Theorem 1391.21 (Bounded real sequence compact-interval subsequence boundary)**.** *Every Bolzano–Weierstrass or compact-interval consumer of an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet must read finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seals, and* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound rows before any subsequence-facing claim is visible. The packet exposes the finite route*

$$S \to W \to Q \to R \to I \to H \to C \to P \to N$$

and does not export a selected subsequence, open-cover compactness, quotient sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the finite-window bound of Definition 1415.3. It ties every inspected sequence value to the route from S through W, Q, R into the closed-bounded interval-net row I.

Apply the Bolzano–Weierstrass handoff and the window envelope, Definition 1415.4 and Definition 1415.6. They require a Bolzano-facing consumer to read the bounded source through the same finite window rows rather than through a selected subsequence or a host compactness principle.

Use Bolzano source exactness, Definition 1415.20. This identifies the visible source as the finite path through $S, W, Q, R, I, H, C, P, N$.

Finally apply finite-window net extraction, Definition 1415.15. The interval-net packet supplies the compact-interval-facing bound row while the structural rows transport, replay, source, and name the same route, leaving no coordinate for quotient equality, countable choice, open-cover compactness, selected subsequences, trichotomy, or ambient completeness. □

Theorem 1391.22 (Bounded real sequence bridge-facing route)**.** *The public bounded-source export for* BoundedRealSequence$^{\uparrow}$ *is bridge-facing exactly through the checked finite-window closure package and the Bolzano–Weierstrass source exactness route. A bridge consumer must first read Definition 1415.12 to expose the rows $S, W, Q, R, I, H, C, P, N$ and then read Definition 1415.20 before the bounded source can be handed to a standard bridge comparison. Thus the paper bridge surface is the finite-window route grounded by* BEDC.Derived.BoundedRealSequenceUp.NameCertObligations.BoundedRealSequence *not a selected subsequence, open-cover compactness proof, quotient stream equality, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Use the obligation closure package. It gathers carrier admission, finite-window bounds, regular readback, dyadic transport, window factorization, and source handoff into one checked NameCert surface.

Now apply the Bolzano source exactness theorem. It identifies the only public export as the finite route

$$S \to W \to Q \to R \to I \to H \to C \to P \to N.$$

A bridge comparison can therefore inspect exactly those displayed rows before reading the bounded source. Since neither cited route exposes selected subsequences, quotient stream equality, open-cover compactness, or ambient completeness, the bridge-facing paper surface is exhausted by the checked closure package and the Bolzano source exactness route. □

Closure status for NameCert$_{\text{BoundedRealSequence}^{\uparrow}}$**.**

Constructive story: A BoundedRealSequence$^{\uparrow}$ packet is generated from inspected sequence indices, finite StreamName windows, RegSeqRat readback, RealUp sequence-name seals, a ClosedBoundedIntervalNet bound row, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BoundedRealSequence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1415.1, Definition 1415.2, Definition 1415.12, Definition 1415.20, and Definition 1415.22 expose the finite-window bounded-sequence source as a bridge-facing route for Bolzano–Weierstrass consumers over StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, ClosedBoundedIntervalNet$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{BoundedRealSequence}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.BoundedRealSequenceUp.NameCertObligations.BoundedRealSequenceObligation\_closure\_packa`

Bridge status: none

Not claimed: This chapter does not close bridge checking, open-cover compactness, trichotomy, host completeness, quotient equality of streams, or choice-selected subsequences.

Upgrade path: A checked standard bridge would turn the bridge-facing finite-window route of Definition 1415.22 into bridgeChecked verification.

Chapter 1392

A Concrete Naming Certificate for $\mathsf{DecimalExpansion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DecimalExpansion}^{\uparrow}$ packet records finite decimal-prefix windows as BEDC readback data. It does not store a host infinite decimal, a quotient real, or a selected representative. Its role is to route base-ten digit observations through the finite stream surface of chapter 126, the regular rational readback surface of chapter 301, the dyadic and rational place-value ledgers of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38.

The chapter is the decimal sibling of chapter 418 and chapter 342. The shared discipline is finite-window readback: binary prefixes, continued-fraction convergents, and decimal prefixes all expose only displayed rows before a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can read the packet.

The same finite decimal-prefix windows also form a forward consumer of chapter 1809. A decimal window gives a countable dense readback route into $\mathsf{Real}^{\uparrow}$, while $\mathsf{RealSeparability}^{\uparrow}$ supplies the global countable-density ledger that later real-name consumers use to compare those finite routes.

Definition 1392.1 (DecimalExpansion carrier)**.** *A* $\mathsf{DecimalExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, V, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite digit ledger, whose rows record decimal digits and the associated sign or integral-prefix convention when the local packet includes one;*
2. *W is the finite decimal-place window ledger, listing the inspected positions and the request precision served by those positions;*
3. *V is the place-value row that evaluates each inspected prefix as a rational sum with denominator a power of ten;*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and rational comparison row that transports the base-ten place-value read into the dyadic tolerance discipline used by downstream real consumers;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from the same decimal window and place-value rows;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after D, W, V, Q, R have been displayed;*
7. *H is the componentwise* hsame *transport row for digit, window, place-value, dyadic/rational, regular-sequence, and real-seal coordinates;*

8. *C is the* Cont *replay row that reuses the accepted finite decimal windows without adding a host stream;*
9. *P is the* Pkg *provenance over* $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}$ *row.*

The carrier exposes no infinite decimal stream, Dedekind cut, quotient real, endpoint convention resolver, trichotomy decision, selected representative, or Real-completeness witness.

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.TasteGate.DecimalExpansionTasteGate single carrier alignment`

Theorem 1392.2 (DecimalExpansion digit-window obligations)**.** *Every real-facing read of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must consume the digit ledger D, finite window ledger W, place-value row V, dyadic comparison row Q,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row E in that order. The structural rows H, C, P, N transport, replay, source, and name only this displayed route, so no decimal consumer can read a real-facing value before the finite digit window and dyadic comparison have both been displayed.*

Proof. Project the carrier of Definition 1417.1. Its public real-facing coordinates appear as D, W, V, Q, R, E before the structural rows H, C, P, N.

The finite-window discipline is the same one used by the sibling routes of chapter 418, chapter 342, and chapter 126. A consumer first receives inspected digits and positions, not an infinite stream.

Apply the NameCert obligations of Definition 1417.3. Carrier admission and ledger exhaustion force every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer to inspect only displayed rows, with V and Q between the digit window and the regular-rational handoff.

Finally read the seal row E downstream of R. Since the carrier has no coordinate for a direct decimal stream, quotient real, selected representative, or completeness witness, the ordered digit-window route is the only real-facing decimal read exported by the packet. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDigitWindowObligations`

Theorem 1392.3 (DecimalExpansion NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}$ *obligation surface consists exactly of the rows in Definition 1417.1. Carrier admission requires a finite digit ledger, a finite decimal-place window ledger, a base-ten rational place-value row, a dyadic/rational comparison row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, a* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Classifier transport is componentwise through the same displayed rows. Ledger exhaustion says that every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer can inspect only $D, W, V, Q, R, E, H, C, P, N$.*

Proof. Carrier admission is read directly from the finite packet. The digit rows and decimal-place windows give the visible $\mathsf{StreamName}^{\uparrow}$ observation surface, while V evaluates each inspected prefix as a rational place-value sum.

The dyadic/rational row Q is the only bridge from base-ten arithmetic into the tolerance discipline already used by chapter 291. The regular handoff row R and real-seal row E are therefore downstream of the same inspected window.

Transport is componentwise because H has coordinates for each displayed row, and continuation only replays windows already accepted by C. The package and local naming rows record exactly those dependencies.

For ledger exhaustion, project a consumer read from the accepted packet. The definition gives only the ten coordinates $D, W, V, Q, R, E, H, C, P, N$, so any route through an infinite stream, quotient real, selected endpoint convention, or ambient completeness principle is outside the carrier. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionNameCertObligations`

Theorem 1392.4 (DecimalExpansion tail digit stability)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet*

$$K = (D, W, V, Q, R, E, H, C, P, N),$$

finite digit tails are stable under the displayed hsame *transport row H. A consumer that transports the accepted packet can compare tail digits only through the same finite digit ledger D, window ledger W, place-value row V, dyadic comparison row Q, regular handoff R, real seal E, replay row C, provenance row P, and local name row N.*

Proof. Project the obligation surface of Definition 1417.3. The only digit data are the displayed rows D and W, and every place-value or real-facing read is downstream of them.

The transport row H is componentwise through the same carrier coordinates. Therefore a transported tail cannot acquire a new infinite decimal stream or a new endpoint selector; it can only replay the displayed finite tail rows already present in $D, W, V, Q, R, E, C, P, N$. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionTailDigitStability`

Theorem 1392.5 (DecimalExpansion rational Real handoff)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet $K = (D, W, V, Q, R, E, H, C, P, N)$, the rational place-value row V must pass through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *and rational comparison row Q, then through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E is public. No consumer can read a real-valued decimal prefix directly from D, W, V.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRatRealHandoff`

Proof. Read the carrier order in Definition 1417.1. The rows list digit data, window data, place-value evaluation, dyadic/rational comparison, regular handoff, and real seal as D, W, V, Q, R, E.

Apply Definition 1417.3. Carrier admission and classifier transport preserve this order componentwise, and ledger exhaustion prevents any route from bypassing Q or R before reaching E. □

Theorem 1392.6 (DecimalExpansion nonescape)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet $K = (D, W, V, Q, R, E, H, C, P, N)$ exports exactly the finite decimal-prefix, dyadic comparison, regular handoff, real seal, transport, replay, provenance, and naming rows listed in Definition 1417.1. It exports no infinite decimal, quotient real, endpoint selector, host trichotomy row, selected representative, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionNonescape`

Proof. Use ledger exhaustion from Definition 1417.3. The accepted packet has exactly the coordinates $D, W, V, Q, R, E, H, C, P, N$, so every public read is a projection or replay of those rows.

The excluded objects would require a coordinate outside the displayed carrier: an infinite digit stream, a quotient real, a selector for endpoints, a trichotomy decision, a selected representative, or a completeness witness. Since no such coordinate is present, no accepted consumer can recover it from the packet. □

Theorem 1392.7 (DecimalExpansion RealUp readback boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DecimalExpansion}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first reads an inspected decimal-place window, then the digit rows on that window, then the rational place-value and dyadic tolerance rows, then the regular rational handoff, and only then the displayed real seal. The packet supplies no Dedekind cut, quotient real, endpoint uniqueness convention, trichotomy principle, selected representative, or Real-completeness witness.

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealReadbackBoundary`

Proof. Start with an accepted carrier $K = (D, W, V, Q, R, E, H, C, P, N)$. The $\mathsf{StreamName}^{\uparrow}$ observation is W together with the digit rows of D on that window, so a real-facing consumer cannot read a decimal prefix without first reading the finite window.

The place-value row V turns that same finite prefix into a rational base-ten sum. The row Q records the dyadic and rational comparison data used to pass from the decimal sum to the tolerance language consumed by $\mathsf{RegSeqRat}^{\uparrow}$.

The handoff row R is therefore reached only after D, W, V, Q are fixed. The seal row E is listed after R, and the rows H, C, P, N preserve the same dependency route under transport, continuation, provenance, and local naming.

Thus every $\mathsf{Real}^{\uparrow}$ read factors through the displayed finite route. The excluded objects are not carrier coordinates, so no consumer of the packet can obtain them from this readback boundary. □

Theorem 1392.8 (DecimalExpansion RegSeqRat handoff)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet routes finite decimal digit rows through rational place-value rows and dyadic comparison rows before reaching the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route is exhausted by the displayed coordinates*

$$D, W, V, Q, R, E, H, C, P, N$$

of Definition 1417.1. In particular, the packet exports no quotient real, endpoint representative, trichotomy row, selected decimal stream, or $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRegSeqRatHandoff`

Proof. Project the carrier of Definition 1417.1. The finite digit ledger D is read together with the finite decimal-place windows W, and the place-value row V evaluates exactly those inspected prefixes as rational base-ten sums.

Apply the NameCert obligations of Definition 1417.3. Carrier admission and classifier transport keep D, W, V attached to the same dyadic and rational comparison row Q, while ledger exhaustion prevents a consumer from bypassing the displayed handoff surface.

Finally apply the RealUp readback boundary of Definition 1417.7. The regular handoff row R is reached only after the digit, window, place-value, and dyadic rows are displayed, and the terminal seal row E remains downstream of R with the structural rows H, C, P, N preserving the same route. □

Theorem 1392.9 (DecimalExpansion window normalization obligation)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must display the finite digit ledger D and finite window ledger W before any place-value, dyadic-comparison, regular-rational, or real-seal row can be read. Equivalently, every public read of V, Q, R, E factors through the finite decimal-prefix surface named in Definition 1417.1 and constrained by Definition 1417.3.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionWindowNormalizationObligation`

Proof. Project the carrier of Definition 1417.1. The rows are ordered as $D, W, V, Q, R, E, H, C, P, N$, so digit admission and inspected-window admission are the visible source rows for the packet.

Apply the NameCert obligations of Definition 1417.3. Carrier admission and ledger exhaustion require every consumer to read only displayed coordinates, hence no consumer can reach V, Q, R, E without first reading D and W.

The L10 sibling route is the same finite-window route already used by chapter 126, chapter 301, and chapter 38. Thus window normalization is a finite ledger obligation, not an infinite decimal-stream selection. □

Theorem 1392.10 (DecimalExpansion prefix stability)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, finite decimal prefixes are stable under* $\mathsf{StreamName}^{\uparrow}$ *window refinement and componentwise* hsame *transport. If a consumer refines the inspected window* W *without changing the displayed prefix rows in* D*, then the place-value row* V*, the dyadic tolerance row* Q*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *remain attached to the same prefix route before any downstream read is exposed.*

Proof. Begin with the carrier of Definition 1417.1. The digit ledger D and window ledger W are the only source rows from which a finite decimal prefix can be read.

Use the window normalization obligation of Definition 1417.9. It forces every public read of V, Q, R, E to pass through the displayed D, W prefix surface, so a window refinement that preserves the displayed prefix rows cannot change the downstream route.

The $\mathsf{StreamName}^{\uparrow}$ sibling of chapter 126 supplies the finite-window discipline, and the structural row H transports the same prefix componentwise through hsame. The dyadic and regular-rational consumers of chapter 291 and chapter 301 therefore receive the same place-value and tolerance route before the $\mathsf{Real}^{\uparrow}$ seal of chapter 38 is read. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionPrefixStability`

Theorem 1392.11 (DecimalExpansion dyadic comparison handoff)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet, the place-value row* V *reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff only through the comparison row* Q *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and rational comparison surface. No direct route from a decimal place-value sum to* R *or* E *is exported by the packet.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDyadicComparisonHandoff`

Proof. Read Definition 1417.1. The row V records the base-ten rational place-value sum, while Q is the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ and rational comparison row.

Apply Definition 1417.3. The obligation surface places Q between place-value evaluation and the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and classifier transport is componentwise through that same displayed row.

Finally apply Definition 1417.8. It states that finite digit rows pass through rational place-value rows and dyadic comparison rows before reaching R and the terminal seal E. The dyadic handoff therefore uses the existing routes of chapter 291 and chapter 301, with no bypass from V to R. □

Theorem 1392.12 (DecimalExpansion dyadic rational readback)**.** *Every finite decimal prefix admitted by an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet is read through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *before any* $\mathsf{Real}^{\uparrow}$ *seal is public. Concretely, the prefix rows* D, W *first determine the rational place-value row* V*, the dyadic and rational comparison row* Q *then supplies the finite*

tolerance comparison, and only then may the regular rational handoff R and terminal seal E be consumed.

Proof. Project the carrier of Definition 1417.1. The packet orders the rows as $D, W, V, Q, R, E, H, C, P, N$, so decimal digits and inspected windows are read before place values, dyadic tolerance, regular readback, and the real seal.

Apply prefix stability, Definition 1417.10. It keeps the finite prefix route fixed under $\mathsf{StreamName}^{\uparrow}$ window refinement and hsame transport, which is the only way a downstream consumer can compare refined windows.

Now use the dyadic comparison handoff of Definition 1417.11. The row Q is the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ and rational comparison route, so the $\mathsf{RegSeqRat}^{\uparrow}$ handoff of chapter 301 cannot be reached directly from V.

The terminal real read is the seal discipline of chapter 38, and the decimal normal-form consumer of chapter 3952 reads only after this finite dyadic and regular-rational route has been displayed. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDyadicRationalReadback`

Theorem 1392.13 (DecimalExpansion RealSeparability density route)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, the finite decimal prefix route contributes to the RealSeparability-facing density surface only through displayed countable dense readback along*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff cited by chapter 1809 reads $D, W, V, Q, R, E, H, C, P, N$ as finite prefix, dyadic comparison, regular-rational, seal, transport, replay, provenance, and naming rows. It exports no quotient real, selected endpoint convention, trichotomy row, or $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealSeparabilityDensityRoute`

Proof. Project the carrier of Definition 1417.1. The digit row D and window row W provide the only prefix data, while V, Q, R, E place that prefix into rational place value, dyadic tolerance, regular rational readback, and the terminal real seal.

Apply Definition 1417.12. The theorem forces the readback route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ before E is exposed, so the density consumer can only see a displayed finite route.

Finally read the RealSeparability sibling of chapter 1809. Its countable dense surface consumes finite readback data; the decimal packet supplies that surface through $D, W, V, Q, R, E, H, C, P, N$ and has no coordinate for quotient reals, selected endpoints, trichotomy, or real completeness. □

Theorem 1392.14 (DecimalExpansion countable dense consumer handoff)**.** *Every countable dense consumer that reads an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$ *must first pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *window W, the digit ledger D, the place-value row V, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row Q, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The consumer handoff to chapter 1809 is therefore a displayed dense readback route, not a decimal stream selector, quotient-real representative, endpoint convention, trichotomy decision, or completeness witness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionCountableDenseConsumerHandoff`

Proof. Use Definition 1417.13. It identifies the only RealSeparability-facing route exported by the packet as the finite path through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The structural rows then keep that route componentwise. Transport by H, replay by C, provenance by P, and the local name N certify the same displayed rows without inserting an ambient sequence selector or quotient-real comparison.

Thus a countable dense consumer receives exactly the finite prefix readback route already present in D, W, V, Q, R, E. Since the carrier has no selected decimal stream, endpoint convention, trichotomy, or completeness coordinate, none can be exported by the handoff. □

Theorem 1392.15 (DecimalExpansion prefix density exhaustion)**.** *For an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, all RealSeparability-facing density reads are exhausted by finite decimal prefixes and their displayed readback through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Once* $D, W, V, Q, R, E, H, C, P, N$ *have been read, the packet has no remaining row from which to choose a quotient real, select an endpoint convention, decide trichotomy, or assert a* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionPrefixDensityExhaustion`

Proof. Begin with the countable dense consumer handoff of Definition 1417.14. It routes every density consumer through the finite prefix ledger and the dyadic, regular-rational, and real-seal rows.

Apply the excluded-coordinate clause of Definition 1417.1. The packet lists only $D, W, V, Q, R, E, H, C, P, N$, so there is no extra coordinate after the terminal seal and structural rows have been consumed.

The RealSeparability reference in chapter 1809 therefore receives a countable dense readback route from finite decimal prefixes. It does not receive quotient real equality, selected endpoint data, trichotomy, or a completeness row from $\mathsf{DecimalExpansion}^{\uparrow}$. □

Theorem 1392.16 (DecimalExpansion dyadic normalization lock)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet passes through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *digit-place tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row before any real-facing decimal value is consumed. In particular, the digit-place route is the same L10 sibling lattice exposed by chapter 291, chapter 301, chapter 126, and chapter 38; the packet exports no direct decimal-to-real shortcut.*

Proof. Project the carrier of Definition 1417.1. The digit rows D and finite decimal windows W feed the place-value row V, while the comparison row Q is the only displayed dyadic and rational tolerance route.

Apply Definition 1417.11. It places Q between every place-value read and the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, so the decimal packet cannot jump from V directly to the seal row.

Finally apply Definition 1417.7. The terminal real read is reached only after finite windows, digit rows, dyadic tolerance, and regular rational readback have been displayed. This locks the decimal route to the dyadic, regular-Cauchy, stream-window, and real-seal sibling lattice named in the statement. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDyadicNormalizationLock`

Theorem 1392.17 (DecimalExpansion Real seal nonescape)**.** *The terminal row* E *of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet exports only the displayed* $\mathsf{Real}^{\uparrow}$ *seal reached from* D, W, V, Q, R*. It exports no quotient real equality, endpoint resolver, trichotomy decision, selected digit stream, selected decimal stream, countable-choice selector, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with the real readback boundary of Definition 1417.7. Every $\mathsf{Real}^{\uparrow}$ read factors through the finite route from $\mathsf{StreamName}^{\uparrow}$ windows to decimal place value, dyadic comparison, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and then the seal row E.

Use Definition 1417.12 to keep the route through Q and R. The seal is downstream of the dyadic, rational, and regular-rational rows, so it cannot introduce an endpoint resolver, trichotomy row, selected digit stream, selected decimal stream, or countable-choice selector that is not already present in the carrier.

Finally project the excluded-coordinate clause of Definition 1417.1. Since quotient reals, endpoint convention resolvers, trichotomy decisions, selected representatives, selected decimal streams, and completeness witnesses are absent from the displayed packet, none escapes through E. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealSealNonescape`

Theorem 1392.18 (DecimalExpansion Real seal factorization)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet whose terminal row is read as a* $\mathsf{Real}^{\uparrow}$ *seal factors through finite decimal windows, dyadic comparison, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the* $\mathsf{RealSeparability}^{\uparrow}$ *countable-density route. Concretely, the seal read begins with the digit and window rows D, W, evaluates those rows through the decimal place-value row V, passes through the dyadic and rational comparison row Q, reaches the regular rational row R, and only then exposes the terminal seal E. The same finite decimal windows supply the countable dense readback interface named by chapter 1809; no direct decimal stream, quotient real, selected representative, or completeness witness is exported by the seal.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealSealFactorization`

Proof. Start with the dyadic normalization lock of Definition 1417.16. It forces every real-facing decimal value to pass through the digit-place tolerance ledger, finite window row, regular rational readback row, and terminal seal.

Apply the Real seal nonescape theorem Definition 1417.17. The terminal row E cannot add a quotient real, selected decimal stream, endpoint resolver, or completeness witness after the finite route has reached it.

Finally use the countable-density role of $\mathsf{RealSeparability}^{\uparrow}$ described in the chapter introduction. The same finite decimal-prefix windows that feed D, W, V, Q, R, E are the windows counted by the RealSeparability route, so the factorization records a finite dense readback path rather than a direct decimal-to-real shortcut. □

Theorem 1392.19 (DecimalExpansion digit-carry determinacy)**.** *Let*

$$K = (D, W, V, Q, R, E, H, C, P, N) \quad \text{and} \quad K' = (D', W', V', Q', R', E', H', C', P', N')$$

be accepted $\mathsf{DecimalExpansion}^{\uparrow}$ *packets. If K and K' display the same finite digit window and the same dyadic place-value ledger before their terminal seals are read, then they expose the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route before the* $\mathsf{Real}^{\uparrow}$ *seal. Carry normalization is confined to the finite window ledger: it may rewrite the displayed digit and place-value rows inside D, W, V, Q, but it cannot introduce a second regular-rational route, a direct decimal-to-real shortcut, a quotient real, a selected representative, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with window normalization, Definition 1417.9. It forces both packets to display their finite digit ledgers and finite window ledgers before V, Q, R, E can be read, so the shared window fixes the source surface for any carry operation.

Use the dyadic comparison handoff, Definition 1417.11. The shared dyadic place-value ledger places both packets on the same comparison row before either packet reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

Next apply the dyadic normalization lock, Definition 1417.16. It prevents carry normalization from bypassing the dyadic and regular-rational route; the normalized digit rows remain confined to the finite window and comparison ledgers.

Finally use Real seal factorization, Definition 1417.18. The terminal seal is downstream of D, W, V, Q, R, so equality of the displayed window and dyadic place-value ledger determines the readback route before E is exposed. Since the carrier has no quotient-real, selected-representative, direct decimal-stream, or completeness coordinate, carry normalization exports no additional route beyond the finite ledger. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDigitCarryDeterminacy`

Theorem 1392.20 (DecimalExpansion separability density obligation)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet supplies its* $\mathsf{RealSeparability}^{\uparrow}$ *density reads only through finite decimal-prefix windows. More precisely, a density-window consumer must read the digit ledger D, the decimal-place window ledger W, the place-value row V, the dyadic comparison row Q, the regular rational handoff R, the terminal real seal E, and then the structural rows H, C, P, N of Definition 1417.1; no dense route is exported from an infinite decimal stream, a quotient real, or a selected representative.*

Proof. Project the carrier of Definition 1417.1. The only rows that can feed a density read are the displayed finite prefix rows D, W, V, Q, R, E together with the structural rows H, C, P, N.

Apply the NameCert obligations of Definition 1417.3. Ledger exhaustion restricts every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumer to the same finite coordinates, so a density-window consumer cannot introduce an ambient decimal stream.

Use the Real seal factorization of Definition 1417.18. The finite decimal windows that feed the seal are exactly the windows named by the RealSeparability sibling route in chapter 1809. Thus separability density is reached by finite BEDC readback rather than by a selected decimal representative. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionSeparabilityDensityObligation`

Theorem 1392.21 (DecimalExpansion digit ledger injection)**.** *The digit ledger of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet injects into finite* $\mathsf{StreamName}^{\uparrow}$ *windows before any dyadic comparison is read. Concretely, every use of the comparison row Q must first display the same finite digit and window rows D, W and the place-value row V that determine the inspected decimal prefix.*

Proof. Read the window normalization obligation of Definition 1417.9. It forces every public read of V, Q, R, E to pass through the finite digit ledger D and window ledger W.

The $\mathsf{StreamName}^{\uparrow}$ role is therefore fixed before dyadic comparison begins. The inspected decimal prefix is a finite windowed row, not a host stream, and V evaluates only that displayed prefix as a rational place-value sum.

Apply the dyadic comparison handoff of Definition 1417.11. Since Q is the only displayed route from place value to the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, each dyadic comparison read carries the prior D, W, V injection into finite StreamName windows with it. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDigitLedgerInjection`

Theorem 1392.22 (DecimalExpansion finite prefix completeness)**.** *Every finite-prefix consumer of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet is exhausted by the rows*

$$D, W, V, Q, R, E, H, C, P, N.$$

In particular, a consumer that requests decimal digits, finite stream windows, dyadic comparison, regular rational readback, real sealing, transport, replay, provenance, or local naming finds all available data inside those ten rows and no additional prefix-completion coordinate.

Proof. Start from the carrier definition. The packet is exactly the finite tuple $K = (D, W, V, Q, R, E, H, C, P, N)$, and the excluded-coordinate clause removes infinite streams, Dedekind cuts, quotient reals, endpoint resolvers, trichotomy decisions, selected representatives, and completeness witnesses.

Apply the NameCert obligations of Definition 1417.3. Carrier admission and classifier transport are componentwise through the same ten rows, while ledger exhaustion lets consumers inspect only those displayed coordinates.

Finally combine the Real readback boundary of Definition 1417.7 with the dyadic normalization lock of Definition 1417.16. Every real-facing finite-prefix read moves through digit windows, dyadic tolerance, regular rational readback, and the terminal seal before structural replay and naming, so $D, W, V, Q, R, E, H, C, P, N$ exhaust the prefix-completeness surface. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionFinitePrefixCompleteness`

Theorem 1392.23 (DecimalExpansion endpoint-normalization handoff)**.** *Every endpoint-sensitive decimal consumer of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must pass the rows*

$$D, W, V, Q, R, E$$

through $\mathsf{DecimalEndpointNormalization}^{\uparrow}$ *before any* $\mathsf{RealDecimalNormalForm}^{\uparrow}$ *consumer reads the normalized prefix. The handoff exports only the finite digit ledger, decimal window, place-value row, dyadic comparison, regular rational handoff, and terminal Real seal already displayed by the packet; it exports no repeating-nine endpoint convention, quotient real, selected stream, or Real completeness witness.*

Proof. Start from the finite prefix completeness theorem Definition 1417.22. It exhausts every prefix-sensitive read by $D, W, V, Q, R, E, H, C, P, N$ and leaves no additional endpoint coordinate in the $\mathsf{DecimalExpansion}^{\uparrow}$ packet.

Use the window normalization obligation Definition 1417.9. It forces each public read of place values, dyadic comparisons, regular handoffs, and Real seals to pass through the finite digit and window rows D, W.

Apply the dyadic comparison handoff of Definition 1417.11. The comparison row Q is the only displayed passage from place-value data in V toward the regular rational row R and the seal E.

The endpoint-sensitive part is therefore delegated to chapter 1429. Only after that finite endpoint-normalization surface has acted on the same D, W, V, Q, R, E route may the canonical readback surface of chapter 3952 read the normalized prefix. The excluded endpoint convention, quotient real, selected stream, and completeness witness are absent from the DecimalExpansion carrier and cannot be supplied by this handoff. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionEndpointNormalizationHandoff`

Theorem 1392.24 (DecimalExpansion endpoint Cauchy schedule)**.** *Every endpoint-sensitive Cauchy schedule consumer of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must traverse the finite digit window rows* D, W*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, endpoint normalization, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *before any real-facing decimal read is exported. The schedule exposes only finite prefix observations and their normalized endpoint route; it does not select a decimal stream, choose a repeating-nine convention, or invoke ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the endpoint-normalization handoff of Definition 1417.23. It already forces every endpoint-sensitive read through the displayed D, W, V, Q, R, E route before the normalized decimal surface is read.

Use finite prefix completeness from Definition 1417.22. The packet has no additional coordinate beyond the displayed digit, window, place-value, dyadic comparison, regular readback, Real seal, transport, replay, provenance, and naming rows.

The Cauchy schedule is therefore read through the same finite route. The dyadic comparison Q supplies the requested tolerance window, R supplies regular rational readback, endpoint normalization resolves only the displayed finite endpoint case, and E is the terminal Real seal for the real-facing read. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionEndpointCauchySchedule`

Theorem 1392.25 (DecimalExpansion finite-prefix separability route)**.** *Every finite-prefix separability consumer of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must read finite digit windows* D, W*, dyadic comparison* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, endpoint normalization, the* $\mathsf{RealSeparability}^{\uparrow}$ *finite-density route, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *before treating the decimal packet as a real-separating datum.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionFinitePrefixSeparabilityRoute`

Proof. Project the carrier through Definition 1417.1. A separability read receives the same finite prefix data as every other consumer: digit windows, place values, dyadic comparisons, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Apply the finite prefix completeness theorem Definition 1417.22. It prevents a separability consumer from asking for an infinite decimal stream or a selected representative outside the packet.

Now use the Real seal factorization already cited by the chapter and route density through chapter 1809. Endpoint normalization acts before this density read, so the finite decimal prefix is normalized, read back through R, and sealed by E before the $\mathsf{RealSeparability}^{\uparrow}$ surface consumes it. □

Theorem 1392.26 (DecimalExpansion real window exhaustion)**.** *For an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet, any* $\mathsf{Real}^{\uparrow}$*-facing decimal read is exhausted by finite digit windows* D, W*, dyadic comparison* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, endpoint normalization, optional* $\mathsf{RealSeparability}^{\uparrow}$ *finite-density inspection, and the terminal Real seal* E*. No real-facing consumer can bypass these rows by importing selected decimal streams, quotient-real equality, trichotomy, or Real completeness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealWindowExhaustion`

Proof. Begin with Definition 1417.7. It places every real-facing read behind the displayed decimal windows, dyadic comparison, regular rational readback, and Real seal.

Add the endpoint-normalization handoff of Definition 1417.23. Endpoint-sensitive reads do not create a second route; they use the same finite prefix rows and then pass through the finite endpoint-normalization surface.

Finally apply Definition 1417.25 when the consumer asks for density or separability data. The $\mathsf{RealSeparability}^{\uparrow}$ surface receives only the finite normalized window, regular readback, and terminal seal, so the displayed rows exhaust the real-facing decimal window. □

Theorem 1392.27 (DecimalExpansion real-window audit route)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, the finite-window exhaustion of Definition 1417.26 is an audit route through exactly*

$$D, W, Q, R, E, H, C, P, N.$$

Every $\mathsf{Real}^{\uparrow}$*-facing read that begins in digit windows or endpoint-sensitive windows must pass through the displayed dyadic comparison,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before it is accepted as a decimal real-window observation.*

Proof. Begin with Definition 1417.26. It already confines real-facing decimal reads to finite digit windows, dyadic comparison, regular rational readback, endpoint normalization, optional finite-density inspection, and the terminal Real seal.

Use Definition 1417.7 and Definition 1417.11 to name the concrete route. The read moves from D, W through Q before it reaches R and E, so no selected decimal stream or quotient-real equality can enter the audit path.

Finally append the structural rows supplied by Definition 1417.3. Componentwise transport, replay, provenance, and local naming are exactly H, C, P, N, and the carrier has no coordinate outside $D, W, V, Q, R, E, H, C, P, N$ from which another audit row could be read. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealWindowExhaustionAuditRoute`

Theorem 1392.28 (DecimalExpansion endpoint-window transport)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet, endpoint-sensitive finite windows transport through the same endpoint-normalization handoff used by Definition 1417.23. The transported read exposes only the displayed digit ledger* D*, window ledger* W*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, and structural rows* H, C, P, N*; it does not select a decimal stream, choose a repeating-nine convention, or import a detached endpoint resolver.*

Proof. Project the packet through Definition 1417.1. Endpoint-sensitive reads have access to the same finite rows as every other decimal consumer and no additional endpoint coordinate.

Apply Definition 1417.23. Its handoff sends the endpoint-sensitive part through D, W, V, Q, R, E before a normalized real-decimal read is exported.

The transport part is supplied by Definition 1417.9 and Definition 1417.22. Window refinement is componentwise through H, replay is through C, provenance through P, and the local name through N, so the endpoint window remains inside the displayed packet instead of selecting an external stream. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionEndpointWindowTransport`

Theorem 1392.29 (DecimalExpansion RegSeqRat prefix coverage)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing decimal prefix read exported by an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet is covered by finite digit windows together with dyadic comparison. Concretely, the read starts in* D, W*, evaluates its place-value and tolerance information through* V, Q*, reaches the regular rational row* R*, and then remains governed by* E, H, C, P, N *before any downstream* $\mathsf{Real}^{\uparrow}$ *consumer may inspect it.*

Proof. Use Definition 1417.8. It places each regular-rational handoff after the finite decimal prefix and its comparison ledger, rather than after an infinite decimal stream.

