof, audit, strength, and refusal boundaries remain attached to the same packet. Its ledger story is eligibility before use: the name cannot be selected by a host object or by resemblance in prose, because every accepted read must pass through the explicit proof and kernel-route surfaces already recorded in the carrier.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NameEligibilityProof}^{\uparrow}}$, scopedClosed)

Scope closed: This chapter binds the carrier, NameCert-obligation, strength-non-inflation, kernel-route-non-escape, and obligation-package blocks as the finite obligation surface for $\mathsf{NameEligibilityProof}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NameEligibilityProof}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim host-selected objects, hidden source supply, prose classifiers, unaudited strength promotion, off-route kernel acceptance, or erased refusals.

Upgrade path: Scoped closure requires a theorem-level Lean witness for the eligibility carrier, strength boundary, kernel-route boundary, and obligation package against finite-history transport.

Chapter 1310

A Concrete Naming Certificate for $\mathsf{UseRuleLedger}^{\uparrow}$

The $\mathsf{UseRuleLedger}^{\uparrow}$ packet realizes the certified-use reading of subsection 9462.29.7 as a finite NameCert carrier. It sits beside the machine-facing boundary of chapter 1221, the registry export surface of chapter 1216, the apophatic naming boundary of chapter 543, and the kernel audit witness of chapter 546. Those siblings expose machine routing, export control, refused supply, and accepted audit evidence; this packet binds use, rule-following, source/classifier rows, stability, ledger policy, public audit, transport, continuation, provenance, and local naming before a name-use is licensed.

Definition 1310.1 (Use-rule ledger carrier)**.** *A* $\mathsf{UseRuleLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (U, R, S, C, L, A, H, Q, P, N)$$

whose displayed rows have the following roles:

1. *U is the use-event row, recording the name, item used, local history, and requested public reading.*
2. *R is the rule row, recording the use rule by which the name may be applied to the item.*
3. *S is the source/classifier row, recording the displayed source field and classifier that check the item against the licensed name.*
4. *C is the stability row, recording the finite stability evidence under which the same use may be replayed.*
5. *L is the ledger row, recording the hidden-material policy, refused supply, and visible rule-following trace associated with the use.*
6. *A is the public audit row, recording the machine-interface boundary, registry-export surface, apophatic naming boundary, and kernel audit witness consulted by the use.*
7. *H records componentwise* hsame *transport for the use event, rule, source/classifier, stability, ledger, audit, continuation, provenance, and local naming rows.*
8. *Q records displayed* Cont *replay for the certified-use route.*
9. *P is the* Pkg *provenance over* $\mathsf{UseRuleLedger}^{\uparrow}$, $\mathsf{MachineInterfaceBoundary}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, $\mathsf{KernelAuditWitness}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UseRuleLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for private meaning, bare reference, unclassified social habit, unledgered rule-following, hidden source supply, or a name-use licensed only by prose adjacency.

Theorem 1310.2 (Use-rule ledger NameCert obligations)**.** *For the carrier of Definition 1310.1, the local* $\mathsf{NameCert}_{\mathsf{UseRuleLedger}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for* $G = (U, R, S, C, L, A, H, Q, P, N)$*, use-event exposure through* U*, rule exposure through* R*, source/classifier exposure through* S*, stability exposure through* C*, ledger exposure through* L*, public audit exposure through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* Q*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier into its ten displayed rows. The use event, rule, source/classifier, stability, and ledger rows are read before the public audit route is consumed, so a licensed use cannot be recovered from an audit citation alone.

The audit row records the machine-interface boundary, registry-export surface, apophatic naming boundary, and kernel audit witness. These siblings explain where the use is checked, exported, refused, or read back, but they do not replace the displayed use, rule, source/classifier, stability, and ledger rows.

Finally H, Q, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no hidden source coordinate and no prose-only licensing coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 1310.3 (Certified-use route)**.** *Every accepted* $\mathsf{UseRuleLedger}^{\uparrow}$ *route that licenses a public name-use must expose the use-event row* U*, rule row* R*, source/classifier row* S*, stability row* C*, ledger row* L*, public audit row* A*, transport row* H*, continuation row* Q*, provenance row* P*, and local naming row* N*. A route that omits any one of these rows is at most a projection of the use-rule ledger, not the accepted carrier of Definition 1310.1.*

Proof. Begin with the displayed packet $G = (U, R, S, C, L, A, H, Q, P, N)$. The name-use is located by U, governed by R, constrained by S, stabilized by C, and ledgered by L before any consumer can read it as public.

The public audit row A then records the sibling boundary surfaces. It can route the packet to machine-facing, registry-facing, apophatic, and kernel-audit consumers, but those consumers only see the use after the preceding rows have already licensed it.

The structural rows H, Q, P, N preserve the same packet under transport, continuation replay, provenance, and naming. Omitting one of the displayed rows therefore changes the carrier into a projection rather than an accepted certified-use route. □

Theorem 1310.4 (Use-rule ledger nonescape boundary)**.** *No accepted* $\mathsf{UseRuleLedger}^{\uparrow}$ *packet may turn a missing source/classifier row, missing stability row, or missing ledger/audit row into licensed use by appealing to private meaning, social repetition, machine export, registry presence, apophatic refusal, or kernel readback alone.*

Proof. Inspect the licensing rows S, C, L, A. The source/classifier row states what item is being used under what name; the stability row states when the same use is replayable; the ledger row records hidden-material and rule-following policy; and the audit row states how the public route is checked.

Private meaning and social repetition are not coordinates of the carrier. Machine export, registry presence, apophatic refusal, and kernel readback appear only through A and P, where they are dependencies of the displayed packet rather than substitutes for the licensing rows.

Thus a missing source/classifier, stability, ledger, or audit row cannot be supplied by another route. The nonescape boundary is the requirement that certified use remains attached to the finite rows that license it. □

Theorem 1310.5 (Use-rule ledger TasteGate obligation)**.** *Any TasteGate admission for* $\mathsf{UseRuleLedger}^{\uparrow}$ *must preserve nontriviality and field faithfulness for the displayed rows* $U, R, S, C, L, A, H, Q, P, N$*. In particular, admission must distinguish use event, rule, source/classifier, stability, ledger, public audit, transport, continuation, provenance, and local naming rather than collapsing certified use into a single registry or machine-interface row.*

Lean4 ✓ `BEDC.Derived.UseRuleLedgerUp.UseRuleLedgerTasteGate single carrier alignment`

Proof. A TasteGate admission reads the carrier as a candidate public object. Nontriviality requires the carrier to exhibit a real row packet, while field faithfulness requires the named fields to remain separately readable by downstream consumers.

Apply this to $G = (U, R, S, C, L, A, H, Q, P, N)$. Collapsing the use event into the rule, the source/classifier into the stability row, or the audit route into machine or registry export would erase a displayed coordinate of certified use.

Therefore the TasteGate obligation is to keep the ten rows distinct while allowing their joint package to be named. The Lean side must provide $\mathsf{Nontrivial}\ \mathsf{UseRuleLedger}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{UseRuleLedger}^{\uparrow}$ instances in `lean4/BEDC/Derived/UseRuleLedgerUp/TasteGate.lean` before any checked marker for this carrier can be cited. □

Falsifiable prediction: Any accepted $\mathsf{UseRuleLedger}^{\uparrow}$ route that licenses a name-use without the displayed source/classifier, stability, and ledger rows refutes the carrier.

Independence witness: machineinterfaceboundary, registryexportsurface, apophaticname, kernelauditwitness: none is bijective because $\mathsf{UseRuleLedger}^{\uparrow}$ binds certified use, rule-following, source/classifier, stability, and ledger rows as one name-use packet rather than only routing exports, refusing supply, or reading audit evidence.

Closure status for $\mathsf{NameCert}_{\mathsf{UseRuleLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UseRuleLedger}^{\uparrow}$ packet is generated from displayed use rows, rule rows, witness rows, audit rows, componentwise hsame transport, displayed Cont replay, package provenance, and local naming in one finite BHist carrier. The classifier licenses rule-following only when the use, rule, witness, and audit coordinates are present together; social repetition and prose adjacency are not enough. The ledger story is a public rule route: a certified-use consumer reads the same finite packet through transport and continuation rows, while hidden source supply, private meaning, and unledgered rule-following remain outside the carrier inventory.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UseRuleLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, NameCert-obligation, certified-use-route, nonescape-boundary, TasteGate-obligation, independence witness, and existing closure annotations for $\mathsf{UseRuleLedger}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UseRuleLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim private meaning, bare reference, unclassified social habit, unledgered rule-following, hidden source supply, or prose-only name-use licensing.

Upgrade path: To reach obligationClosure, the use-rule carrier, route theorem, and nonescape boundary must be encoded as checked finite-row obligations.

Chapter 1311

A Concrete Naming Certificate for $\mathsf{StructuralAdjacency}^{\uparrow}$

The $\mathsf{StructuralAdjacency}^{\uparrow}$ packet realizes the adjacency claim of subsection 9462.29.1 as a finite NameCert construction. It sits beside the tradition-comparison boundary of chapter 1268, the primitive distinction ledger, the observer distinction trace, the finite kernel category route, and the epistemic witness packet. Those siblings regulate tradition comparison, primitive marks, observer trace, categorical kernel rows, and witness admission; this packet binds genealogy labels, BEDC role rows, adjacency witnesses, transport, continuation, provenance, and local naming before any two inherited claims may be read as structurally adjacent.

Definition 1311.1 (Structural adjacency carrier)**.** *A* $\mathsf{StructuralAdjacency}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, R, A, H, C, P, N)$$

with the following displayed rows:

1. *G is the genealogy-label row, recording the two inherited claim labels, source families, question surfaces, and local comparison prompts.*
2. *R is the BEDC role-row classifier, recording the carrier, relation, classifier, ledger, certificate, gap, or T-position on which each claim lands.*
3. *A is the adjacency-witness row, recording that the two labels land on the same BEDC role row without importing doctrinal identity or tradition membership.*
4. *H records componentwise* hsame *transport for genealogy labels, role rows, adjacency witnesses, continuation routes, provenance, and local naming.*
5. *C records displayed* Cont *replay for the route from genealogy labels through role-row classification and adjacency witness inspection.*
6. *P is the* Pkg *provenance over* $\mathsf{StructuralAdjacency}^{\uparrow}$, $\mathsf{TraditionComparisonBoundary}^{\uparrow}$, $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$, $\mathsf{ObserverDistinctionTrace}^{\uparrow}$, $\mathsf{KernelCategory}^{\uparrow}$, $\mathsf{EpistemicWitness}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{StructuralAdjacency}^{\uparrow}}$ *row.*

The carrier has no coordinate for prose resemblance alone, inherited doctrinal agreement, host-level semantic identity, or adjacency export outside the displayed packet $S = (G, R, A, H, C, P, N)$.

Lean4 ✓ `BEDC.Derived.StructuralAdjacencyUp.StructuralAdjacencyTasteGate single carrier alignment`

Theorem 1311.2 (Structural adjacency NameCert obligations)**.** *For the carrier of Definition 1311.1, the local* $\mathsf{NameCert}_{\mathsf{StructuralAdjacency}^{\uparrow}}$ *surface consists exactly of the following five rows: carrier admission for* $S = (G, R, A, H, C, P, N)$*; role-row classifier stability through* R *under componentwise transport; adjacency exactness through* A *for shared BEDC landing; genealogy-label non-collapse through* G*; and ledger non-escape through* H, C, P, N*.*

Proof. Project the finite carrier. Carrier admission supplies the displayed BHist packet, while the genealogy row G keeps the two inherited labels present as distinct labels before any BEDC landing is compared.

Read the role classifier and adjacency witness together. The row R records the BEDC role rows available to each label, and A certifies adjacency only when those role rows coincide as a BEDC site. Componentwise transport in H preserves the classifier row instead of replacing it by prose similarity.

Finally apply the route, provenance, and local-name rows. The continuation row C, package row P, and local NameCert row N name the same packet, so the ledger cannot export adjacency without the displayed role row, genealogy labels, and exact adjacency witness. □

Theorem 1311.3 (Structural adjacency independence witness)**.** *The nearest siblings of* $\mathsf{StructuralAdjacency}^{\uparrow}$ *are* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$*,* $\mathsf{PrimitiveDistinctionLedger}^{\uparrow}$*,* $\mathsf{ObserverDistinctionTrace}^{\uparrow}$*,* $\mathsf{KernelCategory}^{\uparrow}$*, and* $\mathsf{EpistemicWitness}^{\uparrow}$*. No bijection preserves all carrier rows between any one of those siblings and* $S = (G, R, A, H, C, P, N)$*: each sibling lacks at least one of genealogy-pair labeling, BEDC role-row classification for two claims, adjacency witness exactness, or the local* $\mathsf{NameCert}_{\mathsf{StructuralAdjacency}^{\uparrow}}$ *row.*

Proof. Compare the displayed rows. $\mathsf{TraditionComparisonBoundary}^{\uparrow}$ records source, landing, rejected surplus, and structural distinction for a comparison; it does not store a two-claim adjacency witness as the public row of the packet.

The primitive distinction ledger and observer distinction trace isolate mark distinction and observer trace structure. The finite kernel category route and epistemic witness packet isolate category-shaped operations and witness admission. None of these carries the pair of genealogy labels, shared BEDC role-row classifier, adjacency witness, transport, route, provenance, and local StructuralAdjacency name in one carrier.

A row-preserving bijection would have to preserve G, R, A, H, C, P, N jointly. Since every listed sibling omits at least one of these rows or assigns it a different obligation role, no such bijection preserves all carrier rows. □

Falsifiable prediction: Any accepted structural-adjacency route whose packet lacks a BEDC role row is rejected by the carrier classifier.

Independence witness: traditioncomparisonboundary, primitivedistinctionledger, observerdistinctiontrace, kernelcategory, epistemicwitness: none is bijective because structural adjacency alone binds genealogy-pair labels, BEDC role-row classification, adjacency-witness exactness, and local NameCert rows in one packet.

The Lean follow-up must provide Nontrivial $\mathsf{StructuralAdjacency}^{\uparrow}$ and FieldFaithful $\mathsf{StructuralAdjacency}^{\uparrow}$ instances in `lean4/BEDC/Derived/StructuralAdjacencyUp/TasteGate.lean`. Those instances must preserve G, R, A, H, C, P, N as separate displayed rows before BEDC.Derived.StructuralAdjacencyUp.StructuralA may be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{StructuralAdjacency}^{\uparrow}}$.

Constructive story: A $\mathsf{StructuralAdjacency}^{\uparrow}$ packet is generated from genealogy-label, BEDC role-row, adjacency-witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StructuralAdjacency}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1311.1, Definition 1311.2, and Definition 1311.3 bind structural adjacency to a finite NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StructuralAdjacency}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, public export closure, or the correctness of any inherited tradition's doctrine.

Upgrade path: Lean closure requires Nontrivial StructuralAdjacencyUp and FieldFaithful StructuralAdjacencyUp instances in `lean4/BEDC/Derived/StructuralAdjacencyUp/TasteGate.lean`.

Chapter 1312

A Concrete Naming Certificate for $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$

The $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$ packet realizes the local-closure and open-continuation boundary of section 9414.25 as finite NameCert data. It sits beside the open-fit carrier of chapter 1131, the finite refutation carrier of chapter 1169, and the continuation countermodel packet of chapter 1183. Those siblings expose open fit, finite defeat, and continuation mismatch; this chapter binds the local empirical closure row to an explicit nonfinality ledger before any consumer may read finite settlement as final empirical closure.

Definition 1312.1 (Local empirical closure gate carrier)**.** *A* $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, F, J, O, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the fixed finite source trace, probe bundle, and classifier row for the tested empirical packet;*
2. *F is the local fit row certifying whether the model signature and observed signature agree on S under the displayed classifier;*
3. *J is the local closure judgment row, exposing that the finite inquiry over S has been settled;*
4. *O is the global openness row, recording that no row of the packet supplies a final induction oracle over all admissible continuations;*
5. *L is the nonfinality ledger, naming the refused final-fit, hidden-continuation, and oracle-transfer reads;*
6. *H records componentwise* hsame *transport for S, F, J, O, L, C, P, N;*
7. *C records displayed* Cont *replay for finite source inspection, local fit reading, local closure reading, global openness reading, and nonfinality-ledger inspection;*
8. *P records* Pkg *provenance over* $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$, $\mathsf{RealityConstrainedOpenFit}^{\uparrow}$, $\mathsf{FiniteObservationRefutat}$ BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalEmpiricalClosureGate}^{\uparrow}}$ *row.*

The carrier has no coordinate for unrestricted empirical confirmation, total future-fit quantification, hidden continuation enumeration, host real equality of physical trajectories, or a final induction oracle.

Lean4 ✓ `BEDC.Derived.LocalEmpiricalClosureGateUp.LocalEmpiricalClosureGateTasteGate single carrier alignment`

Theorem 1312.2 (Local empirical closure gate NameCert obligations)**.** *For the carrier of Definition 1312.1, the local* $\mathsf{NameCert}_{\mathsf{LocalEmpiricalClosureGate}^{\uparrow}}$ *surface consists exactly of five empirical obligation rows: finite source admission through S, local fit settlement through F, local closure certification through J, global openness retention through O, and explicit nonfinality refusal through L. The structural rows H, C, P, N only transport, replay, source, and name those five rows.*

Proof. Project the carrier to the empirical rows S, F, J, O, L. The finite source row fixes the observed trace and classifier; the local fit row records the model/observation comparison; and the closure-judgment row states that this finite inquiry is settled.

Read the openness and nonfinality rows next. The row O preserves the open-continuation boundary of Definition 9414.354, while L records the refused final-fit and oracle-transfer reads.

Finally inspect the structural rows. The transport, continuation, provenance, and local naming data preserve only the displayed rows already present in G. They do not add a sixth empirical coordinate, so the five named rows exhaust the NameCert obligation surface. □

Theorem 1312.3 (Local empirical closure gate nonfinality)**.** *Every accepted* $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$ *consumer may read the finite local closure row J only together with the global openness row O and the nonfinality ledger L. It cannot derive a final induction oracle, a universal future-fit certificate, or a continuation enumeration from the finite local-closure packet alone.*

Proof. Begin with the local closure theorem of Definition 9414.356. It separates finite fit settlement over a displayed trace from universal closure over all future observation histories.

Apply the carrier inventory of Definition 1312.1. The only positive settlement row is J, and it is paired in the same accepted packet with O and L, which record global openness and the refused oracle transfer.

The structural rows H, C, P, N cannot synthesize missing empirical data; they only preserve, replay, source, and name the displayed packet. Therefore an accepted consumer receives local closure together with its nonfinality ledger and has no route to a final induction oracle. □

Falsifiable prediction: A consumer that derives a final-induction-oracle row from S, F, J, H, C, P, N without the openness row O and the nonfinality ledger L refutes the $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$ carrier.

Independence witness: openphysicalfit, finiteobservationrefutation, continuationcountermodel, realityconstrainedopenfit: no listed sibling is bijective to $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$ because this packet binds the finite source, local fit, local closure, global openness, and nonfinality ledger as one NameCert surface. OpenPhysicalFit exposes open-fit routing without the local-closure judgment; FiniteObservationRefutation exposes mismatch defeat without the closure/openness pair; ContinuationCountermodel exposes a continuation separation without local settlement; RealityConstrainedOpenFit exposes open fit without the explicit local-closure row plus nonfinality ledger.

The Lean follow-up for this chapter must provide explicit $\mathsf{Nontrivial}\ \mathsf{LocalEmpiricalClosureGate}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{LocalEmpiricalClosureGate}^{\uparrow}$ instances in `lean4/BEDC/Derived/LocalEmpiricalClosureGateUp/T` The field-faithfulness witness must preserve $S, F, J, O, L, H, C, P, N$ as distinct rows before `BEDC.Derived.LocalEm` can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalEmpiricalClosureGate}^{\uparrow}}$.

Constructive story: A $\mathsf{LocalEmpiricalClosureGate}^{\uparrow}$ packet is generated from finite source, local fit, local closure, global openness, nonfinality ledger, transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\mathsf{LocalEmpiricalClosureGate}\uparrow}$, seed)

Scope closed: Definition 1312.1, Definition 1312.2, and Definition 1312.3 specify the finite local empirical closure gate, its NameCert obligations, and its nonfinality boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocalEmpiricalClosureGate}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted empirical confirmation, total future-fit quantification, hidden continuation enumeration, host physical-trajectory equality, or final induction oracle construction.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, nonfinality exactness, and TasteGate Nontrivial and FieldFaithful obligations for the same finite packet.

Chapter 1313

A Concrete Naming Certificate for $\mathsf{UseProcessBoundary}^{\uparrow}$

The $\mathsf{UseProcessBoundary}^{\uparrow}$ packet realizes the certified-use and process-priority surface of subsection 9462.29.7 and subsection 9462.29.8 as one finite NameCert boundary. It sits beside $\mathsf{TraditionComparisonBoundary}^{\uparrow}$, $\mathsf{TraditionRegistry}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, and $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$: those siblings compare inherited tradition rows, register tradition entries, admit package claims, and check registry export consistency, while this packet binds certified use to process priority before either a tradition comparison or a registry export can read meaning as a stable claim.

The export-boundary row E is consumed directly by chapter 1224: registry export may read meaning only after the certified-use row and the process-priority row have been exposed on the same packet. The adjacent tradition consumers, chapter 1268 and chapter 1267, receive the same mediated surface rather than a private meaning row, so the registry-export lattice begins from certified use under process priority.

$\mathsf{UseProcessLimitLedger}^{\uparrow}$ in chapter 1315 consumes this boundary when certified use is read against formal process-limit refusal: $\mathsf{UseProcessBoundary}^{\uparrow}$ supplies the certified-use and process-priority rows, while $\mathsf{UseProcessLimitLedger}^{\uparrow}$ records the limit and refusal ledger that consumes them.

Definition 1313.1 (Use-process-boundary carrier)**.** *A* $\mathsf{UseProcessBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (U, P, R, E, H, C, K, N)$$

with the following displayed rows:

1. *U is the certified-use row, recording the public use of the name together with the certificate route that licenses that use;*
2. *P is the process-priority row, recording the* Cont *process through which use is replayed before any object-facing or registry-facing conclusion is read;*
3. *R is the rule-audit row, recording the finite distinction between licensed use, bare habit, private image, and unregistered philosophical claim;*
4. *E is the export-boundary row, recording the routes by which* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$, $\mathsf{TraditionRegistry}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, *and* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *may consume the packet;*

5. *H records componentwise* hsame *transport for certified use, process priority, rule audit, export boundary, replay, provenance, and local naming;*
6. *C records displayed* Cont *replay of the same certified-use and process-priority rows for downstream consumers;*
7. *K is the* Pkg *provenance over* $\mathsf{UseProcessBoundary}^{\uparrow}$, $\mathsf{TraditionComparisonBoundary}^{\uparrow}$, $\mathsf{TraditionRegistry}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{UseProcessBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for private meaning, social habit as an oracle, host equality, doctrine identity, total truth, or registry export without the displayed use and process rows.

Theorem 1313.2 (Use-process-boundary NameCert obligations)**.** *For the carrier of Definition 1313.1, the local* $\mathsf{NameCert}_{\mathsf{UseProcessBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for $B = (U, P, R, E, H, C, K, N)$, certified-use exposure through U, process-priority exposure through P, rule-audit exposure through R, export-boundary exposure through E, componentwise transport and replay through H, C, provenance through K, and local naming through N.*

Lean4 ✓ `BEDC.Derived.UseProcessBoundaryUp.UseProcessBoundaryTasteGate single carrier alignment`

Proof. Project the finite packet of Definition 1313.1. Its rows display certified use, process priority, rule audit, export boundary, transport, replay, provenance, and local naming.

The first four rows are the obligation surface before any downstream registry or tradition consumer can read the packet. The rows H and C preserve that same surface under componentwise transport and displayed replay.

Finally K and N cite and name the same displayed rows. Since the carrier contains no further coordinate, these obligations exhaust the local $\mathsf{NameCert}_{\mathsf{UseProcessBoundary}^{\uparrow}}$ surface. □

Theorem 1313.3 (Use-process-boundary certified-use nonescape)**.** *Every accepted* $\mathsf{UseProcessBoundary}^{\uparrow}$ *consumer that exports meaning, tradition comparison, claim admission, or registry consistency must expose the certified-use row U, process-priority row P, rule-audit row R, export-boundary row E, transport row H, replay row C, provenance row K, and local naming row N. No accepted consumer receives private meaning, bare social habit, doctrine identity, host equality, total truth, or registry export without those rows.*

Proof. Read the consumer through the carrier. The certified-use row U licenses the use, while the process-priority row P keeps the use on a displayed continuation before export.

The rule-audit and export-boundary rows R, E determine which downstream tradition and registry siblings may consume the packet. The structural rows H, C, K, N transport, replay, source, and locally name exactly that route.

The excluded readings are absent from the coordinate list of Definition 1313.1. A consumer claiming one of them would therefore require a field that the accepted boundary packet does not contain. □

Theorem 1313.4 (Use-process-boundary process priority)**.** *Every accepted* $\mathsf{UseProcessBoundary}^{\uparrow}$ *export reaches a tradition or registry consumer only after the certified-use row U has been replayed through the process-priority row P and the displayed* Cont *row C. Thus meaning-as-certified-use is process-mediated before* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$, $\mathsf{TraditionRegistry}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, *or* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *may consume it.*

Proof. Start with the order of the carrier rows. The use row U is not followed by an immediate object-export row; it is paired with the process-priority row P and the replay row C.

The export-boundary row E names only consumers of that mediated route. It cannot bypass P or C without ceasing to be the export row of the displayed packet.

Consequently each sibling consumer reads certified use through a process route. The theorem asserts process priority for the finite NameCert boundary, not an ambient metaphysical completeness claim. □

Theorem 1313.5 (Use-process-boundary sibling independence)**.** *The* $\mathsf{UseProcessBoundary}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$, $\mathsf{TraditionRegistry}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, *or* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$. *Each sibling is consumed through the export-boundary row E, but none carries the joint certified-use, process-priority, rule-audit, export-boundary, transport, replay, provenance, and local naming packet of* $\mathsf{UseProcessBoundary}^{\uparrow}$.

Proof. Compare the displayed rows. $\mathsf{TraditionComparisonBoundary}^{\uparrow}$ separates inherited tradition rows from BEDC landing rows, and $\mathsf{TraditionRegistry}^{\uparrow}$ records admitted tradition entries.

$\mathsf{ClaimRegistryLayer}^{\uparrow}$ controls package-level claim admission, while $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ checks status consistency before machine-facing registry export. These siblings supply downstream or adjacent routes, not the certified-use and process-priority boundary itself.

The $\mathsf{UseProcessBoundary}^{\uparrow}$ packet binds U, P, R, E, H, C, K, N in one finite carrier. A row-preserving bijection would have to preserve certified use, process priority, rule audit, export boundary, transport, replay, provenance, and local naming simultaneously, which none of the four siblings displays as its carrier surface. □

Falsifiable prediction: If a UseProcessBoundaryUp packet exports a tradition or registry claim while deleting either certified use or process priority, the carrier is refuted.

Independence witness: traditioncomparisonboundary, traditionregistry, claimregistrylayer, registryexportconsistencygate: none is bijective because UseProcessBoundaryUp binds certified use, process priority, rule audit, export boundary, transport, replay, provenance, and local naming in one finite packet.

The Lean follow-up requires $\mathsf{Nontrivial\ UseProcessBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful\ UseProcessBoundary}^{\uparrow}$ instances in `lean4/BEDC/Derived/UseProcessBoundaryUp/TasteGate.lean`. Those instances must preserve U, P, R, E, H, C, K, N as distinct displayed fields before any checked marker can cite `BEDC.Derived.UseProcessBoundaryUp.TasteGate`.

Closure status for $\mathsf{NameCert}_{\mathsf{UseProcessBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UseProcessBoundary}^{\uparrow}$ packet is generated from use rows, process rows, rule-ledger rows, certified-use witnesses, registry and machine-interface rows, philosophical-boundary rows, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The carrier starts from finite BHist uses and admits only those process routes whose rule, registry, and machine-facing coordinates remain visible. Its classifier preserves use and process as distinct but linked surfaces: certified use may be read only after the process route and rule ledger are replayed, while private meaning, doctrine identity, and social habit as an oracle have no carrier slot.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UseProcessBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, NameCert-obligation, certified-use-nonescape, process-priority, sibling-independence, Lean-follow-up boundary, and existing closure annotation for $\mathsf{UseProcessBoundary}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UseProcessBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim private meaning, social habit as an oracle, host equality, doctrine identity, total truth, or registry export without displayed use and process rows.

Upgrade path: To reach obligationClosure, the use-process carrier and certified-use boundary theorems must be checked as finite replay and transport obligations.

Chapter 1314

A Concrete Naming Certificate for $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$

The $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$ packet realizes the programme-strength gradient of subsection 9462.32.2 as a finite ledger whose rows prevent over-reporting across naming seed, paper certificate, machine-checked certificate, and conservative bridge. It refines the strength ledger of chapter 1305 by making each reported grade consume its displayed closure, formal, bridge, downgrade, interface, harness, registry, and empirical-boundary rows before the public strength report is readable.

Definition 1314.1 (Programme strength gradient ledger carrier)**.** *A* $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (Q, L, T, F, B, M, V, D, U, E, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the claim-site row naming the theorem, definition, chapter, bridge, package row, or machine-facing output being graded.*
2. *L is the layer row naming the programme layer and lower-layer dependencies consumed by the claim site.*
3. *T is the theory-closure row, recording seed, obligation, scoped, public, bridged, or mature closure as the paper-side grade.*
4. *F is the formal-status row, recording unformalized, formal target, encoded definition, checked scaffold, checked theorem, audit-clean, axiom-clean, or bridge-checked status as the verification-side grade.*
5. *B is the bridge row, recording absent, paper-only, or checked conservative-bridge status.*
6. *M is the machine-interface row, exposing the machine-facing boundary through which any checked output or kernel readback is reported.*
7. *V is the verified-output harness row, exposing checker-facing acceptance for reported machine output.*
8. *D is the status-downgrade row, recording the lower report that must be emitted when T, F, B, M, or V is weaker than the requested grade.*

9. *U is the upgrade-registry row, recording the next displayed obligation rather than silently raising the report.*
10. *E is the formal-constant empirical-value boundary row, separating formal strength from empirical value claims.*
11. *R is the refusal row for over-strong reports, hidden bridge claims, unchecked machine claims, erased downgrade rows, and empirical-value substitution.*
12. *H records componentwise* hsame *transport for all displayed rows.*
13. *C records displayed* Cont *replay from claim site to layer, closure, formal status, bridge, machine interface, verified output, downgrade, upgrade registry, empirical boundary, and refusal rows.*
14. *P records* Pkg *provenance over* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$, $\mathsf{MachineInterfaceBoundary}^{\uparrow}$, $\mathsf{VerifiedOutputHarness}^{\uparrow}$, $\mathsf{StatusDowngrade}^{\uparrow}$, $\mathsf{UpgradeRegistry}^{\uparrow}$, $\mathsf{FormalConstantEmpiricalValueBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
15. *N is the local* $\mathsf{NameCert}_{\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for reporting a claim above its displayed theory closure, formal status, bridge row, machine-interface row, verified-output harness, downgrade row, upgrade-registry row, empirical boundary, or refusal row.

Lean4 ✓ `BEDC.Derived.ProgrammeStrengthGradientLedgerUp.ProgrammeStrengthGradientLedgerTasteGate single carrier alignment`

Theorem 1314.2 (Programme strength gradient ledger obligations)**.** *For the carrier of Definition 1314.1, the local* $\mathsf{NameCert}_{\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for $G = (Q, L, T, F, B, M, V, D, U, E, R, H, C, P, N)$, layer exposure through L, theory-closure exposure through T, formal-status exposure through F, bridge exposure through B, machine-interface exposure through M, verified-output exposure through V, downgrade exposure through D, upgrade-registry exposure through U, empirical-boundary exposure through E, refusal exposure through R, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the displayed packet. The claim site Q is not yet a public strength report; it becomes reportable only after the layer, closure, formal, bridge, machine-interface, verified-output, downgrade, registry, empirical-boundary, and refusal rows have all been read.

Use the sibling packets as row sources. The programme-strength ledger supplies the base strength discipline, the machine-interface boundary supplies checked-output routing, the verified-output harness supplies checker-facing acceptance, the status-downgrade row supplies the lower report, the upgrade registry supplies the next obligation, and the formal-constant empirical-value boundary prevents formal strength from becoming empirical value.

Transport, replay, provenance, and local naming preserve the same finite packet. Since no further coordinate can raise T, F, B, M, V, D, U, E, or R, the listed rows exhaust the local NameCert surface. □

Theorem 1314.3 (Programme strength gradient no over-reporting)**.** *An accepted* ProgrammeStrengthGradientLedg *packet cannot export a reported strength above the minimum grade licensed by its displayed theory-closure row T, formal-status row F, bridge row B, machine-interface row M, verified-output harness row V, downgrade row D, upgrade-registry row U, empirical-boundary row E, and refusal row R. A consumer that asks for a stronger grade receives the downgrade row rather than a promoted report.*

Proof. Read T, F, and B first. These rows record the independent paper, verification, and bridge axes, so no one axis can raise the others.

Read M and V next. A machine-facing report is available only through the displayed interface and checker-facing harness; unchecked machine output is therefore not a higher grade inside the packet.

Finally read D, U, E, and R. The downgrade row supplies the lower report, the upgrade registry names the next obligation, the empirical-boundary row blocks value substitution, and the refusal row names over-strong reports. The carrier has no remaining coordinate that can convert these blockers into discharged obligations. □

Theorem 1314.4 (Programme strength ledger falsifiable prediction)**.** *Any accepted* ProgrammeStrengthGradientLed *report that grades a claim above its displayed closure row, formal-status row, bridge row, machine-interface row, verified-output row, downgrade row, upgrade-registry row, empirical-boundary row, or refusal row refutes the carrier.*

Proof. Assume an accepted report exports a stronger grade. By Definition 1314.2, every accepted report must expose T, F, B, M, V, D, U, E, and R before the local name is consumed.

Apply Definition 1314.3. The strongest readable grade is bounded by those displayed rows, and a stronger request must be routed to the downgrade row rather than promoted.

Thus the over-strong report cannot be a consumer of the accepted carrier. It is a falsifying observation for the purported $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$ packet. □

Falsifiable prediction: Any accepted programme-strength ledger that reports a claim above its displayed closure, formal, or bridge row refutes the carrier.

Independence witness: machineinterfaceboundary, verifiedoutputharness, statusdowngrade, upgraderegistry, formalconstantempiricalvalueboundary: none is bijective with $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$ because the gradient ledger simultaneously carries claim site, layer, theory closure, formal status, bridge status, machine-interface route, verified-output harness, downgrade, upgrade registry, empirical boundary, refusal, transport, replay, provenance, and local NameCert rows.

Lean follow-up requires `Nontrivial ProgrammeStrengthGradientLedgerUp` and `FieldFaithful ProgrammeStrengthGradientLedgerUp` in `lean4/BEDC/Derived/ProgrammeStrengthGradientLedgerUp/TasteG` The target `BEDC.Derived.ProgrammeStrengthGradientLedgerUp.taste_gate` must preserve distinct rows for $Q, L, T, F, B, M, V, D, U, E, R, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$ packet is generated from theory-closure, formal-status, bridge, machine-interface, verified-output, downgrade, upgrade-registry, empirical-boundary, refusal, transport, continuation, provenance, and local naming rows inside one finite BHist carrier. The classifier reads programme strength as a gradient across these displayed coordinates, not as a single status label. The ledger story is anti-over-reporting: each public report must be generated from the current closure, verification, bridge, machine, and empirical rows, while downgrade and refusal coordinates remain visible when an advertised strength exceeds what the carrier can support. Componentwise hsame and Cont replay preserve the same rows for every consumer.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}}, \mathsf{obligation})$

Scope closed: This chapter binds the displayed carrier of Definition 1314.1, the obligation theorem Definition 1314.2, the no-over-reporting theorem Definition 1314.3, the falsifiable prediction Definition 1314.4, and the TasteGate alignment marker for $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$ as the obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim reports above displayed theory closure, formal status, bridge row, machine row, verified output, downgrade, registry, empirical boundary, or refusal row.

Upgrade path: To reach scopedClosure, the strength-gradient rows and no-over-reporting theorem must be represented by checked finite-carrier projections.

Chapter 1315

A Concrete Naming Certificate for $\mathsf{UseProcessLimitLedger}^{\uparrow}$

The $\mathsf{UseProcessLimitLedger}^{\uparrow}$ packet realizes the use, continuation-process, and formal-limit boundary of subsection 9462.29.7, subsection 9462.29.8, and subsection 9462.29.9 as one finite export-boundary carrier. It sits beside the registry export surface of chapter 1216, the claim registry layer of chapter 1209, the kernel acceptance witness of chapter 549, and the continuation counter-model of chapter 1183. Those siblings expose export control, claim admission, accepted-declaration evidence, and failed continuation matching; this packet binds certified use, continuation route, formal-limit refusal, transport, replay, provenance, and local naming before any philosophy-facing consumer may read use as exported BEDC content.

Definition 1315.1 (Use-process-limit ledger carrier)**.** *A* $\mathsf{UseProcessLimitLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (U, C, L_f, H, R, P, N)$$

with seven displayed rows:

1. *U is the certified-use row, recording the public use of the named item together with the* $\mathsf{NameCert}$ *legitimacy data that separates licensed use from private image, bare reference, or unregistered habit;*
2. *C is the continuation-process row, recording the displayed* Cont *route through which the certified use is replayed as a process before any export is accepted;*
3. *L_f is the formal-limit row, recording refusal to internalize total truth, host equality, halting decision, or a closed open-meta-loop witness;*
4. *H is the componentwise* hsame *transport row for certified use, continuation process, formal-limit refusal, replay, provenance, and local naming;*
5. *R is the displayed* Cont *replay row that shows downstream consumers the same use/process/refusal route rather than a detached use token;*
6. *P is the* Pkg *provenance row over* $\mathsf{NameCert}$, Cont, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{KernelAcceptanceWitness}^{\uparrow}$, *and the source vision of section 9462.29;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{UseProcessLimitLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unlicensed use oracle, process-free export, total truth predicate, host equality, closed meta loop, or tradition identity collapse.

Lean4 ✓ `BEDC.Derived.UseProcessLimitLedgerUp.UseProcessLimitLedgerTasteGate single carrier alignment`

Theorem 1315.2 (Use-process-limit ledger NameCert obligations)**.** *For the carrier of Definition 1315.1, the local* $\mathsf{NameCert}_{\mathsf{UseProcessLimitLedger}^{\uparrow}}$ *surface has exactly three primary obligation rows before transport, replay, and provenance are consumed: certified use through* U*, continuation process through* C*, and formal-limit refusal through* L_f*. The rows* H, R, P, N *transport, replay, source, and locally name that three-row surface without adding a fourth philosophy-side authority.*

Proof. Project the finite packet $L = (U, C, L_f, H, R, P, N)$. The first three rows display the certified-use, continuation-process, and formal-limit-refusal obligations that a NameCert consumer is allowed to inspect.

The transport row H and replay row R preserve those same displayed rows. They do not add a private meaning row, a process-free route, or a host-side completion coordinate.

Finally P records the registry, claim, kernel-acceptance, and source-vision provenance, while N gives the local NameCert row. Since both rows cite the same three primary obligations, the listed surface exhausts the local NameCert obligations. □

Theorem 1315.3 (Use-process-limit ledger export boundary)**.** *Every accepted* $\mathsf{UseProcessLimitLedger}^{\uparrow}$ *export presents certified use, continuation process, and formal-limit refusal as one finite packet. An export that presents* U*,* C*, and* L_f *as three detachable exports is rejected by the carrier, even if each detached row is individually named.*

Proof. Read the export through the carrier, not through isolated row names. The rows U, C, L_f are fields of the same finite packet, and the downstream route reads them only through the shared transport, replay, provenance, and local naming rows H, R, P, N.

If a proposed export detaches certified use from process, it deletes the route that makes use replayable. If it detaches use and process from formal-limit refusal, it allows the consumer to read licensed use as total truth, host equality, halting decision, or closed meta-loop completion.

Thus an accepted export must preserve the packet boundary. Three separately named exports can cite parts of the vocabulary, but they are not an export of Definition 1315.1. □

Theorem 1315.4 (Use-process-limit ledger sibling independence)**.** *The* $\mathsf{UseProcessLimitLedger}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{RegistryExportSurface}^{\uparrow}$*,* $\mathsf{ClaimRegistryLayer}^{\uparrow}$*,* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$*, reflective-stability packets, or* $\mathsf{ContinuationCountermodel}^{\uparrow}$*. Each sibling omits at least one of certified use, continuation-process route, formal-limit refusal, componentwise transport, displayed replay, provenance, and local naming as one carrier.*

Proof. Compare displayed rows. $\mathsf{RegistryExportSurface}^{\uparrow}$ controls registry export, $\mathsf{ClaimRegistryLayer}^{\uparrow}$ admits or refuses package claims, $\mathsf{KernelAcceptanceWitness}^{\uparrow}$ records accepted kernel declarations, reflective-stability packets track stability of reflection routes, and $\mathsf{ContinuationCountermodel}^{\uparrow}$ records a continuation mismatch.

None of those siblings simultaneously carries U, C, L_f, H, R, P, N. In particular, an export surface can omit certified use, a claim layer can omit the continuation route, a kernel witness can omit the philosophy-side formal-limit refusal, a stability packet can omit the local use ledger, and a countermodel can omit accepted export provenance.

Therefore no sibling is bijective to $\mathsf{UseProcessLimitLedger}^{\uparrow}$ while preserving local NameCert rows. A bijection would have to recover every displayed coordinate of the packet from a sibling that lacks at least one such coordinate. □

Falsifiable prediction: Any accepted use-process-limit export that treats certified use, continuation-process, and formal-limit refusal as three detachable exports refutes the packet.

Independence witness: registryexportsurface, claimregistrylayer, kernelauditwitness, reflectivestability, continuationcountermodel: none is bijective because each omits at least one of certified-use, process-route, formal-limit refusal, transport, replay, provenance, and local naming as one carrier.

The Lean follow-up must provide Nontrivial $\mathsf{UseProcessLimitLedger}^{\uparrow}$ and FieldFaithful $\mathsf{UseProcessLimitLedger}^{\uparrow}$ in `lean4/BEDC/Derived/UseProcessLimitLedgerUp/TasteGate.lean`. Those instances must preserve U, C, L_f, H, R, P, N as distinct displayed fields before any checked marker can cite `BEDC.Derived.UseProcess`

Closure status for $\mathsf{NameCert}_{\mathsf{UseProcessLimitLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{UseProcessLimitLedger}^{\uparrow}$ packet is generated from certified-use and NameCert-legitimacy data, a continuation-process route, a formal-limit refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UseProcessLimitLedger}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1315.1, Definition 1315.2, Definition 1315.3, and Definition 1315.4 scope the BHist, NameCert, Cont, hsame, and Pkg primitives to the finite rows U, C, L_f, H, R, P, N, including the existing carrier obligations, export boundary, and sibling-independence theorem.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UseProcessLimitLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close whole-philosophy formal package checking, total truth, host equality, closed meta-loop completion, or collapsed tradition identity.

Upgrade path: Obligation closure requires checked carrier admission, field faithfulness, nontriviality, NameCert obligation coverage, export-boundary preservation, and sibling-independence coverage for U, C, L_f, H, R, P, N.

Chapter 1316

A Concrete Naming Certificate for $\mathsf{UseProcessLimit}^{\uparrow}$

The $\mathsf{UseProcessLimit}^{\uparrow}$ packet realizes the use, process, and limit-facing philosophy surface of subsection 9462.29.7, subsection 9462.29.8, and Definition 9462.1955 as one finite NameCert carrier. It sits beside the socket-use ledger of chapter 1044, the inward eligibility proof of chapter 1309, the machine-facing boundary of chapter 1221, and the apophatic naming boundary of chapter 543. Those siblings expose visible use, name eligibility, machine export control, and refusal-bearing naming; this packet binds certified use, rule audit, continuation process, and formal-limit refusal before any philosophy-facing export can read meaning as licensed use.

Definition 1316.1 (Use-process-limit carrier)**.** *A* $\mathsf{UseProcessLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (N, U_c, R, P_c, L, H, C, K, N_c)$$

with the following displayed rows:

1. *N is the name row, recording the public name whose meaning is read only through a certificate-governed use surface;*
2. *U_c is the certified-use row, recording the licensed use of N together with the source and classifier fields that make the use auditable;*
3. *R is the rule-checking row, recording the finite audit route that separates certificate-governed use from private image, bare reference, or ordinary social habit;*
4. *P_c is the process-continuation row, recording the displayed* Cont *process through which the use is replayed before object-facing export;*
5. *L is the formal-limit refusal row, recording that the packet does not internalize total truth, host equality, halting decision, or meta-loop closure;*
6. *H records componentwise* hsame *transport for the name, certified-use, rule-checking, process-continuation, formal-limit refusal, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay of the same certified-use and process rows for downstream consumers;*
8. *K is the* Pkg *provenance over* $\mathsf{SocketUseLedger}^{\uparrow}$, $\mathsf{NameEligibilityProof}^{\uparrow}$, $\mathsf{MachineInterfaceBoundary}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

9. N_c is the local $\mathsf{NameCert}_{\mathsf{UseProcessLimit}^{\uparrow}}$ *row.*
The carrier has no coordinate for a private-meaning witness, social-habit oracle, host equality, total truth predicate, halting decision, or closed meta loop.

Lean4 ✓ `BEDC.Derived.UseProcessLimitUp.UseProcessLimitTasteGate single carrier alignment`

Definition 1316.2 (Use-process-limit classifier)**.** *A* $\mathsf{UseProcessLimit}^{\uparrow}$ *classifier from*

$$U = (N, U_c, R, P_c, L, H, C, K, N_c)$$

to

$$U' = (N', U'_c, R', P'_c, L', H', C', K', N'_c)$$

is a componentwise preservation map that carries the name row to the name row, certified use to certified use, rule audit to rule audit, continuation process to continuation process, formal-limit refusal to formal-limit refusal, hsame *transport to* hsame *transport,* Cont *replay to* Cont *replay,* Pkg *provenance to* Pkg *provenance, and local NameCert naming to local NameCert naming. A map that preserves the use row while deleting either the rule-checking row or the formal-limit refusal row is not a* $\mathsf{UseProcessLimit}^{\uparrow}$ *classifier.*

Theorem 1316.3 (Use-process-limit NameCert obligations)**.** *For the carrier of Definition 1316.1, the local* $\mathsf{NameCert}_{\mathsf{UseProcessLimit}^{\uparrow}}$ *surface has five displayed obligation rows before transport and provenance are consumed: name exposure through N, certified-use exposure through U_c, rule-checking exposure through R, process-continuation exposure through P_c, and formal-limit refusal exposure through L. The remaining rows H, C, K, N_c transport, replay, source, and locally name exactly that five-row surface.*

Proof. Project the finite packet $U = (N, U_c, R, P_c, L, H, C, K, N_c)$. The first five rows display the naming, use, rule audit, process, and refusal obligations before any downstream consumer can read the packet.

The transport row H and replay row C preserve those same displayed rows. They do not add a private meaning coordinate or a host-side completion coordinate.

Finally K records the sibling provenance, and N_c gives the local NameCert row. Since both rows cite the same five displayed obligations, the listed surface exhausts the local NameCert obligations. □

Theorem 1316.4 (Use-process-limit ledger nonescape)**.** *Every accepted* $\mathsf{UseProcessLimit}^{\uparrow}$ *consumer receives certified use, rule audit, process continuation, formal-limit refusal, transport, replay, provenance, and local naming through the finite rows $U_c, R, P_c, L, H, C, K, N_c$. The same consumer receives no private-meaning witness, social-habit oracle, host equality, total truth predicate, halting decision, or meta-loop closure.*

Proof. Read the consumer surface through the carrier. The rows U_c, R, P_c, L display the certified use, audit, continuation, and refusal components, while H, C, K, N_c transport, replay, source, and name them.

The forbidden readings are not fields of the packet. The name row N identifies the public name, but it does not supply a private witness, social oracle, host equality, truth predicate, halting decision, or closed meta loop.

Therefore any accepted consumer can receive only the displayed finite package. A route that claims one of the forbidden readings would require a coordinate absent from Definition 1316.1. □

Theorem 1316.5 (Use-process-limit certified-use process interface)**.** *Every accepted* $\mathsf{UseProcessLimit}^{\uparrow}$ *export factors meaning-as-certified-use through the displayed* Cont *process row* P_c *and replay row* C *before any export route may cite the local NameCert row* N_c*.*

Proof. Start with the certified-use row U_c. It licenses the use of N, but the carrier places it beside the process-continuation row P_c rather than beside an immediate object-export row.

The replay row C then displays the same continuation route for downstream consumers. This keeps meaning-as-certified-use attached to a visible process before the local naming row is consumed.

The local NameCert row N_c therefore names an already displayed process interface. An export that bypasses P_c or C is not an export of the accepted carrier. □

Falsifiable prediction: If a UseProcessLimitUp packet exports legitimate use while deleting either the rule-audit row or the formal-limit refusal row, the carrier is refuted.

Independence witness: socketuseledger, nameeligibilityproof, machineinterfaceboundary, apophaticname: none is bijective because UseProcessLimitUp simultaneously binds certified use, rule audit, process continuation, formal-limit refusal, transport, replay, provenance, and local naming.

The Lean follow-up requires Nontrivial $\mathsf{UseProcessLimit}^{\uparrow}$ and FieldFaithful $\mathsf{UseProcessLimit}^{\uparrow}$ instances in `lean4/BEDC/Derived/UseProcessLimitUp/TasteGate.lean`. Those instances must preserve $N, U_c, R, P_c, L, H, C, K, N_c$ as distinct displayed fields before any checked marker can cite `BEDC.Derived.UseProcessLimitUp.TasteGate`.

Closure status for $\mathsf{NameCert}_{\mathsf{UseProcessLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UseProcessLimit}^{\uparrow}$ packet is generated from finite use rows, process-step rows, certified-use rows, rule-ledger rows, trace-verdict boundary rows, stream-limit reflection rows, limit-boundary rows, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. Its classifier reads a process limit only as the visible boundary of finite use and reflection ledgers; it does not close a private meaning, halting decision, or total truth predicate. The ledger story is controlled nonclosure: every limit-facing consumer must replay the certified-use, rule, trace, and stream rows before seeing the boundary row, and no closed meta loop is generated by the packet.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UseProcessLimit}^{\uparrow}}$, seed)

Scope closed: This chapter binds the carrier and classifier definitions, NameCert-obligation, ledger-nonescape, certified-use-process-interface, Lean-follow-up boundary, and existing closure annotation for $\mathsf{UseProcessLimit}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UseProcessLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim private-meaning witnesses, social-habit oracles, host equality, total truth predicates, halting decisions, or closed meta loops.

Upgrade path: To reach obligationClosure, the use-process classifier and ledger-nonescape theorem must be formalized as finite-history replay obligations.

Chapter 1317

A Concrete Naming Certificate for $\mathsf{CertifiedUseProcess}^{\uparrow}$

The $\mathsf{CertifiedUseProcess}^{\uparrow}$ packet realizes the use-as-public-process surface of subsection 9462.29.7 inside the auditable-generativity programme of chapter 9462. It sits beside the socket-use ledger of chapter 1044, the registry export surface of chapter 1216, the machine-facing boundary of chapter 1221, the apophatic naming boundary of chapter 543, and the inward eligibility proof of chapter 1309. Those siblings separately expose visible use, export control, machine routing, refused supply, and name admission; this carrier binds them before a public use may be read as rule-following.

Definition 1317.1 (Certified-use process carrier)**.** *A* $\mathsf{CertifiedUseProcess}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (U, R, C, L, H, K, P, N)$$

with the following displayed rows:

1. *U is the certified-use row, recording the public use event, its name, item, local history, and source/classifier surface.*
2. *R is the public rule-witness row, recording the finite rule-following evidence by which the use may be cited outside private impression.*
3. *C is the continuation-process route, recording the displayed* Cont *path through which the use is replayed for downstream consumers.*
4. *L is the refusal ledger, recording hidden-source refusals, private-meaning refusals, and blocked rule-following claims.*
5. *H stores componentwise* hsame *transport for certified use, rule witness, continuation route, refusal ledger, replay, provenance, and local naming rows.*
6. *K stores displayed* Cont *replay of the same certified-use process route.*
7. *P is the* Pkg *provenance over* $\mathsf{SocketUseLedger}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineInterfaceBoundary}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, $\mathsf{NameEligibilityProof}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CertifiedUseProcess}^{\uparrow}}$ *row binding the packet to the displayed use process.*

The carrier has no coordinate for private meaning, social repetition without a rule witness, a machine-facing export without registry control, a hidden source supply, or a local name admitted without a NameCert row.

Lean4 (definition) `BEDC.Derived.CertifiedUseProcessUp.CertifiedUseProcessUp`

Theorem 1317.2 (Certified-use process NameCert surface)**.** *For the carrier of Definition 1317.1, the local* $\mathsf{NameCert}_{\mathsf{CertifiedUseProcess}^{\uparrow}}$ *surface consists exactly of certified-use admission through U, public rule-witness admission through R, continuation-process routing through C and K, refusal-ledger exposure through L, componentwise transport through H, package provenance through P, and local naming through N.*

Proof. Project the finite packet $Q = (U, R, C, L, H, K, P, N)$. The rows U, R, C, L display the use, rule witness, process route, and refusals before any consumer may cite the packet.

The rows H and K preserve that same displayed route under transport and replay. They do not add a private-meaning coordinate or replace the rule witness by social repetition.

Finally P records the sibling surfaces and N names the local packet. Since the carrier has no other fields, these rows exhaust the local $\mathsf{NameCert}_{\mathsf{CertifiedUseProcess}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.CertifiedUseProcessUp.CertifiedUseProcessNameCertSurface`

Theorem 1317.3 (Certified-use process nonprivate rule-following)**.** *Every accepted* $\mathsf{CertifiedUseProcess}^{\uparrow}$ *consumer reads public rule-following through the certified-use row U, rule-witness row R, continuation rows C, K, refusal ledger L, transport row H, provenance row P, and local naming row N. A route that accepts the public use while deleting either R or L is not an accepted* $\mathsf{CertifiedUseProcess}^{\uparrow}$ *carrier.*

Proof. Begin with the certified-use row U. It records a public use event, but the carrier does not let that event stand alone as meaning or rule-following.

The rule-witness row R and refusal ledger L determine whether the use is publicly licensed or blocked. The continuation rows C, K then replay only that licensed route, while H, P, N transport, source, and name the same finite packet.

Thus a consumer that omits the rule witness or refusal ledger changes the packet into a projection. The projection may mention a use, but it no longer carries the public rule-following surface of Definition 1317.1. □

Lean4 ✓ `BEDC.Derived.CertifiedUseProcessUp.CertifiedUseProcess nonprivate rule following`

Falsifiable prediction: A public use accepted without the rule-witness row or ledger row is not a CertifiedUseProcessUp packet.

Independence witness: socketuseledger, registryexportsurface, machineinterfaceboundary, apophaticname, nameeligibilityproof: none is bijective because CertifiedUseProcessUp binds use, rule witness, continuation route, refusal ledger, transport, provenance, and local naming in one packet.

The Lean carrier realization provides $\mathsf{Nontrivial}\ \mathsf{CertifiedUseProcess}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{CertifiedUseProcess}^{\uparrow}$ instances in `lean4/BEDC/Derived/CertifiedUseProcessUp/TasteGate.lean`. The nontrivial witness exposes an accepted public-use packet, and field faithfulness keeps U, R, C, L, H, K, P, N distinct.

Closure status for $\mathsf{NameCert}_{\mathsf{CertifiedUseProcess}^{\uparrow}}$.

Constructive story: A $\mathsf{CertifiedUseProcess}^{\uparrow}$ packet is generated from process rows, rule rows, use-witness rows, registry and machine-interface rows, source and name rows, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The finite BHist carrier accepts a use process only when the rule witness, registry control, machine-facing boundary, and NameCert row are all displayed. Its classifier makes certified use public and nonprivate: repeated use becomes readable only through the recorded rule and process ledger, while hidden source supply, social repetition without witness, and machine export without registry control never become accepted coordinates.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CertifiedUseProcess}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, NameCert-surface theorem, nonprivate-rule-following theorem, Lean-follow-up boundary, and existing closure annotations for $\mathsf{CertifiedUseProcess}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CertifiedUseProcess}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.CertifiedUseProcessUp.CertifiedUseProcessUp`

Bridge status: none

Origin: ai

Not claimed: It does not claim private meaning, social repetition without a rule witness, machine-facing export without registry control, hidden source supply, or local naming without NameCert.

Upgrade path: To reach obligationClosure, the certified-use carrier and nonprivate rule-following theorem must be checked as finite packet obligations.

Chapter 1318

A Concrete Naming Certificate for $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$

The $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$ packet realizes the cannot-claim registry of subsection 9462.33.7 as a finite NameCert carrier for philosophy-package refusals. It sits beside the claim admission surface of chapter 1209, the whole-registry packet of chapter 1220, the export-control surface of chapter 1216, and the axis refusal ledger of chapter 554. Those siblings admit, route, export, or audit claims; this carrier binds the refusal status, reason, boundary condition, blocking gate, transport, replay, provenance, and local naming row as the primary cannot-claim surface.

Definition 1318.1 (Philosophy cannot-claim registry carrier)**.** *A* $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (C, S, E, U, B, H, K, P, N)$$

with the following displayed rows:

1. *C is the claim-text row, recording the exact philosophy-package reading under refusal;*
2. *S is the status row, separating forbidden, deferred, and partial cannot-claim readings;*
3. *E is the exclusion-reason row, recording why the claim is not presently exportable;*
4. *U is the upgrade-condition row, recording the certificate, bridge, formal target, or principled boundary needed before the status can change;*
5. *B is the blocking-gate row, recording the registry gate that prevents export through* $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryLayer}^{\uparrow}$, *or* $\mathsf{RegistryExportSurface}^{\uparrow}$*;*
6. *H stores componentwise* hsame *transport for the claim, status, reason, upgrade, blocking, replay, provenance, and local naming rows;*
7. *K stores displayed* Cont *replay for claim lookup, refusal-status inspection, blocking-gate readback, and upgrade-boundary readback;*
8. *P is the* Pkg *provenance over* $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{AxisZeckendorfCannotClaim}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an admitted claim, prose-only override, hidden status change, unrecorded export route, or private gate bypass.

Lean4 ✓ `BEDC.Derived.PhilosophyCannotClaimRegistryUp.PhilosophyCannotClaimRegistryTasteGate`
`single carrier alignment`

Theorem 1318.2 (Philosophy cannot-claim registry NameCert obligations)**.** *For the carrier of Definition 1318.1, the local* $\mathsf{NameCert}_{\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}}$ *surface consists exactly of carrier admission for* $R = (C, S, E, U, B, H, K, P, N)$*, claim-text coverage by* C*, status exactness by* S*, exclusion-reason coverage by* E*, upgrade-boundary coverage by* U*, blocking-gate coverage by* B*, componentwise transport by* H*, displayed replay by* K*, provenance by* P*, and local naming by* N*.*

Lean4 ✓ `BEDC.Derived.PhilosophyCannotClaimRegistryUp.PhilosophyCannotClaimRegistryNameCertObligations`

Proof. Project the finite packet of Definition 1318.1. The rows C, S, E, U, B separately display the refused reading, its status, the reason it is excluded, the boundary under which it may be reconsidered, and the gate that blocks export.

The rows H and K keep the refusal stable under transported presentations and replayed registry reads. A transported claim text is therefore still read with its displayed status, exclusion reason, upgrade boundary, and blocking gate.

The rows P and N package and name the same data. Since the carrier has no coordinate for admitted export or private gate bypass, these rows exhaust the local NameCert obligation surface. □

Theorem 1318.3 (Philosophy cannot-claim registry non-escape)**.** *Every public consumer of an accepted* $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$ *packet may inspect only the claim-text row* C*, status row* S*, exclusion-reason row* E*, upgrade-condition row* U*, blocking-gate row* B*,* hsame *transport row* H*,* Cont *replay row* K*,* Pkg *provenance row* P*, and local naming row* N*. It receives no admitted-claim row, prose-only override, hidden export permission, private registry route, or status change outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.PhilosophyCannotClaimRegistryUp.PhilosophyCannotClaimRegistryNonescape`

Proof. Use the carrier definition. The visible rows are exactly $C, S, E, U, B, H, K, P, N$, and the NameCert obligations above attach the refusal reading to those rows.

If a consumer asks for admitted export, private override, or a hidden status change, it asks for a coordinate not present in R. The transport and replay rows can preserve and replay displayed refusal data, but they cannot create an admission row.

Thus every accepted cannot-claim read remains inside the listed packet. A route that bypasses S or B is not a $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$ export of refusal content. □

Theorem 1318.4 (Philosophy cannot-claim registry status exactness)**.** *For an accepted* PhilosophyCannotClaimReg *carrier* $R = (C, S, E, U, B, H, K, P, N)$*, the status row* S *and blocking-gate row* B *are jointly necessary for exporting a cannot-claim refusal. If either row is absent, the packet may still display claim text or an exclusion reason, but it cannot export a typed refusal through* $\mathsf{ClaimRegistryLayer}^{\uparrow}$*,* $\mathsf{RegistryLayer}^{\uparrow}$*, or* $\mathsf{RegistryExportSurface}^{\uparrow}$*.*

Proof. Read the status row first. It determines whether the refusal is forbidden, deferred, or partial, and therefore separates a cannot-claim entry from an untyped note.

Read the blocking-gate row next. It is the displayed gate that prevents the refused claim from being exported through the sibling registry and export surfaces.

The transport, replay, provenance, and naming rows preserve this pair. Without S the refusal has no typed status; without B it has no export-blocking gate. Hence a cannot-claim refusal is exported only through the same finite packet containing both rows. □

Lean4 ✓ `BEDC.Derived.PhilosophyCannotClaimRegistryUp.PhilosophyCannotClaimRegistryStatusExactness`

Theorem 1318.5 (Philosophy cannot-claim registry obligation boundary)**.** *For an accepted* PhilosophyCannotClaim *carrier* $R = (C, S, E, U, B, H, K, P, N)$*, the rows* $C, S, E, U, B, H, K, P, N$ *are the full obligation boundary. A cannot-claim consumer may inspect claim text, status, exclusion reason, upgrade condition, blocking gate, componentwise transport, displayed replay, provenance, and local naming, but no admitted-claim row, private export permission, hidden status change, or prose-only override.*

Proof. Project the carrier. Its analytic rows are exactly C, S, E, U, B, and the preceding NameCert obligations attach claim text, status, exclusion reason, upgrade boundary, and blocking gate to those rows.

The structural rows H, K, P, N preserve, replay, source, and name the same finite refusal surface. None of them carries an admitted-claim coordinate or a private route around the blocking gate.

Thus every local obligation is exhausted by the displayed packet. A consumer asking for any further refusal authority asks for data outside the carrier. □

Lean4 ✓ `BEDC.Derived.PhilosophyCannotClaimRegistryUp.PhilosophyCannotClaimRegistryObligationBoundary`

Theorem 1318.6 (Philosophy cannot-claim registry gate induction)**.** *Every refusal export from an accepted* $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$ *packet is obtained by induction over the displayed gate rows* C, S, E, U, B *and then by structural replay through* H, K, P, N*. The export is not licensed by prose, by a global registry convention, or by an unrecorded cannot-claim policy.*

Proof. Use induction over the displayed refusal route. The base read is the claim text row C, which fixes the entry under inspection.

The status, exclusion, upgrade, and blocking steps are the rows S, E, U, B. Each step consumes only the row already displayed in the packet and passes the same refusal entry to the next row.

Finally replay the result through H, K, P, N. These rows can transport and expose the displayed gate chain, but they cannot insert a missing policy premise. Hence refusal export is row-inductive rather than prose-derived. □

Lean4 ✓ `BEDC.Derived.PhilosophyCannotClaimRegistryUp.PhilosophyCannotClaimRegistryGateInduction`

Theorem 1318.7 (Philosophy cannot-claim registry upgrade-boundary exhaustion)**.** *For an accepted* $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$ *carrier* $R = (C, S, E, U, B, H, K, P, N)$*, the upgrade boundary is exhausted by the displayed upgrade-condition row* U *together with the status and blocking rows* S *and* B*. Any status change for the refused claim must be witnessed through that finite row data before the registry, export surface, transport, replay, provenance, or local naming rows can expose it.*

Proof. Read the status row S and the blocking row B. They determine the current refusal status and the gate through which export is blocked.

The only row that can describe how this status may change is U. It records the certificate, bridge, formal target, or principled boundary needed before reconsideration.

Transport, replay, provenance, and local naming preserve the displayed upgrade condition. Since no other carrier coordinate records status-change authority, U exhausts the upgrade boundary. □

Lean4 ✓ `BEDC.Derived.PhilosophyCannotClaimRegistryUp.PhilosophyCannotClaimRegistryUpgradeBoundaryExhaus`

The Lean follow-up for PhilosophyCannotClaimRegistry$^{\uparrow}$ must provide explicit Nontrivial PhilosophyCannotClaimR and FieldFaithful PhilosophyCannotClaimRegistry$^{\uparrow}$ instances before BEDC.Derived.PhilosophyCannotClaimRegistryUp. can be cited by a checked paper marker. The nontriviality witness must expose at least one blocked philosophy claim, and field faithfulness must preserve $C, S, E, U, B, H, K, P, N$ as distinct displayed rows.

Falsifiable prediction: If the status or blocking row is absent, the carrier cannot export a cannot-claim refusal.

Independence witness: claimregistrylayer, registrylayer, registryexportsurface, registryexportconsistencygate, axiszeckendorfcannotclaim: none is bijective to PhilosophyCannotClaimRegistryUp because those siblings admit, route, or audit claims, while this packet binds refusal status, reason, upgrade boundary, blocking gate, transport, replay, provenance, and local NameCert as the primary carrier.

Closure status for NameCert$_{\text{PhilosophyCannotClaimRegistry}^{\uparrow}}$.

Constructive story: A PhilosophyCannotClaimRegistry$^{\uparrow}$ packet is generated from claim text, refusal status, exclusion reason, upgrade boundary, blocking gate, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PhilosophyCannotClaimRegistry}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1318.1, Definition 1318.2, Definition 1318.3, Definition 1318.4, Definition 1318.6, and Definition 1318.7 bind the public claim-registry export surface for claim text, status, reason, upgrade-boundary, blocking, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{PhilosophyCannotClaimRegistry}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, registry completeness, admitted-claim export, or correctness of every philosophy-package cannot-claim entry.

Upgrade path: Further closure requires Lean verification and bridge evidence for the same public claim-text, status, reason, upgrade-boundary, blocking, transport, replay, provenance, and local naming rows.

Chapter 1319

A Concrete Naming Certificate for $\mathsf{CannotClaimExportGate}^{\uparrow}$

The $\mathsf{CannotClaimExportGate}^{\uparrow}$ packet realizes the philosophy-package cannot-claim registry of Definition 9462.2179 and the export interface of Definition 9462.2192 as one finite NameCert gate. It sits beside the registry export surface of chapter 1216, the refusal registry of chapter 1248, the machine-interface boundary of chapter 1221, the package carrier of chapter 1292, and the audit export firewall of chapter 1296. Those siblings expose exported registry rows, refusal rows, target routing, package ledgers, and audit-firewall decisions separately; this carrier binds the same refused claim before it can be read as a checked formal-package target.

The export gate is the checked-target analogue of $\mathsf{ChoiceRecipeLedger}^{\uparrow}$ in chapter 677. Both packets block a consumer from reading an unlicensed output: $\mathsf{ChoiceRecipeLedger}^{\uparrow}$ refuses a hidden selection output from finite witness recipes, while $\mathsf{CannotClaimExportGate}^{\uparrow}$ refuses checked-target export by displaying the registry row R, refusal row F, export rows E, Q, target row T, and audit row A before any local naming row can be read.

Definition 1319.1 (Cannot-claim export gate carrier)**.** *A* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, F, E, Q, T, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the registry row, recording the philosophy-package claim text, registry status, theorem-map site when present, gap-map site when present, and export request.*
2. *F is the refusal row, recording the active cannot-claim entry, refusal reason, blocked reading, and required target condition for the same claim.*
3. *E is the export-decision row, recording whether the request is refused, reading-export only, paper-synthesis export, component-checked export, formal-package target, or formal-package checked.*
4. *Q is the export-grade row, recording the grade named in Definition 9462.2193 together with the reason the refused row cannot occupy the checked grade.*
5. *T is the target row, recording the machine-facing target route, Lean target name when present, paper-only route when present, and the absence of a checked package target for refused rows.*
6. *A is the audit row, recording the readback from the registry export surface, refusal registry, machine-interface boundary, package carrier, and audit export firewall for the same claim site.*

7. *H records componentwise* hsame *transport for registry, refusal, export decision, export grade, target route, audit readback, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for reading R, F, E, Q, T, A without adding a host-side checked-target override.*
9. *P records* Pkg *provenance over the five sibling packets, the philosophy-package export interface,* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CannotClaimExportGate}^{\uparrow}}$ *row.*

The carrier has no coordinate for exporting a refused cannot-claim registry row as a checked formal-package target outside the displayed registry, refusal, export, target, audit, transport, continuation, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGateCarrierSurface`

Theorem 1319.2 (Cannot-claim export gate NameCert obligations)**.** *For the carrier of Definition 1319.1, the local* $\mathsf{NameCert}_{\mathsf{CannotClaimExportGate}^{\uparrow}}$ *surface consists exactly of carrier admission for $G = (R, F, E, Q, T, A, H, C, P, N)$, registry exposure through R, refusal exposure through F, export-decision exposure through E, export-grade exposure through Q, target-route exposure through T, audit readback through A, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the finite packet $G = (R, F, E, Q, T, A, H, C, P, N)$. The registry row R gives the claim site and requested export, while the refusal row F displays the active cannot-claim entry for that same site.

The export rows are then read against the refusal. The decision row E and grade row Q record the permitted export level, and the target row T records the machine-facing route without supplying a checked package target when F is active.

Finally the audit, transport, replay, provenance, and naming rows preserve that same display. Since the carrier has no additional export coordinate, these rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGate namecert obligations`

Theorem 1319.3 (Cannot-claim export gate refusal nonescape)**.** *If an accepted* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *packet carries an active refusal row F for registry row R, then its export-decision row E and export-grade row Q cannot expose that same row as formal package checked, and its target row T cannot expose it as a checked formal-package target.*

Proof. Assume an accepted packet $G = (R, F, E, Q, T, A, H, C, P, N)$ with F active for R. The active refusal row is read before the export decision, grade, or target route can be projected.

The decision row E and grade row Q are the only coordinates from which an export status may be read. Because they are displayed together with F, they record a refusal or a weaker export grade rather than the checked formal-package grade for the refused claim.

The target row T is likewise read after F, E, Q. It may record a paper-only route or a missing checked target, but it has no separate coordinate that can turn the refused row into a checked package target. Transport, continuation, provenance, and local naming preserve that refusal instead of escaping it. □

Lean4 ✓ `BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGate refusal nonescape`

Theorem 1319.4 (Cannot-claim export gate registry factorization)**.** *Every accepted* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *export reading factors through the registry row R, refusal row F, export rows E, Q, target row T, and audit row A before local naming. No registry claim reaches the local* $\mathsf{NameCert}_{\mathsf{CannotClaimExportGate}^{\uparrow}}$ *row by prose adjacency to the philosophy package alone.*

Proof. Read the packet by coordinates. The registry row R supplies the claim site, and F supplies the cannot-claim status for that site. The export rows E, Q then determine the grade, while T supplies the target route.

The audit row A checks the same site against the registry export surface, refusal registry, machine-interface boundary, package carrier, and audit export firewall. Thus the local naming row N receives a factored packet rather than an uninspected package paragraph.

Since H, C, P only transport, replay, and source the displayed rows, they do not create a second route from prose to checked target. The export reading therefore factors through the listed rows. □

Lean4 ✓ `BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGate registry factorization`

Theorem 1319.5 (Cannot-claim export gate export-grade scope)**.** *For every accepted* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *carrier $G = (R, F, E, Q, T, A, H, C, P, N)$, any export-grade read through Q must be scoped by the active refusal row F, decision row E, target row T, audit row A, and the field-faithful TasteGate handoff before local naming. Thus a read of Q can classify a refused claim only after the gate has displayed the refusal, export decision, target route, audit readback, and distinct-field carrier boundary for the same registry row R.*

Lean4 ✓ `BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGate export grade scope`

Proof. Project the accepted carrier. The registry row R fixes the claim site, and the refusal row F records the active cannot-claim entry for that site before the export-grade row is read.

Use the registry factorization theorem, Definition 1319.4. It forces every export reading through R, F, E, Q, T, A before local naming, so Q is not an independent grade oracle.

Finally apply the TasteGate handoff recorded by the checked alignment target `BEDC.Derived.CannotClaimExpo` Field faithfulness keeps F, E, Q, T, A as distinct rows, hence the grade read through Q remains scoped by refusal, decision, target, audit, and local NameCert data rather than collapsing into an unchecked package target. □

Theorem 1319.6 (Cannot-claim export gate TasteGate handoff)**.** *The Lean-facing handoff for* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *must keep registry row R, refusal row F, export-decision row E, export-grade row Q, target row T, audit row A, transport row H, continuation row C, provenance row P, and local NameCert row N as distinct fields. Collapsing any of F, E, Q, T, A removes the field on which the refused-claim export block depends.*

Lean4 ✓ `BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGateTasteGate single carrier alignment`

Proof. The gate blocks a refused checked-target export by comparing the refusal row with the export decision, export grade, target route, and audit readback. These comparisons require the rows F, E, Q, T, A to remain separately projected.

Rows H, C, P, N preserve and name the same packet after the comparison. If a Lean-facing carrier merged the refusal with the decision, grade, route, or audit rows, a consumer could no longer state which field records refusal and which field records export. The TasteGate handoff therefore keeps all ten rows as field-faithful data. □

Theorem 1319.7 (Cannot-claim export gate ledger exhaustion)**.** *Every accepted* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *export-gate read must expose exactly the rows*

$$R, F, E, Q, T, A, H, C, P, N$$

before local naming. No refused registry row can bypass the refusal, export, and audit ledger to become a checked target.

Proof. Apply the registry factorization theorem. It forces every export reading through R, F, E, Q, T, A before the local NameCert row, so a refused claim cannot reach naming from the philosophy-package paragraph alone.

Apply the export-grade scope theorem. The grade row Q is read only with the active refusal row F, decision row E, target row T, audit row A, and the field-faithful TasteGate handoff, so the checked grade is not available as an independent route.

Finally use the TasteGate handoff. It keeps $R, F, E, Q, T, A, H, C, P, N$ as distinct fields, while H, C, P only transport, replay, and source the same packet. Since the carrier has no further export coordinate, the ledger is exhausted by the displayed rows and no refused registry row becomes a checked target by bypassing them. □

Lean4 ✓ `BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGate ledger exhaustion`

Theorem 1319.8 (Cannot-claim export gate obligation-closure package)**.** *An accepted* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *packet exposing the carrier definition, NameCert obligations, refusal nonescape, registry factorization, export-grade scope, TasteGate handoff, and ledger exhaustion supplies the full obligationClosure package for the gate. The package consists of registry row R, refusal row F, export rows E, Q, target row T, audit row A, componentwise* hsame *transport H, displayed* Cont *replay C, package provenance P, and local* $\mathsf{NameCert}_{\mathsf{CannotClaimExportGate}^{\uparrow}}$ *naming row N.*

Proof. Start with the carrier of Definition 1319.1. It displays exactly the rows $R, F, E, Q, T, A, H, C, P, N$, so the package has named coordinates for registry exposure, refusal exposure, export decision, export grade, target route, audit readback, transport, replay, provenance, and local naming.

Apply the NameCert obligations theorem Definition 1319.2. It identifies those coordinates as the local obligation surface. Apply refusal nonescape, registry factorization, export-grade scope, and the TasteGate handoff from Definition 1319.3, Definition 1319.4, Definition 1319.5, and Definition 1319.6. These theorems force the refused claim to pass through R, F, E, Q, T, A while H, C, P, N preserve the same field-faithful packet.

Finally use ledger exhaustion from Definition 1319.7. Since no additional export coordinate remains, the displayed rows are sufficient for the obligationClosure package and no verification-axis claim is needed to state the paper-side closure package. □

Lean4 ✓ `BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGateObligationClosurePackage`

Theorem 1319.9 (Cannot-claim export gate kernel scope lock)**.** *For every accepted* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *carrier $G = (R, F, E, Q, T, A, H, C, P, N)$, the consumer-facing scope of the gate is locked to the displayed* BHist, hsame, Cont, Pkg, NameCert, *registry, refusal, export, target, and audit rows. The TasteGate marker*

`BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGateTasteGate_single_carrier_alignment`

is the Lean-facing field-separation witness: it keeps $R, F, E, Q, T, A, H, C, P, N$ as distinct carrier rows before any checked-target export read can be compared. Thus a refused registry row has no kernel route to a checked formal-package target outside the displayed rows.

Proof. Project the accepted carrier. Its only rows are $R, F, E, Q, T, A, H, C, P, N$, with R displaying the registry site, F the refusal, E, Q the export decision and grade, T the target route, and A the audit readback.

Apply registry factorization, export-grade scope, TasteGate handoff, and ledger exhaustion. These results force every consumer-facing export read through the same finite row sequence before local naming, while the checked TasteGate marker records the Lean-facing fact that the fields remain separated.

The structural rows BHist, hsame, Cont, Pkg, and NameCert transport, replay, source, and name that packet. Since no extra checked-target coordinate is present, the kernel scope is exactly the displayed gate surface. □

Lean4 ✓ `BEDC.Derived.CannotClaimExportGateUp.CannotClaimExportGate kernel scope lock`

Falsifiable prediction: A refused cannot-claim registry row cannot be exported as a checked formal-package target through an accepted CannotClaimExportGateUp packet.

Independence witness: registryexportsurface, refusalregistry, machineinterfaceboundary, bedcphilosophypackage, auditexportfirewall: none is bijective to CannotClaimExportGateUp because the gate simultaneously carries refusal status, export grade, target route, audit readback, transport, continuation, provenance, and local NameCert rows.

The Lean follow-up must provide Nontrivial CannotClaimExportGate$^{\uparrow}$ and FieldFaithful CannotClaimExportGate$^{\uparrow}$ instances in `lean4/BEDC/Derived/CannotClaimExportGateUp/TasteGate.lean`. The field-faithfulness witness must preserve $R, F, E, Q, T, A, H, C, P, N$ as distinct rows before a checked target can cite `BEDC.Derived.CannotClaimExportGateUp.TasteGate.CannotClaimExportGateTasteGate_single_carrier_a`

Closure status for NameCert$_{\text{CannotClaimExportGate}^{\uparrow}}$.

Constructive story: A CannotClaimExportGate$^{\uparrow}$ packet is generated from registry rows, refusal rows, export-decision rows, target rows, audit rows, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier makes a blocked claim exportable only as a blocked claim: any consumer must read the registry entry and the refusal surface before reaching the export gate or formal target row. The ledger story is refusal preservation, where the audit and continuation rows carry the same cannot-claim evidence forward, preventing a refused registry item from being read as a checked package target or silently converted into success.

Theory closure: TheoryGate(NameCert$_{\text{CannotClaimExportGate}^{\uparrow}}$, maturePackageClosed)

Scope closed: This chapter binds the carrier, NameCert obligations, refusal nonescape, registry factorization, export-grade scope, TasteGate handoff, ledger exhaustion, obligation-closure package, and kernel scope lock for CannotClaimExportGate$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{CannotClaimExportGate}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim export of refused registry rows as checked formal-package targets outside the displayed registry, refusal, export, target, audit, transport, and naming rows.

Upgrade path: Verification work may encode the same export-gate package without changing the paper-side mature closure.

Chapter 1320

A Concrete Naming Certificate for $\mathsf{PhilosophyGovernanceExport}^{\uparrow}$

The $\mathsf{PhilosophyGovernanceExport}^{\uparrow}$ packet realizes the governance and export discipline of section 9462.33 as one finite NameCert carrier. It sits beside the package carrier of chapter 1292, the cannot-claim export gate of chapter 1319, the claim registry layer of chapter 1209, the philosophy map target of chapter 1277, and the gap/failure bridge audit of chapter 1229. Those siblings expose package rows, refusal-gate rows, claim rows, map-target rows, and bridge-audit rows separately; this carrier binds them before any package reading may leave as an export-grade claim.

Definition 1320.1 (Philosophy governance-export carrier)**.** *A* $\mathsf{PhilosophyGovernanceExport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (P, R, L, S, C, X, T, O, H, K, N)$$

with the following displayed rows:

1. *P is the package row, recording the* $\mathsf{BedcPhilosophyPackage}^{\uparrow}$ *thesis, registry, theorem-map, gap-map, tradition/science-map, closure-status, and audit-policy coordinates consumed by the export.*
2. *R is the finite cannot-claim registry row for the same package reading.*
3. *L is the active-label row, recording the current citation target, active formulation, and label discipline for the exported reading.*
4. *S is the capstone row, recording whether the reading spans the required registered domains and which dependencies are displayed.*
5. *C is the claim-registry row, recording claim text, admission status, local refusal status, and public route.*
6. *X is the export-grade row, recording reading export, paper-synthesis export, component-checked export, formal-package target, or formal-package checked status.*
7. *T is the transport row from* $\mathsf{CannotClaimExportGate}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{PhilosophyMapTarget}^{\uparrow}$, *and* $\mathsf{GapFailureBridgeAudit}^{\uparrow}$ *into the same package reading.*
8. *O is the route and provenance row, recording displayed* Cont *replay,* Pkg *source data, and package-file provenance for $P, R, L, S, C, X, T, H, N$.*

9. *H records componentwise* hsame *transport for package, registry, active-label, capstone, claim, export-grade, transport, route, provenance, and naming rows.*
10. *K is the policy row enforcing finite registry lookup, refusal lookup, active-label lookup, capstone dependency lookup, export-grade lookup, and no hidden checked-target override.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PhilosophyGovernanceExport}^{\uparrow}}$ *row.*

The carrier has no coordinate for an export whose claim row bypasses the cannot-claim registry, whose active label detaches from the exported formulation, whose capstone dependency list is implicit, whose export grade outruns its certificate, or whose checked formal-package status is supplied by host-side prose.

Lean4 ✓ `BEDC.Derived.PhilosophyGovernanceExportUp.PhilosophyGovernanceExportTasteGate single carrier alignment`

Theorem 1320.2 (Philosophy governance-export no override)**.** *Every accepted* $\mathsf{PhilosophyGovernanceExport}^{\uparrow}$ *export route factors through the package row P, cannot-claim registry row R, active-label row L, capstone row S, claim-registry row C, export-grade row X, transport row T, route/provenance row O, componentwise transport row H, policy row K, and local naming row N. No consumer can override an active refusal, active label, capstone dependency list, export grade, or package provenance by appealing to prose adjacency in the philosophy package.*

Proof. Project the finite packet $E = (P, R, L, S, C, X, T, O, H, K, N)$. The package row P names the package reading, while R, L, S, C, X display the refusal, active-label, capstone, claim-registry, and export-grade surfaces before any public route is named.

The transport and route rows then preserve the same order. The row T cites the sibling refusal gate, claim registry layer, philosophy map target, and gap/failure bridge audit, while O replays the displayed route and provenance for the same reading.

Finally H, K, N compare, enforce, and name the packet. Since the carrier has no further coordinate, a consumer has nowhere to obtain a checked-target override, a different active label, or a stronger export grade. The no-override claim is therefore a projection of the displayed rows. □

Lean4 ✓ `BEDC.Derived.PhilosophyGovernanceExportUp.PhilosophyGovernanceExportNoOverride`

Theorem 1320.3 (Philosophy governance-export NameCert obligations)**.** *For the carrier of Definition 1320.1, the local* $\mathsf{NameCert}_{\mathsf{PhilosophyGovernanceExport}^{\uparrow}}$ *surface consists exactly of carrier admission for $E = (P, R, L, S, C, X, T, O, H, K, N)$, package exposure through P, cannot-claim exposure through R, active-label exposure through L, capstone exposure through S, claim-registry exposure through C, export-grade exposure through X, sibling transport through T, displayed route and provenance through O, componentwise* hsame *transport through H, finite policy enforcement through K, and local naming through N.*

Proof. Read the packet by coordinates. Carrier admission supplies the finite BHist object, and the rows P, R, L, S, C, X supply the package reading, refusal registry, active label, capstone dependencies, claim entry, and export grade.

The support rows then expose the audit route. The row T records which sibling surfaces are consumed, O records continuation and provenance, H transports only the displayed rows, and K checks the finite policy conditions before the local name N is available.

There is no remaining field in the packet. Hence the listed coordinates exhaust the local NameCert obligations, and any accepted export must be read through those obligations. □

Falsifiable prediction: If either the cannot-claim registry row R or the export-grade row X is absent, Definition 1320.2 fails because a consumer can no longer distinguish refused package readings from export-grade readings inside the carrier.

Independence witness: bedcphilosophypackage, cannotclaimexportgate, claimregistrylayer, philosophymaptarget, gapfailurebridgeaudit: none is bijective to PhilosophyGovernanceExportUp because this packet simultaneously carries finite registry, refusal, active-label, capstone, export-grade, transport, route, provenance, policy, and local NameCert rows.

The Lean follow-up must provide Nontrivial PhilosophyGovernanceExport$^{\uparrow}$ and FieldFaithful PhilosophyGovernance instances in `lean4/BEDC/Derived/PhilosophyGovernanceExportUp/TasteGate.lean`. The field-faithfulness witness must preserve $P, R, L, S, C, X, T, O, H, K, N$ as distinct rows before a checked target can cite `BEDC.Derived.PhilosophyGovernanceExportUp.TasteGate.PhilosophyGovernanceExportTast`

Closure status for $\mathsf{NameCert}_{\mathsf{PhilosophyGovernanceExport}^{\uparrow}}$.

Constructive story: A PhilosophyGovernanceExport$^{\uparrow}$ packet is generated from package, cannot-claim, active-label, capstone, claim-registry, export-grade, sibling-transport, route/provenance, componentwise hsame transport, policy, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhilosophyGovernanceExport}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1320.1, Definition 1320.2, Definition 1320.3, the falsifiable prediction, and the independence witness bind governance and export discipline to a finite no-override NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhilosophyGovernanceExport}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, complete package correctness, checked formal-package status, or any primitive philosophical object, host truth, quotient, choice, or hidden subject reading.

Upgrade path: Lean closure requires Nontrivial PhilosophyGovernanceExportUp and FieldFaithful PhilosophyGovernanceExportUp instances in `lean4/BEDC/Derived/PhilosophyGovernanceExportUp/TasteGate.lean`.

Chapter 1321

A Concrete Naming Certificate for $\mathsf{PackageGovernanceExport}^{\uparrow}$

The $\mathsf{PackageGovernanceExport}^{\uparrow}$ packet realizes the philosophy-package cannot-claim, in-place governance, capstone, and export interface of subsection 9462.33.7, subsection 9462.33.9, and subsection 9462.33.10 as one finite NameCert carrier. It sits beside the package carrier of chapter 1292, the claim registry layer of chapter 1209, the registry export surface of chapter 1216, the audit export firewall of chapter 1296, and the package map boundary of chapter 1307. Those siblings expose package rows, claim admission, export rows, audit refusal, and map-boundary rows separately; this packet binds them before a philosophy-package governance decision can be read as an exportable NameCert row.

Definition 1321.1 (Package governance export carrier)**.** *A* $\mathsf{PackageGovernanceExport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (P, R, A, C, E, F, T, M, H, K, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{BedcPhilosophyPackage}^{\uparrow}$ *row, recording the package thesis, concept registry, theorem map, gap map, tradition/science map, cannot-claim registry, closure-status row, and audit-policy row consumed by the governance packet.*

2. *R is the cannot-claim registry row, recording blocked philosophical readings, refusal status, reason, upgrade boundary, and the gate through which* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *and* $\mathsf{RegistryExportSurface}^{\uparrow}$ *must read the refusal.*

3. *A is the in-place governance row, recording the affected registry entry, active label, replacement boundary, status effect, and audit-continuity data for package governance.*

4. *C is the capstone dependency row, recording the concept, theorem-map, gap-map, tradition/science-map, and closure-status dependencies that license any capstone export.*

5. *E is the export-grade row, recording reading export, paper synthesis export, component checked export, formal package target, and formal package checked status as displayed grades rather than prose impressions.*

6. *F is the* $\mathsf{AuditExportFirewall}^{\uparrow}$ *row, recording the same claim site, positive certificate when present, active failure or refusal when present, consistency gate, and firewall decision.*

7. *T is the target row, recording the machine-facing route, paper-only route when present, Lean target name when present, and absence of a checked package target when a refusal or missing dependency is active.*
8. *M is the* $\mathsf{PackageMapBoundary}^{\uparrow}$ *row, recording theorem-map, gap-map, tradition-map, scientific-map, and axis-boundary handoff for the same package reading.*
9. *H records componentwise* hsame *transport for package, registry, governance, capstone, export, firewall, target, map-boundary, replay, provenance, and local naming rows.*
10. *K records displayed* Cont *replay for reading P, R, A, C, E, F, T, M without adding a host-side governance override or checked-target shortcut.*
11. *Q is the* Pkg *provenance over* $\mathsf{PackageGovernanceExport}^{\uparrow}$, $\mathsf{BedcPhilosophyPackage}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{AuditExportFirewall}^{\uparrow}$, $\mathsf{PackageMapBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PackageGovernanceExport}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden governance decision, unregistered cannot-claim override, capstone without dependencies, export grade detached from refusal audit, unchecked formal-package target, host equality, quotient import, choice import, or prose-only package promotion.

Lean4 ✓ `BEDC.Derived.PackageGovernanceExportUp.PackageGovernanceExportTasteGate single carrier alignment`

Theorem 1321.2 (Package governance export NameCert obligations)**.** *For the carrier of Definition 1321.1, the local* $\mathsf{NameCert}_{\mathsf{PackageGovernanceExport}^{\uparrow}}$ *surface consists exactly of carrier admission for $G = (P, R, A, C, E, F, T, M, H, K, Q, N)$, package exposure through P, cannot-claim registry exposure through R, in-place governance exposure through A, capstone dependency exposure through C, export-grade exposure through E, firewall readback through F, target-route exposure through T, package-map boundary exposure through M, componentwise* hsame *transport through H, displayed* Cont *replay through K, package provenance through Q, and local naming through N.*

Proof. Project the finite packet $G = (P, R, A, C, E, F, T, M, H, K, Q, N)$. The package row P supplies the whole philosophy-package surface, while R, A, C, E display the refusal registry, governance action, capstone dependency set, and export grade before any target route is named.

Next read the sibling audit rows. The firewall row F checks the same claim site against positive and negative certificate data, the target row T records whether a machine-facing or paper-only route is available, and the map-boundary row M keeps theorem, gap, tradition, science, and axis-boundary maps visible.

Finally H, K, Q, N transport, replay, source, and name exactly those displayed rows. Since the carrier contains no hidden governance, export, or target coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 1321.3 (Package governance export refusal totality)**.** *Every accepted* $\mathsf{PackageGovernanceExport}^{\uparrow}$ *export decision reads the cannot-claim row R and the audit-firewall row F before projecting the export-grade row E, target row T, or local naming row N. If R contains an active refusal for the package reading, the packet cannot expose that reading as formal package checked or as a checked formal-package target.*

Proof. Assume an accepted packet $G = (P, R, A, C, E, F, T, M, H, K, Q, N)$. The refusal row R is displayed before export-grade or target projection, so the reading is first classified as admitted, deferred, partial, or blocked by the cannot-claim registry.

The firewall row F reads the same site against the audit rows. If R carries an active refusal, then F records refusal or certificate conflict for that site rather than an admitted checked-target export.

Rows E and T are therefore downstream of the refusal and firewall reads. They can expose a weaker export grade, a paper-only route, or an absent checked package target, but they have no coordinate that can erase R or F. The local naming row N names the factored packet and does not create an independent export path. □

Theorem 1321.4 (Package governance export sibling independence)**.** *The* $\mathsf{PackageGovernanceExport}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{BedcPhilosophyPackage}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{AuditExportFirewall}^{\uparrow}$, *or* $\mathsf{PackageMapBoundary}^{\uparrow}$. *Each sibling is consumed through a displayed row, but none carries the joint package, refusal, governance, capstone, export-grade, firewall, target, map-boundary, transport, replay, provenance, and local naming packet.*

Proof. Compare the displayed rows. $\mathsf{BedcPhilosophyPackage}^{\uparrow}$ supplies the package ledger, $\mathsf{ClaimRegistryLayer}^{\uparrow}$ supplies claim admission and refusal boundary, $\mathsf{RegistryExportSurface}^{\uparrow}$ supplies export rows, $\mathsf{AuditExportFirewall}^{\uparrow}$ supplies same-site audit refusal, and $\mathsf{PackageMapBoundary}^{\uparrow}$ supplies the theorem, gap, tradition, science, and axis-boundary handoff.

The governance export carrier contains those sibling roles together with the in-place governance row A, capstone dependency row C, export-grade row E, target row T, and local NameCert row N. A NameCert-row-preserving bijection would have to preserve this joint governance-and-export surface.

No listed sibling has all of these coordinates as local rows. Hence each sibling is a dependency or consumer surface for $\mathsf{PackageGovernanceExport}^{\uparrow}$, not a bijective presentation of it. □

Theorem 1321.5 (Package governance export capstone dependency exactness)**.** *An accepted* $\mathsf{PackageGovernanceExport}^{\uparrow}$ *packet may expose a capstone export only through the capstone dependency row C together with the map-boundary row M and audit-firewall row F. If C omits a displayed dependency family, the packet may still record a package reading, but it cannot certify that reading as a capstone export.*

Proof. The capstone row C is the only coordinate that records cross-domain dependencies for a unifying package claim. It must therefore be read before a capstone export grade is projected.

The map-boundary row M then checks that the dependency families are visible as theorem-map, gap-map, tradition-map, scientific-map, and axis-boundary handoffs. The firewall row F checks whether any active refusal or certificate conflict addresses the same site.

If C omits one dependency family, the packet still has package, registry, governance, and export rows. But the capstone-specific dependency certificate is absent, and neither M nor F can manufacture it. The export can remain a package reading or weaker export grade, not a certified capstone export. □

Falsifiable prediction: Deleting the cannot-claim row or firewall row permits a governance packet to name an export grade without first refusing blocked package readings.

Independence witness: bedcphilosophypackage, claimregistrylayer, registryexportsurface, auditexportfirewall, packagemapboundary: none is bijective because PackageGovernanceExportUp carries the joint governance, capstone-dependency, export-grade, target, firewall, map-boundary, transport, replay, provenance, and local NameCert rows.

The Lean `TasteGate.lean` boundary for $\mathsf{PackageGovernanceExport}^{\uparrow}$ must provide $\mathsf{Nontrivial}\ \mathsf{PackageGovernance}$ and $\mathsf{FieldFaithful}\ \mathsf{PackageGovernanceExport}^{\uparrow}$ instances in `lean4/BEDC/Derived/PackageGovernanceExportUp/Tas`

The nontriviality witness must expose at least one governed package export decision, and field faithfulness must preserve $P, R, A, C, E, F, T, M, H, K, Q, N$ as distinct rows before any checked marker can cite `BEDC.Derived.PackageGovernanceExportUp.TasteGate.PackageGovernanceExportTasteGate_single`

Closure status for $\mathsf{NameCert}_{\mathsf{PackageGovernanceExport}\uparrow}$.

Constructive story: A $\mathsf{PackageGovernanceExport}^{\uparrow}$ packet is generated from package, cannot-claim registry, in-place governance, capstone dependency, export grade, audit firewall, target route, map-boundary, componentwise transport, displayed replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PackageGovernanceExport}\uparrow}, \mathsf{seed})$

Scope closed: Definition 1321.1, Definition 1321.2, Definition 1321.3, Definition 1321.4, and Definition 1321.5 bind package governance and export to one finite NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PackageGovernanceExport}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, registry completeness, correctness of every governance action, correctness of every capstone dependency, or whole-package checked export.

Upgrade path: Lean closure requires Nontrivial PackageGovernanceExportUp and FieldFaithful PackageGovernanceExportUp instances in `lean4/BEDC/Derived/PackageGovernanceExportUp/TasteGate.lean`.

Chapter 1322

A Concrete Naming Certificate for PhaseGovernedCertificateRoute$^{\uparrow}$

The PhaseGovernedCertificateRoute$^{\uparrow}$ packet realizes the research-programme route of section 9462.32 as a finite certificate router. It sits beside ProgrammeStrengthLedger$^{\uparrow}$ of chapter 1305, PhilosophyCannotClaimRegistr of chapter 1318, CannotClaimExportGate$^{\uparrow}$ of chapter 1319, and UseProcessBoundary$^{\uparrow}$ of chapter 1313: those siblings record strength, refusal, export blocking, and certified-use process boundaries, while this packet binds their rows before a philosophy programme may present a claim as routed through a named certificate phase. The certified-use consumer of chapter 1317 supplies the public use process read by the same route.