Apply Definition 1417.11. The row Q is the required finite dyadic comparison between place-value data and the regular rational route, so a $\mathsf{RegSeqRat}^{\uparrow}$ consumer cannot read R directly from D, W, V.

Finally combine Definition 1417.22 with Definition 1417.27. The prefix remains covered by finite windows and dyadic comparison after the Real seal and structural rows are inspected, and no selected representative, trichotomy decision, or ambient completeness witness is exported. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRegSeqRatPrefixCoverage`

Theorem 1392.30 (DecimalExpansion prefix normalization triad)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *finite-window read over digit windows* D, W*, place-value row* V*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *normalizes through the triad of finite prefix coverage, dyadic comparison, and Real readback boundary. The normalized read refuses quotient reals, selected decimal streams, endpoint convention selectors, trichotomy, and Real completeness before any downstream consumer may inspect* R *or* E*.*

Proof. Start with Definition 1417.29. It already places each $\mathsf{RegSeqRat}^{\uparrow}$-facing prefix read inside finite digit windows D, W, the place-value row V, and dyadic comparison Q before R is exposed.

Next apply Definition 1417.16. This prevents a normalized prefix from being replaced by a selected stream or by an endpoint convention outside the displayed rows.

Finally use Definition 1417.7. The route reaches E only after D, W, V, Q, R have been inspected, so quotient reals, trichotomy, and ambient completeness are unavailable to the normalized prefix read. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionPrefixNormalizationTriad`

Theorem 1392.31 (DecimalExpansion terminal carry refusal)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet, a terminal-carry read on finite digit windows* D, W *must pass through the place-value row* V*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *as displayed packet data. It cannot discharge the carry by choosing a repeating-nine representative, selecting a decimal stream, invoking endpoint convention selectors, applying trichotomy, identifying quotient reals, or using Real completeness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionTerminalCarryRefusal`

Proof. Read the endpoint side through Definition 1417.28. Endpoint-sensitive finite windows remain attached to D, W, Q, R, E and do not export a detached endpoint resolver.

Use Definition 1417.9 together with Definition 1417.22. A carry inspection is still a finite prefix inspection, so the place-value row V and comparison row Q must remain visible before R is read.

The refusal clause follows from Definition 1417.27. The terminal Real seal E is reached only through the finite-window audit route, leaving no coordinate for a selected stream, quotient-real equality, trichotomy, endpoint convention selector, or completeness witness. □

Theorem 1392.32 (DecimalExpansion RegSeqRat density unblock)**.** *The finite decimal-window route supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *density-facing read required by later real-name consumers: digit windows* D, W *expose place-value data* V*, dyadic comparison* Q *bounds the prefix against the regular rational row* R*, and the terminal seal* E *records the Real handoff. This density-facing read is a finite BEDC route and not a quotient-real argument, selected decimal stream, endpoint selector, trichotomy decision, or Real-completeness application.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRegSeqRatDensityUnblock`

Proof. Begin with Definition 1417.8. It routes decimal prefixes to $\mathsf{RegSeqRat}^{\uparrow}$ through displayed finite windows rather than through an infinite stream representative.

Combine it with Definition 1417.29. The place-value row V and dyadic comparison row Q are the finite density evidence that lets R be consumed by a downstream real-name route.

Finally apply Definition 1417.7 and Definition 1417.27. The Real seal E is a terminal packet row after D, W, V, Q, R, so the density-facing read stays finite and refuses quotient reals, selected streams, endpoint selectors, trichotomy, and ambient completeness. □

Theorem 1392.33 (DecimalExpansion carry normalization totality)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *finite digit-window packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, every carry or borrow read over the inspected decimal window has a normalized finite-window representative using only the rows* D, W, V, Q*. The normalized representative preserves the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and it introduces no selected decimal stream, endpoint convention, quotient real, trichotomy decision, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionCarryNormalizationTotality`

Proof. Induct over the finite digit window named by D, W. The empty and one-place windows normalize by reading the displayed place-value row V and leave Q, R, E unchanged.

For the extension step, replay the local carry ledger inside the next displayed digit position. The dyadic comparison row Q records the tolerance effect of the carry move, so the normalized prefix still reaches the same finite comparison surface.

Finally use Definition 1417.29 and Definition 1417.18. Since R and E are downstream of the normalized finite prefix, no extra stream selector, endpoint convention, quotient representative, trichotomy row, or completeness coordinate can appear. □

Theorem 1392.34 (DecimalExpansion signed window transport)**.** *Let* $K = (D, W, V, Q, R, E, H, C, P, N)$ *be an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet. If a signed decimal consumer attaches a displayed sign row to the same finite window and transports that signed read by the componentwise* hsame *row* H*, then the transported read preserves the digit ledger* D*, window row* W*, place-value row* V*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The sign transport therefore remains a finite decimal-window route and does not create a second magnitude, selected signed expansion, quotient real, trichotomy decision, or detached Real seal.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionSignedWindowTransport`

Proof. Start from the componentwise transport row H in Definition 1417.1. It transports the displayed packet rows and has no independent coordinate for a second magnitude or a selected signed expansion.

The transported signed read still exposes D, W, V, Q before it reaches R. Apply Definition 1417.9 to keep the place-value and dyadic comparison data attached to the same finite window.

The terminal seal is then controlled by Definition 1417.7. Since E is read only after the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, the signed transport cannot bypass the finite decimal route or import quotient equality, trichotomy, or a detached Real-facing value. □

Theorem 1392.35 (DecimalExpansion RegSeqRat digit replay)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet is replayable from the finite digit ledger. Concretely, for* $K = (D, W, V, Q, R, E, H, C, P, N)$*, the row* R *is determined for downstream consumers by replaying* D, W *through the place-value row* V *and dyadic comparison row* Q *before the terminal seal* E *is exposed. No downstream consumer can replace that replay by a quotient real, selected decimal stream, endpoint selector, trichotomy decision, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRegSeqRatDigitReplay`

Proof. Read the digit ledger through Definition 1417.21. Every comparison use of Q first displays the same finite digit and window rows D, W together with the place-value row V.

Next apply Definition 1417.29. The $\mathsf{RegSeqRat}^{\uparrow}$ row is covered by finite digit windows and dyadic comparison, so replaying D, W, V, Q reconstructs the public route to R.

Finally use Definition 1417.32. The density-facing handoff and the Real seal remain finite BEDC routes, leaving no coordinate for quotient reals, selected decimal streams, endpoint selectors, trichotomy, or ambient completeness. □

Theorem 1392.36 (DecimalExpansion public window export)**.** *Every public-facing* $\mathsf{DecimalExpansion}^{\uparrow}$ *consumer must expose the digit ledger D, decimal window row W, place-value row V, dyadic and rational comparison row Q,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport, replay, provenance, and local* NameCert *rows before reading a real-facing decimal value. The export is a finite decimal-window route and not a quotient real, selected decimal expansion, endpoint selector, trichotomy decision, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionPublicWindowExport`

Proof. Start with the window obligations. Theorems 1417.2 and 1417.9 force every decimal read to display D, W, V, Q before any downstream handoff is available.

Next use the RegSeqRat route. Theorems 1417.8, 1417.29, and 1417.35 keep the handoff row R replayable from the finite digit ledger and dyadic comparison rows.

Finally apply the Real boundary and the non-escape audit. Theorems 1417.7, 1417.27, and 1417.34 leave the terminal seal E downstream of the finite route and provide no coordinate for quotient reals, selected expansions, endpoint selectors, trichotomy, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DecimalExpansion}^{\uparrow}$ packet is generated from finite decimal digit rows, decimal-place windows, rational place-value rows, dyadic/rational comparison rows, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal, displayed hsame and Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1417.1, Definition 1417.3, Definition 1417.2, Definition 1417.7, Definition 1417.8, Definition 1417.9, Definition 1417.29, Definition 1417.35, and Definition 1417.36 bind the finite decimal-window carrier, digit classifier, RegSeqRat and Real-facing readback rows, hsame transport, Cont replay, Pkg provenance, local NameCert rows, and the public decimal-window consumer export.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, quotient reals, endpoint uniqueness, trichotomy, selected representatives, RealUp completeness, or a standard bridge.

Upgrade path: No further paper-axis closure is claimed here; bridge and Lean verification remain separate axes.

Chapter 1393

A Concrete Naming Certificate for $\mathsf{ArchimedeanOrderedField}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ packet records a traditional ordered-field comparison certificate over displayed constructive real names. It sits between the algebra/order surface of chapter 766, the rational-bound route of chapter 430, the real-name seal of chapter 38, and the rational source rows of chapter 37. The packet is a comparison carrier for downstream L10 and real-algebra consumers, not an ambient ordered field object.

Definition 1393.1 (ArchimedeanOrderedField carrier)**.** *An* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, A, Q, O, B, H, C, P, N)$$

with the following displayed coordinates:

1. *R is the family of* $\mathsf{Real}^{\uparrow}$ *endpoint rows whose algebra and order reads are being compared;*
2. *A is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *row that supplies displayed addition, negation, multiplication, absolute-value, nonnegative-order, and apartness evidence for those endpoints;*
3. *Q is the finite* $\mathsf{Rat}^{\uparrow}$ *source family used by constant-rational witnesses and Archimedean comparison bounds;*
4. *O is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *rational-bound row attached to the displayed real endpoints;*
5. *B is the local comparison ledger recording the field-operation, order, rational-embedding, and Archimedean-bound reads that the packet exports;*
6. *H stores componentwise* hsame *transports for the real endpoints, algebra/order rows, rational source rows, Archimedean bound rows, and local ledger rows;*
7. *C stores the* Cont *routes that expose the displayed operation, order, rational-bound, and rational-embedding rows to downstream consumers;*
8. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanOrderedField}^{\uparrow}}$ *row.*

The classifier compares two accepted packets only by replaying these finite coordinates. It has no coordinate for real trichotomy, quotient real equality, a host ordered-field carrier, a quotient-reals construction, a selected least bound, or a standard bridge theorem.

Lean4 (definition) `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldCarrier`

Theorem 1393.2 (ArchimedeanOrderedField NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ArchimedeanOrderedField}^{\uparrow}}$ *surface for the carrier of Definition 1419.1 consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed packet* $F = (R, A, Q, O, B, H, C, P, N)$ *with real endpoint, algebra/order, rational source, Archimedean bound, comparison ledger, transport, continuation, provenance, and local naming coordinates;*
2. *classifier transport: classification transports every displayed* $\mathsf{Real}^{\uparrow}$ *endpoint,* $\mathsf{RealAlgOrder}^{\uparrow}$ *operation or order row,* $\mathsf{Rat}^{\uparrow}$ *source row,* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound row, and local ledger row componentwise through the stored* hsame *and* Cont *routes;*
3. *field-row stability: addition, negation, multiplication, unit, zero, and absolute-value reads remain inside the* $\mathsf{RealAlgOrder}^{\uparrow}$ *coordinate* A *after endpoint replacement by classified* $\mathsf{Real}^{\uparrow}$ *rows;*
4. *Archimedean comparison stability: every rational-bound or rational-embedding comparison exposed by* O *and* Q *remains tied to the same displayed real endpoints and the same local ledger rows after transport;*
5. *ledger exactness: every downstream ordered-field or Archimedean read is one of the displayed rows* $R, A, Q, O, B, H, C, P, N$ *before any consumer receives it.*

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldNameCertObligations`

Proof. Carrier admission is projection from Definition 1419.1. The real endpoint family, algebra/order row, rational source family, Archimedean bound row, local comparison ledger, transport table, continuation table, provenance row, and local naming row are exactly the listed coordinates.

Classifier transport is componentwise. The $\mathsf{Real}^{\uparrow}$ endpoints move with their $\mathsf{RealAlgOrder}^{\uparrow}$ operation and order rows, while the rational source rows and Archimedean bound rows move through their own displayed sibling classifiers and the stored hsame routes.

The field-row and Archimedean stability clauses then repack the transported rows into the same ledger shape B. Algebraic reads use only A and the endpoint rows in R; rational-bound reads use only Q, O and the endpoint rows in R.

Ledger exactness follows because every public read is a coordinate of F or a row of B generated from those coordinates. Since no coordinate stores trichotomy, quotient real equality, a host ordered-field carrier, quotient reals, selected least bounds, or bridge-checked data, none of those principles is exported by the local certificate. □

Theorem 1393.3 (ArchimedeanOrderedField RealAlgOrder handoff)**.** *Every ordered-field or Archimedean comparison read exported by an accepted* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *packet factors through the* $\mathsf{RealAlgOrder}^{\uparrow}$ *row* A *and the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *row* O *over the displayed* $\mathsf{Real}^{\uparrow}$ *endpoints* R*. The* $\mathsf{RealAlgOrder}^{\uparrow}$ *side supplies the finite operation and order rows, the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *side supplies explicit rational-bound rows, and the* $\mathsf{Rat}^{\uparrow}$ *coordinate* Q *supplies the rational source data used by both comparison routes.*

Consequently the packet is a handoff between the existing real algebra/order and Archimedean-bound surfaces. It does not identify those surfaces with a host ordered field, quotient-reals carrier, complete real field, trichotomy principle, selected least-bound operation, or bridge-checked standard structure.

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldRealAlgOrderHandoff`

Proof. Project the carrier tuple $F = (R, A, Q, O, B, H, C, P, N)$. The only operation and order coordinate is A, and the only Archimedean-bound coordinate is O.

Read the algebra/order route first. By Definition 766.2, the rows exposed by A are finite endpoint, operation, order, apartness, transport, continuation, provenance, and local naming rows over displayed $\mathsf{Real}^{\uparrow}$ data.

Read the Archimedean route next. By Definition 430.2, the rows exposed by O are finite rational-bound, dyadic-bound, stream-window, regular-Cauchy handoff, ledger, transport, continuation, provenance, and local naming rows for displayed $\mathsf{Real}^{\uparrow}$ data.

The rational source coordinate Q is shared by the two routes. The local ledger B records only those field-operation, order, rational-embedding, and rational-bound reads, and the transports H, C replay them componentwise for consumers.

Thus every exported comparison factors through A, O, and Q over R. The excluded host ordered-field, quotient-reals, trichotomy, completeness, least-bound, and bridge-checked objects have no carrier coordinate and no route through the local ledger. □

Theorem 1393.4 (ArchimedeanOrderedField rational-bound window)**.** *Every Archimedean comparison read exported by an accepted* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *packet must expose the* $\mathsf{Rat}^{\uparrow}$ *source row* Q*, the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound row* O*, and the displayed* $\mathsf{Real}^{\uparrow}$ *endpoints* R *before any ordered-field consumer reads the local comparison ledger* B*. The rational-bound window is therefore the finite route*

$$Q, O, R \longmapsto B.$$

It is not a route through trichotomy, quotient real equality, selected least bounds, a host ordered-field carrier, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldRationalBoundWindow`

Proof. Project the carrier $F = (R, A, Q, O, B, H, C, P, N)$. The rational source row Q, Archimedean bound row O, endpoint family R, and comparison ledger B are displayed coordinates of the same finite packet.

Apply the NameCert obligations of Definition 1419.2. Classifier transport keeps the rational source, bound, endpoint, and ledger rows componentwise aligned, while Archimedean comparison stability ties every rational-bound read to Q, O over the same endpoints R.

Finally use the RealAlgOrder handoff of Definition 1419.3. Ordered-field reads may consume B only after the displayed algebra/order route and the rational-bound route have been replayed, and the carrier has no coordinate for the excluded trichotomy, quotient, least-bound, host-field, or completeness data. □

Theorem 1393.5 (ArchimedeanOrderedField comparison ledger exactness)**.** *For an accepted* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *packet with carrier*

$$F = (R, A, Q, O, B, H, C, P, N),$$

every ordered-field, Archimedean comparison, or rational-embedding consumer of the local comparison ledger B *reads* B *only through the displayed route* R, A, Q, O, H, C, P, N*. Here* A *is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *row,* O *is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *row,* Q *is the* $\mathsf{Rat}^{\uparrow}$ *source row, and* R *is the* $\mathsf{Real}^{\uparrow}$ *endpoint family.*

Thus the ledger is an exhaustive consumer interface for those comparison reads, not a channel for trichotomy, quotient reals, selected least bounds, host ordered-field carriers, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier definition of Definition 1419.1. The only coordinates adjacent to the ledger are the endpoint family R, the algebra/order row A, the rational source row Q, the Archimedean bound row O, the transport table H, the continuation routes C, the provenance row P, and the local naming row N.

Apply the NameCert obligations of Definition 1419.2. Carrier admission and classifier transport force every consumer-visible ledger row to be one of the displayed rows of F.

Field-row stability and Archimedean comparison stability keep ordered-field, rational-embedding, and rational-bound reads attached to the same R, A, Q, O coordinates.

The handoff theorem Definition 1419.3 identifies the ordered-field side with A over R and the Archimedean side with O and Q over the same endpoints. The rational-bound window of Definition 1419.4 then forces any Archimedean comparison read to pass through Q, O, R before it reaches B.

It follows that a downstream ordered-field, Archimedean comparison, or rational-embedding consumer has no remaining entry point into B except the route R, A, Q, O, H, C, P, N. Since the carrier and the cited obligations store no trichotomy, quotient-reals construction, selected least-bound operation, host ordered-field carrier, or ambient real-completeness coordinate, the ledger cannot export any of those structures. □

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldComparisonLedgerExactness`

Theorem 1393.6 (ArchimedeanOrderedField root obligation package)**.** *The carrier of Definition 1419.1, the NameCert obligations of Definition 1419.2, and the RealAlgOrder handoff of Definition 1419.3 assemble the root package consumed by* $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{RealAlgOrder}^{\uparrow}$. *The package consists of displayed ordered-field carrier rows, rational-bound rows, terminal* $\mathsf{Real}^{\uparrow}$ *seal rows, comparison transport, displayed replay, provenance, and the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanOrdere}}$ *row.*

The package exports only those rows. It does not supply trichotomy, quotient equality of real names, selected rational bounds, a selected least-bound operation, a host ordered-field carrier, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldRootObligationPackage`

Proof. Project the packet $F = (R, A, Q, O, B, H, C, P, N)$ from Definition 1419.1. The rows R, A, Q, O, B are respectively the real endpoint source, ordered algebra row, rational source family, Archimedean rational-bound row, and local comparison ledger; the rows H, C, P, N transport, replay, source, and name that finite data.

Apply Definition 1419.2. Its carrier-admission, classifier-transport, field-row stability, Archimedean comparison stability, and ledger-exactness clauses identify every root obligation with one of the displayed coordinates of F.

Apply Definition 1419.3. It routes ordered-field and Archimedean comparison reads through A, O, and Q over the same displayed $\mathsf{Real}^{\uparrow}$ endpoints R, so downstream $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealAlgOrder}^{\uparrow}$ consumers receive a single finite package.

Finally inspect the absent coordinates named in the carrier and handoff statements. Since no row stores trichotomy, quotient equality, selected bounds, host ordered-field structure, least-bound selection, or ambient completeness, the assembled root package cannot export any of those principles. □

Theorem 1393.7 (ArchimedeanOrderedField scoped closure)**.** *The carrier of Definition 1419.1, the NameCert obligations of Definition 1419.2, the RealAlgOrder handoff of Definition 1419.3, the*

rational-bound window of Definition 1419.4, comparison ledger exactness of Definition 1419.5, and the root obligation package of Definition 1419.6 bind every public comparison read to the displayed RealAlgOrder$^{\uparrow}$, ArchimedeanReal$^{\uparrow}$, Rat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldScopedClosure`

Proof. The carrier identifies the only public rows of an accepted packet:

$$F = (R, A, Q, O, B, H, C, P, N).$$

Thus every comparison read must begin with the displayed real endpoints, RealAlgOrder row, rational source row, Archimedean bound row, and local comparison ledger.

The NameCert obligations keep those rows stable under classifier transport. Field-row stability routes algebra and order reads through A over R, while Archimedean comparison stability routes rational-bound reads through Q and O over the same endpoints.

The RealAlgOrder handoff, rational-bound window, and comparison ledger exactness then close the consumer boundary. Ordered-field, rational-embedding, and Archimedean comparison reads reach B only through R, A, Q, O, H, C, P, N.

Finally the root obligation package repacks the same rows for RealAlgOrder$^{\uparrow}$, ArchimedeanReal$^{\uparrow}$, Rat$^{\uparrow}$, and Real$^{\uparrow}$ consumers. Since no coordinate remains outside the displayed transport, replay, provenance, and local naming rows, the chapter closes exactly this scoped comparison interface and no stronger ordered-field or completeness principle. □

Closure status for NameCert$_{\text{ArchimedeanOrderedField}^{\uparrow}}$.

Constructive story: An ArchimedeanOrderedField$^{\uparrow}$ packet is generated from displayed Real$^{\uparrow}$ endpoint rows, a RealAlgOrder$^{\uparrow}$ algebra/order row, Rat$^{\uparrow}$ rational source rows, an ArchimedeanReal$^{\uparrow}$ rational-bound row, a finite comparison ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ArchimedeanOrderedField}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1419.7 binds every public comparison read to the displayed RealAlgOrder$^{\uparrow}$, ArchimedeanReal$^{\uparrow}$, Rat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{ArchimedeanOrderedField}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completeness, trichotomy, quotient reals, selected least bounds, host ordered-field structure, or bridge-checked status.

Upgrade path: Scoped closure requires a checked finite carrier theorem binding the displayed RealAlgOrder and ArchimedeanReal rows to the local comparison ledger.

Chapter 1394

A Concrete Naming Certificate for $\mathsf{LocatedLimit}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LocatedLimit}^{\uparrow}$ packet records located limits as explicit modulus-and-window data for displayed real-name sequences. It is a finite route from the Cauchy-equivalence surface of chapter 1412, the regular-rational readback surface of chapter 301, the finite stream-window surface of chapter 126, and the dyadic tolerance ledger of chapter 291 to the real-name seal of chapter 38. The packet does not introduce host real equality, quotient limits, countable choice, trichotomy, or ambient completeness.

Definition 1394.1 (LocatedLimit carrier)**.** *A* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, M, T, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the displayed* $\mathsf{Real}^{\uparrow}$ *sequence surface whose entries are read only through named finite windows;*
2. *M is the Cauchy/modulus ledger recording the explicit tolerance budget for the displayed sequence;*
3. *T is the located finite-window schedule that says which sequence windows and dyadic tolerances are inspected for each requested precision;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the scheduled windows and the modulus ledger;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *limit seal reached through Q and through no independent host-limit coordinate;*
6. *H stores componentwise* hsame *transports for the sequence surface, modulus ledger, finite-window schedule, regular readback, and real seal;*
7. *C stores the displayed* Cont *replay routes by which consumers reread the same windows and tolerances;*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected host limit, quotient equality of streams, countable-choice schedule, real trichotomy, or ambient completeness principle.

Lean4 (definition) `BEDC.Derived.LocatedLimitUp.LocatedLimitUp`

Definition 1394.2 (LocatedLimit classifier)**.** *Two accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *packets*

$$L = (S, M, T, Q, E, H, C, P, N) \quad \textit{and} \quad L' = (S', M', T', Q', E', H', C', P', N')$$

are classified together exactly when their displayed finite-window schedules expose the same dyadic tolerance comparisons after componentwise transport. Thus the classifier compares L *and* L' *only by shared windows in* T, T'*, the dyadic budgets read by* M, M'*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* Q, Q'*, and the* $\mathsf{Real}^{\uparrow}$ *seal rows* E, E' *reached from those data.*

No classifier step may use host real equality, quotient equality of streams, a selected limiting subsequence, countable choice, trichotomy, or an ambient completeness row.

Theorem 1394.3 (LocatedLimit NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$ *surface for the carrier of Definition 1420.1 consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed packet* $L = (S, M, T, Q, E, H, C, P, N)$*;*
2. *classifier: comparison is the finite-window and dyadic-tolerance classifier of Definition 1420.2;*
3. *transport:* H *and* C *preserve the same sequence surface, modulus ledger, schedule, readback, and seal rows under accepted consumer motion;*
4. *modulus exactness: every limit-facing tolerance request is answered by the stored Cauchy/modulus ledger* M *together with the schedule* T*;*
5. *Real-seal route: every* $\mathsf{Real}^{\uparrow}$ *limit read factors through* Q, E, H, C, P, N *after the displayed rows* S, M, T *have been read.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitNameCertObligations`
↪ variant `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier namecert obligations`

Proof. Carrier admission is projection from the packet $L = (S, M, T, Q, E, H, C, P, N)$. The sequence surface, modulus ledger, located schedule, regular readback, real seal, transport rows, replay routes, provenance, and local naming row are exactly the coordinates named by the carrier.

The classifier row is finite because it reads only the windows named by T, T' and the dyadic tolerances supplied by M, M'. The regular readbacks Q, Q' and real seals E, E' are compared only after those finite observations have been transported.

For transport, use H to move the displayed rows componentwise and C to replay the same consumer route. The replay never creates a new modulus, a host limit, or a quotient of streams; it returns to the stored rows.

Modulus exactness follows because the only tolerance ledger in the carrier is M, and the only located schedule is T. Therefore every downstream tolerance request has to pass through M and T before it can reach Q or E.

The Real-seal route is then the visible composition from S, M, T to Q and finally to E, with H, C, P, N carrying transport, replay, provenance, and naming. The excluded completeness, choice, trichotomy, quotient, and host-equality principles have no carrier coordinate. □

Theorem 1394.4 (LocatedLimit Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *limit read exported by an accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier factors through the displayed route*

$$S, M, T, Q, E, H, C, P, N.$$

The sequence surface S supplies the real-name entries, the ledger M supplies the explicit Cauchy/modulus budget, the schedule T chooses only finite windows for each dyadic tolerance, the row Q repacks those observations as a $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the row E is the sole* $\mathsf{Real}^{\uparrow}$ *limit seal available to consumers. The rows H, C, P, N provide transport, replay, provenance, and local naming for the same route.*

Proof. Project the accepted carrier. Its real-facing coordinates are not free-standing; E is stored together with the sequence surface S, the modulus ledger M, the located schedule T, and the regular readback Q.

Read the limit request in finite order. A consumer first asks T for the displayed windows attached to the requested dyadic tolerance, then reads the matching budget in M, and then uses Q to view the resulting data as a regular rational name.

Only after that route is visible can the consumer read E. The transport and replay rows H and C preserve the same route, while P and N record provenance and local naming.

Thus every $\mathsf{Real}^{\uparrow}$ limit read factors through $S, M, T, Q, E, H, C, P, N$. Since no other coordinate exists, the packet exports no real completeness theorem, selected host limit, quotient equality of streams, countable-choice schedule, trichotomy, or bridge-checked standard interpretation. □

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimit real seal route`

Theorem 1394.5 (LocatedLimit window schedule exactness)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier $L = (S, M, T, Q, E, H, C, P, N)$, each limit-facing tolerance request reads the displayed schedule row T and the modulus ledger M before it reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q or the* $\mathsf{Real}^{\uparrow}$ *seal row E. The exactness claim is the finite routing statement of Definition 1420.1 and Definition 1420.2, with the obligation order supplied by Definition 1420.3 and the terminal route supplied by Definition 1420.4.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitWindowScheduleExactness`

Proof. Project the carrier of Definition 1420.1. The only rows that can answer a tolerance request before readback are the schedule row T and the modulus ledger M.

Use the classifier of Definition 1420.2 to see that comparison is by shared finite windows and dyadic budgets, not by a host limit. Then apply Definition 1420.3: modulus exactness is one of the named local obligations and it places M and T before every read of Q or E.

Finally apply the route of Definition 1420.4. Since E is reached only after S, M, T, Q, every tolerance request has already passed through T and M before any regular readback or real seal can be exported. □

Theorem 1394.6 (LocatedLimit finite-window scope)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier $L = (S, M, T, Q, E, H, C, P, N)$, each finite-window tolerance request is scoped exactly by the* $\mathsf{StreamName}^{\uparrow}$ *window surface S, T, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger M, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$ *row N. The scope is the source-row route named by the carrier, classifier, NameCert obligations, window-schedule exactness, and Real-seal route; it excludes quotient streams, countable choice, trichotomy, selected host limits, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier finite window scope`

Proof. Project the carrier of Definition 1420.1. Its source rows are precisely $S, M, T, Q, E, H, C, P, N$, so a tolerance request has no access to any row outside that finite packet.

Use the classifier of Definition 1420.2. It compares accepted packets only through transported finite windows and dyadic budgets, and therefore binds the request to the $\mathsf{StreamName}^{\uparrow}$ surface S, T and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger M before any readback is visible.

Apply Definition 1420.3 and Definition 1420.5. The obligation rows require modulus exactness and route every tolerance request through T and M before it reaches the $\mathsf{RegSeqRat}^{\uparrow}$ row Q or the $\mathsf{Real}^{\uparrow}$ seal E.

Finally use Definition 1420.4. The terminal route is $S, M, T, Q, E, H, C, P, N$, with H, C, P, N supplying componentwise transport, replay, provenance, and local naming. Quotient streams, countable choice, trichotomy, selected host limits, and ambient completeness have no coordinate in that route, so they are outside the finite-window scope. □

Theorem 1394.7 (LocatedLimit schedule monotonicity)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, enlarging a displayed precision request refines the stored finite-window schedule through the same modulus ledger* M *and schedule row* T*. The refined request may expose later sequence windows, stronger dyadic tolerances, and a downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, but it may not replace* M*, allocate a new schedule row, or bypass the Real-seal route of Definition 1420.4.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier schedule monotonicity`

Proof. Project the carrier of Definition 1420.1. The only rows that answer precision requests before readback are the modulus ledger M and the finite-window schedule T.

Use Definition 1420.2 to compare the original request and the enlarged request through transported finite windows and dyadic budgets. The classifier has no host limit or quotient-stream coordinate, so the comparison remains inside M and T.

Apply Definition 1420.3 and Definition 1420.5. Their modulus exactness clause places M, T before every read of Q or E, and the exactness theorem identifies this placement as the stored route for every displayed tolerance request.

Finally use Definition 1420.4. Since the Real seal is reached only after S, M, T, Q, a stronger request can only refine the visible windows and tolerances in the same schedule; it cannot introduce a separate modulus or an independent seal. □

Theorem 1394.8 (LocatedLimit schedule-tail cofinality)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, any later displayed precision request that refines the same located schedule must reuse the same modulus ledger* M*, schedule row* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The refined tail may ask for later sequence windows and stronger dyadic tolerances, but it cannot allocate a second modulus, quotient stream, selected limit, choice schedule, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitScheduleTailCofinality`
↪ variant `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier schedule tail cofinality`

Proof. Project the accepted packet through Definition 1420.1. The only tolerance-facing rows are M and T, and the only readback and terminal seal rows available after them are Q and E.

Use Definition 1420.2 to read a refined request. Since the classifier compares accepted packets by transported finite windows and dyadic budgets, a later tail that refines the same schedule is still classified through the same displayed rows rather than through a fresh host limit or quotient stream.

Apply Definition 1420.5. Every tolerance request reaches Q or E only after it has already passed through the stored schedule row T and modulus ledger M, so a tail request has no alternative ledger from which to obtain its budget.

Finally apply Definition 1420.4. The public limit read is exhausted by the route $S, M, T, Q, E, H, C, P, N$, hence the refined tail can only continue along that route. The excluded second modulus, quotient stream, selected limit, choice schedule, and ambient completeness row have no carrier coordinate. □

Theorem 1394.9 (LocatedLimit Real seal comparison)**.** *Let $L = (S, M, T, Q, E, H, C, P, N)$ and $L' = (S', M', T', Q', E', H', C', P', N')$ be accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carriers. If their transported schedule rows, modulus ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows match under the displayed* hsame *and* Cont *routes, then any comparison between the two accepted Real seals is exhausted by those rows. No comparison may appeal to host real equality, quotient equality of streams, a selected limit, countable choice, trichotomy, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier real seal comparison`

Proof. Read both carriers through Definition 1420.1. The only comparison-facing rows are the sequence surfaces, modulus ledgers, schedule rows, regular readbacks, Real seals, transport rows, replay rows, provenance rows, and local naming rows.

Apply the classifier of Definition 1420.2. It compares accepted carriers through shared finite windows, dyadic budgets, readback rows, and Real seal rows after componentwise transport; it does not expose host real equality or quotient stream equality.

Use Definition 1420.3 to force the comparison through the transported schedule and modulus rows before any readback or seal is consumed. Then Definition 1420.5 identifies the finite-window route as the exact route for each displayed precision request.

Finally apply Definition 1420.4. The terminal Real seal is reached only after S, M, T, Q on one side and S', M', T', Q' on the other. Therefore matching transported schedules, modulus ledgers, readbacks, and seal rows exhaust the accepted comparison, and the excluded external principles have no carrier coordinate from which to act. □

Theorem 1394.10 (LocatedLimit Cauchy tail uniqueness)**.** *Let $L = (S, M, T, Q, E, H, C, P, N)$ and $L' = (S', M', T', Q', E', H', C', P', N')$ be accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carriers. Suppose the two carriers expose matching transported finite schedules T, T', modulus ledgers M, M',* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks Q, Q', and terminal* $\mathsf{Real}^{\uparrow}$ *seals E, E' through the displayed* hsame *and* Cont *routes. Then every limit-facing consumer comparison of E and E' is exhausted by the common Cauchy-tail route*

$$S, M, T, Q, E, H, C, P, N.$$

It cannot appeal to host real equality, quotient streams, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier cauchy tail uniqueness`

Proof. Project both accepted carriers through Definition 1420.1. The only rows that can feed a limit-facing comparison are the displayed sequence surfaces, modulus ledgers, finite schedules, regular readbacks, Real seals, transport rows, replay rows, provenance rows, and local naming rows.

Use Definition 1420.2 to identify the comparison surface. The classifier reads the transported windows T, T', the dyadic budgets M, M', the readbacks Q, Q', and the seals E, E'; it has no

coordinate for host equality, quotient streams, selected limits, countable choice, trichotomy, or ambient completeness.

Apply Definition 1420.5. Every tolerance request reaches Q or E only after the finite schedule and modulus ledger have already been read, so the two matching schedule-ledger pairs determine the Cauchy-tail route visible to the consumer.

Finally use Definition 1420.4 and Definition 1420.9. The terminal seal comparison is reached only through the same finite route, and the comparison theorem says matching transported schedules, ledgers, readbacks, and seals exhaust the accepted Real-seal comparison. Hence the two seals are unique for this accepted route in the stated Cauchy-tail sense, without invoking any ambient Real-completeness principle. □

Theorem 1394.11 (LocatedLimit RegSeqRat readback stability)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *is stable under the same componentwise* hsame *transports and displayed* Cont *replay rows* H, C *that preserve the sequence surface* S*, modulus ledger* M*, located schedule* T*, and real seal* E*. The stability surface is the one described by Definition 1420.1, classified by Definition 1420.2, obligated by Definition 1420.3, and consumed by Definition 1420.4.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimit regseqrat readback stability`

Proof. Read the accepted packet through Definition 1420.1. The transport row H is componentwise and includes the regular readback row Q together with S, M, T, E.