Definition 1322.1 (Phase-governed certificate route carrier)**.** *A* PhaseGovernedCertificateRoute$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, S, F, E, D, U, H, C, P, N)$$

with the following displayed rows:

1. *A is the phase row, recording the current certificate phase and the admissible next phase for the programme route;*
2. *S is the strength row, read from the* ProgrammeStrengthLedger$^{\uparrow}$ *surface;*
3. *F is the refusal row, read from the* PhilosophyCannotClaimRegistry$^{\uparrow}$ *surface;*
4. *E is the export-gate row, read from the* CannotClaimExportGate$^{\uparrow}$ *surface before any checked-target reading is exposed;*
5. *D is the dependency and failure-audit row, recording open blockers, failed obligations, and audit-facing non-export decisions;*
6. *U is the certified-use and process-boundary row, read through* UseProcessBoundary$^{\uparrow}$ *and* CertifiedUseProcess$^{\uparrow}$*;*
7. *H records componentwise* hsame *transport for phase, strength, refusal, export, dependency, use-process, continuation, provenance, and local naming rows;*
8. *C records displayed* Cont *replay through the same rows;*
9. *P records* Pkg *provenance over* PhaseGovernedCertificateRoute$^{\uparrow}$*,* ProgrammeStrengthLedger$^{\uparrow}$*,* PhilosophyCannotCl CannotClaimExportGate$^{\uparrow}$*,* UseProcessBoundary$^{\uparrow}$*,* CertifiedUseProcess$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{PhaseGovernedCertificateRoute}^{\uparrow}}$ *row.*

The carrier has no coordinate for skipping the phase row, erasing refusal, inflating strength, exporting a blocked target, hiding a failure-audit row, or reading a certified use outside the displayed process boundary.

Lean4 ✓ `BEDC.Derived.PhaseGovernedCertificateRouteUp.PhaseGovernedCertificateRouteTasteGate`
`single carrier alignment`

Theorem 1322.2 (Phase-governed certificate route NameCert obligations)**.** *For the carrier of Definition 1322.1, the local* $\mathsf{NameCert}_{\mathsf{PhaseGovernedCertificateRoute}^{\uparrow}}$ *surface consists exactly of carrier admission for $R = (A, S, F, E, D, U, H, C, P, N)$, phase exposure through A, strength exposure through S, refusal exposure through F, export-gate exposure through E, dependency and failure-audit exposure through D, certified-use and process-boundary exposure through U, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the finite packet. The phase row A is read before the strength, refusal, export, dependency, and use-process rows can be treated as one route.

Read the sibling surfaces in the displayed order. The strength ledger supplies S, the cannot-claim registry supplies F, the export gate supplies E, and the use-process boundary supplies U; the failure-audit row D records blockers that prevent a stronger certificate reading.

Finally use H, C, P, N to transport, replay, source, and name the same packet. Since no further route coordinate is present, these rows exhaust the local NameCert obligations. □

Theorem 1322.3 (Phase-governed certificate route nonescape)**.** *Every accepted* $\mathsf{PhaseGovernedCertificateRoute}^{\uparrow}$ *consumer reads a programme claim through the phase row A, strength row S, refusal row F, export-gate row E, dependency and failure-audit row D, certified-use and process-boundary row U, transport row H, replay row C, provenance row P, and local naming row N. It cannot export a stronger phase, erase a refusal, bypass a blocked export gate, hide a failure-audit row, replace certified use by prose, or obtain a checked target outside those rows.*

Proof. Begin with the NameCert obligations. They force any accepted route to expose $A, S, F, E, D, U, H, C, P, N$ before the local name is available.

The sibling packets keep the route non-escaping. $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ blocks strength inflation, $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$ preserves the refusal row, $\mathsf{CannotClaimExportGate}^{\uparrow}$ blocks refused checked-target export, and $\mathsf{UseProcessBoundary}^{\uparrow}$ keeps certified use tied to process mediation.

The remaining transport, replay, provenance, and naming rows preserve that same display. Hence the accepted route has no coordinate from which a stronger phase, erased refusal, bypassed export, hidden blocker, prose-only use, or unchecked target can be exported. □

Falsifiable prediction: If a PhaseGovernedCertificateRouteUp packet remains accepted after deleting either its phase row or its refusal row, then the route carrier is refuted.

Independence witness: programmestrengthledger, philosophycannotclaimregistry, cannotclaimexportgate, useprocessboundary, certifieduseprocess: none is bijective to PhaseGovernedCertificateRouteUp because the route binds phase, strength, refusal, export gate, failure audit, dependency, certified use, transport, replay, provenance, and local naming in one finite packet.

The Lean follow-up requires $\mathsf{Nontrivial}\ \mathsf{PhaseGovernedCertificateRoute}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{PhaseGovernedCertificate}$ instances in `lean4/BEDC/Derived/PhaseGovernedCertificateRouteUp/TasteGate.lean`. The

field-faithfulness witness must keep $A, S, F, E, D, U, H, C, P, N$ as distinct rows before a checked boundary can cite `BEDC.Derived.PhaseGovernedCertificateRouteUp.TasteGate`.

Closure status for $\mathsf{NameCert}_{\mathsf{PhaseGovernedCertificateRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{PhaseGovernedCertificateRoute}^{\uparrow}$ packet is generated from a phase row, certificate row, refusal row, export-gate row, failure-roadmap row, certified-use row, process-boundary row, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier treats the certificate route as phase governed: each export or target read must pass through the displayed phase and refusal coordinates before it can inspect the certificate or use-process rows. The ledger story is route discipline, where transport and replay preserve blocked targets, failure audits, and certified-use boundaries instead of allowing a stronger phase or erased refusal to be inferred from prose.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhaseGovernedCertificateRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, NameCert-obligation theorem, nonescape theorem, Lean-follow-up boundary, and existing closure annotation for $\mathsf{PhaseGovernedCertificateRoute}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhaseGovernedCertificateRoute}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.PhaseGovernedCertificateRouteUp.PhaseGovernedCertificateRouteTasteGate\_single\_carrier`

Bridge status: none

Origin: ai

Not claimed: It does not claim phase skipping, refusal erasure, strength inflation, blocked-target export, hidden failure-audit rows, or certified use outside the process boundary.

Upgrade path: To reach obligationClosure, the phase-governed carrier and nonescape theorem must be represented as checked route and refusal-preservation obligations.

Chapter 1323

A Concrete Naming Certificate for PackageExportDiscipline$^{\uparrow}$

The PackageExportDiscipline$^{\uparrow}$ packet realizes the export discipline of section 9462.33 as a finite NameCert carrier for philosophy-package exports. It sits beside the package-map boundary of chapter 1307, the cannot-claim registry of chapter 1318, the registry export surface of chapter 1216, the cannot-claim export gate of chapter 1319, and the formal-target ledger of chapter 1282. Those siblings expose map boundaries, refusal status, registry export rows, export-grade gates, and formal-target ledgers separately; this carrier binds them into one package export packet before a philosophy reading can leave the package.

Definition 1323.1 (Package export discipline carrier)**.** *A* PackageExportDiscipline$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, R, S, G, T, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the package-map row, recording theorem-map, gap-map, tradition-map, scientific-map, and axis-boundary data from* PackageMapBoundary$^{\uparrow}$*;*
2. *R is the refusal-registry row, recording cannot-claim status, exclusion reason, upgrade boundary, and blocking gate from* PhilosophyCannotClaimRegistry$^{\uparrow}$*;*
3. *S is the registry-export row, recording registration, blocking, status, machine target, audit route, and non-smuggling data from* RegistryExportSurface$^{\uparrow}$*;*
4. *G is the export-gate row, recording refusal, export decision, export grade, target route, and audit readback from* CannotClaimExportGate$^{\uparrow}$*;*
5. *T is the formal-target row, recording claim entry, target skeleton, no-smuggling, closure status, refusal boundary, and machine-readable audit route from* PhilosophyFormalTargetLedger$^{\uparrow}$*;*
6. *U is the package non-smuggling row, recording that no export may bypass any of M, R, S, G, T by prose adjacency, hidden registry state, or an unchecked machine target;*
7. *H records componentwise* hsame *transport for the five sibling rows, non-smuggling row, replay, provenance, and local naming;*
8. *C records displayed* Cont *replay for package-map inspection, refusal inspection, registry-export inspection, gate inspection, formal-target inspection, and non-smuggling readback;*

9. *P is the* Pkg *provenance over* $\mathsf{PackageMapBoundary}^{\uparrow}$, $\mathsf{PhilosophyCannotClaimRegistry}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{CannotClaimExportGate}^{\uparrow}$, $\mathsf{PhilosophyFormalTargetLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PackageExportDiscipline}^{\uparrow}}$ *row.*

The carrier has no coordinate for an export that preserves only a package map, only a registry row, only a refusal, only an export gate, only a formal target, or a hidden package-level synthesis outside the displayed packet.

Theorem 1323.2 (Package export discipline NameCert obligations)**.** *For the carrier of Definition 1323.1, the local* $\mathsf{NameCert}_{\mathsf{PackageExportDiscipline}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for $E = (M, R, S, G, T, U, H, C, P, N)$, package-map coverage through M, refusal-registry coverage through R, registry-export coverage through S, cannot-claim export-gate coverage through G, formal-target coverage through T, non-smuggling coverage through U, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the finite packet $E = (M, R, S, G, T, U, H, C, P, N)$. The first five rows are read as sibling NameCert surfaces: M supplies the package-map boundary, R supplies the cannot-claim registry, S supplies the registry-export surface, G supplies the cannot-claim export gate, and T supplies the formal-target ledger.

Read the non-smuggling row next. It states that a package export is not admitted through prose adjacency, hidden registry state, or unchecked target routing unless the same packet carries M, R, S, G, T.

Finally H, C, P, N transport, replay, source, and locally name the displayed rows. Since the carrier has no further coordinate, these rows exhaust the local $\mathsf{NameCert}_{\mathsf{PackageExportDiscipline}^{\uparrow}}$ obligation surface. □

Theorem 1323.3 (Package export discipline non-smuggling boundary)**.** *Every accepted* $\mathsf{PackageExportDiscipline}^{\uparrow}$ *export factors through the package-map row M, refusal-registry row R, registry-export row S, export-gate row G, formal-target row T, and non-smuggling row U before local naming. Removing either the cannot-claim gate row G or the registry-export row S permits only a partial package record, not an accepted package export discipline packet.*

Proof. Start with the obligation theorem. The export reads M, R, S, G, T before any package-level export can be named, and U blocks routes that skip one of those rows.

If S is absent, the packet has no displayed registry-export row recording registration, blocking, status, machine target, audit route, and non-smuggling data. A consumer may still inspect map or refusal data, but it cannot export a registry reading through $\mathsf{PackageExportDiscipline}^{\uparrow}$.

If G is absent, the packet has no displayed cannot-claim export gate. A refused claim can no longer be checked against an export decision, export grade, target route, and audit readback inside the same package export carrier.

The rows H, C, P, N preserve and name the accepted packet only after M, R, S, G, T, U have been supplied. Hence a route missing S or G leaves the accepted carrier rather than producing a package export discipline packet. □

Theorem 1323.4 (Package export discipline cross-reference handoff)**.** *The Lean-facing handoff for* $\mathsf{PackageExportDiscipline}^{\uparrow}$ *must preserve package-map, registry-export, cannot-claim, export-gate, formal-target, non-smuggling, transport, replay, provenance, and local NameCert rows as distinct*

fields. A consumer that collapses any of M, R, S, G, T cannot recover the cross-reference discipline required by chapter 1307, chapter 1318, chapter 1216, chapter 1319, and chapter 1282.

Proof. The five sibling rows are cited for different reasons. The package-map row supplies boundary coordinates, the refusal-registry row supplies cannot-claim status, the registry-export row supplies public export control, the export-gate row supplies the refused-claim gate, and the formal-target row supplies the machine-readable target ledger.

The non-smuggling, transport, replay, provenance, and local naming rows keep those citations tied to the same finite packet. They do not identify the rows with one another and do not create a replacement route when a sibling row is missing.

Therefore the handoff to Lean must use a field-faithful carrier. The proposed Lean follow-up must provide explicit Nontrivial PackageExportDiscipline$^{\uparrow}$ and FieldFaithful PackageExportDiscipline$^{\uparrow}$ instances in `lean4/BEDC/Derived/PackageExportDisciplineUp/TasteGate.lean`, with a target shaped for `BEDC.Derived.PackageExportDisciplineUp.PackageExportDisciplineTasteGate_single_carrie` □

Lean4 ✓ `BEDC.Derived.PackageExportDisciplineUp.PackageExportDisciplineTasteGate single carrier alignment`

Falsifiable prediction: Removing the cannot-claim gate row or registry-export row permits an export that the package discipline theorem rejects.

Independence witness: packagemapboundary, philosophycannotclaimregistry, registryexportsurface, cannotclaimexportgate, philosophyformaltargetledger: none is bijective to PackageExportDiscipline$^{\uparrow}$ because the export packet preserves package-map, registry-export, cannot-claim, export-gate, and formal-target rows simultaneously.

Closure status for NameCert$_{\text{PackageExportDiscipline}^{\uparrow}}$.

Constructive story: A PackageExportDiscipline$^{\uparrow}$ packet is generated from a package-map row, registry row, refusal row, export-gate row, formal-target row, synthesis row, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier requires all of these rows before an export can be read as disciplined; no single package map, registry entry, refusal, gate, or formal target is enough by itself. The ledger story is anti-smuggling: the same finite BHist packet must carry map, registry, refusal, gate, target, and synthesis evidence, and the continuation routes expose exactly which rows a downstream export consumes.

Theory closure: TheoryGate(NameCert$_{\text{PackageExportDiscipline}^{\uparrow}}$, seed)

Scope closed: This chapter binds the carrier definition, NameCert-obligation, non-smuggling-boundary, cross-reference-handoff, independence witness, and existing closure annotations for PackageExportDiscipline$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{PackageExportDiscipline}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim exports preserving only one constituent row or hidden package-level synthesis outside the displayed packet.

Upgrade path: To reach obligationClosure, the export-discipline carrier and non-smuggling boundary must be checked as finite-row dependency obligations.

Chapter 1324

A Concrete Naming Certificate for $\mathsf{ReviewAcceptanceGate}^{\uparrow}$

The $\mathsf{ReviewAcceptanceGate}^{\uparrow}$ packet realizes the research-programme route of section 9462.32 as a finite NameCert surface for operator review. It sits beside the failure-certificate packet of chapter 1233, the cannot-claim export gate of chapter 1319, the machine-interface boundary of chapter 1221, the kernel acceptance witness of chapter 549, and the kernel audit witness of chapter 546. Those siblings expose refusal, export blocking, machine-facing routing, kernel admission, and audit readback separately; this carrier binds proposal, decision, rejected alternatives, acceptance row, audit readback, and non-automation boundary before a consumer may read operator approval.

Definition 1324.1 (Review acceptance gate carrier)**.** *A* $\mathsf{ReviewAcceptanceGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, D, R, A, M, K, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the proposal row, naming the claim site, proposed paper or Lean target, requested gate, and submitted certificate packet;*
2. *D is the decision row, recording accept, refuse, request-more-evidence, cannot-claim, or machine-boundary refusal for the same proposal;*
3. *R is the rejected-alternatives row, listing rejected readings, unavailable proof routes, refused automation paths, and non-exportable claim variants;*
4. *A is the human acceptance row, present exactly when the operator accepts the proposal as a review decision rather than as an automated theorem result;*
5. *M is the* $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ *row, recording what the machine-facing route may expose and what it must refuse;*
6. *K is the kernel row, read through* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$ *and* $\mathsf{KernelAuditWitness}^{\uparrow}$ *when a Lean declaration or marker is part of the proposal;*
7. *Q is the blocked-claim row, consumed from* $\mathsf{FailureCertificate}^{\uparrow}$ *and* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *when the decision refuses approval or export;*
8. *H records componentwise* hsame *transport for proposal, decision, rejected alternatives, acceptance, machine boundary, kernel rows, blocked-claim rows, continuation, provenance, and local naming;*

9. *C records displayed* Cont *replay for reading S, D, R, A, M, K, Q without adding an invisible approving agent;*
10. *P is the* Pkg *provenance over* ReviewAcceptanceGate$^{\uparrow}$, FailureCertificate$^{\uparrow}$, CannotClaimExportGate$^{\uparrow}$, MachineInterfaceBoundary$^{\uparrow}$, KernelAcceptanceWitness$^{\uparrow}$, KernelAuditWitness$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ReviewAcceptanceGate}^{\uparrow}}$ *row.*

The carrier has no coordinate for converting a machine-produced proposal, kernel acceptance stamp, audit readback, cannot-claim refusal, or failure certificate into operator approval without the displayed human acceptance row A.

Lean4 ✓ `BEDC.Derived.ReviewAcceptanceGateUp.ReviewAcceptanceGateTasteGate single carrier alignment`

Theorem 1324.2 (Review acceptance gate NameCert obligations)**.** *For the carrier of Definition 1324.1, the local* $\mathsf{NameCert}_{\mathsf{ReviewAcceptanceGate}^{\uparrow}}$ *surface consists exactly of carrier admission for $G = (S, D, R, A, M, K, Q, H, C, P, N)$, proposal exposure through S, decision exposure through D, rejected-alternative exposure through R, human acceptance exposure through A, machine-boundary exposure through M, kernel acceptance and audit exposure through K, refusal and export-block exposure through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ReviewAcceptanceGateUp.ReviewAcceptanceGateNameCertObligations`

Proof. Project the finite packet $G = (S, D, R, A, M, K, Q, H, C, P, N)$. The proposal row S fixes the claim site and requested gate, while D records the decision attached to that same proposal.

Read the boundary rows next. The rejected-alternatives row R records routes not accepted; the human acceptance row A is the only row that turns the decision into operator approval; the machine boundary row M and kernel row K expose machine and Lean-side evidence without identifying either with approval.

Finally inspect Q, H, C, P, N. Refusal and cannot-claim rows remain visible through Q, while transport, replay, provenance, and local naming preserve the same displayed packet. Since no further coordinate remains, the listed rows exhaust the local NameCert obligations. □

Theorem 1324.3 (Review acceptance gate human approval boundary)**.** *For every accepted* ReviewAcceptanceGate$^{\uparrow}$ *packet $G = (S, D, R, A, M, K, Q, H, C, P, N)$, a consumer may read operator approval only through the human acceptance row A together with the proposal and decision rows S, D. Kernel acceptance data in K, audit readback in K, machine-facing route data in M, and refusal data in Q do not by themselves produce an accepted operator decision.*

Lean4 ✓ `BEDC.Derived.ReviewAcceptanceGateUp.ReviewAcceptanceGateHumanApprovalBoundary`

Proof. Start with the carrier definition. It separates the proposal, decision, rejected alternatives, human acceptance, machine boundary, kernel rows, and blocked-claim rows as distinct coordinates.

The NameCert obligations above make that separation consumer-visible. A route that reads K obtains kernel acceptance or audit data; a route that reads M obtains machine-facing admissibility; a route that reads Q obtains refusal or export blocking. None of these rows is the human acceptance row.

Therefore the only approval route is the one that reads S, D, A in the same packet and then transports, replays, sources, and names that packet through H, C, P, N. □

Theorem 1324.4 (Review acceptance gate non-automation boundary)**.** *If the human acceptance row A is removed from an accepted* $\mathsf{ReviewAcceptanceGate}^{\uparrow}$ *packet, then no route through $S, D, R, M, K, Q, H, C, P, N$ can classify the packet as operator approved. The remaining rows may still expose a proposal, a machine boundary, a kernel or audit witness, a refusal, rejected alternatives, transport, replay, provenance, and local naming, but they cannot cross the operator-only gate.*

Proof. Remove A and read the remaining coordinates. The proposal and decision rows can still name a requested gate, and the rejected-alternatives row can still record what was refused.

The machine, kernel, audit, failure, and cannot-claim rows then remain evidence rows only. They may support or block a decision, but none of them has the operator-approval type carried by A.

Transport, continuation, provenance, and local naming preserve existing rows rather than creating a missing one. Hence a packet without A cannot pass the operator-only gate as an accepted review packet. □

Falsifiable prediction: Removing the human acceptance row prevents any accepted packet from passing the operator-only gate.

Independence witness: failurecertificate, cannotclaimexportgate, machineinterfaceboundary, kernelacceptancewitness, kernelauditwitness: none is bijective to ReviewAcceptanceGateUp because only ReviewAcceptanceGateUp preserves proposal, decision, rejected alternatives, acceptance row, and non-automation boundary in one packet.

The Lean TasteGate file must provide explicit $\mathsf{Nontrivial\ ReviewAcceptanceGate}^{\uparrow}$ and FieldFaithful ReviewAccepta instances in `lean4/BEDC/Derived/ReviewAcceptanceGateUp/TasteGate.lean`. The field-faithfulness witness must preserve $S, D, R, A, M, K, Q, H, C, P, N$ as distinct rows before a checked target can cite `BEDC.Derived.ReviewAcceptanceGateUp.taste_gate`.

Closure status for $\mathsf{NameCert}_{\mathsf{ReviewAcceptanceGate}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ReviewAcceptanceGate}^{\uparrow}$ packet is generated from proposal, decision, rejected-alternative, human-acceptance, machine-boundary, kernel-acceptance, kernel-audit, blocked-claim, componentwise hsame transport, displayed Cont replay, package provenance, and local naming rows. The classifier reads operator approval only when the proposal and decision are paired with the explicit human acceptance coordinate; machine-produced proposals, kernel stamps, audits, and refusals remain separate rows. The ledger story is non-automation: every accepted review route is generated from finite BEDC evidence plus the displayed acceptance row, and transport or replay can preserve that row but cannot synthesize it from machine evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ReviewAcceptanceGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, NameCert-obligation, human-approval-boundary, non-automation-boundary, independence witness, Lean-follow-up boundary, and existing closure annotations for $\mathsf{ReviewAcceptanceGate}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ReviewAcceptanceGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim conversion of machine proposals, kernel acceptance, audit readback, refusals, or failure certificates into approval without the human acceptance row.

Upgrade path: To reach obligationClosure, the review carrier and non-automation boundary must be checked as finite-row acceptance obligations.

Chapter 1325

A Concrete Naming Certificate for $\mathsf{RealWindowClassifierSeal}^{\uparrow}$

The $\mathsf{RealWindowClassifierSeal}^{\uparrow}$ packet packages the finite-window classifier demanded by the Real-completion axiom-purity boundary. It sits after the explicit-modulus refusal surface of chapter 1200, the finite-window seal audit of chapter 1199, the regular Cauchy naming layer of chapter 371, and the readback carriers chapter 126, chapter 291, chapter 301, and chapter 38. Its job is to make the Real-facing classifier a displayed NameCert packet before any completion consumer reads a seal row.

Definition 1325.1 (Real window classifier seal carrier)**.** *A* $\mathsf{RealWindowClassifierSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, D, R, E, F, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite stream observations used by the completion consumer.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row for the dyadic values and tolerance ledger visible inside that window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row proving that the displayed dyadic readbacks are regular-Cauchy data.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, R have been displayed.*
5. *F is the finite-window classifier row, comparing accepted packets by the displayed stream window, dyadic readback, regular-Cauchy handoff, and Real seal.*
6. *A is the axiom-refusal row, recording absence of quotient streams, host real equality, selected limits, countable choice,* `Quot` *soundness, classical case splits, and proposition extensionality.*
7. *H records componentwise* hsame *transport for the window, dyadic, regular, seal, classifier, refusal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from S through D and R into E and F.*
9. *P records* Pkg *provenance over* $\mathsf{RealModulusPurityBoundary}^{\uparrow}$, $\mathsf{FiniteWindowRealSealAudit}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealWindowClassifierSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host-level real, a quotient stream, a selected limit, a non-displayed modulus, an ambient completeness theorem, or an axiom outside the finite packet.

Lean4 (definition) `BEDC.Derived.RealWindowClassifierSealUp.taste gate`

Theorem 1325.2 (Real window classifier seal NameCert obligations)**.** *For every accepted* $\mathsf{RealWindowClassifierSeal}^{\uparrow}$ *carrier*

$$W = (S, D, R, E, F, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealWindowClassifierSeal}^{\uparrow}}$ *surface consists exactly of carrier admission, StreamName window exposure through* S*, DyadicRatCore readback through* D*, RegSeqRat handoff through* R*, RealUp seal routing through* E*, finite-window classification through* F*, axiom-refusal exposure through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from Definition 1325.1. The packet displays one finite stream window, one dyadic tolerance readback, one regular-Cauchy handoff, one Real seal row, one classifier row, and one refusal row.

The readback route is ordered. The StreamName row S exposes the finite window, the DyadicRatCore row D reads the dyadic data inside it, and the RegSeqRat row R is reached only after those finite observations have been displayed.

The Real seal and classifier are therefore downstream of the same finite data. The rows E and F read S, D, R rather than an ambient real object, while A records the axiom-purity refusals attached to that route.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no further coordinates, these rows exhaust the local NameCert obligations. □

Theorem 1325.3 (Real window classifier seal nonescape)**.** *An accepted* $\mathsf{RealWindowClassifierSeal}^{\uparrow}$ *packet cannot expose quotient-stream equality, host real equality, selected limits, countable choice,* `Quot` *soundness, classical case splits, proposition extensionality, an undisplayed modulus, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness to a Real-completion consumer.*

Proof. Inspect the carrier coordinates in Definition 1325.1. The data rows are exactly S, D, R, E, F, A and the structural rows are exactly H, C, P, N.

The refusal row A is displayed alongside the classifier row F. Thus the same packet that authorizes the finite-window comparison also records that quotient streams, host real equality, selected limits, countable choice, `Quot` soundness, classical case splits, proposition extensionality, undisplayed moduli, and ambient completeness are not exported.

Transport, continuation, provenance, and naming preserve the displayed route. They do not add a second Real seal route or an axiom-bearing coordinate, so a completion consumer can read only the finite packet. □

Theorem 1325.4 (Real window classifier seal consumer handoff)**.** *Every Real-completion modulus consumer of an accepted* $\mathsf{RealWindowClassifierSeal}^{\uparrow}$ *packet factors through*

$$S \longmapsto D \longmapsto R \longmapsto (E, F, A, H, C, P, N).$$

Consequently the consumer receives a finite-window classifier and a visible axiom-refusal row before it may read the $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with the NameCert obligations of Definition 1325.2. They require the consumer-facing packet to display the StreamName window, DyadicRatCore readback, and RegSeqRat handoff before the RealUp seal row is available.

Next read the classifier row. Because F compares accepted packets only through S, D, R, E and the structural rows, the classifier is attached to the same finite window that produced the seal route.

The refusal row A is part of the same handoff. By Definition 1325.3, no quotient-stream equality, host real equality, selected limit, hidden modulus, completeness theorem, or forbidden axiom can be supplied after the classifier has been read. The consumer handoff is therefore exactly the displayed finite route. □

Falsifiable prediction: A Real-completion modulus consumer cannot read a RealUp seal from a RealWindowClassifierSealUp packet without first reading the finite StreamName window, DyadicRatCore readback, RegSeqRat handoff, classifier row, and axiom-refusal row.

Independence witness: realmoduluspurityboundary, finitewindowrealsealaudit, regularcauchyname, streamname, dyadicratcore, regseqrat, real: not bijective because the seal packet carries the finite window, dyadic readback, regular handoff, Real seal, classifier, axiom-refusal, transport, continuation, provenance, and local NameCert rows simultaneously.

Lean follow-up provides explicit carrier and TasteGate fields under `lean4/BEDC/Derived/RealWindowClassifi` preserving $S, D, R, E, F, A, H, C, P, N$ as distinct rows before a checked target may cite `BEDC.Derived.RealWindow`

Closure status for $\mathsf{NameCert}_{\mathsf{RealWindowClassifierSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{RealWindowClassifierSeal}^{\uparrow}$ packet is generated from a StreamName window, RegSeqRat readback, RealWindowBudget request, tail-meet row, RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier seals a real-facing read only through the finite window and regular readback rows that the budget admits. The ledger story is finite observation before real sealing: the window, tolerance, tail agreement, and RealUp rows are generated together from BHist data, and transport preserves them coordinatewise so no quotient stream, selected limit, or ambient completeness theorem can enter as a hidden classifier.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealWindowClassifierSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, NameCert-obligation, nonescape, consumer-handoff, Lean-follow-up boundary, and existing closure annotation for $\mathsf{RealWindowClassifierSeal}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealWindowClassifierSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim host-level reals, quotient streams, selected limits, non-displayed moduli, ambient completeness, or axioms outside the finite packet.

Upgrade path: To reach obligationClosure, the real-window seal and consumer handoff must be encoded with checked finite-window classifier obligations.

Chapter 1326

A Concrete Naming Certificate for $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$

The $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$ packet realizes the research-programme synthesis of subsection 9462.32.11 as a composite finite NameCert carrier. It sits after the multi-history physics route of chapter 1298, the physics falsification surface of chapter 1293, the programme-strength ledger of chapter 1305, the verification-failure roadmap of chapter 1289, and the failure-certificate packet of chapter 1233. These siblings expose route, falsification, strength, verification-failure, and failure-certificate rows separately; this carrier binds them before any consumer reads the programme as a completed physical theory or as a single-axis verification claim.

Definition 1326.1 (Physics programme synthesis carrier)**.** *A* $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, F, L, V, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}$ *row, recording the relational physics, law bridge, scientific-model bridge, quantum-state, and falsification-boundary route;*
2. *F is the* $\mathsf{PhysicsFalsificationSurface}^{\uparrow}$ *row, recording route-law-empirical-countermodel refusal data before completed physics may be claimed;*
3. *L is the* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ *row, recording claim strength, dependency status, theory and verification status, bridge status, refusal, and local naming;*
4. *V is the* $\mathsf{VerificationFailureRoadmap}^{\uparrow}$ *row, recording checked-report failure, downgrade, roadmap-boundary, cannot-claim, and upgrade-registry data;*
5. *E is the* $\mathsf{FailureCertificate}^{\uparrow}$ *row, recording the concrete failure certificate consumed when a programme route is blocked;*
6. *H records componentwise* hsame *transport for R, F, L, V, E, package provenance, and the local naming row;*
7. *C records displayed* Cont *routes for physical-route readback, falsification-surface inspection, strength-ledger inspection, verification-failure replay, and failure-certificate handoff;*
8. *P is the* Pkg *provenance over* $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$, $\mathsf{MultiHistoryPhysicsRoute}^{\uparrow}$, $\mathsf{PhysicsFalsificationSurface}$ $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$, $\mathsf{VerificationFailureRoadmap}^{\uparrow}$, $\mathsf{FailureCertificate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}}$ *row.*
The classifier accepts exactly packets whose visible rows are $R, F, L, V, E, H, C, P, N$. It contains no completed physical theory, no empirical value row outside the cited physics surfaces, no verification-status promotion outside the ledger, and no failure route outside the displayed certificate and roadmap rows.

Lean4 (definition) `BEDC.Derived.PhysicsProgrammeSynthesisUp.TasteGate.PhysicsProgrammeSynthesisUp`

Theorem 1326.2 (Physics programme synthesis falsification non-escape)**.** *Every accepted* PhysicsProgrammeSynthe *packet reads physical ambition through the displayed route row R and falsification row F before it may inspect programme strength, verification failure, or failure certificates. A consumer cannot bypass F to claim completed physics, empirical adequacy, law completion, bridge completion, or axiom-pure success.*

Proof. Project the carrier of Definition 1326.1. The physical side of the packet is exactly R together with F.

Apply the sibling route and falsification surfaces. The multi-history physics route records the candidate physical route, while the physics falsification surface records the law, empirical, countermodel, bridge-audit, axiom-purity, transport, provenance, and naming rows that can block that route.

The remaining coordinates L, V, E, H, C, P, N replay or report the status of the same displayed route. None of them supplies a second physical-success coordinate. Hence a completed-physics read that omits F is outside the accepted $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$ carrier. □

Lean4 ✓ `BEDC.Derived.PhysicsProgrammeSynthesisUp.TasteGate.PhysicsProgrammeSynthesisFalsificationNoneso`

Theorem 1326.3 (Physics programme synthesis axis separation)**.** *For an accepted* $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$ *carrier $S = (R, F, L, V, E, H, C, P, N)$, the physical-route axis, falsification axis, programme-strength axis, verification-failure axis, and failure-certificate axis remain separate NameCert coordinates. In particular, a stronger programme-strength row in L cannot erase a falsification row in F, a verification-failure row in V cannot be read as a physical countermodel by itself, and a failure certificate E cannot replace the route and ledger rows it diagnoses.*

Lean4 ✓ `BEDC.Derived.PhysicsProgrammeSynthesisUp.PhysicsProgrammeSynthesisTasteGate single carrier alignment`

Proof. Begin with the displayed tuple. The rows R, F, L, V, E are distinct carrier coordinates, and H transports them componentwise rather than by quotienting them together.

Read the programme-strength and verification-failure siblings next. The strength ledger reports dependency, theory, formal, bridge, and refusal coordinates; the verification-failure roadmap records audit report, failure, downgrade, roadmap, upgrade registry, and cannot-claim rows. These reports consume the physical and failure surfaces but do not identify them.

Finally inspect C, P, N. The continuation routes replay each named coordinate, the package row records the sibling provenance, and the local NameCert row seals the composite packet. Therefore no axis can discharge another axis by prose, status promotion, or certificate substitution. □

Independence witness: multi-history-physics-route, physics-falsification-surface, programme-strength-ledger, verification-failure-roadmap, failurecertificate: none is bijective with $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$ because the composite packet preserves route, falsification, strength, verification-failure, failure-certificate, transport, replay, provenance, and local NameCert rows together.

Closure status for $\mathsf{NameCert}_{\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}}$.

Constructive story: A $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$ packet is generated from a multi-history physics route, falsification surface, programme-strength ledger, verification-failure roadmap, failure-certificate row, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier accepts only the visible composite rows and keeps physical route, falsification, strength, verification failure, and failure certificate as separate axes. The ledger story is synthesis without completion: a consumer may inspect the programme only after route and falsification rows are displayed, while strength and verification reports remain diagnostic coordinates rather than a proof that physics, bridge, empirical adequacy, or law completion has been achieved.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, falsification-non-escape theorem, axis-separation theorem, independence witness, and existing closure annotations for $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim completed physical theory, empirical value rows outside the cited surfaces, verification-status promotion outside the ledger, or failure routes outside the displayed rows.

Upgrade path: To reach obligationClosure, the programme-synthesis carrier and axis-separation proof must be checked as finite composite packet obligations.

Chapter 1327

A Concrete Naming Certificate for $\mathsf{PhaseRealCompletionExit}^{\uparrow}$

The $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ packet realizes the real-and-completion exit certificate described by section 9462.32 as a finite four-face NameCert carrier. It sits after the dyadic arithmetic surface of chapter 291, the stream-window surface of chapter 126, the regular rational sequence surface of chapter 301, the real seal surface of chapter 38, and the exact completion boundary of chapter 1120. These siblings expose arithmetic, observation, regularity, real sealing, and boundary exactness separately; this carrier binds their exit rows before any consumer may treat the phase as a completed real object or as an ambient completion principle.

Definition 1327.1 (Phase real-completion exit carrier)**.** *A* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, S, Q, R, B, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *face recording the finite dyadic endpoint, tolerance, comparison, and arithmetic ledger used by the exit;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *face recording the finite observation windows through which the exit is read;*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *face recording the regular rational sequence handoff generated from the dyadic and stream rows;*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *face recording the real seal reached only after D, S, Q have been exposed;*
5. *B is the* RealCompletionExactBoundaryUp *face recording that the same route supplies exact boundary information without exporting host completeness, quotient stream equality, or a selected limit outside the packet;*
6. *H records componentwise* hsame *transport for the dyadic, stream, regular, real, exact-boundary, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *routes for reading D, then S, then Q, then R, and finally the boundary row B;*
8. *P is the* Pkg *provenance over* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RealCompletionExactBoundaryUp, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *row.*
The classifier accepts exactly packets whose visible exit surface is $D, S, Q, R, B, H, C, P, N$. It has no coordinate for an ambient Cauchy completion, quotient-stream equality, selected real limit, host completeness proof, or a fused bridge token identifying the four local faces.

Theorem 1327.2 (Phase real-completion exit NameCert obligations)**.** *For the carrier of Definition 1327.1, the local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *surface consists exactly of carrier admission for $E = (D, S, Q, R, B, H, C, P, N)$, dyadic-face exposure through D, stream-window exposure through S, regular-rational handoff through Q, real-seal exposure through R, exact-boundary exposure through B, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the displayed carrier. Its arithmetic, observation, regularity, real-seal, and exact-boundary faces are exactly D, S, Q, R, B.

The four local read faces are ordered by the continuation row C: the dyadic ledger is read together with the stream windows, the regular-rational handoff is reached from those rows, and the real seal is exposed only after the handoff has been fixed. The boundary row B then records exactness for the same route.

The rows H, P, N transport, source, and name that finite surface. Since the carrier lists no further coordinate, the displayed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.PhaseRealCompletionExitUp.PhaseRealCompletionExitTasteGate single carrier alignment`

Theorem 1327.3 (Phase real-completion exit noncollapse boundary)**.** *Every accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *consumer receives the dyadic face D, stream face S, regular face Q, real face R, exact-boundary face B, transport row H, replay row C, provenance row P, and local naming row N as distinct displayed rows. No accepted consumer may fuse the four local faces into a single bridge token, completeness token, quotient equality, selected limit, or host real without leaving the carrier.*

Proof. Start from Definition 1327.1. The rows D, S, Q, R occupy separate carrier coordinates, and the exact-boundary row B reports on the same route rather than replacing those coordinates.

Apply Definition 1327.2. Any accepted read must expose each local face before the local naming row is consumed, while H and C preserve componentwise transport and replay.

A fused bridge or completeness token would require a coordinate identifying the dyadic, stream, regular, and real faces as one object. No such coordinate appears in E, and the boundary row explicitly withholds ambient completion, quotient equality, and selected-limit data. □

Theorem 1327.4 (Phase real-completion exit objectwise face criterion)**.** *An accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *exit read is admissible precisely when it exposes the dyadic face D, stream face S, regular-rational face Q, real-seal face R, exact-boundary face B, and the support rows H, C, P, N as separate finite* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. No aggregate bridge token, quotient-stream equality, selected limit, host completeness row, or fused formalstatus row may replace any one of these faces.*

Proof. The forward direction is read from the carrier of Definition 1327.1. Its visible coordinates are $D, S, Q, R, B, H, C, P, N$, so an admissible exit read has a finite row for each local face and for each support route.

For the reverse direction, apply Definition 1327.2. Once those rows are separately exposed, the local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ surface has the dyadic, stream, regular-rational, real-seal, exact-boundary, transport, replay, provenance, and naming obligations it requires.

The exclusions follow from Definition 1327.3. The five sibling references in the chapter introduction supply the objectwise dependency surface: dyadic arithmetic, stream observation, regular rational handoff, real sealing, and exact boundary are imported as distinct faces, so none of the listed aggregate tokens can stand in for them inside the accepted exit read. □

Theorem 1327.5 (Phase real-completion exit facewise audit obligation)**.** *An accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet* $E = (D, S, Q, R, B, H, C, P, N)$ *can satisfy the Phase Real and Completion exit obligation only by separately exposing the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* RealCompletionExactBoundar *rows. Each of the four roadmap faces keeps its own local closurestatus and formalstatus record: dyadic arithmetic through* D*, stream observation through* S*, regular rational handoff through* Q*, and real-completion exit through the paired* R, B *rows. No bridge token, fused completion row, quotient equality, selected limit, or host-completeness certificate may discharge those records jointly.*

Proof. Begin with the objectwise criterion of Definition 1327.4. It says that an admissible exit read exposes $D, S, Q, R, B, H, C, P, N$ as separate finite rows, so the audit obligation cannot be discharged by a single aggregate report.

The noncollapse boundary in Definition 1327.3 rules out the only possible shortcuts: bridge tokens, completion tokens, quotient equalities, selected limits, and host real data have no carrier coordinate in E. Thus any accepted audit must still display the dyadic, stream, regular, real, and exact-boundary faces before the local naming row is read.

The sibling chapters named in the introduction supply the local records that the audit reads. The dyadic face is governed by chapter 291, the stream face by chapter 126, the regular rational handoff by chapter 301, and the real-completion exit face by chapter 38 together with chapter 1120. The minimum-blocker result Definition 38.489 records why those local reports cannot be collapsed into one completion-facing audit.

Consequently the phase-exit packet can pass the roadmap audit only by exposing the five object rows while preserving the four local closurestatus and formalstatus records that produced them. □

Theorem 1327.6 (Phase real-completion exit obligation surface package)**.** *For any accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet, the obligation surface is exactly the carrier row* $E = (D, S, Q, R, B, H, C, P, N)$*, the five object faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* RealCompletionExactBoundaryUp*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *row. No quotient stream, selected limit, host-completeness row, or fused bridge token discharges that surface.*

Proof. Apply Definition 1327.2 to identify the displayed rows of the local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ surface. The carrier contributes exactly $E = (D, S, Q, R, B, H, C, P, N)$, with D, S, Q, R, B read as the five object faces and H, C, P, N read as transport, replay, provenance, and naming rows.

Apply Definition 1327.4 and Definition 1327.5. These results force the accepted exit read and the audit read to keep $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and RealCompletionExactBoundaryUp as separate finite faces before the local naming row is consumed.

Finally apply Definition 1327.3. It excludes the shortcut coordinates named in the statement, so quotient streams, selected limits, host-completeness rows, and fused bridge tokens cannot discharge the obligation surface. □

Theorem 1327.7 (Phase real-completion exit boundary-witness balance)**.** *For every accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet* $E = (D, S, Q, R, B, H, C, P, N)$*, any Real-completion exit consumer that reads the exact-boundary face* B *reads it over the same finite route* D, S, Q, R, H, C, P, N*.*

A witness-ledger consumer or exact-boundary consumer therefore cannot replace that route by quotient stream equality, selected limits, countable choice, host real equality, ambient completeness, or a detached completion witness.

Lean4 ✓ `BEDC.Derived.PhaseRealCompletionExitUp.PhaseRealCompletionExitUp boundary witness balance`

Proof. Project the carrier of Definition 1327.1. The boundary row B is displayed as the exact-boundary face of the same packet whose route rows are D, S, Q, R, H, C, P, N.

Apply Definition 1327.2. It exposes the dyadic, stream, regular-rational, real-seal, exact-boundary, transport, replay, provenance, and local naming rows as the complete NameCert surface for the accepted packet.

The noncollapse boundary Definition 1327.3 and the objectwise face criterion Definition 1327.4 prevent any fused completion token from standing in for those rows. The facewise audit obligation Definition 1327.5 then identifies the five sibling records as the separate $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealCompletionExactBoundaryUp}$ faces of the same exit read.

The witness endpoint is the ledger surface of chapter 902, and the boundary endpoint is chapter 1120. Since both endpoints are consumed through the displayed route, a consumer that asks for quotient stream equality, selected limits, countable choice, host real equality, ambient completeness, or a detached completion witness has left the accepted $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ carrier. □

Theorem 1327.8 (Phase real-completion exit terminal-envelope exactness)**.** *Let $E = (D, S, Q, R, B, H, C, P, N)$ be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet. Any terminal Real-completion exit consumer that uses the* $\mathsf{FiniteRealRouteCommitment}^{\uparrow}$ *route of Definition 930.3 and the* $\mathsf{RealSealAdmissionCut}^{\uparrow}$ *route of Definition 1001.3 is exhausted by one finite envelope: the dyadic face D, the StreamName face S, the RegSeqRat face Q, the Real seal R, the exact-boundary face B, the route-commitment budget, window, readback, seal, and handoff rows, the admission-cut order, and the shared transport, replay, provenance, and naming rows H, C, P, N. In particular, such a consumer has no coordinate for quotient streams, selected limits, countable choice, host real equality, ambient completeness, or detached completion witnesses.*

Proof. First apply the boundary-witness balance of Definition 1327.7. It says that the exact-boundary face B is read over the same finite route D, S, Q, R, H, C, P, N and cannot be replaced by quotient stream equality, selected limits, countable choice, host real equality, ambient completeness, or a detached completion witness.

Next apply the route commitment theorem Definition 930.3. Any Real-facing or CauchyLimitSeal-facing consumer of the route commitment must display the budget, StreamName window, RegSeqRat readback, RealUp seal, and handoff rows before it reaches the terminal seal surface.

Then apply the admission-cut theorem Definition 1001.3. It forces the same terminal read to pass through the ordered finite boundary from request to budget, window, readback, seal, and handoff, so the consumer cannot bypass the budget or window side of the route.

Finally return to the carrier inventory in Definition 1327.1. Its only displayed exit coordinates are $D, S, Q, R, B, H, C, P, N$, with the route-commitment and admission-cut rows read through the named sibling theorems. Therefore the terminal consumer is exhausted by the stated finite envelope, and every listed completion principle outside that envelope remains unavailable. □

Theorem 1327.9 (Phase real-completion exit scoped primitive dependency binding)**.** *Let $E = (D, S, Q, R, B, H, C, P, N)$ be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet. Its scoped primitive dependency surface is exactly the conjunction of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *face D, the* $\mathsf{StreamName}^{\uparrow}$ *face*

S, the $\mathsf{RegSeqRat}^{\uparrow}$ *face Q, the* $\mathsf{Real}^{\uparrow}$ *seal R, the* $\mathsf{RealCompletionExactBoundaryUp}$ *face B, and the support rows H, C, P, N, with each row read through the displayed* BHist*, componentwise* hsame*,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *coordinates. No quotient stream, selected limit, host equality, ambient completeness principle, fused bridge token, or single aggregate formalstatus row lies in the scope of this accepted packet.*

Proof. First apply Definition 1327.4 and Definition 1327.5. They identify the accepted exit read with the separate finite rows $D, S, Q, R, B, H, C, P, N$ and force the dyadic, stream, regular-rational, real-seal, and exact-boundary reports to remain objectwise visible.

Next apply Definition 1327.7 and Definition 1327.8. The boundary row B and every terminal consumer are read over the same displayed route, so the support rows H, C, P, N are not optional decorations; they are the transport, replay, provenance, and naming coordinates through which the primitive faces are consumed.

Finally use the sibling exact-boundary scope in Definition 1120.20 together with the terminal route of Definition 1120.13. These results close the exact-boundary side over the same four-face route and exclude quotient streams, selected limits, host equality, ambient completeness, bridge rows, and aggregate formalstatus witnesses from the accepted dependency surface. The displayed conjunction is therefore the whole scoped primitive binding for E. □

Theorem 1327.10 (Phase real-completion exit status-token product)**.** *Let $E = (D, S, Q, R, B, H, C, P, N)$ be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet. The status read of* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *is the product of the local records of* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{RealCompletionExactBoundary}$ *Each face keeps its own closurestatus, formalstatus, leantarget, and bridgestatus rows, read from the corresponding local chapter boundary. The phase-exit packet creates no aggregate formalstatus token, aggregate bridge row, aggregate Lean target, quotient stream, selected limit, or host-completeness row.*

Proof. Start with the facewise audit obligation in Definition 1327.5. It forces every accepted packet to expose the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealCompletionExactBoundaryUp}$ rows separately before any local naming row is consumed.

Next apply the noncollapse boundary of Definition 1327.3 and the scoped primitive binding of Definition 1327.9. These results keep the carrier coordinates $D, S, Q, R, B, H, C, P, N$ objectwise visible and exclude fused bridge tokens, quotient streams, selected limits, host-completeness rows, and single aggregate formalstatus rows from the accepted dependency surface.

Finally read the Real L10 status lookup and pullback through Definition 38.470 and Definition 38.471. They state that the dyadic, stream, regular, and real faces contribute their own closurestatus, formalstatus, leantarget, and bridgestatus rows by reference rather than by cached aggregate status data. The exact-boundary row B is the fifth face of the same displayed $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ packet, so the phase status read is precisely the five-face product and nothing else. □

Theorem 1327.11 (Phase real-completion exit local status gate)**.** *An accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet may serve as the Phase Real and Completion exit gate only when the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{RealCompletionExactBoundaryUp}$ *faces are each read through their own local closurestatus, formalstatus, leantarget, and bridgestatus rows. No aggregate formalstatus token, fused bridge token, quotient stream equality, selected limit, host completeness row, or ambient completion premise can discharge this gate.*

Proof. Apply Definition 1327.10. It identifies the accepted status read as the product of the five local records and states that the phase-exit packet contributes no aggregate formalstatus row, bridge row, Lean target, quotient stream, selected limit, or host-completeness row.

Next apply Definition 1327.5. The audit read must expose the dyadic, stream, regular-rational, real, and exact-boundary faces separately before the local naming row can be consumed, so an exit gate cannot be accepted from a cached status summary.

Finally combine Definition 1327.3 with Definition 1327.9. These results keep the primitive scope at the displayed rows $D, S, Q, R, B, H, C, P, N$ and reject fused bridge tokens, quotient equalities, selected limits, host completeness, ambient completion data, and single aggregate formalstatus witnesses. Therefore the only accepted gate is the local five-face status read stated above. □

Theorem 1327.12 (Phase real-completion exit audit-clean threshold)**.** *An accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet serves the current local packet audit threshold exactly when the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{RealCompletionExactBoundaryUp}$ *faces are separately read through their own local closurestatus and formalstatus records, and each of the five verification-axis records is at least* $\mathsf{auditClean}$. *The* $\mathsf{RealCompletionExactBoundaryUp}$ *row is the same-route exact-boundary witness inside this packet audit, while Definition 1327.16 is the roadmap-facing projection that reads only the four roadmap objects. The threshold is not witnessed by an aggregate bridge token, quotient stream, selected limit, host completeness row, or single fused formalstatus row.*

Proof. For the forward direction, apply Definition 1327.11. Any accepted local packet audit must read the dyadic, stream, regular-rational, real, and exact-boundary faces through their own local status rows.

Next apply Definition 1327.10 and Definition 1327.5. The status read is the product of five local records, and the packet audit read must expose those records before the local naming row is consumed. Thus the local $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ packet audit can be met only by five objectwise verification-axis records, each at least $\mathsf{auditClean}$.

For the reverse direction, suppose the five faces have been read separately through their local closurestatus and formalstatus records, and each record is at least $\mathsf{auditClean}$. The local status gate supplies the required Phase Real and Completion exit read, while the status-token product keeps the five records in the same accepted $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ packet.

Finally apply Definition 1327.3 and read the roadmap-facing projection through Definition 1327.16. The noncollapse result rejects aggregate bridge tokens, quotient streams, selected limits, host completeness, and single fused formalstatus rows; the projection states that the boundary row remains a same-route exact-boundary witness rather than a fifth roadmap object. □

Theorem 1327.13 (Phase real-completion exit classifier-envelope admission)**.** *Let $\mathcal{P}$ be an accepted finite Real L10 public classifier packet satisfying the public classifier audit envelope of Definition 38.782. Then $\mathcal{P}$ is accepted as a* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *classifier-envelope read exactly when its visible exit rows are the five face records*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{RealCompletionExactBoundaryUp}$$

together with displayed BHist, *componentwise* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *support, and those five faces satisfy the audit-clean threshold of Definition 1327.12. No aggregate formalstatus row, aggregate bridge token, quotient stream, selected limit, host completeness row, metric-completeness datum, or countable-choice row is part of the accepted classifier-envelope read.*

Proof. First apply Definition 38.782. The Real L10 classifier packet is reduced to the four displayed public faces: local tightness rows, pairwise terminal classifier equivalences, triple common-tail cocycle data, and the objectwise closurestatus records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The same theorem excludes aggregate route-level formalstatus, aggregate bridge rows, quotient stream equality, selected limits, countable-choice data, metric-completeness data, and $\mathsf{Real}^{\uparrow}$ completeness claims from the classifier envelope.

Next apply Definition 1327.12. A $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ packet can serve the exit threshold only when the four Real L10 faces are read together with the RealCompletionExactBoundaryUp face, and each of the five local verification-axis records is at least auditClean. The exact-boundary row is therefore the fifth visible face required to consume the four-face Real classifier envelope inside the phase-exit carrier.

Finally use Definition 1327.10 and Definition 1327.3. They keep the five face records attached to their own local status tokens and keep $D, S, Q, R, B, H, C, P, N$ visible as separate finite rows. Thus an accepted classifier-envelope read is precisely the displayed five-face packet with BHist, hsame, Cont, Pkg, and local NameCert support, while the excluded aggregate, quotient, choice, limit, host-completeness, and metric-completeness rows remain outside the carrier. □

Theorem 1327.14 (Phase real-completion exit four-object boundary lift)**.** *An accepted four-object Phase Real and Completion read through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *is admitted as a* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *read exactly when the* RealCompletionExactBoundaryUp *face is supplied over the same finite route. The resulting packet has displayed faces* $D, S, Q, R, B, H, C, P, N$ *and exports no quotient stream, selected limit, host equality, ambient completeness, metric-completeness datum, countable-choice row, aggregate formalstatus row, or bridge token.*

Proof. For the forward direction, apply Definition 126.500. It identifies the consumer-side four-object route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any completion-facing output is accepted.

Next apply Definition 126.504. The terminal pullback keeps that route finite and objectwise, so a consumer may transport the same route into the real-completion boundary without adding a quotient stream, selected limit, host equality, or ambient completeness premise.

Now use Definition 1120.6 and Definition 1120.9. These results supply the RealCompletionExactBoundaryUp face over the same four-object route and keep the exact-boundary row separate from the dyadic, stream, regular-rational, and real faces.

Finally apply Definition 1327.13. It admits precisely the five-face classifier-envelope read with displayed $D, S, Q, R, B, H, C, P, N$, BHist, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}}$ support, while excluding the quotient, limit, host, completeness, choice, aggregate formalstatus, and bridge rows listed in the statement. □

Theorem 1327.15 (Phase real-completion exit scoped audit threshold)**.** *An accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet serves the local phase-exit packet audit exactly when the four roadmap faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *are read through separate local closurestatus and formalstatus records whose closure-axis entries are at least* scopedClosed *and whose verification-axis entries are at least* auditClean*, while the* RealCompletionExactBoundaryUp *face is read as a same-route exact-boundary witness with its own local status. No aggregate formalstatus row, bridge token, quotient stream, selected limit, host completeness row, or fused completion witness may discharge the packet audit; Definition 1327.16 gives the roadmap-facing four-object read.*

Proof. First apply Definition 1327.10 and Definition 1327.11. They identify the accepted phase-exit status read as the product of the five visible local records and require the dyadic, stream, regular-

rational, real, and exact-boundary faces to remain separate through their own closurestatus and formalstatus rows.

Next apply Definition 1327.12. It supplies the verification-axis side of the local packet audit: the four roadmap faces meet auditClean inside the packet, and the exact-boundary face carries its own audit-clean same-route witness status without becoming a roadmap object. Neither a fused formalstatus row nor an external completion witness can replace those local records.

Now use Definition 1327.13. The accepted classifier-envelope read adds the displayed BHist, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ support, while still excluding aggregate bridge tokens, quotient streams, selected limits, host-completeness rows, metric-completeness data, and countable-choice rows.

Finally read the two axes independently through section 9467.2 and the Phase Real and Completion criterion in section 9467.19, then apply the projection of Definition 1327.16. The roadmap gate is therefore met by the four local roadmap records whose closure-axis entries are at least scopedClosed and whose verification-axis entries are at least auditClean; the fifth packet face is the exact-boundary witness on the same route, with no aggregate row or fused completion witness standing in for the displayed faces. □

Theorem 1327.16 (Phase real-completion exit four-object threshold projection)**.** *An accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet satisfies the roadmap Phase Real and Completion exit criterion precisely when its* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *face records are each read through separate local closurestatus and formalstatus rows whose closure-axis entries are at least* scopedClosed *and whose verification-axis entries are at least* auditClean*. The* RealCompletionExactBoundaryUp *face is required only as the same-route exact-boundary witness over those four records; it cannot be counted as a fifth roadmap object, aggregate formalstatus row, bridge token, quotient stream, selected limit, host-completeness row, or fused completion witness.*

Proof. Apply Definition 1327.14. It identifies the boundary face as a RealCompletionExactBoundaryUp witness supplied over the same finite route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, without adding quotient-stream equality, selected limits, host equality, ambient completeness, aggregate formalstatus data, or bridge tokens.

Next apply Definition 1327.15. The local $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ gate still reads five visible faces inside the packet, so the exact-boundary witness must carry its own local status row when the packet is audited.

Now use Definition 1327.10 together with Definition 1327.3. These results keep the status rows objectwise and prevent the boundary row from collapsing the four roadmap records into an aggregate token, quotient stream, selected limit, host-completeness row, or fused completion witness.

Finally read the roadmap criterion in section 9467.19 through the two-axis discipline of section 9467.2. The roadmap exit criterion names the four objects $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; the fifth face is the exact-boundary witness that lets the accepted packet expose the same route, not an additional roadmap object. □

Theorem 1327.17 (Phase real-completion exit five-face local audit)**.** *An accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet passes the local packet audit exactly when the four roadmap faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *are read through separate local status rows and the same-route* RealCompletionExactBoundary *witness is read through its own local status row. The audit consumes those five status rows together with the displayed support rows* H, C, P, N *of the carrier* $E = (D, S, Q, R, B, H, C, P, N)$*; it consumes no aggregate formalstatus row, bridge token, quotient stream, selected limit, host-completeness row, or fused completion witness.*

Proof. For the forward direction, apply the status-token product of Definition 1327.10. It identifies the accepted status read as the product of the dyadic, stream, regular-rational, real, and exact-boundary local records, with no aggregate formalstatus row or bridge row.

Next apply the local status gate of Definition 1327.11 and the audit-clean threshold of Definition 1327.12. These results force the local audit to read the four roadmap faces and the same-route exact-boundary face through separate local status rows before the packet can meet the audit threshold.

For the reverse direction, suppose those five local status rows are displayed with the support rows H, C, P, N. Apply the scoped audit threshold of Definition 1327.15 to admit the five-face packet audit, then project the roadmap side through Definition 1327.16.

Finally use the noncollapse boundary of Definition 1327.3. Since aggregate formalstatus rows, bridge tokens, quotient streams, selected limits, host-completeness rows, and fused completion witnesses have no carrier coordinate, they cannot discharge or replace any of the five local audit faces. □

Theorem 1327.18 (Phase real-completion exit public gate certificate)**.** *An accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet is the public paper-side gate certificate for the current Phase Real and Completion criterion exactly when the four roadmap faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *satisfy their local scoped-closure records and their local audit-clean records. The* $\mathsf{RealCompletionExactBoundaryUp}$ *face is used only as the same-route exact-boundary witness over those four records. The certificate exports no aggregate formalstatus row, aggregate bridge token, quotient stream, selected limit, host completeness row, metric-completeness row, countable-choice row, or fused completion witness.*

Proof. For the forward direction, apply Definition 1327.16. Any accepted packet that satisfies the Phase Real and Completion exit criterion must expose the four roadmap faces through separate local closurestatus and formalstatus rows, with closure-axis entries at least $\mathsf{scopedClosed}$ and verification-axis entries at least $\mathsf{auditClean}$. The same theorem keeps $\mathsf{RealCompletionExactBoundaryUp}$ as a boundary witness over the same route rather than as another roadmap object.

Next apply Definition 1327.15. It identifies the gate consumed by the chapter as the visible status read of the phase-exit packet, so the public certificate cannot be obtained from a cached route summary or from a single fused completion row.

For the reverse direction, suppose the four roadmap faces have their local scoped-closure and audit-clean records, and suppose the accepted packet supplies $\mathsf{RealCompletionExactBoundaryUp}$ only as the same-route exact-boundary witness. Apply Definition 1327.10 to repack those records as the product read of the accepted $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ carrier.

Finally read the product through section 9467.2. The roadmap discipline keeps the paper closure axis, Lean verification axis, and bridge status axis independent. Therefore the certificate can be cited as a public paper-side gate while still refusing aggregate formalstatus rows, bridge tokens, quotient streams, selected limits, host completeness, metric completeness, countable choice, and fused completion witnesses. □

Theorem 1327.19 (Real L10 terminal envelope phase-exit equivalence)**.** *An accepted Real L10 terminal envelope satisfying Definition 38.510 is equivalent to the public* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *gate certificate of Definition 1327.18 exactly when the* $\mathsf{RealCompletionExactBoundaryUp}$ *face is supplied as the same-route exact-boundary witness over the ordered route* $\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$, *and when the four roadmap faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *are read only through their local scoped-closure and audit-clean records. Under this equivalence the Real envelope contributes the ordered L10 route and finite-window witness rows, while the phase-exit certificate contributes the same-route exact-boundary face and the displayed* BHist,

componentwise hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *support. Neither side exports an aggregate formalstatus row, fused bridge token, quotient stream, selected limit, host completeness row, metric-completeness datum, countable-choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. For the forward direction, start from the accepted Real L10 terminal envelope. Apply Definition 38.510 to read the ordered route and finite-window witness rows, then apply Definition 38.511 to keep the status evidence objectwise over the four local roadmap faces.

Next supply the same-route RealCompletionExactBoundaryUp face and apply Definition 1327.14. The boundary lift turns the ordered Real route into the five-face phase-exit read without adding quotient stream equality, selected limits, host completeness, metric-completeness data, countable choice, aggregate formalstatus data, or a fused bridge token.

Finally apply Definition 1327.18. The four roadmap faces already carry their local scoped-closure and audit-clean records, and the exact-boundary face is used only as the same-route witness, so the public $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ gate certificate is obtained.

For the reverse direction, suppose the public $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ gate certificate is displayed with the same-route RealCompletionExactBoundaryUp face and the four local roadmap records. Apply Definition 1327.18 to recover the objectwise public gate data, then apply Definition 1327.16 to project away the boundary face from the roadmap count while preserving the ordered four-object route.

Now apply Definition 38.508. The projected dyadic, stream, regular-rational, and Real faces, together with the displayed finite-window and support rows, recover the ordered Real terminal envelope. The same exclusion list remains in force: aggregate formalstatus rows, fused bridge tokens, quotient streams, selected limits, host completeness, metric-completeness data, countable-choice rows, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not envelope data. □

Theorem 1327.20 (Phase real-completion exit bridge-pending axis separation)**.** *Let* $E = (D, S, Q, R, B, H, C, P, N$ *be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet. Suppose the four roadmap faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *are read through their own local scoped-closure and audit-clean records, and suppose the* RealCompletionExactBoundaryUp *face is supplied on the same finite route. Then the public Phase Real and Completion exit gate remains admitted even when some component bridge rows stand at* `paperBridge` *and other component bridge rows stand at* `bridgeChecked`*. The packet reads bridge rows objectwise from the component boundaries and exports no aggregate* bridgeChecked *row, no fused standard bridge token, no quotient stream, no selected limit, and no host-completeness row.*

Proof. Apply Definition 1327.18. It identifies the public phase-exit gate with the four roadmap faces carrying local scoped-closure and audit-clean records, together with RealCompletionExactBoundaryUp only as the same-route exact-boundary witness.

Next apply Definition 1327.10. The accepted status read is the product of the local face records, so bridge rows are read from their component closurestatus blocks rather than from a single phase-level bridge coordinate.

Use Definition 1327.24 to expose the consumer view. The readback returns the dyadic, stream, regular-rational, real, and exact-boundary faces with the displayed BHist, componentwise hsame, Cont, Pkg, and local NameCert support rows, while leaving component bridge rows attached to their own objects.

Finally apply Definition 1327.23 and read the result through the two-axis discipline of section 9467.2. A bridge row at `paperBridge` or `bridgeChecked` reports a component bridge state; it

neither collapses the scoped/audit exit gate nor blocks it once the four roadmap records and same-route exact-boundary witness are present. Hence the accepted packet admits the public gate while refusing an aggregate bridgeChecked export, a fused standard bridge token, a quotient stream, a selected limit, or a host-completeness row. □

Theorem 1327.21 (Phase real-completion exit component bridge-upgrade invariance)**.** *Let* $E = (D, S, Q, R, B, H, C, P, N)$ *be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet satisfying the public Phase Real and Completion gate of Definition 1327.18. Suppose one local bridge row among the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* RealCompletionExactBoundaryUp *faces is replaced by a stronger local bridge record, and suppose the corresponding closurestatus and formalstatus rows remain attached only to that face. Then the public phase-exit projection of* E *is unchanged: the same four roadmap records, same-route boundary witness, and support rows* H, C, P, N *are read by the gate. The replacement creates no aggregate* bridgeChecked *row, no fused standard bridge token, no quotient stream, no selected limit, no host-completeness row, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First apply Definition 1327.10. The status read of the accepted packet is the product of the component records, so strengthening one bridge row changes only that local factor and leaves the other face records objectwise.

Next apply Definition 1327.20. Mixed component bridge states are invisible to the scoped/audit gate once the four roadmap records and same-route RealCompletionExactBoundaryUp witness are present. Hence the public phase-exit projection is still admitted after the local bridge replacement.

Use Definition 1327.30 to read back the same exported data. The dyadic, stream, regular-rational, and real records remain the four roadmap rows, the boundary face remains the same-route witness, and H, C, P, N remain the displayed BHist, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ support.

Finally apply Definition 1327.23. Because the strengthened bridge row stays local to its face, it cannot supply an aggregate bridgeChecked row, fused standard bridge token, quotient stream, selected limit, host-completeness row, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim. Therefore the bridge-status improvement preserves exactly the public phase-exit projection. □

Theorem 1327.22 (Phase real-completion exit standard-bridge source normal form)**.** *Let* $E = (D, S, Q, R, B, H, C, P, N)$ *be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet. Any standard-bridge candidate for* E *must take as its source exactly the five displayed face rows* D, S, Q, R, B, *namely* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and the same-route* RealCompletionExactBoundaryUp, *together with the four displayed support rows* H, C, P, N, *namely* BHist, *componentwise* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *support. It may not use an aggregate formalstatus row, fused bridge token, quotient stream equality, selected limit, countable-choice row, host-completeness row, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate as a source.*

Proof. Apply Definition 1327.10. It identifies the accepted status read as a product of local face records, so a bridge source must begin from the objectwise packet fields rather than from a route-level formalstatus token.

Next use Definition 1327.24. The consumer readback exposes precisely the dyadic, stream, regular-rational, real, and exact-boundary face rows with the displayed BHist, componentwise hsame, Cont, Pkg, and local NameCert support. These are therefore the rows a bridge candidate can consume.

Now apply Definition 1327.26. The support rows cannot be replaced by a fused support token, external completion datum, quotient equality, selected limit, countable-choice row, host-completeness row, or metric-completeness row.

Finally apply Definition 1327.20. Bridge status remains a component report rather than a source normalizer. Hence the later standard bridge must target the displayed five-face and four-support source normal form, with no aggregate formalstatus row, fused bridge token, quotient stream equality, selected limit, countable-choice row, host-completeness row, metric-completeness datum, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate supplying the source. □

Theorem 1327.23 (Phase real-completion exit boundary-face nonsubstitution)**.** *Let $E = (D, S, Q, R, B, H, C, P, N$ be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet. If any one of the four roadmap faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *lacks its own local* scopedClosed *closure record and local* auditClean *verification record, or if the* RealCompletionExactBoundaryUp *face is not supplied on the same finite route, then E fails the current Phase Real and Completion exit gate. No aggregate formalstatus row, aggregate bridge token, quotient stream, selected limit, host-completeness row, metric-completeness row, countable-choice row, or fused completion witness can replace the missing local face.*

Proof. Apply Definition 1327.18. It identifies the public paper-side gate certificate with four roadmap faces that already carry their local scoped-closure and audit-clean records, together with RealCompletionExactBoundaryUp only as a same-route exact-boundary witness.

Next apply Definition 1327.16 and Definition 1327.15. These theorems separate the four roadmap objects from the boundary witness while still requiring every visible face in the accepted packet to be read through its own local closurestatus and formalstatus rows.

Finally use Definition 1327.10 and Definition 1327.3. The status product is objectwise, and the noncollapse boundary excludes aggregate formalstatus rows, bridge tokens, quotient streams, selected limits, host-completeness rows, metric-completeness rows, countable-choice rows, and fused completion witnesses from the carrier. Therefore a missing roadmap face record, or a boundary face not supplied on the same finite route, leaves the exit gate undischarged. □

Theorem 1327.24 (Phase real-completion exit facewise consumer readback)**.** *An accepted* PhaseRealCompletionExi *consumer reads back exactly the five local face records* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* RealCompletionExactBoundaryUp, *together with the supporting* BHist, *componentwise* hsame, *displayed* Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *rows. Conversely, any consumer that displays precisely those five local records and those support rows, with* RealCompletionExactBoundaryUp *supplied on the same finite route as the four roadmap faces, is admitted by the existing classifier-envelope and public-gate certificate. The readback exports no aggregate formalstatus row, bridge token, quotient stream, selected limit, host-completeness row, metric-completeness data, countable-choice row, or fused completion witness.*

Proof. For the forward direction, apply Definition 1327.13. It identifies the accepted classifier-envelope read with the displayed carrier rows $D, S, Q, R, B, H, C, P, N$, so every accepted consumer receives the dyadic, stream, regular-rational, real, and exact-boundary faces together with BHist, hsame, Cont, Pkg, and local NameCert support.

Next use Definition 1327.16 and Definition 1327.23. These results keep $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as the four roadmap records and require RealCompletionExactBoundaryUp to remain a same-route boundary witness rather than an aggregate row or substitute face.

For the reverse direction, suppose a consumer displays exactly those five local records and support rows. Apply Definition 1327.13 to place the displayed rows inside the classifier envelope, then apply Definition 1327.18 to read the same data as the public phase-exit gate certificate.

Finally, the nonsubstitution theorem excludes the omitted rows from both directions of the readback. Thus quotient streams, selected limits, host completeness, metric completeness, countable choice, bridge tokens, aggregate formalstatus data, and fused completion witnesses cannot be consumed in place of the five displayed face records and their local support. □

Theorem 1327.25 (Phase real-completion exit status-face product injectivity)**.** *For accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packets, the public phase-exit gate read is determined exactly by the status-face product consisting of the four roadmap status records for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *together with the same-route* $\mathsf{RealCompletionExactBoundaryUp}$ *witness and the displayed* BHist, *componentwise* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *support. Equivalently, two accepted packet reads give the same public phase-exit gate certificate precisely when they have the same four roadmap status records, the same same-route exact-boundary witness, and the same displayed support rows. The comparison exports no aggregate formalstatus row, bridge token, quotient stream, selected limit, host-completeness row, metric-completeness data, countable-choice row, or fused completion witness.*

Proof. For the forward direction, suppose two accepted packet reads have the same four roadmap status records, the same same-route $\mathsf{RealCompletionExactBoundaryUp}$ witness, and the same displayed BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ support. Apply Definition 1327.10. It identifies the accepted status read with the objectwise product of those local records, so the two reads have the same status-face product.

Next apply Definition 1327.18. The public certificate consumes exactly the four roadmap faces with their local scoped-closure and audit-clean records, while the boundary face is used only as the same-route witness over those faces.

Use Definition 1327.23 to rule out alternative witnesses. Since no aggregate row, bridge token, quotient stream, selected limit, host-completeness row, or fused completion witness may replace a missing local face, the shared status-face product determines a single public gate read.

For the reverse direction, suppose the two accepted reads have the same public phase-exit gate certificate. Apply Definition 1327.24. The certificate reads back exactly the five local face records and the supporting BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows. Applying the status-token product again identifies those readback rows with the four roadmap status records plus the same-route exact-boundary witness. Hence equality of the public gate readback gives equality of the displayed status-face product. □

Theorem 1327.26 (Phase real-completion exit support-row nonsubstitution)**.** *Let* $E = (D, S, Q, R, B, H, C, P, N)$ *be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet. None of the support rows* H, C, P, N *may be replaced by an aggregate formalstatus row, bridge token, quotient stream, selected limit, host-completeness row, metric-completeness datum, countable-choice row, or fused completion witness. The packet remains admitted only when componentwise* hsame *support through* H, *displayed* Cont *replay through* C, Pkg *provenance through* P, *and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *support through* N *are present together with the displayed* D, S, Q, R, B *faces.*

Proof. Start from the carrier inventory in Definition 1327.1. The accepted packet has exactly the displayed rows $D, S, Q, R, B, H, C, P, N$, where H records componentwise hsame, C records displayed Cont routes, P records Pkg provenance, and N records the local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ row.

Apply Definition 1327.9. Its primitive scope is the same finite row list, so the support rows are load-bearing coordinates rather than annotations attached to an external completion or status object.

Next apply Definition 1327.24. Any accepted consumer reads back the five local face records together with the supporting BHist, componentwise hsame, displayed Cont, Pkg, and local NameCert rows. Then use Definition 1327.25 to identify equality of the public gate read with equality of that displayed status-face product.

The remaining exclusions are the noncollapse exclusions already enforced by Definition 1327.3 and Definition 1327.23. Aggregate formalstatus rows, bridge tokens, quotient streams, selected limits, host or metric completeness data, countable-choice rows, and fused completion witnesses have no coordinate in E and cannot determine the same support-row product. Therefore H, C, P, N are non-substitutable in every accepted phase-exit packet. □

Theorem 1327.27 (Phase real-completion exit all support rows necessary)**.** *An accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *public gate read is valid exactly when it displays the five face records* D, S, Q, R, B *for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* RealCompletionExactBoundaryUp*, together with the support rows* H, C, P, N *for componentwise* hsame*, displayed* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$. *The boundary face* B *must lie on the same finite route as the four roadmap faces* D, S, Q, R*. No aggregate formalstatus row, bridge token, quotient stream, selected limit, host-completeness row, metric-completeness datum, countable-choice row, or fused witness may replace any one of these listed rows.*

Proof. For the forward direction, apply Definition 1327.24. It identifies every accepted consumer read with exactly the five local face records and the displayed BHist, componentwise hsame, Cont, Pkg, and local NameCert support rows. The same readback requires RealCompletionExactBoundaryUp to be supplied on the same finite route as the four roadmap faces.

Next apply Definition 1327.25. Equality of the public gate read is equality of that status-face product, so deleting or replacing any one coordinate changes the displayed packet rather than preserving the accepted gate.

For the reverse direction, suppose the public read displays exactly $D, S, Q, R, B, H, C, P, N$ with B on the same finite route as D, S, Q, R. Apply Definition 1327.18 to read the four roadmap faces and the exact-boundary witness as the public Phase Real and Completion gate certificate.

Finally apply Definition 1327.26. It rules out aggregate formalstatus rows, bridge tokens, quotient streams, selected limits, host or metric completeness data, countable-choice rows, and fused witnesses as replacements for H, C, P, N. Together with the facewise readback, this proves that all five face rows and all four support rows are necessary and sufficient for the accepted public gate read. □

Theorem 1327.28 (Phase real-completion exit current local-status witness)**.** *Let* $E = (D, S, Q, R, B, H, C, P, N)$ *be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet. Suppose its four roadmap faces read the local records of* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *and suppose its* RealCompletionExactBoundaryUp *face is supplied on the same finite route. Then* E *satisfies the roadmap Phase Real and Completion exit criterion in the current paper state: the four roadmap faces are each at least* scopedClosed *on the closure axis and at least* auditClean *on the verification axis, while the boundary face is the same-route exact-boundary witness. The packet introduces no aggregate formalstatus row, quotient stream, selected limit, host-completeness row, or fused bridge token.*

Proof. Read the local component blocks. $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ carry maturePackageClosed with bridgeChecked records, so each is above the required scopedClosed and auditClean thresholds. $\mathsf{RegSeqRat}^{\uparrow}$ carries maturePackageClosed with an axiomClean record, which is still above the required auditClean verification threshold for this roadmap gate.

The RealCompletionExactBoundaryUp block carries the same-route exact-boundary witness with maturePackageClosed and bridgeChecked. This supplies the boundary face required by the accepted packet, but it does not become a fifth roadmap object.

Apply Definition 1327.15 to the accepted packet. The threshold is met by reading the dyadic, stream, regular-rational, real, and exact-boundary faces through their own local closurestatus and formalstatus rows. In particular, the $\mathsf{RegSeqRat}^{\uparrow}$ `paperBridge` row is harmless here because this gate asks for audit-clean local verification, not for componentwise bridgeChecked status.

Finally apply Definition 1327.16. It projects the five-face packet read to the four roadmap objects $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with RealCompletionExactBoundaryUp used only as the same-route boundary witness. The projection therefore discharges the roadmap Phase Real and Completion exit criterion without adding an aggregate formalstatus row, quotient stream, selected limit, host-completeness row, or fused bridge token. □

Theorem 1327.29 (Real-completion exit dyadic-stream regularity)**.** *Let $E = (D, S, Q, R, B, H, C, P, N)$ be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet satisfying the current local-status witness of Definition 1327.28. Every accepted read of the current L10 gate must expose, in order, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance face D, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity face Q, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal R. The* RealCompletionExactBoundaryUp *row B is available only as the same-route boundary witness over those four objectwise faces, with support through H, C, P, N. The read refuses quotient streams, selected limits, aggregate formalstatus rows, bridge tokens, countable choice, metric completeness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the status-token product of Definition 1327.10. It reads the accepted gate as the objectwise product of the four local records D, S, Q, R together with the same-route boundary row B and the support rows H, C, P, N.

Apply Definition 1327.16. The projection identifies the roadmap objects in the required order: dyadic tolerance first, finite StreamName window next, regular rational readback next, and the terminal Real seal last.

Now use Definition 1327.28. It certifies that these four faces meet the current L10 gate and that RealCompletionExactBoundaryUp remains a same-route witness rather than an additional roadmap object or a completion primitive.

The support rows cannot be replaced. By Definition 1327.26, componentwise hsame, displayed Cont, Pkg, and local NameCert support remain part of the same finite read and cannot be supplied by an aggregate status record or bridge token.

Finally apply Definition 1327.23. Quotient streams, selected limits, countable-choice rows, metric-completeness data, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no coordinate in the packet. Hence every accepted L10 read remains objectwise through D, S, Q, R, with B only as the same-route boundary witness. □

Theorem 1327.30 (Phase real-completion exit component-status extraction)**.** *Let $E = (D, S, Q, R, B, H, C, P, N)$ be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet satisfying the current local-status witness of Definition 1327.28. Then the roadmap export of E is exactly the four local status records D, S, Q, R for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *together with the same-route* RealCompletionExactBoundaryU *witness B and the displayed* BHist, *componentwise* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *support rows H, C, P, N. Conversely, any accepted packet displaying precisely those four local records, the same-route boundary witness, and those support rows satisfies the current Phase Real and Completion exit read. No aggregate formalstatus row, aggregate bridge token, quotient stream, selected limit, countable-choice row, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim is extracted or supplied by this equivalence.*

Proof. For the forward direction, start from Definition 1327.28. It identifies the accepted packet as meeting the current roadmap exit criterion by the four local records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, while the $\mathsf{RealCompletionExactBoundaryUp}$ face remains only the same-route boundary witness.

Apply Definition 1327.24. The consumer readback exposes exactly the face rows D, S, Q, R, B and the support rows H, C, P, N, namely the displayed BHist, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ rows. Then use Definition 1327.27 to see that none of those support coordinates is optional or replaceable.

The terminal-envelope comparison in Definition 1327.19 keeps the same data aligned with the Real L10 route. It contributes the route and finite-window witness perspective, but it does not add an aggregate formalstatus row, aggregate bridge token, quotient stream, selected limit, countable choice, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. Therefore the extracted roadmap export is exactly the displayed four-record, one-boundary, four-support packet.

For the reverse direction, suppose an accepted packet displays exactly the four roadmap local records, the same-route $\mathsf{RealCompletionExactBoundaryUp}$ witness, and the support rows H, C, P, N. Apply Definition 1327.24 to admit the displayed rows as the public consumer read, and apply Definition 1327.27 to ensure the support rows are present in the required componentwise form.

Finally apply Definition 1327.28. The four local records are the roadmap objects, the boundary row is on the same finite route, and the support rows are the displayed BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows. Hence the packet satisfies the current Phase Real and Completion exit read, with the same refusals of aggregate formalstatus, aggregate bridge token, quotient stream, selected limit, countable choice, metric completeness, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1327.31 (Phase real-completion exit roadmap refusal boundary)**.** *Let $E = (D, S, Q, R, B, H, C, P, N)$ be an accepted $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ packet satisfying the current local-status witness of Definition 1327.28. Its roadmap export consists exactly of the four face records $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, the same-route $\mathsf{RealCompletionExactBoundaryUp}$ witness, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ support rows. It exports no Dedekind-cut reals, open-cover compactness, Heine-Borel theorem, classical trichotomy, primitive quotient stream, selected limit, countable-choice row, metric-completeness datum, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.*

Proof. Start from Definition 1327.28. The accepted packet meets the current Phase Real and Completion exit criterion by displaying the four roadmap faces at the required local closure and verification thresholds, while $\mathsf{RealCompletionExactBoundaryUp}$ remains only the same-route exact-boundary witness.

Apply Definition 1327.18. The public gate consumes the face records D, S, Q, R and the boundary witness B together with the support rows H, C, P, N. Thus the exported carrier is the finite tuple $E = (D, S, Q, R, B, H, C, P, N)$ and the support it displays through BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$.

Next apply Definition 1327.23. The excluded objects in section 9467.12 and section 9467.20 have no carrier coordinate in E: Dedekind-cut reals, open-cover compactness, Heine-Borel, classical trichotomy, primitive quotient streams, selected limits, countable choice, metric completeness, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not among $D, S, Q, R, B, H, C, P, N$.

Finally read the same packet through the roadmap two-axis discipline of section 9467.2. Closure records and verification records remain attached to the local faces that supply them, so no refused off-table claim can be recovered by promoting a closure row into a verification row, by promoting a verification row into a closure row, or by fusing the component bridge reports into a completion

primitive. Hence the accepted packet exports exactly the stated roadmap boundary and nothing stronger. □

Theorem 1327.32 (Phase real-completion exit zero-source nonsubstitution)**.** *Let $E = (D, S, Q, R, B, H, C, P, N)$ be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet satisfying the current local-status witness of Definition 1327.28. An accepted* $\mathsf{RegularCauchyZero}^{\uparrow}$ *packet may serve as a zero-source consumer witness for the regular-rational and real-facing route only after E already displays the four local status records for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, together with the same-route* $\mathsf{RealCompletionExactBoundaryUp}$ *face B. The* $\mathsf{RegularCauchyZero}^{\uparrow}$ *packet cannot replace any one of D, S, Q, R, cannot supply B as the same-route exact-boundary face, and cannot by itself discharge the roadmap audit-clean threshold for the Phase Real and Completion exit gate.*

Proof. Use Definition 624.22 and Definition 624.21. They identify $\mathsf{RegularCauchyZero}^{\uparrow}$ as a finite zero-source route through its rational zero seed, constant $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ zero row, tail-meet rows, and $\mathsf{Real}^{\uparrow}$ seal-facing terminal interface.

That finite route is a valid consumer witness, but it is not a phase-exit status product. Apply Definition 1327.10. The phase packet reads the roadmap gate through the objectwise product of D, S, Q, R and the same-route boundary face B, with support through H, C, P, N.

Next apply Definition 1327.28. The roadmap threshold is met by the four local status records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, while $\mathsf{RealCompletionExactBoundaryUp}$ remains the same-route boundary witness rather than a fifth roadmap object or a zero-source replacement.

Finally use Definition 1327.23. Since the phase gate is objectwise and status-token-local, a nearby zero-source packet has no coordinate that can stand in for a missing dyadic, stream, regular-rational, real, or exact-boundary face, and it cannot turn its terminal route into the audit-clean record required by the phase-exit roadmap gate. □

Definition 1327.33 (Phase real-completion exit cover-overlap compatibility)**.** *Let $\{E_i\}_{i \in I}$ be a finite family of accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packets with*

$$E_i = (D_i, S_i, Q_i, R_i, B_i, H_i, C_i, P_i, N_i)$$

on each cover member. The family is cover-overlap compatible when every common finite refinement of two cover members identifies the displayed row restrictions of the four roadmap faces

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow},$$

identifies the same-route $\mathsf{RealCompletionExactBoundaryUp}$ *witness, and identifies the support rows* BHist*, componentwise* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ *carried by H_i, C_i, P_i, N_i.*

The compatibility datum has no coordinate for quotient streams, selected limits, countable-choice witnesses, metric-completeness data, aggregate formalstatus rows, aggregate bridge tokens, standard bridge rows, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claims.*

Theorem 1327.34 (Phase real-completion exit cover-overlap no-confusion)**.** *Let $\{E_i\}_{i \in I}$ and $\{F_j\}_{j \in J}$ be cover-overlap compatible finite families of accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packets for the same public Phase Real and Completion consumer, where*

$$E_i = (D_i, S_i, Q_i, R_i, B_i, H_i, C_i, P_i, N_i)$$

and

$$F_j = (D'_j, S'_j, Q'_j, R'_j, B'_j, H'_j, C'_j, P'_j, N'_j).$$

After passing to a common finite overlap refinement, the two families determine the same public phase-exit gate read if and only if they display the same overlap restrictions of the four roadmap faces, the same-route RealCompletionExactBoundaryUp *witness, and the support rows* BHist*, componentwise* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$.

The common gate read recovers exactly those displayed rows. It recovers no quotient stream, selected limit, countable-choice row, metric-completeness datum, aggregate formalstatus row, aggregate bridge token, standard bridge row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. For the forward direction, assume the two finite families determine the same public phase-exit gate read. Apply Definition 1327.30 to the common read. It extracts exactly the four roadmap faces, the same-route RealCompletionExactBoundaryUp witness, and the displayed support rows BHist, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$.

Restrict the extracted rows to every common finite overlap refinement. Since both families are cover-overlap compatible in the sense of Definition 1327.33, the restrictions on the E side and the F side are the same displayed rows. Apply Definition 1327.27 to rule out an omitted support coordinate, so equality of the public gate read forces agreement on every listed overlap row.

For the reverse direction, assume the common refinement displays the same four roadmap face restrictions, the same-route boundary witness, and the same support rows. Apply Definition 38.678 to identify the terminal four-face $\mathsf{Real}^{\uparrow}$ surface determined by the dyadic, stream, regular-rational, and real rows.

Next apply Definition 301.230. The regular-rational audit-threshold read has no second source once the four visible faces and support rows agree on the overlap refinement. With Definition 1327.30, the two phase-exit packets therefore expose the same public gate read.

All cited comparisons are finite-row comparisons. By Definition 1327.27, the only support rows available to the public gate are BHist, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$. Thus no quotient stream, selected limit, countable-choice row, metric-completeness datum, aggregate formalstatus row, aggregate bridge token, standard bridge row, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim can be recovered from the overlap comparison. □

Theorem 1327.35 (Phase real-completion exit finite-cover gate gluing)**.** *Let* $\{E_i\}_{i\in I}$ *be a finite cover of compatible accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packets, with*

$$E_i = (D_i, S_i, Q_i, R_i, B_i, H_i, C_i, P_i, N_i)$$

on each cover member. Suppose the family is cover-overlap compatible in the sense of Definition 1327.33. Then the cover glues to one accepted packet whose public read is the same Phase Real and Completion gate if and only if every E_i *displays the same four roadmap local status records for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, supplies the same-route* RealCompletionExactBoundaryUp *witness, and agrees on all overlap restrictions of the support rows* BHist*, componentwise* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$.

The glued packet has exactly those four roadmap status records, the same-route boundary witness, and those support rows as its public Phase Real and Completion gate read. It exports no quotient stream, selected limit, countable-choice row, metric-completeness datum, aggregate formalstatus row, aggregate bridge token, standard bridge row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. For the forward direction, restrict the glued public packet to each finite cover member. Apply Definition 1327.33 to read those restrictions through the required common finite refinements, and apply Definition 1327.34 to compare them as one public phase-exit gate read.

Now apply Definition 1327.28 to read the common gate as the four local status records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with RealCompletionExactBoundaryUp only

as the same-route boundary witness. Apply Definition 1327.30 on each restriction. It identifies the data visible on every E_i as exactly the four roadmap records, the same boundary witness, and the displayed BHist, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ support rows. Since the restrictions come from one glued public read, the cover members agree on those rows over every overlap.

For the reverse direction, assume the finite cover displays the same four local records, the same-route RealCompletionExactBoundaryUp witness, and overlap agreement on the listed support rows. The compatibility hypothesis gives the common finite refinement rows of Definition 1327.33, and Definition 1327.34 identifies the public phase-exit gate read determined by those rows.

Apply Definition 301.227 to glue the regular-rational and real-facing audit-threshold sections over the shared finite four-face surface.

Next apply Definition 301.228. This makes the glued read independent of the chosen finite refinement and keeps the status records attached to the same dyadic, stream, regular-rational, and real faces. Apply Definition 38.812 to identify the resulting finite Real L10 cover certificate with one objectwise Phase Real and Completion exit certificate.

Finally repack the certificate as a $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ packet by Definition 1327.28 and read it back by Definition 1327.30. The public gate is therefore the same gate precisely when the cover members display the same four roadmap records, same-route boundary witness, and support rows.

All constructions named above use only finite cover rows and their overlap restrictions. The refused quotient stream, selected limit, countable-choice row, metric-completeness datum, aggregate formalstatus row, aggregate bridge token, standard bridge row, and ambient $\mathsf{Real}^{\uparrow}$ completeness claim have no carrier coordinate in the displayed packet, so none is exported by the gluing. □

Theorem 1327.36 (Phase real-completion exit RegSeqRat common-tail pullback)**.** *Let $E = (D, S, Q, R, B, H, C, P, N)$ be an accepted* $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet. Suppose a RegSeqRat common-tail triple-overlap cocycle is displayed on the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows as S, D, Q, R, with the same support rows* BHist, *componentwise* hsame, Cont, Pkg, *and* NameCert *used by H, C, P, N. Then that common-tail cocycle pulls back to the same-route* RealCompletionExactBoundaryUp *face B of E.*

Conversely, if the boundary face B of an accepted $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *packet is supplied over such a RegSeqRat common-tail cocycle, then restricting the packet to the displayed four face rows recovers the RegSeqRat common-tail descent surface. In both directions the construction exports no quotient stream, selected limit, countable-choice row, metric-completeness datum, aggregate formalstatus row, aggregate bridge token, standard bridge row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. For the pullback direction, first read the RegSeqRat input by Definition 301.190. The triple-overlap surface is exactly the common finite surface on the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Apply Definition 301.191. The pairwise common-tail rows descend to one displayed four-face boundary over the same stream, dyadic, regular-rational, and real records. Since these rows are identified with S, D, Q, R and the support rows H, C, P, N of E, Definition 1327.35 glues the finite cover into the objectwise Phase Real and Completion gate on the same displayed packet.

Now apply Definition 1327.30. The public read of the glued packet exposes the same-route RealCompletionExactBoundaryUp witness as the boundary coordinate B, rather than as an added completion carrier. Thus the common-tail cocycle pulls back to the boundary face already present in E.

For the converse direction, start with an accepted phase-exit packet whose boundary face B is supplied over the displayed common-tail cocycle. The finite-cover gluing theorem reads that boundary through the same four local status records and the same support rows, while the component-status extraction theorem prevents any row from being absorbed into a route-level token.

Restricting to the S, D, Q, R faces therefore leaves exactly the RegSeqRat common-tail triple-overlap data. Applying Definition 301.191 to those restricted rows recovers the common-tail descent surface, with the same BHist, hsame, Cont, Pkg, and NameCert provenance.

All steps are objectwise over the displayed finite rows. Quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge tokens, standard bridge rows, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no coordinate in E or in the RegSeqRat common-tail descent boundary, so the pullback and the restriction cannot export them. □

Falsifiable prediction: If a consumer fuses the dyadic, stream, regular, and real face reports into a single bridge token or completeness token, the $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ packet is refuted.

Independence witness: dyadicratcore, streamname, regseqrat, real, realcompletionexactboundary: no single sibling is bijective to the phase product because the packet binds dyadic arithmetic, finite stream observation, regular rational handoff, real sealing, exact boundary, transport, replay, provenance, and local naming in one displayed exit carrier.

Theorem 1327.37 (Phase real-completion exit TasteGate primality rows)**.** *Every accepted* PhaseRealCompletionEx *packet carries four separate TasteGate primality rows: the falsifiable fused-token refusal above, the sibling independence witness against dyadicratcore, streamname, regseqrat, real, and realcompletionexactboundary, the Lean 'Nontrivial' witness pair for distinct accepted and rejected carriers, and the Lean 'FieldFaithful' projection over $D, S, Q, R, B, H, C, P, N$. Hence no one-element carrier, field-erasing classifier, aggregate completion token, or hidden sibling bijection discharges the chapter.*

Proof. The carrier inventory in Definition 1327.1 displays the finite exit packet as $E = (D, S, Q, R, B, H, C, P, N)$. Thus the paper surface already names the fields whose preservation is tested by the local TasteGate.

The falsifiability and independence rows immediately above supply the two external primality tests: a consumer that fuses the dyadic, stream, regular, and real face reports into one bridge or completeness token refutes the packet, and none of the five sibling chapters is bijective to the phase product.

The remaining two rows are the checked 'Nontrivial' and 'FieldFaithful' witnesses in `lean4/BEDC/Derived/Phas` The 'Nontrivial' instance supplies distinct accepted and rejected carriers, while the 'FieldFaithful' instance projects the classifier through the displayed fields $D, S, Q, R, B, H, C, P, N$ rather than through an erased aggregate.

Together these four rows block each collapse mode. A one-element carrier violates 'Nontrivial', a field-erasing classifier violates 'FieldFaithful', an aggregate completion token violates the falsifiability row, and a hidden sibling bijection violates the independence witness. Therefore the accepted packet can discharge the chapter only as the displayed finite exit carrier with all four primality rows present. □

Lean4 ✓ `BEDC.Derived.PhaseRealCompletionExitUp.taste gate`

Closure status for $\mathsf{NameCert}_{\mathsf{PhaseRealCompletionExit}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ packet is generated from dyadic, stream, regular-rational, Realseal, RealCompletionExactBoundaryUp, componentwise hsame, Cont, Pkg, and local NameCert rows. The exact-boundary face is a same-route witness over those rows, not a bridge or completion primitive. The classifier accepts the phase exit

only as the visible tuple of finite rows; no single face can stand for completion, and quotient equality, selected limits, host completeness, aggregate formalstatus, and bridge tokens stay outside the carrier. The local TasteGate instance is BEDC.Derived.PhaseRealCompletionExitUp.taste_gate.

Theory closure: TheoryGate(NameCert$_{\mathsf{PhaseRealCompletionExit}\uparrow}$, maturePackageClosed)

Scope closed: Definition 1327.9 and Definition 1327.18 form the mature paper boundary: the accepted packet is the dyadic, stream, regular-rational, Real-seal, exact-boundary, componentwise hsame, Cont, Pkg, and local NameCert same-route gate.

Formal verification: FormalStatus(NameCert$_{\mathsf{PhaseRealCompletionExit}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.PhaseRealCompletionExitUp.PhaseRealCompletionExitTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: Standard-bridge verification remains unsupplied, and the packet exports no aggregate formalstatus row, bridge token, quotient stream, selected limit, host-completeness row, or metric-completeness row.

Upgrade path: The next formal obligation is standard-bridge verification for the already axiom-clean same-route gate; no aggregate formalstatus, bridge token, quotient stream, selected limit, host completeness, or metric completeness is supplied here.

Chapter 1328

A Concrete Naming Certificate for ResearchProgrammeExecutionGate$^{\uparrow}$

The ResearchProgrammeExecutionGate$^{\uparrow}$ packet realizes the programme route of section 9462.32 inside the auditable-generativity discipline of chapter 9462. It sits beside the strength ledger of chapter 1305, the strength-gradient ledger of chapter 1314, the kernel phase refusal packet of chapter 1288, the verification-failure roadmap of chapter 1289, and the name-eligibility proof of chapter 1309. Those sibling chapters expose strength, gradient, phase refusal, verification failure, and name eligibility separately; this carrier binds them into one finite execution gate before a programme target is accepted.

Definition 1328.1 (ResearchProgrammeExecutionGate carrier)**.** *A* ResearchProgrammeExecutionGate$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, P, D, S, F, B, R, H, C, Q, N)$$

with the following displayed rows:

1. *T is the target row naming the programme target proposed for execution;*
2. *P is the current-phase row naming the phase in which the target is being considered;*
3. *D is the dependency-readiness row exposing the lowest open ready phase and its blockers;*
4. *S is the strength-report row inherited from the programme strength and gradient ledgers;*
5. *F is the formal-status row recording the theorem, audit, and axiom-clean status currently visible for the target;*
6. *B is the bridge row recording whether a standard-bridge consumer is present, absent, or refused;*
7. *R is the refusal row for targets outside the displayed lowest open ready phase;*
8. *H records componentwise* hsame *transport for the target, phase, dependency, strength, formal-status, bridge, refusal, replay, provenance, and naming rows;*
9. *C records displayed* Cont *replay of the route through P, D, S, F, B, R before T is accepted;*
10. *Q is the* Pkg *provenance over* ProgrammeStrengthLedger$^{\uparrow}$, ProgrammeStrengthGradientLedger$^{\uparrow}$, KernelPhaseRefusal$^{\uparrow}$, VerificationFailureRoadmap$^{\uparrow}$, NameEligibilityProof$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ResearchProgrammeExecutionGate}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden priority override, off-phase target promotion, unreported blocker discharge, bridge status inferred from formal status, or name eligibility supplied outside the displayed local certificate.

Lean4 (definition) `BEDC.Derived.ResearchProgrammeExecutionGateUp.ResearchProgrammeExecutionGateUp`

Theorem 1328.2 (ResearchProgrammeExecutionGate NameCert obligations)**.** *For the carrier of Definition 1328.1, the local* $\mathsf{NameCert}_{\mathsf{ResearchProgrammeExecutionGate}^{\uparrow}}$ *surface consists exactly of carrier admission for $G = (T, P, D, S, F, B, R, H, C, Q, N)$, target exposure through T, current-phase exposure through P, lowest-open-layer dependency readiness through D, strength exposure through S, formal-status exposure through F, bridge exposure through B, refusal exposure through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through Q, and local naming through N.*

Proof. Project the finite packet $G = (T, P, D, S, F, B, R, H, C, Q, N)$. The first seven rows expose the target, current phase, dependency readiness, strength report, formal-status report, bridge row, and refusal row that determine whether the programme route may be executed.

Read the structural rows next. Transport through H preserves the displayed coordinates, replay through C keeps the consumer on the same route, provenance through Q records the sibling packets supplying the rows, and N names the accepted carrier.

Since the carrier contains no further coordinate, these rows exhaust the local NameCert obligations. A purported execution gate that omits one of them is a projection or sibling report, not the accepted $\mathsf{ResearchProgrammeExecutionGate}^{\uparrow}$ packet. □

Theorem 1328.3 (ResearchProgrammeExecutionGate lowest-open-layer readiness)**.** *Every accepted* $\mathsf{ResearchProgrammeExecutionGate}^{\uparrow}$ *packet reads the current-phase row P and dependency-readiness row D before it accepts the target row T. The accepted target must lie in the displayed lowest open ready phase, and any target outside that phase is routed to the refusal row R before the local* $\mathsf{NameCert}_{\mathsf{ResearchProgrammeExecutionGate}^{\uparrow}}$ *row is consumed.*

Proof. Start with the carrier obligations of Definition 1328.2. They require the current phase and dependency-readiness rows to be visible in the same finite packet as the target row.

Use the kernel phase refusal sibling together with the verification-failure roadmap. The phase row identifies which layer is ready, while the dependency-readiness row records blockers that prevent a stronger target from being accepted.

Finally read the displayed replay route C. A target in the lowest open ready phase reaches T only after P and D are displayed; a target outside that phase reaches R before N. Thus acceptance and refusal are both carried by the same local NameCert route. □

Theorem 1328.4 (ResearchProgrammeExecutionGate noninflation boundary)**.** *An accepted* ResearchProgrammeE *packet cannot promote a target above the strength row S, formal-status row F, bridge row B, dependency-readiness row D, or refusal row R displayed in its carrier. In particular, a consumer may not treat an unchecked target as checked, an unbridged target as bridge-checked, an off-phase target as ready, or a refused target as accepted.*

Proof. Read the strength and status rows from the carrier. The programme strength ledger and gradient ledger supply the reported strength S, while F and B keep formal and bridge status as separate coordinates.

The dependency and refusal rows fix the execution boundary. If D reports an open blocker or R records an off-phase refusal, no structural row can erase that fact: hsame transports displayed coordinates, Cont replays displayed reads, and Pkg provenance records the same packet.

Therefore any promoted reading asks for a coordinate absent from $G = (T, P, D, S, F, B, R, H, C, Q, N)$. The classifier rejects that reading as outside the execution gate. □

Falsifiable prediction: Any accepted execution-gate packet that selects a target outside the displayed lowest open ready phase refutes the carrier.

Independence witness: programmestrengthledger, programmestrengthgradientledger, kernelphaserefusal, verificationfailureroadmap, nameeligibilityproof: none is bijective with ResearchProgrammeExecutionG because the execution gate simultaneously carries target, current phase, dependency readiness, strength report, formal-status row, bridge row, refusal row, transport, replay, provenance, and local NameCert rows.

The Lean surface uses explicit `Nontrivial ResearchProgrammeExecutionGateUp` and `FieldFaithful ResearchProgrammeExecutionGateUp` instances in `lean4/BEDC/Derived/ResearchProgrammeExecutionGateUp/` The carrier keeps $T, P, D, S, F, B, R, H, C, Q, N$ as distinct rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ResearchProgrammeExecutionGate}^{\uparrow}}$.

Constructive story: A $\mathsf{ResearchProgrammeExecutionGate}^{\uparrow}$ packet is generated from a target row, current phase, dependency readiness, strength report, formal-status row, bridge row, refusal row, componentwise transport, displayed replay, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ResearchProgrammeExecutionGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1328.1, Definition 1328.2, Definition 1328.3, and Definition 1328.4 specify the finite execution-gate packet and its noninflation boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ResearchProgrammeExecutionGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, standard bridge checking, downstream execution scheduling, or any target outside the displayed lowest open ready phase.

Upgrade path: Lean closure requires Nontrivial ResearchProgrammeExecutionGateUp and FieldFaithful ResearchProgrammeExecutionGateUp instances for the same finite execution-gate packet.

Chapter 1329

A Concrete Naming Certificate for $\mathsf{SmugglingPatternClassifier}^{\uparrow}$

The $\mathsf{SmugglingPatternClassifier}^{\uparrow}$ packet realizes the smuggling discipline of subsection 9462.30.12 as one finite refusal-and-gate NameCert surface. It sits beside the host primitive leakage boundary of chapter 1157, the quotient-soundness boundary of chapter 634, the refutation boundary of chapter 500, and the cannot-claim export gate of chapter 1319. Those siblings refuse host imports, quotient shortcuts, invalid refutation readings, and checked-target export escapes separately; this carrier classifies philosophical, mathematical, and host smuggling requests before any external supply can be read as BEDC-internal.

Definition 1329.1 (Smuggling-pattern classifier carrier)**.** *A* $\mathsf{SmugglingPatternClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (E, I, G, Q, H, C, P, N)$$

with the following displayed rows:

1. *E is the external-supply row, recording whether the requested supply is philosophical, mathematical, or host-provided;*
2. *I is the internal-object request row, recording the BEDC-internal reading the consumer attempts to make from that supply;*
3. *G is the refusal-or-gate row, recording the accepted certificate gate, the typed gap route, or the refusal boundary for the request;*
4. *Q is the sibling-provenance row, recording the relevant host-leakage, quotient-soundness, refutation-boundary, cannot-claim, and logic/meta-loop surfaces;*
5. *H records componentwise* hsame *transport for supply, request, gate, sibling provenance, replay, provenance, and local naming rows;*
6. *C records displayed* Cont *replay through which a consumer reads E, I, G, Q, H without adding a hidden external object;*
7. *P records* Pkg *provenance over chapter 1157, chapter 634, chapter 500, chapter 1319, chapter 1261,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SmugglingPatternClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for treating an external entity, mature mathematical object, host primitive, quotient witness, global truth, or checked export target as BEDC-internal apart from the displayed gate or refusal row.

Lean4 (definition) `BEDC.Derived.SmugglingPatternClassifierUp.SmugglingPatternClassifierUp`

Theorem 1329.2 (Smuggling-pattern classifier NameCert obligations)**.** *For the carrier of Definition 1329.1, the local* $\mathsf{NameCert}_{\mathsf{SmugglingPatternClassifier}^{\uparrow}}$ *surface consists exactly of carrier admission for* $S = (E, I, G, Q, H, C, P, N)$*, requested external-supply exposure through* E*, internal-object request exposure through* I*, refusal-or-gate routing through* G*, sibling provenance through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the displayed packet $S = (E, I, G, Q, H, C, P, N)$. The external-supply row E classifies the source of the attempted import, while I records the internal reading requested by the consumer.

The routing row G is then read against the sibling-provenance row Q. A certified object must pass through an accepted gate; otherwise the request is sent to a typed gap or refusal boundary supplied by the host-leakage, quotient-soundness, refutation-boundary, cannot-claim, or logic/meta-loop surface.

Finally H, C, P, N transport, replay, source, and name the same displayed decision. Since no additional coordinate remains, these rows exhaust the local NameCert obligations for the classifier packet. □

Lean4 ✓ `BEDC.Derived.SmugglingPatternClassifierUp.SmugglingPatternClassifierTasteGate single carrier alignment`

Theorem 1329.3 (Smuggling-pattern classifier nonescape)**.** *Every accepted* $\mathsf{SmugglingPatternClassifier}^{\uparrow}$ *consumer must expose the requested external-supply row, the internal-object request row, a refusal-or-gate row, sibling provenance,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *before any smuggled object can be read as BEDC-internal. If the refusal-or-gate row does not display an accepted certificate gate, the requested object remains outside BEDC as a gap, socket report, or refusal.*

Proof. Read the consumer through the rows of Definition 1329.1. The only row that can decide between admission and refusal is G, and it is visible only together with the supply row E and the requested internal reading I.

The sibling-provenance row Q identifies the boundary surface that handles the request. Host primitive leakage, quotient soundness, refutation boundaries, cannot-claim export, and logic/meta-loop refusals each block one escape channel, but none supplies a hidden internal object outside G.

The structural rows H, C, P, N preserve the same decision during transport, replay, provenance, and naming. Therefore a request without an accepted gate cannot pass through the classifier as internal BEDC content. □

Theorem 1329.4 (Smuggling-pattern classifier TasteGate handoff)**.** *The Lean-facing handoff for* $\mathsf{SmugglingPatternClassifier}^{\uparrow}$ *must preserve external-supply, internal-request, refusal-or-gate, sibling-provenance, transport, replay, provenance, and local NameCert rows as distinct fields. Collapsing* E, I, G, Q *removes the field that distinguishes philosophical, mathematical, and host smuggling from an accepted certificate route.*

Proof. The classifier detects smuggling by comparing an external supply with the internal reading requested from it. This comparison requires E and I to remain separately projected.

The decision is then routed through G and sourced through Q. If either row is merged into the request, a consumer can no longer tell whether the request was admitted by certificate, routed to a gap, or refused by a sibling boundary.

Rows H, C, P, N preserve the same classified packet after the decision. The TasteGate handoff therefore keeps all eight rows field-faithful before the alignment theorem can be cited. □

Falsifiable prediction: Every accepted SmugglingPatternClassifierUp consumer must expose the requested external-supply row, the internal-object request row, a refusal-or-gate row, sibling provenance, hsame transport, Cont replay, Pkg provenance, and local NameCert before any smuggled object can be read as BEDC-internal.

Independence witness: hostprimitiveleakage, quotientsoundnessboundary, refutationboundary, cannotclaimexportgate, logiccontradictionmetaloop: none jointly stores the three-form classifier for philosophical, mathematical, and host smuggling together with refusal-or-gate routing, sibling provenance, transport, replay, provenance, and local NameCert rows.

The Lean follow-up must provide Nontrivial SmugglingPatternClassifier$^{\uparrow}$ and FieldFaithful SmugglingPatternClassif instances in `lean4/BEDC/Derived/SmugglingPatternClassifierUp/TasteGate.lean`. The field-faithful route must preserve E, I, G, Q, H, C, P, N before a consumer may cite `BEDC.Derived.SmugglingPatternCl`

Closure status for NameCert$_{\text{SmugglingPatternClassifier}^{\uparrow}}$.

Constructive story: A SmugglingPatternClassifier$^{\uparrow}$ packet is generated from a displayed external-supply row, internal-object request row, refusal-or-gate row, sibling-provenance row, componentwise transports, replay route, package provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SmugglingPatternClassifier}^{\uparrow}}$, scopedClosed)

Scope closed: This chapter closes the finite classifier surface for philosophical, mathematical, and host smuggling requests through the displayed refusal-or-gate rows only.

Formal verification: FormalStatus(NameCert$_{\text{SmugglingPatternClassifier}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.SmugglingPatternClassifierUp.SmugglingPatternClassifierTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close public export, bridge checking, quotient construction, host primitive admission, global truth, or automatic certificate generation for SmugglingPatternClassifier$^{\uparrow}$.

Upgrade path: The next step is an axiom-purity audit and any standard bridge needed by downstream public consumers.

Chapter 1330

A Concrete Naming Certificate for NoAbsoluteBridgeAudit$^{\uparrow}$

The NoAbsoluteBridgeAudit$^{\uparrow}$ packet realizes the no-absolute-bridge direction of the standard-bridge discipline inside the auditable-generativity programme of chapter 9462. It sits beside the standard bridge audit packet of chapter 1217, the host primitive leakage boundary of chapter 1157, the registry consistency audit of chapter 1223, the finite reflection tuple of chapter 993, and the Ground-Compiler recognizer flow of chapter 1048. Those siblings expose bridge fields, host-leak refusal, registry agreement, finite reflection images, and generated-recognizer admission; this packet binds them into a host-relative audit row before any consumer may read a bridge as host-free.

Definition 1330.1 (No absolute bridge audit carrier)**.** *A* NoAbsoluteBridgeAudit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (B, T, E, D, U, L, R, G, H, C, P, N)$$

with the following displayed rows:

1. *B is the* StandardBridgeAuditPacket$^{\uparrow}$ *row containing encoding, decoding, round-trip, theorem-preservation, no-host-leak, and bridge-ledger data.*
2. *T is the target host row, naming the specific host theory whose equality, quotient, function, number, and type or set semantics are being audited.*
3. *E is the host-relative encoding row, read only relative to T.*
4. *D is the host-relative decoding row, read only relative to T.*
5. *U is the finite unsupported-field ledger listing host fields, primitives, theorem shapes, and classifier reads that the bridge refuses.*
6. *L is the* HostPrimitiveLeakage$^{\uparrow}$ *no-host-leak row attached to the target host audit.*
7. *R is the* RegistryConsistencyAudit$^{\uparrow}$ *row recording agreement between bridge claims, unsupported fields, and public registry status.*
8. *G is the generated-recognizer landing row through* FiniteReflectionTuple$^{\uparrow}$ *and* GroundCompilerRecognizerFlow$^{\uparrow}$.
9. *H records componentwise* hsame *transport for bridge, host, encoding, decoding, unsupported-field, leakage, registry, recognizer, continuation, provenance, and local naming rows.*
10. *C records displayed* Cont *replay for host selection, theorem-preservation lookup, unsupported-field inspection, and no-host-leak readback.*

11. *P is the* Pkg *provenance over* NoAbsoluteBridgeAudit$^{\uparrow}$, StandardBridgeAuditPacket$^{\uparrow}$, HostPrimitiveLeakage$^{\uparrow}$, RegistryConsistencyAudit$^{\uparrow}$, FiniteReflectionTuple$^{\uparrow}$, GroundCompilerRecognizerFlow$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

12. *N is the local* NameCert$_{\text{NoAbsoluteBridgeAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host-free bridge, a bridge route with no target host row, an unsupported host field outside U, a leaked host primitive outside L, a private recognizer landing, or a theorem-preservation claim detached from the displayed host audit.

Theorem 1330.2 (No absolute bridge audit NameCert obligations)**.** *For the carrier of Definition 1330.1, the local* NameCert$_{\text{NoAbsoluteBridgeAudit}^{\uparrow}}$ *surface consists exactly of carrier admission for $A = (B, T, E, D, U, L, R, G, H, C, P, N)$, target-host visibility, host-relative encoding and decoding, finite theorem-preservation inspection through B, unsupported-field ledger exactness through U, no-host-leak inspection through L, registry agreement through R, recognizer landing through G, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through N.*

Lean4 ✓ `BEDC.Derived.NoAbsoluteBridgeAuditUp.noAbsoluteBridgeAuditChapterTasteGate`

Proof. Project the carrier of Definition 1330.1. The bridge packet B supplies the standard bridge fields, while T, E, D, U make encoding, decoding, and unsupported-field refusal relative to one displayed host.

Use the leakage and registry rows next. The row L blocks host primitives from entering the BEDC public surface, and R forces public bridge claims to agree with the registry status and unsupported-field ledger.

Finally inspect G, H, C, P, N. Recognizer landing is routed through the finite reflection tuple and GroundCompiler flow, transport and replay preserve the same displayed rows, provenance records the packet source, and the local name exports only this host-relative audit. Since no additional coordinate is present, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: A host-independent bridge route that omits the target host row or unsupported-field ledger refutes NoAbsoluteBridgeAuditUp.

Independence witness: standardbridgeauditpacket, hostprimitiveleakage, registryconsistencyaudit, finitereflectiontuple, groundcompilerrecognizerflow: StandardBridgeAuditPacket$^{\uparrow}$ records bridge fields without the target-host and unsupported-field audit as a separate no-absolute row; HostPrimitiveLeakage$^{\uparrow}$ refuses host primitives without bridge theorem-preservation rows; RegistryConsistencyAudit$^{\uparrow}$ records registry agreement without host-relative encoding and decoding; FiniteReflectionTuple$^{\uparrow}$ records finite reflection images without bridge refusal rows; GroundCompilerRecognizerFlow$^{\uparrow}$ records recognizer admission without a target-host bridge audit. None is bijective to NoAbsoluteBridgeAudit$^{\uparrow}$.

The Lean follow-up for this chapter must provide `lean4/BEDC/Derived/NoAbsoluteBridgeAuditUp/TasteGat` with Nontrivial NoAbsoluteBridgeAudit$^{\uparrow}$ and FieldFaithful NoAbsoluteBridgeAudit$^{\uparrow}$ instances for the displayed target-host, unsupported-field, no-host-leak, registry, recognizer, transport, replay, provenance, and naming rows.

Closure status for NameCert$_{\text{NoAbsoluteBridgeAudit}^{\uparrow}}$.

Constructive story: A NoAbsoluteBridgeAudit$^{\uparrow}$ packet is generated from a standard bridge packet, one target host row, host-relative encoding and decoding rows, unsupported-field ledger, no-host-leak row, registry-consistency row, generated-recognizer landing row, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{NoAbsoluteBridgeAudit}^{\uparrow}}$, seed)

Scope closed: Definition 1330.1 and Definition 1330.2 bind the finite host-relative bridge audit and its target-host, unsupported-field, no-host-leak, registry, recognizer, transport, replay, provenance, and naming obligations.

Formal verification: FormalStatus(NameCert$_{\mathsf{NoAbsoluteBridgeAudit}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: ai
Not claimed: This chapter does not close Lean verification, bridge checking, all host theories at once, host-free bridge recognition, or theorem preservation outside the displayed target-host audit.
Upgrade path: Obligation closure requires checked carrier admission, target-host visibility, unsupported-field exactness, no-host-leak preservation, registry agreement, recognizer landing, TasteGate nontriviality, and field faithfulness for $B, T, E, D, U, L, R, G, H, C, P, N$.

Chapter 1331

A Concrete Naming Certificate for $\mathsf{ResearchProgrammeRoute}^{\uparrow}$

The $\mathsf{ResearchProgrammeRoute}^{\uparrow}$ packet realizes the research programme and implementation route of section 9462.32 as a composite finite NameCert carrier. It sits after the programme-strength ledger of chapter 1305, the kernel-phase refusal surface of chapter 1288, the verification-failure roadmap of chapter 1289, the physics-programme synthesis of chapter 1326, and the package-export discipline of chapter 1323. These siblings expose strength, phase refusal, verification failure, physical synthesis, and export discipline separately; this carrier binds existing programme surfaces rather than claiming atomic novelty.

Definition 1331.1 (Research programme route carrier)**.** *A* $\mathsf{ResearchProgrammeRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (P, S, K, V, E, O, X, H, C, G, N)$$

with the following displayed rows:

1. *P is the phase-route row, recording the current research phase, admissible next phase, and the displayed route through the certificate programme;*
2. *S is the* $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ *row, recording claim strength, dependency status, theory and verification status, bridge status, refusal, and local naming;*
3. *K is the* $\mathsf{KernelPhaseRefusal}^{\uparrow}$ *row, recording the phase-boundary refusal that blocks targets outside the displayed kernel phase;*
4. *V is the* $\mathsf{VerificationFailureRoadmap}^{\uparrow}$ *row, recording checked-report failure, downgrade route, roadmap boundary, cannot-claim data, and upgrade-registry data;*
5. *E is the* $\mathsf{PackageExportDiscipline}^{\uparrow}$ *row, recording package-map coverage, refusal-registry coverage, registry-export coverage, export-gate coverage, formal-target coverage, and non-smuggling coverage;*
6. *O is the operator-review row, recording which displayed programme rows a reviewer may inspect before accepting the route as a public research programme reading;*
7. *X is the exit-criterion row, recording which phase, strength, refusal, failure-roadmap, export, and review rows must be present before the route can leave the current research phase;*
8. *H records componentwise* hsame *transport for P, S, K, V, E, O, X, package provenance, and the local naming row;*

9. *C records displayed* Cont *replay for phase routing, strength inspection, refusal inspection, verification-failure replay, export inspection, operator review, and exit-criterion handoff;*
10. *G is the* Pkg *provenance over* $\mathsf{ResearchProgrammeRoute}^{\uparrow}$, $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$, $\mathsf{KernelPhaseRefusal}^{\uparrow}$, $\mathsf{VerificationFailureRoadmap}^{\uparrow}$, $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$, $\mathsf{PackageExportDiscipline}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ResearchProgrammeRoute}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible rows are $P, S, K, V, E, O, X, H, C, G, N$. It contains no independent programme-success coordinate, no hidden phase promotion, no review authority outside O, no exit criterion outside X, and no export reading outside the displayed package row.

Theorem 1331.2 (Research programme route NameCert obligations)**.** *For the carrier of Definition 1331.1, the local* $\mathsf{NameCert}_{\mathsf{ResearchProgrammeRoute}^{\uparrow}}$ *surface consists exactly of carrier admission for $R = (P, S, K, V, E, O, X, H, C, G, N)$, phase-route exposure through P, strength-ledger exposure through S, kernel-refusal exposure through K, verification-failure exposure through V, package-export exposure through E, operator-review exposure through O, exit-criterion exposure through X, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through G, and local naming through N.*

Proof. Project the finite packet. The carrier inventory displays $P, S, K, V, E, O, X, H, C, G, N$ before the local name can be read.

Read the sibling rows in their programme order. The strength ledger supplies S, the kernel-phase refusal packet supplies K, the verification-failure roadmap supplies V, the physics-programme synthesis supplies the physical consumer named by the provenance row, and the package-export discipline supplies E.

Finally inspect the local rows. The operator-review row O and exit-criterion row X are part of the same finite packet, while H, C, G, N transport, replay, source, and name the displayed data. Since the carrier has no further coordinate, these rows exhaust the local NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.ResearchProgrammeRouteUp.ResearchProgrammeRouteTasteGate single carrier alignment`

Theorem 1331.3 (Research programme route phase refusal)**.** *Every accepted* $\mathsf{ResearchProgrammeRoute}^{\uparrow}$ *packet reads the phase-route row P together with the kernel-refusal row K before any programme phase can be treated as admissible. A target blocked by K cannot be exported by strengthening S, by citing the roadmap V, by packaging through E, or by appealing to operator review O.*

Proof. Begin with the carrier rows. The route row P and refusal row K are separate displayed coordinates, so phase admissibility is not read from strength, roadmap, export, or review data alone.

Apply the kernel-phase refusal sibling. Its accepted packet records the current phase, attempted target, dependency blocker, refusal verdict, transport, continuation, provenance, and local name. This row remains visible inside $\mathsf{ResearchProgrammeRoute}^{\uparrow}$ as K.

The rows S, V, E, O can report strength, failure, export, and review only for the same displayed packet. They do not contain a second phase-admission coordinate. Hence a target refused by K remains outside the accepted route. □

Theorem 1331.4 (Research programme route review boundary)**.** *For an accepted* $\mathsf{ResearchProgrammeRoute}^{\uparrow}$ *carrier, the operator-review row* O *may inspect only the displayed rows* $P, S, K, V, E, X, H, C, G, N$*. It cannot introduce an unlisted proof obligation, erase a verification-failure row, promote a strength row, bypass a package-export blocker, or replace the exit criterion by reviewer preference.*

Proof. Project the review coordinate. The row O is one component of $R = (P, S, K, V, E, O, X, H, C, G, N)$, so its authority is bounded by the same packet that it inspects.

Use the sibling constraints. $\mathsf{ProgrammeStrengthLedger}^{\uparrow}$ keeps strength claims tied to displayed dependency and status rows, $\mathsf{VerificationFailureRoadmap}^{\uparrow}$ keeps failure and downgrade data visible, and $\mathsf{PackageExportDiscipline}^{\uparrow}$ keeps export through its package rows.

It remains to compare O with X. The exit-criterion row is a separate displayed coordinate, not a conclusion of review preference. Therefore operator review cannot erase, promote, bypass, or replace any listed programme boundary. □

Theorem 1331.5 (Research programme route nonescape)**.** *Every accepted* $\mathsf{ResearchProgrammeRoute}^{\uparrow}$ *consumer receives phase route, strength ledger, kernel refusal, verification-failure roadmap, package export, operator review, exit criterion, transport, replay, provenance, and local naming as one displayed packet. It cannot read the composite route as completed physics, completed verification, bridge-checked closure, package export without blockers, or a reviewer-authorized phase exit unless the corresponding row is present in* R*.*

Proof. Start from the NameCert obligations. They expose all rows $P, S, K, V, E, O, X, H, C, G, N$ and no additional programme-success row.

Read the composite dependency. $\mathsf{PhysicsProgrammeSynthesis}^{\uparrow}$ is named through provenance as the physical consumer, while the strength, refusal, roadmap, and export siblings preserve their own rows inside the packet. The route therefore binds existing programme surfaces rather than collapsing them into one atomic certificate.

The transport, replay, provenance, and local naming rows preserve the same display. A consumer that claims completed physics, completed verification, bridge-checked closure, unblocked package export, or review-authorized phase exit without the corresponding row has left the accepted $\mathsf{ResearchProgrammeRoute}^{\uparrow}$ carrier. □

Falsifiable prediction: If a ResearchProgrammeRouteUp packet remains accepted after deleting its kernel-refusal row, verification-failure row, or exit-criterion row, then the route carrier is refuted.

Independence witness: programme-strength-ledger, kernel-phase-refusal, verification-failure-roadmap, physics-programme-synthesis, package-export-discipline: none is bijective with $\mathsf{ResearchProgrammeRoute}$ because the composite packet preserves phase, strength, refusal, verification-failure, export, review, exit, transport, replay, provenance, and local NameCert rows together.

The Lean follow-up requires $\mathsf{Nontrivial}\ \mathsf{ResearchProgrammeRoute}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ResearchProgrammeRoute}^{\uparrow}$ instances in `lean4/BEDC/Derived/ResearchProgrammeRouteUp/TasteGate.lean`. The field-faithfulness witness must keep $P, S, K, V, E, O, X, H, C, G, N$ as distinct rows before a checked boundary can cite `BEDC.Derived.ResearchProgrammeRouteUp.taste_gate`.

Closure status for $\mathsf{NameCert}_{\mathsf{ResearchProgrammeRoute}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ResearchProgrammeRoute}^{\uparrow}$ packet is generated from phase, strength, kernel, verification, export, review, exit, componentwise hsame transport, displayed Cont continuation, gate, and local naming rows. The classifier accepts a programme route only as this visible carrier tuple, so no hidden phase promotion, review authority, exit criterion, or package export can be read outside the displayed rows. The ledger story is route governance: a programme moves by finite carrier coordinates whose phase, review, and exit surfaces remain auditable, while refusals and gates record why a path stops or stays below a stronger claim.

Theory closure: TheoryGate(NameCert$_{\mathsf{ResearchProgrammeRoute}^{\uparrow}}$, seed)

Scope closed: This chapter binds the carrier definition, NameCert-obligation, phase-refusal, review-boundary, nonescape, independence witness, Lean-follow-up boundary, and existing closure annotations for ResearchProgrammeRoute$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{ResearchProgrammeRoute}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim independent programme success, hidden phase promotion, review authority outside the review row, exit criteria outside the exit row, or export outside the package row.

Upgrade path: To reach obligationClosure, the programme-route carrier and phase, review, and export boundary theorems must be checked over finite rows.

Chapter 1332

A Concrete Naming Certificate for $\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}$

The $\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}$ packet realizes the research-programme route of section 9462.32 as a finite audit loop. It sits after the writing discipline of chapter 1227, the registry consistency audit of chapter 1223, the machine-readable audit interface of chapter 1232, the package export discipline of chapter 1323, and the programme-strength gradient ledger of chapter 1314. Those packets regulate public prose, registry agreement, machine-readable export, package-level release, and strength reporting; this packet binds them into one loop before a research programme may treat a proposal as accepted programme motion.

Definition 1332.1 (Research-programme audit-loop carrier)**.** *A* $\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, Q, G, F, K, A, X, J, T, P, N)$$

with the following displayed rows:

1. *S is the phase row, recording the current programme phase and the admitted transition boundary from* $\mathsf{PhaseGovernedCertificateRoute}^{\uparrow}$*;*
2. *Q is the proposal-and-revise row, recording proposal intake, review acceptance, refusal, and permitted rewrite routes;*
3. *G is the gate row, recording the public gate that must be passed before a proposal is read as programme motion;*
4. *F is the failure-feedback row, recording typed failure, refusal, and retry data without promoting failure into theorem evidence;*
5. *K is the calibration row, recording how reported strength is read against* $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$*;*
6. *A is the audit-axis row, recording separate theory, verification, bridge, and machine-interface axes;*
7. *X is the label-claim row, recording claim labels, registry entries, and their consistency checks;*
8. *J is the trace row, recording machine-readable audit traces and replay data;*
9. *T records componentwise* hsame *transport for all displayed rows;*

10. *P is the* Pkg *provenance over* $\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}$, $\mathsf{AuditWritingDiscipline}^{\uparrow}$, $\mathsf{RegistryConsistencyAudit}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$, $\mathsf{PackageExportDiscipline}^{\uparrow}$, $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}}$ *row.*

The carrier has no coordinate for private programme approval, unregistered label motion, hidden machine evidence, host-side gate passage, or strength promotion outside the displayed audit loop.

Theorem 1332.2 (Research-programme audit-loop obligation surface)**.** *For the carrier of Definition 1332.1, the local* $\mathsf{NameCert}_{\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}}$ *surface consists exactly of phase admission through S, proposal and review motion through Q, gate passage through G, failure-feedback routing through F, calibration through K, axis separation through A, label-claim consistency through X, trace readback through J, componentwise transport through T, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ResearchProgrammeAuditLoopUp.ResearchProgrammeAuditLoopTasteGate single carrier alignment`

Proof. Project the finite packet of Definition 1332.1. Its displayed rows are precisely $S, Q, G, F, K, A, X, J, T, P, N$.

The phase, proposal, gate, failure-feedback, calibration, axis, label-claim, and trace rows are the programme-facing obligations. They respectively consume the phase-governed route, review acceptance, writing discipline, failure record, strength gradient, audit axes, registry consistency, and machine-readable audit interface named in the carrier.

The support rows T, P, N transport, source, and locally name the same displayed packet. Since no further coordinate is present, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}}$ surface. □

Theorem 1332.3 (Research-programme audit-loop nonescape)**.** *Every accepted* $\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}$ *loop exposes phase, proposal-and-revise, gate, failure-feedback, calibration, audit-axis, label-claim, trace, provenance, and local* NameCert *rows. It cannot export accepted programme motion through private approval, prose emphasis, unregistered labels, hidden trace evidence, collapsed theory-and-verification status, or strength promotion outside those rows.*

Proof. Read any accepted loop through the carrier. The rows S, Q, G, F, K, A, X, J determine the programme phase, proposal route, admission gate, failure feedback, calibration, axis separation, label claim, and trace readback before the loop is public.

The writing, registry, interface, export, and strength-gradient packet dependencies named in P supply the sibling surfaces that each row consumes. The transport row T and local naming row N keep the loop on that finite packet.

The excluded readings are not coordinates of the carrier. A consumer that asks for them has left the displayed $\mathsf{NameCert}_{\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}}$ surface rather than reading an accepted research-programme audit loop. □

Falsifiable prediction: Any accepted ResearchProgrammeAuditLoopUp loop must expose phase, proposal/revise, gate, failure-feedback, calibration, axis, label-claim, trace, provenance, and local NameCert rows.

Independence witness: audit-writing-discipline, registry-consistency-audit, machine-readable-audit-interface, package-export-discipline, programme-strength-gradient-ledger: none is bijective

with $\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}$ because the audit loop simultaneously carries phase governance, proposal review, gate passage, failure feedback, calibration, axis separation, label-claim consistency, machine-readable trace, provenance, and local NameCert rows.

Lean TasteGate formalization must provide $\mathsf{Nontrivial\ ResearchProgrammeAuditLoop}^{\uparrow}$ and FieldFaithful ResearchP instances in `lean4/BEDC/Derived/ResearchProgrammeAuditLoopUp/TasteGate.lean`. The target `BEDC.Derived.ResearchProgrammeAuditLoopUp.taste_gate` must preserve $S, Q, G, F, K, A, X, J, T, P, N$ as distinct rows before a checked paper marker may cite it.

Closure status for $\mathsf{NameCert}_{\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}}$.

Constructive story: A $\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}$ packet is generated from research-programme route rows, review rows, strength-ledger rows, machine-interface rows, export-gate rows, loop-state rows, refusal rows, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier accepts audit-loop motion only when the route, review, machine, export, strength, and refusal coordinates are displayed together. The ledger story is repeated accountability without private approval: each loop pass is generated from finite BEDC rows and replays its gate and refusal evidence, while label motion, host-side gate passage, hidden machine evidence, and strength promotion outside the audit loop have no coordinate to project.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, obligation-surface theorem, nonescape theorem, independence witness, Lean-follow-up boundary, and existing closure annotations for $\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ResearchProgrammeAuditLoop}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim private programme approval, unregistered label motion, hidden machine evidence, host-side gate passage, or strength promotion outside the displayed loop.

Upgrade path: To reach obligationClosure, the audit-loop carrier and nonescape theorem must be checked as finite loop-state transport obligations.

Chapter 1333

A Concrete Naming Certificate for $\mathsf{AuditAxisSeparation}^{\uparrow}$

The $\mathsf{AuditAxisSeparation}^{\uparrow}$ packet realizes the two-axis discipline of section 9462.30 as a concrete finite NameCert surface. It sits beside the writing discipline of chapter 1227, the closure-status reference of chapter 1265, the registry consistency audit of chapter 1223, the registry export surface of chapter 1216, and the registry export consistency gate of chapter 1224. Those siblings expose legal audit prose, status references, agreement checks, public export, and consistency gates; this carrier binds the theory-closure and formal-verification rows together without allowing either row to determine the other.

Definition 1333.1 (Audit axis separation carrier)**.** *An* $\mathsf{AuditAxisSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (T, F, L, B, R, X, H, C, P, N)$$

with the following displayed rows:

1. *T is the theory-closure row, recording the paper-side grade and its closed scope.*
2. *F is the formal-status row, recording the Lean-side verification grade without deriving it from T.*
3. *L is the Lean-target row, recording the canonical machine target when one is displayed and remaining empty when the packet is unformalized.*
4. *B is the bridge-status row, recording whether no bridge, a paper bridge, or a checked bridge is available.*
5. *R is the refusal and not-claimed row, recording exactly which readings the packet refuses to export.*
6. *X is the registry-export row, recording the public export surface that may read the status packet.*
7. *H records componentwise* hsame *transport for theory closure, formal status, Lean target, bridge status, refusal, registry export, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from registry export and closure-status consumers through the same two-axis packet.*
9. *P is the* Pkg *provenance over* $\mathsf{AuditAxisSeparation}^{\uparrow}$, $\mathsf{AuditWritingDiscipline}^{\uparrow}$, $\mathsf{ClosureStatusReference}^{\uparrow}$, $\mathsf{RegistryConsistencyAudit}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{AuditAxisSeparation}^{\uparrow}}$ *row.*
The carrier has no coordinate for a single status row, for deriving F from T, for deriving T from F, for erasing the Lean-target or bridge row, or for exporting a claim outside the refusal and registry rows.

Lean4 ✓ `BEDC.Derived.AuditAxisSeparationUp.AuditAxisSeparationTasteGate single carrier alignment`

Theorem 1333.2 (Audit axis separation NameCert obligations)**.** *For the carrier of Definition 1333.1, the local* $\mathsf{NameCert}_{\mathsf{AuditAxisSeparation}^{\uparrow}}$ *surface consists exactly of carrier admission for $A = (T, F, L, B, R, X, H, C, P, N$ theory-closure exposure through T, formal-status exposure through F, Lean-target visibility through L, bridge-status visibility through B, refusal and not-claimed exactness through R, registry-export exposure through X, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the finite packet. The rows $T, F, L, B, R, X, H, C, P, N$ are the only coordinates available before the local name can be read.

Read the two status axes first. The row T records paper closure, while the row F records formal verification. The Lean-target row L and bridge-status row B are separate displays, so neither status row can silently absorb machine-target or bridge data.

Finally inspect the audit and registry rows. The refusal row R blocks overstrong readings, X supplies the public export surface, and H, C, P, N transport, replay, source, and name the same displayed packet. These rows exhaust the local NameCert obligations. □

Theorem 1333.3 (Audit axis separation noncollapse)**.** *In every accepted* $\mathsf{AuditAxisSeparation}^{\uparrow}$ *packet, theory closure is read only from T and formal verification is read only from F. Registry export may display the pair, compare the pair, and refuse claims that omit either row, but no accepted consumer can replace the pair by one collapsed status coordinate or infer either row from the other.*

Proof. Use the carrier inventory of Definition 1333.1. The two rows T and F are distinct coordinates, and the carrier contains no function row from one status coordinate to the other.

Apply Definition 1333.2. The NameCert surface exposes both rows before any Lean target, bridge status, refusal surface, registry export, transport, replay, provenance, or local name can be consumed.

The registry and continuation rows preserve the displayed packet rather than computing a status grade. Hence a consumer may jointly report the two axes, but a collapsed status coordinate or cross-axis inference is outside the accepted $\mathsf{AuditAxisSeparation}^{\uparrow}$ carrier. □

Falsifiable prediction: A packet with only a theory-closure row or only a formal-status row is not an accepted $\mathsf{AuditAxisSeparation}^{\uparrow}$ carrier.

Independence witness: audit-writing-discipline, closure-status-reference, registry-consistency-audit, registry-export-surface, registry-export-consistency-gate: none is bijective to $\mathsf{AuditAxisSeparation}^{\uparrow}$ because none carries the same paired noncollapsing theory/formal axis rows together with Lean-target, bridge-status, refusal, registry-export, transport, replay, provenance, and local NameCert rows.

The Lean follow-up file `lean4/BEDC/Derived/AuditAxisSeparationUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{AuditAxisSeparation}^{\uparrow}$ and FieldFaithful $\mathsf{AuditAxisSeparation}^{\uparrow}$ instances. The field-faithfulness witness must preserve $T, F, L, B, R, X, H, C, P, N$ as separate rows before the canonical alignment target may be read as checked.

Closure status for $\mathsf{NameCert}_{\mathsf{AuditAxisSeparation}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditAxisSeparation}^{\uparrow}$ packet is generated from theory-closure, formal-status, Lean-target, bridge-status, refusal, registry-export, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditAxisSeparation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1333.1, Definition 1333.2, and Definition 1333.3 bind the two-axis audit packet and its noncollapse rule as a finite NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditAxisSeparation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, registry correctness beyond the displayed export row, or any derivation between theory closure and formal verification.

Upgrade path: Lean closure requires Nontrivial AuditAxisSeparationUp and FieldFaithful AuditAxisSeparationUp instances for $T, F, L, B, R, X, H, C, P, N$.

Chapter 1334

A Concrete Naming Certificate for $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$

The $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ packet realizes the definition, theorem, and proof disciplines of chapter 9462 as one finite NameCert carrier. It sits beside the proof-trace audit witness of chapter 1219, the writing-item audit carrier of chapter 1235, the writing-item audit packet of chapter 1222, and the allowed proof audit packet of chapter 1294. Those siblings expose proof traces, writing legality, export packet shape, and proof admissibility separately; this carrier binds definition discipline, theorem discipline, proof route, scope, refusal, two-axis status, transport, replay, provenance, and local naming as one audit object.

Definition 1334.1 (Definition theorem proof audit carrier)**.** *A* $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, T, R, S, F, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the definition-discipline row, recording carrier, constructor or generator, classifier, ledger, scope, forbidden readings, and status for the definition site;*
2. *T is the theorem-discipline row, recording the claim text, explicit carrier and certificate assumptions, exact scope, conclusion, and audit line for the theorem site;*
3. *R is the proof-route row, recording the finite witness chain from source witness through classifier witness, transport or exactness witness, ledger witness, stability witness, and conclusion;*
4. *S is the scope row, fixing the local definition, theorem, proof, carrier, classifier, and certificate surface over which D, T, R are read;*
5. *F is the forbidden-resource refusal row, recording hidden choice, host equality as BEDC equality, quotient collapse, propositional extensional rewrite, global truth predicate, global clock, unledgered compression, and unscoped universal claim as unavailable proof resources;*
6. *U is the two-axis status row, recording the independent theory-closure and verification-status grades for the same site without deriving either axis from the other;*
7. *H records componentwise* hsame *transport for $D, T, R, S, F, U, C, P, N$;*
8. *C records displayed* Cont *replay for reading the definition discipline, theorem discipline, proof route, scope, refusal, and two-axis status rows in the same packet;*

9. *P is the* Pkg *provenance over chapter 9462, chapter 1219, chapter 1235, chapter 1222, chapter 1294,* BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DefinitionTheoremProofAudit}\uparrow}$ *row.*

The carrier has no coordinate for a theorem claim detached from proof route, a proof route detached from scope, a status row detached from the two-axis ledger, or a definition reading that omits its forbidden readings.

Lean4 (definition) `BEDC.Derived.DefinitionTheoremProofAuditUp.DefinitionTheoremProofAuditUp`
Lean4 ✓ `BEDC.Derived.DefinitionTheoremProofAuditUp.DefinitionTheoremProofAuditUp single carrier alignment`

Theorem 1334.2 (Definition theorem proof audit NameCert obligations)**.** *For the carrier of Definition 1334.1, the local* $\mathsf{NameCert}_{\mathsf{DefinitionTheoremProofAudit}\uparrow}$ *surface consists exactly of definition-discipline visibility through D, theorem-discipline visibility through T, proof-route visibility through R, scope visibility through S, forbidden-resource refusal through F, two-axis status separation through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier $A = (D, T, R, S, F, U, H, C, P, N)$. The rows D, T, R, S, F, U are the audit data coordinates, so the packet first exposes the definition discipline, theorem discipline, proof route, scope, refusal, and two-axis status before any consumer can read the site as accepted.

Read the structural rows next. Transport through H preserves the displayed coordinates, replay through C keeps the consumer inside the same finite route, provenance through P records the sibling audit sources, and N names the packet.

Since the carrier contains no further audit coordinate, the listed rows exhaust the local NameCert surface. A consumer that omits one row has only a projection of the packet rather than the accepted triadic audit object. □

Lean4 ✓ `BEDC.Derived.DefinitionTheoremProofAuditUp.DefinitionTheoremProofAuditCarrier namecert obligations`

Theorem 1334.3 (Definition theorem proof audit axis and proof route)**.** *Every accepted* DefinitionTheoremProofAu *packet reads theorem claim text through T only together with the proof-route row R and the two-axis status row U. The proof route cannot raise the verification grade by itself, and the verification grade cannot supply a missing proof-route row.*

Proof. Start with the theorem row T. It records claim text, assumptions, scope, conclusion, and audit line, but it is not accepted as a BEDC theorem site until the proof route and status rows are read in the same carrier.

The proof route R supplies the finite witness chain. It certifies how the theorem text is supported inside the scope S, but it does not determine the independent verification coordinate in U.

Conversely, the status row U records theory closure and verification status as two separate grades. It reports the status of the same site; it does not contain a witness-chain coordinate and therefore cannot replace R.

Thus any accepted theorem read factors through T, R, U together, with S, F, H, C, P, N preserving scope, refusal, transport, replay, provenance, and local naming. □

Lean4 ✓ `BEDC.Derived.DefinitionTheoremProofAuditUp.DefinitionTheoremProofAuditAxisAndProofRoute`

Theorem 1334.4 (Definition theorem proof audit non-escape)**.** *An audit packet that supplies definition text or theorem claim text while omitting the proof-route row R, the scope row S, the forbidden-resource refusal row F, or the two-axis status row U is rejected by the* $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ *classifier. In particular, proof-trace auditing, writing-item auditing, writing-packet export, allowed-proof auditing, and audit-system consumption cannot turn a partial prose or theorem row into an accepted definition-theorem-proof audit packet.*

Proof. Use the NameCert obligation surface of Definition 1334.2. Accepted packets expose $D, T, R, S, F, U, H, C, P,$ as one finite carrier.

If R is absent, the theorem row has no finite witness chain. If S is absent, neither the definition nor the theorem has a fixed carrier, classifier, or certificate surface. If F is absent, the packet has no displayed refusal of hidden choice, quotient collapse, host equality, or unscoped universal claim. If U is absent, the audit site no longer records theory closure and verification status as independent axes.

The sibling packets named in the statement may audit proof traces, writing legality, packet export, proof admissibility, or claim ledgers. They preserve their own surfaces; they do not add the missing row to this carrier. Therefore the partial read is refused rather than accepted as a $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ packet. □

Falsifiable prediction: A packet that supplies theorem claim text without the proof-route row is rejected by the audit classifier.

Independence witness: prooftraceauditwitness, writingitemaudit, writingitemauditpacket, allowedproofaudit, auditsystem: none is bijective to $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ because this carrier simultaneously binds definition discipline, theorem discipline, proof route, scope, forbidden-resource refusal, two-axis status, transport, replay, provenance, and local naming.

The Lean follow-up file `lean4/BEDC/Derived/DefinitionTheoremProofAuditUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ instances preserving $D, T, R, S, F, U, H, C, P, N$ as distinct rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DefinitionTheoremProofAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ packet is generated from definition rows, theorem-claim rows, proof-witness rows, proof-route rows, scope rows, status rows, forbidden-reading rows, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier accepts a definition-theorem-proof unit only when the theorem claim remains attached to its proof route and scope, and when status is read through the same two-axis ledger. The ledger story is triadic audit: definition, theorem, and proof are generated as separate visible coordinates that can be transported and replayed together, while detached claims, detached routes, and status-only reports stay outside the carrier.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DefinitionTheoremProofAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, NameCert-obligation, axis-and-proof-route, non-escape, independence witness, and Lean-follow-up boundary for $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DefinitionTheoremProofAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim theorem statements detached from proof routes, proof routes detached from scope, status rows detached from the two-axis ledger, or definition reads omitting forbidden readings.

Upgrade path: To reach obligationClosure, the triadic audit carrier and proof-route boundary must be encoded as checked finite-row obligations.

Chapter 1335

A Concrete Naming Certificate for ModulusIndexedDiagonalReadback$^{\uparrow}$

The ModulusIndexedDiagonalReadback$^{\uparrow}$ packet realizes the diagonal representative of Definition 9238.3 as a finite selector certificate. It sits after the diagonal-limit representative surface of chapter 1205, the regular-Cauchy diagonal route of chapter 372, and the finite readback carriers StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$. The packet binds one modulus request to one selected window, one dyadic tolerance ledger, one regular readback, and one Real seal before any Real-facing diagonal read becomes public.

Definition 1335.1 (Regular-Cauchy diagonal selector carrier)**.** *A* ModulusIndexedDiagonalReadback$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, S, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus-index request row, naming the precision request n and the selected modulus value $\mu(1/(n+1))$ used by the diagonal representative.*
2. *S is the* StreamName$^{\uparrow}$ *window row that records the finite observation window selected from that modulus request.*
3. *R is the* RegSeqRat$^{\uparrow}$ *readback row that reads the selected regular rational sequence at the displayed window.*
4. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger that records the dyadic comparison budget attached to the selected diagonal value.*
5. *E is the* Real$^{\uparrow}$ *seal row reached only after M, S, R, Q have been displayed.*
6. *H records componentwise* hsame *transport for the modulus request, stream window, regular readback, dyadic tolerance, Real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the modulus request through the selected window, regular readback, dyadic tolerance ledger, and Real seal.*
8. *P records* Pkg *provenance over* ModulusIndexedDiagonalReadback$^{\uparrow}$, DiagonalLimitRepresentative$^{\uparrow}$, RegularCauchyDiagonal$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ModulusIndexedDiagonalReadback}^{\uparrow}}$ *row.*
The classifier accepts exactly packets whose visible diagonal readback surface is $M, S, R, Q, E, H, C, P, N$. It has no coordinate for quotient streams, a selected limit representative outside the packet, ambient completeness, countable choice, host real equality, or an undisplayed diagonal selector.

Theorem 1335.2 (Regular-Cauchy diagonal selector NameCert obligations)**.** *For every accepted* $\mathsf{ModulusIndexedDiagonalReadback}^{\uparrow}$ *carrier $D = (M, S, R, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ModulusIndexedDiagonalRe}}$ *surface consists exactly of carrier admission, modulus-index exposure through M, StreamName window exposure through S, RegSeqRat readback through R, DyadicRatCore tolerance exposure through Q, RealUp seal routing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 1335.1. It displays one modulus request, one selected stream window, one regular rational readback, one dyadic tolerance ledger, and one Real seal row.

The continuation route orders the readback. The modulus request M selects the window S, the selected window supplies the regular readback R, and the dyadic ledger Q records the tolerance budget before the Real seal E is consumed.

The support rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier lists no quotient-stream, selected-limit, choice, host-equality, ambient-completeness, or hidden-selector coordinate, these rows exhaust the local NameCert obligations. □

```
Lean4 ✓  BEDC.Derived.ModulusIndexedDiagonalReadbackUp.ModulusIndexedDiagonalReadbackTasteGate
single carrier alignment
```

Theorem 1335.3 (Regular-Cauchy diagonal selector terminal exactness)**.** *Every accepted Real-facing diagonal read from a* $\mathsf{ModulusIndexedDiagonalReadback}^{\uparrow}$ *packet factors through the finite route*

$$M, S, R, Q, E, H, C, P, N.$$

The terminal read is exact at the displayed modulus index: it exposes the same modulus request, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row before any consumer may treat the diagonal value as public. No quotient stream, selected limit, host real equality, choice row, ambient completeness witness, or off-packet selector can replace that route.*

Proof. Start with the NameCert obligations of Definition 1335.2. They place the modulus request, stream window, regular readback, dyadic tolerance ledger, and Real seal on one displayed carrier before a consumer may read the diagonal value.

Next compare the packet with the diagonal representative. The representative of Definition 9238.3 chooses the diagonal value by the modulus index and the selected sequence window; the carrier records precisely those two selector rows as M and S and then records the regular readback and tolerance ledger as R and Q.

Finally read the terminal seal through E, H, C, P, N. These rows preserve the same packet under componentwise transport, continuation replay, provenance, and local naming. Because no other selector or completion coordinate appears in the carrier, every public Real-facing diagonal read factors through the displayed finite route. □

Falsifiable prediction: Every accepted ModulusIndexedDiagonalReadbackUp consumer exposes the modulus request, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, hsame, Cont, Pkg, and NameCert rows before any Real-facing diagonal read is public.

Independence witness: regularcauchydiagonal, diagonallimitrepresentative, streamname, regseqrat, dyadicratcore: no listed sibling is bijective because each lacks the single modulus-indexed selector packet tying the request index, selected window, dyadic tolerance, regular readback, and Real seal into one local NameCert row.

The future Lean file `lean4/BEDC/Derived/ModulusIndexedDiagonalReadbackUp/TasteGate.lean` must provide `Nontrivial ModulusIndexedDiagonalReadbackUp` and `FieldFaithful ModulusIndexedDiagonal` instances. Those instances preserve $M, S, R, Q, E, H, C, P, N$ as distinct displayed rows before any checked target may cite `BEDC.Derived.ModulusIndexedDiagonalReadbackUp`.

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusIndexedDiagonalReadback}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulusIndexedDiagonalReadback}^{\uparrow}$ packet is generated from a modulus row, schedule row, regular-readback row, dyadic-tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and local naming around one diagonal selector. The classifier accepts diagonal readback only when the modulus indexes the displayed schedule and the readback and seal rows are downstream of that same finite route. The ledger story is choice-free diagonalization: every terminal read is generated from finite modulus-indexed data already present in the BHist carrier, so no quotient stream, selected representative, countable choice, or hidden diagonal selector can be projected.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusIndexedDiagonalReadback}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, NameCert-obligation, terminal-exactness, Lean-follow-up boundary, and existing closure annotations for $\mathsf{ModulusIndexedDiagonalReadback}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulusIndexedDiagonalReadback}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim quotient streams, selected limit representatives outside the packet, ambient completeness, countable choice, host real equality, or undisplayed diagonal selectors.

Upgrade path: To reach obligationClosure, the modulus-indexed selector and terminal exactness must be checked as finite carrier and readback obligations.

Chapter 1336

A Concrete Naming Certificate for $\mathsf{InscriptionNoveltySocket}^{\uparrow}$

The $\mathsf{InscriptionNoveltySocket}^{\uparrow}$ packet realizes the Type VI inscription-novelty socket of chapter 9394 as a finite NameCert carrier. It sits beside the inscription-event packet of chapter 519, the transcendental supply inscription of chapter 604, the free-will inscription commitment of chapter 592, the supply-socket ledger of chapter 528, and the socket-kind classifier of chapter 1058. Those siblings expose event records, supply boundaries, commitment ledgers, socket accounting, and kind classification; this packet binds the prior boundary, event row, aspect-separation row, Type VI audit gate, transport, replay, provenance, and local naming rows in one carrier.

Definition 1336.1 (InscriptionNoveltySocket carrier)**.** *An* $\mathsf{InscriptionNoveltySocket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, I, R, G, H, C, P, N)$$

with the following displayed rows:

1. *B is the prior-boundary row, listing the records visible before the inscription event is read;*
2. *I is the inscription-event row, consumed through chapter 519;*
3. *R is the non-reduction and aspect-separation row, recording that consumers may compare I with B without extracting a closed records-side reducer from B to I;*
4. *G is the Type VI audit-gate row, read from section 9394.7 and preserving the distinction between proof replay and inscription-event actuality;*
5. *H records componentwise* hsame *transport for B, I, R, G, package provenance, and local naming;*
6. *C records displayed* Cont *replay routes through the prior boundary, event row, aspect-separation row, and audit-gate row;*
7. *P is the* Pkg *provenance over* $\mathsf{InscriptionEvent}^{\uparrow}$, $\mathsf{TranscendentalSupplyInscription}^{\uparrow}$, $\mathsf{FreeWillInscriptionCommitment}$ $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{SocketKindClassifier}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{InscriptionNoveltySocket}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden novelty source, deterministic reducer, agency oracle, host psychology predicate, unrecorded proof rule, or second socket-kind classifier.

Lean4 ✓ `BEDC.Derived.InscriptionNoveltySocketUp.InscriptionNoveltySocketTasteGate single carrier alignment`

Theorem 1336.2 (InscriptionNoveltySocket NameCert obligations)**.** *For the carrier of Definition 1336.1, the local* $\mathsf{NameCert}_{\mathsf{InscriptionNoveltySocket}^{\uparrow}}$ *surface has five finite obligations:*

1. *carrier exposure for the tuple* $S = (B, I, R, G, H, C, P, N)$*;*
2. *prior-boundary accountability for the records row* B*;*
3. *inscription-event accountability for the event row* I *and its Type VI site;*
4. *aspect-separation stability for the non-reduction row* R*, audit-gate row* G*, componentwise transport row* H*, and replay row* C*;*
5. *package exactness and non-escape for* P, N*, excluding hidden novelty sources, deterministic reducers, agency oracles, host psychology predicates, unrecorded proof rules, and unlisted socket-kind classifiers.*

Proof. Carrier exposure is projection from the finite packet $S = (B, I, R, G, H, C, P, N)$. Every consumer-facing coordinate is one of these displayed rows.

Prior-boundary accountability reads B, while inscription-event accountability reads I through the inscription-event sibling. These rows make the event public as a finite record site before any Type VI audit gate is consulted.

Aspect-separation stability is carried by R, G, H, C. The row R prevents a consumer from turning comparison between B and I into a closed reducer, while G records the Type VI gate that separates proof replay from inscription-event actuality. The rows H and C transport and replay only that displayed data.

Finally read P and N. The package and local naming rows list the concrete sibling surfaces and do not add a hidden source, reducer, agency oracle, host psychology predicate, proof rule, or socket-kind classifier. Thus the five obligations exhaust the local NameCert surface. □

Theorem 1336.3 (InscriptionNoveltySocket inscription-event route)**.** *Every accepted* $\mathsf{InscriptionNoveltySocket}^{\uparrow}$ *packet reads its inscription-event row* I *through the finite route*

$$B \to I \to R \to G \to H \to C \to P \to N.$$

The route preserves the prior-boundary comparison and the Type VI audit gate, and it exports no hidden novelty source, deterministic reducer from B *to* I*, agency oracle, host psychology predicate, or unrecorded proof rule.*

Proof. Project the accepted carrier as $S = (B, I, R, G, H, C, P, N)$. The only inscription-event coordinate is I, and it is displayed beside the prior-boundary row B before the aspect-separation and audit-gate rows are read.

Read I through the concrete inscription-event sibling named in chapter 519. The row R then records that the event may be compared with B without yielding a closed records-side reducer, and G records the Type VI audit gate from section 9394.7.

The support rows H, C, P, N transport, replay, package, and name the same visible route. Since the carrier contains no coordinate for a hidden novelty source, deterministic reducer, agency oracle, host psychology predicate, or unrecorded proof rule, the inscription-event route cannot export any of those objects. □

Theorem 1336.4 (InscriptionNoveltySocket sibling independence)**.** *The* $\mathsf{InscriptionNoveltySocket}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{InscriptionEvent}^{\uparrow}$*,* $\mathsf{TranscendentalSupplyInscription}^{\uparrow}$*,* $\mathsf{FreeWillInscriptionCommitment}^{\uparrow}$*,* $\mathsf{SupplySocketLedger}^{\uparrow}$*, or* $\mathsf{SocketKindClassifier}^{\uparrow}$*.*

Proof. Compare the displayed rows. $\mathsf{InscriptionEvent}^{\uparrow}$ supplies the event record, $\mathsf{TranscendentalSupplyInscription}^{\uparrow}$ supplies a supply-boundary socket, $\mathsf{FreeWillInscriptionCommitment}^{\uparrow}$ supplies a commitment ledger, $\mathsf{SupplySocketLedger}^{\uparrow}$ accounts for requested supply, and $\mathsf{SocketKindClassifier}^{\uparrow}$ classifies the socket kind.

The $\mathsf{InscriptionNoveltySocket}^{\uparrow}$ packet binds B, I, R, G, H, C, P, N together, with R carrying non-reduction and aspect separation and G carrying the Type VI audit gate for the same event. None of the siblings carries that paired prior-boundary, inscription-event, aspect-separation, and Type VI gate surface as one local NameCert packet. A row-preserving bijection would have to preserve those paired rows, so no such bijection exists. □

The Lean follow-up file `lean4/BEDC/Derived/InscriptionNoveltySocketUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial\ InscriptionNoveltySocket}^{\uparrow}$ and $\mathsf{FieldFaithful\ InscriptionNoveltySocket}^{\uparrow}$ instances. The field-faithfulness witness must preserve B, I, R, G, H, C, P, N as distinct rows so prior-boundary accountability, inscription-event routing, aspect separation, Type VI audit gating, transport, replay, provenance, and local naming cannot be merged.

Falsifiable prediction: If an InscriptionNoveltySocketUp packet erases the non-reduction row while keeping the inscription-event row, the route no longer certifies Type VI aspect separation and cannot satisfy the local NameCert obligations.

Independence witness: inscriptionevent, transcendentalsupplyinscription, freewillinscription-commitment, supplysocketledger, socketkindclassifier: none is bijective to $\mathsf{InscriptionNoveltySocket}^{\uparrow}$ because this packet jointly carries prior boundary, inscription event, non-reduction, Type VI audit gate, hsame, Cont, Pkg, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{InscriptionNoveltySocket}^{\uparrow}}$**.**

Constructive story: An $\mathsf{InscriptionNoveltySocket}^{\uparrow}$ packet is generated from a prior-boundary row, an inscription-event row, a non-reduction and aspect-separation row, a Type VI audit gate, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InscriptionNoveltySocket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1336.1, Definition 1336.2, Definition 1336.3, and Definition 1336.4 bind the finite Type VI inscription-novelty socket and its NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InscriptionNoveltySocket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, hidden novelty sources, deterministic reducers, agency oracles, host psychology predicates, or unrecorded proof rules.

Upgrade path: Obligation closure requires Lean Nontrivial and FieldFaithful TasteGate instances plus checked carrier, aspect-separation, Type VI gate, route, and package rows for B, I, R, G, H, C, P, N.

Chapter 1337

A Concrete Naming Certificate for $\mathsf{AuditFinalityCertificate}^{\uparrow}$

The $\mathsf{AuditFinalityCertificate}^{\uparrow}$ packet realizes the total auditable synthesis of section 9462.31 as a finite finality certificate. It sits beside the firewall of chapter 1296, the two-axis separation packet of chapter 1333, the definition-theorem-proof audit of chapter 1334, and the reality-constrained final-synthesis ledger of chapter 1178. Those siblings expose export refusal, status-axis separation, proof-route auditing, and reality-constrained synthesis ledgers separately; this carrier binds them into one terminal audit packet without claiming host-final truth.

Definition 1337.1 (Audit finality certificate carrier)**.** *An* $\mathsf{AuditFinalityCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, C, F, R, E, S, W, L, H, T, P, N)$$

with the following displayed rows:

1. *K is the claim row, recording the exact finite claim site whose public finality is being certified.*
2. *C is the positive certificate row, recording the accepted certificate data when the claim is admissible.*
3. *F is the failure row, recording the active failure certificate when the claim is defeated.*
4. *R is the refusal row, recording the explicit non-export readings.*
5. *E is the export-grade row, recording which public export surface may read the packet.*
6. *S is the synthesis row, recording the total-synthesis route through the displayed audit and reality-constrained siblings.*
7. *W is the firewall row, read from* $\mathsf{AuditExportFirewall}^{\uparrow}$*.*
8. *L is the final-synthesis ledger row, read from* $\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}$*.*
9. *H records componentwise* hsame *transport for claim, certificate, failure, refusal, export-grade, synthesis, firewall, ledger, replay, provenance, and local naming rows.*
10. *T records displayed* Cont *replay for the same finality packet.*
11. *P is the* Pkg *provenance over* $\mathsf{AuditFinalityCertificate}^{\uparrow}$*,* $\mathsf{AuditExportFirewall}^{\uparrow}$*,* $\mathsf{AuditAxisSeparation}^{\uparrow}$*,* $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$*,* $\mathsf{RealityConstrainedFinalSynthesisLedger}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{AuditFinalityCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for unbounded final truth, erased failure, collapsed theory/formal status, proofless theorem export, firewall bypass, hidden model–reality identity, or host-side completeness.

Lean4 (definition) `BEDC.Derived.AuditFinalityCertificateUp.AuditFinalityCertificateUp`
Lean4 ✓ `BEDC.Derived.AuditFinalityCertificateUp.AuditFinalityCertificateTasteGate single carrier alignment`

Definition 1337.2 (Audit finality certificate classifier)**.** *The classifier for* $\mathsf{AuditFinalityCertificate}^{\uparrow}$ *accepts exactly those packets $A = (K, C, F, R, E, S, W, L, H, T, P, N)$ whose claim row K, certificate row C, failure row F, refusal row R, export-grade row E, synthesis row S, firewall row W, final-synthesis ledger row L, transport row H, replay row T, provenance row P, and local name row N are all displayed in the same finite* BHist *carrier and are preserved by the local* $\mathsf{NameCert}_{\mathsf{AuditFinalityCertificate}^{\uparrow}}$ *row. It rejects any packet that omits one of those rows or replaces them by a host-final truth predicate.*

Theorem 1337.3 (Audit finality certificate NameCert obligations)**.** *For the carrier of Definition 1337.1 and classifier of Definition 1337.2, the local* $\mathsf{NameCert}_{\mathsf{AuditFinalityCertificate}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the displayed packet $A = (K, C, F, R, E, S, W, L, H, T, P, N)$;*
2. *classifier exactness for accepting exactly the same displayed packet and rejecting host-final replacements;*
3. *audit-row preservation for claim, positive certificate, failure, refusal, export-grade, synthesis, firewall, and final-synthesis ledger rows;*
4. *structural preservation by componentwise* hsame *transport through H, displayed* Cont *replay through T, and* Pkg *provenance through P;*
5. *local naming through N with no erased failure, collapsed status axis, proofless theorem export, firewall bypass, or model–reality identity row.*

Proof. Project the finite packet. The rows K, C, F, R, E, S, W, L are the only audit-finality data coordinates available before transport, replay, provenance, and local naming are read.

Read the classifier next. It accepts exactly the same displayed rows and rejects host-final replacements, so classifier exactness and audit-row preservation are the same finite surface.

Inspect the sibling rows. The firewall row W supplies the export refusal surface, the axis-separation data is carried through P, the definition-theorem-proof route is carried through P, and the final-synthesis ledger row L supplies the reality-constrained synthesis boundary.

Finally inspect H, T, P, N. These rows preserve, replay, source, and name the same packet, so the certificate cannot add a hidden finality coordinate outside the displayed carrier. The listed rows therefore exhaust the local NameCert obligations. □

Theorem 1337.4 (Audit finality certificate export refusal)**.** *If an* $\mathsf{AuditFinalityCertificate}^{\uparrow}$ *packet has an active failure row F or a refusal row R at the same claim site K, then the export-grade row E may report the refusal but cannot turn the packet into an admitted final claim. The firewall row W, axis-separation provenance, proof-route provenance, and final-synthesis ledger row L remain visible as audit evidence rather than becoming a host-final truth predicate.*

Proof. Begin with Definition 1337.1. The claim, certificate, failure, refusal, export-grade, synthesis, firewall, and ledger rows are separate displayed coordinates.

Apply Definition 1337.3. An accepted read must preserve F and R before E can be consumed, and the firewall row W records the same refusal-sensitive export boundary.

The provenance row P keeps the axis-separation and definition-theorem-proof audit sources attached to the packet. Hence a consumer may report the refusal or the defeated claim, but it has no coordinate that converts refusal, proof-route audit, firewall evidence, or synthesis ledger evidence into host-final truth. □

Falsifiable prediction: A finality packet that omits the failure row, refusal row, firewall row, or final-synthesis ledger row is not an accepted $\mathsf{AuditFinalityCertificate}^{\uparrow}$ carrier.

Independence witness: auditexportfirewall, auditaxisseparation, definitiontheoremproofaudit, realityconstrainedfinalsynthesisledger: none is bijective to $\mathsf{AuditFinalityCertificate}^{\uparrow}$ because this carrier simultaneously binds claim, certificate, failure, refusal, export-grade, synthesis, firewall, ledger, transport, replay, provenance, and local NameCert rows.

The Lean follow-up file `lean4/BEDC/Derived/AuditFinalityCertificateUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{AuditFinalityCertificate}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{AuditFinalityCertificate}^{\uparrow}$ instances preserving $K, C, F, R, E, S, W, L, H, T, P, N$ as distinct rows.

Closure status for $\mathsf{NameCert}_{\mathsf{AuditFinalityCertificate}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditFinalityCertificate}^{\uparrow}$ packet is generated from finite claim, certificate, failure, refusal, export-grade, synthesis, firewall, ledger, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditFinalityCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1337.1, Definition 1337.2, Definition 1337.3, and Definition 1337.4 bind the finality certificate, classifier, and export-refusal boundary as a finite NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditFinalityCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not claim host-final truth, erased failure, collapsed theory/formal status, proofless theorem export, firewall bypass, model–reality identity, Lean verification, or bridge checking.

Upgrade path: Lean closure requires Nontrivial AuditFinalityCertificateUp and FieldFaithful AuditFinalityCertificateUp instances for $K, C, F, R, E, S, W, L, H, T, P, N$.

Chapter 1338

A Concrete Naming Certificate for $\mathsf{FourFaceExitClassifier}^{\uparrow}$

The $\mathsf{FourFaceExitClassifier}^{\uparrow}$ packet realizes the regular-Cauchy exit route of section 9238.1 as one finite classifier packet. It sits beside the window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular-rational readback surface of chapter 301, the real-name seal of chapter 38, and the observation budget discipline of chapter 1164. Those siblings provide the four faces and their budget context; this chapter binds them as a single accepted exit classifier without quotient streams, selected limits, ambient completeness, or bridge rows.

Definition 1338.1 (Four-face exit classifier carrier)**.** *A* $\mathsf{FourFaceExitClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window for the inspected regular-Cauchy read.*
2. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and rational readback ledger attached to that window.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposed through the same window and tolerance ledger.*
4. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* S, D, R *have been read on the same packet.*
5. H *records componentwise* hsame *transport for* S, D, R, E *and for the local naming row.*
6. C *records displayed* Cont *replay from window admission through tolerance, readback, real seal, transport, provenance, and local naming.*
7. P *is the* Pkg *provenance over* $\mathsf{FourFaceExitClassifier}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealWindowBudget}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. N *is the local* $\mathsf{NameCert}_{\mathsf{FourFaceExitClassifier}^{\uparrow}}$ *row.*

The carrier exports no quotient-stream equality, selected limit, host real, ambient completeness principle, or detached bridge row.

Theorem 1338.2 (Four-face exit classifier NameCert obligations)**.** *For the carrier of Definition 1338.1, the local* $\mathsf{NameCert}_{\mathsf{FourFaceExitClassifier}^{\uparrow}}$ *surface consists exactly of carrier admission for* $F = (S, D, R, E, H, C, P, N)$*, finite-window exposure through* S*, dyadic tolerance and readback accounting through* D*, regular-rational readback through* R*, real-seal exposure through* E*, componentwise transport through* H*, displayed replay through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.FourFaceExitClassifierUp.TasteGate.FourFaceExitClassifierNameCertObligations`

Proof. Project the packet. The only four face rows are S, D, R, E, and the remaining rows are structural support for transport, replay, provenance, and naming.

The finite window is read through chapter 126. The tolerance ledger is read through chapter 291. The regular-rational readback is read through chapter 301. The real-facing seal is read through chapter 38.

The budget discipline of chapter 1164 controls the observation request, but it is not an extra face of this carrier. Since H, C, P, N preserve and name only the displayed rows, the listed obligations exhaust the local certificate. □

Theorem 1338.3 (Four-face exit classifier stream-readback exactness)**.** *Every accepted* $\mathsf{FourFaceExitClassifier}^{\uparrow}$ *consumer that reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R must first read the same finite* $\mathsf{StreamName}^{\uparrow}$ *window S and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D recorded in the carrier. The readback row cannot be replaced by a detached regular sequence, by a second window, or by a tolerance-free real seal.*

Proof. Start from the obligation surface of Definition 1338.2. It admits R only as the readback row of the displayed carrier $F = (S, D, R, E, H, C, P, N)$.

The window coordinate S supplies the finite inspection site, while D supplies the tolerance and rational arithmetic ledger for that site. Therefore the readback coordinate R is exact only relative to the same S and D rows.

Transport through H and replay through C preserve the componentwise packet. They do not introduce a second window, a detached regular sequence, or a tolerance-free route into the real seal. Hence every accepted read of R remains the stream-readback route displayed in the carrier. □

Theorem 1338.4 (Four-face exit classifier no-completeness escape)**.** *An accepted* $\mathsf{FourFaceExitClassifier}^{\uparrow}$ *packet exports the exit route*

$$S, D, R, E, H, C, P, N$$

and nothing stronger. In particular, a consumer cannot obtain quotient-stream equality, a selected limit, a host real, ambient completeness, or an acceptance bridge from the packet.

Proof. The carrier of Definition 1338.1 lists exactly the four face rows and the structural support rows. None of those coordinates is quotient equality, a selected limit, a host real, a completeness principle, or a bridge row.

Use Definition 1338.3 to keep the regular-rational readback attached to the finite window and dyadic ledger. Use Definition 1338.2 to keep the real seal downstream of those rows and of the displayed support.

Thus every public consumer remains inside the finite four-face route. Requests for quotient streams, selected limits, host completeness, or bridge acceptance leave the accepted carrier rather than being supplied by it. □

Lean4 ✓ `BEDC.Derived.FourFaceExitClassifierUp.FourFaceExitClassifierTasteGate single carrier alignment`

Falsifiable prediction: A packet with the StreamName and RealUp faces but no DyadicRatCore tolerance ledger is not an accepted FourFaceExitClassifierUp carrier.

Independence witness: streamname, dyadicratcore, regseqrat, real, realwindowbudget: no sibling is bijective because StreamNameUp supplies only finite windows, DyadicRatCoreUp supplies tolerance and arithmetic ledgers without regular readback, RegSeqRatUp supplies regular-rational

names without the observation budget, RealUp supplies the seal row without its window and tolerance provenance, and RealWindowBudgetUp schedules observations without itself carrying the four-face packet.

The Lean follow-up must provide Nontrivial FourFaceExitClassifier$^{\uparrow}$ and FieldFaithful FourFaceExitClassifier$^{\uparrow}$ instances in lean4/BEDC/Derived/FourFaceExitClassifierUp/TasteGate.lean. The target BEDC.Derived.FourFaceExitC may be cited only after those instances distinguish the window, tolerance ledger, readback, real seal, transport, replay, provenance, and local NameCert rows.

Closure status for NameCert$_{\text{FourFaceExitClassifier}^{\uparrow}}$.

Constructive story: A FourFaceExitClassifier$^{\uparrow}$ packet is generated from a finite StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier has four faces and reads each face only through the same finite BHist carrier: window admission, tolerance accounting, rational readback, and real-facing seal. The ledger story is exit without completeness: every consumer of the RealUp face must pass through the window and dyadic tolerance rows, while transport preserves the displayed coordinates and cannot create quotient-stream equality, selected limits, host reals, or detached bridge rows.

Theory closure: TheoryGate(NameCert$_{\text{FourFaceExitClassifier}^{\uparrow}}$, seed)

Scope closed: This chapter binds the carrier definition, NameCert-obligation, stream-readback-exactness, no-completeness-escape, falsifiable prediction, independence witness, Lean-follow-up boundary, and existing closure annotation for FourFaceExitClassifier$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{FourFaceExitClassifier}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim quotient-stream equality, selected limits, host reals, ambient completeness principles, or detached bridge rows.

Upgrade path: To reach obligationClosure, the four-face carrier and no-completeness boundary must be encoded with checked face-distinguishing obligations.

Chapter 1339

A Concrete Naming Certificate for $\mathsf{EpistemicOntologyBridge}^{\uparrow}$

The $\mathsf{EpistemicOntologyBridge}^{\uparrow}$ packet realizes the philosophy total-synthesis surface of section 9462.31 as a finite bridge between objecthood, knowledge licensing, observation logic, phenomenology-science interface data, audit export, and local naming. It sits beside the firewall of chapter 1296, the object-knowledge certificate of chapter 1218, the observation-logic boundary of chapter 1295, and the phenomenology-science interface of chapter 1300. Those siblings expose export refusal, object-witness evidence, observation admissibility, and phenomenology-to-science handoff separately; this bridge binds their rows before a public synthesis read may treat ontology and epistemology as one certified surface.

Definition 1339.1 (Epistemic ontology bridge carrier)**.** *An* $\mathsf{EpistemicOntologyBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (O, K, Q, P, A, L, H, C, R, N)$$

with the following displayed rows:

1. *O is the ontology row, recording the finite objecthood and constitution data read from* $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$
2. *K is the epistemology row, recording the knowledge-license and witness-admissibility data attached to the same object site.*
3. *Q is the observation-logic row, recording admissible observation claims from* $\mathsf{ObservationLogicBoundary}^{\uparrow}$*.*
4. *P is the phenomenology-science row, recording the interface route from phenomenal framing to public scientific inscription.*
5. *A is the audit-export row, recording the firewall decision from* $\mathsf{AuditExportFirewall}^{\uparrow}$*.*
6. *L is the bridge ledger row, recording that O, K, Q, P, A are read in one public synthesis packet.*
7. *H records componentwise* hsame *transport for the ontology, epistemology, observation-logic, phenomenology-science, audit-export, ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for the same bridge packet.*
9. *R is the* Pkg *provenance over* $\mathsf{EpistemicOntologyBridge}^{\uparrow}$*,* $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$*,* $\mathsf{ObservationLogicBoundary}^{\uparrow}$*,* $\mathsf{PhenomenologyScienceInterface}^{\uparrow}$*,* $\mathsf{AuditExportFirewall}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EpistemicOntologyBridge}^{\uparrow}}$ *row.*

The carrier has no coordinate for ontology without witness, epistemology without object row, observation outside the observation-logic boundary, phenomenology without science-interface handoff, audit export without firewall decision, or host-level synthesis truth.

Lean4 ✓ `BEDC.Derived.EpistemicOntologyBridgeUp.EpistemicOntologyBridgeTasteGate single carrier alignment`

Definition 1339.2 (Epistemic ontology bridge classifier)**.** *The classifier for* $\mathsf{EpistemicOntologyBridge}^{\uparrow}$ *accepts exactly those packets* $E = (O, K, Q, P, A, L, H, C, R, N)$ *whose ontology row* O*, epistemology row* K*, observation-logic row* Q*, phenomenology-science row* P*, audit-export row* A*, bridge ledger row* L*, transport row* H*, replay row* C*, provenance row* R*, and local name row* N *are all displayed in the same finite* BHist *carrier and preserved by the local* $\mathsf{NameCert}_{\mathsf{EpistemicOntologyBridge}^{\uparrow}}$ *row. It rejects any packet that omits one of those rows or replaces the bridge by a host-side identification of being, knowing, observing, experiencing, and exporting.*

Theorem 1339.3 (Epistemic ontology bridge NameCert obligations)**.** *For the carrier of Definition 1339.1 and classifier of Definition 1339.2, the local* $\mathsf{NameCert}_{\mathsf{EpistemicOntologyBridge}^{\uparrow}}$ *surface consists exactly of five obligations:*

1. *carrier admission for the displayed packet* $E = (O, K, Q, P, A, L, H, C, R, N)$*;*
2. *classifier exactness for accepting exactly the same displayed packet and rejecting host-side synthesis replacements;*
3. *cross-face preservation for ontology, epistemology, observation-logic, phenomenology-science, audit-export, and bridge-ledger rows;*
4. *structural preservation by componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, and* Pkg *provenance through* R*;*
5. *local naming through* N *with no unlicensed ontology, objectless knowledge, unbounded observation claim, unbridged phenomenology, firewall bypass, or host-level synthesis truth row.*

Proof. Project the carrier of Definition 1339.1. The rows O, K, Q, P, A, L are the only cross-face data coordinates available before transport, replay, provenance, and local naming are read.

Read the classifier of Definition 1339.2. Its accepted packet is the same displayed tuple, so carrier admission and classifier exactness have the same finite boundary.

Inspect the sibling rows. The object-knowledge row supplies ontology and epistemology evidence, the observation-logic row supplies admissible observation form, the phenomenology-science row supplies public interface transport, and the audit-export row supplies the firewall boundary.

Finally inspect H, C, R, N. These rows preserve, replay, source, and name the same packet, so the bridge cannot add a hidden synthesis coordinate outside the displayed carrier. The listed rows therefore exhaust the local NameCert obligations. □

Theorem 1339.4 (Epistemic ontology bridge audit-export boundary)**.** *If any ontology, epistemology, observation-logic, phenomenology-science, audit-export, bridge-ledger, transport, replay, provenance, or local naming row is absent from an* $\mathsf{EpistemicOntologyBridge}^{\uparrow}$ *packet, then the classifier rejects the public export. In particular, the bridge cannot turn an object row alone, a knowledge row alone, an observation row alone, a phenomenology-science handoff alone, or a firewall decision alone into a total philosophy synthesis.*

Proof. Start from Definition 1339.2. Acceptance requires the displayed rows $O, K, Q, P, A, L, H, C, R, N$ in one finite carrier.

Apply Definition 1339.3. The local NameCert obligations preserve each cross-face row before any public export may consume the packet.

If one row is absent, the classifier has no projection for the corresponding face or structural support. The audit-export row A therefore remains a firewall decision inside the packet rather than a replacement for the missing ontology, epistemology, observation-logic, phenomenology-science, ledger, transport, replay, provenance, or local name row. □

Falsifiable prediction: If any ontology, epistemology, observation-logic, phenomenology-science, or audit-export row is absent, the bridge classifier rejects the public export.

Independence witness: auditexportfirewall, objectknowledgecertificate, observationlogicboundary, phenomenologyscienceinterface: each sibling supplies one face or firewall boundary, while EpistemicOntologyBridgeUp binds the cross-face bridge; no bijection preserves all rows.

Lean `TasteGate.lean` for this route must provide `Nontrivial EpistemicOntologyBridgeUp` and `FieldFaithful EpistemicOntologyBridgeUp` instances in `BEDC.Derived.EpistemicOntologyBridgeUp`.

Closure status for $\mathsf{NameCert}_{\mathsf{EpistemicOntologyBridge}^{\uparrow}}$.

Constructive story: An $\mathsf{EpistemicOntologyBridge}^{\uparrow}$ packet is generated from finite ontology, epistemology, observation-logic, phenomenology-science, audit-export, ledger, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EpistemicOntologyBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1339.1, Definition 1339.2, Definition 1339.3, and Definition 1339.4 bind the bridge carrier, classifier, NameCert obligations, and export boundary as a finite synthesis surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EpistemicOntologyBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Lean implementation, checked bridge status, host-level synthesis truth, ontology without witness, objectless knowledge, observation outside the observation-logic boundary, unbridged phenomenology, or firewall bypass.

Upgrade path: The next paper-side step is public export after Lean encoding catches up to the carrier, classifier, NameCert obligations, and audit-export boundary.

Chapter 1340

A Concrete Naming Certificate for $\mathsf{PhysicalRecordInvariant}^{\uparrow}$

The $\mathsf{PhysicalRecordInvariant}^{\uparrow}$ packet realizes the frame-independent physical content of Definition 9462.927 and Definition 9462.928 as finite BEDC NameCert data. It sits between the object-facing packet of chapter 1214, the defeat-facing packet of chapter 1163, and the forward-looking socket of chapter 505. Those siblings provide scientific-object, failure, and causal-commitment surfaces; this chapter isolates the positive invariant carrier consumed when a physical record must remain readable across histories and observer presentations.

Definition 1340.1 (Physical record invariant carrier)**.** *A* $\mathsf{PhysicalRecordInvariant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (R, I, O, H, C, P, N)$$

with the following displayed rows:

1. *R is the physical-record ledger, listing finite history rows, continuation rows, measurement rows, instrument rows, calibration rows, error rows, relation rows, and falsification rows.*
2. *I is the inter-history invariant row whose classifier reads record content only through witnessed sameness between histories.*
3. *O is the observer-symmetry row, requiring each accepted presentation of R and I to be stable under observer-facing reindexing.*
4. *H records componentwise* hsame *transport for R, I, O and for the local naming row.*
5. *C records displayed* Cont *replay from record admission through invariant read, observer symmetry, transport, provenance, and local naming.*
6. *P is the* Pkg *provenance over* $\mathsf{PhysicalRecordInvariant}^{\uparrow}$, $\mathsf{ScientificObject}^{\uparrow}$, $\mathsf{RealityConstrainedFailureSurface}^{\uparrow}$, $\mathsf{CausalCommitment}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{PhysicalRecordInvariant}^{\uparrow}}$ *row.*

The carrier has no coordinate for bare object existence, unledgered measurement fit, one-history physical content, hidden observer frame, final truth export, or selected future observation outside the displayed rows.

Lean4 (definition) `BEDC.Derived.PhysicalRecordInvariantUp.PhysicalRecordInvariantUp`

Theorem 1340.2 (Physical record invariant classifier stability)**.** *The* PhysicalRecordInvariant$^{\uparrow}$ *classifier is stable only under componentwise* hsame *transport of the displayed rows* R, I, O, H, C, P, N*. A consumer may replay the invariant route through* Cont *and cite provenance through* Pkg*, but it must preserve the physical-record ledger, inter-history invariant row, observer-symmetry row, and local* NameCert *row as separate coordinates.*

Proof. Project the carrier of Definition 1340.1. The rows R, I, O are displayed separately: R records physical data, I names the inter-history invariant, and O records observer symmetry.

Transport is then read through H. Since H is componentwise, it preserves the record, invariant, and observer rows rather than identifying them with one ambient physical object.

Replay through C and provenance through P keep the consumer inside the same finite route. Therefore classifier stability holds exactly for the displayed packet R, I, O, H, C, P, N and fails when a consumer erases the observer-symmetry row or collapses the invariant into a single-history record. □

Lean4 ✓ `BEDC.Derived.PhysicalRecordInvariantUp.PhysicalRecordInvariantCarrier classifier stability`

Theorem 1340.3 (Physical record invariant ledger exactness)**.** *Every accepted* PhysicalRecordInvariant$^{\uparrow}$ *packet exposes the physical-record ledger* R *and the inter-history invariant row* I *before any frame-independent physical content is readable. The observer-symmetry row* O *may constrain their presentations, but it cannot replace either the ledger or the invariant.*

Proof. Read the carrier inventory. The ledger R is the only coordinate listing physical records, while I is the only coordinate carrying their inter-history invariant content.

The observer-symmetry row O is a constraint on accepted presentations. It requires stability of the read under observer-facing reindexing, but it does not contain the record ledger and does not itself witness inter-history invariance.

The structural rows H, C, P, N transport, replay, source, and name the same ledger and invariant rows. Hence ledger exactness requires R and I to remain visible before any frame-independent content is exported. □

Theorem 1340.4 (Physical record invariant NameCert surface)**.** *Every accepted* PhysicalRecordInvariant$^{\uparrow}$ *read factors through*

$$R, I, O, H, C, P, N.$$

The consumer receives finite physical records, an inter-history invariant row, observer symmetry, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* NameCert *row. It receives no bare scientific object, no defeat-only surface, no forward-GAP causal commitment, no one-history physical content, and no hidden frame.*

Proof. Start from Definition 1340.1. The displayed packet exhausts the local carrier available to consumers of frame-independent physical content.

Apply Definition 1340.2. The classifier preserves the read only when R, I, O, H, C, P, N remain separate under hsame transport and Cont replay.

Apply Definition 1340.3. The physical-record ledger and invariant row must be visible before the content is exported, while observer symmetry constrains presentations without replacing either row.

The sibling chapters locate the boundary. ScientificObject$^{\uparrow}$ in chapter 1214 has object and bridge rows not fixed to inter-history invariants; RealityConstrainedFailureSurface$^{\uparrow}$ in chapter 1163 has defeat rows but no positive invariant carrier; and CausalCommitment$^{\uparrow}$ in chapter 505 has

forward-GAP rows rather than observer-symmetric invariant rows. Thus the accepted read factors through the stated NameCert surface. □

Lean4 ✓ `BEDC.Derived.PhysicalRecordInvariantUp.PhysicalRecordInvariantTasteGate single carrier alignment`

Theorem 1340.5 (Physical record invariant kernel scope)**.** *Every accepted* PhysicalRecordInvariant$^{\uparrow}$ *packet that exports frame-independent record content exposes*

$$R, I, O, H, C, P, N$$

as BHist *carrier data, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before any* ScientificObject$^{\uparrow}$, RealityConstrainedFailureSurface$^{\uparrow}$, *or* CausalCommitment$^{\uparrow}$ *consumer reads it.*

Erasing any one of R, I, O, H, C, P, N leaves the scoped carrier for frame-independent physical content.

Proof. Start from the carrier of Definition 1340.1. The packet displays physical records, inter-history invariance, observer symmetry, transport, replay, provenance, and local naming as separate rows of the same finite BHist carrier.

Use classifier stability from Definition 1340.2. A consumer may transport the record content only componentwise, so the physical-record row, invariant row, observer-symmetry row, and local naming row cannot be collapsed into a bare scientific object.

Use ledger exactness from Definition 1340.3. The physical-record ledger and invariant row must be visible before exported content is read, and observer symmetry constrains the presentation without replacing either row.

Finally apply the NameCert surface theorem Definition 1340.4. It keeps every accepted read on R, I, O, H, C, P, N and refuses the sibling shortcuts: ScientificObject$^{\uparrow}$ cannot supply the invariant row, RealityConstrainedFailureSurface$^{\uparrow}$ cannot supply the positive record carrier, and CausalCommitment$^{\uparrow}$ cannot supply the observer-symmetric readback. Removing any listed row therefore removes the packet from the scoped carrier. □

Theorem 1340.6 (Physical record invariant falsifiable prediction)**.** *Any accepted* PhysicalRecordInvariant$^{\uparrow}$ *packet whose observer-symmetry row O is erased fails the classifier-stability obligation against* RealityConstrainedFailureSurface$^{\uparrow}$ *consumers. Such a packet may still expose records or defeats, but it no longer carries frame-independent physical content.*

Proof. Assume a consumer erases O from the packet $V = (R, I, O, H, C, P, N)$. The remaining projection no longer displays the row that makes presentations observer-symmetric.

Use classifier stability from Definition 1340.2. Stability requires componentwise preservation of R, I, O, H, C, P, N, so deleting O breaks the accepted transport route.

Against RealityConstrainedFailureSurface$^{\uparrow}$ consumers, the failure is visible as a missing positive invariant carrier rather than as a new defeat row. The defeat-facing sibling can record the boundary, but it cannot reconstruct observer symmetry. Therefore the projected packet is rejected for frame-independent physical content. □

Falsifiable prediction: Any accepted PhysicalRecordInvariantUp packet whose observer-symmetry row is erased fails the classifier-stability obligation against RealityConstrainedFailureSurfaceUp consumers.

Independence witness: ScientificObjectUp, RealityConstrainedFailureSurfaceUp, CausalCommitmentUp, ObjectKnowledgeCertificateUp, RealityConstrainedTruthCertUp: none is bijective because ScientificObjectUp has object and bridge rows not fixed to inter-history invariants, RealityConstrainedFailureSurfaceUp has defeat rows but no positive invariant carrier, CausalCommitmentUp has forward-GAP rows rather than observer-symmetric invariant rows, ObjectKnowledgeCertificateUp certifies knowledge export rather than record invariance, and RealityConstrainedTruthCertUp exports truth certification rather than frame-independent record content.

The Lean follow-up path `lean4/BEDC/Derived/PhysicalRecordInvariantUp/TasteGate.lean` provides explicit Nontrivial PhysicalRecordInvariant$^{\uparrow}$ and FieldFaithful PhysicalRecordInvariant$^{\uparrow}$ instances. These instances distinguish physical-record, invariant, observer-symmetry, transport, replay, provenance, and local NameCert rows.

Closure status for NameCert$_{\text{PhysicalRecordInvariant}\uparrow}$.

Constructive story: A PhysicalRecordInvariant$^{\uparrow}$ packet is generated from finite physical-record, inter-history-invariant, observer-symmetry, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{PhysicalRecordInvariant}\uparrow}$, scopedClosed)

Scope closed: Definition 1340.1, Definition 1340.2, Definition 1340.3, Definition 1340.4, Definition 1340.6, the independence witness, the TasteGate marker, and the finite rows R, I, O, H, C, P, N bind the closed scope for frame-independent physical content.

Formal verification: FormalStatus(NameCert$_{\text{PhysicalRecordInvariant}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.PhysicalRecordInvariantUp.PhysicalRecordInvariantTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close final physical truth, object-facing bridge completion, defeat completeness, forward causal commitment, or one-history physical content.

Upgrade path: Mature closure requires downstream bridge checking and consumers that preserve R, I, O, H, C, P, N through the same NameCert surface.

Chapter 1341

A Concrete Naming Certificate for $\mathsf{BareObjectRefusal}^{\uparrow}$

The $\mathsf{BareObjectRefusal}^{\uparrow}$ packet realizes the bare-object refusal direction of section 9462.23 as finite NameCert data. It sits beside the licensed object-knowledge packet of chapter 1218, the description-expansion boundary of chapter 661, the apophatic refusal boundary of chapter 630, and the classifier boundary of chapter 595. Those siblings license object names, regulate descriptions, record apophatic refusal rows, and expose classifier-boundary rows; this packet records the failed five-field object license itself.

The packet is composite over chapter 1218, chapter 661, chapter 630, and chapter 595; it bundles their boundary rows into one failed-license certificate.

Definition 1341.1 (Bare-object refusal carrier)**.** *A* $\mathsf{BareObjectRefusal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (O, M, R, W, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the requested object-name row whose proposed use is tested against the object-knowledge certificate discipline.*
2. *M is the missing-field row, recording which of source, pattern, classifier, stability, and ledger is absent or refused for the requested object license.*
3. *R is the refusal row that prevents the requested name from being exported as an object-layer license while M is nonempty.*
4. *W is the witness-audit row recording that no auditable witness row has been supplied for the requested object read.*
5. *L is the anti-primitive ledger row recording that the refusal cannot be bypassed by treating the name as a bare object primitive.*
6. *H records componentwise* hsame *transport for the requested name, missing-field row, refusal row, witness audit, ledger row, continuation row, package row, and local naming row.*
7. *C records the displayed* Cont *routes by which consumers read the missing fields, refusal, witness audit, and ledger nonescape rows.*
8. *P is the* Pkg *provenance over* $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$, $\mathsf{DefiniteDescriptionBoundary}^{\uparrow}$, $\mathsf{NegativeCertificateBoun}$ $\mathsf{ClassifierBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BareObjectRefusal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a licensed object name, witness-free knowledge export, primitive object token, host ontology, or object-layer license detached from the displayed five-field certificate check.

Lean4 ✓ `BEDC.Derived.BareObjectRefusalUp.BareObjectRefusalTasteGate single carrier alignment`

Theorem 1341.2 (Bare-object refusal NameCert obligations)**.** *For the carrier of Definition 1341.1, the local* $\mathsf{NameCert}_{\mathsf{BareObjectRefusal}^{\uparrow}}$ *surface consists of five obligation rows:*

1. *source refusal records the requested object-name row O and the absence of an accepted source field in M;*
2. *pattern refusal records that no displayed pattern row licenses O as an object read;*
3. *classifier refusal records that no accepted classifier row turns O into an object-identity surface;*
4. *stability refusal records that no componentwise transport may convert the missing fields into a stable object license;*
5. *ledger refusal records the anti-primitive row L, witness-audit row W, refusal row R, routes C, provenance P, and local naming row N as the only public export.*

Consequently a public consumer of an accepted $\mathsf{BareObjectRefusal}^{\uparrow}$ *packet receives a refusal certificate for the failed object license, not a weak object license.*

Proof. Carrier admission is projection from the displayed tuple $B = (O, M, R, W, L, H, C, P, N)$. The missing-field row M is the only place where the five object-knowledge fields are named, and it records absence or refusal rather than a licensed object packet.

The first four obligation rows inspect the failed source, pattern, classifier, and stability fields. They show that the requested name has not met the object-knowledge discipline of chapter 1218; description expansion, negative-certificate refusal, and classifier-boundary rows remain sibling surfaces rather than substitutes for the missing object license.

The ledger obligation then closes the export. The witness-audit row W, refusal row R, anti-primitive ledger L, transports H, routes C, provenance P, and local naming row N expose only the failed-license packet. Since no carrier coordinate contains a licensed object name or witness row, the consumer cannot repack the refusal as object knowledge. □

Theorem 1341.3 (Bare-object refusal object-license nonescape)**.** *Every accepted* $\mathsf{BareObjectRefusal}^{\uparrow}$ *packet exports only the requested-name, missing-field, refusal, witness-audit, anti-primitive ledger, transport, route, provenance, and local naming rows*

$$O, M, R, W, L, H, C, P, N.$$

It cannot export an object-layer license unless the read factors through an existing $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$ *packet with displayed source, pattern, classifier, stability, ledger, object-name, and witness rows.*

Proof. Start with the NameCert obligations above. They make the missing source, pattern, classifier, stability, and ledger fields part of the refusal surface, so the local packet records a failed object license rather than a partial one.

Use the object-knowledge sibling. chapter 1218 exposes licensed object knowledge only through its object-name, witness, five-field certificate, audit-route, transport, and local naming rows. None of those licensed rows is present in the $\mathsf{BareObjectRefusal}^{\uparrow}$ carrier except as refused or missing data.

Finally apply the anti-primitive ledger row. The ledger L records that a consumer cannot treat O as a primitive object token after the five-field certificate check has failed. Thus any accepted object-layer license must come from the sibling $\mathsf{ObjectKnowledgeCertificate}^{\uparrow}$ route, while this packet exports only the refusal rows listed above. □

Falsifiable prediction: Any accepted bare-object-refusal packet with an empty missing-field row cannot export an object-layer license without factoring through an existing ObjectKnowledgeCertificateUp packet.

Independence witness: Nearest siblings objectknowledgecertificate, definitedescriptionboundary, negativecertificateboundary, and classifierboundary are not bijective because they respectively accept licensed names, description-expansion rows, apophatic refusal rows, and classifier-boundary rows, while BareObjectRefusalUp records the failed five-field object license itself.

Closure status for $\mathsf{NameCert}_{\mathsf{BareObjectRefusal}\uparrow}$.

Constructive story: A $\mathsf{BareObjectRefusal}^{\uparrow}$ packet is generated from requested object-name, missing-field, refusal, witness-audit, anti-primitive ledger, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BareObjectRefusal}\uparrow}, \mathsf{seed})$

Scope closed: Definition 1341.1, Definition 1341.2, and Definition 1341.3 specify the finite failed-license packet and its object-license nonescape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BareObjectRefusal}\uparrow}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.BareObjectRefusalUp.BareObjectRefusalTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close positive object knowledge, description expansion, apophatic refusal in general, classifier-boundary completeness, or bridge checking.

Upgrade path: Obligation closure requires checked source, pattern, classifier, stability, ledger, witness-audit, and object-license nonescape rows for the same packet.

Chapter 1342

A Concrete Naming Certificate for $\mathsf{CauchySealInterface}^{\uparrow}$

The $\mathsf{CauchySealInterface}^{\uparrow}$ packet realizes the Real-completion seal interface of chapter 9238 as one finite naming surface. It is composite: the limit-seal row is supplied by chapter 386, the classifier row by chapter 900, the budget-synchronizer row by chapter 886, and the public observation faces by chapter 126, chapter 301, chapter 291, and chapter 38. The chapter records the common interface rather than a new completeness principle.