The classifier in Definition 1420.2 compares only transported finite windows, dyadic budgets, regular readbacks, and real seals. Therefore a transported Q is not compared through quotient stream equality or through a new host sequence.

Apply the transport obligation in Definition 1420.3. The replay row C rereads the same consumer route after H has moved the displayed coordinates. The Real-seal route of Definition 1420.4 then consumes exactly that stable Q before reaching E. □

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier regseqrat readback stability`

Theorem 1394.12 (LocatedLimit source-row scope)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, every limit-facing consumer binds the finite-window schedule* T*, modulus ledger* M*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal* E *to the source rows named by* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *before the seal can be read. The binding is exactly the source-row route of the carrier, classifier, NameCert obligations, window schedule exactness, Real seal route, and RegSeqRat readback stability.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier source row scope`

Proof. Project the carrier of Definition 1420.1. Its consumer-facing rows are $S, M, T, Q, E, H, C, P, N$, so the schedule, modulus, readback, and seal are already stored with their transport, replay, provenance, and local naming rows.

Use the classifier of Definition 1420.2. It compares accepted packets only through transported finite windows, dyadic budgets, regular readbacks, and Real seals; hence T, M, Q, E cannot be detached from the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source rows that classify them.

Apply Definition 1420.3, Definition 1420.5, and Definition 1420.4. These rows force every tolerance request through T and M before Q and E are consumed.

Finally use Definition 1420.11. The readback row Q is stable only under the same hsame and Cont rows that preserve S, M, T, E, and P, N record the same source route. Therefore no consumer can read the seal before these BEDC source rows are bound. □

Theorem 1394.13 (LocatedLimit Real seal nonescape)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *exports no selected host limit, no quotient stream equality, no countable-choice schedule, no trichotomy, and no ambient completeness principle. This nonescape is the carrier exclusion of Definition 1420.1, the classifier exclusion of Definition 1420.2, the Real-seal obligation of Definition 1420.3, and the terminal factorization of Definition 1420.4.*

Proof. Inspect the carrier in Definition 1420.1. The rows are $S, M, T, Q, E, H, C, P, N$, and none is a selected host limit, quotient equality of streams, countable-choice schedule, trichotomy witness, or ambient completeness field.

The classifier of Definition 1420.2 preserves the same boundary: it compares finite windows, dyadic budgets, regular readbacks, and real seals only after componentwise transport.

Apply Definition 1420.3 to force every real-facing read through the named finite rows. Then Definition 1420.4 identifies E as the sole Real seal reached after S, M, T, Q. Since the excluded principles have no carrier coordinate and no classifier clause, they cannot escape through E. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedLimit}^{\uparrow}$ packet is generated from a displayed $\mathsf{Real}^{\uparrow}$ sequence surface, an explicit Cauchy/modulus ledger, a located finite-window schedule, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ limit seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1420.1, Definition 1420.2, Definition 1420.3, Definition 1420.5, Definition 1420.4, Definition 1420.7, Definition 1420.8, Definition 1420.11, Definition 1420.12, and Definition 1420.13 close the mature paper-side finite-window treatment: carrier, classifier, NameCert obligations, window schedule exactness, Real-seal route, schedule monotonicity, tail cofinality, readback stability, source-row scope, and nonescape for located-limit consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, selected host limits, quotient equality of streams, countable choice, trichotomy, or bridge checking.

Upgrade path: The next upgrade is Lean bridge checking for the paper-side located-limit route without adding Real completeness or selected limits.

Chapter 1395

A Concrete Naming Certificate for $\mathsf{IntermediateValueBisection}^{\uparrow}$

Following Bishop and Bridges-style constructive bisection, the $\mathsf{IntermediateValueBisection}^{\uparrow}$ packet records the finite sign-change route that turns an inspected located interval, endpoint sign reads, and a displayed continuity budget into a regular rational window and a real-name seal. It is a NameCert consumer of the dyadic branch ledger of chapter 361, the rational endpoint cells of chapter 354, the located interval surface of chapter 394, the stream windows of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38.

The certificate is narrower than a classical intermediate value theorem. It stores only the finite branch prefix and the sign ledger needed by a consumer at a requested tolerance, then hands the retained window to the existing regular-sequence and real-name surfaces. No coordinate stores a completed root, a quotient stream, an arbitrary limit selector, real trichotomy, open-cover compactness, or an ambient completeness theorem.

Theorem 1395.1 (IntermediateValueBisection finite sign-change carrier)**.** *An* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (J, R, D, S, W, G, E, H, C, P, N)$$

whose visible rows have the following roles:

1. *J is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet, including the lower and upper rational cells and their located order witness;*
2. *R is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger against which endpoint and midpoint sign reads are recorded;*
3. *D is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch prefix that retains an interval with opposite displayed signs at the requested finite precision;*
4. *S is the sign ledger, containing the initial endpoint signs and the midpoint sign row used at each branch of D;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window surface for the retained lower and upper endpoint names;*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the retained stream windows and the requested dyadic tolerance;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal available to downstream consumers only through the retained regular readback;*

8. *H stores the componentwise* hsame *transports for J, R, D, S, W, G, E, and the local certificate row;*
9. *C stores the displayed* Cont *replay routes for endpoint inspection, midpoint inspection, branch retention, regular readback, and real-seal consumption;*
10. *P is the* Pkg *provenance over* LocatedInterval$^{\uparrow}$, RationalInterval$^{\uparrow}$, DyadicBisection$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{IntermediateValueBisection}^{\uparrow}}$ *registration row.*

The carrier predicate says that these rows form one finite sign-change bisection certificate. It has no coordinate for completed root existence, real trichotomy, quotient streams, selected limits, open-cover compactness, or a global completeness principle for Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.IntermediateValueBisectionUp.IntermediateValueBisectionTasteGate single carrier alignment`

Proof. The carrier is read by projection from the displayed packet I. The located interval row J and rational cell ledger R provide the endpoint cells in which signs are inspected.

The dyadic branch prefix D is the only row that can choose a retained interval. Its choices are justified by the sign ledger S, so every branch step is tied to an endpoint or midpoint sign row already present in the packet.

The retained endpoints then expose stream windows through W and regular rational readback through G. The real-facing row E is reached only after that readback route is fixed.

Finally, H, C, P, and N provide transport, replay, provenance, and local naming for the same rows. Since the tuple contains no other analytic coordinate, the excluded classical and completeness principles cannot be exported by the carrier. □

Theorem 1395.2 (IntermediateValueBisection sign-ledger stability)**.** *For every accepted* IntermediateValueBisection *carrier $I = (J, R, D, S, W, G, E, H, C, P, N)$, every branch prefix of D transports the same sign-ledger boundary under the displayed* hsame *rows and the displayed* Cont *replay routes. In particular, if a consumer reads a retained subinterval through C, then the lower and upper sign rows it receives are exactly the transported entries of S attached to the rational cells in R and the located endpoint packet J.*

Proof. Start with a branch prefix of D. Each step in the prefix names one retained dyadic subinterval and one midpoint sign row, so the only available sign data for the next step are the entries already stored in S.

Transport along H acts componentwise on J, R, D, and S. It preserves the attachment between a rational endpoint cell and its displayed sign row because there is no separate sign coordinate outside the ledger.

Replay along C reads the retained subinterval through the same endpoint inspection and midpoint inspection route. Thus a consumer cannot replace the lower or upper sign by an unrelated host comparison; it receives the transported ledger entries bound to the branch prefix.

Package provenance P and the local certificate row N record that this is the accepted IntermediateValueBisection$^{\uparrow}$ route. The branch-prefix and sign-ledger transport are therefore stable under the named hsame, Cont, and Pkg rows. □

Lean4 ✓ `BEDC.Derived.IntermediateValueBisectionUp.IntermediateValueBisectionCarrier sign ledger stability`

Theorem 1395.3 (IntermediateValueBisection regular seal handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *carrier factors through the route*

$$J, R, D, S, W, G, E, H, C, P, N.$$

The consumer first reads the located and rational endpoint cells, then the finite dyadic branch prefix and transported sign ledger, then the retained stream windows, then the regular rational readback, and only then the real-name seal. The handoff exports a finite sign-change window, not a completed root, quotient stream, selected limit, real trichotomy, open-cover compactness, or ambient completeness theorem.

Proof. Project the accepted carrier. A regular-sequence request begins at the retained endpoint windows, but those windows are not independent rows; they are the W coordinate stored with J, R, D, and S.

Read the finite route in order. The located endpoint packet and rational interval cells determine the initial boundary, the dyadic branch prefix selects the retained interval, and Definition 1422.2 keeps the sign ledger attached to that prefix under transport and replay.

The retained windows then pass through G, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row. The $\mathsf{Real}^{\uparrow}$ seal E is exposed only after this regular readback has been reached, with H, C, P, and N preserving the same route for consumers.

No step in this route introduces a host root or a completed intersection object. Therefore the handoff supplies exactly the finite regular window and real-name seal named in the packet, with the listed non-claims remaining outside the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntermediateValueBisection}^{\uparrow}}$**.**

Constructive story: An $\mathsf{IntermediateValueBisection}^{\uparrow}$ packet is generated from a $\mathsf{LocatedInterval}^{\uparrow}$ endpoint packet, a $\mathsf{RationalInterval}^{\uparrow}$ cell ledger, a $\mathsf{DyadicBisection}^{\uparrow}$ branch prefix, finite sign rows, $\mathsf{StreamName}^{\uparrow}$ retained windows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntermediateValueBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1422.1, Definition 1422.2, and Definition 1422.3 seed the finite constructive bisection route from displayed sign change to regular rational and real-name consumption.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntermediateValueBisection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close completed root existence, real trichotomy, quotient streams, selected limits, open-cover compactness, completed nested intersections, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: A checked BEDC.Derived.IntermediateValueBisectionUp carrier and theorem surface matching the displayed finite sign-change packet would raise the verification axis.

Chapter 1396

A Concrete Naming Certificate for $\mathsf{RealCauchyModulus}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RealCauchyModulus}^{\uparrow}$ packet records the explicit modulus-controlled read by which a regular rational Cauchy name reaches a $\mathsf{Real}^{\uparrow}$ seal. It sits over the finite stream-window surface of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the real seal boundary of chapter 38, and the generic modulus schedule of chapter 292. The packet keeps the modulus visible as finite certificate data before any Real-facing consumer may read the seal.

Definition 1396.1 (Real Cauchy modulus carrier)**.** *A* $\mathsf{RealCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the precision-indexed* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule assigning each requested dyadic tolerance a finite threshold.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *family of finite windows selected by the thresholds in M.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the endpoint and radius comparisons read on those windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row whose regularity is witnessed only through M, S, D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the displayed modulus, window, dyadic, and regular-readback rows have been consumed.*
6. *H records componentwise* hsame *transport for the modulus schedule, stream windows, dyadic tolerance row, regular readback, Real seal, continuation, provenance, and local naming rows.*
7. *C records the displayed* Cont *replay from each precision request through M, S, D, Q, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, a selected limit, open-cover compactness, or an unbounded stream read.

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier local cert ledger transport`

Theorem 1396.2 (Real Cauchy modulus NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ *surface for Definition 1423.1 consists exactly of carrier exposure for B, precision/modulus exposure through M, finite-window exposure through S, dyadic tolerance exposure through D, regular rational readback through Q, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N. Each accepted precision request is classified only by the scheduled threshold in M, the finite windows in S, and the tolerance ledger in D.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier namecert obligations`

Proof. Project the carrier tuple $B = (M, S, D, Q, E, H, C, P, N)$. Each coordinate is a displayed finite row, and the final coordinate names the packet as the local $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ surface.

Read the analytic rows in order. The precision request first consumes the threshold row M, then the finite windows S, then the dyadic ledger D, and only then the regular readback Q and terminal seal E.

The structural rows do not add an analytic source. They transport, replay, source, and name the same route, while the excluded objects have no coordinate in the carrier. Hence the listed rows exhaust the seed obligation surface. □

Theorem 1396.3 (Real Cauchy modulus finite-window route)**.** *For every accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet $B = (M, S, D, Q, E, H, C, P, N)$ and every displayed precision request, the Real-facing read factors through the finite route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto (H, C, P, N).$$

The consumer receives no Real completeness theorem, quotient stream equality, host real equality, countable-choice row, trichotomy row, selected-limit row, open-cover compactness row, hidden selector, or detached Real seal.

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.TasteGate.RealCauchyModulusCarrier window modulus route`

Proof. Start with Definition 1423.2. It places the modulus schedule M before the StreamName window S and the dyadic tolerance ledger D.

The regular readback is then forced through the same finite window. The row Q is read only after M, S, D are displayed, so no quotient stream or host equality row can substitute for the scheduled window comparison.

Finally read the Real seal coordinate. The row E is reached after Q, and the rows H, C, P, N only preserve and name that route. This exhausts the advertised finite-window path for the precision request. □

Theorem 1396.4 (Real Cauchy modulus Real seal nonescape)**.** *No* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{RealCauchyModulus}^{\uparrow}$ *carrier can bypass the displayed route*

$$\mathsf{CauchyModulus}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Equivalently, every accepted terminal seal read is attached to the same packet $B = (M, S, D, Q, E, H, C, P, N)$ and cannot be separated from its explicit modulus schedule, finite windows, dyadic tolerance ledger, regular readback, transport, continuation, provenance, and local naming rows.

Proof. Use the finite-window route of Definition 1423.3. It already forces each terminal seal read through M, S, D, Q, E before the structural rows are consumed.

Now inspect the carrier of Definition 1423.1. There is no coordinate for Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, a selected limit, open-cover compactness, a hidden selector, or a detached Real seal.

Thus any purported Real seal read that omits one of the displayed rows is not a read of the accepted carrier. The only terminal route available to a consumer is the one named by B. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier real seal nonescape`

Definition 1396.5 (Real Cauchy modulus classifier)**.** *The* $\mathsf{RealCauchyModulus}^{\uparrow}$ *classifier accepts a packet* $B = (M, S, D, Q, E, H, C, P, N)$ *exactly when it is componentwise* hsame *to a displayed carrier packet*

$$B' = (M', S', D', Q', E', H', C', P', N')$$

with matching rows for the $\mathsf{CauchyModulus}^{\uparrow}$ *schedule,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming certificate. The classifier then replays the same* Cont *route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto (H, C, P, N)$$

and accepts no packet whose Real-facing read omits one of these coordinates.

Lean4 (definition) `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusClassifier`

Theorem 1396.6 (Real Cauchy modulus threshold stability)**.** *Let* $B = (M, S, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. Transporting* B *along the classifier of Definition 1423.5 preserves the scheduled threshold in* M*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row in* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row in* Q*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal in* E*. In particular, the transported packet has the same displayed Real-facing route and cannot replace the modulus threshold by an unbounded stream read or a detached Real seal.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier threshold stability`

Proof. Project the accepted packet by Definition 1423.1. The rows M, S, D, Q, E are named coordinates of the same finite BHist tuple, while H records the componentwise hsame transport for those coordinates.

Apply the classifier of Definition 1423.5. Acceptance requires the transported packet to match the displayed carrier component by component, so the threshold row, finite windows, dyadic tolerance ledger, regular readback, and terminal seal are preserved as the rows read by the consumer.

Finally replay the finite-window route of Definition 1423.3. Since the Cont replay is the same route through $M, S, D, Q, E, H, C, P, N$, no unbounded stream read, hidden selector, or detached Real seal can enter during transport. □

Theorem 1396.7 (Real Cauchy modulus ledger exhaustion)**.** *Every accepted Real-facing read of a* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet is exhausted by the nine displayed rows* $M, S, D, Q, E, H, C, P, N$*. The read therefore cannot introduce Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, open-cover compactness, an unbounded stream read, or any analytic row not already present in the carrier.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier ledger exhaustion`

Proof. Start from the obligation surface in Definition 1423.2. It lists the analytic rows M, S, D, Q, E and the structural rows H, C, P, N as the complete seed surface for the local $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ packet.

Use Definition 1423.6 to transport any accepted read back to the same classifier route. The transported read still consumes the scheduled threshold, finite windows, tolerance ledger, regular readback, and terminal seal in the displayed order.

It remains to inspect the carrier. By Definition 1423.1, none of Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, open-cover compactness, an unbounded stream read, or a detached analytic source has a coordinate in B. Hence every accepted Real-facing read is exhausted by the displayed ledger. □

Theorem 1396.8 (Real Cauchy modulus root-unblock scope)**.** *Every accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet exposes exactly the rows needed by downstream L10 Real-and-Completion consumers: the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold schedule* M*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, the ambient* BHist *carrier, the* hsame *transport row* H*, the* Cont *replay row* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}$ *row* N*. No accepted packet exposes a quotient stream, selected limit, host real equality, countable-choice row, or ambient Real completeness row as part of the unblock surface.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier root unblock scope`

Proof. Project the tuple in Definition 1423.1. Its analytic coordinates are precisely M, S, D, Q, E, and its structural coordinates are precisely H, C, P, N over the finite BHist packet.

The obligation surface of Definition 1423.2 names the same coordinates as the local $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ surface. Thus an L10 consumer can read the schedule, window, dyadic, regular-readback, seal, transport, continuation, package, and naming rows without adding any further analytic source.

Finally apply Definition 1423.3 and Definition 1423.7. The route inspection shows that quotient streams, selected limits, host real equality, countable choice, and ambient Real completeness have no coordinate in the accepted packet, so they cannot be part of the root-unblock scope. □

Theorem 1396.9 (Real Cauchy modulus threshold-window totality)**.** *For every accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet and every displayed precision request, the consumer first reads a threshold from* M *and then a finite window from* S *before the dyadic ledger* D*, the regular readback* Q*, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is available. This ordering is total for the displayed route: there is no accepted access path from the precision request directly to* D, Q, E*, to a quotient stream, to a selected limit, to host real equality, to countable choice, or to ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier threshold window totality`

Proof. Start with the route theorem Definition 1423.3. It factors every accepted precision request through $M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E$ before the structural rows are consumed.

The carrier projection in Definition 1423.1 makes the threshold and window rows named coordinates of the same finite packet. Therefore the consumer cannot obtain the dyadic tolerance ledger, regular readback, or terminal seal without first selecting the scheduled threshold and the corresponding finite window.

The NameCert obligations in Definition 1423.2 and the ledger exhaustion theorem Definition 1423.7 rule out all other sources. Since quotient streams, selected limits, host real equality, countable choice, and ambient Real completeness are absent from the tuple, they cannot provide an alternate totality witness. □

Theorem 1396.10 (Real Cauchy modulus RegSeqRat seal admission)**.** *The* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *of an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet is admitted to the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *only through the displayed modulus, finite-window, and dyadic route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E.$$

No quotient stream equality, selected limit, host real equality, countable-choice principle, or ambient Real completeness theorem can admit Q *to the seal.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier regseqrat seal admission`

Proof. Read the accepted packet through Definition 1423.1. The row Q is a displayed coordinate between the dyadic ledger D and the terminal seal E, not a detached regular sequence or an external limit object.

Use Definition 1423.3. It places Q after the scheduled threshold M, finite window S, and dyadic ledger D, and before the terminal $\mathsf{Real}^{\uparrow}$ seal row E. The continuation row C then replays exactly that admission path.

The obligation list in Definition 1423.2 supplies the same route as local certificate data, while Definition 1423.7 excludes every non-displayed analytic source. Hence Q enters the seal only by the modulus-window-dyadic route, never by quotient streams, selected limits, host real equality, countable choice, or ambient Real completeness. □

Theorem 1396.11 (Real Cauchy modulus precision induction)**.** *Let* $B = (M, S, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. For every finite unary precision request, every finite precision refinement of the accepted request is handled by induction on that unary request and preserves the displayed route through*

$$\mathsf{CauchyModulus}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

At each induction stage the refined read consumes only the scheduled modulus row M*, the finite window row* S*, the dyadic ledger row* D*, the regular readback row* Q*, the terminal seal row* E*, and the structural rows* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier precision induction`

Proof. Project the accepted packet with Definition 1423.1. The precision request is a finite unary object, so the proof proceeds by induction on the displayed request.

In the zero stage, Definition 1423.3 gives the route from M to S, then to D, Q, and E. The classifier rows H, C, P, N replay and name the same route, so no extra analytic coordinate is introduced.

For the successor stage, assume the route has been preserved for the preceding precision request. The next refinement reads the next threshold from M, selects the corresponding finite window in S, extends the tolerance ledger in D, and then replays the regular readback Q before exposing the same terminal $\mathsf{Real}^{\uparrow}$ seal row E.

The replay is the displayed Cont row C, transported componentwise by H and sourced by P, N. The ledger exhaustion theorem Definition 1423.7 rules out Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, open-cover compactness, or an unbounded stream read at any induction stage. □

Theorem 1396.12 (Real Cauchy modulus window monotonicity)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. If a dyadic tolerance request is strengthened inside the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the scheduled threshold in M may enlarge the finite* $\mathsf{StreamName}^{\uparrow}$ *window in S, but the earlier window, dyadic ledger row, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row remain present in the accepted carrier route. In particular, the stronger request cannot delete or detach any previously scheduled window, tolerance entry, regular readback, or terminal* $\mathsf{Real}^{\uparrow}$ *seal row.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier window monotonicity`

Proof. Begin with the accepted route of Definition 1423.3. A stronger tolerance is still classified through the same M, S, D, Q, E route, because the classifier of Definition 1423.5 accepts only componentwise matches of those displayed rows.

The threshold selected by M may point to a larger finite window in S. This changes the amount of displayed stream data read for the stronger tolerance, but it does not remove the earlier finite window, since that earlier window is already a coordinate of the accepted BHist packet and is transported by H.

The dyadic ledger and regular readback follow the same containment. The row D records the earlier tolerance entry and the stronger tolerance entry as finite ledger data, while Q is read only after D has been displayed. Replaying C therefore keeps the earlier window, ledger, readback, and terminal seal available to every downstream consumer. □

Theorem 1396.13 (Real Cauchy modulus cofinal window extraction)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. For any two finite unary precision requests whose second request refines the first, the displayed modulus row M selects a finite* $\mathsf{StreamName}^{\uparrow}$ *window in S for the refined request that is cofinal over the earlier window. The extraction preserves the earlier* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger entry, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows H, C, P, N.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier cofinal window extraction`

Proof. Proceed by induction on the finite unary refinement. The base request is handled by threshold-window totality, Definition 1423.9, which forces the read through M and then the displayed finite window in S before D, Q, E are available.

For the refinement step, use precision induction from Definition 1423.11. The stronger request is still classified by the same carrier rows and therefore reads a scheduled threshold from M and a finite window from S.

Apply window monotonicity, Definition 1423.12. The refined window may enlarge the displayed StreamName data, but it preserves the earlier finite window, dyadic tolerance entry, regular readback, and terminal seal.

The continuation row C, transported by H and sourced by P, N, repacks this preserved route as one accepted carrier read. Thus the finite window extracted for the refined request is cofinal over the earlier one, with the tolerance ledger, readback, seal, and structural rows intact. □

Theorem 1396.14 (Real Cauchy modulus seal determinacy)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ and $B' = (M', S', D', Q', E', H', C', P', N')$ be accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packets. If their modulus schedules, stream windows, dyadic tolerance ledgers, regular readbacks, terminal seal rows, continuation replays, provenance rows, and local naming rows are componentwise* hsame*, then the local classifier exposes the same terminal* $\mathsf{Real}^{\uparrow}$ *seal route for B and B'.*

Proof. Project both accepted packets. By Definition 1423.5, acceptance already identifies each packet with a displayed carrier through componentwise hsame rows for the analytic and structural coordinates.

Use the assumed componentwise hsame witnesses for M and M', S and S', D and D', and Q and Q'. The threshold schedule, finite window, dyadic ledger, and regular readback are therefore read in the same classifier order for both packets.

It remains to compare the terminal seal route. The witnesses for E and E' identify the exposed $\mathsf{Real}^{\uparrow}$ seal rows, and the witnesses for C, P, N identify the replay, provenance, and local naming rows that present that seal to the consumer.

The Real seal nonescape theorem Definition 1423.4 prevents either packet from exposing a detached seal. Hence the classifier exposes one terminal $\mathsf{Real}^{\uparrow}$ route, carried by the componentwise hsame data, for both accepted packets. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier seal determinacy`

Theorem 1396.15 (Real Cauchy modulus window scope)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. Every finite precision request scopes only the displayed rows $M, S, D, Q, E, H, C, P, N$ over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *In particular, the request has no scope over quotient stream equality, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, ambient Real completeness, or an unbounded stream read.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier window scope`

Proof. Project the accepted packet through Definition 1423.1. The carrier lists exactly the modulus schedule, stream window, dyadic ledger, regular readback, terminal seal, transport, replay, provenance, and local naming rows.

Apply the route theorem Definition 1423.3 and the threshold-window totality theorem Definition 1423.9. They force a finite precision request to pass through M, then S, then D, then Q, and finally E, with H, C, P, N supplying the local transport and certificate data.

The exhaustion theorem Definition 1423.7 supplies the negative part of the scope claim. Since the non-displayed analytic principles are not rows of the packet and are not reached by the finite route, they cannot enter the finite-window scope. □

Theorem 1396.16 (Real Cauchy modulus tail-threshold determinacy)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. For any finite unary precision request, strengthening the dyadic request may enlarge the scheduled finite* $\mathsf{StreamName}^{\uparrow}$ *window, but it cannot replace the threshold selected by M, detach the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, or introduce a selected limit. The tail of the accepted route remains determined by the same modulus-controlled passage through M, S, D, Q, E.*

Proof. Proceed by induction on the finite unary precision request. At the zero stage, Definition 1423.15 identifies the available rows, and Definition 1423.9 fixes the order from threshold to window, ledger, readback, and seal.

For the successor stage, assume the preceding request already follows the displayed route. A stronger dyadic tolerance is still classified by Definition 1423.5, so the request reads the next threshold through the same modulus row M and schedules the corresponding finite window in S.

The monotonicity theorem Definition 1423.12 allows this window to grow while preserving the earlier window, ledger entry, readback row, and terminal seal. The RegSeqRat seal admission theorem Definition 1423.10 then keeps Q attached to the route from D to E.

Finally, Definition 1423.7 rules out selected limits and other non-displayed analytic sources at every induction stage. Thus the stronger request changes only the finite amount of displayed tail data, not the threshold route or the seal handoff. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier tail threshold determinacy`

Theorem 1396.17 (Real Cauchy modulus RegSeqRat classifier determinacy)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ and $B' = (M', S', D', Q', E', H', C', P', N')$ be accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packets. If the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows are componentwise* hsame*, then every terminal* $\mathsf{Real}^{\uparrow}$ *seal read factors through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier route before reaching E or E'.*

In particular, the terminal seal cannot be read directly from the dyadic ledger, from a detached stream representative, from host real equality, from countable choice, or from ambient Real completeness. The unique bridge from the dyadic tolerance ledger to the seal is the displayed $D \to Q \to E$ route transported by H, C, P, N.

Proof. Start with the finite-window route Definition 1423.3. It orders every accepted seal read through M, S, D, Q, E before the structural rows are consumed.

Use threshold-window totality from Definition 1423.9. The terminal route cannot skip from a precision request to D, Q, E; it first reads the scheduled threshold and finite StreamName window.

Now apply RegSeqRat seal admission, Definition 1423.10. It places the readback row Q as the only displayed bridge from the dyadic ledger D to the terminal seal E.

Finally use tail-threshold determinacy, Definition 1423.16. Strengthening the tail request may enlarge the finite window, but it preserves the same modulus-controlled route and keeps the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to the seal.

The componentwise hsame assumptions identify the schedules, windows, ledgers, and readback rows of B and B'. Since ledger exhaustion excludes detached stream representatives, host equality, countable choice, and ambient completeness, both terminal seal reads factor through the same $\mathsf{RegSeqRat}^{\uparrow}$ classifier route. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier regseqrat classifier determinacy`

Theorem 1396.18 (Real Cauchy modulus tail handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *completion consumer of an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet must pass through the displayed rows*

$$M, S, D, Q, E, H, C, P, N.$$

Tail-threshold determinacy composes with window monotonicity and seal determinacy: a stronger tail request may enlarge the finite $\mathsf{StreamName}^{\uparrow}$ *window selected by M, but it preserves the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and the structural rows that transport, replay, source, and name the route. No completion consumer can replace this handoff by quotient stream equality, selected limits, host real equality, countable choice, or ambient Real completeness.*

Proof. Start with the finite route theorem Definition 1423.3. It fixes the consumer route through M, S, D, Q, E before the structural rows are used.

Use window monotonicity from Definition 1423.12. Strengthening the requested tail may enlarge the displayed finite window, but it does not delete the earlier window, ledger entry, readback row, or terminal seal.

Apply seal determinacy from Definition 1423.14. Componentwise hsame agreement on the displayed rows exposes the same terminal $\mathsf{Real}^{\uparrow}$ route to the consumer.

Finally use tail-threshold determinacy, Definition 1423.16. The stronger tail request remains on the same modulus-controlled path, so every $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ completion consumer receives exactly the displayed handoff rows and no non-displayed completion principle. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier tail handoff`

Theorem 1396.19 (Real Cauchy modulus seal handoff)**.** *Every downstream Real-facing consumer of an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the same displayed finite route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E.$$

The handoff is mediated by the rows H, C, P, N *and cannot be replaced by Real completeness, quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or an unbounded stream read.*

Proof. Begin with the finite-window scope theorem Definition 1423.15. It identifies the only rows available to a Real-facing consumer and fixes the analytic carriers through which the request may pass.

Use Definition 1423.16 for strengthened tail requests. The consumer may require a larger displayed window, but the threshold route, dyadic ledger, RegSeqRat readback, and terminal seal remain tied to the same modulus-controlled passage.

Now combine the original route theorem Definition 1423.3, threshold stability Definition 1423.6, ledger exhaustion Definition 1423.7, and seal determinacy Definition 1423.14. These results show that H transports the displayed rows, C replays the route, P records provenance, and N names the local certificate without adding another Real-facing access path.

The terminal handoff therefore reaches $\mathsf{Real}^{\uparrow}$ exactly at E. The negative alternatives are absent from the packet and blocked by the exhaustion and nonescape theorems, so every accepted downstream consumer receives the seal through the displayed finite route. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier seal handoff`

Theorem 1396.20 (Real Cauchy modulus cofinal refinement handoff)**.** *Let* $B = (M, S, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. If* B *is read through a cofinal or monotone modulus schedule supplied by the existing* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *and* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *surfaces, then every downstream Real-facing read still factors through the displayed route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto (H, C, P, N).$$

The cofinal or refined schedule may enlarge the finite window selected by M *and replay the same tail route, but it cannot replace the route by quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, Real completeness, or a detached Real seal.*

Proof. Begin with the finite route theorem Definition 1423.3. It fixes the order from the modulus row M to the StreamName window row S, the DyadicRatCore ledger D, the RegSeqRat readback Q, and the terminal Real seal E.

For a stronger precision request, use window monotonicity and tail-threshold determinacy, Definition 1423.12 and Definition 1423.16. These allow the displayed finite window to grow while preserving the threshold route, the dyadic ledger, the regular readback, and the terminal seal handoff.

Now read the sibling cofinal data only as route data. The $\mathsf{CauchyModulusRefinement}^{\uparrow}$ cofinal-window factorization of Definition 885.15 supplies a refinement row for the finite-window schedule, and the $\mathsf{CofinalModulusSeal}^{\uparrow}$ cofinal route of Definition 1198.12 supplies the cofinal seal row. Neither sibling inserts a second Real seal into the $\mathsf{RealCauchyModulus}^{\uparrow}$ carrier.

Finally apply the seal handoff theorem Definition 1423.19. Since every Real-facing consumer of B reaches $\mathsf{Real}^{\uparrow}$ only through M, S, D, Q, E and the support rows H, C, P, N, the cofinal or monotone schedule preserves the same StreamName–DyadicRatCore–RegSeqRat–Real seal route and leaves the excluded completeness, choice, quotient, and host-equality alternatives outside the packet. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier cofinal refinement handoff`

Theorem 1396.21 (Real Cauchy modulus bounded tail-ledger factorization)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet, and let*

$$R_{\mathrm{bd}} = (S', M', B', Q', A', H', C', P', N')$$

be an accepted $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *packet consumed with componentwise matching modulus, window, dyadic ledger, RegSeqRat readback, and Real seal rows. Then every bounded tail-ledger read exported by the joint consumer factors first through the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E$$

and then through the bounded packet route

$$S' \longmapsto M' \longmapsto B' \longmapsto Q' \longmapsto A'.$$

The handoff exports no Real completeness theorem, quotient stream equality, selected limit, countable-choice schedule, trichotomy principle, open-cover compactness proof, or host real equality.

Proof. Begin with the cofinal refinement handoff Definition 1423.20. It shows that strengthened or cofinal tail requests still read the $\mathsf{RealCauchyModulus}^{\uparrow}$ packet through M, S, D, Q, E before any Real-facing seal is reached.

Next apply the seal handoff theorem Definition 1423.19. The terminal row E is therefore not a detachable Real object; it is the endpoint of the displayed modulus, window, dyadic-ledger, and readback route.

Now pass to the bounded consumer. The obligation surface of Definition 1697.2 identifies the bounded packet rows $S', M', B', Q', A', H', C', P', N'$, and the Real-seal boundary of Definition 1697.3 forces every bounded read through M', S', B', Q', A' before the terminal seal A' can be consumed.

The assumed componentwise matches identify the shared modulus, window, dyadic, readback, and seal rows at the interface. Thus a bounded tail-ledger read has only the composite finite passage displayed above, while the excluded completeness, quotient, choice, compactness, trichotomy, selected-limit, and host-equality coordinates remain absent from both carriers. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier bounded tail ledger factorization`

Theorem 1396.22 (Real Cauchy modulus bounded readback coherence)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet and let $R_{\mathrm{bd}} = (S', M', B', Q', A', H', C', P', N')$ be an accepted* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *packet. If the shared modulus, finite window, dyadic ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal rows agree componentwise by* hsame*, then the* $\mathsf{RealCauchyModulus}^{\uparrow}$

readback and the BoundedRegularCauchy$^{\uparrow}$ *readback expose the same terminal finite Real-facing route. In particular, the bounded consumer cannot introduce a detached seal beyond the matched E/A' boundary.*

Proof. Use seal determinacy Definition 1423.14 to pin the terminal Real$^{\uparrow}$ row of the RealCauchyModulus$^{\uparrow}$ packet to the displayed M, S, D, Q route. Ledger exhaustion Definition 1423.7 then prevents a second dyadic or readback ledger from being inserted between Q and E.

On the bounded side, apply tail-window induction Definition 1697.4. Each requested finite threshold is read through the same bounded route to A', and the induction has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, or Real completeness.

The componentwise hsame assumptions transport the modulus, window, dyadic ledger, readback, and seal rows across the interface. Hence the two readbacks terminate at the same finite Real-facing route, and any alleged detached seal would have to be a row not present in either displayed carrier. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier bounded readback coherence`

Theorem 1396.23 (Real Cauchy modulus uniform tail extraction)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* RealCauchyModulus$^{\uparrow}$ *packet whose threshold row has passed through the cofinal refinement handoff of Definition 1423.20. Then there is a single displayed finite tail window, read from the same M, S, D, Q, E route, that every* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *consumer named in the bounded readback coherence theorem Definition 1423.22 may use. Enlarging a requested tolerance only replaces the displayed window by a later cofinal window; it does not introduce quotient stream equality, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, Real completeness, or a detached Real seal.*

Proof. Start with threshold stability, Definition 1423.6. It transports a stronger tolerance request along the same modulus row M, finite window row S, dyadic ledger D, RegSeqRat readback Q, and terminal Real seal E.

Next use the cofinal refinement handoff, Definition 1423.20. A later cofinal threshold may replace the initially requested tail window, but the replacement is still a displayed finite window in the same carrier route and is replayed by the same structural rows H, C, P, N.

Finally apply bounded readback coherence, Definition 1423.22. Its componentwise hsame matches force the RegSeqRat and Real-facing bounded consumers to read the same terminal finite route, so the cofinal window obtained above is uniform for all those consumers.

The excluded alternatives have no coordinate in either carrier and cannot be inserted between the matched readback and seal rows. Therefore the accepted packet exposes one reusable finite tail window for the bounded RegSeqRat and Real consumers. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier uniform tail extraction`

Theorem 1396.24 (Real Cauchy modulus finite-window tightening)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* RealCauchyModulus$^{\uparrow}$ *packet. Suppose a displayed precision request is tightened and the cofinal refinement row of Definition 1423.20 is available for the same packet. Then the resulting later finite* StreamName$^{\uparrow}$ *window still factors through the original route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

The tightened request keeps the same CauchyModulus$^{\uparrow}$ *row M,* DyadicRatCore$^{\uparrow}$ *ledger D,* RegSeqRat$^{\uparrow}$ *readback Q, and* Real$^{\uparrow}$ *seal E. It introduces no detached seal, selected limit, quotient stream, host*

real equality, countable-choice schedule, open-cover compactness, trichotomy, or ambient completeness row.

Proof. Start with the cofinal refinement handoff Definition 1423.20. It permits the tightened precision request to move to a later finite window while preserving the route through M, S, D, Q, E.

Use uniform tail extraction, Definition 1423.23. The later window is not a new endpoint; it is the finite tail window that every named $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumer may reuse through the same structural rows.

Apply bounded readback coherence from Definition 1423.22. It keeps the readback row Q and the terminal seal E componentwise matched with any bounded consumer that reads the tightened window.

Finally use ledger exhaustion, Definition 1423.7. Since the dyadic tolerance ledger is already exhausted by D before Q and E are read, there is no remaining coordinate for a detached seal, selected limit, quotient stream, host real equality, choice schedule, compactness proof, trichotomy principle, or ambient completeness row. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier finite window tightening`

Theorem 1396.25 (Real Cauchy modulus obligation closure package)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. The carrier of Definition 1423.1, classifier of Definition 1423.5, NameCert obligations of Definition 1423.2, finite-window route of Definition 1423.3, threshold stability of Definition 1423.6, ledger exhaustion of Definition 1423.7, cofinal refinement handoff of Definition 1423.20, uniform tail extraction of Definition 1423.23, bounded readback coherence of Definition 1423.22, and finite-window tightening of Definition 1423.24 jointly supply the obligation surface for the nine-row packet B. The package introduces no Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, or open-cover compactness.*

Proof. Project the accepted packet through the carrier and classifier. The only visible rows are the modulus row M, finite $\mathsf{StreamName}^{\uparrow}$ window row S, dyadic tolerance ledger D, $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, terminal $\mathsf{Real}^{\uparrow}$ seal E, componentwise transport H, displayed replay C, provenance P, and local naming row N.

Apply the NameCert obligations and finite-window route. These two sites bind the local naming surface to the displayed route from modulus requests through finite windows, dyadic tolerance data, readback, and the Real seal.

Use threshold stability, cofinal refinement handoff, uniform tail extraction, bounded readback coherence, and finite-window tightening. Together they show that stronger precision requests only move to later displayed windows on the same route and that every bounded consumer reuses the same readback and seal rows.

Finally apply ledger exhaustion. Since the dyadic ledger is already exhausted before the readback and terminal seal are consumed, there is no remaining carrier coordinate for Real completeness, quotient streams, host equality, countable choice, trichotomy, selected limits, or open-cover compactness. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier obligation closure package`

Theorem 1396.26 (Real Cauchy modulus finite modulus-index induction)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. Every finite family of precision requests indexed by a*

unary finite window is handled by induction on the displayed modulus-index spine. At each successor step the same route

$$M \to S \to D \to Q \to E \to H, C, P, N$$

is preserved, and the induction exposes no unbounded stream read, choice schedule, quotient stream equality, selected limit, or Real completeness row.

Proof. Start with precision induction from Definition 1423.11. The base request reads the displayed modulus row M, the finite window row S, the dyadic ledger D, the regular readback Q, and the terminal seal E through the transported and replayed rows H, C, P, N.

For the successor step, apply window monotonicity from Definition 1423.12. Enlarging the unary finite window preserves the earlier request rows and moves only to a later displayed modulus index on the same spine.

Use uniform tail extraction from Definition 1423.23 to reuse the later finite tail for the whole indexed family. This is finite induction on the BEDC request spine, not a host choice over all precisions.

Finally apply ledger exhaustion from Definition 1423.7. Since every step is already routed through $M, S, D, Q, E, H, C, P, N$, there is no coordinate for an unbounded stream read, quotient stream equality, selected limit, countable-choice schedule, or ambient Real-completeness argument. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier finite modulus index induction`

Theorem 1396.27 (Real Cauchy modulus tail-coherence completeness handoff)**.** *Let $B = (M, S, D, Q, E, H, C, P,$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. Any finite tail-coherence read that is passed from B to a completion witness must preserve the displayed route through* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The handoff may tighten a finite window or move to a later cofinal tail window, but it may not replace the route with quotient stream equality, selected limits, countable choice, host real equality, trichotomy, open-cover compactness, or ambient Real completeness.*

Proof. Begin with precision induction, Definition 1423.11. It makes each requested tail threshold a finite step on the displayed modulus spine rather than a global choice over all precisions.

Apply window monotonicity, Definition 1423.12. Enlarging the finite window keeps the same $M, S, D, Q, E, H, C, P, N$ route and only moves to a later displayed window.

Use uniform tail extraction, Definition 1423.23. The tail-coherence read exported to a completion witness is the same finite tail window already available to every named $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumer.

Finally apply ledger exhaustion, Definition 1423.7. The dyadic tolerance data has no unused coordinate from which quotient stream equality, selected limits, countable choice, host equality, trichotomy, compactness, or ambient completeness could be inserted into the handoff. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier tail coherence completeness handoff`

Falsifiable prediction: An accepted $\mathsf{RealCauchyModulus}^{\uparrow}$ consumer that reads a terminal Real seal without the explicit modulus threshold, finite StreamName window, DyadicRatCore tolerance ledger, and RegSeqRat readback refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchymodulus: no listed sibling supplies the whole nine-row packet $B = (M, S, D, Q, E, H, C, P, N)$, because each sibling

contributes only a window, readback, tolerance, seal, or generic schedule surface while this chapter binds all five analytic faces with transport, replay, provenance, and local naming.

Theorem 1396.28 (Real Cauchy modulus uniform cofinal seal)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. If the modulus row M is transported through the sibling lattice*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{CauchyModulus}^{\uparrow}$$

named by chapter 292, then every finite precision request yields a classifier-stable cofinal seal through the displayed route

$$M \to S \to D \to Q \to E \to H, C, P, N.$$

The exported row is uniform over finite precision requests and contains no selected real representative, host convergence principle, quotient stream equality, countable-choice schedule, or detached Real seal.

Proof. Start with finite modulus-index induction from Definition 1423.26. It handles a finite family of precision requests by induction on the displayed modulus-index spine while preserving the route through $M, S, D, Q, E, H, C, P, N$.

Read the sibling lattice as carrier data. The StreamName row supplies the finite windows, the RegSeqRat row supplies the regular readback, the DyadicRatCore row supplies the tolerance ledger, the Real row supplies the terminal seal, and the CauchyModulus chapter cited above supplies the schedule discipline for cofinal requests.

Now apply cofinal refinement handoff and uniform tail extraction. A later cofinal threshold may enlarge the finite window, but the transported request still reaches the same terminal route and is replayed by the same classifier rows H, C, P, N.

Finally use ledger exhaustion. Since every precision request has already consumed the displayed modulus, window, tolerance, readback, and seal rows, the cofinal seal cannot import a selected representative, host convergence theorem, quotient stream equality, countable-choice schedule, or detached Real seal. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier uniform cofinal seal certificate`

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCauchyModulus}^{\uparrow}$ packet is generated from an explicit $\mathsf{CauchyModulus}^{\uparrow}$ precision schedule, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Bridge status: paperBridge

Not claimed: This chapter does not close Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, open-cover compactness, or a Lean theorem.

Upgrade path: Mature closure requires a checked standard bridge for the nine-row carrier and finite-window Real seal route.

Chapter 1397

A Concrete Naming Certificate for $\mathsf{DedekindCauchyComparison}^{\uparrow}$

Following Bishop and Bridges and Troelstra–van Dalen, the $\mathsf{DedekindCauchyComparison}^{\uparrow}$ packet records the finite comparison boundary between rounded located cut observations and regular Cauchy name observations. It reads the cut surface of chapter 436, the Cauchy equivalence surface of chapter 1412, the regular rational name surface of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a representation comparison certificate, not a Dedekind construction of $\mathsf{Real}^{\uparrow}$ and not a completeness theorem.

Definition 1397.1 (DedekindCauchyComparison carrier)**.** *A* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, R, W, T, E, H, C, P, N)$$

with the following displayed coordinates:

1. *D is the* $\mathsf{DedekindCut}^{\uparrow}$ *row, carrying lower and upper rational-observation data together with roundedness, locatedness, and disjointness evidence;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, carrying the regular rational sequence surface that is allowed to answer finite tolerance requests;*
3. *W is the family of finite* $\mathsf{StreamName}^{\uparrow}$ *windows through which R is read by downstream consumers;*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radii, comparison budgets, and finite refinement rows used to compare D with R;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary row reached from the displayed cut and regular-sequence observations, with no independent completed-real coordinate;*
6. *H stores componentwise* hsame *transports for D, R, W, T, E;*
7. *C stores the displayed* Cont *replay routes for rereading the same finite cut observations, stream windows, tolerance rows, and seal boundary rows;*
8. *P is the* Pkg *provenance over* $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}^{\uparrow}}$ *evidence.*

The carrier has no coordinate for a quotient cut, a host real equality proof, a selected limit, countable choice, a construction of $\mathsf{Real}^{\uparrow}$ *from Dedekind cuts, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.DedekindCauchyComparisonUp.DedekindCauchyComparisonTasteGate single carrier alignment`

Theorem 1397.2 (DedekindCauchyComparison NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}}$ *surface for the carrier of Definition 1424.1 consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the packet* $K = (D, R, W, T, E, H, C, P, N)$ *with its displayed cut row, regular sequence row, stream windows, dyadic tolerance ledger, seal boundary, transports, continuations, package provenance, and local naming evidence;*
2. *classifier: comparison reads only rational cut observations in* D*, finite regular-sequence observations in* R*, the windows* W*, and the dyadic budgets* T*;*
3. *transport stability:* H *and* C *preserve the same cut observations, sequence windows, tolerance rows, and seal boundary under accepted consumer motion;*
4. *exactness: every comparison-facing read is supplied by the displayed rows* D, R, W, T, E *after the componentwise transport and replay routes are fixed;*
5. *ledger: every downstream* $\mathsf{Real}^{\uparrow}$ *consumer first reads the comparison packet through* $D, R, W, T, E, H, C, P, N$ *and receives no hidden completion coordinate.*

Proof. Carrier admission is projection from the packet $K = (D, R, W, T, E, H, C, P, N)$. The displayed cut row, regular sequence row, stream-window family, dyadic tolerance ledger, seal boundary, transports, continuations, provenance, and local naming evidence are exactly the coordinates named by the carrier.

The classifier is finite because every comparison request is routed through the stored rational observations in D, the finite windows W of the regular sequence row R, and the dyadic tolerance ledger T. No classifier step can inspect a quotient cut or an unbounded real object.

Transport stability uses H componentwise and then replays the same consumer path through C. The replay returns to the stored rows D, R, W, T, E and therefore preserves the same finite observation surface.

Exactness and the ledger clause follow from the same inventory. Since the carrier contains no selected limit, host real equality proof, countable-choice schedule, Dedekind construction row for $\mathsf{Real}^{\uparrow}$, or completeness principle, every downstream comparison is exhausted by the displayed packet rows. □

Theorem 1397.3 (DedekindCauchyComparison Real boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *carrier is only a representation boundary between the displayed* $\mathsf{DedekindCut}^{\uparrow}$ *row and the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row. The boundary supplies no quotient cut, no host real equality, no selected limit, no countable choice, no Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, and no completeness theorem.*

Proof. Project the accepted carrier. Its real-facing coordinate is the seal boundary row E, and E is stored together with the cut row D, regular rational row R, finite stream-window family W, and dyadic tolerance ledger T.

Read a comparison request in finite order. The consumer first exposes rational cut observations from D, then reads the corresponding finite windows W of R, and then checks the dyadic budgets recorded in T.

Only after those rows have been fixed can the consumer read the seal boundary E. The transport and replay rows H and C preserve that same route, while P and N record provenance and local naming.

Thus the packet exports a comparison boundary only. A quotient cut, host real equality proof, selected limit, countable-choice schedule, Dedekind construction of $\mathsf{Real}^{\uparrow}$, and completeness theorem have no carrier coordinate and cannot be read from the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindCauchyComparison}^{\uparrow}$ packet is generated from a $\mathsf{DedekindCut}^{\uparrow}$ row, a $\mathsf{RegSeqRat}^{\uparrow}$ row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, a $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1424.1, Definition 1424.2, and Definition 1424.3 seed the finite representation-comparison boundary between Dedekind-cut observations and regular Cauchy name observations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DedekindCauchyComparisonUp.DedekindCauchyComparisonTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close quotient cuts, host real equality, selected limits, countable choice, Dedekind construction of $\mathsf{Real}^{\uparrow}$, completeness, or bridge checking.

Upgrade path: Scoped closure requires a checked finite carrier theorem binding the displayed cut row, regular sequence row, stream windows, dyadic tolerance ledger, and Real-seal boundary.

Chapter 1398

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ packet isolates the regular-Cauchy universal-property seed for the L10 Real and Completion route. It refines the general $\mathsf{CompletionUniversalProperty}^{\uparrow}$ surface of chapter 397 by forcing every extension and uniqueness read through the finite regular-name chain already exposed by chapter 652, chapter 1404, chapter 126, chapter 301, chapter 291, and chapter 38.

The purpose of the packet is local. It names the rows needed for extending a regular-Cauchy source route into the terminal $\mathsf{Real}^{\uparrow}$ seal and for comparing any two such extensions by the displayed hsame ledger. It does not claim the full ambient completeness of $\mathsf{Real}^{\uparrow}$, nor does it replace the mature general completion chapter.

Definition 1398.1 (RegularCauchyCompletionUniversal carrier)**.** *A* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, W, D, R, A, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the regular source row whose admissible names are read as* $\mathsf{RegSeqRat}^{\uparrow}$ *data;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used by the same regular source;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows;*
4. *R is the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *comparison row for replacing regular names without leaving the finite route;*
5. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached through the displayed regular source, window, tolerance, and equivalence rows;*
6. *E is the extension route row, read as the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension face restricted to S, W, D, R, A;*
7. *L is the uniqueness* hsame *ledger comparing two extension routes over the same regular source, finite windows, dyadic ledger, equivalence row, and terminal seal;*
8. *H records the componentwise* hsame *transports for S, W, D, R, A, E, L;*
9. *C records the displayed* Cont *routes that replay the extension and uniqueness reads;*

10. *P is the* Pkg *provenance over* CompletionUniversalProperty$^{\uparrow}$, RealCompletionWitnessExtractor$^{\uparrow}$, RegularCauchyEquivalence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{RegularCauchyCompletionUniversal}^{\uparrow}}$ *row.*

The accepted carrier stores no quotient stream, no selected host limit, no host real equality row, no countable-choice selector, and no ambient Real$^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionUniversalUp.RegularCauchyCompletionUniversalTasteGate single carrier alignment`

Theorem 1398.2 (Regular extension route)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* RegularCauchyCompletionUniversal$^{\uparrow}$ *packet. Every extension consumer of E first reads the regular source S, then the finite* StreamName$^{\uparrow}$ *windows W, then the* DyadicRatCore$^{\uparrow}$ *ledger D, then the* RegularCauchyEquivalence$^{\uparrow}$ *comparison row R, and only then reaches the terminal* Real$^{\uparrow}$ *seal A and the restricted* CompletionUniversalProperty$^{\uparrow}$ *extension face.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionUniversalUp.RegularCauchyCompletionUniversal extension route`

Proof. Project the carrier of Definition 1425.1. The extension row E is not stored as a detached completion theorem; it appears after the regular source, the scheduled finite windows, the dyadic ledger, the equivalence row, and the terminal Real seal.

Read the sibling surfaces in the displayed order. The StreamName, RegSeqRat, DyadicRatCore, RegularCauchyEquivalence, and Real chapters provide exactly the finite route named by S, W, D, R, A, while the general completion chapter supplies the extension face only after that route has been exposed.

The continuation row C can replay only those displayed reads, and the provenance row P records no selected limit or host completion object. Therefore every extension consumer factors through the regular-Cauchy route before it reaches the universal-property face. □

Theorem 1398.3 (Regular uniqueness ledger)**.** *For accepted packets $U = (S, W, D, R, A, E, L, H, C, P, N)$ and $U' = (S, W, D, R, A, E', L', H', C', P, N')$ over the same regular source, finite windows, dyadic ledger, equivalence row, terminal seal, and provenance, any comparison between the exported extension routes is exhausted by the displayed uniqueness ledgers L and L' together with their componentwise* hsame *transports. No quotient-stream equality, selected host limit, host real equality, countable choice, or ambient completeness row can contribute to the comparison.*

Proof. Start with the shared coordinates S, W, D, R, A, P. They fix the regular source, scheduled windows, tolerance ledger, regular-Cauchy comparison row, and terminal Real seal for both packets.

The only coordinates that can distinguish the two extension exports are E, L, H, C, N and E', L', H', C', N'. The ledgers L and L' compare the extension rows over the same shared route, while H, H' and C, C' display the permitted transports and replays.

Since neither carrier contains a quotient stream, selected host limit, host real equality row, countable-choice selector, or ambient completeness coordinate, no external equality principle can enter the comparison. The uniqueness judgement is exactly the local hsame ledger over the shared regular-Cauchy route. □

Theorem 1398.4 (Regular section law)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* RegularCauchyCompletionUniversal$^{\uparrow}$ *packet. If a consumer first includes the displayed regular source*

through S, W, D, R into the terminal $\mathsf{Real}^{\uparrow}$ *seal A and then reads the restricted extension face E, the exported route is compared by the local uniqueness ledger L to the original A-sealed route. No quotient stream, selected limit, host real equality, countable choice, or ambient completeness row mediates this section comparison.*

Proof. Project the carrier of Definition 1425.1. The displayed source inclusion has only the coordinates S, W, D, R, A available before the extension face is read.

Apply Definition 1425.2. It forces every consumer of E to pass through the source row, finite windows, dyadic ledger, regular-Cauchy comparison row, and terminal Real seal in that order, so the restricted extension face is attached to the same finite route as the original A-sealed read.

Apply Definition 1425.3 with the shared coordinates fixed by this route. The ledger L, together with the displayed transports H and replays C, is the only comparison surface for the extension export over S, W, D, R, A.

The remaining rows P and N record provenance and the local NameCert seal, and no carrier coordinate stores a quotient stream, selected limit, host real equality, countable-choice selector, or ambient completeness witness. Thus L, H, C, P, N exhaust the section comparison inside the packet. □

Theorem 1398.5 (Regular Real-seal factorization)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of U must read the finite route*

$$S \longrightarrow W \longrightarrow D \longrightarrow R \longrightarrow A$$

before it may inspect the extension face E or the uniqueness ledger L. No quotient stream, selected limit, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate can factor the same accepted read.*

Proof. Project the carrier of Definition 1425.1. The Real-facing rows appear as the regular source S, finite windows W, dyadic ledger D, regular-Cauchy comparison row R, and terminal Real seal A.

Apply Definition 1425.2 to the extension face E. It forces every extension read to pass through S, W, D, R, A before the restricted completion face is available.

Apply Definition 1425.3 to comparisons that use L. The ledger compares extension routes only over the same displayed source, window, dyadic, comparison, and Real-seal rows.

The remaining coordinates H, C, P, N transport, replay, source, and name this route. Since the carrier stores no quotient stream, selected limit, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness row, coordinate exhaustion gives the stated factorization boundary. □

Theorem 1398.6 (RegularCauchyCompletionUniversal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCor}}$ *surface consists exactly of carrier admission, the regular extension route, the uniqueness ledger, the section law, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming over* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*,* $\mathsf{RealCompletionWitnessExtractor}^{\uparrow}$*,* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

Proof. Carrier admission is the packet shape of Definition 1425.1. Its rows name the regular source, finite windows, dyadic ledger, comparison row, terminal Real seal, extension route, uniqueness ledger, componentwise transports, continuation replays, provenance, and local certificate.

The regular extension route is bound by Definition 1425.2. The uniqueness ledger is bound by Definition 1425.3, and the section law is bound by Definition 1425.4.

No remaining coordinate is available in the carrier. Therefore the displayed rows exhaust the local NameCert obligation surface over the listed kernel and sibling objects. □

Theorem 1398.7 (RegularCauchyCompletionUniversal kernel scope)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *packet. The extension, uniqueness, and section obligations of Definition 1425.6 are scoped through the displayed kernel rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*: the only admissible reads are carrier projection from U, componentwise comparison through H, continuation replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier $U = (S, W, D, R, A, E, L, H, C, P, N)$. The rows H, C, P, N are the only structural coordinates after the source, window, ledger, equivalence, seal, extension, and uniqueness entries have been displayed.

The extension route can therefore be replayed only through the Cont rows stored in C. The uniqueness and section comparisons can be transported only through the componentwise hsame rows stored in H.

The remaining structural access is provenance and naming. The rows P and N bind the route to Pkg and NameCert, so the kernel scope is exhausted by the displayed BHist, hsame, Cont, Pkg, and NameCert rows. □

Theorem 1398.8 (RegularCauchyCompletionUniversal real seal scope)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *packet. Every real-facing obligation in the extension, uniqueness, and section surface is scoped through the sibling rows* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*: W supplies the finite windows, S supplies the regular source, D supplies the dyadic ledger, R supplies the equivalence boundary, and A supplies the terminal Real seal.*

Proof. Project U and read the real-facing coordinates in order. The source row S is usable only with the finite windows W, and the tolerance row D is the only dyadic ledger available before equality-facing comparison.

The comparison row R is the displayed $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ boundary. It is reached after S, W, D and before the terminal seal, so no quotient equality or host real equality can intervene.

The row A is the only $\mathsf{Real}^{\uparrow}$ seal in the carrier. Hence every real-facing extension, uniqueness, and section read is sealed by A after the StreamName, RegSeqRat, DyadicRatCore, and RegularCauchyEquivalence rows have been displayed. □

Theorem 1398.9 (RegularCauchyCompletionUniversal extractor scope)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N$ be an accepted* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *packet. The completion-facing obligations are scoped through the displayed* $\mathsf{RealCompletionWitnessExtractor}^{\uparrow}$ *and restricted completion row: the extractor is read only after S, W, D, R, A, the extension face is E, and the section comparison is the local ledger L transported through H and replayed through C.*

Proof. Project the carrier and isolate the completion-facing rows. The extractor-facing source data are exactly S, W, D, R, A, already sealed as the regular-Cauchy route of Definition 1425.8.

The extension face E is downstream of those rows. It cannot read a quotient completion, a selected host limit, or an ambient completeness theorem because none of those objects has a coordinate in U.

The section comparison is then local. The ledger L compares the extension route with the original Real-sealed route, while H and C provide the only permitted transport and replay rows for that comparison. □

Theorem 1398.10 (RegularCauchyCompletionUniversal public export)**.** *Every public consumer of an accepted* RegularCauchyCompletionUniversal$^{\uparrow}$ *packet receives exactly the extension route, uniqueness ledger, section law, componentwise transport, continuation replay, provenance, and local* NameCert *rows scoped by the displayed kernel rows of Definition 1425.7, the Real-seal rows of Definition 1425.8, and the completion-extractor rows of Definition 1425.9. The exported surface contains no quotient stream, selected host limit, host real equality, countable choice, ambient RealUp completeness, or standard bridge row.*

Proof. Start with the accepted carrier $U = (S, W, D, R, A, E, L, H, C, P, N)$. The kernel scope theorem fixes the only structural rows visible to a consumer: carrier projection through U, transport through H, replay through C, provenance through P, and local naming through N.

Next read the Real-facing route. The Real-seal scope theorem requires every extension, uniqueness, or section read to pass through S, W, D, R, A before any completion-facing row is visible, so a public consumer cannot substitute quotient stream equality or host real equality for the displayed seal.

Finally apply the completion-extractor scope theorem. It identifies the completion-facing export as the restricted extension row E together with the local uniqueness and section ledger L transported by H and replayed by C. Thus the public export is exactly the listed route, ledger, law, transport, replay, provenance, and local certificate rows. □

Closure status for NameCert$_{\text{RegularCauchyCompletionUniversal}\uparrow}$.

Constructive story: A RegularCauchyCompletionUniversal$^{\uparrow}$ packet is generated from a regular source row, StreamName windows, a dyadic tolerance ledger, a RegularCauchyEquivalence row, a RealUp seal, an extension route, a uniqueness hsame ledger, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCompletionUniversal}\uparrow}$, maturePackageClosed)

Scope closed: Definition 1425.7, Definition 1425.8, Definition 1425.9, and Definition 1425.10 bind carrier admission, extension, uniqueness, section, transport, replay, provenance, naming, public consumer export, and the restricted completion-interface bridge to the displayed kernel, Real-route, and completion-extractor rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionUniversal}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.RegularCauchyCompletionUniversalUp.RegularCauchyCompletionUniversalTasteGate\_single\_c`

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected host limits, host real equality, countable choice, ambient RealUp completeness, or a standard bridge.

Upgrade path: No further paper-side theory-axis upgrade remains; formal bridge checking remains on the independent verification axis.

Chapter 1399

A Concrete Naming Certificate for $\mathsf{SternBrocotApproximation}^{\uparrow}$

Following Stern–Brocot and Farey rational approximation, the $\mathsf{SternBrocotApproximation}^{\uparrow}$ packet records finite rational bracketing as displayed BEDC data. It reads a pair of rational interval endpoints through chapter 354, a finite mediant path through dyadic tolerance bookkeeping from chapter 291, a $\mathsf{StreamName}^{\uparrow}$ observation window from chapter 126, a $\mathsf{RegSeqRat}^{\uparrow}$ readback from chapter 301, and a terminal $\mathsf{Real}^{\uparrow}$ seal from chapter 38. The packet is a finite bracketing neighbor of the decimal and continued-fraction readback surfaces in chapter 1417 and chapter 342; it does not store an ambient real order or a quotient-real representative.

Definition 1399.1 (Stern–Brocot approximation carrier)**.** *A* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, M, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower rational endpoint row, carrying the left side of the displayed* $\mathsf{RationalInterval}^{\uparrow}$ *bracket.*
2. *U is the upper rational endpoint row, carrying the right side of the displayed* $\mathsf{RationalInterval}^{\uparrow}$ *bracket.*
3. *M is the finite mediant-path ledger, whose rows record the left/right Stern–Brocot choices and the rational mediants actually inspected.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including the dyadic precision requested by the consumer and the displayed bound showing that the bracket width is below that tolerance.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window used to request and replay the inspected rational rows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same endpoint and mediant data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the rational interval, tolerance, stream-window, and regular-rational readback rows have been displayed.*
8. *H stores componentwise* hsame *transports for endpoint, mediant-path, tolerance, stream-window, readback, and seal rows.*
9. *C stores the* Cont *replay from stream windows to mediant inspection, from mediant inspection to rational bracketing, from bracketing to regular readback, and from readback to the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{SternBrocotApproximation}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}$ *row.*

The carrier stores only a finite rational bracketing certificate. It has no coordinate for Dedekind cuts, trichotomy, quotient reals, selected representatives, or RealUp completeness.

Lean4 ✓ `BEDC.Derived.SternBrocotApproximationUp.SternBrocotApproximationTasteGate single carrier alignment`

Theorem 1399.2 (Stern–Brocot NameCert obligations)**.** *For an accepted* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *carrier* $K = (L, U, M, T, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the lower endpoint, upper endpoint, mediant-path, dyadic tolerance, stream-window, regular-rational readback, real-seal, transport, continuation, provenance, and naming rows;*
2. *classifier transport along the stored* hsame *rows and displayed* Cont *routes;*
3. *bracketing exactness, stating that every exported rational bracket is one of the endpoint or mediant rows displayed by L, U, M and checked against T;*
4. *readback discipline, stating that every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer reads through the finite window W and the regular readback row R before receiving the seal row E;*
5. *ledger exclusion, stating that Dedekind cuts, trichotomy, quotient reals, selected representatives, and RealUp completeness are not exported by the packet.*

Proof. Carrier admission is projection from the tuple in Definition 1431.1. The rational endpoints, mediant path, dyadic tolerance, stream window, regular readback, real seal, transports, continuations, package row, and local naming row are precisely the displayed coordinates.

Classifier transport is componentwise. The endpoint and mediant rows move through their stored hsame witnesses, while C replays the same window-to-mediant and bracket-to-readback route after transport.

Bracketing exactness uses the sibling interval and dyadic arithmetic surfaces. The endpoint rows are the displayed $\mathsf{RationalInterval}^{\uparrow}$ bounds from chapter 354, and the tolerance row is the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ comparison row from chapter 291.

The readback discipline then follows the stored route through chapter 126, chapter 301, and chapter 38. The excluded principles are absent from the carrier inventory, so the local certificate cannot export them. □

Theorem 1399.3 (Finite rational bracketing)**.** *Every accepted* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *packet exposes a finite rational bracket*

$$L \leq M_i \leq U$$

at each inspected mediant row M_i of the finite ledger M, and the final displayed bracket has width bounded by the dyadic tolerance row T. Every route to the bracket factors through

$$\mathsf{RationalInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow}.$$

The packet supplies no host trichotomy, no quotient-real equality test, and no choice of a distinguished representative for the sealed real.

Proof. Read the mediant ledger M in order. Each row records a finite left/right choice and the rational mediant computed from the currently displayed endpoints, so the next bracket is formed by replacing exactly one endpoint with that mediant.

The interval side is supplied by chapter 354. It records the endpoint rows and the local comparison data needed to keep the displayed lower endpoint below the displayed upper endpoint at the inspected scale.

The tolerance side is supplied by chapter 291. The row T records the dyadic precision and the displayed comparison showing that the final interval width is below that precision.

The window side is supplied by chapter 126. Since the carrier has no other observation coordinate, every bracket read factors through the displayed finite window and the rational rows it exposes. □

Theorem 1399.4 (Stern–Brocot Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *packet factors through the finite handoff*

$$\mathsf{SternBrocotApproximation}^{\uparrow},\ \mathsf{RationalInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The Stern–Brocot carrier provides the finite rational bracket; the decimal and continued-fraction siblings of chapter 1417 and chapter 342 provide comparison readback neighbors; and the real-facing consumer receives only the displayed regular rational row R and seal row E.

Proof. Start with the accepted packet $K = (L, U, M, T, W, R, E, H, C, P, N)$. The carrier exposes the bracket through L, U, M, T and exposes the observation request through W.

The regular-rational handoff is the row R. By the readback discipline of chapter 301, a real-facing consumer reads the finite rational data through the regular sequence surface before reading a real seal.

The seal row E is therefore downstream of R and the displayed window route. The transports H, continuations C, and provenance row P preserve the same route for classified packets and for repeated finite-window reads.

The comparison with decimal and continued-fraction siblings is only a readback comparison: all three chapters present finite rational observation surfaces before the same $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. None supplies Dedekind cuts, trichotomy, quotient reals, selected representatives, or RealUp completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SternBrocotApproximation}^{\uparrow}$ packet is generated from rational interval endpoints, a finite mediant path, a dyadic tolerance row, a finite StreamName window, a RegSeqRat readback, a RealUp seal, componentwise transports, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1431.1, Definition 1431.2, Definition 1431.3, and Definition 1431.4 seed the finite Stern–Brocot rational-bracketing surface for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, trichotomy, quotient reals, selected representatives, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, bracketing exactness, readback discipline, ledger exclusion, and RealUp seal handoff for the same finite packet.

Chapter 1400

A Concrete Naming Certificate for $\mathsf{CauchyCompletionStability}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyCompletionStability}^{\uparrow}$ packet isolates the finite stability route by which a modulus-indexed regular rational Cauchy read remains attached to the same terminal Real seal under accepted transport. It depends on the finite-window naming surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback surface of chapter 301, the terminal seal of chapter 38, the explicit modulus packet of chapter 1423, and the located comparison boundary of **??**. The chapter records only the constructive L10 completion-stability route over those siblings.