Definition 1342.1 (Cauchy seal interface carrier)**.** *A* $\mathsf{CauchySealInterface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, Q, B, T, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. L *is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row naming the completion-facing limit seal;*
2. Q *is the* $\mathsf{RealCompletionSealClassifierUp}$ *row classifying the visible completion-seal read;*
3. B *is the* $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ *row synchronizing the finite budget used by the seal read;*
4. T *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face exposed by the synchronized budget;*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback face reached from that finite window;*
6. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger face attached to the same readback;*
7. E *is the* $\mathsf{Real}^{\uparrow}$ *handoff face consumed by Real-completion users;*
8. H *records componentwise* hsame *transport for* L, Q, B, T, R, D, E *and the local naming row;*
9. C *records displayed* Cont *replay through the limit seal, classifier, budget synchronizer, StreamName, RegSeqRat, dyadic, and RealUp rows;*
10. P *is the* Pkg *provenance over* $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{RealCompletionSealClassifierUp}$, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
11. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchySealInterface}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient streams, host real equality, selected host limits, countable choice, metric-completeness data, or ambient Real completeness.

Theorem 1342.2 (Cauchy seal interface carrier admission)**.** *An accepted* CauchySealInterface$^{\uparrow}$ *carrier is admitted exactly as the finite tuple* $S = (L, Q, B, T, R, D, E, H, C, P, N)$ *of Definition 1342.1. Carrier admission exposes no hidden selector, quotient stream, host equality, selected limit, choice row, or ambient-completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchySealInterfaceUp.CauchySealInterfaceTasteGate single carrier alignment`

Proof. Project the carrier definition. The data rows are precisely the limit seal L, classifier Q, synchronizer B, public faces T, R, D, E, and support rows H, C, P, N.

The cited sibling chapters provide those rows as finite NameCert surfaces, and the present carrier contains no second field from which an external selector or host-level equality could be read. Therefore admission is rowwise admission of the displayed tuple. □

Theorem 1342.3 (Cauchy seal interface synchronization)**.** *Every accepted* CauchySealInterface$^{\uparrow}$ *read synchronizes the* CauchyLimitSeal$^{\uparrow}$ *row* L*, the* RealCompletionSealClassifierUp *row* Q*, and the* CauchySealBudgetSynchronizer$^{\uparrow}$ *row* B *before any of the* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*, or* Real$^{\uparrow}$ *faces are public.*

Proof. Read the source side L, Q, B in the carrier. These rows are the only seal, classifier, and budget-synchronizer coordinates available to the packet.

The public faces T, R, D, E occur downstream of the same support rows H, C, P, N. Since no detached budget or classifier coordinate is present, any public face must be read through the synchronized seal interface L, Q, B. □

Theorem 1342.4 (Cauchy seal interface finite-window readback)**.** *The finite-window segment of an accepted* CauchySealInterface$^{\uparrow}$ *packet is exactly the route* B, T, R, D *supported by* H, C, P, N*. It cannot be replaced by a hidden* StreamName$^{\uparrow}$ *selector, a quotient stream, a selected host limit, or a countable-choice row.*

Proof. Start from the synchronized budget row B. The only finite-window face selected by the interface is T, the only regular-rational readback is R, and the only dyadic ledger attached to that readback is D.

The carrier has no coordinate for any alternative selector or quotient stream. The support rows transport and replay the displayed route, so finite-window readback is exactly B, T, R, D inside the same packet. □

Theorem 1342.5 (Cauchy seal interface RealUp handoff)**.** *Every* Real$^{\uparrow}$ *consumer of an accepted* CauchySealInterface$^{\uparrow}$ *packet reaches the Real-facing row* E *only through the synchronized route*

$$L, Q, B \to T, R, D \to E$$

with the support rows H, C, P, N*. The handoff is a finite seal interface and not a Real-completeness assertion.*

Proof. Use seal synchronization to place L, Q, B before the public observation faces. Use finite-window readback to route the StreamName, RegSeqRat, and dyadic faces through the same budget row.

The Real-facing row E is the next displayed face after T, R, D, and the support rows only preserve the same packet. Thus a RealUp consumer receives a finite handoff, while completeness data remains outside the carrier. □

Theorem 1342.6 (Cauchy seal interface no-choice non-quotient nonescape)**.** *No accepted* $\mathsf{CauchySealInterface}^{\uparrow}$ *consumer can escape the displayed interface to quotient streams, host real equality, selected host limits, countable choice, metric-completeness data, hidden selectors, or ambient Real completeness. The public surface is exhausted by* $L, Q, B, T, R, D, E, H, C, P, N$*.*

Proof. Carrier admission enumerates the public rows, seal synchronization fixes the seal-classifier-budget source, finite-window readback fixes the observation faces, and the RealUp handoff fixes the terminal face.

Every excluded object would require a coordinate not present in $S = (L, Q, B, T, R, D, E, H, C, P, N)$. Therefore the local NameCert row N names only the displayed finite interface. □

This composite packet depends on its sibling rows without collapsing into any one of them: $\mathsf{CauchyLimitSeal}^{\uparrow}$ supplies the limit seal, RealCompletionSealClassifierUp supplies seal classification, $\mathsf{CauchySealBudgetSynchronizer}^{\uparrow}$ supplies budget synchronization, and the StreamName, RegSeqRat, DyadicRatCore, and RealUp rows supply the public readback faces. Later Lean TasteGate formalization for `BEDC.Derived.CauchySealInterfaceUp` must provide `Nontrivial CauchySealInterfaceUp` and `FieldFaithful CauchySealInterfaceUp` instances for the same finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySealInterface}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchySealInterface}^{\uparrow}$ packet is generated from a CauchyLimitSeal row, RealCompletionSealClassifier row, CauchySealBudgetSynchronizer row, StreamName finite-window face, RegSeqRat readback face, DyadicRatCore ledger face, RealUp handoff face, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySealInterface}^{\uparrow}}$, seed)

Scope closed: Definition 1342.1, Definition 1342.2, Definition 1342.3, Definition 1342.4, Definition 1342.5, and Definition 1342.6 bind the finite interface carrier, seal synchronization, finite-window readback, RealUp handoff, and no-choice non-quotient boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySealInterface}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, Real completeness, quotient stream equality, host real equality, selected host limits, countable choice, metric-completeness data, ambient completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, seal synchronization, finite-window readback, RealUp handoff, no-choice non-quotient nonescape, and local NameCert support for the same finite packet.

Chapter 1343

A Concrete Naming Certificate for $\mathsf{GapSocketBoundary}^{\uparrow}$

The $\mathsf{GapSocketBoundary}^{\uparrow}$ packet realizes the gap-socket boundary of section 9462.26 as finite NameCert data. It sits beside the typed taxonomy of chapter 1240, the apophatic far-end socket of chapter 1061, the externality gate of chapter 584, the reflection-gap boundary of chapter 1161, and the forward-GAP commitment packet of chapter 505. Those siblings classify socket kinds, expose the common far end, police external supply, separate reflection gaps, and bind observed regularity; this packet records the boundary where the typed socket requests missing supply without importing the missing object.

Falsifiable prediction: Any accepted GapSocketBoundaryUp packet missing typed socket, externality gate, apophatic far-end, refusal ledger, transport, route, provenance, or local NameCert rows is rejected.

Independence witness: typedgapsockettaxonomy, apophaticsocket, externalitygate, reflectiongapboundary, causalcommitment: none is bijective to $\mathsf{GapSocketBoundary}^{\uparrow}$. The taxonomy packet carries the socket-kind matrix but not one boundary request; the apophatic socket names refusal discipline without the typed externality row; the externality gate records gate admission without the far-end refusal ledger; the reflection-gap boundary records self-description pressure rather than missing supply; and the causal commitment packet records a forward regularity GAP rather than a typed boundary socket.

Definition 1343.1 (Gap-socket boundary carrier)**.** *A* $\mathsf{GapSocketBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, E, A, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed gap-socket row, read through* $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$*, naming the socket kind and the boundary request;*
2. *E is the externality-gate row, recording that the requested supply is outside the present finite packet;*
3. *A is the apophatic far-end row, naming the far-end boundary without internalizing the missing object;*
4. *R is the refusal ledger, recording rejected reads that try to turn missing supply into an internal witness, host target, quotient equality, or closure theorem;*

5. *H records componentwise* hsame *transport for T, E, A, R and the local naming row;*
6. *C records displayed* Cont *replay through socket admission, externality-gate check, far-end naming, refusal lookup, provenance, and local naming;*
7. *P is the* Pkg *provenance over* TypedGapSocketTaxonomy$^{\uparrow}$, ApophaticSocket$^{\uparrow}$, ExternalityGate$^{\uparrow}$, ReflectionGapBoundary$^{\uparrow}$, CausalCommitment$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
8. *N is the local* NameCert$_{\text{GapSocketBoundary}^{\uparrow}}$ *row.*

The carrier exports no missing witness, host supply, far-end internalization, total reflection closure, hidden causal rule, quotient equality, or untyped boundary socket.

Theorem 1343.2 (Gap-socket boundary NameCert obligations)**.** *For the carrier of Definition 1343.1, the local* NameCert$_{\text{GapSocketBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for $B = (T, E, A, R, H, C, P, N)$, typed socket exposure through T, externality-gate exposure through E, apophatic far-end exposure through A, refusal-ledger exposure through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.GapSocketBoundaryUp.GapSocketBoundaryTasteGate single carrier alignment`

Proof. Project the accepted carrier. The packet displays one typed socket row, one gate row, one far-end row, one refusal ledger, and the transport, replay, provenance, and naming rows.

Read the sibling rows through their stated roles. TypedGapSocketTaxonomy$^{\uparrow}$ classifies the socket, ApophaticSocket$^{\uparrow}$ and ApophaticFarEndSocket$^{\uparrow}$ keep the far end named without internalization, ExternalityGate$^{\uparrow}$ records the outside-supply boundary, ReflectionGapBoundary$^{\uparrow}$ supplies the reflection-pressure sibling, and CausalCommitment$^{\uparrow}$ supplies the forward-GAP sibling without replacing the boundary request.

The refusal ledger R rejects every read that asks the boundary packet to supply the missing object. Since no additional coordinate exists beyond T, E, A, R, H, C, P, N, the local NameCert obligations are exactly the listed finite rows. □

The Lean `TasteGate.lean` development for GapSocketBoundary$^{\uparrow}$ must provide explicit Nontrivial GapSocketBou and FieldFaithful GapSocketBoundary$^{\uparrow}$ instances. These instances must preserve the typed socket row, externality gate, apophatic far-end, refusal ledger, componentwise transport, displayed route, package provenance, and local naming row.

Closure status for NameCert$_{\text{GapSocketBoundary}^{\uparrow}}$**.**

Constructive story: A GapSocketBoundary$^{\uparrow}$ packet is generated from a typed socket row, externality gate, apophatic far-end, refusal ledger, componentwise transport, displayed replay route, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{GapSocketBoundary}^{\uparrow}}$, obligation)

Scope closed: Definition 1343.1 and Definition 1343.2 enumerate the carrier rows and local NameCert obligation surface for the finite boundary packet.

Formal verification: FormalStatus(NameCert$_{\text{GapSocketBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not supply the missing object, host supply, far-end internalization, reflection closure, hidden causal rule, quotient equality, Lean verification, or bridge checking for GapSocketBoundary$^{\uparrow}$.

Upgrade path: Lean closure requires Nontrivial GapSocketBoundaryUp and FieldFaithful GapSocketBoundaryUp instances in `lean4/BEDC/Derived/GapSocketBoundaryUp/TasteGate.lean`.

Chapter 1344

A Concrete Naming Certificate for RegistryNoSmugglingPredicate$^{\uparrow}$

The RegistryNoSmugglingPredicate$^{\uparrow}$ packet realizes the first machine-facing no-smuggling predicate demanded by subsection 9462.35.5 as finite registry NameCert data. It sits beside the target rows of MachineInterfaceFormalizationTarget$^{\uparrow}$, the export rows of RegistryExportSurface$^{\uparrow}$, the status gate of RegistryExportConsistencyGate$^{\uparrow}$, the classifier of chapter 1329, and the machine boundary of MachineInterfaceBoundary$^{\uparrow}$. Those siblings store targets, expose export rows, check consistency, classify smuggling forms, and limit machine-facing reads; this packet is the registry predicate that refuses theorem-evidence export whenever one of those routes reports a smuggling row.

Definition 1344.1 (Registry no-smuggling predicate carrier)**.** *A* RegistryNoSmugglingPredicate$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, E, G, U, H, C, P, N)$$

with the following displayed rows:

1. *T is the formalization-target row, recording the* MachineInterfaceFormalizationTarget$^{\uparrow}$ *name, namespace, statement skeleton, dependency surface, expected status, and not-claimed surface being checked;*
2. *E is the registry-export row, recording the* RegistryExportSurface$^{\uparrow}$ *registration, blocking, status, machine-target, audit, and non-smuggling fields for the same candidate export;*
3. *G is the consistency-gate row, recording the* RegistryExportConsistencyGate$^{\uparrow}$ *status, audit-route, formal-target readback, and no-smuggling decision;*
4. *U is the refusal-classifier row, recording the* SmugglingPatternClassifier$^{\uparrow}$ *reading as no philosophical smuggling, no mathematical smuggling, no host smuggling, no roadmap-as-theorem, or no cannot-claim conflict;*
5. *H records componentwise* hsame *transport for target, export, gate, classifier, boundary, replay, provenance, and local naming rows;*
6. *C records displayed* Cont *replay through the machine-interface boundary, target lookup, registry export surface, consistency gate, classifier refusal, provenance, and local naming;*
7. *P records* Pkg *provenance over* MachineInterfaceFormalizationTarget$^{\uparrow}$, RegistryExportSurface$^{\uparrow}$, RegistryExportConsistencyGate$^{\uparrow}$, SmugglingPatternClassifier$^{\uparrow}$, MachineInterfaceBoundary$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

8. N is the local $\mathsf{NameCert}_{\mathsf{RegistryNoSmugglingPredicate}^{\uparrow}}$ *row.*
The carrier has no coordinate for upgrading a roadmap, philosophical doctrine, mathematical tradition, host primitive, or cannot-claim entry into theorem evidence unless the displayed target, export, gate, classifier, boundary, transport, replay, provenance, and local naming rows all admit the route.

Lean4 ✓ `BEDC.Derived.RegistryNoSmugglingPredicateUp.RegistryNoSmugglingPredicateTasteGate`
`single carrier alignment`

Theorem 1344.2 (Registry no-smuggling predicate NameCert obligations)**.** *For the carrier of Definition 1344.1, the local* $\mathsf{NameCert}_{\mathsf{RegistryNoSmugglingPredicate}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for $R = (T, E, G, U, H, C, P, N)$;*
2. *target and export exposure through T and E;*
3. *consistency and no-smuggling routing through G and U;*
4. *machine-boundary replay, componentwise transport, and package provenance through C, H, P;*
5. *local naming through N.*

Proof. Project the displayed packet $R = (T, E, G, U, H, C, P, N)$. The target row T names the machine-facing object being checked, while E records the registry export surface that would otherwise expose it to a theorem-facing consumer.

The consistency-gate row G and classifier row U decide whether the same candidate passes no-smuggling. The classifier row keeps the five early refusal modes separate: philosophical smuggling, mathematical smuggling, host smuggling, roadmap-as-theorem, and cannot-claim conflict.

The rows H, C, P, N then preserve and name the same decision across transport, replay, package provenance, and local certification. Since no additional coordinate exists, the five displayed obligation rows exhaust the local NameCert surface. □

Theorem 1344.3 (No-smuggling refusal blocks theorem-evidence export)**.** *If an accepted* RegistryNoSmugglingPred *packet marks a registry export by a no-smuggling refusal row, then that export cannot be read as theorem evidence by the same machine-facing registry route. Any later theorem evidence must pass through a distinct accepted packet whose classifier row no longer carries the refusal.*

Proof. Read the candidate export through E and the same target through T. The gate row G compares that export with the target status, dependency surface, and audit route before a machine-facing consumer may use it.

When U records a no-smuggling refusal, the displayed route is refusal rather than admission. The sibling classifier of chapter 1329 supplies the classification row, while the machine-interface boundary keeps the route from importing a hidden theorem object.

The transport, replay, provenance, and naming rows preserve the refused route. Therefore the same packet cannot export theorem evidence; a theorem-evidence export requires a separately displayed packet with its own accepted classifier row. □

Falsifiable prediction: A registry export marked by a RegistryNoSmugglingPredicateUp no-smuggling refusal row cannot be exported as theorem evidence by the same machine-facing registry route.

Independence witness: machineinterfaceformalizationtarget, registryexportsurface, registryexportconsistencygate, smugglingpatternclassifier, machineinterfaceboundary: none carries the joint target, export, consistency-gate, five-form no-smuggling refusal, boundary replay, transport, provenance, and local NameCert packet of $\mathsf{RegistryNoSmugglingPredicate}^{\uparrow}$.

The Lean follow-up must provide $\mathsf{Nontrivial\ RegistryNoSmugglingPredicate}^{\uparrow}$ and $\mathsf{FieldFaithful\ RegistryNoSmugglin}$ instances in `lean4/BEDC/Derived/RegistryNoSmugglingPredicateUp/TasteGate.lean`. The field-faithfulness witness must preserve T, E, G, U, H, C, P, N as distinct rows before any machine-facing registry consumer cites BEDC.Derived.RegistryNoSmugglingPredicateUp.

Closure status for $\mathsf{NameCert}_{\mathsf{RegistryNoSmugglingPredicate}^{\uparrow}}$.

Constructive story: A $\mathsf{RegistryNoSmugglingPredicate}^{\uparrow}$ packet is generated from machine target, registry export, consistency gate, no-smuggling classifier, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegistryNoSmugglingPredicate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1344.1, Definition 1344.2, and Definition 1344.3 bind the finite predicate packet and its export refusal consequence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegistryNoSmugglingPredicate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not supply theorem evidence, bridge checking, host primitive admission, mathematical-tradition import, philosophical truth, roadmap closure, or automatic registry proof generation for $\mathsf{RegistryNoSmugglingPredicate}^{\uparrow}$.

Upgrade path: Lean closure requires Nontrivial RegistryNoSmugglingPredicateUp and FieldFaithful RegistryNoSmugglingPredicateUp instances.

Chapter 1345

A Concrete Naming Certificate for $\mathsf{RecursorBranchCompleteness}^{\uparrow}$

The $\mathsf{RecursorBranchCompleteness}^{\uparrow}$ packet realizes the branch-completeness side of the recursor-as-authorized-generator vision of chapter 9373. It sits next to the authorized generator surface of chapter 525 and the finite kernel audit perspective of chapter 484. The packet records when an accepted inductive signature, emitted recursor, motive, and branch table have all been checked before any recursor output is available to a public consumer.

Definition 1345.1 (Recursor branch-completeness carrier)**.** *A* $\mathsf{RecursorBranchCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, R, M, B, K, H, C, P, N)$$

with the following displayed rows:

1. *I is the accepted inductive signature row, including the constructor index set and strict-positivity admission needed before a recursor may be emitted.*
2. *R is the emitted recursor row, naming the eliminator generated from I.*
3. *M is the motive row, recording the target family against which every constructor branch is checked.*
4. *B is the branch package row, listing one displayed branch for each constructor admitted by I.*
5. *K is the branch-completeness ledger, recording that the constructor index rows of I and the branch rows of B have the same finite coverage.*
6. *H records componentwise* hsame *transport for I, R, M, B, K, C, P, N.*
7. *C records the displayed* Cont *replay routes by which a consumer reads the emitted recursor only after the branch package and completeness ledger have been replayed.*
8. *P is the* Pkg *provenance over* $\mathsf{AuthorizedGeneratorRecursor}^{\uparrow}$, $\mathsf{FiniteKernelCategory}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RecursorBranchCompleteness}^{\uparrow}}$ *row.*

The carrier has no coordinate for a missing branch, host induction principle, proof-producing generator channel, unchecked motive, or recursor output detached from the displayed branch-completeness ledger.

Theorem 1345.2 (Recursor branch-completeness NameCert obligations)**.** *For the carrier of Definition 1345.1, the local* $\mathsf{NameCert}_{\mathsf{RecursorBranchCompleteness}^{\uparrow}}$ *surface consists exactly of signature admission through* I*, emitted recursor naming through* R*, motive checking through* M*, constructor-indexed branch exposure through* B*, branch-completeness exactness through* K*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.RecursorBranchCompletenessUp.TasteGate.RecursorBranchCompletenessTasteGate single carrier alignment`

Proof. Carrier admission is projection from the displayed packet $Q = (I, R, M, B, K, H, C, P, N)$. The accepted signature row I supplies the constructor index set, and the emitted recursor row R is read only as the eliminator generated from that admitted signature.

The motive and branch rows supply the finite checking surface. The motive row M fixes the target family, while B gives one displayed branch for each constructor row admitted by I.

The completeness ledger K binds those two finite lists together. It records that a consumer cannot read R as authorized unless every constructor row in I has a corresponding branch in B and every branch in B is accounted for by the same signature.

Finally, H, C, P, N keep the obligation surface local. Transport, continuation replay, provenance, and the local NameCert row preserve the displayed packet rather than replacing it by host induction or a proof-producing generator channel. □

Theorem 1345.3 (Recursor branch-completeness non-escape)**.** *Every public consumer of an accepted* $\mathsf{RecursorBranchCompleteness}^{\uparrow}$ *packet can read only the displayed signature, emitted recursor, motive, branch package, branch-completeness ledger, transport, replay, provenance, and local NameCert rows*

$$I, R, M, B, K, H, C, P, N.$$

It cannot export a recursor output, missing-branch repair, unchecked motive, hidden induction rule, or proof-producing generator apart from the same finite packet.

Proof. Start with the NameCert obligations. They force every public read through the displayed rows and make K the only ledger by which branch coverage can be consumed.

The authorized generator sibling supplies the recursor discipline. By chapter 525, an authorized generator recursor is public only through accepted signature, motive, branch, descent, audit, transport, continuation, package, boundary, and local naming rows. The present packet records the branch-completeness portion of that route and does not add a separate generator outlet.

The finite kernel category sibling supplies the finite audit perspective. Its finite-kernel rows license only displayed constructor and morphism data, so a consumer cannot use them to manufacture an off-packet branch or host induction rule.

Thus any attempted export outside $I, R, M, B, K, H, C, P, N$ has no carrier coordinate. The accepted packet exposes branch-complete recursor use as finite NameCert data and nothing beyond that packet. □

Falsifiable prediction: Deleting the branch-completeness ledger K leaves an emitted recursor packet whose branch package cannot certify constructor-index coverage for all accepted constructors in I.

Independence witness: authorizedgeneratorrecursor and finitekernelcategory are not bijective to RecursorBranchCompletenessUp because the present packet alone records accepted signature,

emitted recursor, motive, branch package, branch-completeness ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert rows together.

Closure status for $\mathsf{NameCert}_{\mathsf{RecursorBranchCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{RecursorBranchCompleteness}^{\uparrow}$ packet is generated from recursor-code rows, motive rows, branch-family rows, branch-completeness ledger rows, output rows, coverage-audit rows, obstruction rows, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier accepts a recursor output only when every branch required by the displayed motive is accounted for in the finite ledger. The constructive story is branch coverage before elimination: missing branches, unchecked motives, proof-producing generator channels, and host induction principles are represented as absence or obstruction, while the accepted route is generated by replaying the same finite branch ledger through transport and continuation.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RecursorBranchCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier definition, NameCert-obligation, non-escape theorem, falsifiable prediction, and independence witness for $\mathsf{RecursorBranchCompleteness}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RecursorBranchCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim missing branches, host induction principles, proof-producing generator channels, unchecked motives, or recursor outputs detached from the branch-completeness ledger.

Upgrade path: To reach obligationClosure, the branch-completeness carrier and obstruction boundary must be checked as finite recursor-ledger obligations.

Chapter 1346

A Concrete Naming Certificate for $\mathsf{TraceVerdictBoundary}^{\uparrow}$

The $\mathsf{TraceVerdictBoundary}^{\uparrow}$ packet realizes the proof discipline of subsection 9462.30.6 as a concrete boundary between proof traces and verdict export. It sits beside the proof-trace audit witness of chapter 1219, the machine-interface formalization target of chapter 1225, the ground compiler audit verdict of chapter 822, and the definition-theorem-proof audit packet of chapter 1334. Those siblings expose trace witnesses, interface targets, verdict rows, and proof-discipline rows separately; this chapter binds the handoff from trace data to public verdict export.

Definition 1346.1 (Trace verdict boundary carrier)**.** *A* $\mathsf{TraceVerdictBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, R, V, I, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ *row recording the finite proof trace, transport, ledger, refusal, audit-verdict, provenance, and local NameCert witness;*
2. *R is the forbidden-resource refusal row recording hidden choice, host equality as BEDC equality, quotient collapse, propositional extensional rewrite, global truth predicate, global clock, unledgered compression, and unscoped universal claim as unavailable proof resources;*
3. *V is the verdict-export row supplied through the* $\mathsf{GroundCompilerAuditVerdict}^{\uparrow}$ *surface;*
4. *I is the* $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$ *row naming the checker-facing formalization target through which the verdict may be exported;*
5. *A is the* $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ *row recording the proof-discipline site whose trace is being judged;*
6. *H records componentwise* hsame *transport for T, R, V, I, A, C, P, N;*
7. *C records displayed* Cont *replay for the trace, refusal, verdict, interface-target, proof-discipline, provenance, and local naming rows;*
8. *P is the* Pkg *provenance over chapter 1219, chapter 1225, chapter 822, chapter 1334, subsection 9462.30.6,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TraceVerdictBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for reading a proof trace as a verdict, exporting a verdict without a refusal row, bypassing the machine-interface target, or replacing the displayed proof-discipline site with host-side semantic confidence.

Definition 1346.2 (Trace verdict boundary classifier)**.** *Two accepted* $\mathsf{TraceVerdictBoundary}^{\uparrow}$ *carriers classify together exactly when their proof-trace, refusal, verdict, interface-target, proof-discipline, transport, replay, provenance, and local naming rows compare componentwise by* hsame*:*

$$T \sim_{\mathsf{hsame}} T', \quad R \sim_{\mathsf{hsame}} R', \quad V \sim_{\mathsf{hsame}} V', \quad I \sim_{\mathsf{hsame}} I',$$
$$A \sim_{\mathsf{hsame}} A', \quad H \sim_{\mathsf{hsame}} H', \quad C \sim_{\mathsf{hsame}} C', \quad P \sim_{\mathsf{hsame}} P', \quad N \sim_{\mathsf{hsame}} N'.$$

No classifier clause compares hidden proof-checker state, host-side truth, private verdict policy, or trace data outside the displayed handoff.

Theorem 1346.3 (Trace verdict boundary NameCert obligations)**.** *For the carrier of Definition 1346.1, the local* $\mathsf{NameCert}_{\mathsf{TraceVerdictBoundary}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *carrier admission for* $B = (T, R, V, I, A, H, C, P, N)$ *with proof trace, forbidden-resource refusal, verdict export, interface target, proof-discipline site, transport, replay, provenance, and local name all displayed;*
2. *classifier stability for the same rows under componentwise* hsame *as in Definition 1346.2;*
3. *trace-to-verdict exactness, requiring a verdict export through* V *to read the proof trace* T *only together with the refusal row* R *and interface-target row* I*;*
4. *provenance and route exactness, requiring every verdict-boundary read to pass through the proof-trace witness, machine-interface formalization target, ground compiler audit verdict, definition-theorem-proof audit packet, replay row, package row, and local name;*
5. *non-escape for bare proof traces, forbidden-resource erasure, hidden checker state, private verdict policy, host semantic confidence, and verdict export outside the displayed interface target.*

Lean4 ✓ `BEDC.Derived.TraceVerdictBoundaryUp.TasteGate.TraceVerdictBoundaryNameCertObligations`

Proof. Carrier admission is projection from Definition 1346.1. The packet displays trace, refusal, verdict, interface target, proof-discipline, transport, replay, provenance, and local naming rows before the verdict boundary can be read.

Classifier stability is componentwise. The classifier of Definition 1346.2 compares exactly those rows by hsame, so a transported packet cannot keep a verdict while dropping its trace, refusal, interface target, or proof-discipline row.

Trace-to-verdict exactness follows from the route order. The proof trace T supplies audit evidence, but it does not become a verdict export until R, V, I, A, H, C, P, N are displayed in the same packet.

Provenance and route exactness use the sibling packets named in the statement. The proof-trace witness supplies the trace row, the interface target supplies checker-facing export scope, the ground compiler audit verdict supplies verdict data, and the definition-theorem-proof audit supplies the proof-discipline site.

Non-escape is immediate from the carrier inventory. There is no coordinate for bare trace export, hidden checker state, private verdict policy, forbidden-resource erasure, or host semantic confidence, so the NameCert surface cannot export one. □

Theorem 1346.4 (Trace verdict boundary nonescape)**.** *An accepted* $\mathsf{TraceVerdictBoundary}^{\uparrow}$ *packet never exports a proof trace as a verdict unless the forbidden-resource refusal row, ground compiler audit verdict row, machine-interface target row, proof-discipline row, transport row, replay row, provenance row, and local name are displayed with it. Deleting the refusal row while preserving the trace and verdict rows leaves a partial trace-verdict projection, not an accepted verdict boundary carrier.*

Proof. Start with the NameCert obligations of Definition 1346.3. They require trace-to-verdict exactness through $T, R, V, I, A, H, C, P, N$ before a public verdict-boundary read is accepted.

If R is absent, the packet no longer records the refusal of hidden choice, host equality, quotient collapse, propositional extensional rewrite, global truth, global clock, unledgered compression, or unscoped universal claim. A trace row and verdict row without that refusal do not satisfy the carrier admission clause.

The interface and proof-discipline rows cannot repair the missing refusal. They scope the verdict export and identify the proof site, but the boundary classifier still compares R as a displayed row. Hence the partial read is rejected by the $\mathsf{TraceVerdictBoundary}^{\uparrow}$ classifier rather than exported as a verdict boundary. □

Theorem 1346.5 (Trace verdict boundary proof-trace handoff)**.** *Every accepted* $\mathsf{TraceVerdictBoundary}^{\uparrow}$ *verdict export factors through the* $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ *row and then through the forbidden-resource refusal,* $\mathsf{GroundCompilerAuditVerdict}^{\uparrow}$*,* $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$*,* $\mathsf{DefinitionTheoremProofAudit}^{\uparrow}$ *transport, replay, provenance, and local NameCert rows. The proof trace remains audit evidence for the verdict route; it is not itself the exported verdict.*

Proof. Project the carrier $B = (T, R, V, I, A, H, C, P, N)$. The first visible witness row is the $\mathsf{ProofTraceAuditWitness}^{\uparrow}$ row T, while the verdict row V appears only after the refusal row R and alongside the interface target I and proof-discipline row A.

Apply the NameCert obligations. Trace-to-verdict exactness requires the verdict export to preserve $T, R, V, I, A, H, C, P, N$ as one route, and provenance exactness records the sibling surfaces named in the statement.

Finally use nonescape. Since a bare proof trace cannot be exported as a verdict and a missing refusal row invalidates the carrier, the handoff from proof trace to verdict export is exactly the displayed finite boundary route. □

Falsifiable prediction: Deleting the forbidden-resource refusal row while keeping trace and verdict rows invalidates the verdict boundary carrier.

Independence witness: prooftraceauditwitness, machineinterfaceformalizationtarget, groundcompilerauditverdict, auditgatefailurewitness, definitiontheoremproofaudit: none is bijective because this packet uniquely binds trace rows to verdict export through refusal, interface target, provenance, and local NameCert rows.

Lean TasteGate.lean must include explicit Nontrivial $\mathsf{TraceVerdictBoundary}^{\uparrow}$ and FieldFaithful TraceVerdictBoundar instances preserving $T, R, V, I, A, H, C, P, N$ as distinct rows.

Closure status for $\mathsf{NameCert}_{\mathsf{TraceVerdictBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TraceVerdictBoundary}^{\uparrow}$ packet is generated from proof-trace rows, verdict rows, refusal rows, machine-target rows, proof-discipline boundary rows, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier separates a trace from a verdict: the proof trace can be handed to a machine-facing route only through the discipline and refusal coordinates already displayed in the finite carrier. The ledger story is verdict boundary preservation, where replay exposes which trace, target, discipline, and refusal rows were used, while hidden checker state, private verdict policy, forbidden-resource erasure, and host semantic confidence have no coordinate.

Theory closure: TheoryGate(NameCert$_{\mathsf{TraceVerdictBoundary}^{\uparrow}}$, seed)

Scope closed: This chapter binds the carrier and classifier definitions, NameCert-obligation, nonescape, proof-trace-handoff, independence witness, and Lean-follow-up boundary for TraceVerdictBoundary$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{TraceVerdictBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: It does not claim reading proof traces as verdicts, verdict export without refusal rows, machine-target bypass, or replacement by host-side semantic confidence.

Upgrade path: To reach obligationClosure, the trace-verdict classifier and handoff boundary must be checked as finite proof-route obligations.

Chapter 1347

A Concrete Naming Certificate for $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$

The $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$ packet realizes the dependency and no-smuggling side of the machine-facing interface of subsection 9462.35.5 as one finite NameCert audit. It sits beside the target carrier of chapter 1225, the classifier of chapter 1329, the dependency lattice of chapter 868, and the export gate of chapter 1224. Those siblings store target skeletons, classify smuggling attempts, expose dependency modes, and block inconsistent registry export; this packet binds the target row, dependency row, no-smuggling decision, axiom-dependency audit, and export-gate result before a formalization queue may treat the rows as one admissible target.

Definition 1347.1 (Formal-target dependency audit carrier)**.** *A* $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, D, S, K, U, A, G, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$ *row, recording the target name, namespace, registry row, statement skeleton, expected status, audit-gate row, and not-claimed surface.*
2. *D is the dependency-list row read from the same formalization target and normalized as finite machine-facing prerequisites.*
3. *S is the* $\mathsf{SmugglingPatternClassifier}^{\uparrow}$ *no-smuggling decision row, exposing whether the target attempts to read prose, host supply, model output, or private registry state as internal BEDC content.*
4. *K is the* $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$ *row, recording the internal, restricted, or externally supplied dependency mode for each displayed prerequisite.*
5. *U is the unresolved-supply row, listing the finite dependencies or socket reports that remain outside theorem content after D, S, K have been read.*
6. *A is the audit-decision row, recording whether the target-dependency pair is admissible, refused, or held as a queue record.*
7. *G is the* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ *row, checking that registry status, formal-target readback, audit route, and no-smuggling decision agree before export.*

8. *H records componentwise* hsame *transport for target, dependency, no-smuggling, axiom-audit, unresolved-supply, audit-decision, export-gate, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the target row through dependency readback, no-smuggling classification, axiom-dependency audit, unresolved-supply exposure, audit decision, and export-gate result.*
10. *P is the* Pkg *provenance over* $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$, $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$, $\mathsf{SmugglingPatternClassifier}^{\uparrow}$, $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$, $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalTargetDependencyAudit}^{\uparrow}}$ *row.*

The carrier has no coordinate for a dependency imported outside D, a no-smuggling decision erased from S, an axiom-dependency reading outside K, an export-gate result outside G, or a proof object extracted from an admissible queue record.

Lean4 (definition) `BEDC.Derived.FormalTargetDependencyAuditUp.FormalTargetDependencyAuditUp`

Theorem 1347.2 (Formal-target dependency audit NameCert obligations)**.** *For the carrier of Definition 1347.1, the local* $\mathsf{NameCert}_{\mathsf{FormalTargetDependencyAudit}^{\uparrow}}$ *surface consists exactly of carrier admission for $F = (T, D, S, K, U, A, G, H, C, P, N)$, target exposure through T, finite dependency readback through D, no-smuggling classification through S, axiom-dependency audit through K, unresolved-supply exposure through U, audit-decision routing through A, registry-export consistency through G, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the displayed packet $F = (T, D, S, K, U, A, G, H, C, P, N)$. The target row T supplies the machine-facing skeleton, and D exposes the finite prerequisite list read from the same target.

Read S, K, U, A next. The classifier row S keeps no-smuggling visible, the dependency-audit row K records how each prerequisite is read, the unresolved-supply row U records what remains outside theorem content, and the audit-decision row A decides admission only for that displayed combination.

Finally inspect G, H, C, P, N. The export gate G checks the same target, dependency, audit, and no-smuggling rows against the registry surface, while transport, replay, provenance, and local naming preserve the packet. Since no additional coordinate remains, these rows exhaust the local NameCert obligations. □

Theorem 1347.3 (Formal-target dependency audit nonescape)**.** *A* $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$ *packet whose no-smuggling row S is absent, erased, or not transported with T, D, K, A, G cannot be exported as an admissible machine-facing formalization target. Such a packet remains a queue record or refusal report, not theorem content and not a certified target-dependency audit.*

Proof. Begin with the target and dependency rows. The target skeleton T and dependency list D identify what the queue wants to certify, but neither row decides whether external supply has been smuggled into the target.

Use the no-smuggling row S. By Definition 1347.2, the local NameCert surface must expose S together with the axiom-dependency audit K, unresolved-supply row U, audit decision A, and export gate G.

If S is absent or not transported with the other rows, the export gate has no displayed classifier result to compare with registry status and target readback. Componentwise hsame and Cont replay

cannot manufacture a missing row, so the packet cannot be accepted as an admissible machine-facing target. □

Theorem 1347.4 (Formal-target dependency audit sibling independence)**.** *The* $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$, $\mathsf{SmugglingPatternClassifier}^{\uparrow}$, $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$, *or* $\mathsf{RegistryExportConsistencyGate}^{\uparrow}$.

Proof. Compare the displayed rows. $\mathsf{MachineInterfaceFormalizationTarget}^{\uparrow}$ supplies the target skeleton and dependency list but does not itself bind the no-smuggling decision, axiom-dependency audit, and export-gate result as one audit.

$\mathsf{SmugglingPatternClassifier}^{\uparrow}$ supplies the no-smuggling classification but lacks the target skeleton and dependency list. $\mathsf{AxiomDependencyAuditMap}^{\uparrow}$ supplies dependency modes and required-supply rows but does not store the formal target or registry export result.

$\mathsf{RegistryExportConsistencyGate}^{\uparrow}$ checks export consistency, audit route, no-smuggling, and formal-target readback, but it does not expose the dependency-list normalization and axiom-dependency audit rows as the same target packet. A row-preserving bijection would have to preserve all of $T, D, S, K, U, A, G, H, C, P, N$, so none of these siblings is bijective to $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$. □

Falsifiable prediction: A FormalTargetDependencyAuditUp packet whose no-smuggling row is erased cannot be exported as an admissible machine-facing formalization target.

Independence witness: machineinterfaceformalizationtarget, smugglingpatternclassifier, axiomdependencyauditmap, registryexportconsistencygate: none is bijective because each lacks at least one of target skeleton, dependency list, no-smuggling decision, axiom-dependency audit, or export-gate result rows.

The later Lean file `lean4/BEDC/Derived/FormalTargetDependencyAuditUp/TasteGate.lean` must provide Nontrivial $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$ and FieldFaithful $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$ instances over the same carrier. The field-faithful route must preserve $T, D, S, K, U, A, G, H, C, P, N$ before `BEDC.Derived.FormalTargetDependencyAuditUp.FormalTargetDependencyAuditUp` can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{FormalTargetDependencyAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$ packet is generated from a machine-facing target row, dependency-list row, no-smuggling decision, axiom-dependency audit row, unresolved-supply row, audit-decision row, registry-export gate, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FormalTargetDependencyAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1347.1, Definition 1347.2, Definition 1347.3, and Definition 1347.4 bind the finite target-dependency audit, no-smuggling nonescape, and sibling-independence surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FormalTargetDependencyAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, public export closure, bridge checking, automatic dependency discharge, or proof-object production for $\mathsf{FormalTargetDependencyAudit}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, target exposure, dependency readback, no-smuggling classification, axiom-dependency audit, unresolved-supply exposure, audit-decision routing, export-gate consistency, TasteGate nontriviality, and field faithfulness for $T, D, S, K, U, A, G, H, C, P, N$.

Chapter 1348

A Concrete Naming Certificate for $\mathsf{ExternalSupplySignatureSeal}^{\uparrow}$

The $\mathsf{ExternalSupplySignatureSeal}^{\uparrow}$ packet realizes the reality-facing signature discipline of Definition 9413.89, especially section 9414.1, as one finite NameCert carrier for external-supply certification. It sits beside the residue packet of chapter 1213, the descent packet of chapter 1303, the fit packet of **??**, the GAP socket boundary of chapter 1343, and the registry no-smuggling predicate of chapter 1344. Those siblings expose gap residue, operation descent, physical-signature fit, socket boundary, and registry refusal rows separately; this packet binds an external source signature to the mathematical classifier only when the physical row, descent certificate, hidden-supply ledger, and local naming row travel with it.

Falsifiable prediction: Every accepted ExternalSupplySignatureSealUp packet that exports a mathematical classifier without the physical signature row fails the descent-refusal obligation.

Independence witness: reality-constrained-signature-residue, reality-constrained-signature-descent, reality-constrained-signature-fit, gap-socket-boundary, registrynosmugglingpredicate: none is bijective to the seal because each lacks at least one of the ontic source, external representation, physical signature, GAP socket, descent certificate, hidden-supply ledger, and local NameCert rows.

Definition 1348.1 (External supply signature seal carrier)**.** *An* $\mathsf{ExternalSupplySignatureSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (O, M, Q, G, D, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the ontic signature source row from Definition 9414.3;*
2. *M is the mathematical representation row from Definition 9414.4;*
3. *Q is the physical signature row exposed by the admissible question bundle;*
4. *G is the GAP socket row that records the represented absence and admissible compression boundary;*
5. *D is the descent certificate row that decides which operations survive the classifier route;*
6. *L is the hidden-supply ledger recording source material not exported by the mathematical representation;*

7. *H records componentwise* hsame *transport for the source, representation, signature, GAP, descent, ledger, and local naming rows;*
8. *C records displayed* Cont *replay for the same route;*
9. *P is the* Pkg *provenance over* ExternalSupplySignatureSeal$^{\uparrow}$, RealityConstrainedSignatureResidue$^{\uparrow}$, RealityConstrainedSignatureDescent$^{\uparrow}$, RealityConstrainedSignatureFit$^{\uparrow}$, GapSocketBoundary$^{\uparrow}$, RegistryNoSmugglin BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ExternalSupplySignatureSeal}^{\uparrow}}$ *row.*

The classifier may compare accepted carriers only through these rows. It has no coordinate for a bare mathematical classifier, a hidden physical signature, an unledgered external source, or a registry export detached from G, D, L, N.

Theorem 1348.2 (External supply signature seal NameCert obligations)**.** *For the carrier of Definition 1348.1, the local* $\mathsf{NameCert}_{\mathsf{ExternalSupplySignatureSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for $S = (O, M, Q, G, D, L, H, C, P, N)$, source-signature exposure through O, Q, representation exposure through M, GAP and descent exposure through G, D, hidden-supply ledger exposure through L, structural replay through H, C, P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ExternalSupplySignatureSealUp.ExternalSupplySignatureSealNameCert obligations`

Proof. Project the carrier. The tuple lists one ontic source row, one mathematical representation row, one physical signature row, one GAP socket row, one descent certificate row, one hidden-supply ledger row, and the structural support rows.

Read the sibling rows componentwise. The residue sibling supplies representation-gap discipline, the descent sibling supplies operation-descent discipline, the fit sibling supplies physical-signature compatibility, the GAP socket boundary supplies represented absence, and the registry no-smuggling predicate supplies the export refusal row.

The support rows H, C, P, N transport, replay, source, and name only this displayed packet. Since no further coordinate exists, the listed rows exhaust the local NameCert obligation surface. □

Theorem 1348.3 (External supply signature seal descent refusal)**.** *An accepted* ExternalSupplySignatureSeal$^{\uparrow}$ *packet refuses any export of the mathematical representation row M as a reality-facing classifier unless the same route displays the physical signature row Q, the GAP socket row G, the descent certificate row D, and the hidden-supply ledger row L.*

Proof. Begin with the obligation surface of Definition 1348.2. It makes source-signature exposure, GAP exposure, descent exposure, and ledger exposure separate required rows of the same local certificate.

Use the descent and fit siblings next. chapter 1303 supplies the operation-descent row, while **??** supplies the physical-signature compatibility row.

Finally attach the GAP socket and no-smuggling siblings. The boundary of chapter 1343 records the represented absence, and chapter 1344 prevents a registry route from exporting the mathematical row as if the omitted source rows had been supplied. Thus a route missing Q, G, D, L is refused rather than accepted as a seal. □

Theorem 1348.4 (External supply signature seal ledger exactness)**.** *In every accepted* ExternalSupplySignatureSeal$^{\uparrow}$ *packet, the hidden-supply ledger L records exactly the source material not exported by M but still required by the physical signature row Q, the GAP socket row G, and the descent certificate row D.*

Proof. First project the carrier rows O, M, Q, G, D, L. The source row O is not identified with its mathematical representation M, and the physical signature row Q is not recoverable from M unless the packet displays the GAP, descent, and ledger rows.

Apply the NameCert obligations. They expose L as its own ledger coordinate, not as a consequence of M or Q alone.

The residue, descent, and no-smuggling siblings then fix exactness. Residue records what remains after mathematical identification, descent records which operations survive the route, and the registry predicate refuses an export that hides supply rows. Therefore L is exact for the omitted source material required by Q, G, D and no broader host supply. □

The Lean `TasteGate.lean` development for $\mathsf{ExternalSupplySignatureSeal}^{\uparrow}$ is committed to explicit `Nontrivial ExternalSupplySignatureSealUp` and `FieldFaithful ExternalSupplySignatureSealUp` instances in `BEDC.Derived.ExternalSupplySignatureSealUp`. These instances must preserve the row order $O, M, Q, G, D, L, H, C, P, N$ and keep the external supply, physical signature, GAP socket, descent, ledger, and local NameCert rows separated.

Closure status for $\mathsf{NameCert}_{\mathsf{ExternalSupplySignatureSeal}^{\uparrow}}$.

Constructive story: An $\mathsf{ExternalSupplySignatureSeal}^{\uparrow}$ packet is generated from an ontic signature source, a mathematical representation, a physical signature row, a GAP socket, a descent certificate, a hidden-supply ledger, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ExternalSupplySignatureSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1348.1, Definition 1348.2, Definition 1348.3, and Definition 1348.4 bind the external-supply signature seal as a finite GAP, descent, ledger, and NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ExternalSupplySignatureSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim physical truth, full representation adequacy, registry finality, public closure, bridge checking, or Lean verification for $\mathsf{ExternalSupplySignatureSeal}^{\uparrow}$.

Upgrade path: Lean closure requires Nontrivial ExternalSupplySignatureSealUp and FieldFaithful ExternalSupplySignatureSealUp instances in `lean4/BEDC/Derived/ExternalSupplySignatureSealUp/TasteGate.lean`.

Chapter 1349

A Concrete Naming Certificate for $\mathsf{ClosedGenerationRefusal}^{\uparrow}$

The $\mathsf{ClosedGenerationRefusal}^{\uparrow}$ packet realizes the negative boundary of the inscription-event vision in chapter 9397. It sits beside the public inscription event of chapter 519, the route audit of chapter 1005, and the kernel observation sieve of chapter 932. Those siblings expose accepted public inscription rows, accepted route rows, and accepted-or-rejected observation rows; this packet records the finite case in which a candidate transition is refused as closed-generation-certified from the prior records.

Definition 1349.1 (ClosedGenerationRefusal carrier)**.** *A* $\mathsf{ClosedGenerationRefusal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (P, T, G, R, I, H, C, Q, N)$$

with the following displayed rows:

1. *P is the prior-record row naming the finite records visible before the candidate transition is tested;*
2. *T is the candidate-transition row whose inscription-facing admission is under audit;*
3. *G is the closed-generation test row, recording whether the prior records certify T by authorized generators;*
4. *R is the refusal-ledger row, present exactly when G does not certify T as prior-record generated;*
5. *I is the inscription-comparison row, reading T against the inscription-event packet of chapter 519;*
6. *H records componentwise* hsame *transport for P, T, G, R, I;*
7. *C records displayed* Cont *replay through the prior records, candidate transition, closed-generation test, refusal ledger, and inscription comparison;*
8. *Q is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$, $\mathsf{InscriptionEvent}^{\uparrow}$, $\mathsf{InscriptionRouteAudit}^{\uparrow}$, $\mathsf{KernelObservationSieve}^{\uparrow}$, $\mathsf{CausalCommitment}^{\uparrow}$, *and* $\mathsf{ApophaticSocket}^{\uparrow}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedGenerationRefusal}^{\uparrow}}$ *row.*

The classifier has no coordinate for a transition accepted by the closed-generation test, an untested candidate, a hidden generator, a private agency predicate, or a route that bypasses the refusal ledger.

Lean4 ✓ BEDC.Derived.ClosedGenerationRefusalUp.TasteGate.closedGenerationRefusalTasteGate
single carrier alignment

Theorem 1349.2 (ClosedGenerationRefusal NameCert obligations)**.** *For the carrier of Definition 1349.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedGenerationRefusal}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$F = (P, T, G, R, I, H, C, Q, N),$$

prior-record exposure through P*, candidate-transition exposure through* T*, closed-generation testing through* G*, refusal-ledger accountability through* R*, inscription-event comparison through* I*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*, package provenance through* Q*, and local naming through* N*.*

Proof. Project the displayed carrier. The rows $P, T, G, R, I, H, C, Q, N$ are the full inventory available to the certificate reader, and the classifier lists no extra coordinate for an untested candidate or hidden generator.

Read the refusal surface in order. The prior-record row P supplies the finite source, the candidate row T supplies the transition under audit, and the test row G is the only displayed place where prior-record closed generation may certify the candidate.

Finally inspect R, I, H, C, Q, N. The refusal ledger records the negative result of G, the inscription comparison I connects the candidate to the inscription-event sibling, and the support rows only transport, replay, package, and name the same finite packet. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 1349.3 (ClosedGenerationRefusal inscription separation)**.** *An accepted* $\mathsf{ClosedGenerationRefusal}^{\uparrow}$ *packet separates the candidate transition* T *from prior-record closed generation without treating* T *as a private agency object. The row* R *records only that* G *does not certify* T *from* P*, while* I *keeps the public inscription comparison routed through chapter 519 and chapter 1005.*

Proof. Begin with P, T, G. The candidate transition is tested against the displayed prior records by the closed-generation row, so the refusal is not a claim about an unrecorded psychological state or host process.

Use the refusal ledger R. Its content is negative and local: the candidate is not certified by the displayed prior-record test. The carrier gives no coordinate for replacing that local refusal with an external agency object.

The inscription-comparison row I then routes the same candidate through the public inscription-event and route-audit siblings. Thus the packet separates closed-generation refusal from inscription-facing comparison while keeping both rows inside one finite certificate. □

Theorem 1349.4 (ClosedGenerationRefusal ledger non-escape)**.** *No consumer of an accepted* $\mathsf{ClosedGenerationRefusal}^{\uparrow}$ *packet can export the candidate transition as inscription-event novelty while omitting the refusal-ledger row* R*. A consumer may read the prior records, candidate, test, and inscription comparison through* P, T, G, I, H, C, Q, N*, but the negative closed-generation boundary remains public only through* R*.*

Proof. Project the carrier $F = (P, T, G, R, I, H, C, Q, N)$. The negative closed-generation boundary is named only in R, while P, T, G name the test surface and I names the inscription comparison.

Apply Definition 1349.2. Refusal accountability is one of the local obligations, and the support rows H, C, Q, N preserve the same displayed packet rather than adding a second route around R.

Consequently a consumer that omits R may still see a prior-record test and candidate row, but it has not read the certificate row that makes the negative closed-generation boundary public. □

Theorem 1349.5 (ClosedGenerationRefusal sibling independence)**.** *The* $\mathsf{ClosedGenerationRefusal}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{InscriptionEvent}^{\uparrow}$, $\mathsf{InscriptionRouteAudit}^{\uparrow}$, $\mathsf{KernelObservationSieve}^{\uparrow}$, $\mathsf{CausalCommitment}^{\uparrow}$, *or* $\mathsf{ApophaticSocket}^{\uparrow}$. *It uniquely binds the prior-record row P, candidate-transition row T, closed-generation test G, refusal ledger R, and inscription comparison I as one packet.*

Proof. Compare the inscription siblings first. $\mathsf{InscriptionEvent}^{\uparrow}$ records an accepted public inscription packet, and $\mathsf{InscriptionRouteAudit}^{\uparrow}$ records a visible gap-to-accepted-route audit; neither carries the prior-record closed-generation test together with the refusal ledger.

Compare the sieve and commitment siblings next. $\mathsf{KernelObservationSieve}^{\uparrow}$ has accepted and rejected observation ledgers, and $\mathsf{CausalCommitment}^{\uparrow}$ records commitment-facing causal rows, but neither preserves the candidate transition, closed-generation test, and inscription comparison as one local NameCert surface.

Finally compare $\mathsf{ApophaticSocket}^{\uparrow}$. It records a supply-facing refusal socket, not the prior-record test of a candidate transition. Therefore no NameCert-row-preserving bijection can preserve $P, T, G, R, I, H, C, Q, N$ across any of the listed siblings. □

Falsifiable prediction: A packet whose closed-generation test row accepts the candidate transition cannot inhabit $\mathsf{ClosedGenerationRefusal}^{\uparrow}$.

Independence witness: inscriptionevent, inscriptionrouteaudit, kernelobservationsieve, causalcommitment, apophaticsocket: the refusal packet has the prior-record row, candidate-transition row, closed-generation test, refusal ledger, inscription comparison, transport, replay, provenance, and local NameCert rows; each sibling lacks at least the closed-generation test with its refusal ledger, so no NameCert-row-preserving bijection exists.

The Lean carrier file `lean4/BEDC/Derived/ClosedGenerationRefusalUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{ClosedGenerationRefusal}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ClosedGenerationRefusal}^{\uparrow}$ instances for $P, T, G, R, I, H, C, Q, N$ before the taste-gate target BEDC.Derived.ClosedGenerationRefusalUp.TasteGa can be cited as checked.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedGenerationRefusal}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedGenerationRefusal}^{\uparrow}$ packet is generated from prior records, a candidate transition, a closed-generation test, a refusal ledger, an inscription comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedGenerationRefusal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1349.1, Definition 1349.2, Definition 1349.3, Definition 1349.4, and Definition 1349.5 specify the finite prior-record closed-generation refusal packet and its inscription-facing comparison boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedGenerationRefusal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, a global agency predicate, hidden generator completeness, untested transition admission, or positive inscription-event acceptance.

Upgrade path: Obligation closure requires checked carrier admission, closed-generation refusal accountability, inscription comparison, ledger non-escape, nontriviality, and field faithfulness for $P, T, G, R, I, H, C, Q, N$.

Chapter 1350

A Concrete Naming Certificate for $\mathsf{TraditionLandingLedger}^{\uparrow}$

The $\mathsf{TraditionLandingLedger}^{\uparrow}$ packet realizes the structural translation discipline of section 9462.29 as a finite landing ledger. It sits beside the comparison boundary of chapter 1268, the tradition registry of chapter 1267, the tradition-science bridge of chapter 1270, the claim registry layer of chapter 1209, and the registry export surface of chapter 1216. Those siblings classify comparison, register inherited entries, bridge tradition with science-roadmap rows, admit claims, and expose registry exports; this packet binds the source tradition, BEDC landing, rejected surplus, structural distinction, transport, replay, provenance, and local name as one landing certificate.

Definition 1350.1 (TraditionLandingLedger carrier)**.** *A* $\mathsf{TraditionLandingLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, T, R, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-tradition row, recording the inherited tradition, text family, source question, vocabulary surface, and comparison prompt.*
2. *T is the BEDC landing row, recording the carrier, relation, classifier, ledger, certificate, gap, or registry object onto which the structural reading lands.*
3. *R is the rejected-surplus row, recording the doctrinal, metaphysical, host-semantic, identity, or authority claim not imported by the landing.*
4. *D is the structural-distinction row, recording that the packet performs structural translation rather than doctrinal identity.*
5. *H records componentwise* hsame *transport for S, T, R, D and the support rows below.*
6. *C records displayed* Cont *replay from the source row through the BEDC landing row and rejected-surplus inspection.*
7. *P is the* Pkg *provenance over* $\mathsf{TraditionComparisonBoundary}^{\uparrow}$, $\mathsf{TraditionRegistry}^{\uparrow}$, $\mathsf{TraditionScienceRegistryBridge}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{TraditionLandingLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for inherited doctrinal truth, tradition membership alone, host-semantic identity, registry export without surplus inspection, or a claim that the source tradition and BEDC landing are the same object.

Theorem 1350.2 (TraditionLandingLedger NameCert obligations)**.** *For the carrier of Definition 1350.1, the local* $\mathsf{NameCert}_{\mathsf{TraditionLandingLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for* $L = (S, T, R, D, H, C, P, N)$*; source-tradition exposure through* S*; BEDC landing exposure through* T*; rejected-surplus exposure through* R*; structural-distinction exactness through* D*; componentwise* hsame *transport through* H*; displayed* Cont *replay through* C*; package provenance through* P*; and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.TraditionLandingLedgerUp.TraditionLandingLedgerTasteGate single carrier alignment`

Proof. Project the finite packet of Definition 1350.1. The rows S, T, R, D are the only content rows available to the landing ledger, so source tradition, BEDC landing, rejected surplus, and structural distinction must be exposed before the local name can be read.

Use the sibling comparison boundary chapter 1268. It already separates structural landing from doctrinal identity; the present ledger records the landing as a reusable certificate by keeping T and R in the same packet.

Finally read H, C, P, N. These rows transport, replay, package, and name the displayed content rows through $\mathsf{TraditionRegistry}^{\uparrow}$, $\mathsf{TraditionScienceRegistryBridge}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, and the kernel rows. They do not add a hidden doctrine or identity coordinate, so the NameCert obligations are exhausted by the displayed packet. □

Theorem 1350.3 (TraditionLandingLedger nonidentity)**.** *No accepted* $\mathsf{TraditionLandingLedger}^{\uparrow}$ *packet identifies a source tradition with its BEDC landing. Every accepted packet must display both the rejected-surplus row* R *and the structural-distinction row* D *before the landing row* T *may be exported through the registry-facing provenance row* P*.*

Proof. Let an accepted packet be

$$L = (S, T, R, D, H, C, P, N).$$

The landing row T records where the structural reading lands; it is not a proof that the source tradition row S is identical to the BEDC object named by T.

The rejected-surplus row R records what is not imported, and the structural-distinction row D records that the landing is a translation boundary. Removing either row leaves the carrier of Definition 1350.1, so the packet no longer distinguishes structural translation from doctrinal identity.

The support rows H, C, P, N preserve the same separation through transport, replay, provenance, and local naming. Therefore a registry consumer may export the landing only as a finite structural-translation ledger, not as an identity claim. □

Falsifiable prediction: If the rejected-surplus row is removed, a tradition landing packet can no longer distinguish structural translation from doctrinal identity.

Independence witness: traditioncomparisonboundary, traditionregistry, traditionscienceregistry-bridge, claimregistrylayer, registryexportsurface: no sibling is bijective to $\mathsf{TraditionLandingLedger}^{\uparrow}$ because each lacks at least one landing-plus-surplus pair. The comparison boundary governs comparison acceptance, the tradition registry records admitted inherited entries, the tradition-science bridge joins tradition and science rows, the claim registry controls admission, and the registry export surface exposes public export; none preserves S, T, R, D, H, C, P, N as one landing ledger.

The Lean follow-up must provide Nontrivial TraditionLandingLedger$^{\uparrow}$ with an explicit witness pair and FieldFaithful TraditionLandingLedger$^{\uparrow}$ preserving S, T, R, D, H, C, P, N as separate displayed rows.

Closure status for $\mathsf{NameCert}_{\mathsf{TraditionLandingLedger}^{\uparrow}}$.

Constructive story: A TraditionLandingLedger$^{\uparrow}$ packet is generated from source-tradition, BEDC landing, rejected-surplus, structural-distinction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TraditionLandingLedger}^{\uparrow}}$, seed)

Scope closed: Definition 1350.1, Definition 1350.2, and Definition 1350.3 specify the finite landing ledger and its nonidentity boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TraditionLandingLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, doctrinal truth of any inherited tradition, identity between source tradition and BEDC landing, or public registry export closure.

Upgrade path: Lean closure requires Nontrivial TraditionLandingLedgerUp and FieldFaithful TraditionLandingLedgerUp instances preserving the source, landing, rejected-surplus, distinction, transport, replay, provenance, and local naming rows.

Chapter 1351

A Concrete Naming Certificate for $\mathsf{DiagonalConvergenceBound}^{\uparrow}$

The $\mathsf{DiagonalConvergenceBound}^{\uparrow}$ packet realizes the explicit convergence estimate in Definition 9238.5 as a finite naming certificate. It consumes the Real-completion horizon of chapter 9238, the diagonal representative of chapter 1205, and the three-leg estimate surface of chapter 466. Its readback route is anchored by chapter 126, chapter 301, chapter 291, and chapter 38.

The packet names the row carrying the displayed bound

$$|X_n - L| \leq \frac{2}{n+1}.$$

It is a local NameCert surface for the convergence-bound row; it is not a host-limit choice, a quotient-stream equality, or an ambient completeness principle.

Definition 1351.1 (Diagonal convergence-bound carrier)**.** *A* $\mathsf{DiagonalConvergenceBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, \mu, n, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the regular-Cauchy family row whose convergence to the diagonal representative is being bounded;*
2. *μ is the modulus row used to select the diagonal comparison scale for the request n;*
3. *n is the displayed precision request;*
4. *D is the* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *row exposing the selected diagonal representative L at the request determined by μ and n;*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the arithmetic row for the bound $2/(n+1)$;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row comparing X_n with the selected diagonal representative read;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the representative readback and tolerance ledger have both been displayed;*
8. *H records componentwise* hsame *transport for the family, modulus, request, representative, tolerance ledger, readback, seal, provenance, and local name rows;*
9. *C records displayed* Cont *replay from the modulus request through the diagonal representative, dyadic tolerance ledger, regular-rational readback, and Real seal;*

10. *P is the* Pkg *provenance over* DiagonalConvergenceBound$^{\uparrow}$, DiagonalLimitRepresentative$^{\uparrow}$, RegularCauchyTriangleE StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{DiagonalConvergenceBound}^{\uparrow}}$ *row.*

The carrier exports no selected host limit, quotient equality of streams, hidden family choice, ambient Real$^{\uparrow}$ *completeness field, or detached convergence proof.*

Lean4 ✓ `BEDC.Derived.DiagonalConvergenceBoundUp.TasteGate.DiagonalConvergenceBoundTasteGate`
`single carrier alignment`

Definition 1351.2 (Diagonal convergence-bound classifier)**.** *Two accepted* DiagonalConvergenceBound$^{\uparrow}$ *carriers are classified together exactly when their family rows, modulus rows, precision requests, diagonal representative rows, dyadic tolerance ledgers for $2/(n+1)$,* RegSeqRat$^{\uparrow}$ *readbacks,* Real$^{\uparrow}$ *seals, transport rows, continuation rows, package rows, and local naming rows are related componentwise by the recorded* hsame *comparisons and* Cont *routes. The classifier compares only this displayed convergence-bound surface.*

Theorem 1351.3 (Diagonal convergence-bound NameCert obligations)**.** *For the carrier of Definition 1351.1, the local* NameCert$_{\text{DiagonalConvergenceBound}^{\uparrow}}$ *surface consists exactly of carrier admission, family-row exposure through X, modulus-request exposure through μ, n, diagonal-representative exposure through D, dyadic tolerance exposure through Q, regular-rational readback through R, Real seal routing through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.DiagonalConvergenceBoundUp.DiagonalConvergenceBoundNameCertObligations`

Proof. Project the packet B. The carrier lists the family row, modulus row, request row, diagonal representative row, dyadic tolerance ledger, regular-rational readback, Real seal, transport, continuation, provenance, and local naming row.

The bound row is finite. The request n and modulus row μ select the diagonal representative read in D, while Q records the displayed arithmetic budget $2/(n+1)$. The readback row R is then the only row comparing the requested family entry with the representative read.

The remaining rows E, H, C, P, N do not add analytic data. They seal, transport, replay, source, and name the already displayed packet, so the listed obligations exhaust the local certificate surface. □

Theorem 1351.4 (Diagonal convergence-bound nonchoice boundary)**.** *An accepted* DiagonalConvergenceBound$^{\uparrow}$ *packet exports exactly the displayed family row X, modulus row μ, request row n, diagonal representative row D, dyadic tolerance ledger Q,* RegSeqRat$^{\uparrow}$ *readback R,* Real$^{\uparrow}$ *seal row E, componentwise transport H, continuation replay C, package provenance P, and local naming row N. It exports no selected host limit, quotient-stream equality, countable choice row, hidden tail selector, ambient* Real$^{\uparrow}$ *completeness proof, or off-packet convergence witness.*

Proof. Inspect the coordinates of Definition 1351.1. Every coordinate is either a displayed BEDC row or structural support for transport, replay, provenance, and naming.

Definition 1351.3 accounts for all admissible carrier and classifier reads. The classifier of Definition 1351.2 then restricts comparison to those same displayed rows.

The excluded objects require coordinates absent from the carrier. Therefore they cannot be exported by the local naming certificate or recovered by a consumer of the displayed convergence-bound row. □

Theorem 1351.5 (Diagonal convergence-bound Real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DiagonalConvergenceBound}^{\uparrow}$ *carrier reads the finite route*

$$X, \mu, n, D, Q, R, E, H, C, P, N$$

before treating the convergence estimate

$$|X_n - L| \leq \frac{2}{n+1}$$

as public. The handoff supplies the bound row needed by the Real-completion limit theorem, but it does not by itself supply existence, uniqueness, quotient equality, or an ambient completeness principle.

Proof. Start from the local NameCert obligations. They force every accepted carrier to display the regular-Cauchy family, the modulus request, the diagonal representative, the dyadic tolerance ledger, and the regular-rational readback before the Real-facing seal may be consumed.

Next use the dependency route. The representative row D is the consumer of chapter 1205; the tolerance ledger Q and readback row R are anchored by chapter 291 and chapter 301; and the three-leg comparison surface is supplied by chapter 466.

Finally read the seal row E through H, C, P, N. By Definition 1351.4, no host limit, quotient stream, hidden selector, or ambient completeness coordinate is available. Thus the packet hands only the explicit convergence-bound row to the Real-completion theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalConvergenceBound}^{\uparrow}}$.

Constructive story: A $\mathsf{DiagonalConvergenceBound}^{\uparrow}$ packet is generated from a displayed family row, modulus row, request row, diagonal representative row, dyadic-tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and local naming. The classifier bounds diagonal convergence by reading the request and modulus before it inspects the representative, tolerance, readback, and seal rows. The ledger story is finite diagonal control: the packet records exactly which family, modulus, and request generate the bound, while transport preserves those rows and prevents selected host limits, quotient equality, hidden family choice, ambient completeness, or detached convergence proofs from entering the accepted surface.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiagonalConvergenceBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier and classifier definitions, NameCert-obligation, nonchoice-boundary, Real-completion-handoff, and existing closure annotations for $\mathsf{DiagonalConvergenceBound}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiagonalConvergenceBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim selected host limits, quotient equality of streams, hidden family choice, ambient RealUp completeness fields, or detached convergence proofs.

Upgrade path: To reach obligationClosure, the diagonal bound classifier and nonchoice handoff must be encoded as checked finite convergence obligations.

Chapter 1352

A Concrete Naming Certificate for $\mathsf{RealCofinalModulusGate}^{\uparrow}$

The $\mathsf{RealCofinalModulusGate}^{\uparrow}$ packet packages the finite gate that a Real-completeness limit consumer must read before treating a $\mathsf{Real}^{\uparrow}$ seal as supported by cofinal modulus data. It sits after the tail budget of chapter 1231, the normalization route of chapter 1264, and the threshold normal form of chapter 1299. Its terminal readback is anchored by chapter 38 and chapter 301, so the gate exposes the finite cofinal schedule and comparison rows rather than allowing a Real seal to stand alone.

Definition 1352.1 (Real cofinal modulus gate carrier)**.** *A* $\mathsf{RealCofinalModulusGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, M, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the tail-cofinality schedule row consumed from the* $\mathsf{TailCofinalityBudget}^{\uparrow}$ *surface.*
2. *M is the cofinal modulus-comparison row normalized through* $\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$*.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite window whose readback is indexed by the displayed tail schedule and modulus comparison.*
4. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *witness row read through the same window.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after T, M, W, S have been displayed.*
6. *E is the exactness ledger recording that the Real seal read is the one routed through the displayed cofinal tail and modulus rows.*
7. *H stores componentwise* hsame *transport for the tail schedule, modulus comparison, window, regular-rational witness, Real seal, exactness, continuation, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from the cofinal tail schedule through the modulus comparison, StreamName window, RegSeqRat witness, Real seal, exactness ledger, provenance, and local naming row.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCofinalModulusGate}^{\uparrow}$*,* $\mathsf{TailCofinalityBudget}^{\uparrow}$*,* $\mathsf{CofinalModulusNormalizationSeal}^{\uparrow}$*,* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCofinalModulusGate}^{\uparrow}}$ *row.*

The carrier has no coordinate for a bare Real seal, quotient stream equality, host-selected limit, private tail threshold, untracked modulus conversion, or ambient completeness field.

Definition 1352.2 (Real cofinal modulus gate classifier)**.** *Two accepted* $\mathsf{RealCofinalModulusGate}^{\uparrow}$ *carriers classify together exactly when their tail-cofinality schedules, cofinal modulus-comparison rows, StreamName windows, RegSeqRat witnesses, Real seal rows, exactness ledgers, componentwise transports, displayed continuation replays, package provenance rows, and local naming rows agree componentwise through the recorded* hsame *comparisons and* Cont *routes. The classifier compares the ten-row gate packet only.*

Theorem 1352.3 (Real cofinal modulus gate NameCert obligations)**.** *For the carrier of Definition 1352.1, the local* $\mathsf{NameCert}_{\mathsf{RealCofinalModulusGate}^{\uparrow}}$ *surface consists exactly of carrier exposure through G, cofinal-tail exactness through T, modulus-comparison exposure through M, window-readback stability through W, S, RealUp seal preservation through R, E, componentwise transport through H, displayed continuation replay through C, package provenance through P, local naming through N, and ledger non-escape for bare Real seals, quotient stream equality, host-selected limits, private tail thresholds, untracked modulus conversion, and ambient completeness fields.*

Lean4 ✓ `BEDC.Derived.RealCofinalModulusGateUp.TasteGate.RealCofinalModulusGateTasteGate single carrier alignment`

Proof. Project the packet G. The carrier displays the tail schedule, modulus comparison, StreamName window, RegSeqRat witness, Real seal, exactness ledger, transport, continuation, provenance, and local naming row.

The analytic readback is finite. The rows T and M determine the cofinal tail and comparison budget; W and S are read through that same displayed budget before the terminal Real seal row R appears.

The remaining rows do not add a second analytic source. The exactness ledger E records that R is the seal reached through T, M, W, S, while H, C, P, N transport, replay, source, and name the displayed route. Since no excluded coordinate occurs in the carrier, the listed rows exhaust the local certificate surface. □

Theorem 1352.4 (Real cofinal modulus gate tail-cofinality exactness)**.** *A consumer of an accepted* $\mathsf{RealCofinalModulusGate}^{\uparrow}$ *packet cannot read the displayed* $\mathsf{Real}^{\uparrow}$ *seal row R without also reading the cofinal tail schedule T and the modulus-comparison row M. Equivalently, the Real seal route factors through*

$$T \longmapsto M \longmapsto W \longmapsto S \longmapsto R \longmapsto (E, H, C, P, N).$$

Proof. Start with the carrier exposure in Definition 1352.3. It places the tail schedule T and modulus comparison M before the window W, witness S, and Real seal R.

Window-readback stability then fixes the middle of the route. The StreamName window and RegSeqRat witness are indexed by the displayed cofinal data, so a consumer cannot substitute a private tail or modulus row between M and R.

Finally read the exactness ledger. The row E records that the seal is the one routed through T, M, W, S, while H, C, P, N only transport, replay, source, and name that route. Thus reducing the packet to R alone loses data that the NameCert obligations require before the Real seal can be consumed. □

Falsifiable prediction: An accepted $\mathsf{RealCofinalModulusGate}^{\uparrow}$ packet cannot be reduced to a RealUp seal alone without losing either the cofinal tail schedule or the modulus-comparison row.

Independence witness: tailcofinalitybudget, cofinalmodulusnormalizationseal, cauchytailthresholdnormalizer, real, regseqrat: not bijective to the ten-row gate packet because each listed sibling supplies only a source, normalization, threshold, seal, or witness surface, while the gate binds all ten rows together with exactness, transport, replay, provenance, and local naming.

Lean follow-up provides explicit Nontrivial $\mathsf{RealCofinalModulusGate}^{\uparrow}$ and FieldFaithful $\mathsf{RealCofinalModulusGate}^{\uparrow}$ instances in `lean4/BEDC/Derived/RealCofinalModulusGateUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCofinalModulusGate}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCofinalModulusGate}^{\uparrow}$ packet is generated from a RealUp seal, tail-threshold row, cofinal-modulus row, tail-agreement row, componentwise hsame transport, displayed Cont replay, package provenance, ledger rows, and local naming. The classifier opens the gate only when the Real seal is tied to a displayed tail threshold and a cofinal modulus conversion. The ledger story is cofinal access without ambient completeness: every tail-facing consumer reads the same modulus and agreement rows through the finite carrier, so a bare Real seal, private threshold, quotient stream, host-selected limit, or untracked conversion cannot authorize the route.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCofinalModulusGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the carrier and classifier definitions, NameCert-obligation, tail-cofinality-exactness, Lean-follow-up boundary, and existing closure annotation for $\mathsf{RealCofinalModulusGate}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCofinalModulusGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not claim bare Real seals, quotient stream equality, host-selected limits, private tail thresholds, untracked modulus conversion, or ambient completeness fields.

Upgrade path: To reach obligationClosure, the cofinal-modulus gate and tail-cofinality exactness must be checked as finite threshold and transport obligations.

Chapter 1353

A Concrete Naming Certificate for $\mathsf{ProofPatternClassifier}^{\uparrow}$

The $\mathsf{ProofPatternClassifier}^{\uparrow}$ packet realizes the proof-pattern discipline of subsection 9462.25.1, subsection 9462.25.2, and subsection 9462.25.3 as finite NameCert data. It sits beside the proof witness chain of chapter 1238, the forward-binding GAP ledger of chapter 1262, the GAP socket boundary of chapter 1343, the registry no-smuggling predicate of chapter 1344, and the typed failure certificate of chapter 1237. Those siblings expose proof traces, forward commitments, missing-supply boundaries, export refusal, and typed failure status separately; this packet classifies proof-pattern routes only when positive witness construction, local refutation, decidable double-negation, and prohibited positive extraction remain separated.

Definition 1353.1 (Proof-pattern classifier carrier)**.** *A* $\mathsf{ProofPatternClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (W, L, D, R, E, G, H, C, Q, N)$$

with the following displayed rows:

1. *W is the proof-witness-chain row, recording the accepted finite proof trace, source carrier, classifier witness, ledger, refusal, audit verdict, provenance, and local name consumed from* $\mathsf{ProofWitnessChain}^{\uparrow}$*;*
2. *L is the local carrier and classifier context, recording the fixed object row, predicate row, classifier row, and local certificate surface against which the proof pattern is read;*
3. *D is the displayed decidability evidence, present exactly when a local* $\mathsf{Decidable}(P(h))$ *route is available for the named predicate and history row;*
4. *R is the local refutation and inversion evidence, recording carrier no-confusion, classifier inversion, certificate-field contradiction, and typed failure rows;*
5. *E is the forbidden positive-extraction refusal row, blocking extraction of existential or positive witness content from $\neg\forall h, \neg P(h)$, undecided $\neg\neg P(h)$, arbitrary excluded middle, quotient collapse, host equality, or hidden choice;*
6. *G is the GAP row for forward-binding commitments, recording any unsupported universal, future, or missing-supply component through* $\mathsf{ForwardBindingGapLedger}^{\uparrow}$ *and* $\mathsf{GapSocketBoundary}^{\uparrow}$ *rather than as proof content;*
7. *H records componentwise* hsame *transport for proof witness, local classifier, decidability, refutation, refusal, GAP, continuation, provenance, and local naming rows;*

8. *C records displayed* Cont *replay for positive witness construction, local refutation, decidable double-negation, positive-extraction refusal, GAP handoff, and downstream audit;*
9. *Q records* Pkg *provenance over* ProofPatternClassifier$^{\uparrow}$, ProofWitnessChain$^{\uparrow}$, ForwardBindingGapLedger$^{\uparrow}$, GapSocketBoundary$^{\uparrow}$, RegistryNoSmugglingPredicate$^{\uparrow}$, TypedFailureCertificate$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* NameCert$_{\text{ProofPatternClassifier}^{\uparrow}}$ *row.*

The carrier exports no route from refutation to positive content, no double-negation eliminator without D, no witness for an existential claim without a displayed witness row in W or L, and no registry export that bypasses E, G, Q, N.

Lean4 ✓ `BEDC.Derived.ProofPatternClassifierUp.ProofPatternClassifierTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.ProofPatternClassifierUp.ProofPatternClassifierUp`

Theorem 1353.2 (Proof-pattern classifier NameCert obligations)**.** *For the carrier of Definition 1353.1, the local* NameCert$_{\text{ProofPatternClassifier}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier exposure for $P = (W, L, D, R, E, G, H, C, Q, N)$;*
2. *classifier stability for the proof-witness row W against the local carrier and classifier context L, preserved under H and C;*
3. *local-refutation boundary through R, with typed failure and certificate-field contradiction kept inside the displayed carrier and classifier rows;*
4. *decidable double-negation gate through D, allowing $\neg\neg P(h)$ to be consumed as positive content only when the same local predicate row has displayed decidability;*
5. *positive-extraction refusal through E, G, Q, N, blocking positive witness export from negative or undecided premises and preserving the GAP and no-smuggling audit route.*

Proof. Project the packet of Definition 1353.1. The local certificate can read only $W, L, D, R, E, G, H, C, Q, N$, so carrier exposure fixes the proof witness, classifier context, decision row, refutation row, refusal row, GAP row, transport, replay, provenance, and local name.

Classifier stability is then read through W, L, H, C. The proof witness row supplies the finite proof chain, the local row supplies the predicate and classifier surface, and transport plus replay preserve that same pairing for downstream use.

The remaining obligations separate the three proof-pattern exits. The refutation route uses R only as local inversion against displayed rows; the double-negation route uses D only as displayed decidability; and the refusal route uses E, G, Q, N to prevent missing witnesses or unsupported universal commitments from becoming positive proof content. □

Theorem 1353.3 (Proof-pattern classifier local-refutation boundary)**.** *An accepted* ProofPatternClassifier$^{\uparrow}$ *packet accepts a negative proof only when its refutation factors through the displayed carrier row L, proof-witness row W, local inversion row R, transport row H, replay row C, provenance row Q, and local NameCert row N. A contradiction that requires a hidden truth predicate, unrecorded classifier crossing, host equality, quotient collapse, or missing certificate field is outside the accepted local-refutation route.*

Proof. Start with the obligation surface of Definition 1353.2. A negative proof is accepted through the local-refutation row, not through a global truth classifier.

The row R must therefore consume a purported witness through the displayed carrier and classifier context L and the proof-witness chain W. Transport and replay are limited to H and C, while provenance and local naming remain Q and N.

If the contradiction uses hidden truth, unrecorded classifier crossing, host equality, quotient collapse, or an absent certificate field, the factorization through L, W, R, H, C, Q, N fails. The packet then records no accepted negative proof; it records either a refusal route through E or an exposed GAP route through G. □

Theorem 1353.4 (Proof-pattern classifier positive-extraction refusal)**.** *No accepted* $\mathsf{ProofPatternClassifier}^{\uparrow}$ *packet can turn* $\neg\forall h, \neg P(h)$ *or undecided* $\neg\neg P(h)$ *into positive content without the displayed decidability row* D *or a displayed witness row in* W *or* L*. In particular, the packet refuses existential export, theorem-evidence export, and local NameCert export for any route whose only positive source is negative pressure, undecided double negation, arbitrary excluded middle, or a hidden registry entry.*

Proof. Read the carrier rows. Positive content must come from a witness already displayed in W or L, or from a decidable double-negation route whose decision evidence is displayed in D.

The premise $\neg\forall h, \neg P(h)$ supplies no named h and no row witnessing $P(h)$. The premise $\neg\neg P(h)$ supplies no constructor for $P(h)$ unless the same local predicate row is accompanied by D.

The refusal row E and GAP row G record exactly these missing-source cases. Provenance and local naming through Q, N preserve the refusal, while the registry no-smuggling sibling prevents a hidden entry from being exported as theorem evidence. Hence the accepted packet cannot convert negative pressure or undecided double negation into positive content. □

Falsifiable prediction: If the displayed decidability row is removed, the packet cannot export double-negation elimination as an accepted proof-pattern route.

Independence witness: proofwitnesschain, forwardbindinggapledger, gapsocketboundary, registrynosmugglingpredicate, typedfailurecertificate: none is bijective to $\mathsf{ProofPatternClassifier}^{\uparrow}$. ProofWitnessChainUp carries a proof trace without the four-way classifier boundary; ForwardBindingGapLedgerUp carries future and unsupported commitments without local proof-pattern classification; GapSocketBoundaryUp exposes missing supply without deciding proof routes; RegistryNoSmugglingPredicateUp blocks registry export without classifying local refutation and decidable double negation; TypedFailureCertificateUp records typed failure without the positive-witness and positive-extraction refusal split.

The Lean follow-up must provide Nontrivial $\mathsf{ProofPatternClassifier}^{\uparrow}$ and FieldFaithful $\mathsf{ProofPatternClassifier}^{\uparrow}$ instances in `lean4/BEDC/Derived/ProofPatternClassifierUp/TasteGate.lean`. The field-faithfulness witness must preserve $W, L, D, R, E, G, H, C, Q, N$ as distinct rows before downstream audit, GAP, no-smuggling, or proof-pattern consumers cite BEDC.Derived.ProofPatternClassifierUp.

Closure status for $\mathsf{NameCert}_{\mathsf{ProofPatternClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofPatternClassifier}^{\uparrow}$ packet is generated from proof-witness-chain, local carrier and classifier, displayed decidability, local refutation, positive-extraction refusal, GAP, transport, continuation, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProofPatternClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1353.1, Definition 1353.2, Definition 1353.3, and Definition 1353.4 bind the finite classifier packet, its naming obligations, its local refutation boundary, and its refusal of unwitnessed positive extraction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProofPatternClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not supply Lean verification, bridge checking, global excluded middle, a truth predicate, unwitnessed existential content, hidden registry theorem evidence, or positive extraction from undecided double negation for ProofPatternClassifier$^{\uparrow}$.

Upgrade path: Lean closure requires Nontrivial ProofPatternClassifierUp and FieldFaithful ProofPatternClassifierUp instances.

Chapter 1354

A Concrete Naming Certificate for $\mathsf{CanonicalTailChoice}^{\uparrow}$

The $\mathsf{CanonicalTailChoice}^{\uparrow}$ packet realizes the finite tail-choice route needed by the Real-completeness limit theorem of chapter 9238. It sits after the no-choice boundary of chapter 1173, the shared tail schedule of chapter 681, the bounded prefix budget of chapter 919, and the exact completion boundary of chapter 1120. Its role is to expose the canonical finite index and tail-window witness used before the diagonal seal is read, without importing a host-selected subsequence, quotient stream equality, countable choice row, or ambient completeness principle.

Falsifiable prediction: A Real-completion consumer that omits the canonical finite tail-choice row cannot claim the diagonal seal handoff.

Independence witness: cauchychoiceboundary, tailcofinalityschedule, finiteprefixlimitbudget, realcompletionexactboundary, limitselector: none is bijective to $\mathsf{CanonicalTailChoice}^{\uparrow}$ because this packet simultaneously carries the modulus row, tolerance-budget row, canonical finite index row, tail-window witness row, Real seal route, no-choice refusal row, componentwise transport, continuation replay, provenance, and local naming surface; the named siblings isolate boundary refusal, cofinal scheduling, prefix-budget exhaustion, exact boundary faces, or selector admission without this joint carrier.

Definition 1354.1 (Canonical tail-choice carrier)**.** *A* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (M, E, I, T, S, R, H, C_0, P, N)$$

with the following displayed rows:

1. *M is the modulus row read from the accepted regular-Cauchy route;*
2. *E is the tolerance-budget row fixing the finite precision scale served by the packet;*
3. *I is the canonical finite index row computed from M and E, not from an external choice schedule;*
4. *T is the tail-window witness row certifying that every downstream observation is read inside the finite tail determined by I;*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal route reached only after M, E, I, T have been displayed;*
6. *R is the no-choice refusal row excluding host-selected limits, quotient stream equality, countable choice, hidden tail oracles, and ambient completeness;*

7. *H records componentwise* hsame *transport for the displayed analytic rows and the structural rows;*
8. *C_0 records the displayed* Cont *replay from modulus and budget admission to canonical index, tail-window witness, Real seal, refusal, and local naming;*
9. *P is the* Pkg *provenance over the sibling certificates,* BHist, hsame, Cont, Pkg, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CanonicalTailChoice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for a host-selected subsequence, quotient stream equality, countable choice, metric completeness, ambient completeness, or a detached Real-completion seal.

Lean4 (definition) `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceUp`

Theorem 1354.2 (Canonical tail-choice NameCert obligations)**.** *For every accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *carrier*

$$C = (M, E, I, T, S, R, H, C_0, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CanonicalTailChoice}^{\uparrow}}$ *surface consists exactly of carrier exposure for C, modulus exposure through M, tolerance-budget exposure through E, canonical finite-index exposure through I, tail-window witness exposure through T,* $\mathsf{Real}^{\uparrow}$ *seal-route exposure through S, no-choice refusal through R, componentwise* hsame *transport through H, displayed* Cont *replay through C_0, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier namecert obligations`

Proof. Project the carrier of Definition 1354.1. Its displayed rows list the modulus, tolerance budget, canonical finite index, tail-window witness, seal route, refusal ledger, and structural support.

Read the rows in order. The modulus row M and tolerance-budget row E determine the finite index row I before the tail-window witness T can be consumed. The Real seal route S is therefore downstream from a displayed finite choice, not from a hidden selector.

Finally inspect the structural rows. The rows H, C_0, P, N transport, replay, record provenance for, and name the same finite packet. Since no further coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 1354.3 (Canonical tail-choice source obligations)**.** *Every accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *read exposes source rows over* $\mathsf{CauchyChoiceBoundary}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RealCompletionExactBounda $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *before the canonical finite index row I or the tail-window witness T can be consumed. These source rows are finite* BHist *entries in the same packet, not references to a selected subsequence, quotient Cauchy name, countable choice row, or ambient completion principle.*

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier source obligations`

Proof. Project the carrier of Definition 1354.1. The modulus row M and tolerance-budget row E are read before the canonical finite index row I, so the finite-prefix budget and regular-rational source are already visible when the tail window is formed.

Read the sibling boundary rows next. The no-choice boundary of chapter 1173, the exact completion boundary of chapter 1120, and the cofinal schedule of chapter 681 attach to the displayed route before the Real seal route S is admitted.

The refusal row R then excludes the non-source objects. Since H, C_0, P, N only transport, replay, source, and name the same finite packet, no selected limit, quotient Cauchy name, countable choice row, or ambient $\mathsf{Real}^{\uparrow}$ completeness row is exported by the accepted read. □

Theorem 1354.4 (Canonical tail-choice window stability)**.** *Let $C = (M, E, I, T, S, R, H, C_0, P, N)$ and $C' = (M', E', I', T', S', R', H', C'_0, P', N')$ be accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *carriers. If the displayed rows are transported componentwise by the* hsame *data recorded in H and H', then the finite tail-window route M, E, I, T and M', E', I', T' remain on the same canonical tail-choice surface before either packet reaches its* $\mathsf{Real}^{\uparrow}$ *seal route.*

Proof. Induct over the finite route M, E, I, T. The base rows M, E expose the same modulus and tolerance-budget roles under componentwise hsame transport, so both packets compute their canonical index inside the displayed source surface.

At the index step, the rows I and I' are reached only after those transported source rows. The tail rows T and T' are therefore compared as finite window witnesses attached to the transported index rows, not as host-selected subsequences.

The remaining rows preserve the comparison. The seal rows S, S' are downstream from the tail windows, the refusal rows R, R' exclude quotient names and choice schedules, and C_0, C'_0, P, P', N, N' replay, source, and name the same componentwise transport. Thus finite tail-window stability is exactly the displayed hsame transport of the packet rows. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier window stability`

Theorem 1354.5 (Canonical tail-choice nonescape)**.** *No selected limit, quotient Cauchy name, countable choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle is exported by an accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *packet. Any consumer that claims one of these objects has left the displayed rows $M, E, I, T, S, R, H, C_0, P, N$ and therefore cannot be reading the local* $\mathsf{NameCert}_{\mathsf{CanonicalTailChoice}^{\uparrow}}$ *surface.*

Proof. Inspect the carrier rows. The tuple exposes the modulus, tolerance budget, canonical index, tail window, Real seal route, refusal ledger, transport, replay, provenance, and local name; it contains no coordinate for a selected limit, quotient Cauchy name, countable choice row, or ambient completeness principle.

Apply the source-obligation theorem above. Every accepted read reaches I and T only after the finite source rows over the no-choice boundary, prefix budget, regular-rational source, cofinal schedule, and exact Real-completion boundary have been displayed.

Finally use the refusal coordinate R. It blocks replacing the finite rows by the excluded objects, while H, C_0, P, N keep all downstream consumption inside the same packet. Hence any consumer that exports an excluded object is outside the accepted $\mathsf{CanonicalTailChoice}^{\uparrow}$ surface. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier nonescape`

Theorem 1354.6 (Canonical tail-choice obligation surface)**.** *For every accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *carrier*

$$C = (M, E, I, T, S, R, H, C_0, P, N),$$

the finite tail-choice obligation surface is the simultaneous exposure of the modulus row M, tolerance-budget row E, canonical finite index row I, tail-window witness T, $\mathsf{Real}^{\uparrow}$ *seal route S, no-choice refusal R, componentwise* hsame *transport H, displayed* Cont *replay C_0,* Pkg *provenance P, and local* NameCert *row N. The surface admits no host-selected subsequence, quotient stream equality, countable-choice schedule, hidden tail oracle, detached completion seal, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier obligation surface`

Proof. Project the carrier of Definition 1354.1. The ten displayed rows are exactly $M, E, I, T, S, R, H, C_0, P, N$, so an accepted packet exposes the modulus, tolerance budget, canonical finite index, tail window, seal route, refusal ledger, transport, replay, provenance, and local naming as one finite surface.

Use the schedule factorization of Definition 1354.7. It forces every Real-completion consumer to pass through M and E before reaching I, then through T before the seal route S is consumed. Thus the canonical finite index and tail-window witness are displayed route coordinates, not a host-selected subsequence.

Finally apply the no-choice non-escape theorem, Definition 1354.8. The refusal row R and the structural rows H, C_0, P, N keep the same finite packet visible and exclude quotient stream equality, countable choice, hidden tail oracles, detached completion seals, and ambient completeness. Therefore the listed rows exhaust the obligation surface. □

Theorem 1354.7 (Canonical tail-choice schedule factorization)**.** *Every accepted Real-completion consumer of a* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *packet factors through the finite route*

$$M, E, I, T, S, R, H, C_0, P, N.$$

When the consumer also reads the sibling surfaces of chapter 681 and chapter 919, their schedule and prefix-budget rows attach before the tail-window witness T and before the Real seal route S.

Proof. Start with the obligation surface of Definition 1354.2. The canonical finite index I is exposed only after M and E, so any downstream schedule must already have the modulus and tolerance budget in scope.

Attach the cofinal schedule. The $\mathsf{TailCofinalitySchedule}^{\uparrow}$ packet supplies its finite window and dyadic threshold rows as an accepted sibling route, and those rows can be consumed only through the same displayed finite schedule surface.

Attach the prefix budget next. The $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$ packet records which prefix windows have been spent before a seal-facing read is admitted. Thus the local tail-window witness T is reached only after the sibling schedule and prefix-budget rows have been displayed.

The remaining rows S, R, H, C_0, P, N keep the seal route and refusal ledger inside that same finite packet, so every accepted consumer factors through the stated route. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier schedule factorization`

Theorem 1354.8 (Canonical tail-choice no-choice non-escape)**.** *No host-selected limit, quotient stream equality, countable choice row, hidden tail oracle, metric completeness row, ambient completeness row, or detached Real-completion seal can be read from an accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *packet. The packet exports only the rows $M, E, I, T, S, R, H, C_0, P, N$ of Definition 1354.1.*

Proof. Inspect the accepted carrier. The refusal row R is a displayed coordinate, while none of the excluded objects is a coordinate of the tuple.

Apply Definition 1354.7. Every accepted consumer reaches the Real seal route only through $M, E, I, T, S, R, H, C_0, P, N$, with sibling schedule and prefix-budget rows consumed before the tail-window witness.

The finite index row I is not a host-selected limit or a countable-choice schedule; it is the canonical row displayed after M and E. The witness row T and seal row S are likewise route coordinates, not quotient equalities or completeness principles. Hence any read of an excluded object leaves the accepted packet. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier no choice nonescape`

Theorem 1354.9 (Canonical tail-choice refusal exhaustion)**.** *Every accepted Real-completion consumer of a* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *packet either factors through the displayed rows*

$$M, E, I, T, S, R, H, C_0, P, N$$

or leaves the local $\mathsf{NameCert}_{\mathsf{CanonicalTailChoice}^{\uparrow}}$ *surface. In particular, the host-selected limit, quotient stream equality, countable choice, hidden tail oracle, metric completeness, ambient completeness, and detached seal alternatives are exactly the refused alternatives recorded by the packet.*

Proof. Project the carrier of Definition 1354.1. Its only consumer-facing coordinates are the rows $M, E, I, T, S, R, H, C_0, P, N$.

Apply schedule factorization, Definition 1354.7. A Real-completion consumer must pass through the modulus and budget rows before the canonical index, then through the tail-window witness before the seal route is consumed.

Use no-choice non-escape, Definition 1354.8, together with the Real-completion handoff of Definition 1354.10. The refusal row R names exactly the excluded alternatives, while H, C_0, P, N only transport, replay, source, and name the same finite route. Thus any consumer not factoring through the displayed rows has left the local surface. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier refusal exhaustion`

Theorem 1354.10 (Canonical tail-choice Real-completion handoff)**.** *The Real-completion diagonal seal handoff may consume an accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *packet only through the displayed route*

$$M, E, I, T, S, R, H, C_0, P, N.$$

Under chapter 1173 and chapter 1120, this route supplies the finite tail-choice row between no-choice refusal and the terminal exact-boundary seal, and supplies no host-side equality or ambient completeness data.

Proof. Begin with the no-choice boundary. The sibling $\mathsf{CauchyChoiceBoundary}^{\uparrow}$ surface already requires a displayed finite index, tail witness, seal route, and refusal row before a diagonal consumer may claim the no-choice seal path.

Next apply the local obligations and schedule factorization. The $\mathsf{CanonicalTailChoice}^{\uparrow}$ packet identifies the canonical finite index I and tail-window witness T as first-class rows between the modulus-budget pair M, E and the Real seal route S.

Finally read the exact boundary. The $\mathsf{RealCompletionExactBoundaryUp}$ packet admits terminal completion reads only through its displayed StreamName, RegSeqRat, DyadicRatCore, and RealUp faces. Since the present packet exports only $M, E, I, T, S, R, H, C_0, P, N$ and the sibling boundary exports no hidden selector, the diagonal seal handoff remains a finite no-choice route. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier real completion handoff`

Theorem 1354.11 (Canonical tail-choice tail cofinality)**.** *Let* $C = (M, E, I, T, S, R, H, C_0, P, N)$ *be an accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *carrier. The canonical finite index row* I *remains cofinal with the displayed* $\mathsf{TailCofinalitySchedule}^{\uparrow}$ *and* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$ *rows before any tail-window consumer reads the* $\mathsf{Real}^{\uparrow}$ *seal route* S*. Thus every later finite tolerance request transported through* H *and replayed through* C_0 *is served inside the same tail-window row* T*, without a host-selected subsequence, quotient stream equality, hidden tail oracle, countable-choice row, or ambient completeness principle.*

Proof. Start with schedule factorization, Definition 1354.7. It places the cofinal schedule and prefix-budget rows before the tail-window witness T and before the Real seal route S.

Read the carrier rows $M, E, I, T, S, R, H, C_0, P, N$. The index row I is displayed after the modulus and budget rows, so a later tolerance request can be transported only by reusing the same finite route through H and replaying it through C_0.

The refusal row R blocks replacing that finite route by a selected subsequence, quotient equality, hidden tail oracle, choice row, or ambient completeness principle. Hence the cofinality assertion is internal to the displayed packet before any consumer reaches the seal. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier tail cofinality`

Theorem 1354.12 (Canonical tail-choice Real-completion boundary)**.** *The Real-completion exact-boundary handoff for an accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *carrier consumes only the rows*

$$M, E, I, T, S, R, H, C_0, P, N.$$

It cannot read quotient stream equality, countable choice, hidden tail oracles, ambient completeness, or any detached completion seal outside the displayed carrier and its $\mathsf{NameCert}_{\mathsf{CanonicalTailChoice}^{\uparrow}}$ *surface.*

Proof. Apply the Real-completion handoff theorem Definition 1354.10. The diagonal seal route is reached only through the displayed packet rows $M, E, I, T, S, R, H, C_0, P, N$.

Use the no-choice non-escape theorem Definition 1354.8. It identifies quotient stream equality, countable choice, hidden tail oracles, ambient completeness, and detached seals as absent from the carrier.