Definition 1400.1 (CauchyCompletionStability carrier)**.** *A* $\mathsf{CauchyCompletionStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus schedule that assigns each requested completion tolerance a finite threshold and radius budget;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family selected by the thresholds in M;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the finite dyadic comparisons read on those windows;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row whose regularity is witnessed only through M, S, D;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the modulus, window, tolerance, and regular-readback rows have been consumed;*
6. *H records componentwise* hsame *transport for M, S, D, Q, E and for the structural rows of the packet;*
7. *C records the displayed* Cont *replay that rereads the same modulus schedule, StreamName windows, dyadic tolerance rows, RegSeqRat readback, Real seal, and transport ledger;*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionStability}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionStability}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host real equality, countable choice, trichotomy, a selected limit, open-cover compactness, or a general $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 1400.2 (CauchyCompletionStability NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionStability}^{\uparrow}}$ *surface for Definition 1400.1 consists exactly of the following finite obligation rows:*

1. *carrier exposure: the accepted object is the packet* $T = (M, S, D, Q, E, H, C, P, N)$ *with no hidden completion coordinate;*
2. *classifier: each stability request is classified only by the displayed modulus schedule* M*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, dyadic tolerance ledger* D*, and regular readback row* Q*;*
3. *stability: the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *remains attached to the same finite route whenever* H *transports the displayed rows and* C *replays the corresponding consumer path;*
4. *provenance:* P *records exactly the sibling route through* $\mathsf{RealCauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{LocatedReal}^{\uparrow}$*, while* N *names the local packet.*

Proof. Carrier exposure is projection from the tuple $T = (M, S, D, Q, E, H, C, P, N)$. Every accepted coordinate is displayed, and the final coordinate is the local naming row.

The classifier is finite because a stability request first reads the threshold data in M, then the finite windows in S, then the dyadic tolerance ledger in D, and then the regular rational readback in Q. No classifier row can inspect a quotient stream or a host real equality proof.

Transport stability uses H componentwise and then replays the same path through C. The replay returns to the rows M, S, D, Q, E, so the terminal Real seal is stable only along the displayed route.

The provenance and naming clauses follow from P and N. Since the carrier contains no coordinate for countable choice, trichotomy, selected limits, open-cover compactness, or general Real completeness, the four obligation rows exhaust the local certificate surface. □

Theorem 1400.3 (CauchyCompletionStability cross-chapter scope)**.** *Every export of an accepted* $\mathsf{CauchyCompletionStability}^{\uparrow}$ *packet is confined to the finite L10 completion-stability route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto (H, C, P, N).$$

It exports no quotient stream equality, no host real equality, no countable-choice schedule, no trichotomy principle, no selected limit, no open-cover compactness principle, and no general $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Read the packet through the obligations of Definition 1400.2. The only analytic route is the displayed sequence from the modulus schedule to the terminal Real seal.

The structural coordinates do not widen that route. The transport row H and replay row C preserve the same rows, while P and N only record provenance and local naming.

Inspecting the carrier of Definition 1400.1 shows that the excluded principles have no row from which they could be read. Therefore the packet exports exactly the finite completion-stability route and none of the listed ambient or classical principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionStability}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionStability}^{\uparrow}$ packet is generated from a modulus schedule, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1400.1, Definition 1400.2, and Definition 1400.3 seed the finite completion-stability route across StreamName, DyadicRatCore, RegSeqRat, Real, RealCauchyModulus, and LocatedReal siblings.

Formal verification: FormalStatus(NameCert$_{\text{CauchyCompletionStability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, host real equality, countable choice, trichotomy, selected limits, open-cover compactness, general Real$^{\uparrow}$ completeness, or a Lean theorem.

Upgrade path: A formal route can encode the nine-row carrier and prove the NameCert obligation and cross-chapter scope theorems under BEDC.Derived.CauchyCompletionStabilityUp.

Theorem 1400.4 (CauchyCompletionStability L10 sibling route)**.** *Every accepted* CauchyCompletionStability$^{\uparrow}$ *packet reads its L10 dependency lattice through the finite-window* StreamName$^{\uparrow}$ *rows of chapter 126, the regular-rational* RegSeqRat$^{\uparrow}$ *rows of chapter 301, the* DyadicRatCore$^{\uparrow}$ *tolerance rows of chapter 291, the terminal* Real$^{\uparrow}$ *seal of chapter 38, and the* Completion$^{\uparrow}$ *and* SeparatedMetric$^{\uparrow}$ *boundary of chapter 95 and chapter 1411 before it exports completion stability. The route is visible as a finite* BHist *spine whose* Cont *replay and* hsame *transports reread exactly those sibling rows; it does not identify quotient representatives, select limits, invoke countable choice, assert host equality, or import ambient* Real$^{\uparrow}$ *completeness.*

Proof. The carrier of Definition 1400.1 exposes the rows $M, S, D, Q, E, H, C, P, N$. The finite windows are read from S, the dyadic tolerances from D, the regular-rational readback from Q, and the terminal Real seal from E. The completion boundary is the displayed passage from the regular readback to the terminal seal, and the separated-metric boundary is the uniqueness discipline enforced only by the visible transport rows.

The route is therefore a BHist and Cont route, not a quotient construction. The replay coordinate C rereads the same windows, tolerances, readback, seal, and boundary rows, while H gives only componentwise hsame transport. No coordinate of the packet stores quotient representatives, a selected limit, a choice schedule, host equality, or an ambient completeness theorem, so none of those principles can be exported by the local NameCert. □

Chapter 1401

CauchyContinuousMapUp NameCert Construction

Following Bishop and Bridges, the $\mathsf{CauchyContinuousMap}^{\uparrow}$ packet records the finite interface by which a map on regular Cauchy names preserves regularity and hands its output to a $\mathsf{Real}^{\uparrow}$ seal. The construction is a NameCert surface over the dyadic rational core of chapter 291, the stream-name schedule of chapter 126, the regular rational-name carrier of chapter 301, and the real-seal boundary of chapter 38.

The packet is deliberately weaker than the general continuous-map surface of chapter 130. It records a finite Cauchy-name transformer with displayed readback and seal handoff, not a host function on reals, a metric-continuity proof over all points, a uniform-continuity modulus, a quotient-stream map, or a completeness theorem.

Definition 1401.1 (CauchyContinuousMap carrier)**.** *A* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface read by the map, including the source windows and the output windows that the packet promises to fill;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *image-readback row, carrying the source regular rational name, the displayed output rational name, and the finite evidence that output windows remain regular;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare every selected source window with its displayed output tolerance row;*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row reached from the output regular name after the dyadic tolerance checks have been replayed;*
5. *H records componentwise* hsame *transports for W, R, D, E and for the local classifier row;*
6. *C records the displayed* Cont *replay routes by which consumers inspect the same windows, tolerance rows, image readback, and seal handoff;*
7. *P is the* Pkg *provenance over the stream, regular-name, dyadic, real-seal, transport, continuation, and local naming rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyContinuousMap}^{\uparrow}}$ *row.*

The classifier compares two accepted carriers only by replaying these finite rows. It has no coordinate for a full $\mathsf{ContinuousMap}^{\uparrow}$ *object, host real function, metric continuity theorem, uniform-continuity modulus, quotient of streams, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMapTasteGate single carrier alignment`

Theorem 1401.2 (RegSeqRat image preservation)**.** *For every accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *carrier* $M = (W, R, D, E, H, C, P, N)$*, every image read exposed by the packet factors through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*. The readback therefore preserves the regular-Cauchy-name shape visible to chapter 301, without exporting a quotient stream or a host-level function on reals.*

Proof. Project the carrier of Definition 1401.1. The only image-readback coordinate is R, and it is stored beside the finite window surface W and dyadic tolerance ledger D.

Replay the consumer route through C. The route can inspect the selected source windows, the output windows, the dyadic tolerances, and the regular rational output row, but it cannot read an additional stream quotient or host real function because no such row is present.

Transport along H preserves the same displayed rows componentwise. Thus every accepted image read remains a $\mathsf{RegSeqRat}^{\uparrow}$-shaped finite readback assembled from W, D, and R. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap regseqrat image`

Theorem 1401.3 (Real seal handoff)**.** *For every accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *carrier* $M = (W, R, D, E, H, C, P, N)$*, any* $\mathsf{Real}^{\uparrow}$ *seal consumer must first read the finite stream windows* W*, the image regular-name row* R*, and the dyadic tolerance ledger* D*. Only after those rows are replayed can the consumer reach the seal handoff* E*.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap real seal handoff`

Proof. Read the carrier order in Definition 1401.1. The seal handoff row E is not independent; it is listed as the handoff reached from the output regular name after the dyadic tolerance checks.

Use the displayed Cont routes in C to replay the handoff. These routes expose the window schedule, the image readback, and the tolerance ledger before the real-seal row is available.

The componentwise hsame transports in H keep the same dependency order after transport. Hence a seal consumer receives a finite RegSeqRat-to-Real route and no detached real function, quotient stream, or completeness datum. □

Theorem 1401.4 (ContinuousMap boundary)**.** *Every accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *packet supplies only a finite Cauchy-name transformer boundary for the* $\mathsf{ContinuousMap}^{\uparrow}$ *interface. A* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer may read the packet only after the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows have been displayed through* W, R, D, E *and transported through* H, C, P, N*. The packet does not provide a full host function, metric continuity theorem, uniform-continuity modulus, quotient stream map, or completeness witness.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMapPacket continuousmap boundary`
↪ variant `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap continuousmap boundary`

Proof. Read the carrier rows from Definition 1401.1. The rows W, R, D, E display the stream windows, regular rational image readback, dyadic tolerance checks, and real-seal handoff before any continuous-map consumer can inspect the packet.

The sibling boundary is chapter 130. This chapter exposes only the Cauchy-name side of that interface: H transports the displayed rows, C replays them for consumers, P records provenance, and N names the local certificate.

Since the carrier inventory has no coordinate for a host function, metric continuity theorem, uniform-continuity modulus, quotient stream map, or completeness witness, a $\mathsf{ContinuousMap}^{\uparrow}$ read must treat the packet as a finite boundary rather than as the full continuous-map object. □

Theorem 1401.5 (CauchyContinuousMap NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{CauchyContinuousMap}^{\uparrow}}$ *obligation surface consists of five finite rows:*

1. *carrier habitation by a* $\mathsf{StreamName}^{\uparrow}$ *window surface,* $\mathsf{RegSeqRat}^{\uparrow}$ *image-readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal handoff, displayed transports, continuations, provenance, and local naming;*
2. *classifier replay by the finite windows and dyadic tolerance checks that witness regular-name preservation;*
3. *transport stability under the stored* hsame *rows and displayed* Cont *routes;*
4. *real-seal exactness, stating that every* $\mathsf{Real}^{\uparrow}$ *read factors through the image regular-name and dyadic tolerance rows first;*
5. *ledger refusal, stating that full* $\mathsf{ContinuousMap}^{\uparrow}$ *structure, metric continuity, uniform continuity, quotient streams, host real functions, and ambient completeness are not packet coordinates.*

Proof. Carrier habitation is exactly the tuple displayed in Definition 1401.1. It supplies the window, image-readback, tolerance, seal, transport, continuation, provenance, and local naming rows.

The classifier row is finite because it replays only the windows in W and the tolerance checks in D. Definition 1401.2 gives the corresponding regular-name preservation surface.

Transport stability is obtained by projecting the componentwise hsame rows in H and replaying the same reads through C. Definition 1401.3 gives the seal-exactness row.

The refusal row follows from the carrier inventory. None of the displayed coordinates stores a full continuous-map object, metric-continuity proof, uniform-continuity modulus, quotient stream, host real function, or completeness principle. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMapPacket namecert obligations`

Theorem 1401.6 (CauchyContinuousMap composition route)**.** *Let* $M_1 = (W_1, R_1, D_1, E_1, H_1, C_1, P_1, N_1)$ *and* $M_2 = (W_2, R_2, D_2, E_2, H_2, C_2, P_2, N_2)$ *be accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *packets whose first target regular-rational row is the second source row. A public composite read is admitted only by displaying the two* $\mathsf{StreamName}^{\uparrow}$ *window surfaces* W_1, W_2*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* R_1, R_2*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers* D_1, D_2*, the* $\mathsf{Real}^{\uparrow}$ *seal handoffs* E_1, E_2*, the componentwise* hsame *transports* H_1, H_2*, the displayed* Cont *replays* C_1, C_2*, the* Pkg *provenance rows* P_1, P_2*, and the local* NameCert *rows* N_1, N_2*. The resulting route is a concatenation of displayed Cauchy-name packet reads; it exports no host function composition, selected limit, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap composition route`

Proof. Project the first carrier and read its output through W_1, R_1, D_1, E_1. This displays a regular-rational image row and Real-seal handoff, but no detached host value or quotient stream representative.

Use the stated row match to present that displayed output as the second packet's source row. The second carrier must then reopen W_2, R_2, D_2, E_2 before any final seal is visible.

Concatenate the displayed replay rows C_1 and C_2. Componentwise transport through H_1 and H_2 preserves the two window, readback, tolerance, seal, provenance, and local naming rows without adding a new coordinate.

The public route is therefore the ordered packet read

$$W_1, R_1, D_1, E_1, H_1, C_1, P_1, N_1 \longmapsto W_2, R_2, D_2, E_2, H_2, C_2, P_2, N_2.$$

Since neither carrier stores host function composition, a selected limit, quotient stream equality, or ambient completeness, the composite read cannot export those objects. □

Theorem 1401.7 (Window composition)**.** *Let $M_1 = (W_1, R_1, D_1, E_1, H_1, C_1, P_1, N_1)$ and $M_2 = (W_2, R_2, D_2, E_2, H_2, C_2, P_2, N_2)$ be accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *packets. A composite read is admitted only when the* $\mathsf{Real}^{\uparrow}$ *seal handoff exposed by E_1 is replayed as the source-side input window surface inspected by W_2, and the second packet then reopens its* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *image-readback row, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger before exposing E_2. Thus composition is a finite replay of the first packet's Real-seal handoff through the second packet's stream-name and regular-rational-name rows, not a host-level composition theorem for* $\mathsf{ContinuousMap}^{\uparrow}$.

Proof. Project the two carriers from Definition 1401.1. The first packet can expose an output real only through W_1, R_1, D_1, and E_1, so there is no detached function value available to feed into the second packet.

The second packet accepts input only through its own window row W_2. A composite read therefore starts by replaying the first seal handoff through the displayed continuation route C_1, then presenting that finite read as the source-side window data inspected by W_2.

After that handoff, the second packet must still replay R_2 and D_2 before E_2 is visible. The structural rows H_2, C_2, P_2, N_2 preserve that order, so the composite remains a finite Cauchy-name replay rather than a full $\mathsf{ContinuousMap}^{\uparrow}$ composition principle. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap window composition`

Theorem 1401.8 (Regularity transport)**.** *For every accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *carrier $M = (W, R, D, E, H, C, P, N)$, componentwise* hsame *transport along H preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *image-readback row and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows before any* $\mathsf{Real}^{\uparrow}$ *seal handoff is exposed. Consequently a transported packet can be consumed only by replaying the same finite W, R, D regularity surface, and not by replacing it with a quotient stream, host real function, or full* $\mathsf{ContinuousMap}^{\uparrow}$ *object.*

Proof. Read the transport row H in Definition 1401.1. It is componentwise: the stream window row W, the regular-rational image row R, the dyadic tolerance ledger D, and the real-seal handoff row E are transported as named packet coordinates.

Replay the consumer route C after transport. The route can inspect the transported W, R, and D rows before it reaches E, so regularity transport is witnessed at the finite $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ levels.

Because no coordinate in the carrier stores a quotient stream, host function on reals, metric-continuity proof, or completeness datum, the transported read preserves only the displayed regularity surface before the $\mathsf{Real}^{\uparrow}$ seal is exposed. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap regularity transport`

Theorem 1401.9 (CauchyContinuousMap modulus boundary nonescape)**.** *Every accepted* CauchyContinuousMap$^{\uparrow}$ *packet that is read by a modulus-facing consumer must expose only the finite* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* RegSeqRat$^{\uparrow}$ *regularity row,* Real$^{\uparrow}$ *seal handoff,* ContinuousMap$^{\uparrow}$ *boundary row,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The read does not create a uniform-continuity modulus, metric-continuity theorem over all points, quotient-stream function, or completeness claim.*

Proof. Start with the boundary theorem, Definition 1401.4. It identifies the ContinuousMap$^{\uparrow}$ side of the packet as a finite Cauchy-name transformer boundary, not a full host function or all-points continuity theorem.

Use window composition, Definition 1401.7. A downstream read must reopen the finite stream windows, regular-rational rows, dyadic tolerances, and Real seal handoff before any composite or modulus-facing consumer can inspect the packet.

Finally apply regularity transport, Definition 1401.8. The transported packet preserves the same W, R, D regularity surface before the seal is exposed. Since no carrier coordinate stores a uniform-continuity modulus, quotient-stream function, metric-continuity theorem over all points, or completeness datum, the modulus-facing read cannot create one. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap modulus boundary nonescape`

Theorem 1401.10 (CauchyContinuousMap uniform-window obligation)**.** *Any uniform-modulus-facing consumer of an accepted* CauchyContinuousMap$^{\uparrow}$ *packet must expose the finite rows* W, R, D, E, H, C, P, N *before it may hand a regular-name transformer to* ContinuousMap$^{\uparrow}$ *or* UniformModulus$^{\uparrow}$*. The exposed route supplies stream windows, regular rational readback, dyadic tolerance checks, Real-seal handoff, componentwise transport, replay, provenance, and local naming; it does not supply a host function, quotient-stream map, all-points metric-continuity theorem, ambient completeness theorem, or detached uniform-continuity modulus.*

Proof. Start with the boundary theorem, Definition 1401.4. It identifies the ContinuousMap$^{\uparrow}$ side of the packet with a finite Cauchy-name transformer boundary whose rows are displayed through W, R, D, E, H, C, P, N.

Use window composition, Definition 1401.7. A consumer that composes or forwards the packet must reopen the stream windows, regular readback, dyadic tolerances, and seal handoff before a downstream packet can inspect the result.

Apply regularity transport, Definition 1401.8. Transport preserves the same W, R, D regularity surface before the seal is exposed, so the handoff remains a finite regular-name transformer rather than a quotient-stream map.

Finally invoke Definition 1401.9. Since the carrier has no row for a detached uniform-continuity modulus, a modulus-facing consumer can only pass the displayed finite transformer to ContinuousMap$^{\uparrow}$ or UniformModulus$^{\uparrow}$ after all eight rows are visible. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.UniformWindowObligation.CauchyContinuousMap uniform window obligation`

Theorem 1401.11 (CauchyContinuousMap uniform-modulus factorization)**.** *Every uniform-modulus-facing read of an accepted* CauchyContinuousMap$^{\uparrow}$ *packet factors through* StreamName$^{\uparrow}$ *windows* W*,* RegSeqRat$^{\uparrow}$ *readback* R*,* DyadicRatCore$^{\uparrow}$ *tolerance data* D*, the* Real$^{\uparrow}$ *seal* E*, the* ContinuousMap$^{\uparrow}$ *boundary,* hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N *before* UniformModulus$^{\uparrow}$ *may consume it. The factorization exports a finite Cauchy-name transformer route and not a detached uniform-continuity modulus.*

Proof. Start with Definition 1401.4. It identifies the $\mathsf{ContinuousMap}^{\uparrow}$ side as a finite Cauchy-name transformer boundary rather than a host function.

Use window composition and regularity transport, Definition 1401.7 and Definition 1401.8. They keep the stream windows, regular rational readback, dyadic tolerance ledger, and Real seal visible under composition and componentwise transport.

Finally apply the modulus-boundary nonescape and uniform-window obligation theorems. Together they require W, R, D, E, H, C, P, N before any $\mathsf{UniformModulus}^{\uparrow}$ consumer can inspect the packet, so the read factors through the displayed L10 rows. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.UniformModulusFactorization.CauchyContinuousMap uniform modulus factorization`

Theorem 1401.12 (CauchyContinuousMap completion-consumer scope)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *carrier* $M = (W, R, D, E, H, C, P, N)$ *must read the same* W, R, D, E, H, C, P, N *route. The consumer receives finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance checks, a Real seal, componentwise transport, replay, provenance, and local naming; it receives no host function, selected limit, quotient stream map, all-points metric continuity theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The boundary theorem Definition 1401.4 gives the only map-facing surface: a displayed Cauchy-name transformer boundary over the carrier rows.

Window composition Definition 1401.7 and regularity transport Definition 1401.8 force any downstream read to reopen W, R, D before the Real seal E is exposed.

Apply Definition 1401.10. The same route is required for modulus-facing consumers, and a completion-facing consumer has no additional coordinate from which to select limits, quotient stream maps, all-points continuity, host functions, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap completion consumer scope`

Theorem 1401.13 (CauchyContinuousMap bridge-readback factorization)**.** *Every bridge-facing consumer of an accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *carrier* $M = (W, R, D, E, H, C, P, N)$ *must factor its map-facing readback through the* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, the* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *completion rows, and the* $\mathsf{ContinuousMap}^{\uparrow}$ *boundary before any readback is exposed. The factorization exports the displayed finite Cauchy-name transformer route, not a host function, quotient stream, selected representative, all-points metric-continuity theorem, or ambient completeness row.*

Proof. Start with the Real seal handoff, Definition 1401.3. It forces every seal-facing read through the stream windows, regular rational image row, and dyadic tolerance ledger before E is visible.

Apply the ContinuousMap boundary theorem, Definition 1401.4. It identifies the map-facing side as a finite boundary row for the displayed Cauchy-name transformer, not as a host-level function or full metric-continuity object.

Use the uniform-modulus factorization and completion-consumer scope, Definition 1401.11 and Definition 1401.12. Together they require the same W, R, D, E, H, C, P, N route before any modulus-facing, completion-facing, or bridge-facing consumer can inspect the packet.

Finally route the readback through the finite completion rows. Since the carrier has no coordinate for a host function, quotient stream, selected representative, all-points metric-continuity theorem, or ambient completeness row, the bridge-facing consumer can expose only the displayed $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{MetricCompletionFinite}^{\uparrow}$ readback attached to the Cauchy-name transformer surface. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap bridge readback factorization`

Theorem 1401.14 (CauchyContinuousMap completion factorization)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *packet factors through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the* $\mathsf{ContinuousMap}^{\uparrow}$ *boundary row, and the finite* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *consumer route before any completion read is exposed. The factorization exports only the displayed Cauchy-name transformer rows* W, R, D, E, H, C, P, N *and refuses host functions, quotient streams, selected limits, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap completion factorization`

Proof. Start from the carrier of Definition 1401.1. Its rows expose stream windows, regular rational readback, dyadic tolerance checks, the Real seal, componentwise transport, replay, provenance, and local naming.

Use the continuous-map boundary theorem, Definition 1401.4. It says that the map-facing side is already a finite Cauchy-name transformer boundary, not a host function or an all-points metric-continuity object.

The uniform-window obligation and uniform-modulus factorization then force the same W, R, D, E, H, C, P, N route before a downstream modulus or completion-facing reader can inspect the packet. In particular, the reader must pass through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the $\mathsf{ContinuousMap}^{\uparrow}$ boundary before the completion route is visible.

Finally apply Definition 1401.12. Since the completion consumer has no coordinate for selected limits, quotient streams, host functions, or ambient completeness, its only remaining route is the displayed finite $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{MetricCompletionFinite}^{\uparrow}$ consumer path attached to the Cauchy-name transformer rows. □

Theorem 1401.15 (CauchyContinuousMap separated-completion factorization)**.** *Any accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *packet whose source read factors through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *the* $\mathsf{Real}^{\uparrow}$ *seal, and a separated completion target factors its public map through the displayed completion rows before exposing any* $\mathsf{ContinuousMap}^{\uparrow}$ *boundary. The separatedness datum is used only as a visible NameCert row attached to the target completion route; it is not quotient equality, host equality of completed points, selected representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.SeparatedCompletionFactorization.CauchyContinuousMap separated completion factorization`

Proof. First expose the source-side regular image. Use Definition 1401.2 to place the image read on the finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows, then use Definition 1401.3 to pass that read to the $\mathsf{Real}^{\uparrow}$ seal only after those rows are displayed.

Next route the completion consumer. Apply Definition 1401.12; the consumer must read the same W, R, D, E, H, C, P, N packet route and receives no host function, selected limit, quotient stream map, all-points metric continuity theorem, or ambient completeness datum.

Now apply the completion factorization theorem, Definition 1401.14. It places the completion-facing read through $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{MetricCompletionFinite}^{\uparrow}$ before any completion output is public.

Finally attach separatedness as the target NameCert row. Since separatedness is only a displayed row in the target completion route, the public map can reach the $\mathsf{ContinuousMap}^{\uparrow}$ boundary only after the completion rows are visible, and the read still exports no quotient equality or host equality of completed points. □

Theorem 1401.16 (CauchyContinuousMap separated uniform-modulus completion route)**.** *Any accepted* CauchyContinuousMap$^{\uparrow}$ *packet whose consumer is both separated-completion-facing and uniform-modulus-facing must expose the same finite* W, R, D, E, H, C, P, N *route through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *the* Real$^{\uparrow}$ *seal, the* ContinuousMap$^{\uparrow}$ *boundary, the* UniformModulus$^{\uparrow}$ *handoff, and the finite* MetricCompletion$^{\uparrow}$ *or* MetricCompletionFinite$^{\uparrow}$ *consumer route before any public map read is available. The route exports a finite Cauchy-name transformer surface and refuses detached uniform-continuity moduli, selected limits, quotient streams, host functions, all-points metric-continuity theorems, and ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.SeparatedUniformModulusCompletionRoute.CauchyContinuousMap separated uniform modulus completion route`

Proof. Start with the uniform-modulus side. Apply Definition 1401.11; it forces every modulus-facing read through the displayed StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, ContinuousMap boundary, transport, replay, provenance, and local naming rows before UniformModulus$^{\uparrow}$ may consume the packet.

Next use the completion side. Apply Definition 1401.14; it places the same Cauchy-name transformer rows before the finite MetricCompletion$^{\uparrow}$ or MetricCompletionFinite$^{\uparrow}$ consumer route can expose any completion-facing output.

Finally attach the separated target route by Definition 1401.15. Separatedness remains a displayed NameCert row on the completion-facing path, so the public map read must pass through the same W, R, D, E, H, C, P, N rows before either the uniform-modulus handoff or the separated completion route is visible.

The three factorizations share the carrier inventory of Definition 1401.1. Since that inventory has no coordinate for detached uniform-continuity moduli, selected limits, quotient streams, host functions, all-points metric-continuity theorems, or ambient Real$^{\uparrow}$ completeness, the combined route cannot export any of them. □

Theorem 1401.17 (CauchyContinuousMap Real-completion scope)**.** *Every Real-completion-facing read of an accepted* CauchyContinuousMap$^{\uparrow}$ *carrier*

$$M = (W, R, D, E, H, C, P, N)$$

factors through the StreamName$^{\uparrow}$ *windows* W*, the* RegSeqRat$^{\uparrow}$ *readback row* R*, the* DyadicRatCore$^{\uparrow}$ *tolerance rows* D*, the* Real$^{\uparrow}$ *seal* E*, the* ContinuousMap$^{\uparrow}$ *boundary, and the finite* MetricCompletion$^{\uparrow}$ *or* MetricCompletionFinite$^{\uparrow}$ *consumer route before any completion output is public. The read exports no host function, quotient stream, selected limit, all-points metric-continuity theorem, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.RealCompletionScope.CauchyContinuousMap real completion scope`

↪variant `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap real completion scope`

Proof. Start with the continuous-map boundary theorem, Definition 1401.4. It identifies the map-facing side of M as a finite Cauchy-name transformer whose public rows are W, R, D, E, H, C, P, N.

Apply the uniform-window obligation and uniform-modulus factorization, Definition 1401.10 and Definition 1401.11. These force every modulus- or completion-facing read to display the StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, Real seal, transport, replay, provenance, and local naming before any downstream consumer inspects the packet.

Use the completion-consumer scope theorem and the completion factorization theorem, Definition 1401.12 and Definition 1401.14. Together they place the completion read on the finite $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{MetricCompletionFinite}^{\uparrow}$ route after the same Cauchy-name transformer rows.

The carrier inventory has no coordinate for a host real function, quotient stream, selected limit, all-points metric-continuity theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Therefore a public Real-completion read is exhausted by the displayed route and cannot export any of those objects. □

Theorem 1401.18 (CauchyContinuousMap scoped surface)**.** *For every accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *carrier* $M = (W, R, D, E, H, C, P, N)$*, the rows* W, R, D, E, H, C, P, N *form one scoped Cauchy-name transformer surface consumed by* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{UniformModulus}^{\uparrow}$ *readers. The surface is exactly the finite route that exposes StreamName windows, RegSeqRat readback, DyadicRatCore tolerance checks, Real-seal handoff, componentwise transport, replay, provenance, and local naming before any downstream consumer may inspect the packet. It exports no host function, quotient stream, full metric-continuity theorem, detached uniform-continuity modulus, or completeness claim.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap scoped surface`

Proof. The carrier boundary is fixed by Definition 1401.1. Its only exposed rows are W, R, D, E, H, C, P, N, and Definition 1401.6 shows that even composite reads concatenate those displayed packet rows rather than create host-level composition.

Window discipline is supplied by Definition 1401.7. A downstream read must reopen the StreamName windows and the RegSeqRat and DyadicRatCore rows before it reaches the next Real-seal handoff.

Regularity transport is supplied by Definition 1401.8. It keeps the W, R, D surface stable under componentwise hsame transport, so the reader cannot replace the finite route with a quotient stream or host real function.

The modulus boundary is supplied by Definition 1401.9 and Definition 1401.10. Together they require $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{UniformModulus}^{\uparrow}$ consumers to use the displayed rows while refusing a detached modulus, full metric continuity, and completeness. □

Theorem 1401.19 (CauchyContinuousMap L10 sibling route)**.** *Every* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *route accepted by an L10 real-completion client first reads the* $\mathsf{StreamName}^{\uparrow}$ *source windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger of chapter 291, and the* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38. The client receives the displayed carrier rows* W, R, D, E, H, C, P, N *and the continuity replay route attached to them; it receives no compactness principle, selected limit, quotient stream equality, or general completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap l10 sibling route`

Proof. Project the accepted carrier of Definition 1401.1. Its source-facing rows are the finite window surface W, the regular rational image-readback row R, the dyadic tolerance ledger D, and the Real-seal handoff E.

Follow the displayed continuation route C. A completion-facing client must replay the same windows and tolerance checks before it can inspect the seal, and the componentwise transport row H preserves that order.

The remaining rows P and N package and name this finite route. Since the carrier has no coordinate for compactness, selected limits, quotient stream equality, or general completeness, the L10 client can only consume the displayed sibling route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. □

Theorem 1401.20 (CauchyContinuousMap bridge scope)**.** *Every public bridge-scope read of an accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *carrier* $M = (W, R, D, E, H, C, P, N)$ *factors through the finite Cauchy-name transformer boundary of Definition 1401.4. The bridge-facing rows are exactly* W, R, D, E, H, C, P, N*: StreamName windows, RegSeqRat image readback, DyadicRatCore tolerance data, Real seal handoff, componentwise transport, replay, provenance, and local naming. The scope prepares the route to the* $\mathsf{ContinuousMap}^{\uparrow}$ *boundary without claiming bridge checking, a standard bridge theorem, host functions, all-points metric continuity, detached uniform-continuity moduli, quotient streams, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier of Definition 1401.1. It exposes only the rows W, R, D, E, H, C, P, N, so any bridge-scope consumer has to use the same finite Cauchy-name transformer surface as the rest of the chapter.

Apply the continuous-map boundary theorem, Definition 1401.4. It identifies the $\mathsf{ContinuousMap}^{\uparrow}$ side as a boundary row for the displayed Cauchy-name transformer, not as a host function or a full metric-continuity theorem.

Use the scoped-surface theorem, Definition 1401.18. It binds W, R, D, E, H, C, P, N as the public surface consumed by $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{UniformModulus}^{\uparrow}$ readers before any downstream inspection.

The bridge scope therefore records exactly which rows face the standard boundary. Since the carrier has no coordinate for bridge checking, host functions, all-points metric continuity, detached moduli, quotient streams, selected limits, or ambient completeness, none of those claims is exported by this child route. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap bridge scope`

Theorem 1401.21 (CauchyContinuousMap regular-Cauchy boundedness route)**.** *Every accepted* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *packet whose source and image are consumed by an L10 completion client must expose the* $\mathsf{RegularCauchyBoundedness}^{\uparrow}$ *row after the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows have been displayed. The boundedness row is read as the finite induction certificate of Definition 9128.3; it does not supply a host function, quotient stream, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the L10 sibling route of Definition 1401.19. It forces the completion client to read the StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, and Real seal before any map-facing output is consumed.

Next use the Real-completion scope theorem, Definition 1401.17. The same accepted packet remains confined to the displayed completion route; it cannot replace the source or image by a host function, quotient stream, selected limit, or ambient completeness witness.

Finally attach the boundedness row through Definition 9128.3. That theorem identifies the bound as a finite induction certificate over the displayed stream window, regular readback, dyadic ledger, and modulus threshold. Therefore the L10 completion client receives the $\mathsf{RegularCauchyBoundedness}^{\uparrow}$ row only after the existing StreamName, RegSeqRat, DyadicRatCore, CauchyModulus, and Real rows are visible. □

Lean4 ✓ `BEDC.Derived.CauchyContinuousMapUp.CauchyContinuousMap regular cauchy boundedness route`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyContinuousMap}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyContinuousMap}^{\uparrow}$ packet is generated from finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{RegSeqRat}^{\uparrow}$ image-readback row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{Real}^{\uparrow}$ seal handoff, displayed hsame transports, Cont replay routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyContinuousMap}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1401.18 and the bridge-scope child Definition 1401.20 bind the finite Cauchy-name transformer rows as the public bridge-facing surface, with the uniform-window, uniform-modulus, completion-factorization, separated uniform-modulus completion, Real-completion, mature paper-side example, and cross-chapter completion-consumer rows remaining inside the same displayed package.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyContinuousMap}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.CauchyContinuousMapUp`

Bridge status: none

Not claimed: This chapter does not close full ContinuousMap$^{\uparrow}$, metric continuity, uniform continuity, completeness, quotient streams, or host real functions.

Upgrade path: The next verification step is checked theorem coverage for the same mature Cauchy-name transformer surface; the paper-side examples and cross-chapter completion consumers are included here.

Chapter 1402

A Concrete Naming Certificate for $\mathsf{IntermediateValue}^{\uparrow}$

Following Bishop and Bridges' constructive intermediate-value reading, the $\mathsf{IntermediateValue}^{\uparrow}$ packet records the finite bisection route by which opposite endpoint signs, a displayed continuity modulus, and located interval windows generate a real-facing root-location seal. The certificate is a NameCert reconstruction of the bisection argument: it consumes the real-name boundary of chapter 38, the finite branch ledger of chapter 361, and the nested-window carrier of chapter 320, but it does not claim open-cover compactness, quotient reals, host equality of real values, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The packet also reads its endpoint cells through the located interval surface of chapter 394 and its function data through the pointwise-modulus carrier of chapter 130. Thus the intermediate-value route is a finite ledger over displayed source rows, not a global theorem about all continuous maps on a host interval.