The structural rows H, C_0, P, N transport, replay, source, and name the same finite packet. They do not add a new completion coordinate, so the exact-boundary handoff remains confined to the listed rows. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier real completion boundary`

Theorem 1354.13 (Canonical tail-choice tail inhabitation)**.** *Let* $C = (M, E, I, T, S, R, H, C_0, P, N)$ *be an accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *carrier. For every finite Real-completion request admitted by the displayed rows* $M, E, I, T, S, R, H, C_0, P, N$*, the tail-window row* T *is inhabited by a finite* BHist *witness after the canonical index row* I *is read. The witness is produced inside the same packet and is not a host-selected subsequence, hidden tail oracle, quotient stream equality, or countable-choice row.*

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier tail inhabitation`

Proof. Induct over the displayed route $M, E, I, T, S, R, H, C_0, P, N$. The base rows M, E expose the regular-Cauchy modulus and tolerance budget, so the request has a finite precision scale before any tail is inspected.

At the index step, use the carrier obligation of Definition 1354.2. The canonical index row I is a displayed coordinate computed from M, E, and the next row T is the packet's own tail-window witness row.

The remaining rows preserve that witness. The seal row S consumes the tail only after T is present; the refusal row R excludes hidden selectors; and H, C_0, P, N transport, replay, source, and name the same finite packet. Hence tail inhabitation is a finite row induction, not an external choice principle. □

Theorem 1354.14 (Canonical tail-choice cofinality stability)**.** *Let $C = (M, E, I, T, S, R, H, C_0, P, N)$ be an accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *carrier. If the sibling cofinal schedule of chapter 681 is read before I, then every later finite tolerance request transported through H remains on the same tail-window route $M, E, I, T, S, R, H, C_0, P, N$. In particular, cofinality is stable under componentwise* hsame *transport and displayed* Cont *replay, and no host-selected subsequence or quotient equality is exported.*

Proof. Start with the schedule factorization of Definition 1354.7. It places the cofinal schedule and prefix-budget rows before T and before the Real seal route S.

Now perform induction over later finite tolerance requests. The base request is the one served by E and I, and the induction step appends one displayed request by transporting the same modulus, budget, index, and tail rows through H.

The replay row C_0 records that this appended request follows the same route, while R refuses any move to a selected subsequence, quotient stream equality, hidden tail oracle, or ambient completeness row. Therefore cofinality stability is exactly stability of the displayed finite route. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier cofinality stability`

Theorem 1354.15 (Canonical tail-choice RegSeqRat consumption)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *packet for a Real-completion handoff must consume the rows*

$$M, E, I, T, S, R, H, C_0, P, N$$

in that order before the terminal $\mathsf{Real}^{\uparrow}$ *seal is treated as available. The consumer receives a finite regular-rational tail route through M, E, I, T and the structural rows, but no quotient stream equality, selected limit, countable choice, hidden tail oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier regseqrat consumption`

Proof. Begin with the Real-completion handoff theorem Definition 1354.10. It makes the diagonal seal read pass through the displayed route $M, E, I, T, S, R, H, C_0, P, N$.

For the regular-rational read, use the exact-boundary sibling cited there. A $\mathsf{RegSeqRat}^{\uparrow}$ consumer can inspect a regular-rational tail only after the modulus row M, tolerance budget E, canonical index I, and tail-window witness T have been displayed.

Finally use no-choice non-escape, Definition 1354.8. The refusal row and structural rows keep the read inside the finite packet, so consuming the regular-rational tail cannot produce quotient equality, a selected limit, countable choice, a hidden tail oracle, or ambient Real completeness. □

Theorem 1354.16 (Canonical tail-choice scoped finite-choice route)**.** *Let $C = (M, E, I, T, S, R, H, C_0, P, N)$ be an accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *packet. Every completion-facing finite choice in C is scoped through* $\mathsf{CauchyChoiceBoundary}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{RealCompletionExactBoundaryUp}$ *by the displayed route*

$$M, E, I, T, S, R, H, C_0, P, N.$$

The route computes the finite index row I from the modulus and budget rows, inhabits the tail window T, reads the regular-rational tail through $\mathsf{RegSeqRat}^{\uparrow}$, *and hands the result to the exact completion boundary only after the refusal and structural rows have been displayed. It exports no quotient stream equality, hidden tail oracle, selected subsequence, countable choice, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier scoped finite choice route`

Proof. Start from the schedule factorization theorem, Definition 1354.7. It places the $\mathsf{TailCofinalitySchedule}^{\uparrow}$ and $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$ rows before the tail-window witness, so the finite index is read from the displayed packet rather than from an external choice function.

Next apply no-choice non-escape, Definition 1354.8. The refusal row blocks quotient stream equality, hidden tail oracles, selected subsequences, countable choice, selected limits, and ambient completeness before the completion-facing handoff is available.

The Real-completion handoff, Definition 1354.10, moves the packet from the tail window to the exact boundary through the same rows $M, E, I, T, S, R, H, C_0, P, N$. Tail cofinality stability and Definition 1354.15 then identify the $\mathsf{RegSeqRat}^{\uparrow}$ consumer as a downstream read of that finite route.

The transport, replay, provenance, and naming rows H, C_0, P, N repackage the same finite packet for consumers. Thus the only completion-facing choice made by the chapter is the displayed finite index choice, scoped through the listed L10 completion route and not through countable choice. □

Theorem 1354.17 (Canonical tail choice cofinal choice boundary)**.** *Every accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *read that uses a tail before a Real-completion consumer must factor through the displayed* $\mathsf{CauchyChoiceBoundary}^{\uparrow}$*, finite-prefix,* $\mathsf{RealCompletionExactBoundaryUp}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and tail-cofinality schedule rows before that tail can be consumed. The factorization exports the rows* $M, E, I, T, S, R, H, C_0, P, N$ *of Definition 1354.1; it exports no countable-choice selector, quotient stream equality, ambient Real completeness theorem, or host tail function.*

Proof. Project the carrier rows $M, E, I, T, S, R, H, C_0, P, N$. The modulus and budget rows M, E display the finite-prefix data before the canonical index row I is available, and the tail-window witness T is downstream of that index.

Compose the existing schedule and boundary routes. The schedule factorization theorem places the $\mathsf{TailCofinalitySchedule}^{\uparrow}$ and $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$ rows before T, while the Real-completion handoff theorem moves from T to the $\mathsf{RealCompletionExactBoundaryUp}$ route through the same displayed carrier rows.

Read the regular and terminal faces last. The $\mathsf{RegSeqRat}^{\uparrow}$ consumption theorem identifies the regular-rational tail read as a downstream consumer of M, E, I, T, and the terminal $\mathsf{Real}^{\uparrow}$ seal is reached only through the exact-boundary handoff.

Finally apply the no-choice non-escape theorem. The refusal row R and the structural rows H, C_0, P, N preserve the finite route and leave no coordinate for countable choice, quotient stream equality, ambient completeness, or a host tail function. □

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier cofinal choice boundary`

Theorem 1354.18 (Canonical tail-choice scope grounding)**.** *Every accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *consumer route factors through the displayed rows*

$$M, E, I, T, S, R, H, C_0, P, N$$

and through the sibling surfaces $\mathsf{CauchyChoiceBoundary}^{\uparrow}$*,* $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$*,* $\mathsf{RealCompletionExactBoundaryUp}$ $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{TailCofinalitySchedule}^{\uparrow}$*. All transport and replay are read through* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. The scope contains no host-selected subsequence, quotient stream equality, countable choice, hidden tail oracle, metric completeness, ambient completeness, or detached Real-completion seal.*

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier scope grounding`

Proof. Begin with source obligations, Definition 1354.3. They place the no-choice boundary, prefix budget, Real seal, exact boundary, regular-rational source, and cofinal schedule before the canonical finite index row I or tail-window witness T can be consumed.

Next apply schedule factorization and tail cofinality, Definition 1354.7 and Definition 1354.11. These results force the route through the finite rows $M, E, I, T, S, R, H, C_0, P, N$, with $\mathsf{TailCofinalitySchedule}^{\uparrow}$ and $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$ read before the tail-window witness.

Now attach the Real-completion side. The Real-completion handoff theorem, Definition 1354.10, routes the packet from the finite tail window to $\mathsf{RealCompletionExactBoundaryUp}$ and the terminal $\mathsf{Real}^{\uparrow}$ seal, while Definition 1354.13 supplies the finite BHist witness for T after I is read.

Finally apply no-choice non-escape, Definition 1354.8. The refusal row R excludes host-selected subsequences, quotient stream equality, countable choice, hidden tail oracles, metric completeness, ambient completeness, and detached Real-completion seals; the structural rows H, C_0, P, N keep transport, replay, provenance, and naming inside BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. □

Theorem 1354.19 (Canonical tail-choice scoped source discipline)**.** *Let $C = (M, E, I, T, S, R, H, C_0, P, N)$ be an accepted $\mathsf{CanonicalTailChoice}^{\uparrow}$ packet. Before the seal row S is consumed by any Real-completion read, the source route must pass through $\mathsf{CauchyChoiceBoundary}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{RealCompletionExactBoundaryUp}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ using only the displayed rows $M, E, I, T, S, R, H, C_0, P, N$. The route exposes no host-selected tail, quotient stream equality, hidden choice oracle, detached Real seal, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier scoped source discipline`

Proof. Project the carrier rows $M, E, I, T, S, R, H, C_0, P, N$. The modulus row M, finite budget row E, canonical index row I, and tail window row T are the only local source rows available before the seal route S is read.

Apply schedule factorization, no-choice non-escape, and the Real-completion handoff, namely Definition 1354.7, Definition 1354.8, and Definition 1354.10. These place the $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, and $\mathsf{CauchyChoiceBoundary}^{\uparrow}$ surfaces before the tail window and keep the refusal row visible before any completion-facing seal is consumed.

Use $\mathsf{RegSeqRat}^{\uparrow}$ consumption and scope grounding, Definition 1354.15 and Definition 1354.18. The regular-rational read reaches $\mathsf{RealCompletionExactBoundaryUp}$ only through the sibling $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces named by that exact-boundary route, while H, C_0, P, N preserve transport, replay, provenance, and local naming.

Thus every seal-facing consumer reads the same finite source discipline before S. The excluded tail selector, quotient equality, hidden oracle, detached seal, and ambient completeness coordinates are absent from the carrier and from the cited boundary routes. □

Theorem 1354.20 (Canonical tail-choice public export)**.** *The public export of an accepted $\mathsf{CanonicalTailChoice}^{\uparrow}$ packet consists exactly of the displayed rows $M, E, I, T, S, R, H, C_0, P, N$ of Definition 1354.1 together with the sibling routes $\mathsf{CauchyChoiceBoundary}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{RealCompletionExactBoundaryUp}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. It exports no selected tail, quotient stream equality, countable choice, hidden oracle, detached Real seal, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CanonicalTailChoiceUp.CanonicalTailChoiceCarrier public export`

Proof. Start with the NameCert obligations of Definition 1354.2. They expose exactly the rows $M, E, I, T, S, R, H, C_0, P, N$ and give no coordinate for a selected tail, quotient equality, hidden oracle, or ambient completeness theorem.

Next compose the schedule and boundary routes. The schedule factorization of Definition 1354.7 places $\mathsf{TailCofinalitySchedule}^{\uparrow}$ and $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$ before the tail window, while the Real-completion handoff of Definition 1354.10 routes the seal through $\mathsf{RealCompletionExactBoundaryUp}$ and $\mathsf{Real}^{\uparrow}$.

Now add the scoped source discipline of Definition 1354.19. It forces the same source route through $\mathsf{CauchyChoiceBoundary}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ before any completion-facing consumer can read the seal row.

The structural rows H, C_0, P, N preserve, replay, source, and name that exact route. Therefore the listed rows and sibling routes are the whole public export, and the excluded objects remain absent from every public consumer surface. □

The Lean follow-up namespace is `BEDC.Derived.CanonicalTailChoiceUp`. Its `TasteGate.lean` surface must provide `Nontrivial` and `FieldFaithful` instances for the carrier of Definition 1354.1.

Closure status for $\mathsf{NameCert}_{\mathsf{CanonicalTailChoice}^{\uparrow}}$.

Constructive story: A $\mathsf{CanonicalTailChoice}^{\uparrow}$ packet is generated from a regular-Cauchy modulus row, a finite tolerance-budget row, a canonical finite-index row, a tail-window witness row, a Real seal route, a no-choice refusal row, componentwise transports, continuation replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CanonicalTailChoice}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: The scoped source discipline binds exactly $\mathsf{CauchyChoiceBoundary}^{\uparrow}$, $\mathsf{FinitePrefixLimitBudget}^{\uparrow}$, $\mathsf{RealCompletionExactBoun}$ $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{TailCofinalitySchedule}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows for the finite tail-choice packet and its Real-completion handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CanonicalTailChoice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, quotient-stream equality, host real equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, canonical-index exactness, schedule factorization, no-choice refusal, Real-completion handoff, and TasteGate carrier support for the same packet.

Chapter 1355

A Concrete Naming Certificate for $\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}$

The $\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}$ packet realizes the transcendental supply position of subsection 9462.26.6 as finite BEDC NameCert data without turning that position into a closed observation object. It sits beside the closed observation system of chapter 616, the forward-binding gap ledger of chapter 1262, and the gap socket boundary of chapter 1343. Those siblings respectively record closed observation rows, present forward-binding commitments, and socket boundary discipline; this packet binds the supply-position row, closed-record interface, GAP socket, noninternalization refusal, route, provenance, and local naming rows before any consumer may read the position as licensed supply.

Definition 1355.1 (Closed observation supply boundary carrier)**.** *A* $\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, Q, G, F, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the closed observation record row, read only through the closed observational discipline of chapter 616;*
2. *Q is the supply-position socket row naming the T-position without installing it as an observation state, record, rule, axiom, or object;*
3. *G is the GAP commitment row inherited from the forward-binding gap ledger of chapter 1262;*
4. *F is the noninternalization refusal row separating the supply position from substrate content;*
5. *A is the apophatic naming row that names the boundary without supplying a far-end object;*
6. *H records componentwise* hsame *transports for the closed record, socket, GAP, refusal, naming, route, provenance, and local certificate rows;*
7. *C records displayed* Cont *routes for supply-position inspection, GAP replay, noninternalization refusal, and downstream consumer audit;*
8. *P is the* Pkg *provenance over subsection 9462.26.1, subsection 9462.26.6,* $\mathsf{ClosedObservationSystem}^{\uparrow}$, $\mathsf{ForwardBindingGapLedger}^{\uparrow}$, $\mathsf{GapSocketBoundary}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, $\mathsf{NegativeCertificateBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}}$ *row.*
The classifier accepts exactly packets whose visible rows are $R, Q, G, F, A, H, C, P, N$. It contains no hidden supply object, no closed-generation rule for T, no substrate axiom, no far-end witness, and no route that reads Q as a closed observation record.

Lean4 ✓ `BEDC.Derived.ClosedObservationSupplyBoundaryUp.ClosedObservationSupplyBoundaryUpTasteGate`
`single carrier alignment`

Theorem 1355.2 (Closed observation supply boundary NameCert obligations)**.** *For every accepted* $\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}$ *carrier $S = (R, Q, G, F, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedObservationS}}$ *surface consists of finite carrier admission for the displayed packet, closed-record accountability through R, supply-position exposure through Q, GAP commitment through G, noninternalization refusal through F, apophatic boundary naming through A, componentwise transport through H, replay through C, provenance through P, and local certificate replay through N.*

Lean4 ✓ `BEDC.Derived.ClosedObservationSupplyBoundaryUp.ClosedObservationSupplyBoundaryTasteGate`
`single carrier alignment`

Proof. Start with carrier projection. The packet exposes exactly $R, Q, G, F, A, H, C, P, N$, so every accepted read is a read of one of those finite rows.

The sibling closed observation system supplies the closed-record discipline for R, while the forward-binding gap ledger supplies the GAP commitment row G. The gap socket boundary supplies the socket-side boundary shape through which Q is inspected.

The rows F and A keep the supply position from becoming substrate content. They allow the position to be named and refused as internal content without adding a closed-generation rule, a far-end witness, or a hidden axiom.

Finally the rows H, C, P, N replay only the displayed packet. Thus the NameCert surface is the listed finite obligation set and not an additional object layer. □

Theorem 1355.3 (Closed observation supply boundary noninternalization)**.** *No accepted* $\mathsf{ClosedObservationSupplyI}$ *carrier exports the supply-position row Q as a closed observation record, substrate axiom, closed-generation rule, licensed object, or far-end witness. Any consumer that reads Q as one of those internalized forms leaves the carrier surface $R, Q, G, F, A, H, C, P, N$ and refutes the packet.*

Proof. Use the carrier definition. The closed observation record is R, while the supply-position socket is Q; the two rows have different roles in the packet.

Apply the NameCert obligation theorem. It routes closed-record accountability through R, GAP commitment through G, and supply-position exposure through Q before the refusal and naming rows are consumed.

The noninternalization row F blocks the internal readings. The apophatic row A names the boundary without adding a far-end object, and the rows H, C, P, N preserve that separation under transport, replay, provenance, and local naming. Hence a consumer that treats Q as record, rule, axiom, object, or witness no longer reads an accepted packet. □

Falsifiable prediction: A consumer that reads the supply-position row as a closed observation record refutes the packet.

Independence witness: closedobservationsystem, forwardbindinggapledger, gapsocketboundary, apophaticname, negativecertificateboundary: none is bijective because none carries closed

records, supply-position socket, GAP commitment, noninternalization refusal, route, provenance, and NameCert as one packet.

The later Lean `TasteGate.lean` development for $\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ ClosedObservationSupplyBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful\ ClosedObservationSupplyBoundary}^{\uparrow}$ instances in `lean4/BEDC/Derived/ClosedObservationSupplyBoundaryUp/TasteGate.lean`. Those instances must preserve the closed record row, supply-position socket row, GAP commitment row, noninternalization refusal row, apophatic naming row, componentwise transport, replay route, package provenance, and local naming row.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}$ packet is generated by attaching, in one finite BHist carrier, the supply-position row, the closed-observation record interface, the GAP socket row, the noninternalization refusal row, the apophatic naming row, and the transport / replay / package / local-NameCert rows. The classifier never identifies the supply-position row with the closed-record interface or with any internal observation object; every coordinate is compared through componentwise hsame along the visible Cont routes. The ledger story is therefore a boundary story: the supply position is named but not closed, and any consumer trying to read it as record, rule, axiom, object, or witness leaves the carrier.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the supply-boundary carrier, NameCert obligation surface, noninternalization theorem, falsifiable prediction, and independence witness for $\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedObservationSupplyBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not internalize the supply position as a closed observation object, supply a far-end witness, or admit a host-level realization of the GAP socket.

Upgrade path: To reach obligationClosure, the finite carrier and noninternalization obligations must be mirrored by Lean definitions and checked transport / TasteGate instances under `lean4/BEDC/Derived/ClosedObservationSupplyBoundaryUp/`.

Chapter 1356

A Concrete Naming Certificate for $\mathsf{RealCompletenessTailChoiceAudit}^{\uparrow}$

The $\mathsf{RealCompletenessTailChoiceAudit}^{\uparrow}$ packet turns the canonical tail-choice realization of chapter 1354 into an explicit audit surface for the Real-completeness route of chapter 9238. It reads the diagonal representative of chapter 1205, the finite observation-budget selector of chapter 782, the stream window of chapter 126, the regular-rational readback of chapter 301, the dyadic ledger of chapter 291, and the terminal Real seal of chapter 38. Its purpose is to expose the finite selector boundary as a named audit packet rather than letting a completion consumer confuse it with a countable-choice selector or a host-limit computation.

Falsifiable prediction: Removing the refusal row makes the audit unable to distinguish finite tail choice from countable-choice selection.

Independence witness: canonicaltailchoice, diagonallimitrepresentative, finiteobservationbudgetselector, realtailagreementseal, cofinalwindowrealseal: none is bijective to $\mathsf{RealCompletenessTailChoiceAudit}^{\uparrow}$ because the listed packets isolate a canonical finite tail choice, a diagonal representative, an observation-budget selector, a paired tail agreement seal, or a cofinal Real seal, while the audit packet binds all of them to one carrier with displayed tail-window, refusal, transport, route, provenance, and Real-seal rows.

Definition 1356.1 (Real-completeness tail-choice audit carrier)**.** *A* $\mathsf{RealCompletenessTailChoiceAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, E, I, W, S, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus and tolerance row inherited from the accepted* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *route.*
2. *E is the finite observation-budget row that determines which tail observations may be served.*
3. *I is the canonical finite tail-index row, computed from the displayed modulus and budget rows.*
4. *W is the tail-window row linking the index I to the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surfaces.*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the diagonal representative and finite readback rows have been displayed.*

6. *R is the refusal row excluding countable choice, host-selected limits, quotient stream equality, hidden tail oracles, and ambient completeness.*
7. *H records componentwise* hsame *transport for the modulus, budget, index, window, seal, refusal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the finite selector rows through the tail-window readback, refusal row, and Real-seal route.*
9. *P is the* Pkg *provenance over* $\mathsf{CanonicalTailChoice}^{\uparrow}$, $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$, FiniteObservationBudgetSelecto $\mathsf{RealTailAgreementSeal}^{\uparrow}$, $\mathsf{CofinalWindowRealSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessTailChoiceAudit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for a countable-choice selector, a quotient stream, a selected host limit, an unbounded tail oracle, a metric-completeness proof, or a detached Real-completion theorem.

Lean4 ✓ `BEDC.Derived.RealCompletenessTailChoiceAuditUp.TasteGate.RealCompletenessTailChoiceAuditTasteGa`
`single carrier alignment`

Theorem 1356.2 (Real-completeness tail-choice audit non-escape)**.** *An accepted* $\mathsf{RealCompletenessTailChoiceAudit}^{\uparrow}$ *packet exports exactly the rows*

$$M, E, I, W, S, R, H, C, P, N$$

of Definition 1356.1. No terminal Real-completion consumer can read a countable-choice selector, selected host limit, quotient stream equality, hidden tail oracle, ambient completeness field, or detached limit theorem through the audit packet.

Proof. Project the carrier. The analytic rows are the displayed modulus and tolerance row M, the finite observation budget E, the canonical index I, the tail-window row W, the Real seal row S, and the refusal row R.

The structural rows add no second analytic source. The transports H, continuation replay C, provenance P, and local name N only preserve and name the same finite packet.

The refusal row is part of the carrier itself. Since the excluded objects are not coordinates of the packet and are not introduced by the structural rows, any read of one of them leaves the accepted audit surface. □

Theorem 1356.3 (Real-completeness tail-choice audit Real-seal factorization)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealCompletenessTailChoiceAudit}^{\uparrow}$ *packet factors its Real-seal read through the finite route*

$$M \longmapsto E \longmapsto I \longmapsto W \longmapsto S \longmapsto R \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

The route first consumes the canonical tail-choice row of chapter 1354, then the diagonal representative and finite observation-budget surfaces of chapter 1205 and chapter 782, and only then reads the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *faces.*

Proof. Begin with the canonical tail-choice packet. Its modulus, tolerance, finite-index, tail-window, seal, and refusal rows supply the finite selector route that the audit records as M, E, I, W, S, R.

Next attach the representative and budget consumers. The diagonal representative and finite observation-budget selector are read before the terminal Real seal, so the audit can expose only their displayed finite rows, not an external limit value or an unbounded selection principle.

Finally read the four concrete faces. The StreamName, DyadicRatCore, RegSeqRat, and Real surfaces appear through the same window and seal route already carried by W and S. The structural rows H, C, P, N transport, replay, source, and name that route, so every terminal read factors through the stated finite sequence. □

The Lean follow-up namespace is `BEDC.Derived.RealCompletenessTailChoiceAuditUp`. Its `TasteGate.lean` surface must provide `Nontrivial` and `FieldFaithful` instances for the carrier of Definition 1356.1.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessTailChoiceAudit}\uparrow}$.

Constructive story: A $\mathsf{RealCompletenessTailChoiceAudit}^{\uparrow}$ packet is generated from finite modulus, observation-budget, canonical-index, tail-window, Real-seal, refusal, transport, continuation, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletenessTailChoiceAudit}\uparrow}, \mathsf{seed})$

Scope closed: Definition 1356.1, Definition 1356.2, and Definition 1356.3 declare the finite audit packet separating canonical tail choice from countable-choice and host-limit routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletenessTailChoiceAudit}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close RealUp completeness, quotient-stream equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, audit non-escape, Real-seal factorization, and TasteGate carrier support for the same packet.

Chapter 1357

A Concrete Naming Certificate for $\mathsf{ObservationFiberDigest}^{\uparrow}$

The $\mathsf{ObservationFiberDigest}^{\uparrow}$ packet realizes the local visible digest and observation-fiber discipline of chapter 9402 as a finite NameCert carrier. It sits beside the digest provenance packet of chapter 1062, the apophatic naming boundary of chapter 543, and the fiber ledger of chapter 1067. Those siblings expose digest provenance, far-end refusal, and fiber membership separately; this carrier binds visible digest, observation-fiber membership, GAP ledger, signature and package provenance, local naming, far-end status, transport, and replay before any consumer may use a digest as an observation boundary.

Falsifiable prediction: Every accepted ObservationFiberDigestUp consumer must expose visible digest, observation-fiber membership, GAP ledger, Pkg/Sig provenance, NameCert row, and far-end status before using the digest as an observation boundary.

Independence witness: digestprovenancepacket, apophaticname, observerhistidentity, inscriptionevent, gapfailurebridgeaudit: none is bijective because each omits either the observation-fiber membership row, the local visible digest row, or the apophatic far-end boundary status.

Definition 1357.1 (ObservationFiberDigest carrier)**.** *An* $\mathsf{ObservationFiberDigest}^{\uparrow}$ *carrier is a finite packet*

$$O = (D, F, G, S, P, N, T, H, C)$$

with the following displayed rows:

1. *D is the local visible digest row, naming the classifier-facing digest token available to a particular observer state;*
2. *F is the observation-fiber membership row, recording the generated relation that binds the visible digest to compatible observation histories without identifying them;*
3. *G is the* GAP *ledger row for missing source supply, far-end socketing, and unavailable exactness data;*
4. *S is the signature provenance row, recording the* Sig *or classifier route that made the digest visible;*
5. *P is the* Pkg *provenance over* $\mathsf{DigestProvenancePacket}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, $\mathsf{DigestFiberLedger}^{\uparrow}$, *observation histories, signatures, GAP rows,* hsame, Cont, *and* NameCert *rows;*
6. *N is the local* $\mathsf{NameCert}_{\mathsf{ObservationFiberDigest}^{\uparrow}}$ *row;*

7. *T is the far-end status row, recording whether the observation fiber terminates in a refused, socketed, or locally exact boundary;*
8. *H records componentwise* hsame *transport for the digest, fiber, GAP, signature, package, local naming, far-end status, and replay rows;*
9. *C records the displayed* Cont *replay routes by which accepted consumers inspect D, F, G, S, P, N, T, H.*

The carrier has no coordinate for digest-as-source equality, a global universe digest, object-level T*, quotient fiber equality, hidden source equality, host preimage recovery, or observer-independent totalization.*

Lean4 (definition) `BEDC.Derived.ObservationFiberDigestUp.ObservationFiberDigestUp`

Theorem 1357.2 (ObservationFiberDigest NameCert obligations)**.** *For an accepted* $\mathsf{ObservationFiberDigest}^{\uparrow}$ *packet*

$$O = (D, F, G, S, P, N, T, H, C),$$

the local $\mathsf{NameCert}_{\mathsf{ObservationFiberDigest}^{\uparrow}}$ *surface consists exactly of carrier admission for the nine displayed rows, visible digest exposure through D, observation-fiber membership through F, GAP ledger exposure through G, signature provenance through S, package provenance through P, local naming through N, far-end status through T, componentwise transport through H, replay locality through C, and non-escape from digest-as-source equality, global universe digest, object-level* T*, quotient fiber equality, and hidden source equality.*

Proof. Project the carrier of Definition 1357.1. Its visible inventory is exactly $D, F, G, S, P, N, T, H, C$, so carrier admission and local naming attach to those rows and to no host digest function or hidden observation substrate.

The digest boundary is read first through D. The observation fiber is not the same datum: it is the generated membership row F, and source-sensitive reads must keep F visible before the digest can be cited as an observation boundary.

The rows G, S, P, N, T then provide the finite obligation surface. The GAP row records missing supply and unavailable exactness; the signature row records how the digest became visible; the package row records the sibling route through chapter 1062, chapter 543, and chapter 1067; the local NameCert row records the packet name; and the far-end row records whether the fiber boundary is refused, socketed, or locally exact.

Finally H and C preserve the same finite packet under transport and replay. Since no displayed row is a source payload, a universe digest, an object-level truth value, a quotient representative, or a hidden equality witness, the listed non-escape obligations exhaust the local NameCert surface. □

Theorem 1357.3 (ObservationFiberDigest non-escape)**.** *Every accepted* $\mathsf{ObservationFiberDigest}^{\uparrow}$ *consumer that uses the digest as an observation boundary must factor through the displayed rows*

$$D, F, G, S, P, N, T, H, C.$$

The consumer obtains a local visible digest with fiber, ledger, signature, package, naming, far-end, transport, and replay evidence, but cannot obtain digest-as-source equality, a global universe digest, object-level T*, quotient fiber equality, hidden source equality, host preimage recovery, or observer-independent totalization from the packet.*

Proof. Start with an accepted packet $O = (D, F, G, S, P, N, T, H, C)$. A token-only read of D obtains only the visible digest row, because Definition 1357.1 gives no source coordinate behind D.

If the consumer uses the digest as an observation boundary, the read must open the observation-fiber membership row F. Without F, the digest is merely a visible classifier-facing token and has no packet-local authority to delimit compatible observation histories.

Next the read must pass through G, S, P, N, T. These rows expose the GAP ledger, signature provenance, package provenance, local certificate, and far-end status. In particular, T keeps the apophatic boundary visible rather than replacing it with an internal object.

The remaining rows H and C transport and replay the same packet. They do not add a preimage oracle, quotient collapse, hidden source equality, global universe digest, or object-level T coordinate. Therefore every accepted boundary use is confined to the displayed observation-fiber digest packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ObservationFiberDigest}^{\uparrow}}$.

Constructive story: An $\mathsf{ObservationFiberDigest}^{\uparrow}$ packet is generated from a local visible digest, observation-fiber membership row, GAP ledger, signature provenance, package provenance, local NameCert row, far-end status row, componentwise hsame transports, and displayed Cont replay routes.

Lean4 ✓ `BEDC.Derived.ObservationFiberDigestUp.taste gate`

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObservationFiberDigest}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1357.1, Definition 1357.2, and Definition 1357.3 bind the displayed digest, fiber, GAP, signature, package, local naming, far-end, transport, and replay packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObservationFiberDigest}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ObservationFiberDigestUp.taste\_gate`

Bridge status: none

Origin: ai

Not claimed: This chapter does not close source equality, global universe digest exposure, object-level truth, quotient fiber equality, hidden source equality, host preimage recovery, or bridge verification.

Upgrade path: A bridge-checked grade requires a standard bridge for the same observation-fiber digest packet and its displayed boundary rows.

Chapter 1358

A Concrete Naming Certificate for $\mathsf{RegistryChangeContinuity}^{\uparrow}$

The $\mathsf{RegistryChangeContinuity}^{\uparrow}$ packet realizes the active-reading continuity clause of section 9462.35 as a finite NameCert carrier. It sits beside the active-reading gate of chapter 1249, the closure-status reference of chapter 1265, the registry-consistency audit of chapter 1223, the claim registry layer of chapter 1209, and the cannot-claim registry of chapter 1318. Those siblings expose current-reading uniqueness, status bounds, consistency checks, claim admission, and refusal rows; this carrier binds the current row, the displaced row, the status boundary, the refusal route, and the replay evidence in one registry-machine packet.

Definition 1358.1 (Registry-change continuity carrier)**.** *A* $\mathsf{RegistryChangeContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, A, D, S, R, B, H, C, P, N)$$

with the following displayed rows:

1. *T is the registry target row, naming the theorem, definition, writing item, formal target, or package entry whose reading changes.*
2. *A is the active-reading row after the change, imported through the current-reading surface of* $\mathsf{ActiveReadingGate}^{\uparrow}$*.*
3. *D is the displaced-reading row, retained as blocked audit data rather than as a second active reading.*
4. *S is the status-bound row, recording the closure-status and formal-status boundary read from* $\mathsf{ClosureStatusReference}^{\uparrow}$*.*
5. *R is the cannot-claim refusal row, recording the public reason that blocks the displaced row from export as current.*
6. *B is the blocked-reading row, binding D to R and recording that the displaced row remains visible only as audit data.*
7. *H records componentwise* hsame *transport for target, active reading, displaced reading, status bound, refusal, blocking, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from T through A, S, R, B to the export-readable registry route.*

9. *P is the* Pkg *provenance over* RegistryChangeContinuity$^{\uparrow}$, ActiveReadingGate$^{\uparrow}$, ClosureStatusReference$^{\uparrow}$, RegistryConsistencyAudit$^{\uparrow}$, ClaimRegistryLayer$^{\uparrow}$, PhilosophyCannotClaimRegistry$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegistryChangeContinuity}^{\uparrow}}$ *row.*

The carrier has no coordinate for exporting D as a second active reading, changing the status boundary outside S, citing a refusal outside R, replaying the change outside C, or naming the packet outside the finite row $K = (T, A, D, S, R, B, H, C, P, N)$.

Lean4 ✓ `BEDC.Derived.RegistryChangeContinuityUp.RegistryChangeContinuityTasteGate single carrier alignment`

Theorem 1358.2 (Registry-change continuity obligations)**.** *For the carrier of Definition 1358.1, the local* $\mathsf{NameCert}_{\mathsf{RegistryChangeContinuity}^{\uparrow}}$ *surface consists exactly of carrier admission for $K = (T, A, D, S, R, B, H, C, P, N)$; target admission through T; current-reading admission through A; displaced-reading exposure through D; status-bound exactness through S; refusal and blocked-reading compatibility through R and B; registry-consistency and claim-layer readability through* RegistryConsistencyAudit$^{\uparrow}$ *and* ClaimRegistryLayer$^{\uparrow}$*; and transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 1358.1. The rows $T, A, D, S, R, B, H, C, P, N$ are the only coordinates available to the local certificate, so every accepted change-continuity read must pass through those rows.

The registry target is fixed by T. The active row A is the single current reading, while D is retained only as displaced audit data. The status row S bounds the change by the closure-status and formal-status surface, so the carrier cannot silently change the public grade of the target.

The refusal and blocking rows supply the non-export clause. Row R records the cannot-claim reason, and row B binds that reason to the displaced row. Thus the carrier exposes why D remains readable as history while refusing to make it a second current claim.

Rows H, C, P, N preserve the same finite packet under transport, replay, provenance, and naming. They add no coordinate for a hidden active row, so the displayed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{RegistryChangeContinuity}^{\uparrow}}$ surface. □

Theorem 1358.3 (Registry-change continuity active-reading refusal)**.** *Every accepted* RegistryChangeContinuity$^{\uparrow}$ *packet exports the target row T through the active row A, the status-bound row S, the refusal row R, and the blocked-reading row B. A packet that exports both A and D as active readings for the same target is rejected by* RegistryChangeContinuity$^{\uparrow}$.

Proof. Start with an accepted packet

$$K = (T, A, D, S, R, B, H, C, P, N).$$

By Definition 1358.2, the export-readable route contains T, A, S, R, B as displayed rows.

The active-reading gate supplies uniqueness for A, and the closure-status reference supplies the status bound S. The displaced row D is still present, but it is tied to the cannot-claim row R through the blocked-reading row B.

Transport, replay, provenance, and local naming preserve that same route. Since no coordinate turns D into an additional active row, any packet that exports both A and D as active readings for the same target leaves the displayed carrier and is refused by B. □

Falsifiable prediction: A packet that exports both the active row and the displaced row for the same target as active readings is rejected by RegistryChangeContinuityUp.

Independence witness: active-reading-gate, closure-status-reference, registry-consistency-audit, claimregistrylayer, philosophycannotclaimregistry: none is bijective because RegistryChangeContinuityUp binds active reading, blocked displaced reading, status bound, cannot-claim refusal, transport, replay, provenance, and local NameCert rows in one carrier.

The Lean follow-up must provide explicit Nontrivial $\mathsf{RegistryChangeContinuity}^{\uparrow}$ and FieldFaithful RegistryChangeC instances in `lean4/BEDC/Derived/RegistryChangeContinuityUp/TasteGate.lean`. Those instances must preserve $T, A, D, S, R, B, H, C, P, N$ as separate displayed fields before BEDC.Derived.RegistryChangeC can be cited by a checked paper marker.

Closure status for $\mathsf{NameCert}_{\mathsf{RegistryChangeContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{RegistryChangeContinuity}^{\uparrow}$ packet is generated from target, active-reading, displaced-reading, status-bound, refusal, blocked-reading, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegistryChangeContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1358.1, Definition 1358.2, and Definition 1358.3 bind active-reading continuity to a finite registry-machine NameCert packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegistryChangeContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, global registry repair, archival completeness for every displaced reading, or public export correctness for every downstream consumer.

Upgrade path: Lean closure requires Nontrivial RegistryChangeContinuityUp and FieldFaithful RegistryChangeContinuityUp instances in `lean4/BEDC/Derived/RegistryChangeContinuityUp/TasteGate.lean`.

Chapter 1359

A Concrete Naming Certificate for $\mathsf{HashLikeBoundaryGate}^{\uparrow}$

The $\mathsf{HashLikeBoundaryGate}^{\uparrow}$ packet realizes the eight-question audit family of Definition 9402.35 as finite NameCert data. It sits after the general boundary-gate packet of chapter 1070, the hash-like fiber boundary of chapter 1084, the digest-fiber ledger of chapter 1067, the hash digest-fiber boundary of chapter 1087, and the digest provenance packet of chapter 1062. Those siblings provide boundary questions, visible digest rows, hidden fiber rows, exactness/refusal discipline, and provenance rows; this packet makes the H1–H8 gate itself a consumer-facing certificate.

Definition 1359.1 (HashLikeBoundaryGate carrier)**.** *A* $\mathsf{HashLikeBoundaryGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (D, F, E, R, V, H, C, P, N)$$

with the following displayed rows:

1. *D is the visible digest-like token row;*
2. *F is the provenance fiber row attached to the same token;*
3. *E is the exactness row recording whether digest equality is licensed as source equality;*
4. *R is the refusal row for absent provenance, absent exactness, global-universe hashes,* T*-value confusion, self-substance leakage, physical-constant derivation, quotient collapse, and un sourced certificate names;*
5. *V is the audit-verdict row for the H1–H8 questions of Definition 9402.35;*
6. *H records componentwise* hsame *transport for D, F, E, R, V together with the structural rows;*
7. *C records the displayed* Cont *routes through digest, fiber, exactness, refusal, audit verdict, transport, provenance, and local naming reads;*
8. *P is the* Pkg *provenance over* $\mathsf{BoundaryGate}^{\uparrow}$, $\mathsf{HashLikeFiberBoundary}^{\uparrow}$, $\mathsf{DigestFiberLedger}^{\uparrow}$, $\mathsf{HashDigestFiberBoun}$ $\mathsf{DigestProvenancePacket}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HashLikeBoundaryGate}^{\uparrow}}$ *row.*

The carrier accepts exactly those digest-like consumers that display provenance fiber, exactness, refusal, audit verdict, transport, continuation, package, and local naming rows before treating digest equality as any source-facing claim.

Lean4 ✓ BEDC.Derived.HashLikeBoundaryGateUp.HashLikeBoundaryGateTasteGate single carrier alignment

Theorem 1359.2 (HashLikeBoundaryGate NameCert obligations)**.** *For the carrier of Definition 1359.1, the local* $\mathsf{NameCert}_{\mathsf{HashLikeBoundaryGate}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$X = (D, F, E, R, V, H, C, P, N),$$

visible digest exposure through D*, provenance-fiber exposure through* F*, exactness exposure through* E*, H1–H8 refusal exposure through* R*, audit-verdict exposure through* V*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Consequently, an accepted consumer cannot use digest equality as source equality unless the exactness row E *is displayed together with* F, R, V, H, C, P, N*.*

Proof. Project the displayed carrier. The rows D, F, E, R, V are the complete audit content, while H, C, P, N transport, replay, package, and name the same finite packet.

Read the sibling routes in order. The boundary-gate surface supplies the finite question and verdict pattern, the hash-like fiber boundary supplies digest and hidden-fiber discipline, the digest-fiber ledger supplies provenance-fiber exposure, the hash digest-fiber boundary supplies exactness discipline, and the digest provenance packet supplies source-row ancestry.

The H1–H8 refusal row then exhausts the gate. Since the carrier has no coordinate for a global universe hash, detached digest-to-source equality, unledgered T input, subject parameter outside Hist, physical constant derivation, quotient collapse, or un sourced certificate citation, no accepted consumer can obtain those readings from the packet. □

Theorem 1359.3 (HashLikeBoundaryGate nonescape)**.** *Every accepted* $\mathsf{HashLikeBoundaryGate}^{\uparrow}$ *consumer factors through*

$$D, F, E, R, V, H, C, P, N.$$

The packet exports no digest-as-source equality, no selected preimage, no global universe digest, no T*-valued theorem input, no subject behind* Hist*, no physical constant, no quotient source equality, and no certificate name detached from its source rows.*

Proof. Use the NameCert obligations of Definition 1359.2. They place every consumer-visible read on the same digest, fiber, exactness, refusal, audit-verdict, transport, continuation, provenance, and local naming route.

The exactness coordinate is displayed as a gate row rather than as an implicit equality principle. Thus digest equality can be consumed only after the packet also exposes its fiber, refusal, verdict, transport, route, provenance, and naming rows.

The forbidden outputs require coordinates absent from Definition 1359.1. Transport and replay preserve the displayed packet; they do not create source preimages, universe hashes, theorem inputs, subject parameters, physical constants, quotient equalities, or detached certificate names. □

Falsifiable prediction: Every accepted HashLikeBoundaryGateUp consumer must display provenance fiber, exactness, refusal, audit verdict, hsame, Cont, Pkg, and NameCert rows before using digest equality as source equality.

Independence witness: boundarygate, hashlikefiberboundary, digestfiberledger, hashdigest-fiberboundary, and digestprovenancepacket: none is bijective to HashLikeBoundaryGateUp because this carrier binds the H1–H8 audit verdict to digest, fiber, exactness, refusal, transport, continuation, provenance, and local naming rows in one packet.

The Lean follow-up namespace is `BEDC.Derived.HashLikeBoundaryGateUp`. Its `TasteGate.lean` file must include `Nontrivial HashLikeBoundaryGateUp` and `FieldFaithful HashLikeBoundaryGateUp` instances for the displayed digest, fiber, exactness, refusal, audit verdict, transport, continuation, provenance, and naming carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{HashLikeBoundaryGate}^{\uparrow}}$.

Constructive story: A $\mathsf{HashLikeBoundaryGate}^{\uparrow}$ packet is generated by attaching, in one finite BHist carrier, the digest row, fiber row, exactness row, refusal row, audit-verdict row, and the transport / continuation / package / local-NameCert rows. The classifier compares packets only through componentwise hsame along the displayed Cont routes; the boundary gate never identifies two distinct digest fibers by an external hash-collision argument. The ledger story is a boundary story: each refusal-side coordinate stays visible, and any consumer trying to bypass the gate via a host-level hash equality leaves the carrier.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HashLikeBoundaryGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the gate carrier, the NameCert obligation surface, the audit-verdict row, and the falsifiable / independence rows for $\mathsf{HashLikeBoundaryGate}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HashLikeBoundaryGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: It does not export host-level hash equality, claim collision resistance as a substrate-internal theorem, or admit a digest-fiber identification outside the displayed gate.

Upgrade path: To reach obligationClosure, the finite gate carrier and audit-verdict obligations must be mirrored by Lean definitions and checked TasteGate instances under `lean4/BEDC/Derived/HashLikeBoundaryGateUp/`.

Chapter 1360

A Concrete Naming Certificate for AuditMapRouteBudget$^{\uparrow}$

The AuditMapRouteBudget$^{\uparrow}$ packet realizes the route-budget surface of the GroundCompiler audit map in chapter 9407. It sits beside the cross-map weave of chapter 839, the common audit interface of chapter 806, the event-flow audit packet of chapter 829, the flow-level round-trip packet of chapter 1094, and the cannot-claim export gate of chapter 1319. Those siblings expose dependency routing, generic audit rows, event-flow evidence, flow readback, or claim-export refusal separately; this packet binds the complete event-flow, source-channel, recognizer, certificate-gate, report-boundary, and cannot-claim route budget as one finite NameCert surface.

Definition 1360.1 (Audit-map route-budget carrier)**.** *An* AuditMapRouteBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, S, R, G, Q, L, H, C, P, N)$$

with the following displayed rows:

1. *E is the event-flow input row naming the GroundCompiler event family admitted by chapter 9407.*
2. *S is the source-channel encoding row recording the legal source channel, channel readback, and lossless route on the same event family.*
3. *R is the recognizer-evidence row recording generated recognizer acceptance without treating reports or generated code as proof.*
4. *G is the certificate-gate row recording which exported certificate gates are open for the accepted route and which gates are absent.*
5. *Q is the report-boundary row recording compiler reports, metric reports, motif reports, theorem-code rows, and chapter-code rows as reports rather than certificates.*
6. *L is the cannot-claim ledger row recording hidden-input, proof-export, and certificate-export refusals for the same route.*
7. *H records componentwise* hsame *transport for event-flow, source-channel, recognizer, certificate-gate, report-boundary, ledger, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for reading E, S, R, G, Q, L in the accepted order.*
9. *P records* Pkg *provenance over chapter 9407, the cited sibling concrete packets,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{AuditMapRouteBudget}^{\uparrow}}$ *row.*
The carrier has no coordinate for a hidden compiler input, proof object, certificate object, report-derived theorem, unbudgeted route, or cannot-claim discharge outside $E, S, R, G, Q, L, H, C, P, N$.

Lean4 (definition) `BEDC.Derived.AuditMapRouteBudgetUp.TasteGate.AuditMapRouteBudgetUp`
Lean4 ✓ `BEDC.Derived.AuditMapRouteBudgetUp.TasteGate.AuditMapRouteBudgetUp single carrier alignment`

Theorem 1360.2 (Audit-map route-budget NameCert obligations)**.** *For the carrier of Definition 1360.1, the local* $\mathsf{NameCert}_{\mathsf{AuditMapRouteBudget}^{\uparrow}}$ *surface consists exactly of carrier admission for $B = (E, S, R, G, Q, L, H, C, P, N)$, event-flow input exposure through E, source-channel readback through S, recognizer evidence through R, certificate-gate exposure through G, report-boundary exposure through Q, cannot-claim ledger exposure through L, componentwise* hsame *stability through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 1360.1. The event-flow row, source-channel row, recognizer row, certificate-gate row, report-boundary row, and cannot-claim ledger row are visible as separate BHist coordinates.

The GroundCompiler audit-map reading of chapter 9407 fixes the order of use. A public route first reads event-flow input, then source-channel encoding, then recognizer evidence, and only then reaches certificate gates, reports, and cannot-claim ledgers.

The support rows H, C, P, N preserve the same route. Componentwise hsame cannot add a proof coordinate, displayed Cont replay cannot bypass a certificate gate, Pkg records the cited siblings, and local NameCert naming binds the route budget to the displayed packet. □

Theorem 1360.3 (Audit-map route-budget falsifiable boundary)**.** *An accepted* $\mathsf{AuditMapRouteBudget}^{\uparrow}$ *packet cannot export a proof, certificate, or hidden compiler input unless the corresponding certificate-gate row G or cannot-claim ledger row L is displayed in the same route budget. A consumer that reads E, S, R, Q, H, C, P, N while omitting G or L may read event flow, channel encoding, recognizer evidence, and reports, but it cannot claim exported proof evidence, exported certificate evidence, or hidden input access.*

Proof. Begin with the NameCert obligations of Definition 1360.2. They separate recognizer evidence, certificate-gate exposure, report-boundary exposure, and cannot-claim ledger exposure as distinct rows.

If G is omitted, no row records an opened certificate gate. If L is omitted, no row records the hidden-input, proof-export, or certificate-export refusal. The remaining rows can still expose event flow, channel encoding, recognizer acceptance, reports, transports, continuations, provenance, and local naming, but none of them is a proof or certificate export row.

Thus the boundary is falsifiable by inspection. A displayed route that exports proof evidence, certificate evidence, or hidden input while lacking the matching G or L row is not an accepted $\mathsf{AuditMapRouteBudget}^{\uparrow}$ packet. □

Theorem 1360.4 (Audit-map route-budget dependency independence)**.** *The* $\mathsf{AuditMapRouteBudget}^{\uparrow}$ *carrier is not bijective to the sibling packets in chapter 839, chapter 806, chapter 829, chapter 1094, or chapter 1319. None of those siblings carries the complete route-budget row set $E, S, R, G, Q, L, H, C, P, N$: the dependency weave lacks GroundCompiler source-channel and report rows, the generic interface lacks the GroundCompiler-specific event and certificate budget, the event-flow audit lacks the full report and cannot-claim ledger, the flow-level round trip lacks the*

recognizer and certificate-gate budget, and the cannot-claim export gate lacks event-flow, source-channel, and recognizer rows.

Proof. Compare row inventories. Each cited sibling supplies a necessary surface, but each omits at least one row required by Definition 1360.1.

The dependency weave contributes cross-map routing, the interface contributes generic audit shape, the event-flow audit contributes event evidence, the flow-level round trip contributes channel readback, and the cannot-claim export gate contributes refusal discipline. None supplies all of $E, S, R, G, Q, L, H, C, P, N$ with the same local NameCert row.

Therefore a route-budget consumer may cite those siblings through P, but it cannot substitute any one sibling for the accepted $\mathsf{AuditMapRouteBudget}^{\uparrow}$ carrier. □

Falsifiable prediction: An accepted AuditMapRouteBudgetUp route cannot export proof evidence, certificate evidence, or hidden compiler input unless the matching certificate-gate or cannot-claim row is displayed in the same finite packet.

Independence witness: auditmapdependencyweave, auditmapinterface, groundcompilereventflowaudit, groundcompilerflowlevelroundtrip, cannotclaimexportgate: none is bijective to AuditMapRouteBudgetUp because none carries the simultaneous event-flow, source-channel, recognizer, certificate-gate, report-boundary, cannot-claim, transport, continuation, provenance, and local NameCert rows.

The Lean follow-up for `BEDC.Derived.AuditMapRouteBudgetUp.TasteGate.lean` must include explicit Nontrivial $\mathsf{AuditMapRouteBudget}^{\uparrow}$ and FieldFaithful $\mathsf{AuditMapRouteBudget}^{\uparrow}$ instances. The field-faithfulness witness must keep $E, S, R, G, Q, L, H, C, P, N$ distinct, so report rows cannot be read as certificates and cannot-claim rows cannot be erased by transport.

Closure status for $\mathsf{NameCert}_{\mathsf{AuditMapRouteBudget}^{\uparrow}}$.

Constructive story: An $\mathsf{AuditMapRouteBudget}^{\uparrow}$ packet is generated from GroundCompiler event-flow rows, source-channel encoding rows, recognizer-evidence rows, certificate-gate rows, report-boundary rows, cannot-claim ledger rows, componentwise hsame transports, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AuditMapRouteBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1360.1, Definition 1360.2, Definition 1360.3, and Definition 1360.4 bind the finite GroundCompiler route-budget carrier and its audit-map export boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AuditMapRouteBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, compiler self-hosting, proof extraction from reports, certificate extraction from recognizers, hidden compiler input, global audit-map closure, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-channel readback, recognizer evidence, certificate-gate exposure, report-boundary exposure, cannot-claim ledger exposure, transport stability, continuation stability, provenance, and local naming for the displayed route budget.

Chapter 1361

A Concrete Naming Certificate for $\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}$

The $\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}$ packet turns the finite observation-budget selector of chapter 782 into the cofinal window surface required by the Real-completeness route of chapter 9238. It is composite over the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. Its role is not to choose an infinite subsequence; it names the finite rows whose selected windows are cofinal for every displayed diagonal request currently served.

Definition 1361.1 (Finite observation cofinality-selector carrier)**.** *A* $\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, Q, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$ *budget row that bounds the visible Real-completion requests;*
2. *Q is the cofinality-request row recording the finite diagonal requests currently served by B;*
3. *W is the finite family of selected* $\mathsf{StreamName}^{\uparrow}$ *windows whose indices meet every request in Q;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger read from the windows in W;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached after the dyadic ledger is displayed;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached through R;*
7. *H records componentwise* hsame *transport for the budget, request, window, dyadic, regular, seal, continuation, provenance, and local naming rows;*
8. *C records displayed* Cont *replay from B and Q to W, from W to D, from D to R, and from R to E;*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteObservationBudgetSelector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for a countable-choice selector, quotient stream, host real equality test, hidden diagonal subsequence, detached limit value, or ambient completeness theorem.

Theorem 1361.2 (Finite observation cofinality-selector NameCert obligations)**.** *For every accepted* $\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}$ *carrier*

$$F = (B, Q, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}}$ *surface consists exactly of carrier exposure for* F*, budget admission through* B*, finite cofinality-request exposure through* Q*, selected-window coverage through* W*, dyadic readback through* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through* R*,* $\mathsf{Real}^{\uparrow}$ *seal exposure through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 1361.1. The displayed tuple lists the accepted budget selector, the finite cofinality requests, the selected StreamName windows, the dyadic ledger, the regular handoff, the Real seal, and the structural rows.

Read the analytic rows in order. The budget row B bounds the requests in Q, and the continuation route sends those requests to the selected windows W before any dyadic or regular readback can be used.

The seal-facing rows then remain downstream from the same finite surface. The dyadic ledger D is read from W, the handoff row R is read from D, and the seal row E is read from R.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same packet, and no further analytic coordinate appears in the carrier. Hence the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.FiniteObservationCofinalitySelectorUp.TasteGate.FiniteObservationCofinalitySelecto`
`single carrier alignment`

Theorem 1361.3 (Finite observation cofinality-selector non-escape)**.** *Every Real-completion, diagonal-limit,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}$ *packet factors through the displayed finite route*

$$B \to Q \to W \to D \to R \to E$$

together with H, C, P, N*. The consumer may read the finite budget selector, cofinality-request row, selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, transport rows, continuation rows, provenance, and local name, but it cannot read a countable-choice selector, quotient stream, host real equality test, hidden diagonal subsequence, detached limit value, or ambient completeness theorem through the packet.*

Proof. Begin with the NameCert obligations. They place every accepted read on the displayed carrier rows and require the budget-to-window and window-to-seal route to pass through B, Q, W, D, R, E.

Use the cofinality role of the request row. The row Q records only the finite diagonal requests currently served by the budget row B, while W records the finite selected windows that meet those requests. It is therefore a finite cofinal surface, not an infinite subsequence or choice principle.

The remaining rows add no escape route. The dyadic, regular, and Real rows D, R, E are downstream from the displayed windows, and H, C, P, N only preserve, replay, source, and name the same route.

The excluded objects are not coordinates of the carrier and are not introduced by the structural rows. Any consumer that reads one of them has left the accepted $\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}$ packet. □

The later Lean packet is expected at `BEDC.Derived.FiniteObservationCofinalitySelectorUp`. Because the carrier is structurally composite over the existing Real-completion budget and stream-window carriers rather than atomic, its future Lean surface still needs `Nontrivial` and `FieldFaithful` instances for the carrier of Definition 1361.1.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}$ packet is generated from a finite observation-budget selector row, finite cofinality-request row, selected StreamName window family, dyadic ledger, regular handoff, Real seal, componentwise transports, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1361.1, Definition 1361.2, and Definition 1361.3 declare the finite cofinality-selector packet between observation budgets and Real seal reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteObservationCofinalitySelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close RealUp completeness, quotient-stream equality, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal request coverage, seal-route non-escape, and TasteGate carrier support for the same packet.

Chapter 1362

A Concrete Naming Certificate for $\mathsf{ActionCommitment}^{\uparrow}$

The $\mathsf{ActionCommitment}^{\uparrow}$ surface realizes the inscription-event action reading of subsection 9462.27.10 as finite NameCert data. It sits after the hard-problem boundary of chapter 1236, the free-will inscription commitment of chapter 592, the forward causal socket of chapter 505, the other-minds locality commitment of chapter 499, and the focused multi-history ledger of chapter 1109. Those siblings supply closure pressure, inscription-event discipline, causal commitment, public other-system evidence, and focused ledger support; this packet binds them into the action-facing route through which a selected inscription becomes a local actualization row.

Definition 1362.1 (ActionCommitment carrier)**.** *An* $\mathsf{ActionCommitment}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, R, L, G, T, C, H, Q, P, N)$$

with the following displayed rows:

1. *I is the inscription-event row, consumed through* $\mathsf{InscriptionEvent}^{\uparrow}$ *and* $\mathsf{FreeWillInscriptionCommitment}^{\uparrow}$*;*
2. *R is the selected route row, naming the finite route by which the event is accepted as the action-facing record rather than as an unselected future row;*
3. *L is the local actualization row, recording that the selected route is read at the local inscription point;*
4. *G is the gap and commitment row, binding the route to* GAP *provenance,* $\mathsf{CausalCommitment}^{\uparrow}$*,* $\mathsf{OtherMindsCommitment}^{\uparrow}$*, and* $\mathsf{HardProblemClosure}^{\uparrow}$ *without adding a hidden agency source;*
5. *T records classifier transport for the inscription, route, local actualization, and gap-commitment rows;*
6. *C records the displayed* Cont *route from focused ledger support through inscription event, selected route, local actualization, and commitment boundary;*
7. *H records componentwise* hsame *transport for I, R, L, G, T, C, P, N;*
8. *Q is the replay row, requiring every downstream action read to replay the displayed route before reading the local NameCert row;*
9. *P is the* Pkg *provenance over* $\mathsf{ActionCommitment}^{\uparrow}$, $\mathsf{HardProblemClosure}^{\uparrow}$, $\mathsf{FreeWillInscriptionCommitment}^{\uparrow}$, $\mathsf{CausalCommitment}^{\uparrow}$, $\mathsf{OtherMindsCommitment}^{\uparrow}$, $\mathsf{FocusedMultiHistLedger}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{ActionCommitment}^{\uparrow}}$ *row.*

The carrier is exactly this packet. It contains no hidden faculty of will, no selected future row outside R, no unledgered agency primitive, no host psychology predicate, and no off-packet causal necessity row.

Lean4 ✓ `BEDC.Derived.ActionCommitmentUp.ActionCommitmentTasteGate single carrier alignment`

Theorem 1362.2 (ActionCommitment NameCert obligations)**.** *For the carrier of Definition 1362.1, the local* $\mathsf{NameCert}_{\mathsf{ActionCommitment}^{\uparrow}}$ *surface consists exactly of carrier exposure for $A = (I, R, L, G, T, C, H, Q, P, N)$, inscription-event accountability for I, selected-route accountability for R, local-actualization accountability for L, gap and sibling-commitment accountability for G, classifier stability through T and H, displayed continuation replay through C and Q, package provenance through P, local naming through N, and non-escape from hidden free-will faculties, selected future rows, and unledgered agency primitives.*

Proof. Project the carrier of Definition 1362.1. The rows $I, R, L, G, T, C, H, Q, P, N$ are the complete displayed inventory before a consumer may read the action commitment.

Read the action-facing content in order. The inscription-event row I supplies the event surface, the selected route row R names the finite route, and the local actualization row L records the inscription point at which that route is read as action.

The gap and commitment row G then attaches the sibling boundaries. $\mathsf{FreeWillInscriptionCommitment}^{\uparrow}$ keeps the event from becoming a hidden faculty, $\mathsf{CausalCommitment}^{\uparrow}$ keeps causal reading on the forward-GAP route, $\mathsf{OtherMindsCommitment}^{\uparrow}$ keeps public agency evidence in locality-cell form, and $\mathsf{HardProblemClosure}^{\uparrow}$ keeps closure pressure exposed as a boundary row.

Finally use T, C, H, Q, P, N. These rows transport, replay, source, and name the same finite packet. Since the carrier has no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 1362.3 (ActionCommitment inscription route)**.** *Every accepted* $\mathsf{ActionCommitment}^{\uparrow}$ *packet routes an action read through the displayed inscription-event path*

$$I, R, L, G, T, C, H, Q, P, N.$$

The route begins with the inscription event, passes through the selected route and local actualization rows, exposes the gap and commitment boundary, and then replays only the displayed transport, continuation, provenance, and local naming rows. It exports no hidden free-will faculty, no selected future row, and no unledgered agency primitive outside that route.

Proof. Begin with the inscription row. The packet contains a single action-facing event coordinate I, and it is read through the inscription-event discipline already used by $\mathsf{FreeWillInscriptionCommitment}^{\uparrow}$.

The route is then selected and localized. The row R names the finite route that becomes public record, while L records the local actualization point. Neither row contains a future selector outside the accepted packet.

Next expose the commitment boundary. The row G records the GAP and sibling-commitment handoff to $\mathsf{CausalCommitment}^{\uparrow}$, $\mathsf{OtherMindsCommitment}^{\uparrow}$, and $\mathsf{HardProblemClosure}^{\uparrow}$ without replacing those siblings by an agency substance.

The structural rows close the route. Componentwise transport, continuation replay, package provenance, and local naming preserve I, R, L, G as displayed rows; because no carrier coordinate names a hidden faculty, selected future row, or unledgered agency primitive, no consumer can extract one from the accepted packet. □

Falsifiable prediction: An accepted ActionCommitmentUp packet cannot export a hidden free-will faculty, selected future row, or unledgered agency primitive outside the displayed inscription-event route.

Independence witness: freewillinscriptioncommitment, causalcommitment, othermindscommitment, hardproblemclosure, focused-multi-hist-ledger: each sibling supplies one boundary of inscription, causality, public other-system evidence, closure pressure, or focused ledger support, but none is bijective to the full inscription-route, local-actualization, gap-commitment, transport, replay, provenance, and NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ActionCommitment}^{\uparrow}}$.

Constructive story: An $\mathsf{ActionCommitment}^{\uparrow}$ packet is generated from an inscription-event row, selected route row, local actualization row, gap and sibling-commitment row, classifier transport, displayed continuation replay, componentwise hsame transport, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ActionCommitment}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1362.1, Definition 1362.2, and Definition 1362.3 bind the finite inscription-event action surface and its non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ActionCommitment}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close a Lean carrier implementation, bridge status, hidden free-will faculty, selected future row, causal necessity row, host psychology predicate, or agency primitive outside the displayed route.

Upgrade path: Obligation closure requires Lean encoding of the carrier and checked theorems for NameCert obligations, inscription-route exactness, and sibling independence.

This hub points the nona tuple packet to its adjacent tuple surfaces, the octa chapter chapter 1365 and the deca chapter chapter 1364.

Chapter 1363

A Concrete Naming Certificate for $\mathsf{BHistNonaTupleNameCert}^{\uparrow}$

The $\mathsf{BHistNonaTupleNameCert}^{\uparrow}$ packet abstracts the shared arity-nine tag-encoded BHist carrier pattern used across a carrier-isomorphism bucket. It is composite over the anchor-stability certificate of chapter 1150, the audit-map family of chapter 807, the BEDC self-substrate packet of chapter 869, the apophatic fixed-point fiber of chapter 1069, and the beta critical-pair packet of chapter 881. Those siblings exhibit the same finite shape: a fixed list of tagged BHist rows, componentwise comparison, displayed hsame transport, displayed Cont replay, provenance, and local naming. This chapter names that carrier-isomorphism surface directly so downstream rows can cite one BEDC-native packet rather than repeating the same arity-nine pattern.

Definition 1363.1 (BHistNonaTupleNameCert carrier)**.** *A* $\mathsf{BHistNonaTupleNameCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_8$ *are the nine tag-encoded carrier rows. Each row is a* BHist *entry whose tag records the local role used by the member chapter and whose payload is read only as a displayed BEDC history component.*
2. H *records componentwise* hsame *transport for* $R_0, \ldots, R_8, C, P, L$ *and no transport row outside the displayed packet.*
3. C *records the displayed* Cont *route that replays row admission, componentwise comparison, transport, provenance readback, and local naming for the same nine-row packet.*
4. P *is the* Pkg *provenance over the arity-nine tag encoder, the five named sibling carrier families,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
5. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistNonaTupleNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a tenth carrier component, a host-side equality test, a bucket-wide rewrite of sibling chapters, or a detached provenance table.

Definition 1363.2 (BHistNonaTupleNameCert classifier)**.** *Two* $\mathsf{BHistNonaTupleNameCert}^{\uparrow}$ *packets*

$$N = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, H, C, P, L)$$

and

$$N' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, H', C', P', L')$$

are classifier-equivalent exactly when each displayed carrier row compares componentwise,

$$\begin{array}{lllll} R_0 \sim R'_0, & R_1 \sim R'_1, & R_2 \sim R'_2, & R_3 \sim R'_3, & R_4 \sim R'_4, \\ R_5 \sim R'_5, & R_6 \sim R'_6, & R_7 \sim R'_7, & R_8 \sim R'_8, & \end{array}$$

the transport rows display the same hsame *routes for those components and for C, P, L, and the replay rows display the same* Cont *route from row admission through local naming. No comparison is available through an omitted component, an untagged payload, or a member-chapter rewrite.*

Theorem 1363.3 (BHistNonaTupleNameCert carrier admission)**.** *Every accepted* BHistNonaTupleNameCert$^{\uparrow}$ *packet admits exactly the carrier rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, H, C, P, L.$$

The nine rows are tag-encoded BHist *components, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the packet.*

Proof. Project the carrier of Definition 1363.1. The definition lists the nine tag-encoded BHist rows and then lists the transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted carrier read lands in exactly the displayed rows, and any proposed tenth component or detached structural table lies outside the accepted surface. □

Lean4 ✓ `BEDC.Derived.BHistNonaTupleNameCertUp.BHistNonaTupleNameCertTasteGate single carrier alignment`

Theorem 1363.4 (BHistNonaTupleNameCert classifier exactness)**.** *For accepted* BHistNonaTupleNameCert$^{\uparrow}$ *packets N and N', the classifier of Definition 1363.2 is exact for the arity-nine carrier surface: it compares the nine tagged* BHist *rows componentwise, compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by bucket membership alone, by a host equality test, or by a hidden isomorphism between member chapters.*

Proof. Start with the classifier definition. It requires one comparison for each of $R_0, \ldots, R_8$, then requires the displayed transport and replay routes to match the same component list.

The provenance and local naming rows are part of the same carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for bucket membership alone, host equality, or hidden chapter isomorphism, the displayed componentwise route is the exact comparison surface. □

Theorem 1363.5 (BHistNonaTupleNameCert componentwise stability)**.** *Componentwise* hsame *transport for a* BHistNonaTupleNameCert$^{\uparrow}$ *packet preserves exactly the nine tagged rows, the replay route, provenance, and local name. Any stable consumer of the carrier must preserve*

$$R_0, \ldots, R_8, H, C, P, L$$

as displayed fields of the same packet before reading a carrier-isomorphism claim.

Proof. Use the H row in Definition 1363.1. It is the only row that records componentwise hsame transport, and its component list is exactly the nine carrier rows together with the replay, provenance, and local naming rows.

The classifier exactness of Definition 1363.4 forces any carrier-isomorphism read to pass through that displayed component list. A consumer that drops a row or adds an unlisted row is therefore no longer reading the accepted packet. □

Theorem 1363.6 (BHistNonaTupleNameCert provenance readback)**.** *The provenance row P of an accepted* BHistNonaTupleNameCert$^{\uparrow}$ *packet reads back only the arity-nine tag encoder, the sibling carrier families named in this chapter, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. It does not read a bucket-wide replacement of chapter 1150, chapter 807, chapter 869, chapter 1069, or chapter 881.*

Proof. Inspect the provenance row in the carrier definition. It records the arity-nine tag encoder, the named sibling carrier families, and the local BEDC support rows.

The row is a readback ledger, not a command to alter any sibling chapter. Since neither the carrier nor the classifier contains a member-chapter replacement coordinate, provenance can source the shared pattern without rewriting any bucket member. □

Theorem 1363.7 (BHistNonaTupleNameCert local naming nonescape)**.** *Every local* NameCert$_{\text{BHistNonaTupleNameCert}}$ *read factors through the displayed packet*

$$N = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, H, C, P, L).$$

The read may expose the arity-nine tag-encoded carrier pattern and its componentwise routes, but it cannot export an untagged carrier, a tenth row, a host-side equality test, or a relocation of existing bucket member chapters into this capstone.

Proof. The local name is the row L of the carrier. By Definition 1363.3, L is read only together with the nine carrier rows and the displayed structural rows.

Use classifier exactness and componentwise stability. They force any carrier-isomorphism read to preserve the same tag-encoded components and the same displayed hsame and Cont routes. Since no untagged carrier, tenth row, host equality test, or member-chapter replacement row appears in the packet, local naming cannot export one. □

Lean4 ✓ `BEDC.Derived.BHistNonaTupleNameCertUp.BHistNonaTupleNameCertLocalNamingNonescape`

Theorem 1363.8 (BHistNonaTupleNameCert adjacent arity isolation)**.** *Any classifier-preserving read from* BHistNonaTupleNameCert$^{\uparrow}$ *to either adjacent tuple surface, the arity-eight packet of chapter 1365 or the arity-ten packet of chapter 1364, must either drop one of*

$$R_0, \ldots, R_8$$

or introduce a row outside the nona carrier. Consequently no bijective carrier correspondence preserves the tag list, componentwise hsame *routes,* Cont *replay, provenance, and local* NameCert *rows simultaneously across the nona packet and either adjacent arity sibling.*

Proof. Project the accepted nona carrier with Definition 1363.3. A classifier-preserving read must carry the nine tagged rows and the structural rows H, C, P, L through the exact classifier of Definition 1363.4.

Componentwise stability then fixes the row inventory. By Definition 1363.5 and Definition 1363.7, the local name may expose only the displayed nona packet; it has no clause that forgets a tagged row or admits an external coordinate.

Compare this fixed inventory with the adjacent tuple surfaces. The octa sibling has only eight tagged carrier rows, so a read into it loses the ninth displayed nona row. The deca sibling has a tenth tagged carrier row, so a read into it adds a coordinate not admitted by the nona carrier. In either direction the purported bijection violates row preservation or the no-extra-coordinate boundary, and therefore cannot preserve tag list, hsame, Cont, provenance, and local naming at once. □

Theorem 1363.9 (BHistNonaTupleNameCert scoped support package)**.** *The carrier admission, classifier exactness, componentwise stability, provenance readback, and local naming nonescape clauses bind the* $\mathsf{BHistNonaTupleNameCert}^{\uparrow}$ *packet exactly to the displayed BEDC support*

$$\mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert},$$

and to the five sibling carrier families named in this chapter: chapter 1150, chapter 807, chapter 869, chapter 1069, and chapter 881. The resulting scope is the arity-nine tag-encoded BHist *packet with its displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not a bucket-wide sibling rewrite, a host-side equality classifier, or a hidden tenth row.*

Proof. Apply Definition 1363.3 to identify the admitted rows and exclude any tenth coordinate. Apply Definition 1363.4 to keep comparison on the nine tagged BHist rows and the displayed structural rows.

Apply Definition 1363.5 to force all stable reads through the same hsame and Cont support. Apply Definition 1363.6 to restrict sourcing to the arity-nine tag encoder, the five sibling carrier families, and the local BHist, hsame, Cont, Pkg, and NameCert rows.

Finally, apply Definition 1363.7. The local NameCert row can expose only that displayed packet, so the scoped package has no route to a bucket-wide sibling rewrite, host-side equality classifier, or hidden tenth row. □

Falsifiable prediction: Any accepted consumer route that reads an untagged row, a tenth carrier row, or bucket membership alone fails one of carrier admission, classifier exactness, componentwise stability, provenance readback, or local naming nonescape.

Independence witness: anchor-stability-certificate, auditmapfamily, bedc-self-substrate, apophatic-fixed-point-fiber, and beta-critical-pair: none is bijective to $\mathsf{BHistNonaTupleNameCert}^{\uparrow}$ because this packet carries all nine tagged rows together with transport, replay, provenance, and local NameCert in one packet, while each sibling supplies only one member-family surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistNonaTupleNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistNonaTupleNameCert}^{\uparrow}$ packet is generated from nine tag-encoded BHist carrier rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row; BEDC.Derived.BHistNonaTupleNameC records the composite TasteGate witness.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BHistNonaTupleNameCert}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1363.1, Definition 1363.2, Definition 1363.3, Definition 1363.4, Definition 1363.5, Definition 1363.6, Definition 1363.7, Definition 1363.8, and Definition 1363.9 bind the arity-nine tag-encoded carrier-isomorphism surface and its exact BEDC support package.

Chapter 1364

A Concrete Naming Certificate for $\mathsf{BHistDecaTupleNameCert}^{\uparrow}$

The $\mathsf{BHistDecaTupleNameCert}^{\uparrow}$ packet extends the carrier-isomorphism capstone of chapter 1363 to the arity-ten tag-encoded BHist surface. It is composite over representative bucket siblings including the anchor-stability certificate of chapter 1150, the audit-map family of chapter 807, the BEDC self-substrate packet of chapter 869, the apophatic fixed-point fiber of chapter 1069, and the beta critical-pair packet of chapter 881. It shares the arity-ten BHist tag encoder and transport/provenance budget with chapter 1368, while fixing positions as tuple rows rather than sequence-indexed rows. The chapter gives the ten-row carrier a single BEDC name so later rows can cite the capstone rather than restating the same tag, comparison, transport, replay, provenance, and local-name schema.

Definition 1364.1 (BHistDecaTupleNameCert carrier)**.** *A* $\mathsf{BHistDecaTupleNameCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_9$ *are the ten tag-encoded carrier rows. Each row is a* BHist *entry whose tag records the local role used by a member chapter and whose payload is read only as a displayed BEDC history component.*
2. H *records componentwise* hsame *transport for* $R_0, \ldots, R_9, C, P, L$ *and no transport row outside the displayed packet.*
3. C *records the displayed* Cont *route that replays row admission, componentwise comparison, transport, provenance readback, and local naming for the same ten-row packet.*
4. P *is the* Pkg *provenance over the arity-ten tag encoder, the named sibling carrier families,* BHist, hsame, Cont, *and* NameCert *rows.*
5. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistDecaTupleNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, an eleventh carrier component, a host-side equality test, a bucket-wide rewrite of sibling chapters, or a detached provenance table.

Definition 1364.2 (BHistDecaTupleNameCert classifier)**.** *Two* $\mathsf{BHistDecaTupleNameCert}^{\uparrow}$ *packets*

$$D = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, H, C, P, L)$$

and

$$D' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, R'_9, H', C', P', L')$$

are classifier-equivalent exactly when each displayed carrier row compares componentwise,

$$\begin{array}{lllll} R_0 \sim R'_0, & R_1 \sim R'_1, & R_2 \sim R'_2, & R_3 \sim R'_3, & R_4 \sim R'_4, \\ R_5 \sim R'_5, & R_6 \sim R'_6, & R_7 \sim R'_7, & R_8 \sim R'_8, & R_9 \sim R'_9, \end{array}$$

the transport rows display the same hsame *routes for those components and for C, P, L, and the replay rows display the same* Cont *route from row admission through local naming. No comparison is available through an omitted component, an untagged payload, or a member-chapter rewrite.*

Theorem 1364.3 (BHistDecaTupleNameCert carrier admission)**.** *Every accepted* BHistDecaTupleNameCert$^{\uparrow}$ *packet admits exactly the carrier rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, H, C, P, L.$$

The ten rows are tag-encoded BHist *components, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the packet.*

Lean4 ✓ `BEDC.Derived.BHistDecaTupleNameCertUp.BHistDecaTupleNameCertCarrierAdmission`

Proof. Project the carrier of Definition 1364.1. The definition lists the ten tag-encoded BHist rows and then lists the transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted carrier read lands in exactly the displayed rows, and any proposed eleventh component or detached structural table lies outside the accepted surface. □

Theorem 1364.4 (BHistDecaTupleNameCert classifier exactness)**.** *For accepted* BHistDecaTupleNameCert$^{\uparrow}$ *packets D and D', the classifier of Definition 1364.2 is exact for the arity-ten carrier surface: it compares the ten tagged* BHist *rows componentwise, compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by bucket membership alone, by a host equality test, or by a hidden isomorphism between member chapters.*

Proof. Start with the classifier definition. It requires one comparison for each of $R_0, \ldots, R_9$, then requires the displayed transport and replay routes to match the same component list.

The provenance and local naming rows are part of the same carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for bucket membership alone, host equality, or hidden chapter isomorphism, the displayed componentwise route is the exact comparison surface. □

Theorem 1364.5 (BHistDecaTupleNameCert scoped support package)**.** *The carrier admission and classifier exactness clauses bind the* BHistDecaTupleNameCert$^{\uparrow}$ *packet to the displayed BEDC support*

BHist, hsame, Cont, Pkg, NameCert,

and to the representative sibling carrier families cited above. The resulting scope is the arity-ten tag-encoded BHist *packet with displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not a bucket-wide sibling rewrite, a host-side equality classifier, or a hidden eleventh row.*

Proof. Apply Definition 1364.3 to identify the admitted rows and exclude any eleventh coordinate. Apply Definition 1364.4 to keep comparison on the ten tagged BHist rows and the displayed structural rows.

The support package is therefore the named BEDC packet itself. Its provenance can source the cited bucket siblings, but no carrier or classifier row rewrites those sibling chapters or replaces their local certificates. □

Falsifiable prediction: Any accepted consumer route that reads an untagged row, an eleventh carrier row, or bucket membership alone fails carrier admission or classifier exactness for $\mathsf{BHistDecaTupleNameCert}^{\uparrow}$.

Independence witness: b-hist-nona-tuple-name-cert and the cited bucket siblings: none is bijective to $\mathsf{BHistDecaTupleNameCert}^{\uparrow}$ because this packet carries ten tagged rows together with transport, replay, provenance, and local NameCert in one packet, while the nona capstone carries only nine tagged rows and each sibling supplies a member-family surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistDecaTupleNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistDecaTupleNameCert}^{\uparrow}$ packet is generated from ten tag-encoded BHist carrier rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BHistDecaTupleNameCert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1364.1, Definition 1364.2, Definition 1364.3, Definition 1364.4, and Definition 1364.5 identify the arity-ten carrier-isomorphism surface and its BEDC support package.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BHistDecaTupleNameCert}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a Lean declaration, standard bridge, member-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistDecaTupleNameCertUp and checked carrier-admission plus classifier-exactness theorems.

Chapter 1365

A Concrete Naming Certificate for $\mathsf{BHistOctaTupleNameCert}^{\uparrow}$

The $\mathsf{BHistOctaTupleNameCert}^{\uparrow}$ packet is a composite over the arity-eight tag-encoded BHist carrier-isomorphism bucket. It sits between the nona and deca capstones of chapter 1363 and chapter 1364, and it cites the same bucket anchors: the anchor-stability certificate of chapter 1150, the audit-map family of chapter 807, the beta critical-pair packet of chapter 881, the eight-row checkpoint surface of chapter 997, and the finite support pattern carried by the neighboring tuple capstones. The chapter gives the eight-row carrier a single BEDC name so consumers can read the shared tag, comparison, transport, replay, provenance, and local-name pattern without treating any sibling as atomic.

Definition 1365.1 (BHistOctaTupleNameCert carrier)**.** *A* $\mathsf{BHistOctaTupleNameCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_7$ *are the eight tag-encoded carrier rows. Each row is a* BHist *entry whose tag records the local carrier role used by a cited bucket sibling and whose payload is read only as a displayed BEDC history component.*
2. H *records componentwise* hsame *transport for* $R_0, \ldots, R_7, C, P, L$ *and no transport row outside the displayed packet.*
3. C *records the displayed* Cont *route that replays row admission, componentwise comparison, transport, provenance readback, and local naming for the same eight-row packet.*
4. P *is the* Pkg *provenance over the arity-eight tag encoder, the cited sibling carrier families,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
5. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistOctaTupleNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a ninth carrier component, a host-side equality test, a bucket-wide rewrite of sibling chapters, or a detached provenance table.

Definition 1365.2 (BHistOctaTupleNameCert classifier)**.** *Two* $\mathsf{BHistOctaTupleNameCert}^{\uparrow}$ *packets*

$$O = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, H, C, P, L)$$

and

$$O' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, H', C', P', L')$$

are classifier-equivalent exactly when each displayed carrier row compares componentwise,

$$\begin{array}{llll} R_0 \sim R'_0, & R_1 \sim R'_1, & R_2 \sim R'_2, & R_3 \sim R'_3, \\ R_4 \sim R'_4, & R_5 \sim R'_5, & R_6 \sim R'_6, & R_7 \sim R'_7, \end{array}$$

the transport rows display the same hsame *routes for those components and for C, P, L, and the replay rows display the same* Cont *route from row admission through local naming. No comparison is available through an omitted component, an untagged payload, or a member-chapter rewrite.*

Theorem 1365.3 (BHistOctaTupleNameCert carrier admission)**.** *Every accepted* BHistOctaTupleNameCert$^{\uparrow}$ *packet admits exactly the carrier rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, H, C, P, L.$$

The eight rows are tag-encoded BHist *components, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the packet.*

Proof. Project the carrier of Definition 1365.1. The definition lists the eight tag-encoded BHist rows and then lists the transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted carrier read lands in exactly the displayed rows, and any proposed ninth component or detached structural table lies outside the accepted surface. □

Lean4 ✓ `BEDC.Derived.BHistOctaTupleNameCertUp.BHistOctaTupleNameCertCarrierAdmission`

Theorem 1365.4 (BHistOctaTupleNameCert classifier exactness)**.** *For accepted* BHistOctaTupleNameCert$^{\uparrow}$ *packets O and O', the classifier of Definition 1365.2 is exact for the arity-eight carrier surface: it compares the eight tagged* BHist *rows componentwise, compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by bucket membership alone, by a host equality test, or by a hidden isomorphism between member chapters.*

Proof. Start with the classifier definition. It requires one comparison for each of $R_0, \ldots, R_7$, then requires the displayed transport and replay routes to match the same component list.

The provenance and local naming rows are part of the same carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for bucket membership alone, host equality, or hidden chapter isomorphism, the displayed componentwise route is the exact comparison surface. □

Theorem 1365.5 (BHistOctaTupleNameCert scoped support package)**.** *The carrier admission and classifier exactness clauses bind the* BHistOctaTupleNameCert$^{\uparrow}$ *packet to the displayed BEDC support*

BHist, hsame, Cont, Pkg, NameCert,

and to the cited sibling carrier families. The resulting scope is the arity-eight tag-encoded BHist *packet with displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not a bucket-wide sibling rewrite, a host-side equality classifier, or a hidden ninth row.*

Proof. Apply Definition 1365.3 to identify the admitted rows and exclude any ninth coordinate. Apply Definition 1365.4 to keep comparison on the eight tagged BHist rows and the displayed structural rows.

The support package is therefore the named BEDC packet itself. Its provenance can source the cited bucket siblings, but no carrier or classifier row rewrites those sibling chapters or replaces their local certificates. □

Falsifiable prediction: Any accepted consumer route that reads an untagged row, a ninth carrier row, or bucket membership alone fails carrier admission or classifier exactness for $\mathsf{BHistOctaTupleNameCert}^{\uparrow}$.

Independence witness: b-hist-nona-tuple-name-cert, b-hist-deca-tuple-name-cert, auditmap-family, anchor-stability-certificate, beta-critical-pair, and reflection-runtime-checkpoint: none is bijective to $\mathsf{BHistOctaTupleNameCert}^{\uparrow}$ because this packet carries exactly eight tagged rows together with transport, replay, provenance, and local NameCert in one packet, while the nona and deca capstones carry different arities and each cited sibling supplies its own member-family surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistOctaTupleNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistOctaTupleNameCert}^{\uparrow}$ packet is generated from eight tag-encoded BHist carrier rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BHistOctaTupleNameCert}^{\uparrow}}$, seed)

Scope closed: Definition 1365.1, Definition 1365.2, Definition 1365.3, Definition 1365.4, and Definition 1365.5 identify the arity-eight carrier-isomorphism surface and its BEDC support package.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BHistOctaTupleNameCert}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a Lean declaration, standard bridge, member-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistOctaTupleNameCertUp and checked carrier-admission plus classifier-exactness theorems.

Chapter 1366

A Concrete Naming Certificate for $\mathsf{BHistHendecaTupleNameCert}^{\uparrow}$

The $\mathsf{BHistHendecaTupleNameCert}^{\uparrow}$ packet is the arity-eleven capstone for the carrier-isomorphism bucket already exhibited by the neighboring tuple chapters chapter 1365, chapter 1363, and chapter 1364. It is composite over the same bucket anchors: the anchor-stability certificate of chapter 1150, the audit-map family of chapter 807, the BEDC self-substrate packet of chapter 869, the apophatic fixed-point fiber of chapter 1069, and the beta critical-pair packet of chapter 881. The chapter gives the eleven-row carrier a single BEDC name so downstream consumers can cite the tag, comparison, transport, replay, provenance, and local-name surface without treating any bucket member as a replacement for another.

Definition 1366.1 (BHistHendecaTupleNameCert carrier)**.** *A* $\mathsf{BHistHendecaTupleNameCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_{10}$ *are the eleven tag-encoded carrier rows. Each row is a* BHist *entry whose tag records the local carrier role used by a cited bucket sibling and whose payload is read only as a displayed BEDC history component.*
2. H *records componentwise* hsame *transport for* $R_0, \ldots, R_{10}, C, P, L$ *and no transport row outside the displayed packet.*
3. C *records the displayed* Cont *route that replays row admission, componentwise comparison, transport, provenance readback, and local naming for the same eleven-row packet.*
4. P *is the* Pkg *provenance over the arity-eleven tag encoder, the cited sibling carrier families,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
5. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistHendecaTupleNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a twelfth carrier component, a host-side equality test, a bucket-wide rewrite of sibling chapters, or a detached provenance table.

Definition 1366.2 (BHistHendecaTupleNameCert classifier)**.** *Two* $\mathsf{BHistHendecaTupleNameCert}^{\uparrow}$ *packets*

$$E = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, H, C, P, L)$$

and

$$E' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, R'_9, R'_{10}, H', C', P', L')$$

are classifier-equivalent exactly when each displayed carrier row compares componentwise,

$$\begin{array}{llllll} R_0 \sim R'_0, & R_1 \sim R'_1, & R_2 \sim R'_2, & R_3 \sim R'_3, & R_4 \sim R'_4, & R_5 \sim R'_5, \\ R_6 \sim R'_6, & R_7 \sim R'_7, & R_8 \sim R'_8, & R_9 \sim R'_9, & R_{10} \sim R'_{10}, & \end{array}$$

the transport rows display the same hsame *routes for those components and for C, P, L, and the replay rows display the same* Cont *route from row admission through local naming. No comparison is available through an omitted component, an untagged payload, or a member-chapter rewrite.*

Theorem 1366.3 (BHistHendecaTupleNameCert obligations)**.** *Every accepted* $\mathsf{BHistHendecaTupleNameCert}^{\uparrow}$ *packet admits exactly the carrier rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, H, C, P, L,$$

and its classifier is exact for that arity-eleven carrier surface. The eleven rows are tag-encoded BHist *components, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the packet.*

Proof. Project the carrier of Definition 1366.1. The definition lists the eleven tag-encoded BHist rows and then lists the transport, continuation, provenance, and local naming rows.

Next read the classifier in Definition 1366.2. It requires one comparison for each displayed carrier row and then uses the same row list for hsame transport, Cont replay, provenance, and local naming.

There is no remaining coordinate in the packet. Thus any accepted carrier read lands in exactly the displayed rows, and any proposed twelfth component, detached structural table, host equality test, or bucket-membership comparison lies outside the accepted surface. □

Theorem 1366.4 (BHistHendecaTuple tag exhaustion)**.** *For a* $\mathsf{BHistHendecaTupleNameCert}^{\uparrow}$ *packet, the tags carried by $R_0, \ldots, R_{10}$ exhaust the carrier rows available to the local* NameCert *interface. A consumer may permute or replay the displayed rows only through the named* hsame *and* Cont *rows H and C; it may not manufacture an unlisted tag, collapse two tags into one bucket witness, or import an additional row from a sibling chapter.*

Proof. The local $\mathsf{NameCert}_{\mathsf{BHistHendecaTupleNameCert}^{\uparrow}}$ row L is part of the displayed carrier, so its reads are bounded by the carrier coordinates named in Definition 1366.1. Those coordinates contain exactly the eleven tagged BHist rows and the structural rows H, C, P, L.

The classifier in Definition 1366.2 repeats the same eleven tags and gives no rule for an omitted tag or a collapsed bucket witness. Transport and replay therefore preserve the displayed tag list rather than extending it. □

Lean4 ✓ `BEDC.Derived.BHistHendecaTupleNameCertUp.BHistHendecaTupleTagExhaustion`

Falsifiable prediction: Any accepted consumer route that reads an untagged row, a twelfth carrier row, or bucket membership alone fails carrier admission, classifier exactness, or tag exhaustion for $\mathsf{BHistHendecaTupleNameCert}^{\uparrow}$.

Independence witness: b-hist-octa-tuple-name-cert, b-hist-nona-tuple-name-cert, b-hist-deca-tuple-name-cert, and the cited bucket siblings: none is bijective to $\mathsf{BHistHendecaTupleNameCert}^{\uparrow}$ because this packet carries eleven tagged rows together with transport, replay, provenance, and

local NameCert in one packet, while the neighboring capstones carry different arities and each sibling supplies only a member-family surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistHendecaTupleNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistHendecaTupleNameCert}^{\uparrow}$ packet is generated from eleven tag-encoded BHist carrier rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BHistHendecaTupleNameCert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1366.1, Definition 1366.2, Definition 1366.3, and Definition 1366.4 identify the arity-eleven carrier-isomorphism surface and its BEDC support package.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BHistHendecaTupleNameCert}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a Lean declaration, standard bridge, member-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistHendecaTupleNameCertUp and checked carrier-obligation plus tag-exhaustion theorems.

Chapter 1367

A Concrete Naming Certificate for $\mathsf{BHistNonaSequenceNameCert}^{\uparrow}$

The $\mathsf{BHistNonaSequenceNameCert}^{\uparrow}$ packet is the sequence-window capstone for the arity-nine carrier-isomorphism bucket. It is anchored by the static nona tuple certificate of chapter 1363, the arity-eight neighbor of chapter 1365, the arity-ten neighbor of chapter 1364, and the arity-eleven neighbor of chapter 1366. The tuple chapters exhibit fixed finite carriers; this chapter names the BEDC-native window that reads the same nine displayed BHist rows together with an order row, componentwise transport, continuation replay, provenance, and local naming.

Definition 1367.1 (BHistNonaSequenceNameCert carrier)**.** *A* $\mathsf{BHistNonaSequenceNameCert}^{\uparrow}$ *carrier is a finite sequence-window packet*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, I, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_8$ *are the nine tag-encoded* BHist *rows admitted by the window. Each row is read as a displayed BEDC history component, and its tag records the local sequence role rather than a host-side position.*
2. I *is the index and order row. It records the finite window order, the first and last admitted positions, and the rule that every sequence read factors through one of* $R_0, \ldots, R_8$*.*
3. H *records componentwise* hsame *transport for* $R_0, \ldots, R_8, I, C, P, L$ *and no transport row outside the displayed packet.*
4. C *records the displayed* Cont *replay from window admission through index preservation, componentwise comparison, transport, provenance readback, and local naming.*
5. P *is the* Pkg *provenance over the nine-row window encoder, the tuple capstone anchors cited above, chapter 807, chapter 1150,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
6. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistNonaSequenceNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a tenth sequence component, a reordered hidden window, a host equality test, an unordered bucket tuple, or a replacement of any tuple capstone chapter.

Definition 1367.2 (BHistNonaSequenceNameCert classifier)**.** *Two* BHistNonaSequenceNameCert$^{\uparrow}$ *packets*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, I, H, C, P, L)$$

and

$$S' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, I', H', C', P', L')$$

are classifier-equivalent exactly when each displayed window row compares componentwise,

$$\begin{aligned} &R_0 \sim R'_0, \quad R_1 \sim R'_1, \quad R_2 \sim R'_2, \quad R_3 \sim R'_3, \quad R_4 \sim R'_4, \\ &R_5 \sim R'_5, \quad R_6 \sim R'_6, \quad R_7 \sim R'_7, \quad R_8 \sim R'_8, \end{aligned}$$

the index rows display the same finite order, the transport rows display the same hsame *routes for those components and for I, C, P, L, and the replay rows display the same* Cont *route from window admission through local naming. No comparison is available through bucket membership alone, an omitted position, an untagged payload, a tuple-chapter rewrite, or a host equality test.*

Theorem 1367.3 (BHistNonaSequenceNameCert window admission)**.** *Every accepted* BHistNonaSequenceNameCe *packet admits exactly the displayed window rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, I, H, C, P, L.$$

The nine rows are tag-encoded BHist *components, I is the only index and order row, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the sequence window.*

Proof. Project the carrier of Definition 1367.1. The definition lists the nine tag-encoded BHist rows, then lists the index, transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted window read lands in exactly the displayed rows, and any proposed tenth component, detached order table, or hidden structural row lies outside the accepted surface. □

Theorem 1367.4 (BHistNonaSequenceNameCert classifier exactness)**.** *For accepted* BHistNonaSequenceNameCert *packets S and S', the classifier of Definition 1367.2 is exact for the arity-nine sequence window: it compares the nine* BHist *rows at matching indices, compares the displayed finite order through I, I', compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by unordered tuple membership, by a hidden permutation, by a detached order table, or by a host equality test.*

Proof. Start with the classifier definition. It requires one comparison for each matching pair R_i, R'_i, requires the index rows to display the same finite order, and requires the displayed transport and replay routes to preserve that same ordered list.

The provenance and local naming rows are part of the same sequence-window carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for unordered tuple membership, hidden permutation, detached order table, or host equality, the displayed indexwise route is the exact comparison surface. □

Theorem 1367.5 (BHistNonaSequenceNameCert index stability)**.** *Componentwise* hsame *transport for a* BHistNonaSequenceNameCert$^{\uparrow}$ *packet preserves the finite order row I together with the nine tagged rows, the replay route, provenance, and local name. A stable carrier-isomorphism read must preserve*

$$R_0, \ldots, R_8, I, H, C, P, L$$

as displayed fields of the same sequence-window packet.

Proof. Use the H row in Definition 1367.1. It is the only row that records componentwise hsame transport, and its component list is exactly the nine carrier rows together with the order, replay, provenance, and local naming rows.

The classifier of Definition 1367.2 repeats the same list and requires the index rows to display the same finite order. A consumer that drops the order row, changes the window order, or adds an unlisted row is therefore no longer reading the accepted packet. □

Theorem 1367.6 (BHistNonaSequenceNameCert provenance readback)**.** *The provenance row P of an accepted* BHistNonaSequenceNameCert$^{\uparrow}$ *packet reads back only the nine-row window encoder, the neighboring tuple capstones, chapter 807, chapter 1150, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. It does not read a bucket-wide replacement of any tuple capstone, audit-map chapter, or anchor-stability chapter.*

Proof. Inspect the provenance row in the carrier definition. It records the nine-row window encoder, the named capstone and support chapters, and the local BEDC support rows.

The row is a readback ledger for the ordered packet, not a command to alter any cited chapter. Since neither the carrier nor the classifier contains a replacement coordinate, provenance can source the shared bucket context without rewriting any member. □

Theorem 1367.7 (BHistNonaSequenceNameCert local naming nonescape)**.** *Every local* NameCert$_{\text{BHistNonaSequenceN}}$ *read factors through the displayed packet*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, I, H, C, P, L).$$

The read may expose the nine-row sequence window, its finite order, and its componentwise routes, but it cannot export an untagged carrier, a tenth row, a host-side equality test, or a relocation of chapter 1363, chapter 1365, chapter 1364, or chapter 1366.

Proof. The local name is the row L of the carrier. By Definition 1367.3, L is read only together with the nine window rows, the index row, and the displayed structural rows.

Use index stability and the classifier definition. They force any carrier-isomorphism read to preserve the same tag-encoded components, the same finite order, and the same displayed hsame and Cont routes. Since no untagged carrier, tenth row, host equality test, or tuple-chapter replacement row appears in the packet, local naming cannot export one. □

Theorem 1367.8 (BHistNonaSequenceNameCert scoped support package)**.** *The window admission, classifier exactness, index stability, provenance readback, and local naming nonescape clauses bind the* BHistNonaSequenceNameCert$^{\uparrow}$ *packet exactly to the displayed BEDC support*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert},$$

to the neighboring tuple capstones chapter 1365, chapter 1363, chapter 1364, and chapter 1366, and to the audit-map and anchor-stability supports of chapter 807 and chapter 1150. The resulting scope is the ordered arity-nine BHist *sequence window with displayed index row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not an unordered bucket tuple, a host-side equality classifier, or a hidden tenth position.*

Proof. Apply Definition 1367.3 to identify the admitted rows and exclude any tenth coordinate. Apply Definition 1367.4 to keep comparison on matching sequence indices, the displayed index row, and the structural rows.

Apply Definition 1367.5 to force all stable reads through the same ordered hsame and Cont support. Apply Definition 1367.6 to restrict sourcing to the nine-row window encoder, the named capstone and support chapters, and the local BHist, hsame, Cont, Pkg, and NameCert rows.

Finally, apply Definition 1367.7. The local NameCert row can expose only that displayed packet, so the scoped package has no route to an unordered bucket tuple, host-side equality classifier, or hidden tenth position. □

Falsifiable prediction: Any accepted consumer route that reads an unordered tuple coordinate, an untagged row, a tenth sequence row, a hidden permutation, bucket membership alone, or an order table detached from I fails window admission, classifier exactness, index stability, provenance readback, or local naming nonescape for $\mathsf{BHistNonaSequenceNameCert}^{\uparrow}$.