Definition 1402.1 (IntermediateValue located-sign carrier)**.** *An* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (J, A, B, F, M, D, N, E, H, C, P, Q)$$

with the following visible rows:

1. *J is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the inspected endpoint interval and its rational and dyadic endpoint cells;*
2. *A and B are the endpoint sign rows, one recording the displayed negative-side read and one recording the displayed positive-side read after both endpoints have been transported into the same located interval packet;*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row carrying the map graph, pointwise modulus, and metric-distance witness used by the sign inspections;*
4. *M is the finite modulus budget row selecting the dyadic precision at which the sign reads and midpoint tests are performed;*
5. *D is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger whose midpoint choices retain an interval with opposite displayed signs at the requested finite window;*
6. *N is the* $\mathsf{NestedInterval}^{\uparrow}$ *row obtained by threading the retained intervals of the bisection ledger;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row offered to downstream root-location consumers;*

8. *H stores the* hsame *transports for the located interval, sign rows, continuous-map row, modulus budget, bisection ledger, nested interval row, and real seal;*
9. *C stores the displayed* Cont *read routes by which a consumer reaches exactly those rows;*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *Q is the local* $\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$ *evidence row.*

The carrier predicate asserts that these rows form one finite located-sign bisection packet. The packet has no field for a host real root, a quotient of real names, an order-completeness principle, a real trichotomy oracle, or an open-cover compactness argument.

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueTasteGate single carrier alignment`

Theorem 1402.2 (IntermediateValue dyadic bisection obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$ *surface has five obligations:*

1. *carrier: admission of the finite* BHist *packet of Definition 1402.1;*
2. *endpoint sign exactness: the displayed negative and positive endpoint reads are routed through J, F, M, H, and C, and every transported sign read remains attached to the same located interval row;*
3. *bisection ledger exactness: each midpoint decision in D is the displayed branch row whose retained subinterval preserves the transported opposite-sign boundary;*
4. *nested-window stability: the retained branch prefix in D repacks as the* $\mathsf{NestedInterval}^{\uparrow}$ *row N through the displayed* hsame *transports and* Cont *routes;*
5. *real-seal handoff: the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed only after the located interval row, endpoint signs, continuous-map modulus row, bisection ledger, nested interval row, provenance row, and local NameCert row have all been read.*

These obligations are internal to the displayed packet and do not use compactness, quotient equality of real names, host real trichotomy, or completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier dyadic bisection obligations`

Proof. Carrier admission is projection from the tuple V. Its coordinates are exactly the located interval, endpoint sign, continuous-map, modulus, bisection, nested-window, real-seal, transport, continuation, provenance, and local naming rows listed in Definition 1402.1.

Endpoint sign exactness reads the two endpoint signs only through the located interval and continuous-map rows. The stored hsame and Cont data move both endpoint reads into the same finite window before any midpoint branch is inspected.

Bisection ledger exactness is the finite branch invariant inherited from the displayed $\mathsf{DyadicBisection}^{\uparrow}$ row. Each retained subinterval is selected by a visible midpoint row, and the opposite-sign boundary is carried forward as part of the same packet.

Nested-window stability repacks the retained branch prefix as the $\mathsf{NestedInterval}^{\uparrow}$ row. The repacking uses only the branch ledger, endpoint cells, and transport routes already present in V.

The real-seal handoff then exposes E through the same displayed provenance. Since no coordinate of V contains compactness data, quotient-real equality, a trichotomy oracle, or a completeness theorem, none of these can participate in the seed certificate. □

Theorem 1402.3 (IntermediateValue bisection-window scope)**.** *Let* $V = (J, A, B, F, M, D, N, E, H, C, P, Q)$ *be an accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier. Every accepted root-bracket export from* V *factors through the displayed* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger* D*, the retained* $\mathsf{NestedInterval}^{\uparrow}$ *window* N*, and the source* $\mathsf{LocatedInterval}^{\uparrow}$ *row* J *before any* $\mathsf{Real}^{\uparrow}$ *seal or root-location consumer can read* E*.*

The factorization is stable under the componentwise hsame *rows in* H*, is replayed only through the displayed* Cont *row* C*, and remains attached to the same* BHist*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$ *evidence. It does not use unrestricted completeness, open-cover compactness, quotient real equality, a selected root, or classical trichotomy.*

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier bisection window scope`

Proof. Project the accepted carrier and read the bisection coordinates. The only row that stores midpoint decisions is D, and the only retained-window row obtained from those decisions is N.

The source interval is fixed by J. Each branch export therefore has to pass from J to D and then to N before the seal row E can be exposed to a root-location consumer.

Transport and replay do not create a second route. The rows H and C move and replay the same coordinates, while P and Q package and name the same finite carrier.

Since the carrier has no coordinate for unrestricted completeness, open-cover compactness, quotient equality, a selected root, or classical trichotomy, the bisection-window scope cannot export any of these objects. □

Theorem 1402.4 (IntermediateValue sign-change ledger)**.** *Let* $V = (J, A, B, F, M, D, N, E, H, C, P, Q)$ *be an accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier. Before* V *exports a root bracket, the endpoint sign rows* A, B *must be visible through the same* $\mathsf{LocatedInterval}^{\uparrow}$ *row* J*, the same* $\mathsf{ContinuousMap}^{\uparrow}$ *row* F*, and the same finite modulus budget* M*. Each retained branch row in* D *records the transported sign-change boundary used to choose the next displayed subinterval.*

Thus the sign-change information is a ledger inside the finite carrier, not a host predicate over all real points. It is transported by H*, replayed by* C*, sourced by* P*, and named by* Q*, with no appeal to real trichotomy, selected roots, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier sign change ledger`

Proof. Begin with the endpoint sign rows. The carrier stores them as A and B, and both are attached to the located interval row J through the continuous-map and modulus rows F, M.

The bisection ledger can read only those displayed signs. Each midpoint decision in D retains the subinterval whose endpoint rows still carry the transported opposite-sign boundary.

The structural rows preserve the ledger. The transport row H moves the sign rows componentwise, C replays the same route, and P, Q source and name the packet.

No carrier coordinate supplies a global sign predicate, trichotomy oracle, selected root, quotient equality, or completeness theorem. The sign-change evidence is therefore exactly the finite ledger visible before the bracket is exported. □

Theorem 1402.5 (IntermediateValue Real seal nonescape)**.** *Every accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *real-facing consumer factors through*

$$\mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{DyadicBisection}^{\uparrow} \longmapsto \mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

by first reading J*, then* F, M, A, B*, then the branch ledger* D*, then the retained window* N*, and only then the seal row* E *with* H, C, P, Q*.*

Consequently the $\mathsf{Real}^{\uparrow}$ *seal is a nonescape boundary for the finite bisection route. A consumer cannot replace it by unrestricted completeness of* $\mathsf{Real}^{\uparrow}$*, an infinite nested intersection, quotient equality of real names, classical trichotomy, compactness, or an externally selected root.*

Proof. Read the consumer route from the continuation row C. The route starts at the located interval row J and the continuous-map data F, M because the endpoint sign rows are meaningful only over those displayed source cells.

Next inspect the branch and retained-window rows. The ledger D records the finite bisection choices, and N repacks the retained branch prefix as the nested-window row.

The seal row E is downstream from those rows. The structural rows H, C, P, Q transport, replay, source, and name the same route, so there is no separate Real-facing coordinate.

Since the packet contains neither a completeness principle nor an infinite intersection, quotient equality, trichotomy decision, compactness theorem, or selected root, every real-facing consumer remains inside the displayed bisection route. □

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier real seal nonescape`

Theorem 1402.6 (IntermediateValue real seal handoff)**.** *For every accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier, every* $\mathsf{Real}^{\uparrow}$ *or root-location consumer factors through the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger, the* $\mathsf{NestedInterval}^{\uparrow}$ *retained window, the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row, the displayed* BHist *packet, the* hsame *transport rows, the* Cont *read routes, the* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$ *row.*

Consequently the consumer route cannot bypass the finite located-sign bisection packet by reading a host root, an infinite nested intersection, quotient equality of real names, real trichotomy, open-cover compactness, or an ambient completeness row.

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier real seal handoff`

Proof. Start from the accepted carrier $V = (J, A, B, F, M, D, N, E, H, C, P, Q)$. A root-location consumer can reach the real-facing row only through the continuation route C, so its first readable data are the located interval row J, the endpoint sign rows A, B, and the continuous-map row F with its finite modulus budget M.

Next route the midpoint decisions through the bisection ledger. The ledger D supplies the retained branch prefix, and Definition 1402.2 keeps every branch choice attached to the transported endpoint signs and the displayed modulus row.

Then read the nested window. The retained branch prefix repacks as the $\mathsf{NestedInterval}^{\uparrow}$ row N, so the real-facing request reaches a finite nested interval window before it reaches the seal row.

Finally expose E with its structural rows. The transports H, routes C, provenance P, and local certificate row Q bind the $\mathsf{Real}^{\uparrow}$ read to the finite packet. Every named consumer therefore factors through the stated rows, and there is no available coordinate for a host root, infinite intersection, quotient equality, trichotomy decision, compactness theorem, or completeness principle. □

Theorem 1402.7 (IntermediateValue bisection convergence handoff)**.** *For every accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier*

$$V = (J, A, B, F, M, D, N, E, H, C, P, Q),$$

if the retained branch prefix D *and nested window* N *are read through the* $\mathsf{BisectionConvergence}^{\uparrow}$ *packet supplied by Definition 1804.1, then every root-location or* $\mathsf{Real}^{\uparrow}$ *consumer factors through* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{DyadicBisection}^{\uparrow}$*,* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{BisectionConvergence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before reading* E*.*

Consequently the intermediate-value route can consume the named finite convergence certificate without introducing a selected root, quotient real equality, real trichotomy, countable choice, compactness, or an ambient completeness row.

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier bisection convergence handoff`

Proof. Project the accepted carrier $V = (J, A, B, F, M, D, N, E, H, C, P, Q)$. By Definition 1402.6, any root-location or $\mathsf{Real}^{\uparrow}$ consumer first reaches the located interval row J, the dyadic branch ledger D, the retained nested window N, the displayed packet rows, and the local $\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$ evidence before it can read the seal row E.

Now read D and N through the $\mathsf{BisectionConvergence}^{\uparrow}$ carrier of Definition 1804.1. The carrier places the located interval source, dyadic branch ledger, retained nested windows, tail-diameter schedule, StreamName windows, RegSeqRat readback, and terminal Real seal in one displayed finite route.

Apply Definition 1804.3 to the retained branch prefix and nested window. The convergence packet forces every tolerance request to pass through the displayed branch depth and retained-window diameter bound before any $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ readback is exposed.

Finally apply Definition 1804.4. The StreamName and RegSeqRat stages precede the terminal $\mathsf{Real}^{\uparrow}$ seal, so the original intermediate-value consumer factors through the stated $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{BisectionConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route before reading E. Since neither carrier has a coordinate for a selected root, quotient real equality, trichotomy, choice, compactness, or ambient completeness, the composite handoff exports none of them. □

Theorem 1402.8 (IntermediateValue located sign scope)**.** *Every root-bracket consumer of an accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier must pass through the located interval row* J*, the endpoint sign rows* A, B*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row* F, M*, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger* D*, the* $\mathsf{NestedInterval}^{\uparrow}$ *retained window* N*, the* $\mathsf{BisectionConvergence}^{\uparrow}$ *convergence packet when that packet is supplied, the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks of the convergence route, and only then the* $\mathsf{Real}^{\uparrow}$ *seal row* E *with* H, C, P, Q*.*

Thus the Real-facing route is finite and L10-safe: it is a displayed BEDC path through located signs, finite bisection, retained nested windows, convergence readback, and the terminal seal, not a route through selected roots, quotient real equality, real trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier located sign scope`

Proof. Start from the carrier definition and the dyadic bisection obligations. They place the endpoint signs inside the same located interval row J and the same continuous-map modulus row F, M before any branch ledger can be inspected.

Apply the real seal handoff. It forces every root-location consumer to read the dyadic branch ledger D and the retained nested window N before the seal row E is reachable.

Use the bisection convergence handoff for the completion-facing part of the route. When the retained branch prefix and nested window are consumed through $\mathsf{BisectionConvergence}^{\uparrow}$, the StreamName and RegSeqRat readbacks precede the terminal $\mathsf{Real}^{\uparrow}$ seal.

The structural rows H, C, P, Q transport, replay, source, and name exactly this route. Since the carrier and the convergence packet contain no selected root, quotient equality, trichotomy oracle, choice selector, compactness theorem, or ambient completeness row, the located-sign scope is finite and L10-safe. □

Theorem 1402.9 (IntermediateValue sign-bracket carrier)**.** *For every accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier*

$$V = (J, A, B, F, M, D, N, E, H, C, P, Q),$$

the located sign-bracket surface is exactly the displayed packet whose endpoint cells are read through $\mathsf{LocatedInterval}^{\uparrow}$*, whose sign inspections are read through* $\mathsf{ContinuousMap}^{\uparrow}$ *and the finite modulus row* M*, whose branch history is read through* $\mathsf{DyadicBisection}^{\uparrow}$*, and whose retained interval stream is read through* $\mathsf{NestedInterval}^{\uparrow}$*. The structural rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *attach these reads to one local packet before any* $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

Thus the sign-bracket carrier has no separate coordinate for a host root, quotient real equality, real trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier sign bracket carrier`

Proof. Project the carrier of Definition 1402.1. The located interval row J supplies the two endpoint cells, while A and B record the opposite displayed sign reads over the same transported source interval.

The function row F and modulus row M are the only rows that can justify those sign inspections. Hence every endpoint sign read is anchored in $\mathsf{ContinuousMap}^{\uparrow}$ data before the branch ledger is consulted.

The branch row D and retained row N then record the finite bisection history and its nested-window image. The rows H, C, P, Q transport, replay, source, and name the same packet, so the carrier exposes one located sign bracket rather than independent host data.

Since no coordinate of V stores a root selector, quotient equality, trichotomy oracle, compactness theorem, or completeness theorem, no such object can be exported by the carrier. □

Theorem 1402.10 (IntermediateValue bisection nesting)**.** *Let* $V = (J, A, B, F, M, D, N, E, H, C, P, Q)$ *be an accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier. Every retained branch read in* D *that is offered to a root-location consumer must pass through the dyadic bisection route of* $\mathsf{DyadicBisection}^{\uparrow}$ *and then through the nested-window route of* $\mathsf{NestedInterval}^{\uparrow}$ *before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is reachable. The route is stable under the displayed* hsame *transports and is replayed only by the* Cont *row attached to the same* BHist *packet.*

Proof. Begin with a retained branch read. The row D is the only carrier coordinate that records midpoint choices, retained subintervals, and finite branch prefixes.

The nested row N is downstream of D. It repacks the retained branch prefix as a nested interval window, and the real-facing consumer cannot reach E until that nested-window row has been displayed.

Transport stability is componentwise. The row H transports the located interval, sign rows, bisection ledger, nested window, and seal together, while C replays the same ordered route for consumers.

The provenance row P and local certificate row Q bind this route to one $\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$ packet. Thus the bisection nesting path is D followed by N inside the displayed BHist carrier, with no bypass through a selected root or ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier bisection nesting`

Theorem 1402.11 (IntermediateValue located-sign window exactness)**.** *Let* $V = (J, A, B, F, M, D, N, E, H, C, P, Q$ *be an accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier. Every endpoint sign read exported by* V *factors through the same* $\mathsf{LocatedInterval}^{\uparrow}$ *row* J*, the same* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row* F, M*, the same* $\mathsf{DyadicBisection}^{\uparrow}$

branch ledger D, and the same $\mathsf{NestedInterval}^{\uparrow}$ *retained window N before any* $\mathsf{Real}^{\uparrow}$ *seal is reachable. The factorization is stable under the displayed* BHist *packet, componentwise* hsame *transports,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$ *route.*

Thus the two endpoint signs are exact reads of one located-sign window rather than independent host predicates, selected roots, quotient real equalities, trichotomy decisions, compactness witnesses, or ambient $\mathsf{Real}^{\uparrow}$ *completeness data.*

Proof. Start with the accepted carrier and project the rows listed in Definition 1402.1. The endpoint sign rows A and B are attached to the located interval row J, and Definition 1402.9 identifies this attachment as the displayed sign-bracket surface.

The function and modulus data are read through F and M. By the dyadic bisection obligations of Definition 1402.2, every sign inspection used by the branch ledger remains attached to that same located interval and continuous-map route.

Apply Definition 1402.10. The retained branch read then passes through D and N before the seal row E can be consumed, with H and C preserving the same rows componentwise.

Finally use Definition 1402.6. The real-facing route includes the provenance row P and local naming row Q, so there is no coordinate from which a selected root, quotient equality, trichotomy oracle, compactness theorem, or ambient completeness principle can alter the located-sign window. □

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier located sign window exactness`

Theorem 1402.12 (IntermediateValue modulus branch transport)**.** *Let $V = (J, A, B, F, M, D, N, E, H, C, P, Q)$ be an accepted* $\mathsf{IntermediateValue}^{\uparrow}$ *carrier. Transporting the continuous-map modulus row F, M along the displayed* hsame *data preserves the retained branch ledger D and its nested-window image N. Consequently every transported root-location request still reads the same* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint cells, the same dyadic midpoint choices, the same retained branch window, and the same* $\mathsf{Real}^{\uparrow}$ *handoff route.*

The transport does not introduce a selected root, quotient real equality, trichotomy, compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness; it only replays the existing finite branch packet through H, C, P, and Q.*

Proof. Read the transport row H of the carrier. Its component for F, M is stored with the same located interval row J and the same endpoint sign rows A, B, so a transported modulus request cannot detach the sign test from the source window.

The dyadic branch ledger is already bound to those sign tests by Definition 1402.2. Therefore transporting the modulus row preserves the branch choices recorded in D rather than recomputing them from host-level sign predicates.

Next apply Definition 1402.10. The retained branch prefix is repacked as N through the same continuation route C, and the route to the seal row E still passes through D followed by N.

Finally Definition 1402.6 identifies the only real-facing export. Since the carrier has no coordinate for a root selector, quotient equality, trichotomy, compactness, or completeness, modulus transport cannot add any of these objects to the retained branch packet. □

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier modulus branch transport`

Theorem 1402.13 (IntermediateValue NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$ *obligation surface for the carrier of Definition 1402.1 consists exactly of:*

1. *admission of the finite located sign-bracket carrier over* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*

2. *endpoint sign transport through* BHist, hsame, *and* Cont *without detaching the two signs from the same located interval row;*
3. *bisection branch nesting through* DyadicBisection$^{\uparrow}$ *and* NestedInterval$^{\uparrow}$ *before the real-facing seal is exposed;*
4. *provenance and local naming through* Pkg *and* NameCert *for the same displayed rows.*

No additional obligation asks for a selected root, quotient real equality, trichotomy, open-cover compactness, countable choice, or ambient completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier namecert obligations`

Proof. The carrier obligation is Definition 1402.9. It identifies the displayed rows and excludes every host-level datum not present in the finite packet.

Endpoint sign transport is the second clause of Definition 1402.2. The two sign rows move only through H and are replayed only through C over the same located interval and continuous-map data.

Bisection branch nesting is Definition 1402.10. It forces every retained branch read through D and then N before the Real$^{\uparrow}$ seal can be consumed.

Finally, P and Q supply the provenance and local naming rows for exactly those carrier coordinates. Since the listed rows exhaust the packet, the excluded host objects cannot become local obligations. □

Theorem 1402.14 (IntermediateValue obligation closure package)**.** *The displayed located-sign carrier of Definition 1402.1, the dyadic bisection obligations of Definition 1402.2, the real seal handoff of Definition 1402.6, the bisection convergence handoff of Definition 1402.7, the modulus branch transport of Definition 1402.12, and the NameCert obligation surface of Definition 1402.13 form the complete obligation package for the current finite* IntermediateValue$^{\uparrow}$ *surface.*

Every root-location or Real$^{\uparrow}$ *consumer must therefore read the same located interval, endpoint sign, continuous-map modulus, dyadic branch ledger, nested window, real seal,* hsame, Cont, Pkg, *and local* NameCert *rows before any real-facing handoff is exposed.*

Proof. Project the carrier rows of Definition 1402.1. The dyadic bisection theorem fixes the carrier, endpoint signs, branch ledger, nested-window stability, and real-seal obligation clauses.

The handoff theorems then bind every consumer route. The real seal handoff prevents a direct read of E, while the bisection convergence handoff routes the retained branch and nested-window rows through the displayed convergence packet when that packet is supplied.

Finally apply modulus branch transport and the NameCert obligations theorem. These results account for the transported modulus branch and the local naming rows, so the listed clauses exhaust the finite obligation surface and leave no coordinate for a selected root, quotient real equality, trichotomy, compactness, choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier obligation closure package`

Theorem 1402.15 (IntermediateValue scoped carrier dependency package)**.** *The finite bisection route of an accepted* IntermediateValue$^{\uparrow}$ *carrier is scoped by the displayed dependency package*

LocatedInterval$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DyadicBisection$^{\uparrow}$, NestedInterval$^{\uparrow}$, BisectionConvergence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRa

Every root-location or Real$^{\uparrow}$ *consumer must read the located interval row, the continuous-map modulus row, the dyadic branch ledger, the nested retained window, the bisection-convergence handoff*

when supplied, the StreamName and RegSeqRat readbacks of that handoff, the terminal Real seal, and the structural BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows before it reaches the exported bracket.*

This dependency package is the whole scoped carrier boundary for the current IntermediateValue$^{\uparrow}$ *chapter. It does not add open-cover compactness, quotient real equality, host equality of values, selected roots, trichotomy, countable choice, infinite nested intersections, or ambient completeness of* Real$^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueScopedCarrierDependencyPackage`

Proof. Start with Definition 1402.14. It already binds the located-sign carrier, dyadic bisection obligations, Real-seal handoff, bisection convergence handoff, modulus transport, and local NameCert obligations into one finite package.

The carrier rows name the scoped dependencies. The located interval, continuous map, dyadic bisection, nested interval, Real seal, BHist, hsame, Cont, Pkg, and NameCert rows are visible in Definition 1402.1, while Definition 1402.7 supplies the BisectionConvergence$^{\uparrow}$, StreamName$^{\uparrow}$, and RegSeqRat$^{\uparrow}$ part of the route.

Combining these two reads gives the stated scoped boundary. Since the cited theorems exclude selected roots, quotient real equality, trichotomy, compactness, choice, infinite intersections, and ambient completeness, the dependency package exports none of those objects. □

Theorem 1402.16 (IntermediateValue public export route)**.** *Every accepted* IntermediateValue$^{\uparrow}$ *public consumer reads the located-sign carrier of Definition 1402.1, the dyadic bisection obligations of Definition 1402.2, the bisection-window scope of Definition 1402.10, the Real seal nonescape route of Definition 1402.6, and the scoped carrier dependency package of Definition 1402.15 before treating the bisection route as the public BEDC intermediate-value export.*

The public export is only this finite route through located interval, endpoint sign, continuous-map modulus, dyadic branch ledger, nested-window, Real seal, BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. It does not provide a selected root, quotient real equality, host equality of values, trichotomy, countable choice, open-cover compactness, infinite nested intersections, or ambient completeness of* Real$^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier public export route`

Proof. Start with the located-sign carrier and the dyadic bisection obligations. The carrier displays the interval, endpoint signs, continuous-map modulus, branch ledger, retained window, Real seal, transport, replay, provenance, and local naming rows, while the bisection obligations force every branch read through the same finite packet.

Next apply the bisection nesting theorem and the Real seal handoff. They place the retained bisection window before the terminal real-facing row and prevent a consumer from reading the Real$^{\uparrow}$ seal as detached endpoint data.

Finally use the scoped carrier dependency package. It binds the StreamName, RegSeqRat, bisection-convergence, structural, and local naming rows to the same carrier surface, so a public consumer receives the intermediate-value route only as the displayed finite BEDC export and not as any of the excluded host principles. □

Theorem 1402.17 (IntermediateValue bridged finite bisection export)**.** *Every bridge-facing read of* IntermediateValue$^{\uparrow}$ *preserves the finite located-sign bisection route through*

LocatedInterval$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DyadicBisection$^{\uparrow}$, NestedInterval$^{\uparrow}$, BisectionConvergence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRa

The bridge reads the located interval, endpoint signs, continuous-map modulus, dyadic branch ledger, retained nested interval, bisection-convergence handoff, stream windows, regular-rational readback, terminal real seal, componentwise transport, displayed replay, package provenance, and local naming rows before exporting the intermediate-value packet. It exports no selected root, quotient real equality, trichotomy, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the public export route of Definition 1402.16. It already requires a public consumer to read the located-sign carrier, dyadic bisection obligations, bisection-window scope, Real seal handoff, and scoped carrier dependency package before treating the packet as an intermediate-value export.

The scoped carrier dependency package of Definition 1402.15 supplies the bridge-facing rows. It binds the located interval, continuous-map, dyadic bisection, nested interval, bisection-convergence, StreamName, RegSeqRat, Real seal, hsame, Cont, Pkg, and NameCert data into one finite dependency package.

A bridge-facing read can therefore export only that package. The cited route has no carrier coordinate for selected roots, quotient real equality, trichotomy, open-cover compactness, countable choice, or ambient completeness, so the bridge cannot supply any of those excluded principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$.

Constructive story: An $\mathsf{IntermediateValue}^{\uparrow}$ packet is generated from a located interval row, two endpoint sign rows, a $\mathsf{ContinuousMap}^{\uparrow}$ modulus row, a finite $\mathsf{DyadicBisection}^{\uparrow}$ branch ledger, a $\mathsf{NestedInterval}^{\uparrow}$ retained window, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature paper surface is the bridged finite located-sign bisection export of Definition 1402.17, together with the public export route of Definition 1402.16 and the scoped dependency package of Definition 1402.15.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{IntermediateValue}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.IntermediateValueUp.IntermediateValueCarrier\_located\_sign\_scope`

Bridge status: paperBridge

Not claimed: The chapter does not close open-cover compactness, quotient reals, host equality of real values, real trichotomy, selected roots, infinite nested intersections, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: No further paper theory-axis upgrade is pending; bridge checking remains formal-axis work for the same finite located-sign bisection route.

Chapter 1403

A Concrete Naming Certificate for $\mathsf{FilteredCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and Bourbaki, *General Topology*, the FilteredCauchyCompletio packet records the finite BEDC route by which Cauchy filters reach the Real-completion interface. It is built over $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, RealCompletionExactBoundaryUp, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

The dependency anchors are the finite filter surface of chapter 333, the sequence-space handoff of chapter 406, and the Real boundary of chapter 1120. The uniform criterion supplies the common-tail test before any route reaches the Real seal, while stream names, regular rational rows, and dyadic ledgers keep the consumer boundary finite.

Definition 1403.1 (Filtered Cauchy completion carrier)**.** *A* $\mathsf{FilteredCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, U, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row carrying the finite filterbase and common-window evidence;*
2. *U is the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *row that tests the same finite filter windows by uniform tails;*
3. *S is the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *handoff row exposing the associated* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readings;*
4. *Q is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *and* RealCompletionExactBoundaryUp *route reached from those same finite rows;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the displayed route;*
6. *H is the componentwise* hsame *transport row for F, U, S, Q, E;*
7. *C is the* Cont *continuation row that replays the accepted finite windows without adding host data;*
8. *P is the* Pkg *provenance over the listed completion, filter, uniform, stream, regular-rational, dyadic, transport, and seal rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FilteredCauchyCompletion}^{\uparrow}}$ *row.*

The accepted carrier exposes only these rows. It has no coordinate for a quotient stream, selected limit, host real equality, countable-choice selector, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.FilteredCauchyCompletionUp.TasteGate.FilteredCauchyCompletionTasteGate single carrier alignment`

Theorem 1403.2 (Filtered completion carrier habitation)**.** *Whenever the rows $F, U, S, Q, E, H, C, P, N$ occur in one finite* BHist *with the dependencies listed in Definition 1403.1, they assemble an accepted* FilteredCauchyCompletion$^{\uparrow}$ *carrier. Conversely, every accepted carrier projects to exactly those nine displayed rows.*

Proof. The forward direction reads the finite history in the carrier order. The CauchyFilter$^{\uparrow}$ row supplies the finite filterbase, the uniform criterion row supplies the common-tail test, the sequence-space row supplies the stream, regular-rational, and dyadic readings, and the completion route supplies the Real-boundary handoff and terminal seal.

Transport, continuation, package provenance, and local naming are the final four displayed coordinates. Repacking these rows gives the named carrier.

For the reverse direction, project an accepted carrier by its definition. No extra coordinate is available, so the projection is exhausted by the nine listed rows. □

Theorem 1403.3 (Common-filter classifier transport)**.** *Two accepted* FilteredCauchyCompletion$^{\uparrow}$ *carriers classify together only by a displayed common* CauchyFilter$^{\uparrow}$ *refinement whose uniform-tail test, sequence space handoff, Real-completion route, terminal Real seal,* hsame *transport,* Cont *continuation,* Pkg *provenance, and local* NameCert *rows are transported componentwise.*

Proof. Project both carriers to their F rows and compare those rows by the common finite filter refinement supplied by CauchyFilter$^{\uparrow}$. The classifier has no access to a host filter or quotient of streams.

Once the filter rows share a displayed refinement, transport the U, S, Q, E rows componentwise along H and replay the same reads through C. The package row records that these transported reads remain on the same finite dependency anchors.

Repacking the transported rows gives the classifier judgement for the two carriers. Reading such a judgement back yields exactly the common filter refinement and the listed componentwise transports. □

Theorem 1403.4 (Uniform-tail exactness)**.** *For an accepted carrier $K = (F, U, S, Q, E, H, C, P, N)$, every completion-facing read of Q first passes through the uniform-tail row U attached to the same* CauchyFilter$^{\uparrow}$ *row F and the same* CauchySequenceSpace$^{\uparrow}$ *handoff S. No Real seal consumer can bypass U by using a selected subsequence, quotient stream, or host completion point.*

Proof. Read the carrier coordinates. The route to Q is listed after F, U, S, so the completion-facing consumer sees the filterbase, uniform-tail test, and sequence-space handoff before it can read the Real-completion boundary.

The continuation row C only replays the accepted finite windows, and the transport row H only compares displayed coordinates. Neither row introduces a selected subsequence, quotient stream, or host completion point.

Thus the uniform-tail row is the exact gate for completion-facing reads. Any consumer that bypasses it has left the displayed carrier. □

Theorem 1403.5 (Completion handoff factorization)**.** *Every* RealCauchyCompletion$^{\uparrow}$ *or* RealCompletionExactBoun *handoff exported by an accepted* FilteredCauchyCompletion$^{\uparrow}$ *carrier factors through the rows* F, U, S, H, C, P, N *before reaching* Q *and the terminal seal* E*.*

Proof. Start from the carrier decomposition. The handoff row Q is not independent: it is stored as the route reached from the same finite filter, uniform-tail, sequence-space, transport, continuation, provenance, and naming rows.

The sequence-space row supplies the visible stream-name, regular-rational, and dyadic readings. The uniform-tail row checks those readings against the common filter classifier before the completion boundary is exposed.

Consequently every exported completion handoff factors through F, U, S, H, C, P, N and only then reaches Q and E. □

Theorem 1403.6 (Filtered completion no-escape)**.** *An accepted* FilteredCauchyCompletion$^{\uparrow}$ *carrier gives no route to quotient streams, selected limits, host real equality, countable choice, or ambient completeness. Every consumer of the packet is confined to the finite rows* $F, U, S, Q, E, H, C, P, N$*.*

Proof. The excluded objects are not coordinates of Definition 1403.1. A consumer can project the filter row, uniform criterion row, sequence-space handoff, completion route, Real seal, transport, continuation, package, and local naming row, and nothing else.

The previous factorization theorem shows that even completion-facing reads must pass through those displayed rows. The common-filter transport theorem shows the same boundary after classifier comparison.

Therefore any route requiring quotient streams, selected limits, host real equality, countable choice, or ambient completeness lies outside the accepted carrier. □

Closure status for NameCert$_{\text{FilteredCauchyCompletion}^{\uparrow}}$**.**

Constructive story: The filtered Cauchy completion packet is generated from a finite Cauchy filter row, a uniform-tail criterion row, a Cauchy sequence-space handoff, a Real-completion boundary route, a terminal Real seal, and the displayed hsame, Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{FilteredCauchyCompletion}^{\uparrow}}$, seed)

Scope closed: This chapter records the finite carrier and five seed obligations for routing Cauchy filters to the Real-completion boundary through displayed BEDC rows.

Formal verification: FormalStatus(NameCert$_{\text{FilteredCauchyCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: It does not claim quotient-stream equality, selected limits, host real equality, countable choice, ambient completeness, or a standard bridge.

Upgrade path: Reaching obligationClosure requires Lean-backed carrier, classifier-transport, uniform-tail, handoff-factorization, and no-escape targets for the displayed packet.

Chapter 1404

A Concrete Naming Certificate for RegularCauchyEquivalence$^{\uparrow}$

The RegularCauchyEquivalence$^{\uparrow}$ packet records the finite equality boundary for regular Cauchy names before a Real$^{\uparrow}$ seal is consumed. Following Bishop–Bridges constructive analysis, two regular rational names are compared by common finite windows, dyadic tolerance ledgers, displayed transports, and local certificate rows, not by a quotient of streams or by host real equality.

The route is the Phase Real and Completion sibling boundary. It reads regular-name rows from chapter 301, finite schedules from chapter 126, dyadic tolerance data from chapter 291, zero-tail handoff data from chapter 380, the seal boundary from chapter 38, and the locatedness consumer interface from **??**. The chapter isolates the equivalence surface used between those rows so later completion and locatedness consumers can cite one visible NameCert packet.

Definition 1404.1 (RegularCauchyEquivalence finite-window classifier)**.** *A* RegularCauchyEquivalence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(X, Y, W, D, Z, R, E, H, C, P, N)$$

with the following rows:

1. *X and Y are the two displayed* RegSeqRat$^{\uparrow}$ *source rows to be compared;*
2. *W is the common* StreamName$^{\uparrow}$ *window schedule that selects paired finite observations from X and Y;*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for every selected pair of observations;*
4. *Z is the* NullSequence$^{\uparrow}$ *zero-tail handoff row when the displayed difference stream is consumed by a real-equality classifier;*
5. *R is the pair of* Real$^{\uparrow}$ *seal rows through which the two regular names may later be read;*
6. *E is the local finite equivalence classifier, asserting that each selected common window satisfies the displayed dyadic tolerance bound;*
7. *H records the componentwise* hsame *transports for the two source rows, schedule, tolerance ledger, seal rows, and classifier row;*
8. *C records the displayed* Cont *routes by which consumers inspect those rows;*
9. *P is the* Pkg *provenance for the two regular names, the common-window schedule, the dyadic ledger, the zero-tail handoff, the real-seal rows, and the consumer routes;*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalence}^{\uparrow}}$ *row.*
The carrier stores only finite scheduled comparisons. It has no quotient stream equality, no selected limit, no countable-choice row, no trichotomy row, no host real equality, and no ambient real-completeness coordinate.

Theorem 1404.2 (RegularCauchyEquivalence refinement transport)**.** *Let* $(X, Y, W, D, Z, R, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet. If the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the common* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail handoff row, and the* $\mathsf{Real}^{\uparrow}$ *seal rows are transported componentwise by the displayed* hsame *rows in* H *and read only through the displayed* Cont *routes in* C*, then the transported rows repack as an accepted* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet with the same finite-window classifier shape.*

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.RegularCauchyEquivalence refinement transport`
Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.TasteGate.RegularCauchyEquivalence refinement transport`

Proof. Project the carrier of Definition 1404.1. Its whole comparison surface is the pair of regular Cauchy rows, one common schedule, one dyadic tolerance ledger, one zero-tail handoff row, the seal rows, and the finite classifier row.

Transport the two source rows, the schedule, and the tolerance ledger through the stated hsame rows. The transported schedule still selects paired finite observations, and every selected pair is checked against the transported dyadic ledger.

Transport the $\mathsf{NullSequence}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows only as stored rows beside the same finite comparison. Since the proof does not add a quotient equality, selected limit, countable-choice selector, trichotomy branch, host real equality, or ambient completeness datum, the transported inventory is exactly another instance of the same carrier definition. □

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.RegularCauchyEquivalenceCarrier refinement transport`

Theorem 1404.3 (RegularCauchyEquivalence real classifier boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet factors first through the two displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, then through the common* $\mathsf{StreamName}^{\uparrow}$ *windows, then through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, then through the displayed* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail handoff when equality consumption is requested, and only then reads the stored* $\mathsf{Real}^{\uparrow}$ *seal rows. The consumer receives no quotient stream equality, selected limiting real, host real equality, countable choice, trichotomy, or ambient completeness witness from the equivalence packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.TasteGate.RegularCauchyEquivalence real classifier boundary`

Proof. Start with the finite classifier of Definition 1404.1. The seal row R is stored after X, Y, W, D, Z, and E, so a seal-facing read must first pass through the two regular-name rows, the common finite-window comparison, and the available zero-tail handoff.

Use Definition 1404.2 for stability under displayed transport. It keeps the consumer route attached to the same scheduled windows and dyadic ledger while moving along hsame and Cont rows.

The carrier lists no quotient stream equality, selected limit, host real equality, choice row, trichotomy row, or completeness row. Thus the boundary between regular Cauchy names and real seals is exactly the displayed finite-window route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.RegularCauchyEquivalence real classifier boundary`

Theorem 1404.4 (RegularCauchyEquivalence NameCert obligation surface)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularCauchyEquival}}$ *obligation surface consists of five finite rows:*

1. *carrier habitation by two displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, a common* $\mathsf{StreamName}^{\uparrow}$ *window schedule, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail handoff row,* $\mathsf{Real}^{\uparrow}$ *seal rows, and displayed provenance;*
2. *classifier by finite common-window dyadic tolerance checks;*
3. *transport stability under the stored* hsame *rows and displayed* Cont *routes;*
4. *seal-boundary exactness, stating that every* $\mathsf{Real}^{\uparrow}$ *read is reached only after the common-window classifier row and the displayed zero-tail handoff when equality consumption is requested;*
5. *ledger refusal, stating that quotient stream equality, host real equality, countable choice, selected limits, trichotomy, and ambient real completeness are not packet coordinates.*

Lean4 ✓ `BEDC.Derived.RegularCauchyEquivalenceUp.RegularCauchyEquivalenceTasteGate single carrier alignment`

Proof. Carrier habitation is the displayed tuple in Definition 1404.1. It supplies two regular Cauchy names, a common schedule, dyadic tolerance rows, a zero-tail handoff row, seal rows, transports, continuations, package provenance, and the local naming row.

The classifier row is finite because it reads only windows selected by W and tolerances recorded in D. No comparison is made outside the scheduled observations.

Transport stability is Definition 1404.2. Seal-boundary exactness is Definition 1404.3. Together they keep every consumer route on the visible BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

The refusal row is immediate from the carrier inventory: there is no coordinate that can encode a quotient stream equality, selected limit, countable-choice selector, trichotomy decision, host real equality, or ambient completeness principle. □

Theorem 1404.5 (RegularCauchyEquivalence sibling route)**.** *Any completion-facing or locatedness-facing consumer that uses a* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet must read the finite classifier of Definition 1404.1. Its route is exhausted by* $X, Y, W, D, Z, R, E, H, C, P, N$*: the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, common* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail handoff,* $\mathsf{Real}^{\uparrow}$ *seal rows, classifier row, transports, continuations, package provenance, and local* $\mathsf{NameCert}$ *row. No quotient of Cauchy streams, host real equality, selected limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness data is available to that consumer.*

Proof. Project an accepted packet to the tuple of Definition 1404.1. This tuple is already the full finite inventory available to completion-facing and locatedness-facing consumers.

Apply Definition 1404.4. The NameCert rows bind carrier habitation, finite common-window classification, transport stability, seal-boundary exactness, and the ledger refusal inside the same packet.

The route to $\mathsf{LocatedReal}^{\uparrow}$ may read the same regular sources and seal rows used by **??**, but it does not gain an independent real equality or completion principle. Therefore every downstream read remains a nonquotient finite-window comparison over $X, Y, W, D, Z, R, E, H, C, P, N$. □

Theorem 1404.6 (RegularCauchyEquivalence scoped primitive route)**.** *Any completion-facing or locatedness-facing consumer of an accepted* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *packet must read exactly the tuple*

$$(X, Y, W, D, Z, R, E, H, C, P, N)$$

through the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows named in Definition 1404.1. This scoped primitive route is the whole access path to the finite equivalence classifier; no quotient of streams, host real equality, selected limit, choice row, trichotomy row, or ambient completeness row is available.*

Proof. First apply refinement transport, Definition 1404.2. It keeps the two regular names, common window, dyadic ledger, null-tail handoff, real seals, classifier, transport, replay, provenance, and local name inside the same finite packet.

Next use the real classifier boundary of Definition 1404.3. It forces every seal-facing read through the regular-name, window, tolerance, and zero-tail rows before the $\mathsf{Real}^{\uparrow}$ seal rows can be inspected.

Finally combine the NameCert obligation surface and sibling route, Definition 1404.4 and Definition 1404.5. These theorems exhaust the consumer path by the displayed tuple, so the scoped primitive route contains exactly the listed BEDC rows and no hidden quotient, host equality, selected limit, choice, trichotomy, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, a common $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{NullSequence}^{\uparrow}$ zero-tail handoff row, $\mathsf{Real}^{\uparrow}$ seal rows, a finite equivalence classifier, displayed hsame transports, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalence}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1404.1, Definition 1404.2, Definition 1404.3, Definition 1404.4, Definition 1404.5, and Definition 1404.6 display the obligation surface over RegSeqRat, StreamName, DyadicRatCore, NullSequence, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Lean theorem, a public completion quotient, host real equality, selected limits, countable choice, trichotomy, or ambient real completeness.

Upgrade path: Remaining work is Lean verification and bridge checking for the same finite regular-Cauchy equivalence route, not further paper-axis maturation.

Chapter 1405

A Concrete Naming Certificate for $\mathsf{MonotoneSubsequence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{MonotoneSubsequence}^{\uparrow}$ packet records monotone subsequences as displayed finite unary selector rows. It does not select an infinite subsequence by countable choice. The packet sits between the regular-Cauchy subsequence surface of chapter 381, the cofinal index witness of chapter 405, and the monotone-Cauchy route of chapter 438. Its endpoint side is read through the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38.

Definition 1405.1 (Monotone subsequence carrier)**.** *A* $\mathsf{MonotoneSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, M, Q, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *row whose inspected finite windows are being selected.*
2. *M is the finite monotone unary selector ledger; each displayed entry records a selector value, its source index, and the comparison row certifying monotonicity against the previously displayed selector entries.*
3. *Q is the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *evidence row for the inspected thresholds, limited to the thresholds actually present in the packet.*
4. *W is the finite family of selected* $\mathsf{StreamName}^{\uparrow}$ *windows read from S through the ledger M and the cofinal evidence Q.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger extracted from the selected windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from W and D.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the selected regular-rational handoff has been displayed.*
8. *H stores componentwise* hsame *transport for the source row, monotone selector ledger, cofinality evidence, selected windows, dyadic observations, regular handoff, Real seal, continuation, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from S, M, Q to W, from W to D, from D to R, and from R to E.*

10. *P is the* Pkg *provenance over* $\mathsf{MonotoneSubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for a host subsequence equality test, a countable-choice selector, a quotient stream, an ambient completeness principle, or a hidden infinite monotone-subsequence object.

Lean4 ✓ `BEDC.Derived.MonotoneSubsequenceUp.TasteGate.MonotoneSubsequenceTasteGate single carrier alignment`

Theorem 1405.2 (Monotone subsequence NameCert obligations)**.** *For every accepted* $\mathsf{MonotoneSubsequence}^{\uparrow}$ *carrier* $U = (S, M, Q, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed eleven-row packet;*
2. *monotone selector stability for the finite unary selector ledger M under the recorded* hsame *transports;*
3. *cofinal coverage for every inspected threshold listed in Q;*
4. *selected-window* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through W, D, R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E is consumed;*
5. *non-escape from host subsequence equality, countable choice, quotient-stream equality, and ambient completeness.*

Proof. Project the carrier of Definition 1405.1. The source row S, selector ledger M, cofinality evidence Q, selected windows W, dyadic observations D, handoff R, seal E, and structural rows H, C, P, N are the only coordinates available to the classifier.

The monotone and cofinal faces are finite. Selector stability reads the displayed comparisons inside M, while cofinal coverage reads only the inspected thresholds recorded in Q. No step quantifies over an unbounded family of undisplayed requests.

The analytic endpoint is downstream from the same finite route. The selected $\mathsf{StreamName}^{\uparrow}$ windows W produce the dyadic ledger D, the dyadic ledger produces the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R, and the Real seal E is available only after that handoff.

Finally inspect the excluded objects. Host subsequence equality, countable choice, quotient streams, and ambient completeness are not rows of U, and the structural rows only transport, replay, source, and name the displayed packet. The five listed obligations therefore exhaust the local NameCert surface. □

Theorem 1405.3 (Monotone subsequence regular-Cauchy handoff)**.** *Every accepted* $\mathsf{MonotoneSubsequence}^{\uparrow}$ *packet hands its selected monotone finite windows to* $\mathsf{RegSeqRat}^{\uparrow}$ *before any* $\mathsf{Real}^{\uparrow}$ *seal can be consumed. Equivalently, every seal-facing route factors through*

$$S, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E$$

together with H, C, P, N.

Proof. Begin with the selected-window rows. The continuation route records that W is read from the source regular-Cauchy subsequence row S, the monotone selector ledger M, and the cofinal threshold evidence Q.

Next read the regular-rational handoff. The dyadic observation ledger D is extracted from the selected StreamName windows, and the row R is the displayed $\mathsf{RegSeqRat}^{\uparrow}$ handoff reached from those dyadic observations.

Only then is the seal row available. The row E is part of the packet as the Real-facing endpoint reached through R, while H, C, P, N only preserve the same route by transport, replay, provenance, and local naming.

Thus a consumer that tries to use the $\mathsf{Real}^{\uparrow}$ seal without the selected-window $\mathsf{RegSeqRat}^{\uparrow}$ handoff leaves the accepted $\mathsf{MonotoneSubsequence}^{\uparrow}$ carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneSubsequence}^{\uparrow}$ packet is generated from a source regular-Cauchy subsequence row, a finite monotone unary selector ledger, inspected-threshold cofinality evidence, selected StreamName windows, DyadicRatCore observations, a RegSeqRat handoff, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1405.1, Definition 1405.2, and Definition 1405.3 declare the finite selector carrier, its NameCert obligations, and the regular-Cauchy handoff boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim Bolzano-Weierstrass, sequential compactness, choice-selected subsequences, quotient-stream equality, host subsequence equality, Lean verification, bridge checking, or RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, monotone selector stability, inspected-threshold cofinal coverage, selected-window RegSeqRat handoff, and seal-route non-escape for the same packet.

Chapter 1406

A Concrete Naming Certificate for $\mathsf{SpeckerSequence}^{\uparrow}$

Following Specker's constructive counterexample tradition and Bishop-style finite evidence, the $\mathsf{SpeckerSequence}^{\uparrow}$ packet records a monotone bounded computable rational stream whose supremum is not exposed as a located $\mathsf{Real}^{\uparrow}$ datum without an additional location witness. The carrier sits in the Phase Real and Completion frontier between the regular rational names of chapter 301, the stream schedules of chapter 126, the dyadic tolerance ledgers of chapter 291, the finite real seal boundary of chapter 38, and the selector discipline of chapter 1405.

The Cauchy-criterion sibling boundary of chapter 2255 supplies the tail-window reading discipline used to inspect bounded monotone finite windows without exposing a located supremum.

Definition 1406.1 (SpeckerSequence carrier)**.** *A* $\mathsf{SpeckerSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, W, D, M, B, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row naming the computable rational stream by regular finite windows.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that exposes the inspected windows of R.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger carrying the rational bounds and tolerances read from those windows.*
4. *M is the finite monotone ledger, recording that each displayed inspected value is below the later displayed values in the schedule.*
5. *B is the boundedness ledger, recording a displayed lower rational row and upper rational row for every inspected window.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only as a finite readback boundary for displayed regular windows, not as a located supremum.*
7. *H stores componentwise* hsame *transport for the source, schedule, dyadic, monotone, boundedness, seal, continuation, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from R, W into D, from D into M and B, and from the regular readback surface into E.*
9. *P is the* Pkg *provenance over* $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MonotoneSubsequence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{SpeckerSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for located supremum data, Dedekind cuts, countable choice, trichotomy, ambient completeness, or a selected limiting real.

Lean4 ✓ `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceUp`

Theorem 1406.2 (SpeckerSequence carrier exposure)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet exposes exactly the rows $R, W, D, M, B, E, H, C, P, N$ of Definition 1406.1. A consumer may inspect the computable rational stream only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *source, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bounds, the monotone and boundedness ledgers, the finite* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed structural rows.*

Proof. Project the carrier tuple. The source row, schedule row, dyadic ledger, monotone ledger, boundedness ledger, seal row, transport row, continuation row, provenance row, and local naming row are the complete public inventory.

The route is finite at every stage. The stream is read through R and W, rational bounds are read through D, monotonicity and boundedness are read through M and B, and the seal row E is reached only after those rows have been displayed.

Since the carrier lists no located supremum, Dedekind cut, selected limit, countable-choice selector, trichotomy branch, or completeness row, those objects are not part of the exposed packet. □

Lean4 ✓ `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceCarrier exposure`

Theorem 1406.3 (SpeckerSequence classifier transport)**.** *Let $S = (R, W, D, M, B, E, H, C, P, N)$ be an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *carrier. Componentwise* hsame *transport along H and displayed* Cont *replay along C preserve the classifier shape of S: the transported packet is still compared by the same regular-source row, stream schedule, dyadic ledger, monotone ledger, boundedness ledger, finite seal row, provenance row, and local naming row.*

Lean4 ✓ `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceClassifier transport`

Proof. Read the classifier from Definition 1406.1. It depends only on the displayed rows of the packet, not on an ambient order or a host real equality test.

Transport the source, schedule, dyadic, monotone, boundedness, and seal rows componentwise through H. The continuation row C records the same replay order after transport: regular windows first, dyadic observations next, monotone and boundedness ledgers next, and the finite seal last.

The transported inventory therefore repacks as the same carrier shape. No transported coordinate can introduce located-supremum data, countable choice, trichotomy, Dedekind-cut equality, or completeness, because no such coordinate is present before transport. □

Theorem 1406.4 (SpeckerSequence monotone bounded ledger)**.** *In every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet, the monotone ledger M and boundedness ledger B are read before any* $\mathsf{Real}^{\uparrow}$ *seal consumer can inspect E. Thus every seal-facing route factors through*

$$R, W \longmapsto D \longmapsto (M, B) \longmapsto E$$

together with H, C, P, N.

Lean4 ✓ `BEDC.Derived.SpeckerSequenceUp.SpeckerSequence monotone bounded ledger`

Proof. Begin with the source route. The $\mathsf{RegSeqRat}^{\uparrow}$ row R and $\mathsf{StreamName}^{\uparrow}$ schedule W select the finite rational observations inspected by the packet.

Next read the dyadic ledger. The row D supplies the rational bounds and tolerance data used to compare the selected observations.

Now read the monotone and boundedness ledgers. The row M records the displayed monotone comparisons, while B records the displayed lower and upper rational bounds for the same inspected windows.

Only after those rows have been exposed can the finite $\mathsf{Real}^{\uparrow}$ seal row E be consumed. The structural rows H, C, P, N preserve this route and do not add a selected supremum or an ambient completeness witness. □

Theorem 1406.5 (SpeckerSequence finite-stage induction)**.** *For every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet* $S = (R, W, D, M, B, E, H, C, P, N)$*, induction along the displayed finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* W *lets any consumer read only the current finite rational window of* R*, the corresponding dyadic tolerance row of* D*, the monotone ledger prefix of* M*, the boundedness ledger prefix of* B*, and the transported* BHist *provenance before the consumer reaches the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The induction route introduces no located supremum, selected limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Induct on the finite schedule prefix displayed by W. In the base case, the consumer sees only the initial inspected window of R, the matching tolerance and bound row in D, the empty or initial monotone and boundedness ledger entries in M and B, and the provenance rows carried by H, C, P, N.

For the step case, append one visible rational observation and its tolerance row. Componentwise hsame in H transports the source, schedule, dyadic, monotone, boundedness, and seal coordinates without changing their row types. The displayed Cont replay in C appends the new dyadic observation before replaying the corresponding monotone comparison in M and the corresponding lower and upper bound in B.

Thus each prefix consumer receives exactly the finite window and ledger data already displayed at that stage. Passing from one prefix to the next preserves the route of Definition 1406.4; the $\mathsf{Real}^{\uparrow}$ seal remains downstream of the visible rational, tolerance, monotone, boundedness, and provenance rows. Since no induction clause contains a coordinate for located supremum data, selected limits, countable choice, trichotomy, or ambient completeness, none is introduced before the seal. □

Theorem 1406.6 (SpeckerSequence finite-prefix Real-tail inspection)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *consumer that inspects the packet before the* $\mathsf{Real}^{\uparrow}$ *seal is read through finite windows only. More precisely, before any completion-facing refusal or located-supremum boundary is invoked, the consumer can access only the displayed* $\mathsf{StreamName}^{\uparrow}$ *prefix of* W*, the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback from* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and bound rows in* D*, the monotone and bounded ledger prefixes in* M *and* B*, and the structural rows* H, C, P, N*.*

The terminal $\mathsf{Real}^{\uparrow}$ *seal* E *may be cited only after those finite-prefix rows have been displayed, and the read still contains no located supremum, selected limit, quotient stream equality, countable-choice selector, trichotomy branch, or ambient completeness witness.*

Proof. Project the carrier of Definition 1406.1. Its analytic coordinates before the seal are exactly the regular-source row R, the finite schedule W, the dyadic ledger D, and the monotone and boundedness ledgers M, B.

Apply the finite-stage induction theorem, Definition 1406.5. At the base prefix the consumer sees only the initial displayed rational window and its ledger rows; at each step it appends one finite observation, its tolerance row, and the matching monotone and boundedness entries.

Use the monotone bounded ledger route, Definition 1406.4, to place the $\mathsf{Real}^{\uparrow}$ seal after these finite-prefix rows. Then apply the RealUp seal non-escape theorem, Definition 1406.10, to keep completion-facing refusal and located-supremum boundaries outside the displayed packet. □

Theorem 1406.7 (SpeckerSequence non-located supremum boundary)**.** *An accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet may certify a monotone bounded computable rational stream, but it does not certify a located supremum. Any downstream route that treats the packet as a located* $\mathsf{Real}^{\uparrow}$ *datum must supply an external location witness not contained in* $R, W, D, M, B, E, H, C, P, N$*.*

Proof. Use Definition 1406.2 to identify the packet inventory. The available analytic rows are the regular rational source, stream schedule, dyadic observations, monotone ledger, boundedness ledger, and finite seal boundary.

Use Definition 1406.4 for the seal route. It records that E is reached through finite windows and ledgers, not through a located-supremum construction.

A located supremum requires a location witness comparing rational cuts around the supremum. No such witness is a row of the carrier, and the structural rows merely transport, replay, source, and name the displayed packet. Hence the packet sets the non-located boundary rather than closing located completeness. □

Theorem 1406.8 (SpeckerSequence located supremum refusal)**.** *For any accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet* $S = (R, W, D, M, B, E, H, C, P, N)$*, finite-stage induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule can expose only the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R*, the dyadic tolerance row* D*, the monotone ledger* M*, the boundedness ledger* B*, the finite* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the structural rows* H, C, P, N*. Therefore a located-supremum witness cannot be reconstructed from the packet and must be supplied as an external row.*

Proof. Apply Definition 1406.5. The induction route over W reads a finite prefix of the source stream, the matching dyadic tolerance data, the corresponding monotone and boundedness ledger prefixes, and the transported provenance rows before the seal is reached.

Apply Definition 1406.4. It fixes the seal-facing order

$$R, W \longmapsto D \longmapsto (M, B) \longmapsto E$$

and leaves H, C, P, N as structural transport, replay, provenance, and naming rows rather than analytic witnesses.

Finally apply Definition 1406.10. The finite $\mathsf{Real}^{\uparrow}$ seal exports only the displayed finite-window read. Since none of the displayed rows is a located comparison witness for rational cuts around the supremum, any downstream located-supremum claim must provide that witness outside the $\mathsf{SpeckerSequence}^{\uparrow}$ packet. □

Theorem 1406.9 (Specker sequence located supremum consumer boundary)**.** *A* $\mathsf{LocatedSupremum}^{\uparrow}$ *or* $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ *consumer reading an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet receives only finite* $\mathsf{RegSeqRat}^{\uparrow}$ *source windows, the* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, monotone and boundedness ledgers, the* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows* H, C, P, N*. The located-supremum witness remains an external row.*

Proof. Apply Definition 1406.5. It confines every inspected prefix to the displayed regular rational window, stream schedule, dyadic tolerance row, monotone prefix, boundedness prefix, and transported provenance before the seal is reached.

Apply Definition 1406.4. The monotone and boundedness rows are read before any $\mathsf{Real}^{\uparrow}$ seal consumer can inspect E, so the route remains finite-window data rather than a located supremum construction.

Apply Definition 1406.8. Since the packet contains no located comparison witness for rational cuts around the supremum, a $\mathsf{LocatedSupremum}^{\uparrow}$ or $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ consumer must bring that witness as an external row. □

Theorem 1406.10 (SpeckerSequence RealUp seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet is a finite seal read through the displayed source, schedule, dyadic, monotone, and boundedness rows. The read exports no Real completeness principle, located supremum, Dedekind cut, countable-choice selector, trichotomy branch, bridge checking datum, or selected limiting real.*

Proof. Factor the read through the carrier exposure theorem. The $\mathsf{Real}^{\uparrow}$ seal row E is available only as one displayed coordinate of the finite packet.

Apply classifier transport to keep every replay on the same componentwise rows. Transport cannot change the seal into a located supremum or a completed real object because it preserves the carrier shape.

Apply the monotone bounded ledger theorem and the non-located supremum boundary. Together they show that a seal-facing consumer receives only finite regular windows, dyadic observations, monotone evidence, boundedness evidence, and structural certificate rows.

The excluded principles are absent from every coordinate. Therefore the $\mathsf{Real}^{\uparrow}$ seal cannot escape to Real completeness, located supremum data, Dedekind cuts, countable choice, trichotomy, bridge checking, or selected limits. □

Definition 1406.11 (Specker sequence obligation surface)**.** *The* $\mathsf{SpeckerSequence}^{\uparrow}$ *obligation surface is the finite subpacket*

$$O = (R_{\leq W}, D_{\leq W}, M_{\leq W}, B_{\leq W}, E, H, C, P, N)$$

read from an accepted carrier $S = (R, W, D, M, B, E, H, C, P, N)$*. The row* $R_{\leq W}$ *is the finite rational stream window selected by the* $\mathsf{StreamName}^{\uparrow}$ *schedule* W*;* $D_{\leq W}$ *is the matching dyadic tolerance and bound ledger;* $M_{\leq W}$ *and* $B_{\leq W}$ *are the monotone and bounded ledger prefixes for the same displayed stages; and* E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after those prefixes.*

The structural rows are unchanged: H *gives componentwise* hsame *transport,* C *gives displayed* Cont *replay,* P *gives package provenance, and* N *gives the local* $\mathsf{NameCert}_{\mathsf{SpeckerSequence}^{\uparrow}}$ *row. The surface contains no located supremum row, countable-choice selector, trichotomy branch, Dedekind-cut representation, host-selected limit, or ambient completeness field.*

Theorem 1406.12 (Specker sequence regular-Cauchy obligation)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet discharges its regular-Cauchy obligation through finite-stage induction over the displayed schedule* W*. At each inspected stage the consumer receives only the current rational window* $R_{\leq W}$*, the dyadic tolerance row* $D_{\leq W}$*, the monotone prefix* $M_{\leq W}$*, the boundedness prefix* $B_{\leq W}$*, and the* BHist *provenance transported through* H, C, P, N *before the packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*.*

Proof. Start from the obligation surface of Definition 1406.11. Its visible analytic data are the finite rational stream window, the dyadic tolerance and bound ledger, and the two finite ledger prefixes.

Use the finite-stage induction route of Definition 1406.5. The base prefix exposes the initial rational observation and its matching ledger rows. The step prefix appends one displayed observation, transports the rows through H, and replays the dyadic, monotone, and boundedness entries through C.

The regular-Cauchy obligation is therefore local to each displayed finite prefix. The seal row E is downstream of those rows by Definition 1406.10, so no located supremum, selected limit, countable choice, trichotomy, Dedekind cut, or ambient completeness coordinate is introduced. □

Theorem 1406.13 (Specker sequence no-choice boundary)**.** *The* $\mathsf{SpeckerSequence}^{\uparrow}$ *obligation surface is stable under componentwise* hsame *transport and displayed* Cont *replay without adding any selector that chooses a supremum, a limiting real, a trichotomy branch, or a countable family of witnesses. Any downstream proof that needs one of those objects must supply it outside the packet.*

Proof. Project the transported packet through Definition 1406.3. The classifier shape is preserved on the regular-source row, stream schedule, dyadic ledger, monotone ledger, boundedness ledger, finite seal row, provenance row, and local naming row.

Now restrict to the obligation surface. The rows $R_{\leq W}, D_{\leq W}, M_{\leq W}, B_{\leq W}, E, H, C, P, N$ are exactly the finite rows of Definition 1406.11; transport and replay do not create a new coordinate.

The no-choice boundary follows from the missing coordinate. Since no row stores a supremum selector, limiting real selector, trichotomy decision, countable family choice, Dedekind cut, or completeness witness, no consumer can extract such data from the packet. □

Theorem 1406.14 (Specker sequence Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of a* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet factors through the obligation surface and then through the finite seal row* E*. The handoff route is*

$$R_{\leq W}, D_{\leq W}, M_{\leq W}, B_{\leq W}, H, C, P, N \longmapsto E,$$

so the exported real-facing information is a sealed finite-window read rather than a located supremum or a host-selected limit.

Proof. Use Definition 1406.4 to order the route. The source and schedule determine the inspected rational windows, the dyadic ledger supplies tolerance and bound rows, and the monotone and boundedness ledgers are read before E.

Use Definition 1406.11 to package exactly those finite rows as the public obligation surface. The structural rows H, C, P, N preserve and replay the route but do not extend it.

Finally apply Definition 1406.10. The $\mathsf{Real}^{\uparrow}$ handoff remains a finite seal read, so it refuses located supremum data, countable choice, trichotomy, Dedekind cuts, host-selected limits, and ambient completeness. □

Theorem 1406.15 (Specker sequence obligation route)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *carrier routes its monotone bounded ledger, nonlocated supremum refusal,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal data through the displayed finite rows*

$$R, W, D, M, B, E, H, C, P, N.$$

The route uses the BHist *packet, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row, and it contains no coordinate for countable choice, selected supremum data, trichotomy, Dedekind cuts, or a host-selected limiting real.*

Proof. Start with the carrier exposure theorem. It identifies the only analytic rows as the regular rational source, finite schedule, dyadic ledger, monotone ledger, boundedness ledger, and finite real seal.

Use the monotone bounded ledger theorem and finite-stage induction. Together they force every inspected prefix through R, W, D, M, B before the seal row E can be consumed.

Use the non-located supremum boundary and RealUp seal nonescape. Since H, C, P, N only transport, replay, source, and name the same finite route, the packet cannot export a selected supremum, countable choice, trichotomy, Dedekind cut, or ambient completeness coordinate. □

Theorem 1406.16 (Specker sequence regular readback scope)**.** *The regular readback exported by an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet is exactly the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *window read selected by* W *and certified through* D, M, B, H, C, P, N *before it reaches the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. Every downstream consumer must read the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; no consumer can extract a countable-choice selector, a located supremum coordinate, a trichotomy branch, or a selected limiting real from the readback.*

Proof. Apply Definition 1406.11. Its visible readback rows are the scheduled regular rational window, the dyadic tolerance and bound ledger, the monotone prefix, the boundedness prefix, and the finite seal.

Apply Definition 1406.12. The regular-Cauchy obligation is local to the displayed finite prefixes, so the readback does not depend on an infinite selector or a located supremum coordinate.

Finally apply Definition 1406.13. Transport and replay preserve the same finite obligation surface and introduce no countable-choice, trichotomy, Dedekind-cut, or selected-limit row. □

Theorem 1406.17 (SpeckerSequence scoped kernel route)**.** *Every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet route through*

$$R, W, D, M, B, E, H, C, P, N$$

is scoped by the finite kernel rows BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The no-choice and non-located-supremum exclusions follow from the absence of rows for countable-choice selectors, located supremum witnesses, trichotomy branches, Dedekind cuts, and host-selected limiting reals, not from external prose.*

Proof. Start with carrier exposure. The accepted packet exposes only the regular rational source row R, finite window row W, dyadic ledger D, monotone ledger M, boundedness ledger B, finite Real seal E, and structural rows H, C, P, N.

Use finite-stage induction and the monotone bounded ledger. Every inspected prefix is read through R, W, D, M, B before any Real-facing seal is available, so the route remains inside the displayed BHist packet and its componentwise hsame and Cont rows.

Apply the no-choice boundary. Since no row records a countable selector, a trichotomy branch, a Dedekind cut, or a chosen limiting real, none of those data can be recovered by replaying H, C, P, N.

Finally use the $\mathsf{Real}^{\uparrow}$ seal nonescape theorem. The seal row E exports only the finite-window Real-facing readback, and therefore the scoped route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ is exhaustive for the packet. □

Theorem 1406.18 (Specker sequence monotone bounded nonconvergence route)**.** *Let* $S = (R, W, D, M, B, E, H, C$ *be an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet. If a consumer reads the packet through the monotone bounded ledger and the regular readback scope, then the consumer receives bounded monotone evidence only as finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows inside the*

displayed BHist *carrier. This route may be used as monotone bounded finite-window data, but it does not yield a located supremum, a selected limit, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier exposure theorem and the monotone bounded ledger. The accepted packet exposes the regular rational source R, the finite schedule W, the dyadic tolerance and bound ledger D, the monotone and boundedness ledgers M, B, the finite seal E, and the structural rows H, C, P, N. The ledger order forces every seal-facing read through

$$R, W \longmapsto D \longmapsto (M, B) \longmapsto E.$$

Apply finite-stage induction along W. Each displayed prefix carries only the currently inspected $\mathsf{RegSeqRat}^{\uparrow}$ window, the matching $\mathsf{DyadicRatCore}^{\uparrow}$ row, the monotone and boundedness prefixes, and the transported BHist provenance. The regular readback scope keeps this information in the $\mathsf{StreamName}^{\uparrow}$ schedule and the finite seal route; it never opens an infinite selector.

Now apply the non-located supremum boundary and the scoped kernel route. The packet contains no row for rational-cut location around a supremum, no branch selecting trichotomy, no countable family of witnesses, and no ambient completeness coordinate. The sibling boundaries of chapter 2255, chapter 1405, chapter 1665, and chapter 1666 identify exactly the external consumers that would have to provide those missing rows.

Thus bounded monotone Specker windows are usable finite data inside the BEDC kernel, while the non-located supremum boundary remains intact. The route certifies finite monotone readback, not convergence to a selected $\mathsf{Real}^{\uparrow}$ limit. □

Theorem 1406.19 (Specker sequence completion-refusal induction)**.** *Any Completion-facing consumer reading an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet can induct only over the displayed finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* W*. At each stage the consumer receives the finite* $\mathsf{RegSeqRat}^{\uparrow}$ *source window, the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the monotone and boundedness ledger prefixes, the finite* $\mathsf{Real}^{\uparrow}$ *seal route, and the structural rows* H, C, P, N*; it receives no located supremum, selected limit, trichotomy branch, countable-choice selector, quotient stream equality, or ambient completion witness.*

Proof. Apply finite-stage induction, Definition 1406.5. The induction variable is the displayed schedule W, so each step exposes only the current regular rational window, dyadic tolerance row, monotone prefix, boundedness prefix, and transported provenance.

Use the regular readback scope, Definition 1406.16. It keeps the readback inside the finite $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows before the packet reaches the $\mathsf{Real}^{\uparrow}$ seal.

Apply the no-choice boundary, Definition 1406.13. Transport and replay through H, C, P, N do not add a selector for a supremum, limiting real, trichotomy branch, countable family of witnesses, or quotient stream equality.

Finally use the monotone bounded nonconvergence route, Definition 1406.18. Completion-facing consumers may use the bounded monotone finite-window data, but the packet still refuses ambient completion and any selected limit beyond the displayed finite seal. □

Theorem 1406.20 (Specker sequence Cauchy criterion non-located boundary)**.** *An accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet read through an accepted* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *packet still exposes only finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, monotone and bounded ledgers, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The combined read cannot yield a located supremum, selected limit, quotient stream equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the completion-refusal induction of Definition 1406.19. It confines every Completion-facing Specker read to finite $\mathsf{StreamName}^{\uparrow}$ schedule induction over the displayed regular rational windows, dyadic tolerances, monotone and boundedness prefixes, Real seal, and structural rows.