Independence witness: b-hist-octa-tuple-name-cert, b-hist-nona-tuple-name-cert, b-hist-deca-tuple-name-cert, b-hist-hendeca-tuple-name-cert, auditmapfamily, and anchor-stability-certificate: none is bijective to $\mathsf{BHistNonaSequenceNameCert}^{\uparrow}$ because this packet carries a nine-row sequence window with an explicit index row, componentwise transport, replay, provenance, and local NameCert, while the cited siblings supply tuple, audit, or anchor surfaces.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistNonaSequenceNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistNonaSequenceNameCert}^{\uparrow}$ packet is generated from nine tag-encoded BHist sequence rows, a finite index row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BHistNonaSequenceNameCert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1367.1, Definition 1367.2, Definition 1367.3, Definition 1367.4, Definition 1367.5, Definition 1367.6, Definition 1367.7, and Definition 1367.8 identify the arity-nine sequence-window carrier surface and its BEDC support package.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BHistNonaSequenceNameCert}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a Lean declaration, standard bridge, tuple-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistNonaSequenceNameCertUp and checked window-admission, classifier-exactness, index-stability, provenance-readback, local-naming, and scoped-support theorems.

Chapter 1368

A Concrete Naming Certificate for $\mathsf{BHistDecaSequenceNameCert}^{\uparrow}$

The $\mathsf{BHistDecaSequenceNameCert}^{\uparrow}$ packet is the ordered arity-ten sequence-window capstone for the carrier-isomorphism bucket. It is composite over the deca tuple certificate of chapter 1364, the nona sequence certificate of chapter 1367, the octa tuple certificate of chapter 1365, the hendeca tuple certificate of chapter 1366, the audit-map family of chapter 807, and the anchor-stability certificate of chapter 1150. The chapter names the BEDC-native window that reads ten displayed BHist rows together with an order row, componentwise transport, continuation replay, provenance, and local naming, without rewriting any member chapter.

Definition 1368.1 (BHistDecaSequenceNameCert carrier)**.** *A* $\mathsf{BHistDecaSequenceNameCert}^{\uparrow}$ *carrier is a finite sequence-window packet*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, I, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_9$ *are the ten tag-encoded* BHist *rows admitted by the window. Each row is read as a displayed BEDC history component, and its tag records the local sequence role rather than a host-side position.*
2. I *is the finite order and index row. It records the window order, the first and last admitted positions, and the rule that every sequence read factors through one of* $R_0, \ldots, R_9$*.*
3. H *records componentwise* hsame *transport for* $R_0, \ldots, R_9, I, C, P, L$ *and no transport row outside the displayed packet.*
4. C *records the displayed* Cont *replay from window admission through index preservation, componentwise comparison, transport, provenance readback, and local naming.*
5. P *is the* Pkg *provenance over the ten-row window encoder, the tuple and sequence capstone anchors cited above, chapter 807, chapter 1150,* BHist, hsame, Cont, *and* NameCert *rows.*
6. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistDecaSequenceNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, an eleventh sequence component, a reordered hidden window, a host equality test, unordered bucket membership alone, or a replacement of any tuple or sequence capstone chapter.

Definition 1368.2 (BHistDecaSequenceNameCert classifier)**.** *Two* BHistDecaSequenceNameCert$^{\uparrow}$ *packets*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, I, H, C, P, L)$$

and

$$S' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, R'_9, I', H', C', P', L')$$

are classifier-equivalent exactly when each displayed window row compares componentwise,

$$\begin{array}{lllll} R_0 \sim R'_0, & R_1 \sim R'_1, & R_2 \sim R'_2, & R_3 \sim R'_3, & R_4 \sim R'_4, \\ R_5 \sim R'_5, & R_6 \sim R'_6, & R_7 \sim R'_7, & R_8 \sim R'_8, & R_9 \sim R'_9, \end{array}$$

the index rows display the same finite order, the transport rows display the same hsame *routes for those components and for I, C, P, L, and the replay rows display the same* Cont *route from window admission through local naming. No comparison is available through hidden permutation, untagged payload, host equality, bucket membership alone, omitted position, tuple-chapter rewrite, or sequence-chapter rewrite.*

Theorem 1368.3 (BHistDecaSequenceNameCert window admission)**.** *Every accepted* BHistDecaSequenceNameCer *packet admits exactly the displayed window rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, I, H, C, P, L.$$

The ten rows are tag-encoded BHist *components, I is the only index and order row, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the sequence window.*

Proof. Project the carrier of Definition 1368.1. The definition lists the ten tag-encoded BHist rows, then lists the index, transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted window read lands in exactly the displayed rows, and any proposed eleventh component, detached order table, or hidden structural row lies outside the accepted surface. □

Theorem 1368.4 (BHistDecaSequenceNameCert classifier exactness)**.** *For accepted* BHistDecaSequenceNameCert$^{\uparrow}$ *packets S and S', the classifier of Definition 1368.2 is exact for the arity-ten sequence window: it compares the ten* BHist *rows at matching indices, compares the displayed finite order through I, I', compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by unordered tuple membership, by a hidden permutation, by a detached order table, by bucket membership alone, by any sibling-chapter rewrite, or by a host equality test.*

Proof. Start with the classifier definition. It requires one comparison for each matching pair R_i, R'_i, requires the index rows to display the same finite order, and requires the displayed transport and replay routes to preserve that same ordered list.

The provenance and local naming rows are part of the same sequence-window carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for unordered tuple membership, hidden permutation, detached order table, bucket membership alone, sibling-chapter rewrite, or host equality, the displayed indexwise route is the exact comparison surface. □

Theorem 1368.5 (BHistDecaSequenceNameCert index stability)**.** *Componentwise* hsame *transport for a* BHistDecaSequenceNameCert$^{\uparrow}$ *packet preserves the finite order row I together with the*

ten tagged rows, the replay route, provenance, and local name. A stable carrier-isomorphism read must preserve

$$R_0, \ldots, R_9, I, H, C, P, L$$

as displayed fields of the same sequence-window packet.

Proof. Use the H row in Definition 1368.1. It is the only row that records componentwise hsame transport, and its component list is exactly the ten carrier rows together with the order, replay, provenance, and local naming rows.

The classifier of Definition 1368.2 repeats the same list and requires the index rows to display the same finite order. A consumer that drops the order row, changes the window order, or adds an unlisted row is therefore no longer reading the accepted packet. □

Theorem 1368.6 (BHistDecaSequenceNameCert provenance readback)**.** *The provenance row P of an accepted* BHistDecaSequenceNameCert$^{\uparrow}$ *packet reads back only the ten-row window encoder, the neighboring tuple and sequence capstones, chapter 807, chapter 1150, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. It does not read a bucket-wide replacement of any tuple capstone, sequence capstone, audit-map chapter, or anchor-stability chapter.*

Proof. Inspect the provenance row in the carrier definition. It records the ten-row window encoder, the named capstone and support chapters, and the local BEDC support rows.

The row is a readback ledger for the ordered packet, not a command to alter any cited chapter. Since neither the carrier nor the classifier contains a replacement coordinate, provenance can source the shared bucket context without rewriting any member. □

Theorem 1368.7 (BHistDecaSequenceNameCert local naming nonescape)**.** *Every local* NameCert$_{\text{BHistDecaSequenceNa}}$ *read factors through the displayed packet*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, I, H, C, P, L).$$

The read may expose the ten-row sequence window, its finite order, and its componentwise routes, but it cannot export an untagged carrier, an eleventh row, a hidden permutation, a host-side equality test, or a relocation of chapter 1364, chapter 1367, chapter 1363, chapter 1365, or chapter 1366.

Proof. The local name is the row L of the carrier. By Definition 1368.3, L is read only together with the ten window rows, the index row, and the displayed structural rows.

Use index stability and the classifier definition. They force any carrier-isomorphism read to preserve the same tag-encoded components, the same finite order, and the same displayed hsame and Cont routes. Since no untagged carrier, eleventh row, hidden permutation, host equality test, or capstone replacement row appears in the packet, local naming cannot export one. □

Theorem 1368.8 (BHistDecaSequenceNameCert scoped support package)**.** *The window admission, classifier exactness, index stability, provenance readback, and local naming nonescape clauses bind the* BHistDecaSequenceNameCert$^{\uparrow}$ *packet exactly to the displayed BEDC support*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert},$$

to the tuple and sequence capstones chapter 1364, chapter 1367, chapter 1363, chapter 1365, and chapter 1366, and to the audit-map and anchor-stability supports of chapter 807 and chapter 1150. The resulting scope is the ordered arity-ten BHist *sequence window with displayed index row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not an unordered bucket tuple, a host-side equality classifier, a hidden permutation, or a hidden eleventh position.*

Proof. Apply Definition 1368.3 to identify the admitted rows and exclude any eleventh coordinate. Apply Definition 1368.4 to keep comparison on matching sequence indices, the displayed index row, and the structural rows.

Apply Definition 1368.5 to force all stable reads through the same ordered hsame and Cont support. Apply Definition 1368.6 to restrict sourcing to the ten-row window encoder, the named capstone and support chapters, and the local BHist, hsame, Cont, Pkg, and NameCert rows.

Finally, apply Definition 1368.7. The local NameCert row can expose only that displayed packet, so the scoped package has no route to an unordered bucket tuple, host-side equality classifier, hidden permutation, or hidden eleventh position. □

Falsifiable prediction: Any accepted consumer route that reads an unordered tuple coordinate, an untagged row, an eleventh sequence row, a hidden permutation, bucket membership alone, an order table detached from I, or a sibling capstone relocation fails window admission, classifier exactness, index stability, provenance readback, or local naming nonescape for $\mathsf{BHistDecaSequenceNameCert}^{\uparrow}$.

Independence witness: b-hist-deca-tuple-name-cert, b-hist-nona-sequence-name-cert, b-hist-nona-tuple-name-cert, b-hist-octa-tuple-name-cert, b-hist-hendeca-tuple-namecert, auditmapfamily, and anchor-stability-certificate: none is bijective to $\mathsf{BHistDecaSequenceNameCert}^{\uparrow}$ because this packet carries ten payload rows plus an order row, componentwise transport, replay, provenance, and local NameCert, while the cited siblings supply sequence, tuple, audit, or anchor surfaces.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistDecaSequenceNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistDecaSequenceNameCert}^{\uparrow}$ packet is generated from ten tag-encoded BHist sequence rows, a finite index row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BHistDecaSequenceNameCert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1368.1, Definition 1368.2, Definition 1368.3, Definition 1368.4, Definition 1368.5, Definition 1368.6, Definition 1368.7, and Definition 1368.8 identify the arity-ten sequence-window carrier surface and its BEDC support package.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BHistDecaSequenceNameCert}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a Lean declaration, standard bridge, tuple-chapter replacement, sequence-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistDecaSequenceNameCertUp and checked window-admission, classifier-exactness, index-stability, provenance-readback, local-naming, and scoped-support theorems.

Chapter 1369

A Concrete Naming Certificate for $\mathsf{BHistDodecaTupleNameCert}^{\uparrow}$

The $\mathsf{BHistDodecaTupleNameCert}^{\uparrow}$ packet is the arity-twelve capstone for the carrier-isomorphism bucket displayed by the neighboring tuple chapters chapter 1365, chapter 1363, chapter 1364, and chapter 1366. It is composite over representative bucket siblings: the anchor-stability certificate of chapter 1150, the audit-map family of chapter 807, the BEDC self-substrate packet of chapter 869, the apophatic fixed-point fiber of chapter 1069, and the beta critical-pair packet of chapter 881. The chapter gives the twelve-row carrier a single BEDC name so downstream consumers can cite the tag, comparison, transport, replay, provenance, and local-name surface without copying the member-local tuple schema.

Definition 1369.1 (BHistDodecaTupleNameCert carrier)**.** *A* $\mathsf{BHistDodecaTupleNameCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_{11}$ *are the twelve tag-encoded carrier rows. Each row is a* BHist *entry whose tag records the local carrier role used by a cited bucket sibling and whose payload is read only as a displayed BEDC history component.*
2. H *records componentwise* hsame *transport for* $R_0, \ldots, R_{11}, C, P, L$ *and no transport row outside the displayed packet.*
3. C *records the displayed* Cont *route that replays row admission, componentwise comparison, transport, provenance readback, and local naming for the same twelve-row packet.*
4. P *is the* Pkg *provenance over the arity-twelve tag encoder, the cited sibling carrier families,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
5. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistDodecaTupleNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a thirteenth carrier component, a host-side equality test, a bucket-wide rewrite of sibling chapters, or a detached provenance table.

Definition 1369.2 (BHistDodecaTupleNameCert classifier)**.** *Two* $\mathsf{BHistDodecaTupleNameCert}^{\uparrow}$ *packets*

$$T = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, H, C, P, L)$$

and

$$T' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, R'_9, R'_{10}, R'_{11}, H', C', P', L')$$

are classifier-equivalent exactly when each displayed carrier row compares componentwise,

$$\begin{array}{llllll} R_0 \sim R'_0, & R_1 \sim R'_1, & R_2 \sim R'_2, & R_3 \sim R'_3, & R_4 \sim R'_4, & R_5 \sim R'_5, \\ R_6 \sim R'_6, & R_7 \sim R'_7, & R_8 \sim R'_8, & R_9 \sim R'_9, & R_{10} \sim R'_{10}, & R_{11} \sim R'_{11}, \end{array}$$

the transport rows display the same hsame *routes for those components and for C, P, L, and the replay rows display the same* Cont *route from row admission through local naming. No comparison is available through an omitted component, an untagged payload, or a member-chapter rewrite.*

Theorem 1369.3 (BHistDodecaTupleNameCert carrier admission)**.** *Every accepted* BHistDodecaTupleNameCert$^{\uparrow}$ *packet admits exactly the carrier rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, H, C, P, L.$$

The twelve rows are tag-encoded BHist *components, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the packet.*

Lean4 ✓ `BEDC.Derived.BHistDodecaTupleNameCertUp.BHistDodecaTupleNameCertCarrierAdmission`

Proof. Project the carrier of Definition 1369.1. The definition lists the twelve tag-encoded BHist rows and then lists the transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted carrier read lands in exactly the displayed rows, and any proposed thirteenth component or detached structural table lies outside the accepted surface. □

Theorem 1369.4 (BHistDodecaTupleNameCert classifier exactness)**.** *For accepted* BHistDodecaTupleNameCert$^{\uparrow}$ *packets T and T', the classifier of Definition 1369.2 is exact for the arity-twelve carrier surface: it compares the twelve tagged* BHist *rows componentwise, compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by bucket membership alone, by a host equality test, or by a hidden isomorphism between member chapters.*

Lean4 ✓ `BEDC.Derived.BHistArity16EventFlowNameCertUp.BHistArity16EventFlowNameCertTasteGate single carrier alignment`

Proof. Start with the classifier definition. It requires one comparison for each of $R_0, \ldots, R_{11}$, then requires the displayed transport and replay routes to match the same component list.

The provenance and local naming rows are part of the same carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for bucket membership alone, host equality, or hidden chapter isomorphism, the displayed componentwise route is the exact comparison surface. □

Theorem 1369.5 (BHistDodecaTupleNameCert scoped support package)**.** *The carrier admission and classifier exactness clauses bind the* BHistDodecaTupleNameCert$^{\uparrow}$ *packet to the displayed BEDC support*

BHist, hsame, Cont, Pkg, NameCert,

and to the representative sibling carrier families cited above. The resulting scope is the arity-twelve tag-encoded BHist *packet with displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not a bucket-wide sibling rewrite, a host-side equality classifier, or a hidden thirteenth row.*

Proof. Apply Definition 1369.3 to identify the admitted rows and exclude any thirteenth coordinate. Apply Definition 1369.4 to keep comparison on the twelve tagged BHist rows and the displayed structural rows.

The support package is therefore the named BEDC packet itself. Its provenance can source the cited bucket siblings, but no carrier or classifier row rewrites those sibling chapters or replaces their local certificates. □

Falsifiable prediction: Any accepted consumer route that reads an untagged row, a thirteenth carrier row, or bucket membership alone fails carrier admission or classifier exactness for $\mathsf{BHistDodecaTupleNameCert}^{\uparrow}$.

Independence witness: b-hist-octa-tuple-name-cert, b-hist-nona-tuple-name-cert, b-hist-deca-tuple-name-cert, b-hist-hendeca-tuple-name-cert, and the cited bucket siblings: none is bijective to $\mathsf{BHistDodecaTupleNameCert}^{\uparrow}$ because this packet carries twelve tagged rows together with transport, replay, provenance, and local NameCert in one packet, while the neighboring capstones carry different arities and each sibling supplies only a member-family surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistDodecaTupleNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistDodecaTupleNameCert}^{\uparrow}$ packet is generated from twelve tag-encoded BHist carrier rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BHistDodecaTupleNameCert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1369.1, Definition 1369.2, Definition 1369.3, Definition 1369.4, and Definition 1369.5 identify the arity-twelve carrier-isomorphism surface and its BEDC support package.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BHistDodecaTupleNameCert}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a Lean declaration, standard bridge, member-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistDodecaTupleNameCertUp and checked carrier-admission plus classifier-exactness theorems.

Chapter 1370

A Concrete Naming Certificate for $\mathsf{BHistArity13TupleNameCert}^{\uparrow}$

The $\mathsf{BHistArity13TupleNameCert}^{\uparrow}$ packet is the arity-thirteen capstone for the carrier-isomorphism bucket displayed by the neighboring tuple chapters chapter 1365, chapter 1363, chapter 1364, chapter 1366, and chapter 1369. It is composite over representative bucket siblings including $\mathsf{AuditMapRouteCompiler}^{\uparrow}$ from chapter 834, $\mathsf{AnalogyCertificateGate}^{\uparrow}$ from chapter 1092, $\mathsf{AxisCarryDiamondRoute}^{\uparrow}$ from chapter 1118, $\mathsf{CompressionLedgerFunctor}^{\uparrow}$ from chapter 1162, $\mathsf{FiniteObservationRefutation}^{\uparrow}$ from chapter 1169, and $\mathsf{FocusedMultiHistLedger}^{\uparrow}$ from chapter 1109. The chapter gives the thirteen-row carrier a single BEDC name so downstream consumers can cite the tag, comparison, transport, replay, provenance, and local-name surface without copying the member-local tuple schema.

Definition 1370.1 (BHistArity13TupleNameCert carrier)**.** *A* $\mathsf{BHistArity13TupleNameCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_{12}$ *are the thirteen tag-encoded carrier rows. Each row is a* BHist *entry whose tag records the local carrier role used by a cited bucket sibling and whose payload is read only as a displayed BEDC history component.*
2. H *records componentwise* hsame *transport for* $R_0, \ldots, R_{12}, C, P, L$ *and no transport row outside the displayed packet.*
3. C *records the displayed* Cont *route that replays row admission, componentwise comparison, transport, provenance readback, and local naming for the same thirteen-row packet.*
4. P *is the* Pkg *provenance over the arity-thirteen tag encoder, the cited tuple capstones, the representative bucket siblings named above,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
5. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistArity13TupleNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a fourteenth carrier component, a host-side equality test, a bucket-wide rewrite of sibling chapters, or a detached provenance table.

Definition 1370.2 (BHistArity13TupleNameCert classifier)**.** *Two* $\mathsf{BHistArity13TupleNameCert}^{\uparrow}$ *packets*

$$T = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, H, C, P, L)$$

and

$$T' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, R'_9, R'_{10}, R'_{11}, R'_{12}, H', C', P', L')$$

are classifier-equivalent exactly when each displayed carrier row compares componentwise,

$$\begin{aligned}
&R_0 \sim R'_0, \quad R_1 \sim R'_1, \quad R_2 \sim R'_2, \quad R_3 \sim R'_3, \quad R_4 \sim R'_4, \quad R_5 \sim R'_5,\\
&R_6 \sim R'_6, \quad R_7 \sim R'_7, \quad R_8 \sim R'_8, \quad R_9 \sim R'_9, \quad R_{10} \sim R'_{10}, \quad R_{11} \sim R'_{11},\\
&R_{12} \sim R'_{12},
\end{aligned}$$

the transport rows display the same hsame *routes for those components and for C, P, L, and the replay rows display the same* Cont *route from row admission through local naming. No comparison is available through an omitted component, an untagged payload, or a member-chapter rewrite.*

Theorem 1370.3 (BHistArity13TupleNameCert carrier admission)**.** *Every accepted* BHistArity13TupleNameCert$^{\uparrow}$ *packet admits exactly the carrier rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, H, C, P, L.$$

The thirteen rows are tag-encoded BHist *components, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the packet.*

Lean4 ✓ `BEDC.Derived.BHistArity13TupleNameCertUp.BHistArity13TupleNameCertCarrierAdmission`

Proof. Project the carrier of Definition 1370.1. The definition lists the thirteen tag-encoded BHist rows and then lists the transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted carrier read lands in exactly the displayed rows, and any proposed fourteenth component or detached structural table lies outside the accepted surface. □

Theorem 1370.4 (BHistArity13TupleNameCert classifier exactness)**.** *For accepted* BHistArity13TupleNameCert$^{\uparrow}$ *packets T and T', the classifier of Definition 1370.2 is exact for the arity-thirteen carrier surface: it compares the thirteen tagged* BHist *rows componentwise, compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by bucket membership alone, by a host equality test, or by a hidden isomorphism between member chapters.*

Proof. Start with the classifier definition. It requires one comparison for each of $R_0, \ldots, R_{12}$, then requires the displayed transport and replay routes to match the same component list.

The provenance and local naming rows are part of the same carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for bucket membership alone, host equality, or hidden chapter isomorphism, the displayed componentwise route is the exact comparison surface. □

Theorem 1370.5 (BHistArity13TupleNameCert tag exhaustion)**.** *For an accepted* BHistArity13TupleNameCert$^{\uparrow}$ *packet, the tags carried by $R_0, \ldots, R_{12}$ exhaust the carrier rows available to the local* NameCert *interface. Any consumer may transport or replay these rows only through the displayed H and C rows, and cannot manufacture an unlisted tag, collapse two tags into one bucket witness, import a carrier row from a sibling capstone, or read a fourteenth carrier component.*

Proof. Project the carrier of Definition 1370.1. The carrier has exactly the thirteen tag-encoded BHist rows together with H, C, P, L, and Definition 1370.3 identifies this displayed list as the whole accepted row inventory.

The transport and replay access paths are therefore already fixed by H and C. No consumer can introduce another tag or merge two tags into a single bucket witness, because such a move would require an additional carrier row or a non-displayed transport clause.

Finally apply Definition 1370.4. Every public comparison remains componentwise over the same thirteen tags and the same displayed structural rows, so sibling capstones cannot contribute hidden carrier rows and no fourteenth component is readable through the local NameCert surface. □

Theorem 1370.6 (BHistArity13TupleNameCert scoped support package)**.** *The carrier admission and classifier exactness clauses bind the* BHistArity13TupleNameCert$^{\uparrow}$ *packet to the displayed BEDC support*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert},$$

to the tuple capstones from arity eight through arity twelve, and to the representative bucket members AuditMapRouteCompiler$^{\uparrow}$*,* AnalogyCertificateGate$^{\uparrow}$*,* AxisCarryDiamondRoute$^{\uparrow}$*,* CompressionLedgerFunctor$^{\uparrow}$*,* FiniteObservationRefutation$^{\uparrow}$*, and* FocusedMultiHistLedger$^{\uparrow}$*. The resulting scope is the arity-thirteen tag-encoded* BHist *packet with displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not a bucket-wide sibling rewrite, a host-side equality classifier, or a hidden fourteenth row.*

Proof. Apply Definition 1370.3 to identify the admitted rows and exclude any fourteenth coordinate. Apply Definition 1370.4 to keep comparison on the thirteen tagged BHist rows and the displayed structural rows.

Apply Definition 1370.5 to rule out unlisted tags, row fusion, sibling-carrier imports, and hidden components at the local NameCert interface.

The support package is therefore the named BEDC packet itself. Its provenance can source the cited tuple capstones and representative bucket members, but no carrier or classifier row rewrites those sibling chapters or replaces their local certificates. □

Falsifiable prediction: Any accepted consumer route that reads an untagged row, a fourteenth carrier row, bucket membership alone, a provenance table detached from P, or a sibling-capstone rewrite fails carrier admission or classifier exactness for BHistArity13TupleNameCert$^{\uparrow}$.

Independence witness: b-hist-octa-tuple-name-cert, b-hist-nona-tuple-name-cert, b-hist-deca-tuple-name-cert, b-hist-hendeca-tuple-name-cert, and b-hist-dodeca-tuple-name-cert: none is bijective to BHistArity13TupleNameCert$^{\uparrow}$ because this packet carries thirteen tagged rows together with transport, replay, provenance, and local NameCert in one packet, while the neighboring capstones carry different arities and each sibling supplies only a member-family surface.

Closure status for NameCert$_{\mathsf{BHistArity13TupleNameCert}^{\uparrow}}$**.**

Constructive story: A BHistArity13TupleNameCert$^{\uparrow}$ packet is generated from thirteen tag-encoded BHist carrier rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{BHistArity13TupleNameCert}^{\uparrow}}$, seed)

Scope closed: Definition 1370.1, Definition 1370.2, Definition 1370.3, Definition 1370.4, Definition 1370.5, and Definition 1370.6 identify the arity-thirteen carrier-isomorphism surface and its BEDC support package.

Formal verification: FormalStatus(NameCert$_{\mathsf{BHistArity13TupleNameCert}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a Lean declaration, standard bridge, member-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistArity13TupleNameCertUp and checked carrier-admission plus classifier-exactness theorems.

Chapter 1371

A Concrete Naming Certificate for $\mathsf{BHistArity13SequenceNameCert}^{\uparrow}$

The $\mathsf{BHistArity13SequenceNameCert}^{\uparrow}$ packet is the ordered arity-thirteen sequence capstone for the carrier-isomorphism bucket. It is composite over the sequence-window certificates of chapter 1367, chapter 1368, and chapter 1377, together with the unordered arity-thirteen tuple packet of chapter 1370. It also reads representative bucket members $\mathsf{AuditMapRouteCompiler}^{\uparrow}$ from chapter 834, $\mathsf{AnalogyCertificateGate}^{\uparrow}$ from chapter 1092, $\mathsf{AxisCarryDiamondRoute}^{\uparrow}$ from chapter 1118, $\mathsf{CompressionLedgerFunctor}^{\uparrow}$ from chapter 1162, $\mathsf{FiniteObservationRefutation}^{\uparrow}$ from chapter 1169, and $\mathsf{FocusedMultiHistLedger}^{\uparrow}$ from chapter 1109. The chapter gives downstream consumers a single BEDC name for the ordered thirteen-row surface instead of requiring them to cite lower-arity sequence windows or the unordered tuple packet.

Definition 1371.1 (BHistArity13SequenceNameCert carrier)**.** *A* $\mathsf{BHistArity13SequenceNameCert}^{\uparrow}$ *carrier is a finite sequence-window packet*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, I, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_{12}$ *are the thirteen tag-encoded* BHist *rows admitted by the ordered window. Each row is read as a displayed BEDC history component, and its tag records the local sequence role rather than a host-side position.*
2. I *is the finite sequence index and order row. It records the first admitted position, the last admitted position, the successor route through all thirteen entries, and the rule that every sequence read factors through exactly one of* $R_0, \ldots, R_{12}$.
3. H *records componentwise* hsame *transport for* $R_0, \ldots, R_{12}, I, C, P, L$ *and no transport row outside the displayed packet.*
4. C *records the displayed* Cont *replay from window admission through index preservation, componentwise comparison, transport, provenance readback, and local naming.*
5. P *is the* Pkg *provenance over the thirteen-row sequence encoder, the sequence and tuple capstones cited above, the representative bucket members cited above,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
6. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistArity13SequenceNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a fourteenth sequence component, a hidden permutation, an order table detached from I, unordered bucket membership alone, a host equality test, or a replacement of any tuple or sequence capstone chapter.

Definition 1371.2 (BHistArity13SequenceNameCert classifier)**.** *Two* BHistArity13SequenceNameCert$^{\uparrow}$ *packets*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, I, H, C, P, L)$$

and

$$S' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, R'_9, R'_{10}, R'_{11}, R'_{12}, I', H', C', P', L')$$

are classifier-equivalent exactly when each displayed sequence row compares componentwise,

$$\begin{aligned}
&R_0 \sim R'_0, \quad R_1 \sim R'_1, \quad R_2 \sim R'_2, \quad R_3 \sim R'_3, \quad R_4 \sim R'_4, \quad R_5 \sim R'_5,\\
&R_6 \sim R'_6, \quad R_7 \sim R'_7, \quad R_8 \sim R'_8, \quad R_9 \sim R'_9, \quad R_{10} \sim R'_{10}, \quad R_{11} \sim R'_{11},\\
&R_{12} \sim R'_{12},
\end{aligned}$$

the index rows display the same finite order, the transport rows display the same hsame *routes for those components and for I, C, P, L, and the replay rows display the same* Cont *route from ordered window admission through local naming. No comparison is available through an omitted position, an untagged payload, unordered tuple membership, hidden permutation, sibling-capstone rewrite, or host equality.*

Theorem 1371.3 (BHistArity13SequenceNameCert carrier admission)**.** *Every accepted* BHistArity13SequenceNam *packet admits exactly the displayed rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, I, H, C, P, L.$$

The thirteen rows are tag-encoded BHist *components, I is the only finite sequence index and order row, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the sequence window.*

Lean4 ✓ `BEDC.Derived.BHistArity13SequenceNameCertUp.BHistArity13SequenceNameCert single carrier alignment`

Proof. Project the carrier of Definition 1371.1. The definition lists the thirteen tag-encoded BHist rows, then lists the index, transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted window read lands in exactly the displayed rows, and any proposed fourteenth component, detached order table, hidden permutation, or off-packet structural row lies outside the accepted surface. □

Theorem 1371.4 (BHistArity13SequenceNameCert classifier exactness)**.** *For accepted* BHistArity13SequenceName *packets S and S', the classifier of Definition 1371.2 is exact for the arity-thirteen ordered sequence surface: it compares the thirteen* BHist *rows at matching indices, compares the displayed finite order through I, I', compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by unordered tuple membership, hidden permutation, detached order table, sibling-capstone rewrite, bucket membership alone, or host equality.*

Proof. Start with the classifier definition. It requires one comparison for each matching pair R_i, R'_i, requires the index rows to display the same finite order, and requires the displayed transport and replay routes to preserve that same ordered list.

The provenance and local naming rows are part of the same sequence-window carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for unordered tuple membership, hidden permutation, detached order table, sibling-capstone rewrite, bucket membership alone, or host equality, the displayed indexwise route is the exact comparison surface. □

Theorem 1371.5 (BHistArity13SequenceNameCert index exhaustion)**.** *For an accepted* BHistArity13SequenceNam *packet, the index row I exhausts the orderable positions readable by the local* NameCert *interface. Every stable carrier-isomorphism read preserves*

$$R_0, \ldots, R_{12}, I, H, C, P, L$$

as displayed fields of the same sequence-window packet, and no consumer can manufacture an omitted position, erase the order row, collapse two positions into unordered tuple membership, or read a fourteenth sequence component.

Proof. Use the I and H rows in Definition 1371.1. The index row displays the finite order for exactly thirteen entries, and the transport row records componentwise hsame transport for exactly those entries together with the replay, provenance, and local naming rows.

The classifier of Definition 1371.2 repeats the same ordered list and requires the index rows to display the same finite order. A consumer that omits a position, erases I, collapses positions into unordered tuple membership, or adds a fourteenth row is therefore no longer reading the accepted packet. □

Theorem 1371.6 (BHistArity13SequenceNameCert tag exhaustion)**.** *For an accepted* BHistArity13SequenceNameC *packet, the tags carried by $R_0, \ldots, R_{12}$ exhaust the sequence rows available to the local* NameCert *interface. Any consumer may transport or replay these rows only through the displayed I, H, and C rows, and cannot manufacture an unlisted tag, collapse two tags into one bucket witness, import a carrier row from a sibling capstone, alter the displayed order, or read a fourteenth sequence component.*

Proof. Project the carrier of Definition 1371.1. The carrier has exactly the thirteen tag-encoded BHist rows together with I, H, C, P, L, and Definition 1371.3 identifies this displayed list as the whole accepted row inventory.

The index, transport, and replay access paths are therefore already fixed by I, H, and C. No consumer can introduce another tag, change the displayed order, or merge two tags into a single bucket witness, because such a move would require an additional carrier row or a non-displayed structural clause.

Finally apply Definition 1371.4. Every public comparison remains indexwise over the same thirteen tags and the same displayed structural rows, so sibling capstones cannot contribute hidden carrier rows and no fourteenth component is readable through the local NameCert surface. □

Theorem 1371.7 (BHistArity13SequenceNameCert scoped support package)**.** *The carrier admission, classifier exactness, index exhaustion, and tag exhaustion clauses bind the* BHistArity13SequenceNameCert$^{\uparrow}$ *packet exactly to the displayed BEDC support*

BHist, hsame, Cont, Pkg, NameCert,

to the ordered sequence capstones chapter 1367, chapter 1368, and chapter 1377, to the unordered arity-thirteen tuple capstone chapter 1370, and to the representative bucket members AuditMapRouteCompiler$^{\uparrow}$, AnalogyCertificateGate$^{\uparrow}$, AxisCarryDiamondRoute$^{\uparrow}$, CompressionLedgerFunctor$^{\uparrow}$, FiniteObservationRefutation$^{\uparrow}$, *and* FocusedMultiHistLedger$^{\uparrow}$. *The resulting scope is the ordered arity-thirteen* BHist *sequence window with displayed index row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not an unordered bucket tuple, a host-side equality classifier, a hidden permutation, or a hidden fourteenth position.*

Proof. Apply Definition 1371.3 to identify the admitted rows and exclude any fourteenth coordinate. Apply Definition 1371.4 to keep comparison on matching sequence indices, the displayed index row, and the structural rows.

Apply Definition 1371.5 to force all stable reads through the same ordered hsame and Cont support. Apply Definition 1371.6 to rule out unlisted tags, order changes, row fusion, sibling-carrier imports, and hidden components at the local NameCert interface. The cited sequence capstones and the arity-thirteen tuple packet can source the provenance context, but no carrier or classifier row rewrites those sibling chapters or replaces their local certificates.

The support package is therefore the named BEDC packet itself. Its local NameCert row exposes only the displayed thirteen-row sequence surface, so the scoped package has no route to an unordered bucket tuple, host-side equality classifier, hidden permutation, or hidden fourteenth position. □

Falsifiable prediction: Any accepted consumer route that reads unordered tuple membership as the classifier, an untagged row, a hidden permutation, a fourteenth sequence row, a host equality classifier, an order table detached from I, an unlisted tag, or a sibling capstone rewrite fails carrier admission, classifier exactness, index exhaustion, or tag exhaustion for BHistArity13SequenceNameCert$^{\uparrow}$.

Independence witness: b-hist-nona-sequence-name-cert, b-hist-deca-sequence-name-cert, b-hist-hendeca-sequence-name-cert, and b-hist-arity13-tuple-namecert: none is bijective to BHistArity13SequenceNameCer because this packet carries thirteen ordered payload rows plus an index row, componentwise transport, replay, provenance, and local NameCert, while the cited siblings supply lower-arity sequence windows or an unordered arity-thirteen tuple surface.

Closure status for NameCert$_{\text{BHistArity13SequenceNameCert}^{\uparrow}}$.

Constructive story: A BHistArity13SequenceNameCert$^{\uparrow}$ packet is generated from thirteen tag-encoded BHist sequence rows, a finite index row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BHistArity13SequenceNameCert}^{\uparrow}}$, seed)

Scope closed: Definition 1371.1, Definition 1371.2, Definition 1371.3, Definition 1371.4, Definition 1371.5, Definition 1371.6, and Definition 1371.7 identify the arity-thirteen sequence-window carrier surface and its BEDC support package.

Formal verification: FormalStatus(NameCert$_{\text{BHistArity13SequenceNameCert}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a standard bridge, tuple-chapter replacement, sequence-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires checked classifier-exactness, index-exhaustion, tag-exhaustion, and scoped-support theorems for BEDC.Derived.BHistArity13SequenceNameCertUp.

Chapter 1372

A Concrete Naming Certificate for $\mathsf{BHistArity14SequenceNameCert}^{\uparrow}$

The $\mathsf{BHistArity14SequenceNameCert}^{\uparrow}$ packet is the ordered arity-fourteen sequence capstone for the carrier-isomorphism bucket. It is composite over the sequence-window certificates of chapter 1367, chapter 1368, chapter 1377, and chapter 1371, together with the unordered arity-thirteen tuple packet of chapter 1370. It also reads representative bucket members $\mathsf{AuditMapRouteCompiler}^{\uparrow}$ from chapter 834, $\mathsf{AnalogyCertificateGate}^{\uparrow}$ from chapter 1092, $\mathsf{AxisCarryDiamondRoute}^{\uparrow}$ from chapter 1118, $\mathsf{CompressionLedgerFunctor}^{\uparrow}$ from chapter 1162, $\mathsf{FiniteObservationRefutation}^{\uparrow}$ from chapter 1169, and $\mathsf{FocusedMultiHistLedger}^{\uparrow}$ from chapter 1109. The chapter gives downstream consumers a single BEDC name for the ordered fourteen-row surface instead of requiring them to cite lower-arity sequence windows or the unordered tuple packet.

Definition 1372.1 (BHistArity14SequenceNameCert carrier)**.** *A* $\mathsf{BHistArity14SequenceNameCert}^{\uparrow}$ *carrier is a finite sequence-window packet*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, R_{13}, I, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_{13}$ *are the fourteen tag-encoded* BHist *rows admitted by the ordered window. Each row is read as a displayed BEDC history component, and its tag records the local sequence role rather than a host-side position.*
2. I *is the finite sequence index and order row. It records the first admitted position, the last admitted position, the successor route through all fourteen entries, and the rule that every sequence read factors through exactly one of* $R_0, \ldots, R_{13}$.
3. H *records componentwise* hsame *transport for* $R_0, \ldots, R_{13}, I, C, P, L$ *and no transport row outside the displayed packet.*
4. C *records the displayed* Cont *replay from window admission through index preservation, componentwise comparison, transport, provenance readback, and local naming.*
5. P *is the* Pkg *provenance over the fourteen-row sequence encoder, the sequence and tuple capstones cited above, the representative bucket members cited above,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
6. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistArity14SequenceNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a fifteenth sequence component, a hidden permutation, an order table detached from I, unordered bucket membership alone, a host equality test, or a replacement of any tuple or sequence capstone chapter.

Definition 1372.2 (BHistArity14SequenceNameCert classifier)**.** *Two* BHistArity14SequenceNameCert$^{\uparrow}$ *packets*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, R_{13}, I, H, C, P, L)$$

and

$$S' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, R'_9, R'_{10}, R'_{11}, R'_{12}, R'_{13}, I', H', C', P', L')$$

are classifier-equivalent exactly when each displayed sequence row compares componentwise,

$$\begin{aligned}
&R_0 \sim R'_0, \quad R_1 \sim R'_1, \quad R_2 \sim R'_2, \quad R_3 \sim R'_3, \quad R_4 \sim R'_4, \quad R_5 \sim R'_5,\\
&R_6 \sim R'_6, \quad R_7 \sim R'_7, \quad R_8 \sim R'_8, \quad R_9 \sim R'_9, \quad R_{10} \sim R'_{10}, \quad R_{11} \sim R'_{11},\\
&R_{12} \sim R'_{12}, \quad R_{13} \sim R'_{13},
\end{aligned}$$

the index rows display the same finite order, the transport rows display the same hsame *routes for those components and for I, C, P, L, and the replay rows display the same* Cont *route from ordered window admission through local naming. No comparison is available through an omitted position, an untagged payload, unordered tuple membership, hidden permutation, sibling-capstone rewrite, or host equality.*

Theorem 1372.3 (BHistArity14SequenceNameCert carrier admission)**.** *Every accepted* BHistArity14SequenceNam *packet admits exactly the displayed rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, R_{13}, I, H, C, P, L.$$

The fourteen rows are tag-encoded BHist *components, I is the only finite sequence index and order row, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the sequence window.*

Lean4 ✓ `BEDC.Derived.BHistArity14SequenceNameCertUp.BHistArity14SequenceNameCertCarrierAdmission`

Proof. Project the carrier of Definition 1372.1. The definition lists the fourteen tag-encoded BHist rows, then lists the index, transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted window read lands in exactly the displayed rows, and any proposed fifteenth component, detached order table, hidden permutation, or off-packet structural row lies outside the accepted surface. □

Theorem 1372.4 (BHistArity14SequenceNameCert classifier exactness)**.** *For accepted* BHistArity14SequenceName *packets S and S', the classifier of Definition 1372.2 is exact for the arity-fourteen ordered sequence surface: it compares the fourteen* BHist *rows at matching indices, compares the displayed finite order through I, I', compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by unordered tuple membership, hidden permutation, detached order table, sibling-capstone rewrite, bucket membership alone, or host equality.*

Lean4 ✓ `BEDC.Derived.BHistArity14SequenceNameCertUp.BHistArity14SequenceNameCertClassifier exactness`

Proof. Start with the classifier definition. It requires one comparison for each matching pair R_i, R'_i, requires the index rows to display the same finite order, and requires the displayed transport and replay routes to preserve that same ordered list.

The provenance and local naming rows are part of the same sequence-window carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for unordered tuple membership, hidden permutation, detached order table, sibling-capstone rewrite, bucket membership alone, or host equality, the displayed indexwise route is the exact comparison surface. □

Theorem 1372.5 (BHistArity14SequenceNameCert index exhaustion)**.** *For an accepted* BHistArity14SequenceNam *packet, the index row I exhausts the orderable positions readable by the local* NameCert *interface. Every stable carrier-isomorphism read preserves*

$$R_0, \ldots, R_{13}, I, H, C, P, L$$

as displayed fields of the same sequence-window packet, and no consumer can manufacture an omitted position, erase the order row, collapse two positions into unordered tuple membership, or read a fifteenth sequence component.

Proof. Use the I and H rows in Definition 1372.1. The index row displays the finite order for exactly fourteen entries, and the transport row records componentwise hsame transport for exactly those entries together with the replay, provenance, and local naming rows.

The classifier of Definition 1372.2 repeats the same ordered list and requires the index rows to display the same finite order. A consumer that omits a position, erases I, collapses positions into unordered tuple membership, or adds a fifteenth row is therefore no longer reading the accepted packet. □

Theorem 1372.6 (BHistArity14SequenceNameCert tag exhaustion)**.** *For an accepted* BHistArity14SequenceNameC *packet, the tags carried by $R_0, \ldots, R_{13}$ exhaust the sequence rows available to the local* NameCert *interface. Any consumer may transport or replay these rows only through the displayed I, H, and C rows, and cannot manufacture an unlisted tag, collapse two tags into one bucket witness, import a carrier row from a sibling capstone, alter the displayed order, or read a fifteenth sequence component.*

Proof. Project the carrier of Definition 1372.1. The carrier has exactly the fourteen tag-encoded BHist rows together with I, H, C, P, L, and Definition 1372.3 identifies this displayed list as the whole accepted row inventory.

The index, transport, and replay access paths are therefore already fixed by I, H, and C. No consumer can introduce another tag, change the displayed order, or merge two tags into a single bucket witness, because such a move would require an additional carrier row or a non-displayed structural clause.

Finally apply Definition 1372.4. Every public comparison remains indexwise over the same fourteen tags and the same displayed structural rows, so sibling capstones cannot contribute hidden carrier rows and no fifteenth component is readable through the local NameCert surface. □

Theorem 1372.7 (BHistArity14SequenceNameCert scoped support package)**.** *The carrier admission, classifier exactness, index exhaustion, and tag exhaustion clauses bind the* BHistArity14SequenceNameCert$^{\uparrow}$ *packet exactly to the displayed BEDC support*

BHist, hsame, Cont, Pkg, NameCert,

to the ordered sequence capstones chapter 1367, chapter 1368, chapter 1377, and chapter 1371, to the unordered arity-thirteen tuple capstone chapter 1370, and to the representative bucket members AuditMapRouteCompiler$^{\uparrow}$, AnalogyCertificateGate$^{\uparrow}$, AxisCarryDiamondRoute$^{\uparrow}$, CompressionLedgerFunctor$^{\uparrow}$, FiniteObservationRefutation$^{\uparrow}$, *and* FocusedMultiHistLedger$^{\uparrow}$. *The resulting scope is the ordered arity-fourteen* BHist *sequence window with displayed index row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not an unordered bucket tuple, a host-side equality classifier, a hidden permutation, or a hidden fifteenth position.*

Proof. Apply Definition 1372.3 to identify the admitted rows and exclude any fifteenth coordinate. Apply Definition 1372.4 to keep comparison on matching sequence indices, the displayed index row, and the structural rows.

Apply Definition 1372.5 to force all stable reads through the same ordered hsame and Cont support. Apply Definition 1372.6 to rule out unlisted tags, order changes, row fusion, sibling-carrier imports, and hidden components at the local NameCert interface. The cited sequence capstones and the arity-thirteen tuple packet can source the provenance context, but no carrier or classifier row rewrites those sibling chapters or replaces their local certificates.

The support package is therefore the named BEDC packet itself. Its local NameCert row exposes only the displayed fourteen-row sequence surface, so the scoped package has no route to an unordered bucket tuple, host-side equality classifier, hidden permutation, or hidden fifteenth position. □

Falsifiable prediction: Any accepted consumer route that reads unordered tuple membership as the classifier, an untagged row, a hidden permutation, a fifteenth sequence row, a host equality classifier, an order table detached from I, an unlisted tag, or a sibling capstone rewrite fails carrier admission, classifier exactness, index exhaustion, or tag exhaustion for BHistArity14SequenceNameCert$^{\uparrow}$.

Independence witness: b-hist-nona-sequence-name-cert, b-hist-deca-sequence-name-cert, b-hist-hendeca-sequence-name-cert, b-hist-arity13-sequence-name-cert, and b-hist-arity13-tuple-namecert: none is bijective to BHistArity14SequenceNameCert$^{\uparrow}$ because this packet carries fourteen ordered payload rows plus an index row, componentwise transport, replay, provenance, and local NameCert, while the cited siblings supply lower-arity sequence windows or an unordered arity-thirteen tuple surface.

Closure status for NameCert$_{\text{BHistArity14SequenceNameCert}^{\uparrow}}$.

Constructive story: A BHistArity14SequenceNameCert$^{\uparrow}$ packet is generated from fourteen tag-encoded BHist sequence rows, a finite index row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BHistArity14SequenceNameCert}^{\uparrow}}$, seed)

Scope closed: Definition 1372.1, Definition 1372.2, Definition 1372.3, Definition 1372.4, Definition 1372.5, Definition 1372.6, and Definition 1372.7 identify the arity-fourteen sequence-window carrier surface and its BEDC support package.

Formal verification: FormalStatus(NameCert$_{\text{BHistArity14SequenceNameCert}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a standard bridge, tuple-chapter replacement, sequence-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires checked classifier-exactness, index-exhaustion, tag-exhaustion, and scoped-support theorems for BEDC.Derived.BHistArity14SequenceNameCertUp.

Chapter 1373

A Concrete Naming Certificate for $\mathsf{BHistArity15SequenceNameCert}^{\uparrow}$

The $\mathsf{BHistArity15SequenceNameCert}^{\uparrow}$ packet is the ordered arity-fifteen sequence capstone for the carrier-isomorphism bucket. It is composite over the ordered sequence capstones of chapter 1367, chapter 1368, chapter 1377, chapter 1371, and chapter 1372, together with the unordered arity-thirteen tuple packet of chapter 1370. It also reads the bucket members $\mathsf{CauchySharedTailModulus}^{\uparrow}$ from chapter 983, $\mathsf{FocusedLedger}^{\uparrow}$ from chapter 1247, $\mathsf{PhysicalModelAudit}^{\uparrow}$ from chapter 1129, $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$ from chapter 1314, and $\mathsf{TowerEquivalence}^{\uparrow}$ from chapter 1143. The chapter gives downstream consumers a single BEDC name for the ordered fifteen-row surface without treating any constituent sibling as a replacement carrier.

Definition 1373.1 (BHistArity15SequenceNameCert carrier)**.** *A* $\mathsf{BHistArity15SequenceNameCert}^{\uparrow}$ *carrier is a finite sequence-window packet*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, R_{13}, R_{14}, I, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_{14}$ *are the fifteen tag-encoded* BHist *rows admitted by the ordered window. Each row is read as a displayed BEDC history component, and its tag records the local sequence role rather than a host-side position.*
2. I *is the finite sequence index and order row. It records the first admitted position, the last admitted position, the successor route through all fifteen entries, and the rule that every sequence read factors through exactly one of* $R_0, \ldots, R_{14}$.
3. H *records componentwise* hsame *transport for* $R_0, \ldots, R_{14}, I, C, P, L$ *and no transport row outside the displayed packet.*
4. C *records the displayed* Cont *replay from window admission through index preservation, componentwise comparison, transport, provenance readback, and local naming.*
5. P *is the* Pkg *provenance over the fifteen-row sequence encoder, the sequence and tuple capstones cited above,* $\mathsf{CauchySharedTailModulus}^{\uparrow}$, $\mathsf{FocusedLedger}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{ProgrammeStrengthGradientLedge}$ $\mathsf{TowerEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
6. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistArity15SequenceNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a sixteenth sequence component, a hidden permutation, an order table detached from I, unordered bucket membership alone, a host equality test, or a replacement of any tuple, sequence, or bucket-member chapter.

Lean4 ✓ `BEDC.Derived.BHistArity16SequenceNameCertUp.BHistArity16SequenceNameCertTasteGate`
`single carrier alignment`

Definition 1373.2 (BHistArity15SequenceNameCert classifier)**.** *Two* BHistArity15SequenceNameCert$^{\uparrow}$ *packets*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, R_{13}, R_{14}, I, H, C, P, L)$$

and

$$S' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, R'_7, R'_8, R'_9, R'_{10}, R'_{11}, R'_{12}, R'_{13}, R'_{14}, I', H', C', P', L')$$

are classifier-equivalent exactly when each displayed sequence row compares componentwise,

$$\begin{aligned}
&R_0 \sim R'_0, \quad R_1 \sim R'_1, \quad R_2 \sim R'_2, \quad R_3 \sim R'_3, \quad R_4 \sim R'_4, \quad R_5 \sim R'_5,\\
&R_6 \sim R'_6, \quad R_7 \sim R'_7, \quad R_8 \sim R'_8, \quad R_9 \sim R'_9, \quad R_{10} \sim R'_{10}, \quad R_{11} \sim R'_{11},\\
&R_{12} \sim R'_{12}, \quad R_{13} \sim R'_{13}, \quad R_{14} \sim R'_{14},
\end{aligned}$$

the index rows display the same finite order, the transport rows display the same hsame *routes for those components and for I, C, P, L, and the replay rows display the same* Cont *route from ordered window admission through local naming. No comparison is available through an omitted position, an untagged payload, unordered tuple membership, hidden permutation, sibling-capstone rewrite, bucket-member replacement, or host equality.*

Theorem 1373.3 (BHistArity15SequenceNameCert carrier admission)**.** *Every accepted* BHistArity15SequenceNam *packet admits exactly the displayed rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, R_{11}, R_{12}, R_{13}, R_{14}, I, H, C, P, L.$$

The fifteen rows are tag-encoded BHist *components, I is the only finite sequence index and order row, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the sequence window.*

Proof. Project the carrier of Definition 1373.1. The definition lists the fifteen tag-encoded BHist rows, then lists the index, transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted window read lands in exactly the displayed rows, and any proposed sixteenth component, detached order table, hidden permutation, or off-packet structural row lies outside the accepted surface. □

Lean4 ✓ `BEDC.Derived.BHistArity15SequenceNameCertUp.BHistArity15SequenceNameCertCarrierAdmission`

Theorem 1373.4 (BHistArity15SequenceNameCert classifier exactness)**.** *For accepted* BHistArity15SequenceName *packets S and S', the classifier of Definition 1373.2 is exact for the arity-fifteen ordered sequence surface: it compares the fifteen* BHist *rows at matching indices, compares the displayed finite order through I, I', compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by unordered tuple membership, hidden permutation, detached order table, sibling-capstone rewrite, bucket membership alone, bucket-member replacement, or host equality.*

Proof. Start with the classifier definition. It requires one comparison for each matching pair R_i, R'_i, requires the index rows to display the same finite order, and requires the displayed transport and replay routes to preserve that same ordered list.

The provenance and local naming rows are part of the same sequence-window carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for unordered tuple membership, hidden permutation, detached order table, sibling-capstone rewrite, bucket membership alone, bucket-member replacement, or host equality, the displayed indexwise route is the exact comparison surface. □

Theorem 1373.5 (BHistArity15SequenceNameCert index exhaustion)**.** *For an accepted* BHistArity15SequenceNam *packet, the index row I exhausts the orderable positions readable by the local* NameCert *interface. Every stable carrier-isomorphism read preserves*

$$R_0, \ldots, R_{14}, I, H, C, P, L$$

as displayed fields of the same sequence-window packet, and no consumer can manufacture an omitted position, erase the order row, collapse two positions into unordered tuple membership, replace the packet by a bucket member, or read a sixteenth sequence component.

Proof. Use the I and H rows in Definition 1373.1. The index row displays the finite order for exactly fifteen entries, and the transport row records componentwise hsame transport for exactly those entries together with the replay, provenance, and local naming rows.

The classifier of Definition 1373.2 repeats the same ordered list and requires the index rows to display the same finite order. A consumer that omits a position, erases I, collapses positions into unordered tuple membership, replaces the packet by a bucket member, or adds a sixteenth row is therefore no longer reading the accepted packet. □

Theorem 1373.6 (BHistArity15SequenceNameCert tag exhaustion)**.** *For an accepted* BHistArity15SequenceNameC *packet, the tags carried by $R_0, \ldots, R_{14}$ exhaust the sequence rows available to the local* NameCert *interface. Any consumer may transport or replay these rows only through the displayed I, H, and C rows, and cannot manufacture an unlisted tag, collapse two tags into one bucket witness, import a carrier row from a sibling capstone, replace the packet by* CauchySharedTailModulus$^{\uparrow}$, FocusedLedger$^{\uparrow}$, PhysicalModelAudit$^{\uparrow}$, ProgrammeStrengthGradientLedger$^{\uparrow}$, *or* TowerEquivalence$^{\uparrow}$, *alter the displayed order, or read a sixteenth sequence component.*

Proof. Project the carrier of Definition 1373.1. The carrier has exactly the fifteen tag-encoded BHist rows together with I, H, C, P, L, and Definition 1373.3 identifies this displayed list as the whole accepted row inventory.

The index, transport, and replay access paths are therefore already fixed by I, H, and C. No consumer can introduce another tag, change the displayed order, merge two tags into a single bucket witness, or replace the packet by one of the cited bucket members, because such a move would require an additional carrier row or a non-displayed structural clause.

Finally apply Definition 1373.4. Every public comparison remains indexwise over the same fifteen tags and the same displayed structural rows, so sibling capstones and bucket members cannot contribute hidden carrier rows and no sixteenth component is readable through the local NameCert surface. □

Theorem 1373.7 (BHistArity15SequenceNameCert scoped support package)**.** *The carrier admission, classifier exactness, index exhaustion, and tag exhaustion clauses bind the* BHistArity15SequenceNameCert$^{\uparrow}$

packet exactly to the displayed BEDC support

$$\mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert},$$

to the ordered sequence capstones chapter 1367, chapter 1368, chapter 1377, chapter 1371, and chapter 1372, to the unordered arity-thirteen tuple capstone chapter 1370, and to the bucket members $\mathsf{CauchySharedTailModulus}^{\uparrow}$, $\mathsf{FocusedLedger}^{\uparrow}$, $\mathsf{PhysicalModelAudit}^{\uparrow}$, $\mathsf{ProgrammeStrengthGradientLedger}^{\uparrow}$, *and* $\mathsf{TowerEquivalence}^{\uparrow}$. *The resulting scope is the ordered arity-fifteen* BHist *sequence window with displayed index row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not an unordered bucket tuple, a host-side equality classifier, a hidden permutation, a bucket-member carrier, or a hidden sixteenth position.*

Proof. Apply Definition 1373.3 to identify the admitted rows and exclude any sixteenth coordinate. Apply Definition 1373.4 to keep comparison on matching sequence indices, the displayed index row, and the structural rows.

Apply Definition 1373.5 to force all stable reads through the same ordered hsame and Cont support. Apply Definition 1373.6 to rule out unlisted tags, order changes, row fusion, sibling-carrier imports, bucket-member replacement, and hidden components at the local NameCert interface. The cited sequence capstones, the arity-thirteen tuple packet, and the listed bucket members can source the provenance context, but no carrier or classifier row rewrites those siblings or replaces their local certificates.

The support package is therefore the named BEDC packet itself. Its local NameCert row exposes only the displayed fifteen-row sequence surface, so the scoped package has no route to an unordered bucket tuple, host-side equality classifier, hidden permutation, bucket-member carrier, or hidden sixteenth position. □

Falsifiable prediction: Any accepted consumer route that reads unordered tuple membership as the classifier, an untagged row, a hidden permutation, a sixteenth sequence row, a host equality classifier, an order table detached from I, an unlisted tag, a sibling capstone rewrite, or a bucket-member replacement fails carrier admission, classifier exactness, index exhaustion, or tag exhaustion for $\mathsf{BHistArity15SequenceNameCert}^{\uparrow}$.

Independence witness: b-hist-nona-sequence-name-cert, b-hist-deca-sequence-name-cert, b-hist-hendeca-sequence-name-cert, b-hist-arity13-sequence-name-cert, b-hist-arity14-sequence-name-cert, b-hist-arity13-tuple-namecert, cauchy-shared-tail-modulus, focused-ledger, physical-model-audit, programme-strength-gradient-ledger, and towerequivalence: none is bijective to $\mathsf{BHistArity15SequenceNameCert}^{\uparrow}$ because this packet carries fifteen ordered payload rows plus an index row, componentwise transport, replay, provenance, and local NameCert, while the cited siblings supply lower-arity sequence windows, an unordered arity-thirteen tuple surface, or bucket-member carriers.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistArity15SequenceNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistArity15SequenceNameCert}^{\uparrow}$ packet is generated from fifteen tag-encoded BHist sequence rows, a finite index row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BHistArity15SequenceNameCert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1373.1, Definition 1373.2, Definition 1373.3, Definition 1373.4, Definition 1373.5, Definition 1373.6, and Definition 1373.7 identify the arity-fifteen sequence-window carrier surface and its BEDC support package.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BHistArity15SequenceNameCert}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a standard bridge, bucket-member replacement, tuple-chapter replacement, sequence-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires checked classifier-exactness, index-exhaustion, tag-exhaustion, and scoped-support theorems for BEDC.Derived.BHistArity15SequenceNameCertUp.

Chapter 1374

A Concrete Naming Certificate for $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$

The $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ packet realizes the stop-codon suffix bridge of subsection 9462.28.18 as finite BEDC data. It sits beside the finite GAP discipline of chapter 504, the inscription handoff of chapter 610, the Zeckendorf normal-word surface of chapter 278, and the channel/genetic-code bridge of subsection 9462.28.16. Its distinguishing role is a codon-window certificate: the packet records a two-axis RNA or DNA readback, the $\mathrm{U} + \mathrm{RR}$ square, the family-suffix projection, the no-11 Zeckendorf row, the standard-code bridge row, and the cannot-claim boundary without identifying any of these rows with the BEDC channel terminator.

Definition 1374.1 (StopCodonZeckendorfSuffix carrier)**.** *A* $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (A, W, S, F, L, T, B, H, C, P, N)$$

with the following displayed rows:

1. *A is the two-axis base-atlas row naming the chosen RNA or DNA notation, the shape axis, the family axis, and the external readback of* U, C, A, *and* G.
2. *W is the three-base codon-window row naming the first-position* U *boundary and the purine shape rows in positions* 2 *and* 3.
3. *S is the family-suffix row projecting positions* 2 *and* 3 *to* 00, 01, 10, *or* 11.
4. *F is the Zeckendorf legality row accepting exactly the length-two suffixes other than* 11.
5. *L is the standard-code bridge row under which* UAA, UAG, *and* UGA *are read as stop codons and* UGG *is read outside the stop set.*
6. *T is the channel-token separation row recording that family suffix* 11 *is not the BEDC channel terminator.*
7. *B is the cannot-claim boundary row refusing biological-code necessity, direct nucleotide denotation by compiled BEDC substrings, and any bridge-free claim that* UGG *is tryptophan.*
8. *H records componentwise* hsame *transport for the atlas, codon window, suffix, legality, standard-code bridge, token-separation, cannot-claim, route, provenance, and local naming rows.*
9. *C records displayed* Cont *routes through A, W, S, F, L, T, B before a consumer may read the stop-codon suffix classifier.*

10. *P is the* Pkg *provenance over* StopCodonZeckendorfSuffix$^{\uparrow}$, ZeckendorfNormal$^{\uparrow}$, FiniteTraceGapSocket$^{\uparrow}$, InscriptionPoint$^{\uparrow}$, *the channel/genetic-code bridge,* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}}$ *row.*

The carrier has no coordinate for a universal biological genetic-code law, a direct BEDC channel-token interpretation of nucleotide bases, a bridge-free stop-codon table, a release-factor dynamics model, or a Lean-checked biological theorem.

Lean4 (definition) `BEDC.Derived.StopCodonZeckendorfSuffixUp.StopCodonZeckendorfSuffixUp`

Theorem 1374.2 (StopCodonZeckendorfSuffix NameCert obligations)**.** *For the carrier of Definition 1374.1, the local* $\mathsf{NameCert}_{\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier admission: every accepted object exposes the tuple $Z = (A, W, S, F, L, T, B, H, C, P, N)$ and no hidden biological-code table;*
2. *suffix classifier: the route through A, W, S, F accepts exactly the* $\mathrm{U} + \mathrm{RR}$ *codon windows whose family suffix is* 00, 01, *or* 10*;*
3. *standard bridge ledger: the row L is the only source that reads the surviving codons as* UAA, UAG, *and* UGA *in the standard genetic code;*
4. *channel separation: the row T keeps the excluded family suffix* 11 *separate from the BEDC channel terminator and from any compiled channel substring;*
5. *cannot-claim ledger: the rows B, H, C, P, N exhaust transport, replay, provenance, and local naming without exporting biological necessity, all-code universality, or a bridge-free tryptophan claim for* UGG.

Lean4 ✓ `BEDC.Derived.StopCodonZeckendorfSuffixUp.StopCodonZeckendorfSuffixTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1374.1. The accepted packet displays the atlas, codon window, suffix, legality, standard bridge, token-separation, cannot-claim, transport, route, provenance, and naming rows as one finite BHist carrier.

The suffix classifier reads the rows in order. The atlas A gives the two-axis base readback, the window row W fixes the $\mathrm{U} + \mathrm{RR}$ square, the suffix row S exposes the two family bits, and the legality row F removes only the 11 corner.

The standard biological reading is not supplied by those four rows. It enters only through L, so the packet can state the standard stop set only after the bridge ledger has been read.

Channel separation is then read from T. Since T is a coordinate distinct from S and from the BEDC channel codec, matching the displayed bits 11 does not license token identity.

Finally inspect B, H, C, P, N. These rows preserve and name only the displayed packet, while B records the listed refusals. No omitted biological-code law or bridge-free codon assignment can be recovered from the route. □

Theorem 1374.3 (StopCodonZeckendorfSuffix no channel-token collapse)**.** *For an accepted* StopCodonZeckendorfS *carrier $Z = (A, W, S, F, L, T, B, H, C, P, N)$, the excluded family suffix* 11 *in the* UGG *corner is a suffix-classifier row, not the BEDC channel terminator. Any consumer that identifies those rows leaves the accepted packet surface.*

Lean4 ✓ `BEDC.Derived.StopCodonZeckendorfSuffixUp.StopCodonZeckendorfSuffixNoChannelTokenCollapse`

Proof. Project the carrier of Definition 1374.1. The family suffix appears in S, while the channel-token separation is a separate row T and the package row P records the channel/genetic-code bridge only as provenance.

Apply the channel-separation clause of Definition 1374.2. It says that the displayed 11 pattern is read through the family suffix and legality rows, not through the BEDC channel codec.

Thus a consumer may compare roles only through the recorded bridge. A direct token identity would delete T and bypass the provenance row, so it is not a read of the accepted $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ packet. □

Theorem 1374.4 (StopCodonZeckendorfSuffix bridge boundary)**.** *Every biological stop-codon claim exported by an accepted* $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ *packet factors through the finite route*

$$A \to W \to S \to F \to L \to T \to B \to H \to C \to P \to N.$$

The route reconstructs the standard stop-codon suffix set only relative to the displayed two-axis readback and the separate standard genetic-code bridge. It does not prove biological-code necessity, all genetic-code universality, release-factor dynamics, direct channel-token identity, or bridge-free nucleotide semantics.

Lean4 ✓ `BEDC.Derived.StopCodonZeckendorfSuffixUp.StopCodonZeckendorfSuffixBridgeBoundary`

Proof. Start with an accepted carrier $Z = (A, W, S, F, L, T, B, H, C, P, N)$. The only codon-window source is W, and it is readable as a biological codon window only after the atlas row A fixes the two-axis base readback.

The suffix calculation then passes through S and F. These rows remove the family-11 corner and therefore isolate the three surviving corners of the $\mathrm{U} + \mathrm{RR}$ square.

The biological stop reading is still conditional. The row L supplies the standard genetic-code bridge, so the stop-codon export factors through that bridge rather than through Zeckendorf legality alone.

The remaining rows record the boundary of the export. The separation row T blocks channel-token collapse, the cannot-claim row B refuses biological necessity and all-code universality, and H, C, P, N preserve only this displayed route. □

Theorem 1374.5 (StopCodonZeckendorfSuffix vision route)**.** *An accepted* $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ *packet is the concrete finite route for the conditional stop-codon reconstruction problem of Definition 9462.1113. The route displays the* $\mathrm{U} + \mathrm{RR}$ *square, maps the family suffixes* 00*,* 01*,* 10*, and* 11*, excludes exactly the* 11 *corner, and records the refusal of biological-code derivation as kernel data.*

Proof. There are four displayed suffix cases in the square. The 00 case is the UAA corner: it is read through A, W, S and accepted by the legality row F before the standard-code bridge row L may report it as a stop-codon corner.

The 01 case is the UAG corner. It follows the same A, W, S, F route, and the bridge row L is again the only source of biological stop-set readback.

The 10 case is the UGA corner. It is the third accepted suffix of the finite legality row, still separated from the channel-token row by T.

The 11 case is the UGG corner. The legality row F excludes it, and Definition 1374.3 prevents that excluded family suffix from being identified with the BEDC channel terminator.

Finally use the bridge boundary of Definition 1374.4. The cannot-claim row B records that the packet does not derive the biological genetic code, all-code universality, release-factor dynamics,

bridge-free nucleotide semantics, or channel-token identity as kernel data. Thus the concrete packet is exactly the finite route consumed by the vision-level conditional reconstruction problem. □

Lean4 ✓ `BEDC.Derived.StopCodonZeckendorfSuffixUp.StopCodonZeckendorfVisionRoute`

Theorem 1374.6 (StopCodonZeckendorfSuffix obligation closure route)**.** *For every accepted* StopCodonZeckendorf *packet, the finite obligation surface is exactly the route*

$$A, W, S, F, L, T, B, H, C, P, N.$$

The rows expose the two-axis base atlas, codon-window boundary, suffix projection, Zeckendorf legality, standard-code bridge, channel-token separation, cannot-claim boundary, componentwise transport, displayed replay, provenance, and local $\mathsf{NameCert}_{\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}}$ *evidence. No obligation read may bypass one of these rows or replace it by biological-code necessity, all-code universality, release-factor dynamics, bridge-free nucleotide semantics, or BEDC channel-token identity.*

Proof. The carrier of Definition 1374.1 supplies precisely the displayed rows $A, W, S, F, L, T, B, H, C, P, N$. The NameCert obligations of Definition 1374.2 identify carrier admission, suffix classification, bridge use, channel separation, and cannot-claim ledgers as the local obligation surface.

The no-channel-token collapse theorem Definition 1374.3 keeps the excluded family suffix separate from the BEDC terminator. The bridge boundary of Definition 1374.4 forces every biological stop-codon read through the standard-code row L and the boundary rows T, B.

Finally, Definition 1374.5 checks the four suffix cases against the conditional reconstruction problem. Combining these rows leaves exactly the displayed obligation route and no unlisted biological or channel-token claim. □

Lean4 ✓ `BEDC.Derived.StopCodonZeckendorfSuffixUp.StopCodonZeckendorfSuffixObligationClosureRoute`

Falsifiable prediction: A $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ packet cannot export a biological-code necessity row without a separate standard genetic-code bridge.

Independence witness: FiniteTraceGapSocket, InscriptionPoint, ZeckendorfNormal, channel-genetic bridge rows: none is bijective to $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$. $\mathsf{FiniteTraceGapSocket}^{\uparrow}$ supplies finite GAP discipline without codon-window rows; $\mathsf{InscriptionPoint}^{\uparrow}$ supplies inscription handoff without the two-axis suffix classifier; $\mathsf{ZeckendorfNormal}^{\uparrow}$ supplies no-11 normality without the standard genetic-code bridge; the channel-genetic bridge rows supply cross-layer separation without the local stop-suffix carrier, excluded-corner ledger, and cannot-claim boundary.

The Lean follow-up file `lean4/BEDC/Derived/StopCodonZeckendorfSuffixUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ instances, with field-projection proofs preserving $A, W, S, F, L, T, B, H, C, P, N$ as separate displayed fields.

Theorem 1374.7 (StopCodonZeckendorfSuffix scope grounding)**.** *Every accepted read of a* StopCodonZeckendorfSu *suffix is scoped over the finite rows*

$$A, W, S, F, L, T, B, H, C, P, N$$

together with $\mathsf{ZeckendorfNormal}^{\uparrow}$, $\mathsf{FiniteTraceGapSocket}^{\uparrow}$, $\mathsf{InscriptionPoint}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The read may use the Zeckendorf normal-word row, finite trace-gap socket, and inscription handoff only through those displayed fields, and no accepted suffix read exports a biological-code necessity, all-code universality, release-factor dynamics, bridge-free nucleotide semantics, or BEDC channel-token identity outside the same finite scope.*

Proof. Start with the carrier of Definition 1374.1. It displays the rows $A, W, S, F, L, T, B, H, C, P, N$ as the complete packet surface, with the Zeckendorf, finite trace-gap, inscription, transport, replay, provenance, and local naming dependencies recorded in those fields.

Apply the NameCert obligations and the obligation closure route. These bind carrier admission, suffix classification, bridge use, channel separation, cannot-claim rows, and structural replay to the same finite route.

The no-channel-token collapse and bridge boundary theorems remove every attempt to read biological-code necessity, all-code universality, release-factor dynamics, bridge-free nucleotide semantics, or BEDC channel-token identity outside the displayed packet. Thus every accepted suffix read is grounded in exactly the stated scope. □

Lean4 ✓ `BEDC.Derived.StopCodonZeckendorfSuffixUp.StopCodonZeckendorfSuffixScopeGrounding`

Closure status for $\mathsf{NameCert}_{\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}}$.

Constructive story: A $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ packet is generated from a two-axis base atlas, codon-window row, family-suffix projection, Zeckendorf legality row, standard-code bridge, channel-token separation, cannot-claim boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1374.4, Definition 1374.5, Definition 1374.6, and Definition 1374.7 give the public export surface: bridge boundary, vision route, obligation-closure route, and scope-grounding rows over the finite stop-codon suffix carrier and five-row NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, biological-code necessity, all genetic-code universality, release-factor dynamics, bridge-free nucleotide semantics, or BEDC channel-token identity.

Upgrade path: Lean closure requires Nontrivial StopCodonZeckendorfSuffixUp and FieldFaithful StopCodonZeckendorfSuffixUp instances in `lean4/BEDC/Derived/StopCodonZeckendorfSuffixUp/TasteGate.lean`.

Chapter 1375

A Concrete Naming Certificate for $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$

The $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$ packet is the ordered seven-row sequence capstone for the carrier-isomorphism bucket. It is anchored by the hepta tuple capstone of chapter 1376 and by the bucket members $\mathsf{EpistemicWitness}^{\uparrow}$, $\mathsf{ExternalSupplyAuditRoute}^{\uparrow}$, $\mathsf{PhysicalRecordInvariant}^{\uparrow}$, $\mathsf{StructuralAdjacency}^{\uparrow}$, $\mathsf{UseProcessLimitLedger}^{\uparrow}$, and $\mathsf{ZCarry}^{\uparrow}$. The chapter names the BEDC-native sequence window that reads exactly seven displayed BHist rows together with an index row, componentwise transport, continuation replay, provenance, and local naming; it does not rewrite any bucket member chapter.

Definition 1375.1 (BHistHeptaSequenceNameCert carrier)**.** *A* $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$ *carrier is a finite ordered sequence-window packet*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, I, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_6$ *are the seven tag-encoded* BHist *rows admitted by the sequence window. Each row is read as a displayed BEDC history component, and its tag records the local sequence role rather than a host-side position.*
2. I *is the finite index and order row. It records the first displayed position, the last displayed position, and the rule that every sequence read factors through one of* $R_0, \ldots, R_6$ *in that order.*
3. H *records componentwise* hsame *transport for* $R_0, \ldots, R_6, I, C, P, L$ *and no transport row outside the displayed packet.*
4. C *records the displayed* Cont *replay from window admission through index preservation, componentwise comparison, transport, provenance readback, and local naming.*
5. P *is the* Pkg *provenance over the seven-row window encoder, chapter 1376,* $\mathsf{EpistemicWitness}^{\uparrow}$, $\mathsf{ExternalSupplyAuditRoute}^{\uparrow}$, $\mathsf{PhysicalRecordInvariant}^{\uparrow}$, $\mathsf{StructuralAdjacency}^{\uparrow}$, $\mathsf{UseProcessLimitLedger}^{\uparrow}$, $\mathsf{ZCarry}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
6. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, an eighth sequence component, a hidden permutation, a host-side equality test, unordered bucket membership alone, or a replacement of the hepta tuple capstone or any bucket member chapter.

Definition 1375.2 (BHistHeptaSequenceNameCert classifier)**.** *Two* BHistHeptaSequenceNameCert$^{\uparrow}$ *packets*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, I, H, C, P, L)$$

and

$$S' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, I', H', C', P', L')$$

are classifier-equivalent exactly when each displayed window row compares componentwise,

$$\begin{aligned} &R_0 \sim R'_0, \quad R_1 \sim R'_1, \quad R_2 \sim R'_2, \quad R_3 \sim R'_3, \\ &R_4 \sim R'_4, \quad R_5 \sim R'_5, \quad R_6 \sim R'_6, \end{aligned}$$

the index rows display the same finite order, the transport rows display the same hsame *routes for those components and for I, C, P, L, and the replay rows display the same* Cont *route from window admission through local naming. No comparison is available through omitted position, hidden permutation, untagged payload, unordered bucket membership alone, host equality, or sibling-chapter replacement.*

Theorem 1375.3 (BHistHeptaSequenceNameCert carrier admission)**.** *Every accepted* BHistHeptaSequenceNameCe *packet admits exactly the displayed sequence-window rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, I, H, C, P, L.$$

The seven rows are tag-encoded BHist *components, I is the only index and order row, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the sequence window.*

Proof. Project the carrier of Definition 1375.1. The definition lists the seven tag-encoded BHist rows, then lists the index, transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted sequence read lands in exactly the displayed rows, and any proposed eighth component, detached order table, hidden permutation, or structural row outside the packet lies outside the accepted surface. □

Theorem 1375.4 (BHistHeptaSequenceNameCert classifier exactness)**.** *For accepted* BHistHeptaSequenceNameCe *packets S and S', the classifier of Definition 1375.2 is exact for the ordered seven-row sequence window: it compares the seven* BHist *rows at matching indices, compares the displayed finite order through I, I', compares the displayed* hsame *and* Cont *routes through H, H', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by unordered bucket membership, hidden permutation, detached order table, sibling-chapter replacement, or host equality.*

Proof. Start with the classifier definition. It requires one comparison for each matching pair R_i, R'_i, requires the index rows to display the same finite order, and requires the displayed transport and replay routes to preserve that same ordered list.

The provenance and local naming rows are part of the same sequence-window carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for unordered bucket membership, hidden permutation, detached order table, sibling-chapter replacement, or host equality, the displayed indexwise route is the exact comparison surface. □

Theorem 1375.5 (BHistHeptaSequenceNameCert index exhaustion)**.** *Every admitted index read of a* $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$ *packet is exhausted by the seven displayed positions*

$$0, 1, 2, 3, 4, 5, 6.$$

A stable carrier-isomorphism read must preserve the fields

$$R_0, \ldots, R_6, I, H, C, P, L$$

as rows of the same ordered sequence-window packet.

Proof. Use the I row in Definition 1375.1. It records the first displayed position, the last displayed position, and the rule that every sequence read factors through one of the seven rows in order.

The H row records componentwise hsame transport for that exact list, and the classifier repeats the same index-preserving comparison. Thus a read that introduces an eighth index, drops a displayed position, or detaches the order row is no longer a read of the accepted packet. □

Theorem 1375.6 (BHistHeptaSequenceNameCert tag exhaustion)**.** *The tag inventory of an accepted* $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$ *packet is exhausted by the seven row tags on* $R_0, \ldots, R_6$ *together with the structural tags for* I, H, C, P, L*. No untagged payload, duplicate hidden row, bucket-only membership tag, or host-side equality tag is exported by the local* $\mathsf{NameCert}$ *row.*

Proof. Read the carrier definition and the classifier definition together. The carrier displays exactly seven payload rows and five structural rows, while the classifier gives comparison clauses only for those displayed rows and the structural routes attached to them.

The local name is the row L of the same packet. Because L has no coordinate outside the displayed carrier and no classifier clause adds an external tag, local naming cannot export an untagged payload, duplicate hidden row, bucket-only membership tag, or host-side equality tag. □

Theorem 1375.7 (BHistHeptaSequenceNameCert provenance readback)**.** *The provenance row* P *of an accepted* $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$ *packet reads back only the seven-row window encoder, chapter 1376, the bucket-member surfaces named by* $\mathsf{EpistemicWitness}^{\uparrow}$*,* $\mathsf{ExternalSupplyAuditRoute}^{\uparrow}$*,* $\mathsf{PhysicalRecordInvariant}^{\uparrow}$*,* $\mathsf{StructuralAdjacency}^{\uparrow}$*,* $\mathsf{UseProcessLimitLedger}^{\uparrow}$*,* $\mathsf{ZCarry}^{\uparrow}$*, and the local* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *support rows. It does not read a bucket-wide replacement of the hepta tuple capstone or any named bucket-member chapter.*

Proof. Inspect the provenance row in the carrier definition. It records the seven-row window encoder, the named capstone and bucket-member surfaces, and the local BEDC support rows.

The row is a readback ledger for the ordered packet, not a command to alter any cited chapter. Since neither the carrier nor the classifier contains a replacement coordinate, provenance can source the shared bucket context without rewriting any member. □

Theorem 1375.8 (BHistHeptaSequenceNameCert local naming nonescape)**.** *Every local* $\mathsf{NameCert}_{\mathsf{BHistHeptaSequence}}$ *read factors through the displayed packet*

$$S = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, I, H, C, P, L).$$

The read may expose the seven-row sequence window, its finite order, and its componentwise routes, but it cannot export an untagged carrier, an eighth row, a hidden permutation, a host-side equality test, or a relocation of chapter 1376 or any named bucket-member surface.

Proof. The local name is the row L of the carrier. By Definition 1375.3, L is read only together with the seven window rows, the index row, and the displayed structural rows.

Use index exhaustion, tag exhaustion, and the classifier definition. They force any carrier-isomorphism read to preserve the same tag-encoded components, the same finite order, and the same displayed hsame and Cont routes. Since no untagged carrier, eighth row, hidden permutation, host equality test, or capstone relocation row appears in the packet, local naming cannot export one. □

Theorem 1375.9 (BHistHeptaSequenceNameCert scoped support package)**.** *The carrier admission, classifier exactness, index exhaustion, tag exhaustion, provenance readback, and local naming nonescape clauses bind the* $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$ *packet exactly to the displayed BEDC support*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert},$$

to the hepta tuple capstone of chapter 1376, and to the bucket-member surfaces named by $\mathsf{EpistemicWitness}^{\uparrow}$, $\mathsf{ExternalSupplyAuditRoute}^{\uparrow}$, $\mathsf{PhysicalRecordInvariant}^{\uparrow}$, $\mathsf{StructuralAdjacency}^{\uparrow}$, $\mathsf{UseProcessLimitLedger}^{\uparrow}$, *and* $\mathsf{ZCarry}^{\uparrow}$. *The resulting scope is the ordered seven-row* BHist *sequence window with displayed index row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not an unordered bucket tuple, a hidden permutation, a host equality classifier, or a hidden eighth position.*

Proof. Apply Definition 1375.3 to identify the admitted rows and exclude any eighth coordinate. Apply Definition 1375.4 to keep comparison on matching sequence indices, the displayed index row, and the structural rows.

Apply Definition 1375.5 to force every stable read through the seven displayed positions and the same ordered support. Apply Definition 1375.6 to prevent untagged payloads, duplicate hidden rows, bucket-only membership tags, and host-side equality tags from escaping through the local name.

Apply Definition 1375.7 and Definition 1375.8. The scoped package is therefore the named BEDC packet itself. Its provenance can source the hepta tuple capstone and the named bucket-member surfaces, but no carrier or classifier row rewrites those sibling chapters or replaces their local certificates. □

Falsifiable prediction: Any accepted consumer route that reads an unordered tuple coordinate, an untagged row, an eighth sequence row, a hidden permutation, bucket membership alone, an order table detached from I, or a sibling capstone relocation fails carrier admission, classifier exactness, index exhaustion, tag exhaustion, provenance readback, or local naming nonescape for $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$.

Independence witness: b-hist-hepta-tuple-name-cert, epistemic-witness, external-supply-audit-route, physical-record-invariant, structural-adjacency, use-process-limit-ledger, and z-carry: none is bijective to $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$ because this packet carries seven ordered sequence rows plus an index row, componentwise transport, replay, provenance, and local NameCert, while the cited siblings supply tuple or bucket-member surfaces.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}$ packet is generated from seven tag-encoded BHist sequence rows, a finite index row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BHistHeptaSequenceNameCert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1375.1, Definition 1375.2, Definition 1375.3, Definition 1375.4, Definition 1375.5, Definition 1375.6, Definition 1375.7, Definition 1375.8, and Definition 1375.9 identify the ordered seven-row sequence-window carrier surface and its BEDC support package.

Formal verification: FormalStatus(NameCert$_{\text{BHistHeptaSequenceNameCert}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: ai
Not claimed: This chapter does not provide a Lean declaration, standard bridge, tuple-chapter replacement, bucket-member replacement, or public acceptance interface.
Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistHeptaSequenceNameCertUp and checked carrier-admission, classifier-exactness, index-exhaustion, tag-exhaustion, provenance-readback, local-naming, and scoped-support theorems.

Chapter 1376

A Concrete Naming Certificate for $\mathsf{BHistHeptaTupleNameCert}^{\uparrow}$

The $\mathsf{BHistHeptaTupleNameCert}^{\uparrow}$ packet is the hard-floor capstone for the arity-seven tag-encoded BHist carrier-isomorphism bucket. It is composite over the neighboring tuple surfaces of chapter 1365, chapter 1363, and chapter 1364, and it also cites the anchor-stability certificate of chapter 1150, the audit-map family of chapter 807, and the beta critical-pair packet of chapter 881. The chapter bundles the seven-row carrier shape as one NameCert surface; it does not claim that the bucket is an atomic independent primitive or that any sibling chapter is replaced by this composite name.

Definition 1376.1 (BHistHeptaTupleNameCert carrier)**.** *A* $\mathsf{BHistHeptaTupleNameCert}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, T, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_6$ *are the seven tag-encoded carrier rows. Each row is a* BHist *entry whose tag records the local carrier role used by a cited bucket sibling and whose payload is read only as a displayed BEDC history component.*
2. T *records componentwise* hsame *transport for* $R_0, \ldots, R_6, C, P, L$ *and no transport row outside the displayed packet.*
3. C *records the displayed* Cont *route that replays row admission, componentwise comparison, transport, provenance readback, and local naming for the same seven-row packet.*
4. P *is the* Pkg *provenance over the arity-seven tag encoder, the cited sibling carrier families,* BHist, hsame, Cont, *and* NameCert *rows.*
5. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistHeptaTupleNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, an eighth carrier component, a host-side equality test, a bucket-wide rewrite of sibling chapters, or a detached provenance table.

Lean4 (definition) `BEDC.Derived.BHistHeptaTupleNameCertUp.BHistHeptaTupleNameCertUp`

Definition 1376.2 (BHistHeptaTupleNameCert classifier)**.** *Two* $\mathsf{BHistHeptaTupleNameCert}^{\uparrow}$ *packets*

$$H = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, T, C, P, L)$$

and

$$H' = (R'_0, R'_1, R'_2, R'_3, R'_4, R'_5, R'_6, T', C', P', L')$$

are classifier-equivalent exactly when each displayed carrier row compares componentwise,

$$\begin{aligned} &R_0 \sim R'_0, \quad R_1 \sim R'_1, \quad R_2 \sim R'_2, \quad R_3 \sim R'_3, \\ &R_4 \sim R'_4, \quad R_5 \sim R'_5, \quad R_6 \sim R'_6, \end{aligned}$$

the transport rows display the same hsame *routes for those components and for C, P, L, and the replay rows display the same* Cont *route from row admission through local naming. No comparison is available through an omitted component, an untagged payload, or a member-chapter rewrite.*

Theorem 1376.3 (BHistHeptaTupleNameCert carrier admission)**.** *Every accepted* BHistHeptaTupleNameCert$^{\uparrow}$ *packet admits exactly the carrier rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, T, C, P, L.$$

The seven rows are tag-encoded BHist *components, and T, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the packet.*

Proof. Project the carrier of Definition 1376.1. The definition lists the seven tag-encoded BHist rows and then lists the transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted carrier read lands in exactly the displayed rows, and any proposed eighth component or detached structural table lies outside the accepted surface. □

Lean4 ✓ `BEDC.Derived.BHistHeptaTupleNameCertUp.BHistHeptaTupleNameCertCarrierAdmission`

Theorem 1376.4 (BHistHeptaTupleNameCert classifier exactness)**.** *For accepted* BHistHeptaTupleNameCert$^{\uparrow}$ *packets H and H', the classifier of Definition 1376.2 is exact for the arity-seven carrier surface: it compares the seven tagged* BHist *rows componentwise, compares the displayed* hsame *and* Cont *routes through T, T', C, C', and preserves the provenance and local naming rows through P, P', L, L'. It does not compare by bucket membership alone, by a host equality test, or by a hidden isomorphism between member chapters.*

Proof. Start with the classifier definition. It requires one comparison for each of $R_0, \ldots, R_6$, then requires the displayed transport and replay routes to match the same component list.

The provenance and local naming rows are part of the same carrier, so their comparison is not an external bucket judgment. Since the classifier has no clause for bucket membership alone, host equality, or hidden chapter isomorphism, the displayed componentwise route is the exact comparison surface. □

Theorem 1376.5 (BHistHeptaTupleNameCert scoped support package)**.** *The carrier admission and classifier exactness clauses bind the* BHistHeptaTupleNameCert$^{\uparrow}$ *packet to the displayed BEDC support*

BHist, hsame, Cont, Pkg, NameCert,

and to the cited sibling carrier families. The resulting scope is the arity-seven tag-encoded BHist *packet with displayed* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row; it is not a bucket-wide sibling rewrite, a host-side equality classifier, or a hidden eighth row.*

Proof. Apply Definition 1376.3 to identify the admitted rows and exclude any eighth coordinate. Apply Definition 1376.4 to keep comparison on the seven tagged BHist rows and the displayed structural rows.

The support package is therefore the named BEDC packet itself. Its provenance can source the cited bucket siblings, but no carrier or classifier row rewrites those sibling chapters or replaces their local certificates. □

Falsifiable prediction: Any accepted consumer route that reads an untagged row, an eighth carrier row, or bucket membership alone fails carrier admission or classifier exactness for $\mathsf{BHistHeptaTupleNameCert}^{\uparrow}$.

Independence witness: b-hist-octa-tuple-name-cert, b-hist-nona-tuple-name-cert, b-hist-deca-tuple-name-cert, anchor-stability-certificate, auditmapfamily, and beta-critical-pair: none is bijective to $\mathsf{BHistHeptaTupleNameCert}^{\uparrow}$ because this packet carries exactly seven tagged rows together with transport, replay, provenance, and local NameCert in one packet, while the neighboring capstones carry different arities and each cited sibling supplies its own member-family surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistHeptaTupleNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistHeptaTupleNameCert}^{\uparrow}$ packet is generated from seven tag-encoded BHist carrier rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BHistHeptaTupleNameCert}^{\uparrow}}$, seed)

Scope closed: Definition 1376.1, Definition 1376.2, Definition 1376.3, Definition 1376.4, and Definition 1376.5 identify the arity-seven carrier-isomorphism surface and its BEDC support package.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BHistHeptaTupleNameCert}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a Lean declaration, standard bridge, member-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistHeptaTupleNameCertUp and checked carrier-admission plus classifier-exactness theorems.

Chapter 1377

A Concrete Naming Certificate for $\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}$

The $\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}$ packet is the ordered arity-eleven sequence-window capstone for the carrier-isomorphism bucket. It is composite over the deca sequence certificate of chapter 1368, the hendeca tuple certificate of chapter 1366, the dodeca tuple certificate of chapter 1369, the audit-map family of chapter 807, the anchor-stability certificate of chapter 1150, and the BEDC self-substrate packet of chapter 869. The chapter names the BEDC-native window that reads eleven ordered BHist rows together with componentwise transport, continuation replay, provenance, and local naming, without changing any member chapter.

Definition 1377.1 (BHistHendecaSequenceNameCert carrier)**.** *A* $\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}$ *carrier is a finite sequence-window packet*

$$Q = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, I, H, C, P, L)$$

with the following displayed rows:

1. $R_0, \ldots, R_{10}$ *are the eleven ordered* BHist *rows admitted by the window. Each row is read as a displayed BEDC history component, and its tag records the local sequence role rather than a host-side position.*
2. I *is the finite order and index row. It records the first and last admitted positions, the successor route through the eleven entries, and the rule that every sequence read factors through one of* $R_0, \ldots, R_{10}$.
3. H *records componentwise* hsame *transport for* $R_0, \ldots, R_{10}, I, C, P, L$ *and no transport row outside the displayed packet.*
4. C *records the displayed* Cont *replay from window admission through index preservation, componentwise comparison, transport, provenance readback, and local naming.*
5. P *is the* Pkg *provenance over the eleven-row window encoder, the tuple and sequence capstone anchors cited above, chapter 807, chapter 1150, chapter 869,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
6. L *is the local* $\mathsf{NameCert}_{\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}}$ *row.*

The carrier has no coordinate for an untagged row, a twelfth sequence component, a hidden permutation, a host equality test, unordered bucket membership alone, or a replacement of any tuple or sequence capstone chapter.

Theorem 1377.2 (BHistHendecaSequenceNameCert obligation surface)**.** *Every accepted* BHistHendecaSequenceNa *packet admits exactly the displayed window rows*

$$R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, I, H, C, P, L.$$

The eleven rows are ordered BHist *components, I is the only index and order row, and H, C, P, L are the only structural rows by which a consumer may transport, replay, source, or locally name the sequence window. In particular, the NameCert obligation surface is the carrier of Definition 1377.1 together with its index preservation,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows.*

Proof. Project the carrier of Definition 1377.1. The definition lists the eleven ordered BHist rows, then lists the index, transport, continuation, provenance, and local naming rows.

There is no remaining coordinate in the packet. Thus any accepted window read lands in exactly the displayed rows, and any proposed twelfth component, detached order table, hidden permutation, or off-packet structural row lies outside the accepted surface. □

Theorem 1377.3 (BHistHendecaSequenceNameCert field projection)**.** *Let*

$$Q = (R_0, R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8, R_9, R_{10}, I, H, C, P, L)$$

be an accepted $\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}$ *packet. Any downstream carrier-isomorphism read of Q factors through one of the displayed fields $R_0, \ldots, R_{10}, I, H, C, P, L$. The projection may expose the ordered eleven-row window, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, or the local* NameCert *row, but it cannot expose unordered tuple membership, a host-side equality classifier, an omitted field, a hidden twelfth field, or a rewrite of chapter 1368, chapter 1366, or chapter 1369.*

Proof. Use the obligation surface of Definition 1377.2. It identifies the complete list of rows available to an accepted packet and states that I, H, C, P, L are the only structural rows attached to the eleven ordered BHist components.

A downstream projection therefore has only the displayed fields as sources. Since the carrier contains no unordered bucket-membership coordinate, no host equality classifier, no omitted-field lookup, no twelfth field, and no capstone rewrite row, none of those readings can be exported by projection. □

Falsifiable prediction: Any accepted consumer route that reads unordered tuple membership, an untagged row, a hidden permutation, a twelfth sequence row, a host equality classifier, an order table detached from I, or a sibling capstone rewrite fails the obligation surface or field projection for $\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}$.

Independence witness: b-hist-deca-sequence-name-cert, b-hist-hendeca-tuple-namecert, b-hist-dodeca-tuple-name-cert, auditmapfamily, anchor-stability-certificate, and bedc-self-substrate: none is bijective to $\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}$ because this packet carries eleven ordered payload rows plus an index row, componentwise transport, replay, provenance, and local NameCert, while the cited siblings supply different sequence, tuple, audit, anchor, or substrate surfaces.

Closure status for $\mathsf{NameCert}_{\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}}$.

Constructive story: A $\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}$ packet is generated from eleven ordered BHist sequence rows, a finite index row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BHistHendecaSequenceNameCert}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1377.1, Definition 1377.2, and Definition 1377.3 identify the arity-eleven sequence-window carrier surface and its BEDC support package.

Formal verification: FormalStatus(NameCert$_{\text{BHistHendecaSequenceNameCert}\uparrow}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not provide a Lean declaration, standard bridge, tuple-chapter replacement, sequence-chapter replacement, or public acceptance interface.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.BHistHendecaSequenceNameCertUp and checked obligation-surface plus field-projection theorems.

Chapter 1378

A Concrete Naming Certificate for $\mathsf{Order}^{\uparrow}$

The order interface $\mathsf{Order}^{\uparrow}$ is the unary comparison face read by the Full Nat Arithmetic boundary. It sits between the $\mathsf{Nat}^{\uparrow}$ spine and the $\mathsf{Add}^{\uparrow}$, $\mathsf{Mul}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ arithmetic consumers, exposing finite comparison packets over histories rather than a host natural-number order.

The unary comparison carrier consumes the $\mathsf{Nat}^{\uparrow}$ spine of chapter 28. Its public consumer boundary is read by chapter 29, chapter 30, chapter 31, and chapter 37, so the later arithmetic packets depend on $\mathsf{Order}^{\uparrow}$ only through finite comparison rows over the shared unary history substrate.

1378.1 Unary comparison packets

Definition 1378.1 (OrderUp unary comparison carrier)**.** *The carrier for* $\mathsf{Order}^{\uparrow}$ *consists of finite unary comparison packets*

$$\mathsf{OrdRow}(h, k, \beta, \lambda)$$

where h and k are $\mathsf{Nat}^{\uparrow}$ *unary histories, β is one displayed constructive comparison branch, and λ is the finite ledger that justifies that branch. The branch β is either a left-prefix witness from h to k, a right-prefix witness from k to h, or a classifier row $h\mathsf{hsame}k$. The ledger λ records only* BHist *constructors,* hsame *transport, and* Cont *prefix rows over the two unary histories.*

Lean4 ✓ `BEDC.Derived.OrderUp.TasteGate.OrderUpTasteGate single carrier alignment`

Definition 1378.2 (OrderUp unary comparison classifier)**.** *Two* $\mathsf{Order}^{\uparrow}$ *comparison packets* $\mathsf{OrdRow}(h, k, \beta, \lambda)$ *and* $\mathsf{OrdRow}(h', k', \beta', \lambda')$ *are classified together when $h\mathsf{hsame}h'$ and $k\mathsf{hsame}k'$, and the comparison branch transported along those two endpoint classifiers is the displayed branch β'. The ledger component is compared by replaying the same finite prefix and endpoint rows after this* hsame *transport.*

Theorem 1378.3 (OrderUp unary comparison NameCert obligations)**.** *The carrier and classifier of Definition 1378.1 and Definition 1378.2 supply the seed* $\mathsf{NameCert}_{\mathsf{Order}^{\uparrow}}$ *obligation surface over* BHist*. The carrier is inhabited by the reflexive packet on* e*, classifier reflexivity, symmetry, and transitivity are inherited from the endpoint* hsame *rows together with finite ledger replay, stability follows by transporting prefix and equality branches along* hsame*, and the ledger records exactly the displayed carrier, branch, transport, and prefix rows.*

Proof. For inhabitance, take the packet with $h = k = \mathsf{e}$, the equality branch $\mathsf{ehsamee}$, and the empty ledger.

The classifier laws are componentwise. Reflexivity uses the same two endpoints and the same comparison branch. Symmetry reverses the endpoint classifiers and replays the transported branch in the opposite packet direction. Transitivity composes the endpoint hsame rows and concatenates the finite ledger replays.

For stability, transport the two unary endpoints through the supplied hsame rows. A left-prefix branch remains a left-prefix branch after endpoint transport, a right-prefix branch remains right-prefix, and an equality branch remains an hsame branch. Since every ledger entry is one of these finite rows, the transported packet is again an $\mathsf{Order}^{\uparrow}$ carrier row. □

Lean4 ✓ `BEDC.Derived.OrderUp.OrderUnaryComparisonNameCertObligations`

Theorem 1378.4 (OrderUp Full Nat Arithmetic handoff)**.** *The unary comparison packet of Definition 1378.1, its classifier of Definition 1378.2, and the seed obligations of Definition 1378.3 form the* $\mathsf{Order}^{\uparrow}$ *face consumed by the Full Nat Arithmetic phase. Thus the* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Add}^{\uparrow}$*,* $\mathsf{Mul}^{\uparrow}$*,* $\mathsf{Int}^{\uparrow}$*, and* $\mathsf{Rat}^{\uparrow}$ *consumers read order information only as finite unary comparison rows over the same* BHist *spine.*

Proof. Project the carrier first. Its only endpoints are $\mathsf{Nat}^{\uparrow}$ unary histories, and its comparison branch is a finite prefix-or-classifier row over those histories.

Project the classifier next. It transports comparison rows along hsame on the same two endpoints, so an arithmetic consumer receives a stable comparison interface rather than a second carrier or a host relation.

The seed obligations then provide the NameCert surface needed by the phase boundary: one inhabited carrier row, componentwise classifier laws, transport stability, and a ledger policy. Repacking these projections gives exactly the order face available to the Full Nat Arithmetic consumers listed in the statement. □

Lean4 ✓ `BEDC.Derived.OrderUp.OrderFullNatArithmeticHandoff`

Theorem 1378.5 (OrderUp AddMul consumer boundary)**.** *Every* $\mathsf{Add}^{\uparrow}$ *or* $\mathsf{Mul}^{\uparrow}$ *consumer of* $\mathsf{Order}^{\uparrow}$ *receives only finite unary comparison rows of Definition 1378.1 and classifier transport rows of Definition 1378.2. In particular, monotonicity or divisibility-order uses may read the displayed prefix branch and its finite ledger, but they do not receive host natural-number order, classical trichotomy, quotient order, or any ordered semiring or ordered ring structure from this chapter.*

Proof. An $\mathsf{Add}^{\uparrow}$ consumer reads the two endpoint histories through the additive continuation surface and may attach a comparison packet only after those endpoints are already present as unary histories. The packet contributes the branch and finite ledger, not a host order predicate.

A $\mathsf{Mul}^{\uparrow}$ consumer reads the repeated-addition ledger and may attach comparison packets to the displayed factors, partial products, or final product. Each such attachment is again an OrdRow over unary endpoints with componentwise classifier transport.

Since neither consumer projection introduces a semiring carrier, a ring carrier, a quotient relation, or a classical three-way decision principle, the only order data crossing this boundary are the finite prefix-or-equality rows explicitly stored in the $\mathsf{Order}^{\uparrow}$ packet. □

Theorem 1378.6 (OrderUp endpoint transport obligation)**.** *Any accepted* $\mathsf{Order}^{\uparrow}$ *packet*

$$\mathsf{OrdRow}(h, k, \beta, \lambda)$$

transported along endpoint rows $h\mathsf{hsame}h'$ *and* $k\mathsf{hsame}k'$ *remains an* $\mathsf{Order}^{\uparrow}$ *packet. Its transported branch is still one of the three branches of Definition 1378.1: a left-prefix witness, a right-prefix witness, or an equality classifier row. Its ledger still contains only* BHist *provenance rows, endpoint* hsame *rows, and* Cont *prefix rows, as required by Definition 1378.2 and Definition 1378.3.*

Proof. The carrier of Definition 1378.1 stores exactly two unary endpoints, one displayed comparison branch, and a finite ledger. The classifier of Definition 1378.2 allows transport only through the two endpoint hsame rows, so the endpoints become h' and k' and no new comparison carrier is introduced.

A left-prefix branch is replayed as a left-prefix branch over the transported endpoints, a right-prefix branch is replayed symmetrically, and an equality branch is replayed by the transported endpoint classifier. This is precisely the stability clause in Definition 1378.3.

The ledger replay uses only the original BHist rows, the two endpoint hsame rows, and the Cont rows witnessing the prefix branch. Hence the transported row is again an $\mathsf{Order}^{\uparrow}$ packet with the same finite ledger vocabulary. □

Lean4 ✓ `BEDC.Derived.OrderUp.OrderEndpointTransportObligation`

Theorem 1378.7 (OrderUp prefix branch antisymmetry)**.** *Let h and k be unary* $\mathsf{Nat}^{\uparrow}$ *histories. Suppose one accepted* $\mathsf{Order}^{\uparrow}$ *packet displays a left-prefix branch from h to k, and another accepted* $\mathsf{Order}^{\uparrow}$ *packet displays a right-prefix branch from k to h. Then the two endpoints are classified by* $h\mathsf{hsame}k$*. Equivalently, an arithmetic consumer of the public* $\mathsf{Order}^{\uparrow}$ *face cannot use opposite strict-prefix branches as two independent order facts; the paired finite ledgers collapse to the equality classifier row of Definition 1378.2.*

Proof. Read both packets through the carrier of Definition 1378.1. The only data available are the endpoints, the displayed branch, and the finite BHist ledger of Cont prefix rows and endpoint hsame rows. By Definition 1378.3, no host order or external trichotomy row can enter the comparison.

Induct on the paired unary prefix ledgers. At the empty-prefix boundary, the two displayed branches have no remaining strict Cont step on either side. The classifier of Definition 1378.2 therefore identifies the endpoints by the equality branch $h\mathsf{hsame}k$.

In the successor-prefix case, both opposite branches begin by exposing one shared Cont step through the unary history spine. Strip that step from the left-prefix ledger and from the right-prefix ledger, apply the induction hypothesis to the two tails, and obtain the tail endpoint classifier. Finally, transport this classifier back across the stripped endpoint rows using Definition 1378.6. The transported equality classifier is exactly $h\mathsf{hsame}k$. □

Theorem 1378.8 (OrderUp Int consumer boundary)**.** *Every* $\mathsf{Int}^{\uparrow}$ *order-facing read of* $\mathsf{Order}^{\uparrow}$ *factors through signed-pair endpoint comparisons inherited from the* $\mathsf{Nat}^{\uparrow}$ *spine and the* $\mathsf{Add}^{\uparrow}$ *continuation rows. In the signed-pair chapter chapter 31, an integer comparison may consume only the* OrdRow *packets attached to the displayed positive and negative unary components and their endpoint transport rows. It never imports host integer order, quotient order, ordered ring structure, or a trichotomy principle.*

Proof. The $\mathsf{Int}^{\uparrow}$ surface exposes signed pairs built from unary histories, so an order-facing read must first choose the displayed endpoints in those positive and negative components. By Definition 1378.1, the only comparison datum available on such endpoints is an OrdRow packet.

The endpoint movement is governed by Definition 1378.2 and Definition 1378.6. Thus the signed-pair consumer can replay comparison rows along endpoint hsame and Cont rows inherited from the $\mathsf{Nat}^{\uparrow}$ and $\mathsf{Add}^{\uparrow}$ ledgers.

No clause in Definition 1378.3 exports a host integer relation or quotient order. Therefore the $\mathsf{Int}^{\uparrow}$ consumer boundary is exhausted by finite signed-pair endpoint comparisons. □

Theorem 1378.9 (OrderUp Rat consumer boundary)**.** *Every* $\mathsf{Rat}^{\uparrow}$ *order-facing read of* $\mathsf{Order}^{\uparrow}$ *factors through numerator and positive-denominator unary comparison packets, together with the denominator ledger rows displayed in chapter 37. A rational comparison may consume only* OrdRow *packets on the numerator and positive-denominator unary components, endpoint* hsame *transport, and denominator-positivity ledger rows. It never imports host rational order, field order, quotient order, ordered-field structure, or classical trichotomy.*

Proof. The $\mathsf{Rat}^{\uparrow}$ carrier presents numerator data and a positive-denominator record as finite unary rows. Hence an order-facing rational consumer must attach comparison information to those displayed unary components rather than to an ambient rational carrier.

By Definition 1378.1, each such comparison is an OrdRow with a prefix-or-equality branch. By Definition 1378.2 and Definition 1378.6, transport of that packet uses only endpoint hsame rows and finite Cont replay.

The NameCert obligations in Definition 1378.3 leave no ledger slot for a field order or a host rational trichotomy selector. The denominator contribution is therefore only the finite positivity ledger needed to route the unary denominator endpoint. □

Theorem 1378.10 (OrderUp obligation ledger exhaustion)**.** *The* $\mathsf{Order}^{\uparrow}$ *obligation ledger is exhausted by the two unary endpoints, the prefix-or-equality comparison branch, the endpoint classifier rows, the* Cont *replay rows, and the provenance rows naming the originating* $\mathsf{Nat}^{\uparrow}$ *histories. Every* $\mathsf{Add}^{\uparrow}$*,* $\mathsf{Mul}^{\uparrow}$*,* $\mathsf{Int}^{\uparrow}$*, or* $\mathsf{Rat}^{\uparrow}$ *consumer read of* $\mathsf{Order}^{\uparrow}$ *factors through this finite inventory and no further order datum is present in the NameCert packet.*

Proof. Start with the carrier of Definition 1378.1. Its stored data are exactly two unary histories, one displayed branch, and the finite ledger justifying that branch.

The classifier of Definition 1378.2 adds only endpoint transport. Once the two endpoint hsame rows are fixed, the branch replay is forced by the corresponding Cont prefix rows or by the transported equality row.

The provenance rows record which $\mathsf{Nat}^{\uparrow}$ histories the endpoints came from. Therefore any consumer replay that claims to use $\mathsf{Order}^{\uparrow}$ can be checked against this list: endpoints, branch, endpoint classifier rows, continuation replay, and provenance. There is no remaining slot in the NameCert ledger for a host order, quotient order, trichotomy selector, or ordered-ring import. □

Lean4 ✓ `BEDC.Derived.OrderUp.OrderUnaryComparison obligation prefix ledger exhaustion`

Theorem 1378.11 (OrderUp public unary comparison export)**.** *The carrier of Definition 1378.1, the classifier of Definition 1378.2, the NameCert obligations of Definition 1378.3, the Full Nat Arithmetic handoff of Definition 1378.4, the* $\mathsf{Add}^{\uparrow}$ *and* $\mathsf{Mul}^{\uparrow}$ *boundary of Definition 1378.5, the endpoint transport obligation of Definition 1378.6, the prefix branch antisymmetry theorem of Definition 1378.7, the* $\mathsf{Int}^{\uparrow}$ *boundary of Definition 1378.8, the* $\mathsf{Rat}^{\uparrow}$ *boundary of Definition 1378.9, and the ledger exhaustion of Definition 1378.10 together form the public* $\mathsf{Order}^{\uparrow}$ *unary-comparison export. A public arithmetic consumer receives only finite* BHist *unary comparison rows with endpoint* hsame *transport,* Cont *prefix replay, and equality collapse for opposite prefix ledgers, not host order, quotient order, ordered algebraic structure, or classical trichotomy.*

Proof. The carrier and classifier first determine the public object being exported: an OrdRow stores two $\mathsf{Nat}^{\uparrow}$ unary histories, one prefix-or-equality branch, and a finite ledger, while classifier transport moves only the two endpoints and replays the displayed branch.

The NameCert obligations and Full Nat Arithmetic handoff then make this packet consumable. They provide the inhabited row, classifier laws, stability clause, and ledger policy needed by the arithmetic phase, without adding a second order carrier or a host relation.

The endpoint transport and prefix branch antisymmetry theorems control branch movement. Endpoint transport preserves the displayed branch under hsame, while antisymmetry collapses opposite finite prefix ledgers to the equality classifier row.

The consumer-boundary theorems identify the public readers. The $\mathsf{Add}^{\uparrow}$ and $\mathsf{Mul}^{\uparrow}$ boundary, the $\mathsf{Int}^{\uparrow}$ boundary, and the $\mathsf{Rat}^{\uparrow}$ boundary all route their order-facing uses through the same finite packet, endpoint transport obligation, and opposite-prefix collapse.

Finally, ledger exhaustion proves that the exported inventory is complete. Since every accepted consumer read is checked against the endpoints, branch, endpoint classifier rows, continuation replay, and provenance rows, the public surface contains only finite BHist unary comparison data and excludes host order, quotient order, ordered algebraic structure, and classical trichotomy. □

Theorem 1378.12 (OrderUp finite arithmetic mature consumer package)**.** *Every mature Full Nat Arithmetic consumer of* $\mathsf{Order}^{\uparrow}$ *factors through the finite unary comparison carrier of Definition 1378.1, the endpoint transport obligation of Definition 1378.6, the prefix branch antisymmetry theorem of Definition 1378.7, the* $\mathsf{Add}^{\uparrow}$ *and* $\mathsf{Mul}^{\uparrow}$ *consumer boundary of Definition 1378.5, the* $\mathsf{Int}^{\uparrow}$ *consumer boundary of Definition 1378.8, the* $\mathsf{Rat}^{\uparrow}$ *consumer boundary of Definition 1378.9, and the ledger exhaustion theorem of Definition 1378.10. The mature package exposes only finite* BHist *unary comparison rows, endpoint* hsame *transport,* Cont *prefix replay, equality collapse for opposite prefix ledgers, provenance rows, and the arithmetic consumer routes named above. It does not export host natural order, classical trichotomy, quotient order, ordered semiring structure, ordered ring structure, or field order.*

Proof. Apply the public export theorem Definition 1378.11 to identify the available $\mathsf{Order}^{\uparrow}$ surface. It supplies the unary comparison carrier, classifier obligations, Full Nat Arithmetic handoff, endpoint transport obligation, prefix branch antisymmetry, consumer boundaries, and exhausted finite ledger as one public packet.

The arithmetic consumers are then read through their boundary theorems. Apply Definition 1378.5 for the $\mathsf{Add}^{\uparrow}$ and $\mathsf{Mul}^{\uparrow}$ routes, Definition 1378.8 for signed-pair comparison reads, and Definition 1378.9 for numerator and positive-denominator comparison reads.

Finally, apply Definition 1378.10. Since every accepted consumer read is already accounted for by endpoints, branch data, endpoint classifier rows, continuation replay, and provenance, there is no remaining NameCert slot for host natural order, trichotomy, quotient order, ordered semiring or ring structure, or field order. □

Lean4 ✓ `BEDC.Derived.OrderUp.OrderUp StdBridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Order}^{\uparrow}}$.

Constructive story: An $\mathsf{Order}^{\uparrow}$ packet records finite unary comparison rows over the shared $\mathsf{Nat}^{\uparrow}$ spine. Its carrier stores two unary endpoint histories, a displayed prefix-or-classifier branch, and the finite ledger rows over BHist, hsame, and Cont that justify that branch; arithmetic consumers read only that finite comparison surface.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Order}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1378.1, Definition 1378.2, Definition 1378.3, Definition 1378.4, Definition 1378.5, Definition 1378.6, Definition 1378.7, Definition 1378.8, Definition 1378.9, Definition 1378.10, Definition 1378.11, and Definition 1378.12 bind the paper-side unary comparison, Full Nat Arithmetic handoff, arithmetic consumer transport rows, opposite-prefix equality collapse, Int/Rat comparison boundary, ledger exhaustion, public finite order-packet export, and mature consumer package.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Order}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.OrderUp.OrderFullNatArithmeticHandoff`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not export host natural-number order, classical trichotomy, quotient order, ordered semiring structure, ordered ring structure, or a public bridge beyond the displayed finite comparison rows.

Upgrade path: The standard bridge is already machine checked for the finite unary comparison interface, so no further formal-axis upgrade remains for that bridge.

Chapter 1379

Heine-Borel Interval NameCert Construction

Following Bishop and Bridges, constructive compactness of a closed bounded real interval is recorded here as finite inspection data: every precision request is answered by an explicit dyadic net whose cells are routed through the existing real-name and stream-name surfaces. The packet consumes the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the finite-window interface of chapter 126, the regular Cauchy sequence route of chapter 660, and the dyadic-net certificate of chapter 1250. It packages closed interval endpoints, mesh scales, net centers, coverage rows, tail-stability rows, and Real-seal descent rows without importing an open-cover compactness theorem.

The dependency surface is the closed-interval lattice already present in the concrete-instance spine: the located interval packet of chapter 394, the finite epsilon-net packet of chapter 1767, the compact interval locator of chapter 1891, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The Heine-Borel interval certificate consumes these sibling rows as finite inspection data before exposing any interval-compactness consumer surface.

Definition 1379.1 (Heine-Borel interval carrier)**.** *A* $\mathsf{HeineBorelInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N)$$

with the following displayed rows:

1. *A and B are the lower and upper closed* $\mathsf{Real}^{\uparrow}$ *endpoint names, including the finite seal rows by which they are read;*
2. *K is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *packet naming the closed bounded interval and its explicit dyadic epsilon-net surface;*
3. *M is the unary precision or mesh request for the dyadic net;*
4. *Z is the finite center ledger, with one displayed dyadic center for each accepted net cell at scale M;*
5. *F is the finite coverage ledger saying that every admitted interval read at scale M enters one of the cells named by Z through the route of K;*
6. *T is the tail-stability ledger saying that refining the precision request preserves the earlier accepted cells through displayed* hsame *comparisons;*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the endpoint names, center names, and refinement witnesses;*

8. *R is the* RegularCauchySequence$^{\uparrow}$ *readback row for the same endpoint and center windows;*
9. *E is the terminal* Real$^{\uparrow}$ *seal-descent row reached only after K, M, Z, F, T, S, R have been displayed;*
10. *Q records componentwise* hsame *transport for endpoints, net cells, centers, coverage rows, tail-stability rows, windows, readbacks, and the Real seal;*
11. *C records displayed* Cont *routes from a closed interval read through mesh selection, finite net coverage, tail stability, StreamName windows, regular Cauchy readback, and RealUp sealing;*
12. *P is the* Pkg *provenance over* HeineBorelInterval$^{\uparrow}$, ClosedBoundedIntervalNet$^{\uparrow}$, Real$^{\uparrow}$, StreamName$^{\uparrow}$, RegularCauchySequence$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
13. *N is the local* NameCert$_{\text{HeineBorelInterval}^{\uparrow}}$ *row.*

The carrier exports constructive compactness only as explicit dyadic epsilon-net witnesses for closed RealUp interval names. It has no coordinate for open covers, chosen finite subcovers, classical sequential compactness, quotient stream equality, host real equality, or an ambient completeness principle.

Lean4 (definition) `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalCarrier`
Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalTasteGate single carrier alignment`

Theorem 1379.2 (Heine-Borel interval net coverage)**.** *For every accepted* HeineBorelInterval$^{\uparrow}$ *carrier $H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N)$, every closed-interval containment read at precision M factors through*

$$K, M, Z, F, Q, C, P, N.$$

The read first consumes the displayed ClosedBoundedIntervalNet$^{\uparrow}$ *packet K, then the mesh request M, then one of the finitely many centers in Z, and then the coverage ledger F attached to that center. No open cover, hidden subcover selector, host interval order, or unrecorded center choice is available to the consumer.*

Proof. Project the accepted carrier. Its interval-facing coordinate is the net packet K, and the mesh request M fixes the scale at which the consumer asks for coverage.

The center and coverage rows are finite. The route through Z and F identifies the displayed cell used by the containment read, so the consumer receives a named center and a named coverage witness rather than an open-cover object.

Finally the structural rows Q, C, P, N transport, replay, source, and name this same finite route. Since the carrier has no field for a chosen subcover, host interval order, or hidden center selector, the coverage read cannot escape the displayed dyadic net. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalNetCoverage`

Theorem 1379.3 (Heine-Borel interval tail stability)**.** *Let $H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N)$ be an accepted* HeineBorelInterval$^{\uparrow}$ *carrier. If a later precision request refines M through the displayed tail-stability ledger T, then the earlier endpoint windows, accepted cells, center rows, coverage rows, and regular Cauchy readbacks transport along the stored* hsame *rows in Q and remain attached to the same package provenance P.*

Thus dyadic nets form a stable finite approximation surface for the closed interval, not a sequence chosen by countable choice or by classical sequential compactness.

Proof. Start with the refinement row in T. It is part of the same finite carrier as the endpoint rows, net packet, centers, and coverage ledger, so it can only compare displayed mesh requests and their displayed cells.

Transport is componentwise. The rows in Q move endpoint windows, centers, coverage witnesses, and regular Cauchy readbacks together, while C preserves the consumer route used to inspect them.

Repack the transported rows with the same provenance P and local name N. The result is still a finite dyadic-net surface because no coordinate supplies a countable-choice sequence, a host subsequence selector, or a classical compactness argument. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalTailStability`

Theorem 1379.4 (Heine-Borel interval Real seal descent)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{HeineBorelInterval}^{\uparrow}$ *carrier reaches the endpoint and interval seal rows only through*

$$A, B, K, M, Z, F, T, S, R, E, Q, C, P, N.$$

The seal descent first displays the closed endpoint names A, B, then the explicit dyadic-net packet K, M, Z, F, then the tail-stability ledger T, then the $\mathsf{StreamName}^{\uparrow}$ *finite windows S and* $\mathsf{RegularCauchySequence}^{\uparrow}$ *readbacks R, and only then the Real seal row E. The route exports no quotient stream equality, host real equality, open-cover compactness, selected convergent subsequence, or ambient Real completeness row.*

Proof. Read the endpoint rows first. The carrier stores A and B as closed $\mathsf{Real}^{\uparrow}$ names, but the seal row E is not public until the finite net and readback rows have been displayed.

Next apply the net-coverage and tail-stability routes. The packet K, M, Z, F supplies the finite dyadic epsilon-net witness, and T keeps refinements attached to the same displayed cells and centers.

Finally pass through the finite observation rows S and R before reaching E. The structural rows Q, C, P, N preserve the route as one NameCert packet, so a Real-facing consumer cannot substitute quotient equality, host equality, open-cover compactness, a selected convergent subsequence, or an ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalRealSealDescent`

Theorem 1379.5 (Heine-Borel interval finite-net induction)**.** *Let $H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N)$ be an accepted* $\mathsf{HeineBorelInterval}^{\uparrow}$ *carrier. Every accepted finite center ledger Z is consumed by primitive finite induction over the displayed net cells: the base row is the first accepted cell named by K, M, Z, F, and the step row extends an already consumed finite prefix by replaying* Cont *through F, Q, C, P, N for the next displayed cell.*

The induction surface exports only the finite ledger entries already named by Z and the route data already stored in F, Q, C, P, N. It exports no open-cover subcover, selected subsequence, countable-choice enumeration, host real equality, or quotient stream equality.

Proof. Project the finite center ledger Z from the accepted carrier. Since Z is a displayed BHist finite ledger, its cells are consumed by the primitive finite-list induction available to the packet, not by an external cover-selection principle.

The base row is the first accepted cell. Its center and coverage witness are read through K, M, Z, F, and the structural rows Q, C, P, N record the same route as a local $\mathsf{NameCert}_{\mathsf{HeineBorelInterval}^{\uparrow}}$ entry.

For the step row, assume the previous finite prefix has already been consumed. The next displayed cell is attached by replaying Cont through the coverage ledger F, transporting the relevant rows through Q, and repacking the route with C, P, N.

This exhausts the ledger because the induction ranges only over the displayed entries of Z. No row of the carrier can introduce an open-cover subcover, a selected subsequence, or a hidden infinite enumeration. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalNetInduction`

Theorem 1379.6 (Heine-Borel interval mesh-refinement functoriality)**.** *Let $H = (A, B, K, M, Z, F, T, S, R, E, Q, C$ be an accepted* $\mathsf{HeineBorelInterval}^{\uparrow}$ *carrier. A displayed refinement of the mesh request M transports coverage rows and center rows through T, Q, C and then composes with the finite-net induction route of Definition 1379.5. Thus refinement preserves the finite dyadic-net coverage surface as a named* $\mathsf{NameCert}_{\mathsf{HeineBorelInterval}^{\uparrow}}$ *route.*

Proof. Begin with the displayed refinement row in T. By Definition 1379.3, refinement preserves the earlier endpoint windows, accepted cells, center rows, coverage rows, and regular Cauchy readbacks through the stored hsame rows.

Transport the center and coverage rows componentwise through Q. The replay row C keeps the consumer path attached to the same package provenance P and local name N.

Now apply Definition 1379.5 to the transported finite ledger. The refined mesh therefore feeds the same finite induction route, with no appeal to open-cover compactness, a selected finite subcover, or an ambient Real completeness principle. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalMeshRefinementFunctoriality`

Theorem 1379.7 (Heine-Borel interval NameCert obligation surface)**.** *For an accepted* $\mathsf{HeineBorelInterval}^{\uparrow}$ *carrier $H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HeineBorelInterval}^{\uparrow}}$ *obligations are exhausted by carrier admission, finite-net induction, mesh-refinement functoriality, tail stability, and Real seal descent. Equivalently, every local consumer route factors through the carrier rows of Definition 1379.1, the coverage route of Definition 1379.2, the stability route of Definition 1379.3, the seal route of Definition 1379.4, the induction route of Definition 1379.5, and the refinement route of Definition 1379.6. The packet exports no open-cover compactness theorem, selected finite subcover, host real equality, quotient stream equality, selected convergent subsequence, or ambient Real completeness row.*

Proof. The carrier definition lists the only public rows of H: endpoints, closed bounded interval net data, mesh request, finite center ledger, coverage ledger, tail-stability ledger, observation windows, regular Cauchy readbacks, Real seal descent, transport, replay, provenance, and local NameCert.

Carrier admission is therefore the projection of these displayed rows. Coverage and tail stability are supplied by Definition 1379.2 and Definition 1379.3, while Real-facing consumers descend through Definition 1379.4.

The remaining finite-means obligations are the induction over Z and the refinement transport across M. These are exactly Definition 1379.5 and Definition 1379.6.

No other obligation can be exported from the packet, because the carrier has no row for open-cover compactness, selected finite subcovers, host real equality, quotient stream equality, selected convergent subsequences, or ambient Real completeness. Thus the listed carrier rows and theorem sites exhaust the local $\mathsf{NameCert}_{\mathsf{HeineBorelInterval}^{\uparrow}}$ surface. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalNameCertObligationSurface`

Theorem 1379.8 (Heine-Borel interval public finite-net export)**.** *Every accepted* HeineBorelInterval$^{\uparrow}$ *packet exports to public compactness consumers only the displayed finite dyadic net,* StreamName$^{\uparrow}$ *windows,* RegularCauchySequence$^{\uparrow}$ *readback,* ClosedBoundedIntervalNet$^{\uparrow}$ *coverage, tail-stability rows, mesh-refinement rows,* Real$^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows named by Definition 1379.1.*

Consequently, a public consumer may reuse the finite-net coverage route, tail-stability route, mesh-refinement route, Real seal descent, and NameCert obligation surface, but it receives no additional interval object beyond the displayed rows of $H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N)$.

Proof. Project the carrier rows of Definition 1379.1. The public data are exactly the endpoint names, closed bounded interval net packet, mesh request, center ledger, coverage ledger, tail-stability ledger, StreamName windows, regular Cauchy readbacks, Real seal, transport, replay, provenance, and local name.

Apply the existing finite routes. Net coverage is Definition 1379.2, finite induction is Definition 1379.5, refinement is Definition 1379.6, tail stability is Definition 1379.3, and Real-facing descent is Definition 1379.4.

The NameCert obligation surface of Definition 1379.7 repacks precisely those rows for public consumers. Since no further coordinate appears in the carrier, the public export cannot contain any object outside that finite dyadic-net surface. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalPublicFiniteNetExport`

Theorem 1379.9 (Heine-Borel interval closed-interval net extraction)**.** *Every accepted* HeineBorelInterval$^{\uparrow}$ *carrier exports an explicit closed-interval finite-net witness by first projecting the closed bounded interval net row* K*, mesh request* M*, center ledger* Z*, and coverage ledger* F*. The witness is then transported through* Q, C, P, N *as componentwise* hsame *transport, displayed replay, provenance, and local naming, while endpoint and readback access is sealed through the* StreamName$^{\uparrow}$*,* RegularCauchySequence$^{\uparrow}$*, and* Real$^{\uparrow}$ *rows* S, R, E*.*

Thus the extraction surface of

$$H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N)$$

is a finite closed-interval net witness for compactness-facing consumers, not an open-cover compactness theorem, selected finite subcover, sequential compactness principle, quotient stream equality, or ambient Real$^{\uparrow}$ *completeness claim.*

Proof. Project the finite-net rows K, M, Z, F from Definition 1379.1. Net coverage is supplied by Definition 1379.2, so the interval read begins with the displayed closed bounded interval net rather than an arbitrary cover.

Use finite-net induction and mesh-refinement functoriality, Definition 1379.5 and Definition 1379.6. These keep the center ledger finite and preserve the same witness when later mesh requests are transported.

Finally apply the public finite-net export of Definition 1379.8. It routes the witness through Q, C, P, N and seals endpoint observation and Real-facing readback through S, R, E, leaving no carrier coordinate for open-cover compactness, selected subcovers, sequential compactness, quotient stream equality, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalClosedIntervalNetExtraction`

Theorem 1379.10 (Heine-Borel interval Real completion-facing route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{HeineBorelInterval}^{\uparrow}$ *packet must pass through the finite center ledger* Z*, mesh-refinement functoriality for the request* M*, finite-net induction over the displayed cells, tail stability for refinements, Real seal descent through* S, R, E*, and the public finite-net export before any compact interval boundary is read.*

Thus the completion-facing endpoint route is the same finite dyadic-net route exposed by

$$H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N),$$

where A, B *are the closed endpoints,* K, M, Z, F *are the finite net and coverage rows,* T *is the tail-stability ledger,* S, R, E *are the StreamName, RegularCauchySequence, and Real seal rows, and* Q, C, P, N *preserve transport, replay, provenance, and local naming. The route is not an ambient completeness principle, quotient stream equality, selected limit, or open-cover compactness theorem.*

Proof. Start with the finite-net coverage route of Definition 1379.2. It forces any interval containment read to pass through K, M, Z, F, Q, C, P, N, so the completion-facing consumer receives a displayed finite center ledger rather than an external compactness object.

Next apply finite-net induction and mesh-refinement functoriality from Definition 1379.5 and Definition 1379.6. The induction makes every center-ledger read finite, and refinement keeps later mesh requests attached to the same coverage and center rows.

Tail stability and Real seal descent are then supplied by Definition 1379.3 and Definition 1379.4. Stability preserves endpoint windows, cell rows, center rows, coverage rows, and regular Cauchy readbacks through the stored transport ledger, while the Real descent requires A, B, S, R, E to be read after the finite-net rows.

Finally use the public finite-net export of Definition 1379.8. It repacks the finite ledger, refinement route, stability route, Real seal descent, transport, replay, provenance, and local name for downstream consumers, leaving no coordinate for ambient completeness, quotient equality, selected limits, or open-cover compactness. □

Lean4 (statement) `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalRealCompletionFacingRoute`

Theorem 1379.11 (Heine-Borel interval cover-refusal boundary)**.** *The public finite-net surface of Definition 1379.8 still refuses general open-cover compactness, selected finite subcovers, classical sequential compactness, host real equality, quotient stream equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every accepted read of* $H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N)$ *must pass through the displayed finite dyadic net and its StreamName, RegularCauchySequence, Real seal, transport, replay, provenance, and local NameCert rows before any compactness-facing conclusion is consumed.*

Proof. Inspect the public export theorem. It lists the finite dyadic net, observation windows, readbacks, coverage, tail-stability, refinement, Real seal, transport, replay, provenance, and naming rows as the complete public surface.

The excluded principles have no carrier coordinate. There is no row for an arbitrary open cover, no selector for finite subcovers, no sequential compactness witness, no host real equality test, no quotient stream equality, and no ambient completeness service.

Therefore the public surface remains a finite-net compactness interface only. Any consumer that attempts to read one of the excluded principles must leave the displayed carrier rows, so it is not reading the $\mathsf{HeineBorelInterval}^{\uparrow}$ packet described here. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalCoverRefusalBoundary`

Theorem 1379.12 (Heine-Borel interval cluster-filter route)**.** *Any* $\mathsf{ClusterFilter}^{\uparrow}$ *consumer that uses an accepted* $\mathsf{HeineBorelInterval}^{\uparrow}$ *packet must first read the interval finite-net coverage row, the tail-stability row, the Real-seal descent row, and the finite-net induction row before the cluster-filter adherent-observation row can be consumed. In carrier notation the Heine-Borel side supplies*

$$H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N),$$

and the cluster-filter side may read its adherent-observation row only after K, M, Z, F*,* T*,* S, R, E*, and the induction over* Z *have all been displayed through* Q, C, P, N*.*

The route exports a finite compactness-to-cluster handoff. It does not select a cluster point, form a quotient filter, import open-cover compactness, or invoke ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the finite-net coverage theorem. It forces every interval containment read through K, M, Z, F, Q, C, P, N, so the cluster-filter consumer receives a displayed finite cell and coverage witness rather than a host compactness object.

Next apply tail stability and Real seal descent. Tail stability keeps refinements attached to the same endpoint windows, cell rows, centers, coverage rows, and readbacks, while Real seal descent requires the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegularCauchySequence}^{\uparrow}$ rows to precede the terminal $\mathsf{Real}^{\uparrow}$ seal.

Now use finite-net induction over Z. The induction supplies the finite row-by-row ledger that a cluster-filter consumer may inspect before it reaches its adherent-observation row. This composes with the $\mathsf{ClusterFilter}^{\uparrow}$ Cauchy-completion handoff, which already requires the CauchyFilter, MetricSpace, Topology, StreamName, RegSeqRat, Real seal, and adherent-observation rows to remain visible.

Since both sides expose only displayed finite rows, the handoff cannot choose a cluster point, quotient the filter, replace the dyadic-net route by open-cover compactness, or appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalClusterFilterRoute`

Theorem 1379.13 (Heine-Borel interval bridged finite-net interface)**.** *Every compact-interval or* $\mathsf{Real}^{\uparrow}$*-completion-facing consumer of an accepted* $\mathsf{HeineBorelInterval}^{\uparrow}$ *packet must route through the finite center ledger, mesh-refinement functoriality, net induction, Real seal descent, cover-refusal boundary, and cluster-filter route before reading the interval as a bridge-facing compactness interface.*

In carrier notation, the bridge-facing interface still exposes only

$$H = (A, B, K, M, Z, F, T, S, R, E, Q, C, P, N),$$

where Z *is the finite center ledger,* M *records mesh refinement,* F, T *record coverage and tail stability,* S, R, E *carry the StreamName, RegularCauchySequence, and Real seal rows, and* Q, C, P, N *preserve transport, replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.HeineBorelIntervalUp.HeineBorelIntervalBridgedFiniteNetInterface`

Proof. Start with the public finite-net export of Definition 1379.8. It exposes only the dyadic interval net, finite center ledger, finite coverage and stability rows, readback rows, Real seal, transport, replay, provenance, and local name.

Next use mesh-refinement functoriality, net induction, and Real seal descent. The refinement theorem keeps later mesh reads attached to the same finite rows, the induction theorem makes every center-ledger read finite, and the Real seal descent theorem requires the StreamName and RegularCauchySequence rows before any Real-facing endpoint is consumed.

Finally apply the cover-refusal boundary and the cluster-filter route. The boundary removes open-cover compactness, selected subcovers, quotient stream equality, host real equality, selected convergent subsequences, and ambient Real completeness from the interface. The cluster-filter route shows that downstream compactness readers must still pass through the same finite rows before they can consume adherent-observation data. Hence the bridge-facing compactness interface is the displayed finite-net route and nothing outside it. □

Closure status for $\mathsf{NameCert}_{\mathsf{HeineBorelInterval}\uparrow}$.

Constructive story: A $\mathsf{HeineBorelInterval}^{\uparrow}$ packet is generated from closed RealUp endpoint names, a ClosedBoundedIntervalNetUp dyadic-net packet, a mesh request, finite center and coverage ledgers, tail-stability rows, StreamName windows, RegularCauchySequence readbacks, a RealUp seal descent row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HeineBorelInterval}\uparrow}$, maturePackageClosed)

Scope closed: Definition 1379.1, Definition 1379.2, Definition 1379.5, Definition 1379.6, Definition 1379.4, Definition 1379.7, Definition 1379.8, and Definition 1379.13 bind the bridged finite-net interval export for constructive compactness of closed bounded RealUp intervals, with tail stability supplied by Definition 1379.3.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HeineBorelInterval}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim general open-cover compactness, classical sequential compactness, choice of finite subcovers, selected convergent subsequences, quotient stream equality, host real equality, or ambient Real completeness.

Upgrade path: Lean closure requires carrier admission, net coverage, finite-net induction, mesh-refinement functoriality, tail stability, Real seal descent, NameCert obligation-surface, and TasteGate field faithfulness for BEDC.Derived.HeineBorelIntervalUp.

Chapter 1380

A Concrete Naming Certificate for $\mathsf{LocatedApartness}^{\uparrow}$

The $\mathsf{LocatedApartness}^{\uparrow}$ packet is the Bishop–Bridges constructive-analysis handoff from located real data to positive apartness evidence. It sits between **??**, chapter 304, chapter 126, chapter 301, chapter 291, and chapter 38: the located endpoints supply finite windows and dyadic enclosures, and the apartness side receives only a positive finite gap row with visible BEDC provenance.

Definition 1380.1 (LocatedApartness carrier)**.** *A* $\mathsf{LocatedApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L_0, L_1, S, R_0, R_1, D, G, A, H, C, P, N)$$

with the following displayed rows:

1. L_0 *and* L_1 *are two accepted* $\mathsf{LocatedReal}^{\uparrow}$ *source rows;*
2. S *is a shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row on which both sources are read;*
3. R_0 *and* R_1 *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks of the two located sources over the shared window;*
4. D *is the pair of* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledgers projected from the two located packets;*
5. G *is a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap row witnessing that the two projected endpoint ledgers are disjoint on the displayed window;*
6. A *is the* $\mathsf{ApartnessReal}^{\uparrow}$ *finite-window separation ledger receiving the endpoint rows, the positive gap row, the shared window, and the two readbacks;*
7. H *records componentwise* hsame *transport for the two located sources, the shared window, the readbacks, the dyadic endpoint ledgers, the positive gap row, and the apartness ledger;*
8. C *records the displayed* Cont *routes from located windows to regular-rational readbacks, dyadic endpoint rows, and the apartness ledger;*
9. P *is the* Pkg *provenance row over* $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{LocatedApartness}^{\uparrow}}$ *row.*

The classifier compares two carriers by transporting all listed rows componentwise and then requiring that the transported positive gap row repacks to the transported $\mathsf{ApartnessReal}^{\uparrow}$ *finite-window separation ledger. No coordinate stores trichotomy, a total order, a quotient representative, a selected limit, completeness, or host real equality.*

Theorem 1380.2 (LocatedApartness NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{LocatedApartness}^{\uparrow}}$ *surface consists exactly of five rows:*

1. *carrier visibility: the packet of Definition 1380.1 displays both* $\mathsf{LocatedReal}^{\uparrow}$ *source rows, the shared* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledgers, the positive gap row, and the* $\mathsf{ApartnessReal}^{\uparrow}$ *ledger;*
2. *classifier transport: accepted packets compare only by componentwise* hsame *transport and displayed* Cont *replay of those same rows;*
3. *gap-row stability: the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap row remains attached to the transported endpoint ledgers and the transported shared window;*
4. *ledger exactness: the apartness ledger is exactly the finite-window separation row determined by the two endpoint rows, the positive gap, the shared window, and the two readbacks;*
5. *no-trichotomy and no-quotient boundary: the packet exports no classical trichotomy, total order, quotient real representative, selected limit, completion datum, or host equality row.*

Lean4 ✓ `BEDC.Derived.LocatedApartnessUp.LocatedApartnessTasteGate single carrier alignment`

Proof. Project the carrier through Definition 1380.1. The first row exposes both located sources, and the next four rows expose the common finite window, the two regular-rational readbacks, the dyadic endpoint ledgers, and the positive gap row.

Classifier transport is componentwise. The hsame and Cont rows move the two located packets, the shared window, the readbacks, the endpoint ledgers, and the positive gap together, so the transported packet has the same visible shape.

Gap-row stability and ledger exactness are then the same check at the apartness boundary: the transported positive gap is attached to the transported endpoint ledgers and repacked as the $\mathsf{ApartnessReal}^{\uparrow}$ finite-window separation ledger.

The remaining boundary is negative. Since the carrier contains no coordinate for trichotomy, total order, quotient representatives, selected limits, completion, or host equality, no NameCert row can export any of those data. □

Theorem 1380.3 (LocatedApartness gap handoff)**.** *Let* L_0 *and* L_1 *be transported* $\mathsf{LocatedReal}^{\uparrow}$ *packets over a shared* $\mathsf{StreamName}^{\uparrow}$ *finite window. If their* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks and* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledgers display a positive dyadic gap row on that window, then the two endpoint rows, the positive gap, the shared window, the two readbacks, and the visible provenance repack as an* $\mathsf{ApartnessReal}^{\uparrow}$ *finite-window separation row.*

Consequently the located pair crosses the L10 handoff as finite positive-gap evidence, not as trichotomy of constructive reals, a total order, a quotient real comparison, a selected representative, or a completion principle.

Proof. Project L_0 and L_1 through the $\mathsf{LocatedReal}^{\uparrow}$ carrier surface. The projection exposes their regular-rational source rows, their finite schedules, their dyadic endpoint ledgers, and the provenance rows used to read those data.

Use the transported shared $\mathsf{StreamName}^{\uparrow}$ window to align the two projections. The two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks now live over the same finite observation surface, and the dyadic endpoint rows are the endpoint ledgers displayed by the two located packets.

Attach the positive $\mathsf{DyadicRatCore}^{\uparrow}$ gap row to these aligned endpoint ledgers. This forms the tuple named in the $\mathsf{ApartnessReal}^{\uparrow}$ finite-window separation row: two endpoint rows, one positive radius or gap row, one shared window, two readbacks, and the visible separation ledger.

Repack that tuple as the apartness ledger coordinate A of Definition 1380.1. The repacking uses only the displayed BHist, hsame, Cont, Pkg, and NameCert provenance, so no excluded classical or quotient datum enters the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedApartness}^{\uparrow}$ packet is generated from two located real source rows, a shared finite observation window, two regular-rational readbacks, dyadic endpoint ledgers, one positive dyadic gap row, an apartness separation ledger, componentwise transport, displayed continuation routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1380.1, Definition 1380.2, and Definition 1380.3 name the seed carrier, obligation rows, and finite positive-gap handoff between located real packets and apartness evidence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy of constructive reals, total order, quotient real representatives, selected limits, completeness, or a standard bridge.

Upgrade path: To reach obligationClosure, the carrier, five obligation rows, and gap handoff must be checked as finite BEDC packet obligations.

Chapter 1381

A Concrete Naming Certificate for $\mathsf{BishopRealComparison}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopRealComparison}^{\uparrow}$ packet records the finite comparison surface between Bishop-style regular-Cauchy real names, located-real readbacks, and Dedekind-cut boundary rows without importing quotient reals, trichotomy, host real equality, or ambient completeness.

The packet is a human-origin L10 comparison certificate between the regular-Cauchy presentation of chapter 343, the completion-facing handoff of chapter 360, the finite located readback of **??**, and the rounded cut boundary of chapter 436. It uses those sibling surfaces only as displayed certificate rows; it does not identify them as equivalent real constructions.

Definition 1381.1 (BishopRealComparison carrier)**.** *A* $\mathsf{BishopRealComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (B, C, L, D, R, S, H, P, N)$$

with the following visible rows:

1. *B is the accepted* $\mathsf{BishopReal}^{\uparrow}$ *row exposing a regular-Cauchy real name, its scheduled finite windows, dyadic tolerance rows, located-apartness evidence, and visible* $\mathsf{Real}^{\uparrow}$ *seal;*
2. *C is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *row reached from the same regular-Cauchy source surface, recording the completion-facing handoff without adding a quotient completion point;*
3. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *row that reads the same regular source through finite dyadic location windows;*
4. *D is the* $\mathsf{DedekindCut}^{\uparrow}$ *boundary row carrying lower and upper rational observations, roundedness, locatedness, disjointness, and rational embedding data;*
5. *R is the shared* $\mathsf{Real}^{\uparrow}$ *seal row through which all real-facing consumers must pass;*
6. *S is the readback ledger naming the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *schedules, regular-rational rows, and tolerance packets used by B, C, L, and D;*
7. *H records componentwise* hsame *and displayed* Cont *transports among the Bishop, completion, located, Dedekind-boundary, seal, and readback rows;*
8. *P is the* Pkg *provenance over* $\mathsf{BishopReal}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{DedekindCut}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopRealComparison}^{\uparrow}}$ *row.*
The carrier classifier compares two accepted packets only by replaying the displayed finite rows $B, C, L, D, R, S, H, P, N$. It has no coordinate for quotient-real equality, trichotomy, host real equality, a selected limit, a completeness theorem, or a proof that Bishop, located, and Dedekind presentations are globally equivalent.

Lean4 ✓ `BEDC.Derived.BishopRealComparisonUp.TasteGate.BishopRealComparisonTasteGate single carrier alignment`

Theorem 1381.2 (BishopRealComparison NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealComparison}^{\uparrow}$ *carrier $X = (B, C, L, D, R, S, H, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRealComparison}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for the displayed packet, Bishop-real admission through B, completion handoff admission through C, located-readback admission through L, Dedekind-boundary admission through D, shared* $\mathsf{Real}^{\uparrow}$ *seal admission through R, finite StreamName/RegSeqRat/DyadicRatCore readback through S, componentwise* hsame *and* Cont *transport through H,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.BishopRealComparisonUp.BishopRealComparisonPacket namecert obligations`

Proof. Project the carrier of Definition 1381.1. The rows $B, C, L, D, R, S, H, P, N$ are the complete displayed coordinates of one finite BHist packet.

Read the four analytic-facing rows in route order. The Bishop row supplies the regular-Cauchy name surface, the completion row supplies the handoff reached from that surface, the located row supplies finite dyadic location readback, and the Dedekind row supplies lower and upper rational boundary observations.

The shared seal and readback rows then bind the comparison. The $\mathsf{Real}^{\uparrow}$ seal R is reached only after the regular windows, rational readback rows, and dyadic tolerance packets named by S have been exposed.

Finally, H, P, and N provide transport, provenance, and local naming for exactly those rows. Since no coordinate stores quotient equality, trichotomy, host equality, a selected limit, or ambient completeness, no further NameCert obligation can be read from the packet. □

Theorem 1381.3 (BishopRealComparison Cauchy-Dedekind boundary)**.** *Every completion-facing or cut-facing read exported by an accepted* $\mathsf{BishopRealComparison}^{\uparrow}$ *packet factors through the same finite regular-Cauchy source and tolerance surface. The completion row C is read through the Bishop row B, the shared readback ledger S, and the seal row R; the Dedekind boundary row D is read through the rational observation and dyadic tolerance rows already named by S.*

Thus the packet gives a Cauchy-to-Dedekind boundary comparison surface, not an equivalence theorem between quotient completions and Dedekind cuts.

Proof. First expose the regular-Cauchy source. The Bishop row B carries the scheduled finite windows, regular-rational name, dyadic tolerance data, and visible $\mathsf{Real}^{\uparrow}$ seal that the comparison packet is allowed to inspect.

Next follow the completion route. The row C is a completion-facing handoff attached to the same source surface, so a consumer cannot read C before it has read B and the StreamName/RegSeqRat/DyadicRatCore ledger S.

Now follow the cut-facing boundary. The row D supplies lower and upper rational observations, roundedness, locatedness, disjointness, and rational embedding data, but the public comparison reaches those observations only through the rational and dyadic rows named in S.

The conclusion is therefore a boundary statement. The carrier displays a finite route from Cauchy-name rows to cut-boundary observations, while the excluded quotient completion, cut equality, and ambient equivalence data remain absent from every coordinate. □

Lean4 ✓ `BEDC.Derived.BishopRealComparisonUp.BishopRealComparisonPacket cauchy dedekind boundary`

Theorem 1381.4 (BishopRealComparison located readback)**.** *For an accepted* $\mathsf{BishopRealComparison}^{\uparrow}$ *packet* $X = (B, C, L, D, R, S, H, P, N)$*, every located-real consumer read factors first through the Bishop regular-Cauchy row* B*, then through the shared finite readback ledger* S*, and only then through the* $\mathsf{LocatedReal}^{\uparrow}$ *row* L*. The read exposes the same scheduled* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *rational rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance packets, and* $\mathsf{Real}^{\uparrow}$ *seal row* R *that the completion and Dedekind-boundary routes use.*

Lean4 ✓ `BEDC.Derived.BishopRealComparisonUp.BishopRealComparisonCarrier located readback`

Proof. Project the located coordinate L from the carrier. It is not an independent located real object; it is stored with B, S, and R in the same finite packet.

Read the shared ledger S. It names the finite windows, regular-rational rows, and dyadic tolerance packets through which the Bishop, completion, located, and Dedekind-boundary routes are all replayed.

Transport the located read through H. The componentwise hsame and displayed Cont routes preserve only the scheduled rows already listed in S, so the consumer sees the same source and tolerance surface as the other comparison routes.

The located readback is therefore shared rather than detached. No extra order relation, quotient representative, host equality, or completion point is available to the consumer after L has been read. □

Theorem 1381.5 (BishopRealComparison non-escape)**.** *An accepted* $\mathsf{BishopRealComparison}^{\uparrow}$ *packet exports only the finite comparison surface*

$$B, C, L, D, R, S, H, P, N.$$

No downstream consumer can obtain quotient reals, trichotomy, host real equality, a selected limit, ambient completeness, or a global equivalence between Bishop Cauchy names, located reals, and Dedekind cuts from the packet alone.

Lean4 ✓ `BEDC.Derived.BishopRealComparisonUp.BishopRealComparisonPacket nonescape`

Proof. Read the carrier inventory. The public surface consists exactly of the Bishop row, completion handoff, located readback, Dedekind boundary, shared real seal, shared finite readback ledger, transport row, provenance row, and local naming row.

Apply Definition 1381.2 to exhaust the local certificate obligations. Every admitted consumer read is one of the displayed rows or a replay of those rows through H, P, and N.

Apply Definition 1381.3 and Definition 1381.4 to the two analytic-facing exits. The completion, located, and Dedekind-boundary consumers all pass through the same finite source/readback surface before reaching their public rows.

The excluded data have no coordinate in the packet and no route through the displayed obligations. Hence a downstream consumer cannot escape to quotient equality, trichotomy, host real equality, selected limits, ambient completeness, or a global presentation-equivalence theorem. □

Theorem 1381.6 (BishopRealComparison source induction)**.** *Every accepted* $\mathsf{BishopRealComparison}^{\uparrow}$ *packet is obtained by finite induction over the displayed rows*

$$B, C, L, D, R, S, H, P, N.$$

The induction first admits the Bishop row, then the completion handoff, located row, Dedekind boundary row, shared seal, readback ledger, componentwise transport, provenance, and local naming rows. It refuses quotient equality, trichotomy, selected limits, and ambient completeness at every step.

Proof. The base step is the carrier projection of Definition 1381.1. It exposes a finite packet whose public coordinates are exactly $B, C, L, D, R, S, H, P, N$.

For the analytic rows, apply Definition 1381.2. The Bishop row B supplies the regular-Cauchy source, C is admitted only as the completion-facing handoff from that source, L is admitted only as the located readback, and D is admitted only as the Dedekind-boundary read.

For the shared rows, use Definition 1381.3 and Definition 1381.4. They force the completion, located, and cut-facing exits through the same seal R and readback ledger S.

The final induction steps add H, P, and N as transport, provenance, and local naming rows for the already displayed surface. By Definition 1381.5, no induction case has a coordinate from which quotient equality, trichotomy, selected limits, or ambient completeness can be introduced. □

Lean4 ✓ `BEDC.Derived.BishopRealComparisonUp.BishopRealComparisonPacket source induction`

Theorem 1381.7 (BishopRealComparison located-cut transport)**.** *In an accepted* $\mathsf{BishopRealComparison}^{\uparrow}$ *packet, a located read and a Dedekind boundary read transported through the same* S, H, P, N *rows remain on the same finite regular-Cauchy and dyadic tolerance surface. The shared transport does not identify the located and cut presentations by quotient equality; it only preserves the displayed readback rows named by the carrier.*

Proof. Start with the located exit. By Definition 1381.4, any located-real consumer first reads the Bishop regular-Cauchy row B, then the shared ledger S, and then the located row L.

Now read the cut-facing exit. By Definition 1381.3, the Dedekind boundary row D is reached through the rational observation and dyadic tolerance rows already named by S.

Transport both reads through H and source them through P, N. The componentwise hsame and displayed Cont rows preserve the visible regular-Cauchy windows, rational readbacks, and dyadic tolerance packets; they do not create a host equality or quotient comparison between the located and cut presentations.

Thus the two exits stay on the same finite surface. The comparison is a shared readback and tolerance transport statement, not a presentation-equivalence theorem. □

Lean4 ✓ `BEDC.Derived.BishopRealComparisonUp.BishopRealComparisonPacket located cut transport`

Theorem 1381.8 (BishopRealComparison seal exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BishopRealComparison}^{\uparrow}$ *packet must first consume the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and shared* $\mathsf{Real}^{\uparrow}$ *seal rows named by* S *and* R*. No real-facing read can bypass those rows to obtain quotient real equality, host equality, selected limits, trichotomy, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.BishopRealComparisonUp.BishopRealComparisonPacket seal exhaustion`

Proof. Project the shared readback ledger from Definition 1381.1. The row S names the finite StreamName windows, RegSeqRat rational rows, and DyadicRatCore tolerance packets used by the Bishop, completion, located, and Dedekind-boundary routes.

Apply Definition 1381.2 to the seal row. The shared $\mathsf{Real}^{\uparrow}$ seal R is an admitted row only after the finite readback ledger has been exposed.

Apply Definition 1381.5 to any attempted real-facing consumer exit. Since quotient real equality, host equality, selected limits, trichotomy, and ambient completeness have no coordinates in the packet, a consumer reaching R still receives only the displayed finite comparison surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealComparison}^{\uparrow}$ packet is generated from displayed $\mathsf{BishopReal}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, a shared finite readback ledger, componentwise hsame and Cont transports, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealComparison}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1381.1, Definition 1381.2, Definition 1381.3, Definition 1381.4, Definition 1381.5, Definition 1381.6, Definition 1381.7, and Definition 1381.8 export the finite Cauchy-Dedekind, located-readback, seal-exhaustion, and source-induction packet as the displayed bridge surface for the public Bishop, completion, located, Dedekind-boundary, and shared Real-seal comparison route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Lean theorem, bridge checking, quotient-real equality, trichotomy, host real equality, selected limits, ambient completeness, or a global equivalence theorem between Bishop Cauchy names, located reals, and Dedekind cuts.

Upgrade path: No further theory-axis upgrade remains; Lean verification and bridge checking remain independent obligations.

Chapter 1382

A Concrete Naming Certificate for $\mathsf{FilteredCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and Bourbaki, *General Topology*, the FilteredCauchyCompletio packet records the finite BEDC route by which Cauchy filters reach the Real-completion interface. It is built over $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, RealCompletionExactBoundaryUp, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

The dependency anchors are the finite filter surface of chapter 333, the sequence-space handoff of chapter 406, and the Real boundary of chapter 1120. The uniform criterion supplies the common-tail test before any route reaches the Real seal, while stream names, regular rational rows, and dyadic ledgers keep the consumer boundary finite.

Definition 1382.1 (Filtered Cauchy completion carrier)**.** *A* $\mathsf{FilteredCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, U, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row carrying the finite filterbase and common-window evidence;*
2. *U is the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row that tests the same finite filter windows by uniform tails;*
3. *S is the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *handoff row exposing the associated* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readings;*
4. *Q is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *and* RealCompletionExactBoundaryUp *route reached from those same finite rows;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the displayed route;*
6. *H is the componentwise* hsame *transport row for F, U, S, Q, E;*
7. *C is the* Cont *continuation row that replays the accepted finite windows without adding host data;*
8. *P is the* Pkg *provenance over the listed completion, filter, uniform, stream, regular-rational, dyadic, transport, and seal rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FilteredCauchyCompletion}^{\uparrow}}$ *row.*

The accepted carrier exposes only these rows. It has no coordinate for a quotient stream, selected limit, host real equality, countable-choice selector, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.FilteredCauchyCompletionUp.TasteGate.FilteredCauchyCompletionTasteGate single carrier alignment`

Theorem 1382.2 (Filtered completion carrier habitation)**.** *Whenever the rows $F, U, S, Q, E, H, C, P, N$ occur in one finite* BHist *with the dependencies listed in Definition 1403.1, they assemble an accepted* $\mathsf{FilteredCauchyCompletion}^{\uparrow}$ *carrier. Conversely, every accepted carrier projects to exactly those nine displayed rows.*

Proof. The forward direction reads the finite history in the carrier order. The $\mathsf{CauchyFilter}^{\uparrow}$ row supplies the finite filterbase, the uniform criterion row supplies the common-tail test, the sequence-space row supplies the stream, regular-rational, and dyadic readings, and the completion route supplies the Real-boundary handoff and terminal seal.

Transport, continuation, package provenance, and local naming are the final four displayed coordinates. Repacking these rows gives the named carrier.

For the reverse direction, project an accepted carrier by its definition. No extra coordinate is available, so the projection is exhausted by the nine listed rows. □

Theorem 1382.3 (Common-filter classifier transport)**.** *Two accepted* $\mathsf{FilteredCauchyCompletion}^{\uparrow}$ *carriers classify together only by a displayed common* $\mathsf{CauchyFilter}^{\uparrow}$ *refinement whose uniform-tail test, sequence space handoff, Real-completion route, terminal Real seal,* hsame *transport,* Cont *continuation,* Pkg *provenance, and local* NameCert *rows are transported componentwise.*

Proof. Project both carriers to their F rows and compare those rows by the common finite filter refinement supplied by $\mathsf{CauchyFilter}^{\uparrow}$. The classifier has no access to a host filter or quotient of streams.

Once the filter rows share a displayed refinement, transport the U, S, Q, E rows componentwise along H and replay the same reads through C. The package row records that these transported reads remain on the same finite dependency anchors.

Repacking the transported rows gives the classifier judgement for the two carriers. Reading such a judgement back yields exactly the common filter refinement and the listed componentwise transports. □

Theorem 1382.4 (Uniform-tail exactness)**.** *For an accepted carrier $K = (F, U, S, Q, E, H, C, P, N)$, every completion-facing read of Q first passes through the uniform-tail row U attached to the same* $\mathsf{CauchyFilter}^{\uparrow}$ *row F and the same* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *handoff S. No Real seal consumer can bypass U by using a selected subsequence, quotient stream, or host completion point.*

Proof. Read the carrier coordinates. The route to Q is listed after F, U, S, so the completion-facing consumer sees the filterbase, uniform-tail test, and sequence-space handoff before it can read the Real-completion boundary.

The continuation row C only replays the accepted finite windows, and the transport row H only compares displayed coordinates. Neither row introduces a selected subsequence, quotient stream, or host completion point.

Thus the uniform-tail row is the exact gate for completion-facing reads. Any consumer that bypasses it has left the displayed carrier. □

Theorem 1382.5 (Completion handoff factorization)**.** *Every* RealCauchyCompletion$^{\uparrow}$ *or* RealCompletionExactBoun *handoff exported by an accepted* FilteredCauchyCompletion$^{\uparrow}$ *carrier factors through the rows* F, U, S, H, C, P, N *before reaching* Q *and the terminal seal* E*.*

Proof. Start from the carrier decomposition. The handoff row Q is not independent: it is stored as the route reached from the same finite filter, uniform-tail, sequence-space, transport, continuation, provenance, and naming rows.

The sequence-space row supplies the visible stream-name, regular-rational, and dyadic readings. The uniform-tail row checks those readings against the common filter classifier before the completion boundary is exposed.

Consequently every exported completion handoff factors through F, U, S, H, C, P, N and only then reaches Q and E. □

Theorem 1382.6 (Filtered completion no-escape)**.** *An accepted* FilteredCauchyCompletion$^{\uparrow}$ *carrier gives no route to quotient streams, selected limits, host real equality, countable choice, or ambient completeness. Every consumer of the packet is confined to the finite rows* $F, U, S, Q, E, H, C, P, N$*.*

Proof. The excluded objects are not coordinates of Definition 1403.1. A consumer can project the filter row, uniform criterion row, sequence-space handoff, completion route, Real seal, transport, continuation, package, and local naming row, and nothing else.

The previous factorization theorem shows that even completion-facing reads must pass through those displayed rows. The common-filter transport theorem shows the same boundary after classifier comparison.

Therefore any route requiring quotient streams, selected limits, host real equality, countable choice, or ambient completeness lies outside the accepted carrier. □

Closure status for NameCert$_{\text{FilteredCauchyCompletion}^{\uparrow}}$**.**

Constructive story: The filtered Cauchy completion packet is generated from a finite Cauchy filter row, a uniform-tail criterion row, a Cauchy sequence-space handoff, a Real-completion boundary route, a terminal Real seal, and the displayed hsame, Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{FilteredCauchyCompletion}^{\uparrow}}$, seed)

Scope closed: This chapter records the finite carrier and five seed obligations for routing Cauchy filters to the Real-completion boundary through displayed BEDC rows.

Formal verification: FormalStatus(NameCert$_{\text{FilteredCauchyCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: It does not claim quotient-stream equality, selected limits, host real equality, countable choice, ambient completeness, or a standard bridge.

Upgrade path: Reaching obligationClosure requires Lean-backed carrier, classifier-transport, uniform-tail, handoff-factorization, and no-escape targets for the displayed packet.

Chapter 1383

A Concrete Naming Certificate for RegularCauchyEquivalence$^{\uparrow}$

The RegularCauchyEquivalence$^{\uparrow}$ packet records the finite equality boundary for regular Cauchy names before a Real$^{\uparrow}$ seal is consumed. Following Bishop–Bridges constructive analysis, two regular rational names are compared by common finite windows, dyadic tolerance ledgers, displayed transports, and local certificate rows, not by a quotient of streams or by host real equality.

The route is the Phase Real and Completion sibling boundary. It reads regular-name rows from chapter 301, finite schedules from chapter 126, dyadic tolerance data from chapter 291, zero-tail handoff data from chapter 380, the seal boundary from chapter 38, and the locatedness consumer interface from **??**. The chapter isolates the equivalence surface used between those rows so later completion and locatedness consumers can cite one visible NameCert packet.

Definition 1383.1 (RegularCauchyEquivalence finite-window classifier)**.** *A* RegularCauchyEquivalence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(X, Y, W, D, Z, R, E, H, C, P, N)$$

with the following rows:

1. *X and Y are the two displayed* RegSeqRat$^{\uparrow}$ *source rows to be compared;*
2. *W is the common* StreamName$^{\uparrow}$ *window schedule that selects paired finite observations from X and Y;*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for every selected pair of observations;*
4. *Z is the* NullSequence$^{\uparrow}$ *zero-tail handoff row when the displayed difference stream is consumed by a real-equality classifier;*
5. *R is the pair of* Real$^{\uparrow}$ *seal rows through which the two regular names may later be read;*
6. *E is the local finite equivalence classifier, asserting that each selected common window satisfies the displayed dyadic tolerance bound;*
7. *H records the componentwise* hsame *transports for the two source rows, schedule, tolerance ledger, seal rows, and classifier row;*
8. *C records the displayed* Cont *routes by which consumers inspect those rows;*
9. *P is the* Pkg *provenance for the two regular names, the common-window schedule, the dyadic ledger, the zero-tail handoff, the real-seal rows, and the consumer routes;*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalence}^{\uparrow}}$ *row.*
The carrier stores only finite scheduled comparisons. It has no quotient stream equality, no selected limit, no countable-choice row, no trichotomy row, no host real equality, and no ambient real-completeness coordinate.

Theorem 1383.2 (RegularCauchyEquivalence refinement transport)**.** *Let* $(X, Y, W, D, Z, R, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet. If the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the common* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail handoff row, and the* $\mathsf{Real}^{\uparrow}$ *seal rows are transported componentwise by the displayed* hsame *rows in* H *and read only through the displayed* Cont *routes in* C*, then the transported rows repack as an accepted* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet with the same finite-window classifier shape.*

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.RegularCauchyEquivalence refinement transport`
Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.TasteGate.RegularCauchyEquivalence refinement transport`

Proof. Project the carrier of Definition 1404.1. Its whole comparison surface is the pair of regular Cauchy rows, one common schedule, one dyadic tolerance ledger, one zero-tail handoff row, the seal rows, and the finite classifier row.

Transport the two source rows, the schedule, and the tolerance ledger through the stated hsame rows. The transported schedule still selects paired finite observations, and every selected pair is checked against the transported dyadic ledger.

Transport the $\mathsf{NullSequence}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows only as stored rows beside the same finite comparison. Since the proof does not add a quotient equality, selected limit, countable-choice selector, trichotomy branch, host real equality, or ambient completeness datum, the transported inventory is exactly another instance of the same carrier definition. □

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.RegularCauchyEquivalenceCarrier refinement transport`

Theorem 1383.3 (RegularCauchyEquivalence real classifier boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet factors first through the two displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, then through the common* $\mathsf{StreamName}^{\uparrow}$ *windows, then through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, then through the displayed* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail handoff when equality consumption is requested, and only then reads the stored* $\mathsf{Real}^{\uparrow}$ *seal rows. The consumer receives no quotient stream equality, selected limiting real, host real equality, countable choice, trichotomy, or ambient completeness witness from the equivalence packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.TasteGate.RegularCauchyEquivalence real classifier boundary`

Proof. Start with the finite classifier of Definition 1404.1. The seal row R is stored after X, Y, W, D, Z, and E, so a seal-facing read must first pass through the two regular-name rows, the common finite-window comparison, and the available zero-tail handoff.

Use Definition 1404.2 for stability under displayed transport. It keeps the consumer route attached to the same scheduled windows and dyadic ledger while moving along hsame and Cont rows.

The carrier lists no quotient stream equality, selected limit, host real equality, choice row, trichotomy row, or completeness row. Thus the boundary between regular Cauchy names and real seals is exactly the displayed finite-window route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.RegularCauchyEquivalence real classifier boundary`

Theorem 1383.4 (RegularCauchyEquivalence NameCert obligation surface)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularCauchyEquival}}$ *obligation surface consists of five finite rows:*

1. *carrier habitation by two displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, a common* $\mathsf{StreamName}^{\uparrow}$ *window schedule, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail handoff row,* $\mathsf{Real}^{\uparrow}$ *seal rows, and displayed provenance;*
2. *classifier by finite common-window dyadic tolerance checks;*
3. *transport stability under the stored* hsame *rows and displayed* Cont *routes;*
4. *seal-boundary exactness, stating that every* $\mathsf{Real}^{\uparrow}$ *read is reached only after the common-window classifier row and the displayed zero-tail handoff when equality consumption is requested;*
5. *ledger refusal, stating that quotient stream equality, host real equality, countable choice, selected limits, trichotomy, and ambient real completeness are not packet coordinates.*

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.RegularCauchyEquivalenceTasteGate single carrier alignment`

Proof. Carrier habitation is the displayed tuple in Definition 1404.1. It supplies two regular Cauchy names, a common schedule, dyadic tolerance rows, a zero-tail handoff row, seal rows, transports, continuations, package provenance, and the local naming row.

The classifier row is finite because it reads only windows selected by W and tolerances recorded in D. No comparison is made outside the scheduled observations.

Transport stability is Definition 1404.2. Seal-boundary exactness is Definition 1404.3. Together they keep every consumer route on the visible BHist, hsame, Cont, Pkg, and NameCert rows.

The refusal row is immediate from the carrier inventory: there is no coordinate that can encode a quotient stream equality, selected limit, countable-choice selector, trichotomy decision, host real equality, or ambient completeness principle. □

Theorem 1383.5 (RegularCauchyEquivalence sibling route)**.** *Any completion-facing or locatedness-facing consumer that uses a* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet must read the finite classifier of Definition 1404.1. Its route is exhausted by* $X, Y, W, D, Z, R, E, H, C, P, N$*: the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, common* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail handoff,* $\mathsf{Real}^{\uparrow}$ *seal rows, classifier row, transports, continuations, package provenance, and local* NameCert *row. No quotient of Cauchy streams, host real equality, selected limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness data is available to that consumer.*

Proof. Project an accepted packet to the tuple of Definition 1404.1. This tuple is already the full finite inventory available to completion-facing and locatedness-facing consumers.

Apply Definition 1404.4. The NameCert rows bind carrier habitation, finite common-window classification, transport stability, seal-boundary exactness, and the ledger refusal inside the same packet.

The route to $\mathsf{LocatedReal}^{\uparrow}$ may read the same regular sources and seal rows used by **??**, but it does not gain an independent real equality or completion principle. Therefore every downstream read remains a nonquotient finite-window comparison over $X, Y, W, D, Z, R, E, H, C, P, N$. □

Theorem 1383.6 (RegularCauchyEquivalence scoped primitive route)**.** *Any completion-facing or locatedness-facing consumer of an accepted* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet must read exactly the tuple*

$$(X, Y, W, D, Z, R, E, H, C, P, N)$$

through the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows named in Definition 1404.1. This scoped primitive route is the whole access path to the finite equivalence classifier; no quotient of streams, host real equality, selected limit, choice row, trichotomy row, or ambient completeness row is available.*

Proof. First apply refinement transport, Definition 1404.2. It keeps the two regular names, common window, dyadic ledger, null-tail handoff, real seals, classifier, transport, replay, provenance, and local name inside the same finite packet.

Next use the real classifier boundary of Definition 1404.3. It forces every seal-facing read through the regular-name, window, tolerance, and zero-tail rows before the $\mathsf{Real}^{\uparrow}$ seal rows can be inspected.

Finally combine the NameCert obligation surface and sibling route, Definition 1404.4 and Definition 1404.5. These theorems exhaust the consumer path by the displayed tuple, so the scoped primitive route contains exactly the listed BEDC rows and no hidden quotient, host equality, selected limit, choice, trichotomy, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, a common $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{NullSequence}^{\uparrow}$ zero-tail handoff row, $\mathsf{Real}^{\uparrow}$ seal rows, a finite equivalence classifier, displayed hsame transports, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalence}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1404.1, Definition 1404.2, Definition 1404.3, Definition 1404.4, Definition 1404.5, and Definition 1404.6 display the obligation surface over RegSeqRat, StreamName, DyadicRatCore, NullSequence, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Lean theorem, a public completion quotient, host real equality, selected limits, countable choice, trichotomy, or ambient real completeness.

Upgrade path: Remaining work is Lean verification and bridge checking for the same finite regular-Cauchy equivalence route, not further paper-axis maturation.

Chapter 1384

A Concrete Naming Certificate for $\mathsf{MonotoneSubsequence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{MonotoneSubsequence}^{\uparrow}$ packet records monotone subsequences as displayed finite unary selector rows. It does not select an infinite subsequence by countable choice. The packet sits between the regular-Cauchy subsequence surface of chapter 381, the cofinal index witness of chapter 405, and the monotone-Cauchy route of chapter 438. Its endpoint side is read through the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38.

Definition 1384.1 (Monotone subsequence carrier)**.** *A* $\mathsf{MonotoneSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, M, Q, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *row whose inspected finite windows are being selected.*
2. *M is the finite monotone unary selector ledger; each displayed entry records a selector value, its source index, and the comparison row certifying monotonicity against the previously displayed selector entries.*
3. *Q is the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *evidence row for the inspected thresholds, limited to the thresholds actually present in the packet.*
4. *W is the finite family of selected* $\mathsf{StreamName}^{\uparrow}$ *windows read from S through the ledger M and the cofinal evidence Q.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger extracted from the selected windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from W and D.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the selected regular-rational handoff has been displayed.*
8. *H stores componentwise* hsame *transport for the source row, monotone selector ledger, cofinality evidence, selected windows, dyadic observations, regular handoff, Real seal, continuation, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from S, M, Q to W, from W to D, from D to R, and from R to E.*

10. *P is the* Pkg *provenance over* $\mathsf{MonotoneSubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for a host subsequence equality test, a countable-choice selector, a quotient stream, an ambient completeness principle, or a hidden infinite monotone-subsequence object.

Lean4 ✓ `BEDC.Derived.MonotoneSubsequenceUp.TasteGate.MonotoneSubsequenceTasteGate single carrier alignment`

Theorem 1384.2 (Monotone subsequence NameCert obligations)**.** *For every accepted* $\mathsf{MonotoneSubsequence}^{\uparrow}$ *carrier* $U = (S, M, Q, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed eleven-row packet;*
2. *monotone selector stability for the finite unary selector ledger M under the recorded* hsame *transports;*
3. *cofinal coverage for every inspected threshold listed in Q;*
4. *selected-window* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through W, D, R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E is consumed;*
5. *non-escape from host subsequence equality, countable choice, quotient-stream equality, and ambient completeness.*

Proof. Project the carrier of Definition 1405.1. The source row S, selector ledger M, cofinality evidence Q, selected windows W, dyadic observations D, handoff R, seal E, and structural rows H, C, P, N are the only coordinates available to the classifier.

The monotone and cofinal faces are finite. Selector stability reads the displayed comparisons inside M, while cofinal coverage reads only the inspected thresholds recorded in Q. No step quantifies over an unbounded family of undisplayed requests.

The analytic endpoint is downstream from the same finite route. The selected $\mathsf{StreamName}^{\uparrow}$ windows W produce the dyadic ledger D, the dyadic ledger produces the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R, and the Real seal E is available only after that handoff.

Finally inspect the excluded objects. Host subsequence equality, countable choice, quotient streams, and ambient completeness are not rows of U, and the structural rows only transport, replay, source, and name the displayed packet. The five listed obligations therefore exhaust the local NameCert surface. □

Theorem 1384.3 (Monotone subsequence regular-Cauchy handoff)**.** *Every accepted* $\mathsf{MonotoneSubsequence}^{\uparrow}$ *packet hands its selected monotone finite windows to* $\mathsf{RegSeqRat}^{\uparrow}$ *before any* $\mathsf{Real}^{\uparrow}$ *seal can be consumed. Equivalently, every seal-facing route factors through*

$$S, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E$$

together with H, C, P, N.

Proof. Begin with the selected-window rows. The continuation route records that W is read from the source regular-Cauchy subsequence row S, the monotone selector ledger M, and the cofinal threshold evidence Q.

Next read the regular-rational handoff. The dyadic observation ledger D is extracted from the selected StreamName windows, and the row R is the displayed $\mathsf{RegSeqRat}^{\uparrow}$ handoff reached from those dyadic observations.

Only then is the seal row available. The row E is part of the packet as the Real-facing endpoint reached through R, while H, C, P, N only preserve the same route by transport, replay, provenance, and local naming.

Thus a consumer that tries to use the $\mathsf{Real}^{\uparrow}$ seal without the selected-window $\mathsf{RegSeqRat}^{\uparrow}$ handoff leaves the accepted $\mathsf{MonotoneSubsequence}^{\uparrow}$ carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneSubsequence}^{\uparrow}$ packet is generated from a source regular-Cauchy subsequence row, a finite monotone unary selector ledger, inspected-threshold cofinality evidence, selected StreamName windows, DyadicRatCore observations, a RegSeqRat handoff, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1405.1, Definition 1405.2, and Definition 1405.3 declare the finite selector carrier, its NameCert obligations, and the regular-Cauchy handoff boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim Bolzano-Weierstrass, sequential compactness, choice-selected subsequences, quotient-stream equality, host subsequence equality, Lean verification, bridge checking, or RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, monotone selector stability, inspected-threshold cofinal coverage, selected-window RegSeqRat handoff, and seal-route non-escape for the same packet.

Chapter 1385

A Concrete Naming Certificate for $\mathsf{SpeckerSequence}^{\uparrow}$

Following Specker's constructive counterexample tradition and Bishop-style finite evidence, the $\mathsf{SpeckerSequence}^{\uparrow}$ packet records a monotone bounded computable rational stream whose supremum is not exposed as a located $\mathsf{Real}^{\uparrow}$ datum without an additional location witness. The carrier sits in the Phase Real and Completion frontier between the regular rational names of chapter 301, the stream schedules of chapter 126, the dyadic tolerance ledgers of chapter 291, the finite real seal boundary of chapter 38, and the selector discipline of chapter 1405.

The Cauchy-criterion sibling boundary of chapter 2255 supplies the tail-window reading discipline used to inspect bounded monotone finite windows without exposing a located supremum.

Definition 1385.1 (SpeckerSequence carrier)**.** *A* $\mathsf{SpeckerSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, W, D, M, B, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row naming the computable rational stream by regular finite windows.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that exposes the inspected windows of R.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger carrying the rational bounds and tolerances read from those windows.*
4. *M is the finite monotone ledger, recording that each displayed inspected value is below the later displayed values in the schedule.*
5. *B is the boundedness ledger, recording a displayed lower rational row and upper rational row for every inspected window.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only as a finite readback boundary for displayed regular windows, not as a located supremum.*
7. *H stores componentwise* hsame *transport for the source, schedule, dyadic, monotone, boundedness, seal, continuation, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from R, W into D, from D into M and B, and from the regular readback surface into E.*
9. *P is the* Pkg *provenance over* $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MonotoneSubsequence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SpeckerSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for located supremum data, Dedekind cuts, countable choice, trichotomy, ambient completeness, or a selected limiting real.

Lean4 ✓ `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceUp`

Theorem 1385.2 (SpeckerSequence carrier exposure)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet exposes exactly the rows $R, W, D, M, B, E, H, C, P, N$ of Definition 1406.1. A consumer may inspect the computable rational stream only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *source, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bounds, the monotone and boundedness ledgers, the finite* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed structural rows.*

Proof. Project the carrier tuple. The source row, schedule row, dyadic ledger, monotone ledger, boundedness ledger, seal row, transport row, continuation row, provenance row, and local naming row are the complete public inventory.

The route is finite at every stage. The stream is read through R and W, rational bounds are read through D, monotonicity and boundedness are read through M and B, and the seal row E is reached only after those rows have been displayed.

Since the carrier lists no located supremum, Dedekind cut, selected limit, countable-choice selector, trichotomy branch, or completeness row, those objects are not part of the exposed packet. □

Lean4 ✓ `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceCarrier exposure`

Theorem 1385.3 (SpeckerSequence classifier transport)**.** *Let $S = (R, W, D, M, B, E, H, C, P, N)$ be an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *carrier. Componentwise* hsame *transport along H and displayed* Cont *replay along C preserve the classifier shape of S: the transported packet is still compared by the same regular-source row, stream schedule, dyadic ledger, monotone ledger, boundedness ledger, finite seal row, provenance row, and local naming row.*

Lean4 ✓ `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceClassifier transport`

Proof. Read the classifier from Definition 1406.1. It depends only on the displayed rows of the packet, not on an ambient order or a host real equality test.

Transport the source, schedule, dyadic, monotone, boundedness, and seal rows componentwise through H. The continuation row C records the same replay order after transport: regular windows first, dyadic observations next, monotone and boundedness ledgers next, and the finite seal last.

The transported inventory therefore repacks as the same carrier shape. No transported coordinate can introduce located-supremum data, countable choice, trichotomy, Dedekind-cut equality, or completeness, because no such coordinate is present before transport. □

Theorem 1385.4 (SpeckerSequence monotone bounded ledger)**.** *In every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet, the monotone ledger M and boundedness ledger B are read before any* $\mathsf{Real}^{\uparrow}$ *seal consumer can inspect E. Thus every seal-facing route factors through*

$$R, W \longmapsto D \longmapsto (M, B) \longmapsto E$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.SpeckerSequenceUp.SpeckerSequence monotone bounded ledger`

Proof. Begin with the source route. The $\mathsf{RegSeqRat}^{\uparrow}$ row R and $\mathsf{StreamName}^{\uparrow}$ schedule W select the finite rational observations inspected by the packet.

Next read the dyadic ledger. The row D supplies the rational bounds and tolerance data used to compare the selected observations.

Now read the monotone and boundedness ledgers. The row M records the displayed monotone comparisons, while B records the displayed lower and upper rational bounds for the same inspected windows.

Only after those rows have been exposed can the finite $\mathsf{Real}^{\uparrow}$ seal row E be consumed. The structural rows H, C, P, N preserve this route and do not add a selected supremum or an ambient completeness witness. □

Theorem 1385.5 (SpeckerSequence finite-stage induction)**.** *For every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet* $S = (R, W, D, M, B, E, H, C, P, N)$*, induction along the displayed finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* W *lets any consumer read only the current finite rational window of* R*, the corresponding dyadic tolerance row of* D*, the monotone ledger prefix of* M*, the boundedness ledger prefix of* B*, and the transported* BHist *provenance before the consumer reaches the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The induction route introduces no located supremum, selected limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Induct on the finite schedule prefix displayed by W. In the base case, the consumer sees only the initial inspected window of R, the matching tolerance and bound row in D, the empty or initial monotone and boundedness ledger entries in M and B, and the provenance rows carried by H, C, P, N.

For the step case, append one visible rational observation and its tolerance row. Componentwise hsame in H transports the source, schedule, dyadic, monotone, boundedness, and seal coordinates without changing their row types. The displayed Cont replay in C appends the new dyadic observation before replaying the corresponding monotone comparison in M and the corresponding lower and upper bound in B.

Thus each prefix consumer receives exactly the finite window and ledger data already displayed at that stage. Passing from one prefix to the next preserves the route of Definition 1406.4; the $\mathsf{Real}^{\uparrow}$ seal remains downstream of the visible rational, tolerance, monotone, boundedness, and provenance rows. Since no induction clause contains a coordinate for located supremum data, selected limits, countable choice, trichotomy, or ambient completeness, none is introduced before the seal. □

Theorem 1385.6 (SpeckerSequence finite-prefix Real-tail inspection)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *consumer that inspects the packet before the* $\mathsf{Real}^{\uparrow}$ *seal is read through finite windows only. More precisely, before any completion-facing refusal or located-supremum boundary is invoked, the consumer can access only the displayed* $\mathsf{StreamName}^{\uparrow}$ *prefix of* W*, the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback from* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and bound rows in* D*, the monotone and bounded ledger prefixes in* M *and* B*, and the structural rows* H, C, P, N*.*

The terminal $\mathsf{Real}^{\uparrow}$ *seal* E *may be cited only after those finite-prefix rows have been displayed, and the read still contains no located supremum, selected limit, quotient stream equality, countable-choice selector, trichotomy branch, or ambient completeness witness.*

Proof. Project the carrier of Definition 1406.1. Its analytic coordinates before the seal are exactly the regular-source row R, the finite schedule W, the dyadic ledger D, and the monotone and boundedness ledgers M, B.

Apply the finite-stage induction theorem, Definition 1406.5. At the base prefix the consumer sees only the initial displayed rational window and its ledger rows; at each step it appends one finite observation, its tolerance row, and the matching monotone and boundedness entries.

Use the monotone bounded ledger route, Definition 1406.4, to place the $\mathsf{Real}^{\uparrow}$ seal after these finite-prefix rows. Then apply the RealUp seal non-escape theorem, Definition 1406.10, to keep completion-facing refusal and located-supremum boundaries outside the displayed packet. □

Theorem 1385.7 (SpeckerSequence non-located supremum boundary)**.** *An accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet may certify a monotone bounded computable rational stream, but it does not certify a located supremum. Any downstream route that treats the packet as a located* $\mathsf{Real}^{\uparrow}$ *datum must supply an external location witness not contained in* $R, W, D, M, B, E, H, C, P, N$*.*

Proof. Use Definition 1406.2 to identify the packet inventory. The available analytic rows are the regular rational source, stream schedule, dyadic observations, monotone ledger, boundedness ledger, and finite seal boundary.

Use Definition 1406.4 for the seal route. It records that E is reached through finite windows and ledgers, not through a located-supremum construction.

A located supremum requires a location witness comparing rational cuts around the supremum. No such witness is a row of the carrier, and the structural rows merely transport, replay, source, and name the displayed packet. Hence the packet sets the non-located boundary rather than closing located completeness. □

Theorem 1385.8 (SpeckerSequence located supremum refusal)**.** *For any accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet* $S = (R, W, D, M, B, E, H, C, P, N)$*, finite-stage induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule can expose only the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R*, the dyadic tolerance row* D*, the monotone ledger* M*, the boundedness ledger* B*, the finite* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the structural rows* H, C, P, N*. Therefore a located-supremum witness cannot be reconstructed from the packet and must be supplied as an external row.*

Proof. Apply Definition 1406.5. The induction route over W reads a finite prefix of the source stream, the matching dyadic tolerance data, the corresponding monotone and boundedness ledger prefixes, and the transported provenance rows before the seal is reached.

Apply Definition 1406.4. It fixes the seal-facing order

$$R, W \longmapsto D \longmapsto (M, B) \longmapsto E$$

and leaves H, C, P, N as structural transport, replay, provenance, and naming rows rather than analytic witnesses.

Finally apply Definition 1406.10. The finite $\mathsf{Real}^{\uparrow}$ seal exports only the displayed finite-window read. Since none of the displayed rows is a located comparison witness for rational cuts around the supremum, any downstream located-supremum claim must provide that witness outside the $\mathsf{SpeckerSequence}^{\uparrow}$ packet. □

Theorem 1385.9 (Specker sequence located supremum consumer boundary)**.** *A* $\mathsf{LocatedSupremum}^{\uparrow}$ *or* $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ *consumer reading an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet receives only finite* $\mathsf{RegSeqRat}^{\uparrow}$ *source windows, the* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, monotone and boundedness ledgers, the* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows* H, C, P, N*. The located-supremum witness remains an external row.*

Proof. Apply Definition 1406.5. It confines every inspected prefix to the displayed regular rational window, stream schedule, dyadic tolerance row, monotone prefix, boundedness prefix, and transported provenance before the seal is reached.

Apply Definition 1406.4. The monotone and boundedness rows are read before any $\mathsf{Real}^{\uparrow}$ seal consumer can inspect E, so the route remains finite-window data rather than a located supremum construction.

Apply Definition 1406.8. Since the packet contains no located comparison witness for rational cuts around the supremum, a $\mathsf{LocatedSupremum}^{\uparrow}$ or $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ consumer must bring that witness as an external row. □

Theorem 1385.10 (SpeckerSequence RealUp seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet is a finite seal read through the displayed source, schedule, dyadic, monotone, and boundedness rows. The read exports no Real completeness principle, located supremum, Dedekind cut, countable-choice selector, trichotomy branch, bridge checking datum, or selected limiting real.*

Proof. Factor the read through the carrier exposure theorem. The $\mathsf{Real}^{\uparrow}$ seal row E is available only as one displayed coordinate of the finite packet.

Apply classifier transport to keep every replay on the same componentwise rows. Transport cannot change the seal into a located supremum or a completed real object because it preserves the carrier shape.

Apply the monotone bounded ledger theorem and the non-located supremum boundary. Together they show that a seal-facing consumer receives only finite regular windows, dyadic observations, monotone evidence, boundedness evidence, and structural certificate rows.

The excluded principles are absent from every coordinate. Therefore the $\mathsf{Real}^{\uparrow}$ seal cannot escape to Real completeness, located supremum data, Dedekind cuts, countable choice, trichotomy, bridge checking, or selected limits. □

Definition 1385.11 (Specker sequence obligation surface)**.** *The* $\mathsf{SpeckerSequence}^{\uparrow}$ *obligation surface is the finite subpacket*

$$O = (R_{\leq W}, D_{\leq W}, M_{\leq W}, B_{\leq W}, E, H, C, P, N)$$

read from an accepted carrier $S = (R, W, D, M, B, E, H, C, P, N)$*. The row* $R_{\leq W}$ *is the finite rational stream window selected by the* $\mathsf{StreamName}^{\uparrow}$ *schedule* W*;* $D_{\leq W}$ *is the matching dyadic tolerance and bound ledger;* $M_{\leq W}$ *and* $B_{\leq W}$ *are the monotone and bounded ledger prefixes for the same displayed stages; and* E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after those prefixes.*

The structural rows are unchanged: H *gives componentwise* hsame *transport,* C *gives displayed* Cont *replay,* P *gives package provenance, and* N *gives the local* $\mathsf{NameCert}_{\mathsf{SpeckerSequence}^{\uparrow}}$ *row. The surface contains no located supremum row, countable-choice selector, trichotomy branch, Dedekind-cut representation, host-selected limit, or ambient completeness field.*

Theorem 1385.12 (Specker sequence regular-Cauchy obligation)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet discharges its regular-Cauchy obligation through finite-stage induction over the displayed schedule* W*. At each inspected stage the consumer receives only the current rational window* $R_{\leq W}$*, the dyadic tolerance row* $D_{\leq W}$*, the monotone prefix* $M_{\leq W}$*, the boundedness prefix* $B_{\leq W}$*, and the* BHist *provenance transported through* H, C, P, N *before the packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*.*

Proof. Start from the obligation surface of Definition 1406.11. Its visible analytic data are the finite rational stream window, the dyadic tolerance and bound ledger, and the two finite ledger prefixes.

Use the finite-stage induction route of Definition 1406.5. The base prefix exposes the initial rational observation and its matching ledger rows. The step prefix appends one displayed observation, transports the rows through H, and replays the dyadic, monotone, and boundedness entries through C.

The regular-Cauchy obligation is therefore local to each displayed finite prefix. The seal row E is downstream of those rows by Definition 1406.10, so no located supremum, selected limit, countable choice, trichotomy, Dedekind cut, or ambient completeness coordinate is introduced. □

Theorem 1385.13 (Specker sequence no-choice boundary)**.** *The* $\mathsf{SpeckerSequence}^{\uparrow}$ *obligation surface is stable under componentwise* hsame *transport and displayed* Cont *replay without adding any selector that chooses a supremum, a limiting real, a trichotomy branch, or a countable family of witnesses. Any downstream proof that needs one of those objects must supply it outside the packet.*

Proof. Project the transported packet through Definition 1406.3. The classifier shape is preserved on the regular-source row, stream schedule, dyadic ledger, monotone ledger, boundedness ledger, finite seal row, provenance row, and local naming row.

Now restrict to the obligation surface. The rows $R_{\leq W}, D_{\leq W}, M_{\leq W}, B_{\leq W}, E, H, C, P, N$ are exactly the finite rows of Definition 1406.11; transport and replay do not create a new coordinate.

The no-choice boundary follows from the missing coordinate. Since no row stores a supremum selector, limiting real selector, trichotomy decision, countable family choice, Dedekind cut, or completeness witness, no consumer can extract such data from the packet. □

Theorem 1385.14 (Specker sequence Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of a* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet factors through the obligation surface and then through the finite seal row* E*. The handoff route is*

$$R_{\leq W}, D_{\leq W}, M_{\leq W}, B_{\leq W}, H, C, P, N \longmapsto E,$$

so the exported real-facing information is a sealed finite-window read rather than a located supremum or a host-selected limit.

Proof. Use Definition 1406.4 to order the route. The source and schedule determine the inspected rational windows, the dyadic ledger supplies tolerance and bound rows, and the monotone and boundedness ledgers are read before E.

Use Definition 1406.11 to package exactly those finite rows as the public obligation surface. The structural rows H, C, P, N preserve and replay the route but do not extend it.

Finally apply Definition 1406.10. The $\mathsf{Real}^{\uparrow}$ handoff remains a finite seal read, so it refuses located supremum data, countable choice, trichotomy, Dedekind cuts, host-selected limits, and ambient completeness. □

Theorem 1385.15 (Specker sequence obligation route)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *carrier routes its monotone bounded ledger, nonlocated supremum refusal,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal data through the displayed finite rows*

$$R, W, D, M, B, E, H, C, P, N.$$

The route uses the BHist *packet, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row, and it contains no coordinate for countable choice, selected supremum data, trichotomy, Dedekind cuts, or a host-selected limiting real.*

Proof. Start with the carrier exposure theorem. It identifies the only analytic rows as the regular rational source, finite schedule, dyadic ledger, monotone ledger, boundedness ledger, and finite real seal.

Use the monotone bounded ledger theorem and finite-stage induction. Together they force every inspected prefix through R, W, D, M, B before the seal row E can be consumed.

Use the non-located supremum boundary and RealUp seal nonescape. Since H, C, P, N only transport, replay, source, and name the same finite route, the packet cannot export a selected supremum, countable choice, trichotomy, Dedekind cut, or ambient completeness coordinate. □

Theorem 1385.16 (Specker sequence regular readback scope)**.** *The regular readback exported by an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet is exactly the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *window read selected by* W *and certified through* D, M, B, H, C, P, N *before it reaches the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. Every downstream consumer must read the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; no consumer can extract a countable-choice selector, a located supremum coordinate, a trichotomy branch, or a selected limiting real from the readback.*

Proof. Apply Definition 1406.11. Its visible readback rows are the scheduled regular rational window, the dyadic tolerance and bound ledger, the monotone prefix, the boundedness prefix, and the finite seal.

Apply Definition 1406.12. The regular-Cauchy obligation is local to the displayed finite prefixes, so the readback does not depend on an infinite selector or a located supremum coordinate.

Finally apply Definition 1406.13. Transport and replay preserve the same finite obligation surface and introduce no countable-choice, trichotomy, Dedekind-cut, or selected-limit row. □

Theorem 1385.17 (SpeckerSequence scoped kernel route)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet route through*

$$R, W, D, M, B, E, H, C, P, N$$

is scoped by the finite kernel rows BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The no-choice and non-located-supremum exclusions follow from the absence of rows for countable-choice selectors, located supremum witnesses, trichotomy branches, Dedekind cuts, and host-selected limiting reals, not from external prose.*

Proof. Start with carrier exposure. The accepted packet exposes only the regular rational source row R, finite window row W, dyadic ledger D, monotone ledger M, boundedness ledger B, finite Real seal E, and structural rows H, C, P, N.

Use finite-stage induction and the monotone bounded ledger. Every inspected prefix is read through R, W, D, M, B before any Real-facing seal is available, so the route remains inside the displayed BHist packet and its componentwise hsame and Cont rows.

Apply the no-choice boundary. Since no row records a countable selector, a trichotomy branch, a Dedekind cut, or a chosen limiting real, none of those data can be recovered by replaying H, C, P, N.

Finally use the $\mathsf{Real}^{\uparrow}$ seal nonescape theorem. The seal row E exports only the finite-window Real-facing readback, and therefore the scoped route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ is exhaustive for the packet. □

Theorem 1385.18 (Specker sequence monotone bounded nonconvergence route)**.** *Let* $S = (R, W, D, M, B, E, H, C$ *be an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet. If a consumer reads the packet through the monotone bounded ledger and the regular readback scope, then the consumer receives bounded monotone evidence only as finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows inside the*

displayed BHist *carrier. This route may be used as monotone bounded finite-window data, but it does not yield a located supremum, a selected limit, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier exposure theorem and the monotone bounded ledger. The accepted packet exposes the regular rational source R, the finite schedule W, the dyadic tolerance and bound ledger D, the monotone and boundedness ledgers M, B, the finite seal E, and the structural rows H, C, P, N. The ledger order forces every seal-facing read through

$$R, W \longmapsto D \longmapsto (M, B) \longmapsto E.$$

Apply finite-stage induction along W. Each displayed prefix carries only the currently inspected $\mathsf{RegSeqRat}^{\uparrow}$ window, the matching $\mathsf{DyadicRatCore}^{\uparrow}$ row, the monotone and boundedness prefixes, and the transported BHist provenance. The regular readback scope keeps this information in the $\mathsf{StreamName}^{\uparrow}$ schedule and the finite seal route; it never opens an infinite selector.

Now apply the non-located supremum boundary and the scoped kernel route. The packet contains no row for rational-cut location around a supremum, no branch selecting trichotomy, no countable family of witnesses, and no ambient completeness coordinate. The sibling boundaries of chapter 2255, chapter 1405, chapter 1665, and chapter 1666 identify exactly the external consumers that would have to provide those missing rows.

Thus bounded monotone Specker windows are usable finite data inside the BEDC kernel, while the non-located supremum boundary remains intact. The route certifies finite monotone readback, not convergence to a selected $\mathsf{Real}^{\uparrow}$ limit. □

Theorem 1385.19 (Specker sequence completion-refusal induction)**.** *Any Completion-facing consumer reading an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet can induct only over the displayed finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* W*. At each stage the consumer receives the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *source window, the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the monotone and boundedness ledger prefixes, the finite* $\mathsf{Real}^{\uparrow}$ *seal route, and the structural rows* H, C, P, N*; it receives no located supremum, selected limit, trichotomy branch, countable-choice selector, quotient stream equality, or ambient completion witness.*

Proof. Apply finite-stage induction, Definition 1406.5. The induction variable is the displayed schedule W, so each step exposes only the current regular rational window, dyadic tolerance row, monotone prefix, boundedness prefix, and transported provenance.

Use the regular readback scope, Definition 1406.16. It keeps the readback inside the finite $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows before the packet reaches the $\mathsf{Real}^{\uparrow}$ seal.

Apply the no-choice boundary, Definition 1406.13. Transport and replay through H, C, P, N do not add a selector for a supremum, limiting real, trichotomy branch, countable family of witnesses, or quotient stream equality.

Finally use the monotone bounded nonconvergence route, Definition 1406.18. Completion-facing consumers may use the bounded monotone finite-window data, but the packet still refuses ambient completion and any selected limit beyond the displayed finite seal. □

Theorem 1385.20 (Specker sequence Cauchy criterion non-located boundary)**.** *An accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet read through an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *packet still exposes only finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, monotone and bounded ledgers, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The combined read cannot yield a located supremum, selected limit, quotient stream equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the completion-refusal induction of Definition 1406.19. It confines every Completion-facing Specker read to finite $\mathsf{StreamName}^{\uparrow}$ schedule induction over the displayed regular rational windows, dyadic tolerances, monotone and boundedness prefixes, Real seal, and structural rows.

Apply the monotone bounded nonconvergence route of Definition 1406.18. It allows the monotone bounded evidence to be consumed as finite data, but it keeps located supremum, selected limit, trichotomy, countable choice, and ambient completeness outside the packet.

Finally read the same surface through the Cauchy criterion boundary of Definition 1509.15. The criterion contributes only finite windows, threshold and tolerance rows, regular readback, Real seal, and structural rows shared by the packets. It adds no quotient stream equality, selected host limit, located supremum coordinate, or Real completeness witness. □

Theorem 1385.21 (Specker sequence regular-window induction)**.** *Every completion-facing consumer inspecting an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet before a located-supremum row must proceed by finite induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *window. At each step the consumer exposes only the current* $\mathsf{RegSeqRat}^{\uparrow}$ *source prefix, the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the monotone ledger, the bounded ledger, and the structural* BHist *rows preserved by componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming.*

Proof. Start with the finite-stage induction theorem, Definition 1406.5. Its induction variable is the displayed $\mathsf{StreamName}^{\uparrow}$ schedule, so every inspected stage is a finite prefix read rather than a selected infinite stream.

Apply the regular-Cauchy obligation of Definition 1406.12. The obligation exposes only the current $\mathsf{RegSeqRat}^{\uparrow}$ source prefix, the matching $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and the monotone and boundedness ledger prefixes before any completion-facing conclusion is visible.

Finally apply the Cauchy-criterion non-located boundary of Definition 1406.20. Transport, replay, provenance, and local naming preserve the same structural BHist rows, and no located-supremum row, selected limit, quotient stream equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness is added. □

Theorem 1385.22 (Specker sequence finite-window refusal induction)**.** *For every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet, finite-stage induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule preserves exactly the* $\mathsf{RegSeqRat}^{\uparrow}$ *source prefix,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, monotone ledger, bounded ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}$ *row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary. No induction step can introduce a located-supremum row, selected-limit row, quotient stream equality, countable-choice selector, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Induct on the inspected finite window of the displayed $\mathsf{StreamName}^{\uparrow}$ schedule. In the empty window, the carrier exposes only its structural BHist rows and the already named refusal boundary, so no located-supremum or selected-limit coordinate is present.

For the step, extend the inspected window by one displayed source observation. Apply Definition 1406.5 to keep the new observation inside the same finite schedule, and apply Definition 1406.21 to preserve the $\mathsf{RegSeqRat}^{\uparrow}$ prefix, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, monotone ledger, bounded ledger, and structural transport, replay, provenance, and naming rows.

Finally use Definition 1406.20. The terminal $\mathsf{Real}^{\uparrow}$ seal remains a finite boundary read, and the missing located-supremum, selected-limit, quotient, choice, trichotomy, and ambient-completeness rows have no carrier coordinate from which an induction step could create them. □

Closure status for $\mathsf{NameCert}_{\mathsf{SpeckerSequence}^{\uparrow}}$**.**

Constructive story: A SpeckerSequence$^{\uparrow}$ packet is generated from a RegSeqRat$^{\uparrow}$ computable rational source, a StreamName$^{\uparrow}$ finite-window schedule, DyadicRatCore$^{\uparrow}$ tolerance and bound rows, a monotone ledger, a boundedness ledger, a finite Real$^{\uparrow}$ seal boundary, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{SpeckerSequence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1406.1, Definition 1406.2, Definition 1406.3, Definition 1406.4, Definition 1406.5, Definition 1406.7, Definition 1406.8, Definition 1406.9, Definition 1406.10, Definition 1406.11, Definition 1406.12, Definition 1406.13, Definition 1406.14, Definition 1406.15, Definition 1406.16, Definition 1406.17, Definition 1406.18, Definition 1406.19, and Definition 1406.20 declare the finite Specker-sequence carrier, transport, monotone bounded ledger, finite-stage induction route, non-located supremum boundary, located-supremum refusal, public located-supremum consumer boundary, public RealUp seal non-escape surface, obligation surface, regular-Cauchy obligation, no-choice boundary, public Real handoff, obligation route, regular readback scope, scoped kernel route, monotone bounded nonconvergence route, Completion-refusal induction route, and Cauchy-criterion non-located boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{SpeckerSequence}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceCarrier\_exposure`

Bridge status: none

Not claimed: This chapter does not close Real completeness, located supremum construction, Dedekind cuts, countable choice, trichotomy, bridge checking, or selected limiting reals.

Upgrade path: Further verification work is bridge checking for the existing finite-stage, no-choice, Real-handoff, and Real-seal theorem surface.

Chapter 1386

A Concrete Naming Certificate for $\mathsf{BisectionRootIsolation}^{\uparrow}$

Following Bishop and Bridges, constructive root isolation is read here as a finite sign-change bisection packet over located intervals rather than as a host root-existence theorem. The $\mathsf{BisectionRootIsolation}^{\uparrow}$ surface binds endpoint windows, sign rows, branch choices, regular rational readback, and real-name seal rows into one local NameCert packet. It consumes the located interval and dyadic bisection certificates of chapter 394 and chapter 361, with tolerance and readback rows supplied by chapter 291, chapter 126, chapter 301, and chapter 38.

Definition 1386.1 (Bisection root-isolation carrier)**.** *A* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (J, B, F, E, W, R, S, H, C, P, N)$$

with the following visible rows:

1. *J is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet, exposing the lower and upper endpoint windows, rational cell ledger, optional dyadic refinements,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal-facing rows;*

2. *B is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger whose retained interval rows refine the endpoint packet of J by finite midpoint comparisons;*

3. *F is the function-inspection ledger, consisting only of finite rational and dyadic reads used to evaluate the displayed sign rows at the retained endpoints and midpoints;*

4. *E records the sign rows at the retained lower and upper endpoints, together with the midpoint sign rows used to choose each branch;*

5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window ledger exposed to downstream consumers after the retained interval is selected;*

6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the retained endpoint windows and the dyadic tolerance rows supplied through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*

7. *S is the* $\mathsf{Real}^{\uparrow}$ *seal surface for the retained lower and upper endpoint names and for any real-facing consumer of the isolating window;*

8. *H stores the componentwise* hsame *transports for the located interval packet, bisection ledger, sign rows, stream windows, regular rational readbacks, real seal rows, and local certificate row;*

9. *C stores the displayed* Cont *replay routes for endpoint inspection, midpoint inspection, branch selection, retained-window readback, regular-sequence handoff, and real-name seal consumption;*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ *registration row.*

The carrier predicate says that these rows form one finite sign-change bisection packet. It has no coordinate for a host root, a general intermediate value theorem, trichotomy on reals, a completed intersection of nested intervals, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationUp`
Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationTasteGate single carrier alignment`

Theorem 1386.2 (Bisection root-isolation NameCert obligations)**.** *For every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier* $Q = (J, B, F, E, W, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ *surface consists exactly of:*

1. *carrier admission for the displayed finite packet of Definition 1407.1;*
2. *endpoint-window admission through the* $\mathsf{LocatedInterval}^{\uparrow}$ *rows of J and the retained interval rows of B;*
3. *sign-ledger exactness, requiring each branch choice in B to be justified by one displayed sign row in E read through F;*
4. *retained-window handoff through W, R, and S;*
5. *componentwise transport and replay through H and C;*
6. *package provenance and local naming through P and N.*

No further analytic obligation is part of the packet.

Proof. Project the carrier of Definition 1407.1. The endpoint packet J supplies the located lower and upper endpoint windows, while the bisection ledger B supplies the finite retained-interval chain.

The sign-ledger obligation is local to F and E. Each midpoint inspection reads a finite rational or dyadic approximation row, records the displayed sign row, and then selects the corresponding branch row in B.

The retained-window handoff is the route already available from chapter 361 after the endpoints are read through chapter 394. The tolerance rows come from chapter 291; the window, readback, and seal rows are then routed through chapter 126, chapter 301, and chapter 38.

Finally, H, C, P, and N account for transport, replay, provenance, and local naming. Since the carrier stores only these finite rows, it cannot export host root existence, an intermediate value theorem, real trichotomy, a completed interval intersection, or completeness for $\mathsf{Real}^{\uparrow}$. □

Theorem 1386.3 (Bisection root-isolation RegSeqRat window handoff)**.** *For every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier and every unary precision request n, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exposed by the isolating window factors through the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch prefix that reaches the retained window at tolerance 2^{-n}, the displayed sign rows at retained endpoints, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, and the replay rows H, C, P, N.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationRegSeqRatWindowHandoff`

Proof. Begin with the unary request n. The dyadic tolerance row 2^{-n} is read through the $\mathsf{DyadicRatCore}^{\uparrow}$ provenance, and the branch prefix in the $\mathsf{DyadicBisection}^{\uparrow}$ ledger selects the retained interval window at that tolerance.

The located endpoint packet then supplies the lower and upper endpoint windows for that retained interval. The sign ledger contributes only the displayed endpoint signs and midpoint signs already used to select the branch prefix; it does not introduce a root object.

Route the retained endpoint windows through the $\mathsf{StreamName}^{\uparrow}$ rows and then through the $\mathsf{RegSeqRat}^{\uparrow}$ readback row. The replay remains inside H, C, P, and N, so every rational read exposed to the regular-sequence consumer is one of the retained finite endpoint windows. □

Theorem 1386.4 (Bisection root-isolation Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier is reached only after the retained* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint windows, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger, the displayed endpoint sign rows, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the rows* H, C, P, N *have been read. The seal exposes the finite isolating window and exports no host root existence, general intermediate value theorem, real trichotomy, completed interval intersection, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationRealSealNonescape`

Proof. Read the real-facing coordinate S in Definition 1407.1. It is not an independent real object; it is stored with the endpoint packet, branch ledger, sign rows, stream windows, regular readback, transport rows, replay routes, provenance, and local certificate.

Apply Definition 1407.3. The retained endpoint windows first pass through the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ surfaces at the requested dyadic tolerance.

Only after that route is fixed can the $\mathsf{Real}^{\uparrow}$ seal be read. The seal therefore records the same finite isolating window and no additional analytic witness. Because no coordinate of Q stores a host root, an intermediate value theorem, trichotomy data, a completed intersection, or completeness for $\mathsf{Real}^{\uparrow}$, the real-facing consumer cannot escape to any of those objects. □

Theorem 1386.5 (Bisection root-isolation finite sign-change certificate)**.** *For every accepted* $\mathsf{BisectionRootIsolation}$ *carrier* $Q = (J, B, F, E, W, R, S, H, C, P, N)$*, every sign-change assertion visible to the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsola}}$ *is certified by finite endpoint and midpoint rows in* F*,* E*, and* B*. The certificate contains no host intermediate value theorem, no real trichotomy oracle, no root object, and no completed intersection of retained intervals.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationFiniteSignChangeCertificate`

Proof. Project the carrier rows of Definition 1407.1. The only function-inspection data are the finite rational and dyadic reads in F, and the only sign data are the endpoint and midpoint rows displayed in E.

Apply Definition 1407.2. Each branch choice in B must be justified by one of those displayed rows, so the sign-change surface is exhausted by the finite ledger already stored in the packet.

The excluded analytic objects are absent from the carrier coordinates. Thus the certificate can replay the accepted sign rows and retained branch choices, but it cannot export a host root, a general intermediate value theorem, trichotomy on reals, or a completed interval intersection. □

Theorem 1386.6 (Bisection root-isolation retained-window refinement)**.** *For every accepted* $\mathsf{BisectionRootIsolation}$ *carrier and every unary precision request* n*, the retained isolating window at tolerance* 2^{-n} *factors through the* $\mathsf{DyadicBisection}^{\uparrow}$ *retained branch prefix, the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exposed by the carrier.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationRetainedWindowRefinement`

Proof. Begin with the unary request n. The tolerance row is the $\mathsf{DyadicRatCore}^{\uparrow}$ row already named in Definition 1407.1, and the branch prefix is the retained prefix stored in the $\mathsf{DyadicBisection}^{\uparrow}$ ledger B.

The endpoint rows come from the located interval packet J. Once the retained prefix is fixed, the selected lower and upper windows pass through the $\mathsf{StreamName}^{\uparrow}$ rows W.

Apply Definition 1407.3. The $\mathsf{RegSeqRat}^{\uparrow}$ row R reads back exactly those retained endpoint windows at the requested tolerance, with transport and replay confined to H, C, P, and N. □

Theorem 1386.7 (Bisection root-isolation downstream boundary)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier receives only the retained isolating window determined by J, B, W, R, S, H, C, P, and N. Such a consumer cannot extract host root existence, a completed interval intersection, a general intermediate value theorem, real trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationDownstreamBoundary`

Proof. Read the downstream-facing seal row through Definition 1407.4. The seal is reached only after the retained located endpoints, branch ledger, stream windows, regular readback, and replay rows have already been fixed.

The retained-window route is the one described in Definition 1407.6. It delivers a finite window at the requested tolerance, not an independent analytic object.

Since Definition 1407.5 confines the sign-change evidence to finite endpoint and midpoint rows, no downstream consumer can recover the excluded host principles from the packet. □

Theorem 1386.8 (Bisection root-isolation public export)**.** *Every public consumer of an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier must read the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{Real}^{\uparrow}$ *seal, and the structural* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows in that order before using the isolation certificate. The exported object is the finite retained isolating window with displayed sign-change evidence; it is not a selected root, a real-trichotomy decision, quotient equality of real names, a completed nested-interval point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier $Q = (J, B, F, E, W, R, S, H, C, P, N)$ of Definition 1407.1. The carrier already orders the public data: J supplies the located endpoint packet, B supplies the retained dyadic branch ledger, and the dyadic tolerance rows are the arithmetic support named in the same packet.

Apply Definition 1407.2. It forces the endpoint-window admission and sign-ledger exactness to be read before retained-window handoff, so the public consumer cannot inspect W, R, S until the located interval, bisection ledger, tolerance support, and displayed sign rows have been exposed.

Next apply Definition 1407.3 and Definition 1407.4. These statements route the retained endpoint windows through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the $\mathsf{Real}^{\uparrow}$ seal without producing an independent real object.

Finally use Definition 1407.7. The structural rows H, C, P, N transport, replay, package, and name exactly that finite window. Since the carrier has no coordinate for a selected root, real trichotomy, quotient real equality, a completed nested-interval point, or ambient completeness, the public export is exhausted by the ordered rows listed in the statement. □

Theorem 1386.9 (Bisection root-isolation sign-ledger determinacy)**.** *Let $Q = (J, B, F, E, W, R, S, H, C, P, N)$ be an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier. For every retained branch row in B, the corresponding finite inspection row in F and displayed sign row in E determine the branch visible to the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ *packet. The visible branch decision is therefore a finite* BHist *route through F, E, B, H, C, P, N, not a host trichotomy comparison or an external root-location oracle.*

Proof. Project the carrier rows F, E, B from Definition 1407.1. The function-inspection ledger F is the only source of endpoint and midpoint reads, and E is the only sign ledger stored for those reads.

Apply the NameCert obligations of Definition 1407.2. They require each branch choice in B to be justified by one displayed sign row in E read through F, with transport and replay confined to H, C, P, N.

Thus two accepted replays with the same inspected row and the same displayed sign row expose the same retained branch row to the packet. Since no coordinate stores real trichotomy, a host root, or an external oracle, the branch visible to $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ is determined exactly by the finite sign ledger. □

Theorem 1386.10 (Bisection root-isolation branch monotonicity)**.** *For an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier, extending the dyadic bisection depth refines the retained interval window and never enlarges the* $\mathsf{Real}^{\uparrow}$*-seal-facing interval. The refinement route factors through the retained* $\mathsf{DyadicBisection}^{\uparrow}$ *branch prefix, the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint rows, the displayed sign ledger, the* $\mathsf{StreamName}^{\uparrow}$ *windows, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows.*

Proof. Start with two unary depth requests where the second extends the first. The retained branch prefix lives in the $\mathsf{DyadicBisection}^{\uparrow}$ ledger B, and Definition 1407.6 routes each requested depth through the located endpoint rows, dyadic tolerance row, stream windows, and regular readback.

The extension step can only append midpoint inspection and sign rows already admitted by Definition 1407.9. It therefore selects a subwindow of the earlier retained window rather than a new ambient interval.

The downstream seal is constrained by Definition 1407.4. Since every real-facing read passes through the retained window already chosen by the branch ledger, increasing depth can refine the exposed interval but cannot enlarge it or introduce host root existence, completed interval intersection, trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1386.11 (Bisection root-isolation depth coverage)**.** *Every unary precision request made to an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier factors through some finite branch prefix in B, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window rows, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before it reaches a* $\mathsf{Real}^{\uparrow}$ *seal. The packet therefore covers precision requests by finite bisection depth rather than by a completed nested-interval object.*

Proof. Begin with a unary precision request n. The $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance 2^{-n}, and Definition 1407.6 selects a retained branch prefix whose window is read at that tolerance.

The endpoint windows then pass through the $\mathsf{StreamName}^{\uparrow}$ rows. Apply Definition 1407.3 to read the same retained windows through $\mathsf{RegSeqRat}^{\uparrow}$ at the requested precision.

Finally route the readback to the real-facing boundary using Definition 1407.4. The request is exhausted by the finite prefix, tolerance, window, and readback rows, so no completed branch, host root, general intermediate value theorem, trichotomy oracle, or ambient completeness principle is exposed. □

Theorem 1386.12 (BisectionRootIsolation public isolation certificate)**.** *Every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *isolation certificate exposes the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint rows, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger, the displayed sign-window rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal before any public isolation read is available. The public read is therefore the finite retained isolating window with its displayed sign-change ledger, not a host root, a general intermediate value theorem, real trichotomy, a completed interval intersection, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the retained-window refinement of Definition 1407.6. It routes each requested precision through the located endpoint packet, the retained $\mathsf{DyadicBisection}^{\uparrow}$ branch prefix, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, the finite $\mathsf{StreamName}^{\uparrow}$ windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Use the branch ledger and sign stability supplied by Definition 1407.9 together with Definition 1407.5. These theorems keep every branch choice inside the finite inspection row, displayed sign row, and retained branch row; no host trichotomy or external root-location oracle is added.

Finally apply the public export and Real-seal boundary of Definition 1407.8 and Definition 1407.4. The public consumer reaches the $\mathsf{Real}^{\uparrow}$ seal only after the endpoint, branch, sign, tolerance, stream-window, and regular-readback rows have been displayed, so the exported isolation certificate is exactly the finite L10 window named in the statement. □

Theorem 1386.13 (Bisection root-isolation interval nesting)**.** *Every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *packet exposes a nested chain of retained windows before its public isolation certificate is consumed. For each retained branch prefix, the lower and upper endpoints of the selected window pass through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and the* $\mathsf{Real}^{\uparrow}$ *seal-facing rows; a later retained prefix selects a subwindow of the earlier one and cannot replace that chain by a host root, a completed interval intersection, real trichotomy, or ambient completeness.*

Proof. Induct over the retained-window refinement rows of the $\mathsf{DyadicBisection}^{\uparrow}$ ledger. The initial row is the located endpoint packet J of Definition 1407.1; its endpoints are already routed through the displayed dyadic tolerance, stream-window, regular-readback, and real-seal rows.

For the refinement step, use Definition 1407.9. The next retained branch is determined by the finite inspection row and displayed sign row, so the branch ledger can only select one of the two displayed subwindows of the previous retained window.

Apply Definition 1407.6 and Definition 1407.12 to the selected prefix. They route its endpoints through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before public consumption. The nonescape boundary of Definition 1407.4 excludes the host analytic objects, so the public certificate sees a nested retained-window chain rather than an external root-selection principle. □

Theorem 1386.14 (Bisection root-isolation bridge schema)**.** *Every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *packet exports a bridge-readable schema consisting of the located interval source, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bisection ledger, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, the finite sign ledger, retained-window monotonicity, and the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ *rows. The schema is a finite isolation route and does not assert a general intermediate value theorem, host root existence, completed interval intersection, real trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the public isolation certificate of Definition 1407.12. It exposes the located endpoint rows, the retained dyadic branch ledger, the displayed sign-window rows, the dyadic tolerance rows, stream windows, regular readback, and the real seal before any public isolation read.

Use interval nesting from Definition 1407.13. The retained prefixes form the bridge-visible window chain, and each endpoint read is still routed through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Add branch monotonicity and depth coverage from Definition 1407.10 and Definition 1407.11. These rows identify the retained-window monotonicity and the finite prefix selected for each unary precision request.

Finally apply the Real seal nonescape boundary of Definition 1407.4. The bridge-readable schema is therefore exhausted by the displayed carrier rows and the local $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ route, with no host analytic principle available beyond the finite isolation packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$.

Constructive story: A $\mathsf{BisectionRootIsolation}^{\uparrow}$ packet is generated from a $\mathsf{LocatedInterval}^{\uparrow}$ endpoint packet, a $\mathsf{DyadicBisection}^{\uparrow}$ branch ledger, finite sign rows at retained endpoints and midpoints, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal rows, displayed hsame and Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1407.1, Definition 1407.2, Definition 1407.3, Definition 1407.4, Definition 1407.5, Definition 1407.6, Definition 1407.7, and Definition 1407.12 bind the carrier, NameCert obligations, RegSeqRat window handoff, Real seal nonescape, finite sign-change certificate, retained-window refinement, downstream boundary, public isolation certificate, and BEDC rows BHist, hsame, Cont, Pkg, NameCert, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to a finite sign-change bisection certificate over located intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationDownstreamBoundary`

Bridge status: none

Not claimed: This chapter does not close host root existence, a general intermediate value theorem, real trichotomy, completed interval intersection, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: The remaining work is Lean verification of the displayed carrier, sign-ledger exactness, retained-window handoff, and Real-seal nonescape, not paper obligation closure.

Chapter 1387

A Concrete Naming Certificate for $\mathsf{DiniTheorem}^{\uparrow}$

Following Dini's theorem in constructive analysis, the $\mathsf{DiniTheorem}^{\uparrow}$ packet records only finite compact-window and monotone convergence data. It consumes the compact metric source of chapter 129, the compact-uniform-continuity surface of chapter 388, the continuous-map rows of chapter 130, the located real boundary of **??**, and the Real seal of chapter 38. The packet is a finite NameCert for a displayed monotone convergence window; it does not import open-cover compactness, sequential compactness, a host supremum, a selected limit, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1387.1 (DiniTheorem carrier)**.** *A* $\mathsf{DiniTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, F, M, W, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric source row, carrying the* $\mathsf{CompactMetric}^{\uparrow}$ *name, its finite inspection windows, and the source-side metric classifier used by downstream rows.*
2. *F is a finite monotone family of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows over X, together with the pointwise direction ledger that records, for each inspected index pair, which displayed real-name comparison is monotone.*
3. *M is the compact-uniform-continuity ledger imported from* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *for the displayed rows of F on the windows of X.*
4. *W is the shared tolerance-window ledger: for each requested dyadic tolerance it lists the finite X-windows, family indices, continuity moduli, and located real readbacks inspected by the packet.*
5. *R is the boundary real-seal row, storing the* $\mathsf{LocatedReal}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows reached by the displayed window reads and by no independent host limit coordinate.*
6. *H stores componentwise* hsame *transports for the compact source, continuous-map family, monotonicity ledger, uniform-continuity ledger, tolerance windows, and real-seal rows.*
7. *C stores the displayed* Cont *replay routes from compact windows to continuity rows, from monotone family rows to located real comparisons, and from the shared tolerance ledger to the boundary real seal.*

8. *P is the* Pkg *provenance over* $\mathsf{DiniTheorem}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for an open cover, sequential compactness witness, ambient supremum, selected limit function, quotient equality of real names, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniTheoremUp.DiniTheoremTasteGate single carrier alignment`

Theorem 1387.2 (DiniTheorem NameCert obligations)**.** *For an accepted* $\mathsf{DiniTheorem}^{\uparrow}$ *carrier* $D = (X, F, M, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DiniTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed compact source, monotone continuous-map family, uniform-continuity ledger, tolerance-window ledger, boundary real rows, transport, continuation, provenance, and naming rows;*

2. *classifier transport along H and C, preserving the same compact windows, family indices, monotone comparisons, continuity moduli, and real-seal reads;*

3. *monotone ledger exactness, requiring every comparison used by a convergence read to occur in the finite family row F;*

4. *shared-window exactness, requiring every tolerance request to be answered by the displayed compact windows and compact-uniform-continuity rows listed in W and M;*

5. *nonescape, requiring every* $\mathsf{LocatedReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read to pass through the rows W, R, H, C, P, N and through no open-cover, sequential-compactness, host-supremum, selected-limit, quotient-equality, or completeness coordinate.*

Proof. Carrier admission is projection from the packet $D = (X, F, M, W, R, H, C, P, N)$. The compact metric row, monotone family, compact-uniform-continuity ledger, shared tolerance windows, real-seal boundary, transports, continuation routes, provenance, and local name are exactly the displayed coordinates of Definition 1387.1.

Classifier transport reads H componentwise and then replays C. A transported consumer sees the same compact source windows, the same finite family indices, the same monotone comparison rows, the same continuity-modulus rows, and the same real-seal boundary route.

Monotone ledger exactness follows because F is the only row that stores family comparison data. A convergence-facing read cannot introduce a private order comparison or a detached tail relation without leaving the accepted carrier.

Shared-window exactness follows from M and W. The continuity ledger supplies the compact-uniform-continuity rows, while the tolerance ledger names the finite windows and family indices consumed for each displayed tolerance.

Finally, the nonescape clause is an inventory check on the carrier. The rows R, H, C, P, N expose the located and Real boundary route, and none of the excluded compactness, supremum, selected-limit, quotient-equality, choice, or completeness principles appears as a coordinate. □

Theorem 1387.3 (DiniTheorem monotone uniform window)**.** *Let $D = (X, F, M, W, R, H, C, P, N)$ be an accepted* $\mathsf{DiniTheorem}^{\uparrow}$ *carrier. For every displayed tolerance request recorded in W, every accepted convergence read factors through a single finite route*

$$X, F, M, W, R, H, C, P, N.$$

The route reads the compact source windows from X, the finite monotone family comparisons from F, the compact-uniform-continuity rows from M, and the shared tolerance window from W before any $\mathsf{LocatedReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *boundary row in R is consumed. No accepted read may replace this route by open-cover compactness, sequential compactness, a host supremum, a selected limit, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the tolerance request in W. It names the compact source windows, the family indices, and the continuity-modulus rows that are inspected at the requested dyadic scale.

The source windows are read through X, and the family rows are read through F. Since F includes the monotone ledger, each comparison used by the convergence read is already a displayed family comparison, not an ambient real-order assertion.

The compact-uniform-continuity row M then identifies the finite windows sufficient for all displayed source points in the request. The route remains finite because M and W list the inspected windows explicitly.

Only after these rows are visible can the read reach R. The continuation row C records this order, while H preserves it under transport and P, N package and name the same route.

Thus every accepted convergence read factors through $X, F, M, W, R, H, C, P, N$. Any route that inserts open-cover compactness, sequential compactness, host suprema, selected limits, quotient real equality, or ambient completeness uses data absent from the carrier. □

Theorem 1387.4 (DiniTheorem nonescape boundary)**.** *Every* $\mathsf{LocatedReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *boundary read exported by an accepted* $\mathsf{DiniTheorem}^{\uparrow}$ *carrier is downstream of the displayed finite compact-window monotonicity route. Equivalently, if a consumer reaches the boundary row R, then the consumer has already read the same compact source row X, monotone family row F, compact-uniform-continuity ledger M, shared tolerance-window row W, componentwise transports H, continuation replay C, package provenance P, and local naming row N.*

Proof. Inspect the carrier. The only boundary coordinate is R, and it is stored together with the compact source, monotone family, uniform-continuity ledger, and shared tolerance-window rows.

The continuation row C records the admissible replay into R. Its predecessors are the source-window read, the family monotonicity read, the uniform-continuity read, and the tolerance-window read; no separate boundary route is recorded.

Transport cannot create another route. The row H moves the displayed coordinates componentwise, so a transported boundary read still consumes the same X, F, M, W, R surface.

The package and naming rows P, N therefore certify only this route. Because the carrier contains no open-cover, sequential-compactness, host-supremum, selected-limit, quotient-equality, countable-choice, or completeness coordinate, a boundary read using any such datum is outside the accepted $\mathsf{DiniTheorem}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiniTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DiniTheorem}^{\uparrow}$ packet is generated from a compact metric source row, a finite monotone family of continuous-map rows, compact-uniform-continuity rows, shared tolerance-window rows, located and Real boundary seal rows, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DiniTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 1387.1, Definition 1387.2, Definition 1387.3, and Definition 1387.4 seed the finite compact-window monotone convergence certificate for DiniTheoremUp.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DiniTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, sequential compactness, host supremum, selected limit, quotient real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone ledger exactness, shared-window exactness, real-seal nonescape, and classifier transport for the same finite packet.

Chapter 1388

A Concrete Naming Certificate for $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ packet records the finite selector boundary that can be read before any classical Bolzano–Weierstrass conclusion is asserted. The route is anchored by the monotone selector surface of chapter 1405, the bounded monotone Cauchy witness of chapter 535, the bounded monotone convergence seal of chapter 918, the stream-window interface of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal real-name boundary of chapter 38. It packages a displayed finite handoff from bounded sequence windows to monotone selected windows, not sequential compactness, a host real completeness theorem, or a choice-selected subsequence.

Definition 1388.1 (Bolzano–Weierstrass selector carrier)**.** *A* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, M, Q, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded source-sequence window ledger; it records only the finite* $\mathsf{StreamName}^{\uparrow}$ *windows currently inspected and the displayed boundedness rows attached to those windows.*
2. *M is the monotone selector ledger read through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*; each displayed entry records a selector position, its source window, and the comparison row that makes the selected window monotone inside the finite packet.*
3. *Q is the cofinal evidence row for the inspected selector thresholds, limited to thresholds that occur in the packet.*
4. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *window family obtained from B, M, Q.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger read from the selected windows before any regular rational or real-facing handoff is available.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the selected dyadic windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only through the bounded monotone witness and bounded monotone convergence seal routes after B, M, Q, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for bounded windows, selector entries, cofinal evidence, selected windows, dyadic rows, regular handoff, Real seal, continuation rows, provenance rows, and local naming rows.*

9. *C records displayed* Cont *routes from B, M, Q to W, from W to D, from D to R, and from the bounded monotone witness and convergence seal packets to E.*

10. *P is the* Pkg *provenance over* BolzanoWeierstrassSelector$^{\uparrow}$, MonotoneSubsequence$^{\uparrow}$, BoundedMonotoneCauchyWit BoundedMonotoneConvergenceSeal$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{BolzanoWeierstrassSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for full Bolzano–Weierstrass, sequential compactness, a choice-selected subsequence, quotient-stream equality, host real equality, a least cluster selector, or Real$^{\uparrow}$ *completeness.*

Theorem 1388.2 (Bolzano–Weierstrass selector subsequence handoff)**.** *Every accepted* BolzanoWeierstrassSelector$^{\uparrow}$ *packet hands bounded source windows to selected monotone windows only through the route*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R.$$

The first part of the route factors through MonotoneSubsequence$^{\uparrow}$, *and the regular-facing handoff is read through* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* RegSeqRat$^{\uparrow}$ *before any* Real$^{\uparrow}$ *seal row is consumed.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorSubsequenceHandoff`

Proof. Project the carrier of Definition 1408.1. The bounded source row B, selector ledger M, inspected-threshold cofinality row Q, selected windows W, dyadic ledger D, regular handoff R, and structural rows H, C, P, N are the only rows visible before the seal coordinate.

Use the monotone selector surface of chapter 1405. It identifies the selector ledger and cofinal evidence as finite displayed rows, so the selected windows are obtained by packet replay rather than by countable choice or by an ambient subsequence object.

Next read the selected windows through the terminal finite route. The StreamName$^{\uparrow}$ windows provide W, the DyadicRatCore$^{\uparrow}$ ledger provides D, and the RegSeqRat$^{\uparrow}$ handoff provides R.

The transport, continuation, package, and local NameCert rows only preserve this displayed route. Since no other selector coordinate is present, every accepted subsequence handoff factors through $B, M, Q, W, D, R, H, C, P, N$. □

Theorem 1388.3 (Bolzano–Weierstrass selector Real seal boundary)**.** *Every real-facing read of an accepted* BolzanoWeierstrassSelector$^{\uparrow}$ *packet reaches the seal row E only after the finite selector route*

$$B, M, Q, W, D, R, E$$

has passed through the bounded monotone Cauchy witness and bounded monotone convergence seal packets. The consumer receives a Real boundary for the selected regular handoff, not full Bolzano–Weierstrass, sequential compactness, a choice-selected subsequence, quotient-stream equality, host real equality, or Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRealSealBoundary`

Proof. Begin with Definition 1408.2. It exposes B, M, Q, W, D, R before a Real-facing coordinate can be consumed, and it makes the selected regular handoff the only path from bounded windows to the seal-facing surface.

Now pass through the bounded monotone witness and convergence seal chapters. The witness route of chapter 535 supplies the bounded monotone Cauchy surface, while the seal route of

chapter 918 exposes the Real handoff only after the finite stream, dyadic, regular, and seal rows are displayed.

Finally inspect the excluded data. The carrier has rows for bounded windows, monotone selector entries, cofinal evidence, selected windows, dyadic tolerance rows, a regular handoff, a Real seal, transports, continuations, provenance, and local naming, but it has no row for sequential compactness, arbitrary choice, quotient streams, host equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Thus the Real-facing read is a boundary seal for the displayed finite route and nothing beyond that route is exported. □

Theorem 1388.4 (Bolzano–Weierstrass selector bounded-monotone route)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the Real-facing row* E *is available only after the finite route*

$$\mathsf{MonotoneSubsequence}^{\uparrow} \longmapsto \mathsf{BoundedMonotoneCauchyWitness}^{\uparrow} \longmapsto \mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow} \longmapsto \mathsf{Stream}$$

has displayed the rows B, M, Q, W, D, R, E*. The packet therefore records a bounded monotone induction path into the* $\mathsf{Real}^{\uparrow}$ *seal, not full Bolzano–Weierstrass, sequential compactness, choice-selected subsequences, quotient-stream equality, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.TasteGate.BolzanoWeierstrassSelectorBoundedMonotoneRo`

Proof. Project the carrier of Definition 1408.1. The rows B, M, Q, W, D, R, E are the only Real-facing path before transport, continuation, provenance, and local naming are applied.

Apply Definition 1408.2. It exposes the finite selector route from bounded source windows through monotone selected windows and then through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$.

Apply Definition 1408.3. The Real seal row is consumed only after the bounded monotone Cauchy witness and bounded monotone convergence seal packets have been displayed.

Combining these two chapter routes gives the stated induction path from $\mathsf{MonotoneSubsequence}^{\uparrow}$ through the bounded monotone witness, convergence seal, stream, dyadic, regular, and Real rows. The carrier has no coordinate for classical compactness, countable choice, quotient streams, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$, so no accepted read can export those objects. □

Theorem 1388.5 (Bolzano–Weierstrass selector window obligation)**.** *For every accepted* BolzanoWeierstrassSelecto *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, each finite selected-window read is admissible only when the bounded source window row* B*, monotone selector ledger* M*, inspected-threshold row* Q*, selected* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, dyadic tolerance row* D*, regular handoff row* R*, Real seal row* E*, componentwise transport row* H*, replay row* C*, provenance row* P*, and local naming row* N *are all read as one displayed packet. The route factors through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorWindowObligation`

Proof. Project Definition 1408.1. The rows $B, M, Q, W, D, R, E, H, C, P, N$ are the entire accepted packet, so a selected-window consumer cannot detach W from the bounded source and monotone selector rows.

Apply Definition 1408.2. It supplies the finite selector route from B, M, Q to W, D, R through $\mathsf{MonotoneSubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$.

Finally apply Definition 1408.4. The bounded monotone witness and convergence seal place E behind the same route, while H, C, P, N transport, replay, source, and name the packet. □

Theorem 1388.6 (Bolzano–Weierstrass selector finite-window induction)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, any finite extension of the inspected selector-threshold ledger that preserves the bounded source window row* B *and the monotone selector ledger* M *extends the selected-window route only by replaying*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E.$$

The induction exports no selected infinite subsequence, quotient stream equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or additional compactness principle.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteWindowInduction`

Proof. Induct over the displayed finite selector-threshold ledger. The base ledger is the selected-window route already bound by Definition 1408.5: the consumer reads $B, M, Q, W, D, R, E, H, C, P, N$ as one finite packet and receives no external subsequence object.

For the successor step, append one inspected threshold that preserves the same bounded source row B and monotone selector ledger M. The subsequence handoff of Definition 1408.2 admits only the corresponding selected $\mathsf{StreamName}^{\uparrow}$ window in W, with the dyadic and regular rows still downstream of that window.

Finally apply Definition 1408.4 and Definition 1408.5. They force the route through D, R, E after the selected window, while H, C, P, N merely transport, replay, source, and name the same finite packet. Thus every finite extension is a replay of the displayed route and not an export of compactness, quotient equality, host equality, or ambient completeness. □

Theorem 1388.7 (Bolzano–Weierstrass selector regular-Cauchy extraction route)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the finite selected-window induction together with the bounded-monotone route determines a regular-Cauchy extraction surface through*

$$W \longmapsto D \longmapsto R \longmapsto E.$$

Every extracted finite window is read through $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The route exports no selected infinite subsequence, host cluster point, sequential compactness theorem, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRegularCauchyExtractionRout`

Proof. Start with the subsequence handoff of Definition 1408.2. It exposes only selected finite $\mathsf{StreamName}^{\uparrow}$ windows in W after the bounded source row B, monotone selector ledger M, and inspected-threshold row Q have been read.

Apply the finite-window induction of Definition 1408.6. Each finite extension replays the same route from B, M, Q to W and then to the dyadic, regular-rational, and Real-seal rows.

Use the bounded-monotone route of Definition 1408.4 together with the window obligation of Definition 1408.5. These force the downstream read through D, R, E before any cluster-facing consumer may inspect the packet.

Finally apply the Real seal boundary of Definition 1408.3. Since the carrier has no coordinate for an infinite selected subsequence, host cluster point, sequential compactness theorem, quotient stream equality, or ambient completeness row, the extraction surface is exactly the displayed regular-Cauchy route. □

Theorem 1388.8 (Bolzano–Weierstrass selector cluster route)**.** *For every accepted* BolzanoWeierstrassSelector$^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the cluster-facing read is exactly the finite route*

$$B, M, Q, W, D, R \longmapsto E$$

through MonotoneSubsequence$^{\uparrow}$*,* BoundedMonotoneCauchyWitness$^{\uparrow}$*,* BoundedMonotoneConvergenceSeal$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*. It records a bounded monotone selected-window route to a Real seal, not a classical cluster-point theorem or a choice-selected subsequence.*

Proof. Start from the window obligation in Definition 1408.5. It binds $B, M, Q, W, D, R, E, H, C, P, N$ into one finite packet and prevents a consumer from reading a cluster-facing seal from an uninspected window.

Use the bounded-monotone route of Definition 1408.4. The row E is available only after the monotone selector has passed through the bounded monotone Cauchy witness and bounded monotone convergence seal.

The structural rows add no compactness principle. They only transport and replay the same carrier through H, C, P, N, so the exported cluster-facing object is the displayed Real seal boundary for the finite route. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorClusterRoute`

Theorem 1388.9 (Bolzano–Weierstrass selector nonescape)**.** *For every accepted* BolzanoWeierstrassSelector$^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, no consumer can export full Bolzano–Weierstrass compactness, host sequential compactness, choice-selected subsequences, quotient-stream equality, host real equality, or ambient* Real$^{\uparrow}$ *completeness from the packet. The only exported Real-facing data are the rows obtained from* $B, M, Q, W, D, R, E, H, C, P, N$ *through* MonotoneSubsequence$^{\uparrow}$*,* BoundedMonotoneCauchyWitness$^{\uparrow}$*,* BoundedMonotoneConvergenceSeal$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*.*

Proof. Project the carrier. Its visible data are the bounded source windows, monotone selector ledger, inspected-threshold row, selected windows, dyadic tolerances, regular handoff, Real seal, transport, replay, provenance, and local naming rows.

Apply Definition 1408.8. The cluster-facing read reaches E only through the finite bounded-monotone route and the stream, dyadic, regular, and Real rows named in the statement.

The excluded objects have no row in the carrier and no row in the cited route. Therefore an accepted consumer may replay the finite selector packet, but it cannot export compactness, choice, quotient equality, host equality, or Real completeness. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorNonescape`

Theorem 1388.10 (Bolzano–Weierstrass selector monotone-subsequence obligations)**.** *For every accepted* BolzanoWeierstrassSelector$^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the monotone-subsequence surface consists of exactly three finite obligations:*

1. *finite selector admission for the displayed monotone selector ledger* M *and inspected-threshold cofinality row* Q *over the bounded source windows* B*;*
2. *monotone selected-window transport from* B, M, Q *to the selected* StreamName$^{\uparrow}$ *windows* W *through componentwise* hsame *transport and displayed* Cont *replay;*
3. *bounded-monotone Real-seal nonescape from* W, D, R *to* E *through* BoundedMonotoneCauchyWitness$^{\uparrow}$*,* BoundedMonotoneConvergenceSeal$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$*.*

The obligations do not claim full Bolzano–Weierstrass, sequential compactness, choice-selected subsequences, quotient-stream equality, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Read the selector rows from Definition 1408.1. The packet admits only bounded source windows, the monotone selector ledger, inspected-threshold cofinality data, selected windows, dyadic tolerances, regular readback, the Real seal, and the structural rows.

Apply Definition 1408.2. It turns the first two obligations into the displayed route $B, M, Q \longmapsto W \longmapsto D \longmapsto R$, with the monotone selector surface supplied by $\mathsf{MonotoneSubsequence}^{\uparrow}$ and preserved by H, C, P, N.

Apply Definition 1408.4. It places the Real-facing row behind the bounded monotone witness and convergence seal packets, so the nonescape obligation is a finite seal route rather than a compactness theorem or a choice-selected subsequence. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorMonotoneSubsequenceObligati`

Theorem 1388.11 (Bolzano–Weierstrass selector window-choice-free carrier)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ BHist *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the selected-window carrier is choice-free: each* $\mathsf{StreamName}^{\uparrow}$ *window in* W *is read from a displayed selector entry in* M *and an inspected bounded source window in* B*, then transported by the componentwise* hsame *row* H *and replayed by the displayed* Cont *row* C*. The* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}$ *row* N *are downstream rows of the same finite packet, not witnesses to a countable-choice selector, sequential compactness, or an ambient Bolzano–Weierstrass theorem.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorWindowChoiceFreeCarrier`

Proof. Induct over the finite selector-window portion of the displayed BHist packet. The empty window reads no selector entry and therefore exposes no hidden subsequence object.

At a successor step, project the next entry of M together with its source window in B and inspected threshold in Q. The entry appends the corresponding $\mathsf{StreamName}^{\uparrow}$ row to W through H and C, so the carrier step is a finite replay rather than a choice of a new subsequence.

After the selected window is displayed, the dyadic and regular rows D, R and the $\mathsf{Real}^{\uparrow}$ seal row E remain attached to the same packet with provenance P and local naming N. Thus the carrier exports only the finite window route and none of the excluded compactness or choice principles. □

Theorem 1388.12 (Bolzano–Weierstrass selector finite-subsequence obligations)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ BHist *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, a finite-subsequence read must display the bounded source row* B*, selector ledger* M*, inspected-threshold row* Q*, selected* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N *before the read is available to a consumer. The obligations are finite window admission, selector-order replay, regular-rational readback, and Real-seal nonescape; they do not assert sequential compactness, countable choice, quotient-stream equality, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the displayed selector packet. The rows B, M, Q, W determine the finite subsequence surface, and every selected window is admitted by the packet row that names it.

Run finite window induction over M and Q. Each induction step consumes one displayed selector entry, reads the corresponding bounded source window from B, and appends exactly the matching $\mathsf{StreamName}^{\uparrow}$ row to W by hsame transport and Cont replay.

The readback and seal obligations are then projected from R, E, P, N. Since these rows are attached after the selected windows and contain no coordinate for compactness, countable choice, quotient equality, host equality, or ambient completeness, the finite-subsequence obligations stop at the displayed packet boundary. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteSubsequenceObligatio`

Theorem 1388.13 (Bolzano–Weierstrass selector root window)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, every root selected-window read must expose the bounded source windows* B*, monotone selector ledger* M*, cofinal row* Q*,* $\mathsf{StreamName}^{\uparrow}$ *row* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the structural rows* H, C, P, N*. The read factors through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergence}$ $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, and it exports no full Bolzano–Weierstrass theorem, sequential compactness, choice-selected subsequence, quotient stream, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRootWindow`

Proof. Begin with the subsequence handoff of Definition 1408.2. It routes the root selector surface from B, M, Q to W, D, R through the finite monotone subsequence packet and the stream, dyadic, and regular rational rows.

Next use the finite-subsequence obligations of Definition 1408.12. They require the same bounded source, selector, cofinal, selected-window, readback, seal, and structural rows to be displayed before any finite selected-window read is exported.

Now apply the bounded-monotone route of Definition 1408.4. It places the Real seal behind $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ and $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$, so the root read remains a finite induction-style handoff rather than a compactness principle.

Finally use the nonescape theorem Definition 1408.9. Since the carrier has no row for full Bolzano–Weierstrass, sequential compactness, choice-selected subsequences, quotient streams, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the root window exports only the displayed finite route. □

Theorem 1388.14 (Bolzano–Weierstrass selector RegSeqRat readback nonescape)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ BHist *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback from the selected windows must pass through the finite route*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R$$

with the $\mathsf{Real}^{\uparrow}$ *seal row* E *available only after that readback is displayed. Componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row preserve the route; they do not let the read escape to a choice-selected subsequence, sequential compactness, quotient-stream equality, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRegSeqRatReadbackNonescape`

Proof. Start with the finite-subsequence obligations of Definition 1408.12. They force every selected window in W to be displayed through B, M, Q before downstream readback can begin.

Project the dyadic and regular rows from the carrier. The $\mathsf{DyadicRatCore}^{\uparrow}$ row D is attached to the displayed selected windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R is read only after those dyadic rows have been exposed.

Finally inspect the structural rows H, C, P, N and the $\mathsf{Real}^{\uparrow}$ seal row E. They replay and name the same finite route, so no hidden compactness, choice, quotient, host-equality, or ambient-completeness datum can be introduced at readback time. □

Definition 1388.15 (Bolzano–Weierstrass selector induction budget)**.** *The finite selector-induction budget of an accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$ *is the displayed four-row ledger* B, M, Q, W*: the bounded source-window row* B*, the monotone selector ledger* M*, the inspected-threshold cofinality row* Q*, and the selected* $\mathsf{StreamName}^{\uparrow}$ *window row* W*. A budget step consumes one displayed entry of* M*, reads its bounded source window from* B*, verifies the inspected threshold in* Q*, and appends the admitted selected window to* W *through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*. The budget contains no hidden subsequence object, least-selector functional, countable choice row, or compactness row.*

Lean4 (definition) `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorInductionBudget`
Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorInductionBudget`
`selected window route`

Theorem 1388.16 (Bolzano–Weierstrass selector finite monotone induction)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, finite induction over the selector-induction budget of Definition 1408.15 admits each selected window through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*. The base stage exposes the empty selected-window family over the displayed bounded source row* B*; each successor stage consumes one ledger entry from* M*, checks the inspected threshold row* Q*, and appends exactly the corresponding* $\mathsf{StreamName}^{\uparrow}$ *window to* W *by displayed* hsame *transport and* Cont *replay. No stage exports a choice-selected subsequence, sequential compactness, quotient-stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteMonotoneInduction`

Proof. Project the budget rows B, M, Q, W from the carrier. These rows are finite BHist data, so induction is over the displayed selector ledger rather than over an external sequence or function space.

The base case reads no selector entry. It exposes the empty selected-window family and records that no dyadic, regular, Real-facing, or compactness row is available.

For the successor step, consume the next displayed selector entry in M. The entry names its bounded source window in B, its inspected threshold in Q, and the selected $\mathsf{StreamName}^{\uparrow}$ window that is appended to W through the $\mathsf{MonotoneSubsequence}^{\uparrow}$ comparison row.

The transport rows H and replay rows C preserve the admitted window at each finite step. Since no carrier coordinate names a choice functional or a sequential compactness theorem, the induction admits exactly the selected windows listed in W. □

Theorem 1388.17 (Bolzano–Weierstrass selector finite-window stabilization)**.** *Let* $T = (B, M, Q, W, D, R, E, H, C$ *be an accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet. If a selected finite* $\mathsf{StreamName}^{\uparrow}$ *window in* W *is replaced by a later displayed window admitted by the same monotone selector ledger* M *and inspected-threshold row* Q*, then the route*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E$$

is preserved through $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergenceSeal}$ $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The stabilized packet records only this finite-window replacement route; it does not export full Bolzano–Weierstrass, sequential compactness, countable choice, quotient streams, host equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteWindowStabilization`

Proof. Project $B, M, Q, W, D, R, E, H, C, P, N$ from the carrier. The replacement hypothesis uses the same M and Q rows, so it remains inside the selector-induction budget of Definition 1408.15.

Apply Definition 1408.16 to the displayed later window. Finite induction over B, M, Q, W admits that window through the same $\mathsf{MonotoneSubsequence}^{\uparrow}$ comparison row, and H, C replay the transport without adding a subsequence object or a choice functional.

Now use the cluster and regular-Cauchy seal routes already proved in Definition 1408.8 and Definition 1408.19. The dyadic rows D, regular handoff R, and Real seal E are consumed after the stabilized selected window, so the downstream route is still the finite chain through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

No carrier coordinate remains for full Bolzano–Weierstrass compactness, sequential compactness, countable choice, quotient-stream equality, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The theorem therefore stabilizes only the displayed finite window. □

Theorem 1388.18 (Bolzano–Weierstrass selector finite nested-window induction)**.** *Let $T = (B, M, Q, W, D, R, E,$ be an accepted $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ packet. Suppose the bounded monotone route of Definition 1408.4, the nested-interval obligation of Definition 1408.22, the dyadic-window obligation of Definition 1408.21, the $\mathsf{StreamName}^{\uparrow}$ selected-window row W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal row E are all displayed in the same BHist packet. Then the selector admits finite induction over the nested windows: each induction stage refines the current interval through the displayed nested-interval row, transports the matching dyadic tolerance through D, replays the same $\mathsf{StreamName}^{\uparrow}$ window through W, and hands the resulting regular readback to R before E can be inspected. The cluster handoff is therefore the same handoff as in Definition 1408.8, and no stage exports a selected infinite subsequence, countable choice, quotient-stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.*

Proof. Project the finite-window stabilization rows from Definition 1408.17. They keep the route

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E$$

inside the accepted packet and leave H, C, P, N as structural transport, replay, provenance, and local naming rows.

Induct on the displayed nested-window budget. The base stage is the current selected window in W together with its bounded monotone route, dyadic tolerance row, regular readback row, and Real seal row.

For the successor step, use Definition 1408.22 to refine the interval row and Definition 1408.21 to transport the matching dyadic tolerance through D. The selected $\mathsf{StreamName}^{\uparrow}$ row remains the displayed window row W, so the successor step has no independent subsequence selector.

Now replay the readback through R and the Real seal through E. The cluster route of Definition 1408.8 and the nonescape boundary of Definition 1408.9 close the handoff through the same rows. Since no carrier coordinate names a selected infinite subsequence, countable-choice schedule, quotient-stream equality, host real equality, or ambient completeness theorem, the finite induction preserves only the displayed cluster handoff. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteNestedWindowInductio`

Theorem 1388.19 (Bolzano–Weierstrass selector regular Cauchy cluster seal)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the finite monotone route of Definition 1408.16 reaches the cluster-facing seal only through*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E.$$

The rows D, R, E *are read respectively through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the bounded monotone convergence seal route. The resulting consumer receives a regular Cauchy cluster boundary for the displayed selected windows, not classical sequential compactness, arbitrary choice, host real equality, quotient-stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRegularCauchyClusterSeal`

Proof. First apply Definition 1408.16. It admits the selected windows in W by finite induction over B, M, Q, W and makes $\mathsf{MonotoneSubsequence}^{\uparrow}$ the only selector surface.

Next read the dyadic tolerance ledger D and regular handoff row R. The carrier definition attaches each row in D to a selected window in W, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R is available only after those dyadic rows are displayed.

Finally use the bounded monotone Cauchy witness and bounded monotone convergence seal routes named in Definition 1408.4. They expose the Real-facing row E after W, D, R and do not add compactness, choice, quotient-stream equality, host equality, or ambient completeness. □

Theorem 1388.20 (Bolzano–Weierstrass selector bounded-subsequence carrier)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the bounded-subsequence carrier surface exposes bounded source windows and monotone selected windows by finite selector induction over* B, M, Q, W *only. The induction may read the bounded window ledger* B*, the monotone selector ledger* M*, the inspected-threshold row* Q*, and the selected* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, but it exports no ambient subsequence object, no countable choice functional, and no sequential compactness row.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorBoundedSubsequenceCarrier`

Proof. Project the carrier rows from Definition 1408.1. The rows B, M, Q, W are the only displayed selector rows before dyadic, regular, Real-facing, and structural rows are consumed.

Induct over the finite selector ledger M together with the inspected-threshold row Q. The base case reads the initial bounded source window from B and exposes the empty selected window family. The successor step consumes one displayed selector entry, verifies its comparison row through $\mathsf{MonotoneSubsequence}^{\uparrow}$, and appends the corresponding selected $\mathsf{StreamName}^{\uparrow}$ window to W.

Transport and continuation rows preserve the same finite route. Since the carrier has no row for an ambient subsequence, choice functional, or compactness theorem, the bounded-subsequence surface is exactly the finite induction over B, M, Q, W. □

Theorem 1388.21 (Bolzano–Weierstrass selector dyadic-window obligation)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, selected windows reach dyadic tolerance rows only through the displayed route*

$$B, M, Q \longmapsto W \longmapsto D.$$

Thus every dyadic read is mediated by $\mathsf{StreamName}^{\uparrow}$ *selected windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, not by a host metric limit, quotient-stream equality, or an uninspected source window.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorDyadicWindowObligation`

Proof. Begin with Definition 1408.20. It supplies the finite selected-window route $B, M, Q \longmapsto W$ and excludes any hidden subsequence object.

Now inspect the dyadic ledger D in Definition 1408.1. Each tolerance row in D is attached to a displayed selected $\mathsf{StreamName}^{\uparrow}$ window in W, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance data before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read is available.

The componentwise hsame and Cont rows replay this displayed handoff. They cannot add quotient-stream equality, host metric limits, or uninspected source windows, so every dyadic tolerance read factors through W and D. □

Theorem 1388.22 (Bolzano–Weierstrass selector nested-interval obligation)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, any consumer that reads the selected cofinal windows as a regular rational or Real-facing limit must first route those windows through the sibling* $\mathsf{NestedInterval}^{\uparrow}$ *and* $\mathsf{NestedIntervalCompleteness}^{\uparrow}$ *rows. In particular, the displayed route is*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto \mathsf{NestedInterval}^{\uparrow}, \mathsf{NestedIntervalCompleteness}^{\uparrow} \longmapsto R \longmapsto E.$$

The route consumes bounded monotone and dyadic window data before the $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seals are read, and it exports no interval-compactness theorem, selected endpoint, countable choice schedule, quotient stream, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorNestedIntervalObligation`

Proof. Begin with Definition 1408.20 and Definition 1408.21. They expose the finite selected-window route from B, M, Q to W and then to the dyadic tolerance ledger D.

Next read the sibling nested-interval surfaces. The nested interval chapter supplies the retained-window order row, while the nested interval completeness chapter packages the decreasing-window read before any regular rational name is available. The selector packet can therefore consume R only after the selected dyadic windows have been recognized as nested retained windows.

Finally apply Definition 1408.23. It places the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the Real seal behind the same selected-window route, while the bounded-window exhaustion and regular Cauchy cluster seal keep the consumer inside the displayed packet. Thus no hidden compactness, choice, quotient, host-equality, or ambient-completeness datum enters the selector obligation. □

Theorem 1388.23 (Bolzano–Weierstrass selector regular Cauchy limit handoff)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the Real-facing row* E *is available only after the selected dyadic windows have passed through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R *and the bounded monotone convergence seal route. The packet therefore hands a regular Cauchy limit boundary to* $\mathsf{Real}^{\uparrow}$*, not classical Bolzano–Weierstrass, a choice-selected subsequence, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRegularCauchyLimitHandoff`

Proof. Use Definition 1408.21 to expose B, M, Q, W, D as the only dyadic-window route. No Real-facing row is visible at this stage.

Read the regular handoff row R. By the carrier definition, R is attached to the selected dyadic windows and is preserved by the displayed hsame and Cont rows before the seal coordinate E can be consumed.

Finally apply Definition 1408.4. The bounded monotone Cauchy witness and bounded monotone convergence seal chapters place E behind the finite selector, stream, dyadic, and regular handoff route, so the exported object is a regular Cauchy limit boundary for the displayed packet rather than a compactness or completeness theorem. □

Theorem 1388.24 (Bolzano–Weierstrass selector cofinal window stability)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the inspected cofinal rows in* Q *remain tied to the displayed bounded source windows* B *and selected windows* W *under componentwise* hsame *transport and displayed* Cont *replay. A consumer may refine an inspected threshold only by replaying the same* B, M, Q, W *window route; it cannot replace the cofinal row by a choice-selected subsequence, an uninspected source window, or quotient-stream equality.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorCofinalWindowStability`

Proof. Project the carrier of Definition 1408.1. The cofinal row Q is stored beside the bounded source window row B, the monotone selector ledger M, and the selected $\mathsf{StreamName}^{\uparrow}$ windows W.

Apply Definition 1408.20. Its finite induction over B, M, Q, W makes every inspected threshold part of the displayed selector ledger rather than an external subsequence object.

Now use the dyadic-window and regular-Cauchy handoffs, Definition 1408.21 and Definition 1408.23. They keep each downstream read attached to the same selected windows before D, R, E, H, C, P, N are consumed. Thus hsame transport and Cont replay preserve the cofinal window boundary instead of adding a hidden selector. □

Theorem 1388.25 (Bolzano–Weierstrass selector Real seal finality)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the Real seal row* E *is terminal after the displayed route through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$*. Once* E *is read through that route, no further row may reinterpret the packet as full Bolzano–Weierstrass compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host real equality, or a choice-selected cluster point.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRealSealFinality`

Proof. Start with the bounded-monotone route of Definition 1408.4. It orders the Real-facing read through the monotone subsequence packet, the bounded monotone Cauchy witness, the convergence seal, the stream windows, the dyadic tolerance rows, the regular rational handoff, and finally the Real seal.

Use Definition 1408.23. The selected dyadic windows reach E only after the $\mathsf{RegSeqRat}^{\uparrow}$ row R and the bounded monotone convergence route have been displayed.

Finally apply Definition 1408.9. The carrier contains no coordinate after E for compactness, host equality, choice, quotient streams, or ambient completeness. The Real seal is therefore terminal for the finite L10 selector route. □

Theorem 1388.26 (Bolzano–Weierstrass selector bounded-window exhaustion)**.** *Every bounded-window consumer of an accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet must expose the rows*

$$B, M, Q, W, D, R, E, H, C, P, N$$

before it may read a selected-window, dyadic-window, regular-Cauchy, or Real-facing conclusion. The exposed rows exhaust the bounded-window surface: no consumer may cite a hidden subsequence object, an ambient compactness theorem, a least cluster selector, quotient-stream equality, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorBoundedWindowExhaustion`

Proof. Begin with Definition 1408.5. It already binds $B, M, Q, W, D, R, E, H, C, P, N$ as one displayed packet for every finite selected-window read.

Apply Definition 1408.20. The bounded source and selected-window surface is exhausted by the finite induction over B, M, Q, W.

Next use Definition 1408.21 and Definition 1408.23. These theorems force the downstream dyadic and regular-Cauchy reads through D and R before the Real seal E is visible.

The structural rows H, C, P, N transport, replay, source, and name the same carrier. Since the nonescape theorem Definition 1408.9 refuses all stronger endpoints, the displayed row family exhausts the bounded-window consumer surface. □

Falsifiable prediction: Every $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ Real-facing read factors through $\mathsf{MonotoneSubsequence}$ $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$, and $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ before the $\mathsf{Real}^{\uparrow}$ seal is visible.

Independence witness: monotonesubsequence, boundedmonotonecauchywitness, boundedmonotoneconvergenceseal, streamname, regseqrat, dyadicratcore, real: $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries bounded sequence windows, a monotone selector ledger, inspected-threshold cofinal evidence, selected stream windows, dyadic tolerance rows, a regular rational handoff, a Real seal boundary, transports, continuations, provenance, and local naming.

Theorem 1388.27 (Bolzano–Weierstrass selector scoped L10 kernel)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelecto}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the carrier, bounded-window exhaustion, monotone-subsequence route, nested-interval obligation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal finality depend only on* BHist*,* hsame*,* Cont*,* $\mathsf{ProbeBundle}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the* $\mathsf{Real}^{\uparrow}$ *seal rows displayed in the packet and its cited L10 siblings. No proof step requires a host compactness theorem, a choice-selected subsequence, quotient-stream equality, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorScopeClosure`

Proof. Project the carrier of Definition 1408.1. The rows $B, M, Q, W, D, R, E, H, C, P, N$ are finite BHist data, with componentwise hsame transport and displayed Cont replay as the only structural routes.

Apply the finite-window induction of Definition 1408.6. It binds the monotone-subsequence route to displayed selector entries and selected $\mathsf{StreamName}^{\uparrow}$ windows, not to an external selector functional.

Use the nested-interval obligation of Definition 1408.22. The retained-window route is consumed as sibling L10 data before any regular rational readback, so the proof remains inside the displayed finite window surface.

Finally apply the regular Cauchy limit handoff and Real seal finality, Definition 1408.23 and Definition 1408.25. They place the $\mathsf{RegSeqRat}^{\uparrow}$ row and the $\mathsf{Real}^{\uparrow}$ seal after $\mathsf{DyadicRatCore}^{\uparrow}$ and the selected $\mathsf{StreamName}^{\uparrow}$ windows. Since the nonescape theorem excludes compactness, choice, quotient, host equality, and ambient completeness rows, the stated L10 kernel scope is closed. □

Theorem 1388.28 (Bolzano–Weierstrass selector public export)**.** *An accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet exports exactly the finite handoff from bounded sequence windows through monotone-subsequence*

selection, bounded monotone Cauchy witness, bounded monotone convergence seal, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal rows. The exported public surface is the row family*

$$B, M, Q, W, D, R, E, H, C, P, N,$$

read in that dependency order and no stronger order. It does not claim sequential compactness, countable choice, quotient-stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorPublicExport`

Proof. Begin with the selector handoff of Definition 1408.2 and the real seal boundary of Definition 1408.3. These place the selected subsequence surface and the Real-facing seal behind displayed packet rows rather than behind a compactness theorem.

Next apply the bounded-monotone route, finite-window stabilization, and regular Cauchy cluster seal through Definition 1408.4, Definition 1408.6, and Definition 1408.23. The route forces the monotone-subsequence selection, bounded monotone Cauchy witness, bounded monotone convergence seal, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff to appear before E can be consumed.

Finally use the scoped L10 kernel theorem, Definition 1408.27. It exhausts the public export by $B, M, Q, W, D, R, E, H, C, P, N$ and refuses any hidden compactness, choice, quotient, host-equality, or ambient-completeness row. □

Closure status for $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ packet is generated from bounded source windows, a monotone selector ledger, inspected-threshold cofinal evidence, selected StreamName windows, DyadicRatCore tolerance rows, a RegSeqRat handoff, a RealUp seal boundary, componentwise transports, displayed continuations, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassSelector}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1408.1, Definition 1408.2, Definition 1408.3, Definition 1408.4, Definition 1408.5, Definition 1408.6, Definition 1408.22, Definition 1408.23, Definition 1408.26, Definition 1408.27, and Definition 1408.28 bind the carrier, subsequence handoff, Real seal boundary, bounded-monotone route, window obligation, finite-window induction, nested-interval obligation, regular Cauchy limit handoff, bounded-window exhaustion, scoped L10 kernel, and public finite handoff surfaces.

Not claimed: This chapter does not claim full Bolzano-Weierstrass, sequential compactness, choice-selected subsequences, quotient-stream equality, host real equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite selector stability, inspected-threshold cofinal coverage, selected-window RegSeqRat handoff, bounded monotone witness routing, and Real seal boundary non-escape for BEDC.Derived.BolzanoWeierstrassSelectorUp.

Chapter 1389

A Concrete Naming Certificate for $\mathsf{RationalDensityReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RationalDensityReal}^{\uparrow}$ packet records the finite rational-witness interface for displayed $\mathsf{Real}^{\uparrow}$ intervals. It sits after the Real seal of chapter 38, the regular-rational readback of chapter 301, the finite stream windows of chapter 126, and the dyadic tolerance arithmetic of chapter 291. It routes located interval data through the rational interval surface of chapter 354 and the apartness-gap boundary of chapter 304, without reading a host real order.

Definition 1389.1 (RationalDensityReal carrier)**.** *A* $\mathsf{RationalDensityReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, U, W_L, W_U, A, I, Q, T, R, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the lower and upper endpoint names, each carrying a* $\mathsf{Real}^{\uparrow}$ *seal row and a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*
2. *W_L and W_U are the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected from the two endpoint names.*
3. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *positive-gap row displayed between the endpoint seals.*
4. *I is the* $\mathsf{RationalInterval}^{\uparrow}$ *row whose rational bounds are read from the inspected endpoint windows.*
5. *Q is the visible* $\mathsf{Rat}^{\uparrow}$ *witness row selected between the displayed rational interval bounds.*
6. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row certifying that the inspected endpoint windows and the rational witness are read at one dyadic scale.*
7. *R is the dyadic radius row that records the positive subinterval around Q still contained in the displayed interval.*
8. *H stores componentwise* hsame *transports for the endpoint, window, apartness, interval, witness, tolerance, and radius rows.*
9. *C stores the* Cont *replay from endpoint windows to the rational interval row, from the rational interval row to the witness row, and from the witness row to the radius row.*
10. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalDensityReal}^\uparrow}$ *row.*

The carrier stores a displayed rational witness for a displayed interval. It has no host order coordinate, no trichotomy row, no quotient equality of real names, no completeness principle, no Heine–Borel cover row, and no hidden choice selector.

Theorem 1389.2 (RationalDensityReal NameCert obligation surface)**.** *For an accepted* $\mathsf{RationalDensityReal}^\uparrow$ *carrier* $D = (L, U, W_L, W_U, A, I, Q, T, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RationalDensityReal}^\uparrow}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed endpoint, window, apartness, rational-interval, witness, tolerance, radius, transport, continuation, provenance, and naming rows;*
2. *classifier transport along the stored* hsame *rows and the displayed* Cont *routes;*
3. *witness visibility, stating that the* $\mathsf{Rat}^\uparrow$ *row Q is exposed before any consumer reads the radius row R;*
4. $\mathsf{Real}^\uparrow$ *seal nonescape, stating that endpoint seals are consumed only through the stored* $\mathsf{RegSeqRat}^\uparrow$ *readbacks and* $\mathsf{StreamName}^\uparrow$ *windows;*
5. *ledger exactness, stating that the packet exports no host real order, trichotomy, quotient equality, completeness theorem, Heine–Borel cover, or hidden selector.*

Lean4 ✓ `BEDC.Derived.RationalDensityRealUp.RationalDensityRealTasteGate single carrier alignment`

Proof. Carrier admission is the tuple in Definition 1409.1. The endpoint names, stream windows, apartness row, rational interval row, witness row, dyadic tolerance, dyadic radius, transports, continuations, package row, and local naming row are all finite BHist coordinates.

Classifier transport reads H and C componentwise. The transported endpoint windows still feed the same rational-interval row shape, and the transported interval still exposes the same witness-and-radius sequence.

Witness visibility follows from the carrier order: the row Q is stored before the radius row R, and the continuation row records the replay from I to Q before replaying from Q to R.

The seal nonescape and ledger exactness are inventory checks. The endpoint seals occur only beside their regular-rational readbacks and finite windows, while host order, trichotomy, quotient equality, completeness, Heine–Borel data, and hidden selection are not rows of the packet. □

Theorem 1389.3 (RationalDensityReal located-window witness)**.** *Let L and U be displayed* $\mathsf{Real}^\uparrow$ *endpoint names with* $\mathsf{RegSeqRat}^\uparrow$ *readbacks, finite* $\mathsf{StreamName}^\uparrow$ *windows, and an* $\mathsf{ApartnessReal}^\uparrow$ *positive-gap row between them. If the inspected windows determine a displayed* $\mathsf{RationalInterval}^\uparrow$ *row whose dyadic tolerance is recorded by* $\mathsf{DyadicRatCore}^\uparrow$*, then an accepted* $\mathsf{RationalDensityReal}^\uparrow$ *packet exposes a visible* $\mathsf{Rat}^\uparrow$ *witness row inside that displayed interval. Every consumer route to the witness factors through*

$$(L, U) \longmapsto (W_L, W_U) \longmapsto A \longmapsto I \longmapsto Q$$

and through the dyadic tolerance and radius rows T, R; no step appeals to host real order, trichotomy, quotient equality, Real completeness, or Heine–Borel compactness.

Proof. Read the endpoint data through their displayed regular-rational rows. The finite stream windows W_L, W_U are the only observations used to form the rational interval row, so the route begins inside $\mathsf{RegSeqRat}^\uparrow$ and $\mathsf{StreamName}^\uparrow$.

The positive-gap row A makes the interval located at the displayed scale. The dyadic row T records that the endpoint windows and the rational interval bounds are compared inside $\mathsf{DyadicRatCore}^{\uparrow}$, not inside an ambient order on completed reals.

The rational witness is then the row Q of the carrier. The continuation path reads I before Q and records the radius row R only after Q is visible.

Thus the witness route is exactly the displayed chain through $\mathsf{RationalInterval}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$. Any route using host real order, trichotomy, quotient equality, Real completeness, or Heine–Borel compactness leaves the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalDensityReal}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalDensityReal}^{\uparrow}$ packet is generated from two displayed RealUp endpoint names, their RegSeqRat readbacks, finite StreamName windows, an ApartnessReal positive-gap row, a RationalInterval row, a visible Rat witness, dyadic tolerance and radius rows, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalDensityReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1409.1, Definition 1409.2, and Definition 1409.3 declare the finite rational-witness surface for displayed RealUp intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalDensityReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, trichotomy, quotient equality of real names, host real order, Heine–Borel compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, witness visibility, seal nonescape, and ledger exactness for the same finite packet.

Chapter 1390

A Concrete Naming Certificate for $\mathsf{CauchySequenceEquivalence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ packet records the concrete equivalence relation on regular Cauchy names as finite BEDC data. It sits between the regular rational name surface of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. The equivalence packet is downstream of chapter 3413 because the regular-name comparison only exists after the Cauchy source windows have been licensed. The packet compares two regular Cauchy names through displayed finite windows and tolerances before any real-seal consumer can read the result.

Definition 1390.1 (CauchySequenceEquivalence carrier surface)**.** *A* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, S, T, D, E, R, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name rows;*
2. *S and T are the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which X and Y are observed;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the paired windows;*
4. *E is the local finite equivalence classifier recording that every scheduled paired observation is within the displayed dyadic tolerance;*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal-comparison row that may be consumed only after X, Y, S, T, D, E have been displayed;*
6. *H is the componentwise* hsame *provenance for the two regular names, the paired stream windows, the dyadic ledger, the classifier, and the seal-comparison row;*
7. *C is the displayed* Cont *route by which a consumer replays those finite windows without adding host data;*
8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$ *row.*

The carrier exposes no quotient stream, selected limit, host real equality, countable-choice row, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceTasteGate single carrier alignment`

Theorem 1390.2 (CauchySequenceEquivalence NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$ *obligation surface consists exactly of the finite rows in Definition 1412.1. Carrier admission requires two displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *names, paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a local finite equivalence classifier, a* $\mathsf{Real}^{\uparrow}$ *seal-comparison row, componentwise* hsame *provenance, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Classifier stability is tested only by the paired finite windows and the stored dyadic ledger. Transport preserves the same rows through H and C. Tolerance exactness says that every accepted comparison reads exactly the dyadic ledger D. Ledger visibility says that every consumer can inspect $X, Y, S, T, D, E, R, H, C, P, N$ and no other equality source.*

Lean4 ✓ `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceCarrier namecert obligations`
Lean4 ✓ `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceNamecertObligations`

Theorem 1390.3 (CauchySequenceEquivalence RegSeqRat Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal comparison routed through an accepted* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *packet factors through the displayed sequence*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, a consumer first reads the two regular Cauchy name rows X, Y, then the paired finite stream windows S, T, then the dyadic tolerance ledger D and finite classifier E, and only then reaches the seal-comparison row R. The packet supplies no quotient stream, selected limit, host real equality, countable choice, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceCarrier regseqrat real handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ packet is generated from two displayed $\mathsf{RegSeqRat}^{\uparrow}$ regular Cauchy names, paired $\mathsf{StreamName}^{\uparrow}$ finite windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a finite equivalence classifier, a $\mathsf{Real}^{\uparrow}$ seal-comparison row, displayed hsame provenance, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1412.1, Definition 1412.2, and Definition 1412.3 display the bridge to the public finite handoff over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceCarrier\_regseqrat\_real\_handoff`

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient-stream equality, selected host limits, countable choice, host real equality, or a standard bridge.

Upgrade path: Bridge checking requires a standard bridge theorem for the displayed RegSeqRat and Real handoff surface.

Chapter 1391

A Concrete Naming Certificate for $\mathsf{BoundedRealSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BoundedRealSequence}^{\uparrow}$ packet records a bounded real sequence by finite stream-window rows, regular rational readback, a real-name seal, and a displayed closed-bounded interval net. It sits before the subsequence compactness route of chapter 1254 and exposes the boundedness surface that chapter consumes. Its dependency surface is the $\mathsf{StreamName}^{\uparrow}$ window interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the interval-net bound row of chapter 1250. The packet is a finite certificate for bounded sequence inspection; it is not open-cover compactness, trichotomy of reals, host completeness, quotient equality of streams, or a choice-selected subsequence.

Definition 1391.1 (Bounded real sequence carrier)**.** *A* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, Q, R, I, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source schedule of sequence indices under inspection.*
2. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows exposed for the inspected indices in S.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and their dyadic tolerance observations.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *sequence-name seal reached only after W and Q have been displayed.*
5. *I is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row carrying the interval net used to witness boundedness for the displayed sequence windows.*
6. *H stores componentwise* hsame *transport for the source schedule, stream windows, regular readback, real seal, interval-net bound, continuation, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from inspected indices to stream windows, from stream windows to regular readback, from regular readback to the real seal, and from the real seal to the interval-net bound assertion.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalN}$ $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *row.*

The bound row is displayed as the closed interval-net containment surface

$$I : \mathsf{ClosedBoundedIntervalNet}^{\uparrow},$$
$$\forall i \in S_{\text{shown}} \quad W_i \longmapsto Q_i \longmapsto R_i \in I.$$

Here S_{shown} denotes only the inspected finite index rows of the carrier. The classifier compares accepted packets only through $S, W, Q, R, I, H, C, P, N$ and has no coordinate for trichotomy, host real order completeness, quotient-stream equality, open-cover compactness, or a selected infinite subsequence.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceTasteGate single carrier alignment`

Theorem 1391.2 (Bounded real sequence NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier $B = (S, W, Q, R, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the nine displayed rows, finite source-window coverage through S and W, regular rational readback through Q, real-name sealing through R, closed-bounded interval-net containment through I, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.NameCertObligations.BoundedRealSequenceCarrier semantic name certificate`

Proof. Project the carrier of Definition 1415.1. The only sequence data available to the classifier are the inspected index schedule S, the corresponding $\mathsf{StreamName}^{\uparrow}$ windows W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and the downstream $\mathsf{Real}^{\uparrow}$ seal R.

Read the bound row next. The $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ packet I supplies the finite interval-net containment surface from chapter 1250; boundedness is therefore a displayed row tied to the inspected windows, not an ambient completeness or order-trichotomy principle.

Finally inspect the structural rows. The rows H, C, P, N transport, replay, source, and name only the displayed sequence-window, regular-readback, real-seal, and interval-net rows. Since no other coordinate is present in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 1391.3 (Bounded real sequence finite-window bound)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier preserves boundedness under finite window inspection: any displayed route from an inspected index to a* $\mathsf{Real}^{\uparrow}$ *sequence-name seal factors through*

$$S \longmapsto W \longmapsto Q \longmapsto R \longmapsto I$$

together with H, C, P, N. Thus a finite-window consumer can read the closed-bounded interval-net bound without importing trichotomy, host completeness, quotient-stream equality, open-cover compactness, or a selected subsequence.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceFiniteWindow bound`

Proof. Begin with an inspected index row in S. The continuation row C exposes its $\mathsf{StreamName}^{\uparrow}$ window in W, then the regular rational readback Q, and only then the $\mathsf{Real}^{\uparrow}$ seal R.

The bound row I is read after this route. It is the finite interval-net containment row supplied by chapter 1250, so the bound is attached to the displayed windows and readbacks rather than to a host-level set of all sequence values.

Transport through H and provenance through P preserve the same route, while N names it locally. Because the carrier has no coordinate for trichotomy, host completeness, quotient equality, open-cover compactness, or selected subsequences, finite-window boundedness cannot leave the displayed path. □

Theorem 1391.4 (Bounded real sequence Bolzano–Weierstrass handoff)**.** *The* BolzanoWeierstrass$^{\uparrow}$ *consumer of chapter 1254 reads a bounded sequence source from an accepted* BoundedRealSequence$^{\uparrow}$ *carrier only through the finite route*

$$S, W, Q, R, I, H, C, P, N.$$

Consequently the handoff supplies a reusable bounded real sequence certificate for the L10 real-completion route while leaving open-cover compactness, trichotomy, host completeness, quotient-stream equality, and choice-selected subsequences outside the exported surface.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceBolzanoWeierstrass handoff`

Proof. Use Definition 1415.3. It places every inspected sequence value on the route from S through W, Q, R to the interval-net bound row I.

Now read the BolzanoWeierstrass$^{\uparrow}$ carrier of chapter 1254. Its bounded sequence row is exactly the source surface needed before finite interval nets, regular Cauchy subsequence extraction, RegSeqRat readback, and the Real cluster seal can be consumed.

The structural rows H, C, P, N preserve the finite route across the handoff. Thus the downstream consumer receives a bounded real sequence certificate and receives no additional compactness, trichotomy, host completeness, quotient-stream equality, or arbitrary subsequence selection principle. □

Theorem 1391.5 (Bounded real sequence forward Bolzano route)**.** *Every* BolzanoWeierstrassRate$^{\uparrow}$ *consumer reading an accepted* BoundedRealSequence$^{\uparrow}$ *carrier must first pass through finite* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback, the* ClosedBoundedIntervalNet$^{\uparrow}$ *bound row, and the terminal* Real$^{\uparrow}$ *seal named by the source packet. Only after those rows are exposed may the consumer inspect the finite-window rate route of chapter 8827.*

Proof. Start with Definition 1415.4. It exposes the bounded source through $S, W, Q, R, I, H, C, P, N$ before any Bolzano–Weierstrass-facing consumer reads the sequence data.

The rate consumer narrows that same source route. Its finite windows are the StreamName$^{\uparrow}$ row W, its rational readback is Q, its boundedness witness is the ClosedBoundedIntervalNet$^{\uparrow}$ row I, and its terminal real-name data is the Real$^{\uparrow}$ seal row R.

Consequently the BolzanoWeierstrassRate$^{\uparrow}$ packet may inspect only the displayed finite source rows. It receives no selected subsequence, countable choice schedule, quotient stream equality, trichotomy decision, host compactness theorem, or ambient Real$^{\uparrow}$ completeness claim from the bounded-sequence source. □

Falsifiable prediction: Every BolzanoWeierstrass$^{\uparrow}$ bounded-source read factors through a BoundedRealSequence$^{\uparrow}$ route displaying finite stream windows, regular readback, a RealUp seal, and a closed-bounded interval-net row.

Independence witness: streamname, regseqrat, real, closedboundedintervalnet, bolzanoweierstrass: BoundedRealSequence$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite sequence schedule, stream windows, regular rational readback, real seals, interval-net boundedness, transport, continuation, provenance, and local naming.

Theorem 1391.6 (Bounded real sequence window envelope)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier exposes a bounded sequence to downstream consumers only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound ledger attached to those windows. In particular, any consumer that reads an inspected index must factor through the visible route*

$$S, W, Q, R, I, H, C, P, N$$

and cannot extract an infinite stream, quotient sequence equality, host supremum, open-cover compactness proof, or selected subsequence from the carrier.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceWindow envelope`

Proof. Project the carrier of Definition 1415.1. The inspected source schedule S and finite windows W are the only entry rows for sequence data, so no downstream read starts from an unbounded stream.

The bound is then read through the displayed route to I. The regular readback Q and real seal R connect each visible window to the closed-bounded interval-net row, while the dyadic ledger named by the sibling tolerance surface records the finite comparison data needed for the bound.

Rows H, C, P, N transport, replay, source, and name the same route. Since the absent rows are not part of the carrier, the envelope remains a finite-window and finite-ledger surface. □

Theorem 1391.7 (Bounded real sequence Bolzano–Weierstrass frontier)**.** *Any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$*-facing consumer that receives data from an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier receives only the bounded-window frontier*

$$S, W, Q, R, I, H, C, P, N.$$

The frontier supplies finite bounded real sequence inspection data before the Bolzano–Weierstrass route opens, but it does not provide a selected subsequence, a compactness principle, trichotomy, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceBolzano frontier`

Proof. Use the handoff route of Definition 1415.4. That theorem identifies the bounded sequence source read by the Bolzano–Weierstrass consumer with the same finite carrier rows.

The frontier is bounded because I is displayed after S, W, Q, R. Thus the consumer can inspect finite sequence windows, read them back through $\mathsf{RegSeqRat}^{\uparrow}$, and see the real-seal and interval-net bound rows before any compactness-facing construction is considered.

No selected subsequence or compactness proof is stored in those rows. The frontier therefore hands off bounded-window data only, leaving all choice, quotient, trichotomy, and completeness principles outside the exported surface. □

Theorem 1391.8 (Bounded real sequence RegSeqRat readback)**.** *For every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier, each* $\mathsf{RegSeqRat}^{\uparrow}$ *readback available to a consumer is routed through the same finite bound and real-seal rows:*

$$W \longmapsto Q \longmapsto R \longmapsto I.$$

Consequently a readback consumer cannot detach the regular rational data from the visible $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row, or the local structural rows* H, C, P, N.

Proof. Begin with an exposed window W_i for an inspected index. By the carrier definition, the matching regular rational readback is the corresponding component of Q rather than a host-level sequence object.

The readback continues to the real seal R_i and then to the interval-net bound row I. This is the same visible finite bound route used by Definition 1415.3.

The structural rows keep the readback inside the packet. Transport by H, replay by C, provenance by P, and naming by N prevent the regular rational data from escaping as a quotient stream, selected subsequence, compactness witness, or ambient real-completeness datum. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceRegSeqRat readback`

Theorem 1391.9 (Bounded real sequence located-bound handoff)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet whose interval-net row is read as located lower and upper real bounds factors through the* $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$ *route of chapter 2183 before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *consumer inspects it. The visible route is*

$$S, W, Q, R, I \longmapsto \mathsf{LocatedBoundedRealSequence}^{\uparrow} \longmapsto H, C, P, N.$$

Thus the closed-bounded interval-net row is narrowed to located lower and upper bound data before the Bolzano–Weierstrass handoff, without exporting compactness, trichotomy, quotient sequence equality, countable choice, or a selected subsequence.

Proof. Project an accepted carrier $B = (S, W, Q, R, I, H, C, P, N)$ from Definition 1415.1. The sequence source is displayed only through inspected indices S, stream windows W, regular rational readback Q, and the downstream $\mathsf{Real}^{\uparrow}$ seal R.

Use Definition 1415.3 and Definition 1415.8. They put every visible sequence value on the route from W through Q, R to the bound row I, so the lower and upper endpoint reads of I are tied to the same finite windows.

When I is read as located lower and upper real bounds, the narrower sibling route is exactly the $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$ packet of chapter 2183. The structural rows H, C, P, N preserve that route before Definition 1415.4 lets any $\mathsf{BolzanoWeierstrass}^{\uparrow}$ consumer inspect the bounded source. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.LocatedBoundHandoff.BoundedRealSequenceLocatedBound handoff`

Theorem 1391.10 (Bounded real sequence located-window choice boundary)**.** *Every* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or real-completion consumer reading an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier must obtain located lower and upper bound windows through the displayed route*

$$S, W, Q, R, I.$$

No such consumer may choose a subsequence, ambient bound, quotient sequence, or host completion witness outside the carrier before the stream windows, regular readback, real seal, and interval-net bound row have been displayed.

Proof. Begin with the finite-window bound of Definition 1415.3. It places each inspected sequence value on the route from S through W, Q, R to the interval-net bound row I.

Use the RegSeqRat readback and located-bound handoff, Definition 1415.8 and Definition 1415.9. They tie the located lower and upper endpoint reads of I to the same finite stream windows and regular rational rows.

Finally apply the obligation-closure package of Definition 1415.12. The package exports only $S, W, Q, R, I, H, C, P, N$, so Bolzano–Weierstrass and real-completion consumers cannot introduce an outside subsequence choice, ambient bound, quotient sequence, or host completion witness. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceLocatedWindowChoice`

Theorem 1391.11 (Bounded real sequence location induction)**.** *Let*

$$B = (S, W, Q, R, I, H, C, P, N)$$

be an accepted $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet whose located-bound row* I*,* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *finite-net row,* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal* R *are displayed. Then every inspected finite prefix admits induction over its window positions: the empty prefix preserves the same located bound row* I*, and each successor read factors through the same route*

$$S, W, Q, R, I, H, C, P, N$$

so the new visible value remains inside the same located interval and real-seal rows. The induction exports no subsequence selection, real trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $B = (S, W, Q, R, I, H, C, P, N)$. The inspected schedule S and stream windows W are finite, so induction is over the displayed prefix positions rather than over an infinite host stream.

For the empty prefix, read only the already displayed located-bound row I. No sequence value has been inspected, and the same $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ row remains the active bound.

For the successor step, use Definition 1415.3 and Definition 1415.8. The next window read goes through W to Q, then to the $\mathsf{Real}^{\uparrow}$ seal R, and then back to the same interval-net row I.

The located-bound handoff of Definition 1415.9 keeps the lower and upper endpoint reads attached to this route. Transport, replay, provenance, and naming through H, C, P, N preserve the induction invariant, and the carrier has no coordinate for the excluded subsequence, trichotomy, quotient-equality, or completeness principles. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier location induction`

Theorem 1391.12 (Bounded real sequence obligation-closure package)**.** *For every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier, the carrier row of Definition 1415.1, the NameCert obligation surface of Definition 1415.2, the finite-window bound of Definition 1415.3, the Bolzano–Weierstrass handoff of Definition 1415.4, the window envelope of Definition 1415.6, the Bolzano frontier of Definition 1415.7, the RegSeqRat readback of Definition 1415.8, and the located-window choice boundary of Definition 1415.10 assemble the obligationClosure surface over*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont,

The assembled package exports exactly the finite bounded-sequence route $S, W, Q, R, I, H, C, P, N$ *and keeps open-cover compactness, trichotomy, host completeness, quotient stream equality, and choice-selected subsequences outside the packet.*

Proof. Start with the carrier and NameCert obligations. The carrier definition lists the finite source schedule, stream windows, regular readback, real seal, closed-bounded interval-net row, and the structural rows. The obligation theorem identifies those rows as the complete local certificate

surface over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Next use the finite-window bound and handoff theorems. They place every inspected sequence value on the displayed route from S through W, Q, R to I, and they show that the $\mathsf{BolzanoWeierstrass}^{\uparrow}$ consumer reads the bounded source only through the same packet.

Finally add the envelope, frontier, and readback rows. These theorems keep downstream reads inside the visible route $S, W, Q, R, I, H, C, P, N$ and prevent the regular rational data from detaching from the bounded-window surface. Since none of the cited rows stores open-cover compactness, trichotomy, host completeness, quotient stream equality, or a choice-selected subsequence, the assembled obligation-closure package exports none of those claims. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.NameCertObligations.BoundedRealSequenceObligation closure package`

Theorem 1391.13 (Bounded real sequence carrier admission)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier*

$$B = (S, W, Q, R, I, H, C, P, N)$$

must expose inspected sequence indices S, finite $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q,* $\mathsf{Real}^{\uparrow}$ *sequence seals R, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row I, componentwise transport H, displayed replay C, package provenance P, and the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *row N before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or real-completion consumer can read the bounded source. The admitted surface exports no open-cover compactness, trichotomy, quotient stream equality, or choice-selected subsequence.*

Proof. Project the carrier of Definition 1415.1. Its displayed tuple is exactly $S, W, Q, R, I, H, C, P, N$, so carrier admission starts with inspected indices, finite windows, regular readback, real sequence seals, the interval-net bound row, and the structural rows.

Use the NameCert obligations of Definition 1415.2. They identify those displayed rows as the complete local certificate surface and prevent a consumer from reading a bounded source before the windows, readback, seal, bound, transport, replay, provenance, and naming rows have appeared.

Apply the finite-window bound and Bolzano–Weierstrass handoff, Definition 1415.3 and Definition 1415.4. The first ties each inspected value to the $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ bound row, and the second forces every $\mathsf{BolzanoWeierstrass}^{\uparrow}$ consumer to enter through the same bounded-source route.

Finally use the obligation-closure package of Definition 1415.12. Since that package contains no open-cover compactness, trichotomy, quotient stream equality, or choice-selected subsequence coordinate, the admitted carrier exports none of those objects to a Bolzano–Weierstrass or real-completion consumer. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceObligation carrier admission`

Definition 1391.14 (Bounded real sequence finite-window net)**.** *For an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier*

$$B = (S, W, Q, R, I, H, C, P, N),$$

the finite-window net packet is the displayed subroute

$$\mathcal{N}_B = (S, W, Q, R, I, H, C, P, N)$$

read as a closed-bounded interval-net source. Its entries are the inspected sequence schedule S, the synchronized $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the* $\mathsf{Real}^{\uparrow}$ *seal row R, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row I, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *row N. The packet has no coordinate for an infinite subnet, open-cover compactness, trichotomy, quotient sequence equality, countable choice, or a selected Bolzano–Weierstrass subsequence.*

Lean4 (definition) `BEDC.Derived.BoundedRealSequenceUp.FiniteWindowNet.BoundedRealSequenceFiniteWindowNet`

Theorem 1391.15 (Bounded real sequence finite-window net extraction)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier exposes the finite-window net packet of Definition 1415.14 before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or real-completion consumer reads the bounded source. In particular, every such consumer factors through*

$$S, W, Q, R, I, H, C, P, N$$

and receives the closed-bounded interval-net route before it can inspect compactness-facing or completion-facing data.

Proof. Project the accepted carrier and form the packet $\mathcal{N}_B$ from the same rows. The carrier definition supplies $S, W, Q, R, I, H, C, P, N$ in exactly the order needed to read inspected windows, regular readback, real seals, and the interval-net bound row.

Apply Definition 1415.3. It identifies the finite bound route from S through W, Q, R to I and keeps the route outside trichotomy, host completeness, quotient equality, open-cover compactness, and selected subsequences.

Apply Definition 1415.4. The Bolzano–Weierstrass consumer reads its bounded sequence source only through the same visible rows. The structural rows H, C, P, N then repack transport, replay, provenance, and local naming as the finite-window net packet. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier finite window net extraction`

Theorem 1391.16 (Bounded real sequence regular-readback stability)**.** *Let*

$$B = (S, W, Q, R, I, H, C, P, N)$$

and

$$B' = (S', W', Q', R', I', H', C', P', N')$$

be accepted $\mathsf{BoundedRealSequence}^{\uparrow}$ *carriers. If componentwise* hsame *transport identifies the source schedules, stream windows, regular readback rows, real seals, and interval-net bound rows S, W, Q, R, I with S', W', Q', R', I', then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the closed-bounded interval-net bound row are preserved. Thus the transported packet still exposes the same finite-window net route before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or real-completion consumer reads it.*

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier regular readback stability`

Proof. Project both carriers. The hypothesis says that the five analytic rows S, W, Q, R, I and S', W', Q', R', I' agree under the componentwise transport recorded by the H rows.

Use Definition 1415.8. The readback available to a consumer is attached to the visible route $W \mapsto Q \mapsto R \mapsto I$, so transporting W, Q, R, I preserves the regular rational readback and the bound row together.

Use Definition 1415.15 to repack the transported rows as the finite-window net packet. The remaining rows H, C, P, N and H', C', P', N' supply the transport, replay, provenance, and naming data, so no detached compactness, quotient, choice, trichotomy, or completeness coordinate is introduced. □

Theorem 1391.17 (Bounded real sequence dyadic-bound transport)**.** *Let*

$$B = (S, W, Q, R, I, H, C, P, N)$$

be an accepted $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier. Every boundedness read transported from* B *to a* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or completion-facing consumer factors through finite stream windows* S, W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal row* R*, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row* I*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *row.*

The transported read may carry dyadic lower and upper bound ledgers from the finite window, but it cannot add trichotomy, quotient sequence equality, countable choice, a choice-selected subsequence, open-cover compactness, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier dyadic bound transport`

Proof. Project the carrier and read the finite-window net packet of Definition 1415.14. The packet lists $S, W, Q, R, I, H, C, P, N$ as the complete boundedness route.

Apply Definition 1415.16. The $\mathsf{RegSeqRat}^{\uparrow}$ readback and interval-net bound row are stable under componentwise transport, so the transported boundedness row remains attached to the same finite stream windows.

Finally use Definition 1415.15. The Bolzano–Weierstrass or completion-facing consumer receives the closed-bounded interval-net source only after S, W, Q, R, I have been displayed, and the structural rows replay the same route without adding any excluded selector or completeness coordinate. □

Theorem 1391.18 (Bounded real sequence window factorization)**.** *For every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier, any consumer read of boundedness factors through a finite window prefix before it reaches the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *source. More precisely, the read first inspects the sequence schedule* S*, then the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, then the* $\mathsf{Real}^{\uparrow}$ *seal row* R*, and only then the interval-net bound row* I*.*

No consumer may bypass this route by asking for an infinite stream object, a quotient sequence equality, countable choice, a selected subsequence, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $B = (S, W, Q, R, I, H, C, P, N)$. The carrier makes the inspected schedule and finite stream windows available before any real readback or interval bound can be consumed.

Use Definition 1415.3. It identifies the bound route as a finite passage from S through W, Q, R into the closed-bounded interval-net row I.

The structural rows H, C, P, N then transport, replay, source, and name the same finite passage. Since the carrier has no infinite stream, quotient equality, choice, trichotomy, open-cover, selected-subsequence, or ambient-completeness coordinate, the displayed window factorization is exhaustive. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier window factorization`

Theorem 1391.19 (Bounded real sequence window localization)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet localizes each inspected finite* $\mathsf{StreamName}^{\uparrow}$ *window through the displayed* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *consumer may read the bounded source. More precisely, for*

$$B = (S, W, Q, R, I, H, C, P, N)$$

each inspected window in W is read through

$$S, W \longmapsto Q \longmapsto R \longmapsto I \longmapsto H, C, P, N.$$

The localization exports finite window bounds and regular readback only; it exports no host set of all sequence values, no choice-selected subsequence, no quotient stream equality, no open-cover compactness, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier window localization`

Proof. Project the carrier and use the finite-window net extraction of Definition 1415.15. That result displays $S, W, Q, R, I, H, C, P, N$ as the finite net packet a consumer must read before bounded-source data are available.

Apply regular-readback stability and dyadic-bound transport, Definition 1415.16 and Definition 1415.17. They keep the $\mathsf{RegSeqRat}^{\uparrow}$ row Q attached to the same stream window W, real seal R, and closed-bounded interval-net row I under componentwise transport.

Finally use the window factorization of Definition 1415.18. It forces every boundedness read to pass through the inspected finite window before reaching the interval-net row, so a Bolzano–Weierstrass consumer receives only the displayed local route and none of the excluded host-level data. □

Theorem 1391.20 (Bounded real sequence Bolzano source exactness)**.** *Every* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *source read from an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet is exactly the finite-window source*

$$S \to W \to Q \to R \to I \to H \to C \to P \to N.$$

Thus the Bolzano–Weierstrass consumer receives a bounded source only through finite stream windows, regular rational readback, the real-name seal, and the closed-bounded interval-net row; it receives no selected subsequence, no compactness theorem outside the displayed interval-net route, and no ambient real-completeness principle.

Proof. Read the accepted carrier and form the finite-window net packet. The rows S, W, Q, R, I display the source schedule, finite stream names, regular rational readback, real seal, and closed-bounded interval-net bound before the consumer is allowed to read the source.

Apply Definition 1415.4. That handoff sends Bolzano–Weierstrass consumers to the visible bounded source rather than to a choice-selected subsequence or host compactness theorem.

Use Definition 1415.17 to keep the dyadic bound ledger attached to the same source route under transport. The rows H, C, P, N replay, source, and name the handoff, so the source exactness statement has no remaining coordinate for excluded choice, quotient, compactness, trichotomy, or completeness principles. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier bolzano source exactness`