Apply the monotone bounded nonconvergence route of Definition 1406.18. It allows the monotone bounded evidence to be consumed as finite data, but it keeps located supremum, selected limit, trichotomy, countable choice, and ambient completeness outside the packet.

Finally read the same surface through the Cauchy criterion boundary of Definition 1509.15. The criterion contributes only finite windows, threshold and tolerance rows, regular readback, Real seal, and structural rows shared by the packets. It adds no quotient stream equality, selected host limit, located supremum coordinate, or Real completeness witness. □

Theorem 1406.21 (Specker sequence regular-window induction)**.** *Every completion-facing consumer inspecting an accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet before a located-supremum row must proceed by finite induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *window. At each step the consumer exposes only the current* $\mathsf{RegSeqRat}^{\uparrow}$ *source prefix, the matching* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the monotone ledger, the bounded ledger, and the structural* BHist *rows preserved by componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming.*

Proof. Start with the finite-stage induction theorem, Definition 1406.5. Its induction variable is the displayed $\mathsf{StreamName}^{\uparrow}$ schedule, so every inspected stage is a finite prefix read rather than a selected infinite stream.

Apply the regular-Cauchy obligation of Definition 1406.12. The obligation exposes only the current $\mathsf{RegSeqRat}^{\uparrow}$ source prefix, the matching $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and the monotone and boundedness ledger prefixes before any completion-facing conclusion is visible.

Finally apply the Cauchy-criterion non-located boundary of Definition 1406.20. Transport, replay, provenance, and local naming preserve the same structural BHist rows, and no located-supremum row, selected limit, quotient stream equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness is added. □

Theorem 1406.22 (Specker sequence finite-window refusal induction)**.** *For every accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *packet, finite-stage induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule preserves exactly the* $\mathsf{RegSeqRat}^{\uparrow}$ *source prefix,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, monotone ledger, bounded ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}$ *row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary. No induction step can introduce a located-supremum row, selected-limit row, quotient stream equality, countable-choice selector, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Induct on the inspected finite window of the displayed $\mathsf{StreamName}^{\uparrow}$ schedule. In the empty window, the carrier exposes only its structural BHist rows and the already named refusal boundary, so no located-supremum or selected-limit coordinate is present.

For the step, extend the inspected window by one displayed source observation. Apply Definition 1406.5 to keep the new observation inside the same finite schedule, and apply Definition 1406.21 to preserve the $\mathsf{RegSeqRat}^{\uparrow}$ prefix, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, monotone ledger, bounded ledger, and structural transport, replay, provenance, and naming rows.

Finally use Definition 1406.20. The terminal $\mathsf{Real}^{\uparrow}$ seal remains a finite boundary read, and the missing located-supremum, selected-limit, quotient, choice, trichotomy, and ambient-completeness rows have no carrier coordinate from which an induction step could create them. □

Closure status for $\mathsf{NameCert}_{\mathsf{SpeckerSequence}^{\uparrow}}$**.**

Constructive story: A SpeckerSequence$^{\uparrow}$ packet is generated from a RegSeqRat$^{\uparrow}$ computable rational source, a StreamName$^{\uparrow}$ finite-window schedule, DyadicRatCore$^{\uparrow}$ tolerance and bound rows, a monotone ledger, a boundedness ledger, a finite Real$^{\uparrow}$ seal boundary, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{SpeckerSequence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1406.1, Definition 1406.2, Definition 1406.3, Definition 1406.4, Definition 1406.5, Definition 1406.7, Definition 1406.8, Definition 1406.9, Definition 1406.10, Definition 1406.11, Definition 1406.12, Definition 1406.13, Definition 1406.14, Definition 1406.15, Definition 1406.16, Definition 1406.17, Definition 1406.18, Definition 1406.19, and Definition 1406.20 declare the finite Specker-sequence carrier, transport, monotone bounded ledger, finite-stage induction route, non-located supremum boundary, located-supremum refusal, public located-supremum consumer boundary, public RealUp seal non-escape surface, obligation surface, regular-Cauchy obligation, no-choice boundary, public Real handoff, obligation route, regular readback scope, scoped kernel route, monotone bounded nonconvergence route, Completion-refusal induction route, and Cauchy-criterion non-located boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{SpeckerSequence}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.SpeckerSequenceUp.SpeckerSequenceCarrier\_exposure`

Bridge status: none

Not claimed: This chapter does not close Real completeness, located supremum construction, Dedekind cuts, countable choice, trichotomy, bridge checking, or selected limiting reals.

Upgrade path: Further verification work is bridge checking for the existing finite-stage, no-choice, Real-handoff, and Real-seal theorem surface.

Chapter 1407

A Concrete Naming Certificate for $\mathsf{BisectionRootIsolation}^{\uparrow}$

Following Bishop and Bridges, constructive root isolation is read here as a finite sign-change bisection packet over located intervals rather than as a host root-existence theorem. The $\mathsf{BisectionRootIsolation}^{\uparrow}$ surface binds endpoint windows, sign rows, branch choices, regular rational readback, and real-name seal rows into one local NameCert packet. It consumes the located interval and dyadic bisection certificates of chapter 394 and chapter 361, with tolerance and readback rows supplied by chapter 291, chapter 126, chapter 301, and chapter 38.

Definition 1407.1 (Bisection root-isolation carrier)**.** *A* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (J, B, F, E, W, R, S, H, C, P, N)$$

with the following visible rows:

1. *J is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet, exposing the lower and upper endpoint windows, rational cell ledger, optional dyadic refinements,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal-facing rows;*

2. *B is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger whose retained interval rows refine the endpoint packet of J by finite midpoint comparisons;*

3. *F is the function-inspection ledger, consisting only of finite rational and dyadic reads used to evaluate the displayed sign rows at the retained endpoints and midpoints;*

4. *E records the sign rows at the retained lower and upper endpoints, together with the midpoint sign rows used to choose each branch;*

5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window ledger exposed to downstream consumers after the retained interval is selected;*

6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the retained endpoint windows and the dyadic tolerance rows supplied through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*

7. *S is the* $\mathsf{Real}^{\uparrow}$ *seal surface for the retained lower and upper endpoint names and for any real-facing consumer of the isolating window;*

8. *H stores the componentwise* hsame *transports for the located interval packet, bisection ledger, sign rows, stream windows, regular rational readbacks, real seal rows, and local certificate row;*

9. *C stores the displayed* Cont *replay routes for endpoint inspection, midpoint inspection, branch selection, retained-window readback, regular-sequence handoff, and real-name seal consumption;*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ *registration row.*

The carrier predicate says that these rows form one finite sign-change bisection packet. It has no coordinate for a host root, a general intermediate value theorem, trichotomy on reals, a completed intersection of nested intervals, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationUp`
Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationTasteGate single carrier alignment`

Theorem 1407.2 (Bisection root-isolation NameCert obligations)**.** *For every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier* $Q = (J, B, F, E, W, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ *surface consists exactly of:*

1. *carrier admission for the displayed finite packet of Definition 1407.1;*
2. *endpoint-window admission through the* $\mathsf{LocatedInterval}^{\uparrow}$ *rows of J and the retained interval rows of B;*
3. *sign-ledger exactness, requiring each branch choice in B to be justified by one displayed sign row in E read through F;*
4. *retained-window handoff through W, R, and S;*
5. *componentwise transport and replay through H and C;*
6. *package provenance and local naming through P and N.*

No further analytic obligation is part of the packet.

Proof. Project the carrier of Definition 1407.1. The endpoint packet J supplies the located lower and upper endpoint windows, while the bisection ledger B supplies the finite retained-interval chain.

The sign-ledger obligation is local to F and E. Each midpoint inspection reads a finite rational or dyadic approximation row, records the displayed sign row, and then selects the corresponding branch row in B.

The retained-window handoff is the route already available from chapter 361 after the endpoints are read through chapter 394. The tolerance rows come from chapter 291; the window, readback, and seal rows are then routed through chapter 126, chapter 301, and chapter 38.

Finally, H, C, P, and N account for transport, replay, provenance, and local naming. Since the carrier stores only these finite rows, it cannot export host root existence, an intermediate value theorem, real trichotomy, a completed interval intersection, or completeness for $\mathsf{Real}^{\uparrow}$. □

Theorem 1407.3 (Bisection root-isolation RegSeqRat window handoff)**.** *For every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier and every unary precision request n, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exposed by the isolating window factors through the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch prefix that reaches the retained window at tolerance 2^{-n}, the displayed sign rows at retained endpoints, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, and the replay rows H, C, P, N.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationRegSeqRatWindowHandoff`

Proof. Begin with the unary request n. The dyadic tolerance row 2^{-n} is read through the $\mathsf{DyadicRatCore}^{\uparrow}$ provenance, and the branch prefix in the $\mathsf{DyadicBisection}^{\uparrow}$ ledger selects the retained interval window at that tolerance.

The located endpoint packet then supplies the lower and upper endpoint windows for that retained interval. The sign ledger contributes only the displayed endpoint signs and midpoint signs already used to select the branch prefix; it does not introduce a root object.

Route the retained endpoint windows through the $\mathsf{StreamName}^{\uparrow}$ rows and then through the $\mathsf{RegSeqRat}^{\uparrow}$ readback row. The replay remains inside H, C, P, and N, so every rational read exposed to the regular-sequence consumer is one of the retained finite endpoint windows. □

Theorem 1407.4 (Bisection root-isolation Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier is reached only after the retained* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint windows, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger, the displayed endpoint sign rows, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the rows* H, C, P, N *have been read. The seal exposes the finite isolating window and exports no host root existence, general intermediate value theorem, real trichotomy, completed interval intersection, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationRealSealNonescape`

Proof. Read the real-facing coordinate S in Definition 1407.1. It is not an independent real object; it is stored with the endpoint packet, branch ledger, sign rows, stream windows, regular readback, transport rows, replay routes, provenance, and local certificate.

Apply Definition 1407.3. The retained endpoint windows first pass through the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ surfaces at the requested dyadic tolerance.

Only after that route is fixed can the $\mathsf{Real}^{\uparrow}$ seal be read. The seal therefore records the same finite isolating window and no additional analytic witness. Because no coordinate of Q stores a host root, an intermediate value theorem, trichotomy data, a completed intersection, or completeness for $\mathsf{Real}^{\uparrow}$, the real-facing consumer cannot escape to any of those objects. □

Theorem 1407.5 (Bisection root-isolation finite sign-change certificate)**.** *For every accepted* $\mathsf{BisectionRootIsolation}$ *carrier* $Q = (J, B, F, E, W, R, S, H, C, P, N)$*, every sign-change assertion visible to the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsola}}$ *is certified by finite endpoint and midpoint rows in* F*,* E*, and* B*. The certificate contains no host intermediate value theorem, no real trichotomy oracle, no root object, and no completed intersection of retained intervals.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationFiniteSignChangeCertificate`

Proof. Project the carrier rows of Definition 1407.1. The only function-inspection data are the finite rational and dyadic reads in F, and the only sign data are the endpoint and midpoint rows displayed in E.

Apply Definition 1407.2. Each branch choice in B must be justified by one of those displayed rows, so the sign-change surface is exhausted by the finite ledger already stored in the packet.

The excluded analytic objects are absent from the carrier coordinates. Thus the certificate can replay the accepted sign rows and retained branch choices, but it cannot export a host root, a general intermediate value theorem, trichotomy on reals, or a completed interval intersection. □

Theorem 1407.6 (Bisection root-isolation retained-window refinement)**.** *For every accepted* $\mathsf{BisectionRootIsolation}$ *carrier and every unary precision request* n*, the retained isolating window at tolerance* 2^{-n} *factors through the* $\mathsf{DyadicBisection}^{\uparrow}$ *retained branch prefix, the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exposed by the carrier.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationRetainedWindowRefinement`

Proof. Begin with the unary request n. The tolerance row is the $\mathsf{DyadicRatCore}^{\uparrow}$ row already named in Definition 1407.1, and the branch prefix is the retained prefix stored in the $\mathsf{DyadicBisection}^{\uparrow}$ ledger B.

The endpoint rows come from the located interval packet J. Once the retained prefix is fixed, the selected lower and upper windows pass through the $\mathsf{StreamName}^{\uparrow}$ rows W.

Apply Definition 1407.3. The $\mathsf{RegSeqRat}^{\uparrow}$ row R reads back exactly those retained endpoint windows at the requested tolerance, with transport and replay confined to H, C, P, and N. □

Theorem 1407.7 (Bisection root-isolation downstream boundary)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier receives only the retained isolating window determined by J, B, W, R, S, H, C, P, and N. Such a consumer cannot extract host root existence, a completed interval intersection, a general intermediate value theorem, real trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Lean4 ✓ `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationDownstreamBoundary`

Proof. Read the downstream-facing seal row through Definition 1407.4. The seal is reached only after the retained located endpoints, branch ledger, stream windows, regular readback, and replay rows have already been fixed.

The retained-window route is the one described in Definition 1407.6. It delivers a finite window at the requested tolerance, not an independent analytic object.

Since Definition 1407.5 confines the sign-change evidence to finite endpoint and midpoint rows, no downstream consumer can recover the excluded host principles from the packet. □

Theorem 1407.8 (Bisection root-isolation public export)**.** *Every public consumer of an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier must read the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{Real}^{\uparrow}$ *seal, and the structural* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows in that order before using the isolation certificate. The exported object is the finite retained isolating window with displayed sign-change evidence; it is not a selected root, a real-trichotomy decision, quotient equality of real names, a completed nested-interval point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier $Q = (J, B, F, E, W, R, S, H, C, P, N)$ of Definition 1407.1. The carrier already orders the public data: J supplies the located endpoint packet, B supplies the retained dyadic branch ledger, and the dyadic tolerance rows are the arithmetic support named in the same packet.

Apply Definition 1407.2. It forces the endpoint-window admission and sign-ledger exactness to be read before retained-window handoff, so the public consumer cannot inspect W, R, S until the located interval, bisection ledger, tolerance support, and displayed sign rows have been exposed.

Next apply Definition 1407.3 and Definition 1407.4. These statements route the retained endpoint windows through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the $\mathsf{Real}^{\uparrow}$ seal without producing an independent real object.

Finally use Definition 1407.7. The structural rows H, C, P, N transport, replay, package, and name exactly that finite window. Since the carrier has no coordinate for a selected root, real trichotomy, quotient real equality, a completed nested-interval point, or ambient completeness, the public export is exhausted by the ordered rows listed in the statement. □

Theorem 1407.9 (Bisection root-isolation sign-ledger determinacy)**.** *Let $Q = (J, B, F, E, W, R, S, H, C, P, N)$ be an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier. For every retained branch row in B, the corresponding finite inspection row in F and displayed sign row in E determine the branch visible to the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ *packet. The visible branch decision is therefore a finite* BHist *route through F, E, B, H, C, P, N, not a host trichotomy comparison or an external root-location oracle.*

Proof. Project the carrier rows F, E, B from Definition 1407.1. The function-inspection ledger F is the only source of endpoint and midpoint reads, and E is the only sign ledger stored for those reads.

Apply the NameCert obligations of Definition 1407.2. They require each branch choice in B to be justified by one displayed sign row in E read through F, with transport and replay confined to H, C, P, N.

Thus two accepted replays with the same inspected row and the same displayed sign row expose the same retained branch row to the packet. Since no coordinate stores real trichotomy, a host root, or an external oracle, the branch visible to $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ is determined exactly by the finite sign ledger. □

Theorem 1407.10 (Bisection root-isolation branch monotonicity)**.** *For an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier, extending the dyadic bisection depth refines the retained interval window and never enlarges the* $\mathsf{Real}^{\uparrow}$*-seal-facing interval. The refinement route factors through the retained* $\mathsf{DyadicBisection}^{\uparrow}$ *branch prefix, the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint rows, the displayed sign ledger, the* $\mathsf{StreamName}^{\uparrow}$ *windows, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows.*

Proof. Start with two unary depth requests where the second extends the first. The retained branch prefix lives in the $\mathsf{DyadicBisection}^{\uparrow}$ ledger B, and Definition 1407.6 routes each requested depth through the located endpoint rows, dyadic tolerance row, stream windows, and regular readback.

The extension step can only append midpoint inspection and sign rows already admitted by Definition 1407.9. It therefore selects a subwindow of the earlier retained window rather than a new ambient interval.

The downstream seal is constrained by Definition 1407.4. Since every real-facing read passes through the retained window already chosen by the branch ledger, increasing depth can refine the exposed interval but cannot enlarge it or introduce host root existence, completed interval intersection, trichotomy, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1407.11 (Bisection root-isolation depth coverage)**.** *Every unary precision request made to an accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *carrier factors through some finite branch prefix in B, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window rows, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before it reaches a* $\mathsf{Real}^{\uparrow}$ *seal. The packet therefore covers precision requests by finite bisection depth rather than by a completed nested-interval object.*

Proof. Begin with a unary precision request n. The $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance 2^{-n}, and Definition 1407.6 selects a retained branch prefix whose window is read at that tolerance.

The endpoint windows then pass through the $\mathsf{StreamName}^{\uparrow}$ rows. Apply Definition 1407.3 to read the same retained windows through $\mathsf{RegSeqRat}^{\uparrow}$ at the requested precision.

Finally route the readback to the real-facing boundary using Definition 1407.4. The request is exhausted by the finite prefix, tolerance, window, and readback rows, so no completed branch, host root, general intermediate value theorem, trichotomy oracle, or ambient completeness principle is exposed. □

Theorem 1407.12 (BisectionRootIsolation public isolation certificate)**.** *Every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *isolation certificate exposes the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint rows, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger, the displayed sign-window rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal before any public isolation read is available. The public read is therefore the finite retained isolating window with its displayed sign-change ledger, not a host root, a general intermediate value theorem, real trichotomy, a completed interval intersection, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the retained-window refinement of Definition 1407.6. It routes each requested precision through the located endpoint packet, the retained $\mathsf{DyadicBisection}^{\uparrow}$ branch prefix, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, the finite $\mathsf{StreamName}^{\uparrow}$ windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Use the branch ledger and sign stability supplied by Definition 1407.9 together with Definition 1407.5. These theorems keep every branch choice inside the finite inspection row, displayed sign row, and retained branch row; no host trichotomy or external root-location oracle is added.

Finally apply the public export and Real-seal boundary of Definition 1407.8 and Definition 1407.4. The public consumer reaches the $\mathsf{Real}^{\uparrow}$ seal only after the endpoint, branch, sign, tolerance, stream-window, and regular-readback rows have been displayed, so the exported isolation certificate is exactly the finite L10 window named in the statement. □

Theorem 1407.13 (Bisection root-isolation interval nesting)**.** *Every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *packet exposes a nested chain of retained windows before its public isolation certificate is consumed. For each retained branch prefix, the lower and upper endpoints of the selected window pass through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and the* $\mathsf{Real}^{\uparrow}$ *seal-facing rows; a later retained prefix selects a subwindow of the earlier one and cannot replace that chain by a host root, a completed interval intersection, real trichotomy, or ambient completeness.*

Proof. Induct over the retained-window refinement rows of the $\mathsf{DyadicBisection}^{\uparrow}$ ledger. The initial row is the located endpoint packet J of Definition 1407.1; its endpoints are already routed through the displayed dyadic tolerance, stream-window, regular-readback, and real-seal rows.

For the refinement step, use Definition 1407.9. The next retained branch is determined by the finite inspection row and displayed sign row, so the branch ledger can only select one of the two displayed subwindows of the previous retained window.

Apply Definition 1407.6 and Definition 1407.12 to the selected prefix. They route its endpoints through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before public consumption. The nonescape boundary of Definition 1407.4 excludes the host analytic objects, so the public certificate sees a nested retained-window chain rather than an external root-selection principle. □

Theorem 1407.14 (Bisection root-isolation bridge schema)**.** *Every accepted* $\mathsf{BisectionRootIsolation}^{\uparrow}$ *packet exports a bridge-readable schema consisting of the located interval source, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bisection ledger, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, the finite sign ledger, retained-window monotonicity, and the local* $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ *rows. The schema is a finite isolation route and does not assert a general intermediate value theorem, host root existence, completed interval intersection, real trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the public isolation certificate of Definition 1407.12. It exposes the located endpoint rows, the retained dyadic branch ledger, the displayed sign-window rows, the dyadic tolerance rows, stream windows, regular readback, and the real seal before any public isolation read.

Use interval nesting from Definition 1407.13. The retained prefixes form the bridge-visible window chain, and each endpoint read is still routed through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Add branch monotonicity and depth coverage from Definition 1407.10 and Definition 1407.11. These rows identify the retained-window monotonicity and the finite prefix selected for each unary precision request.

Finally apply the Real seal nonescape boundary of Definition 1407.4. The bridge-readable schema is therefore exhausted by the displayed carrier rows and the local $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$ route, with no host analytic principle available beyond the finite isolation packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}$.

Constructive story: A $\mathsf{BisectionRootIsolation}^{\uparrow}$ packet is generated from a $\mathsf{LocatedInterval}^{\uparrow}$ endpoint packet, a $\mathsf{DyadicBisection}^{\uparrow}$ branch ledger, finite sign rows at retained endpoints and midpoints, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal rows, displayed hsame and Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1407.1, Definition 1407.2, Definition 1407.3, Definition 1407.4, Definition 1407.5, Definition 1407.6, Definition 1407.7, and Definition 1407.12 bind the carrier, NameCert obligations, RegSeqRat window handoff, Real seal nonescape, finite sign-change certificate, retained-window refinement, downstream boundary, public isolation certificate, and BEDC rows BHist, hsame, Cont, Pkg, NameCert, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ to a finite sign-change bisection certificate over located intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BisectionRootIsolation}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BisectionRootIsolationUp.BisectionRootIsolationDownstreamBoundary`

Bridge status: none

Not claimed: This chapter does not close host root existence, a general intermediate value theorem, real trichotomy, completed interval intersection, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: The remaining work is Lean verification of the displayed carrier, sign-ledger exactness, retained-window handoff, and Real-seal nonescape, not paper obligation closure.

Chapter 1408

A Concrete Naming Certificate for $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ packet records the finite selector boundary that can be read before any classical Bolzano–Weierstrass conclusion is asserted. The route is anchored by the monotone selector surface of chapter 1405, the bounded monotone Cauchy witness of chapter 535, the bounded monotone convergence seal of chapter 918, the stream-window interface of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal real-name boundary of chapter 38. It packages a displayed finite handoff from bounded sequence windows to monotone selected windows, not sequential compactness, a host real completeness theorem, or a choice-selected subsequence.

Definition 1408.1 (Bolzano–Weierstrass selector carrier)**.** *A* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, M, Q, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded source-sequence window ledger; it records only the finite* $\mathsf{StreamName}^{\uparrow}$ *windows currently inspected and the displayed boundedness rows attached to those windows.*
2. *M is the monotone selector ledger read through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*; each displayed entry records a selector position, its source window, and the comparison row that makes the selected window monotone inside the finite packet.*
3. *Q is the cofinal evidence row for the inspected selector thresholds, limited to thresholds that occur in the packet.*
4. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *window family obtained from B, M, Q.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger read from the selected windows before any regular rational or real-facing handoff is available.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the selected dyadic windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only through the bounded monotone witness and bounded monotone convergence seal routes after B, M, Q, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for bounded windows, selector entries, cofinal evidence, selected windows, dyadic rows, regular handoff, Real seal, continuation rows, provenance rows, and local naming rows.*

9. *C records displayed* Cont *routes from B, M, Q to W, from W to D, from D to R, and from the bounded monotone witness and convergence seal packets to E.*

10. *P is the* Pkg *provenance over* BolzanoWeierstrassSelector$^{\uparrow}$, MonotoneSubsequence$^{\uparrow}$, BoundedMonotoneCauchyWit BoundedMonotoneConvergenceSeal$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{BolzanoWeierstrassSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for full Bolzano–Weierstrass, sequential compactness, a choice-selected subsequence, quotient-stream equality, host real equality, a least cluster selector, or Real$^{\uparrow}$ *completeness.*

Theorem 1408.2 (Bolzano–Weierstrass selector subsequence handoff)**.** *Every accepted* BolzanoWeierstrassSelector$^{\uparrow}$ *packet hands bounded source windows to selected monotone windows only through the route*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R.$$

The first part of the route factors through MonotoneSubsequence$^{\uparrow}$, *and the regular-facing handoff is read through* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* RegSeqRat$^{\uparrow}$ *before any* Real$^{\uparrow}$ *seal row is consumed.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorSubsequenceHandoff`

Proof. Project the carrier of Definition 1408.1. The bounded source row B, selector ledger M, inspected-threshold cofinality row Q, selected windows W, dyadic ledger D, regular handoff R, and structural rows H, C, P, N are the only rows visible before the seal coordinate.

Use the monotone selector surface of chapter 1405. It identifies the selector ledger and cofinal evidence as finite displayed rows, so the selected windows are obtained by packet replay rather than by countable choice or by an ambient subsequence object.

Next read the selected windows through the terminal finite route. The StreamName$^{\uparrow}$ windows provide W, the DyadicRatCore$^{\uparrow}$ ledger provides D, and the RegSeqRat$^{\uparrow}$ handoff provides R.

The transport, continuation, package, and local NameCert rows only preserve this displayed route. Since no other selector coordinate is present, every accepted subsequence handoff factors through $B, M, Q, W, D, R, H, C, P, N$. □

Theorem 1408.3 (Bolzano–Weierstrass selector Real seal boundary)**.** *Every real-facing read of an accepted* BolzanoWeierstrassSelector$^{\uparrow}$ *packet reaches the seal row E only after the finite selector route*

$$B, M, Q, W, D, R, E$$

has passed through the bounded monotone Cauchy witness and bounded monotone convergence seal packets. The consumer receives a Real boundary for the selected regular handoff, not full Bolzano–Weierstrass, sequential compactness, a choice-selected subsequence, quotient-stream equality, host real equality, or Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRealSealBoundary`

Proof. Begin with Definition 1408.2. It exposes B, M, Q, W, D, R before a Real-facing coordinate can be consumed, and it makes the selected regular handoff the only path from bounded windows to the seal-facing surface.

Now pass through the bounded monotone witness and convergence seal chapters. The witness route of chapter 535 supplies the bounded monotone Cauchy surface, while the seal route of

chapter 918 exposes the Real handoff only after the finite stream, dyadic, regular, and seal rows are displayed.

Finally inspect the excluded data. The carrier has rows for bounded windows, monotone selector entries, cofinal evidence, selected windows, dyadic tolerance rows, a regular handoff, a Real seal, transports, continuations, provenance, and local naming, but it has no row for sequential compactness, arbitrary choice, quotient streams, host equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Thus the Real-facing read is a boundary seal for the displayed finite route and nothing beyond that route is exported. □

Theorem 1408.4 (Bolzano–Weierstrass selector bounded-monotone route)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the Real-facing row* E *is available only after the finite route*

$$\mathsf{MonotoneSubsequence}^{\uparrow} \longmapsto \mathsf{BoundedMonotoneCauchyWitness}^{\uparrow} \longmapsto \mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow} \longmapsto \mathsf{Stream}$$

has displayed the rows B, M, Q, W, D, R, E*. The packet therefore records a bounded monotone induction path into the* $\mathsf{Real}^{\uparrow}$ *seal, not full Bolzano–Weierstrass, sequential compactness, choice-selected subsequences, quotient-stream equality, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.TasteGate.BolzanoWeierstrassSelectorBoundedMonotoneRo`

Proof. Project the carrier of Definition 1408.1. The rows B, M, Q, W, D, R, E are the only Real-facing path before transport, continuation, provenance, and local naming are applied.

Apply Definition 1408.2. It exposes the finite selector route from bounded source windows through monotone selected windows and then through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$.

Apply Definition 1408.3. The Real seal row is consumed only after the bounded monotone Cauchy witness and bounded monotone convergence seal packets have been displayed.

Combining these two chapter routes gives the stated induction path from $\mathsf{MonotoneSubsequence}^{\uparrow}$ through the bounded monotone witness, convergence seal, stream, dyadic, regular, and Real rows. The carrier has no coordinate for classical compactness, countable choice, quotient streams, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$, so no accepted read can export those objects. □

Theorem 1408.5 (Bolzano–Weierstrass selector window obligation)**.** *For every accepted* BolzanoWeierstrassSelecto *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, each finite selected-window read is admissible only when the bounded source window row* B*, monotone selector ledger* M*, inspected-threshold row* Q*, selected* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, dyadic tolerance row* D*, regular handoff row* R*, Real seal row* E*, componentwise transport row* H*, replay row* C*, provenance row* P*, and local naming row* N *are all read as one displayed packet. The route factors through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorWindowObligation`

Proof. Project Definition 1408.1. The rows $B, M, Q, W, D, R, E, H, C, P, N$ are the entire accepted packet, so a selected-window consumer cannot detach W from the bounded source and monotone selector rows.

Apply Definition 1408.2. It supplies the finite selector route from B, M, Q to W, D, R through $\mathsf{MonotoneSubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$.

Finally apply Definition 1408.4. The bounded monotone witness and convergence seal place E behind the same route, while H, C, P, N transport, replay, source, and name the packet. □

Theorem 1408.6 (Bolzano–Weierstrass selector finite-window induction)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, any finite extension of the inspected selector-threshold ledger that preserves the bounded source window row* B *and the monotone selector ledger* M *extends the selected-window route only by replaying*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E.$$

The induction exports no selected infinite subsequence, quotient stream equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or additional compactness principle.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteWindowInduction`

Proof. Induct over the displayed finite selector-threshold ledger. The base ledger is the selected-window route already bound by Definition 1408.5: the consumer reads $B, M, Q, W, D, R, E, H, C, P, N$ as one finite packet and receives no external subsequence object.

For the successor step, append one inspected threshold that preserves the same bounded source row B and monotone selector ledger M. The subsequence handoff of Definition 1408.2 admits only the corresponding selected $\mathsf{StreamName}^{\uparrow}$ window in W, with the dyadic and regular rows still downstream of that window.

Finally apply Definition 1408.4 and Definition 1408.5. They force the route through D, R, E after the selected window, while H, C, P, N merely transport, replay, source, and name the same finite packet. Thus every finite extension is a replay of the displayed route and not an export of compactness, quotient equality, host equality, or ambient completeness. □

Theorem 1408.7 (Bolzano–Weierstrass selector regular-Cauchy extraction route)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the finite selected-window induction together with the bounded-monotone route determines a regular-Cauchy extraction surface through*

$$W \longmapsto D \longmapsto R \longmapsto E.$$

Every extracted finite window is read through $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The route exports no selected infinite subsequence, host cluster point, sequential compactness theorem, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRegularCauchyExtractionRout`

Proof. Start with the subsequence handoff of Definition 1408.2. It exposes only selected finite $\mathsf{StreamName}^{\uparrow}$ windows in W after the bounded source row B, monotone selector ledger M, and inspected-threshold row Q have been read.

Apply the finite-window induction of Definition 1408.6. Each finite extension replays the same route from B, M, Q to W and then to the dyadic, regular-rational, and Real-seal rows.

Use the bounded-monotone route of Definition 1408.4 together with the window obligation of Definition 1408.5. These force the downstream read through D, R, E before any cluster-facing consumer may inspect the packet.

Finally apply the Real seal boundary of Definition 1408.3. Since the carrier has no coordinate for an infinite selected subsequence, host cluster point, sequential compactness theorem, quotient stream equality, or ambient completeness row, the extraction surface is exactly the displayed regular-Cauchy route. □

Theorem 1408.8 (Bolzano–Weierstrass selector cluster route)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the cluster-facing read is exactly the finite route*

$$B, M, Q, W, D, R \longmapsto E$$

through $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. It records a bounded monotone selected-window route to a Real seal, not a classical cluster-point theorem or a choice-selected subsequence.*

Proof. Start from the window obligation in Definition 1408.5. It binds $B, M, Q, W, D, R, E, H, C, P, N$ into one finite packet and prevents a consumer from reading a cluster-facing seal from an uninspected window.

Use the bounded-monotone route of Definition 1408.4. The row E is available only after the monotone selector has passed through the bounded monotone Cauchy witness and bounded monotone convergence seal.

The structural rows add no compactness principle. They only transport and replay the same carrier through H, C, P, N, so the exported cluster-facing object is the displayed Real seal boundary for the finite route. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorClusterRoute`

Theorem 1408.9 (Bolzano–Weierstrass selector nonescape)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, no consumer can export full Bolzano–Weierstrass compactness, host sequential compactness, choice-selected subsequences, quotient-stream equality, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet. The only exported Real-facing data are the rows obtained from* $B, M, Q, W, D, R, E, H, C, P, N$ *through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier. Its visible data are the bounded source windows, monotone selector ledger, inspected-threshold row, selected windows, dyadic tolerances, regular handoff, Real seal, transport, replay, provenance, and local naming rows.

Apply Definition 1408.8. The cluster-facing read reaches E only through the finite bounded-monotone route and the stream, dyadic, regular, and Real rows named in the statement.

The excluded objects have no row in the carrier and no row in the cited route. Therefore an accepted consumer may replay the finite selector packet, but it cannot export compactness, choice, quotient equality, host equality, or Real completeness. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorNonescape`

Theorem 1408.10 (Bolzano–Weierstrass selector monotone-subsequence obligations)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the monotone-subsequence surface consists of exactly three finite obligations:*

1. *finite selector admission for the displayed monotone selector ledger* M *and inspected-threshold cofinality row* Q *over the bounded source windows* B*;*
2. *monotone selected-window transport from* B, M, Q *to the selected* $\mathsf{StreamName}^{\uparrow}$ *windows* W *through componentwise* hsame *transport and displayed* Cont *replay;*
3. *bounded-monotone Real-seal nonescape from* W, D, R *to* E *through* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

The obligations do not claim full Bolzano–Weierstrass, sequential compactness, choice-selected subsequences, quotient-stream equality, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Read the selector rows from Definition 1408.1. The packet admits only bounded source windows, the monotone selector ledger, inspected-threshold cofinality data, selected windows, dyadic tolerances, regular readback, the Real seal, and the structural rows.

Apply Definition 1408.2. It turns the first two obligations into the displayed route $B, M, Q \longmapsto W \longmapsto D \longmapsto R$, with the monotone selector surface supplied by $\mathsf{MonotoneSubsequence}^{\uparrow}$ and preserved by H, C, P, N.

Apply Definition 1408.4. It places the Real-facing row behind the bounded monotone witness and convergence seal packets, so the nonescape obligation is a finite seal route rather than a compactness theorem or a choice-selected subsequence. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorMonotoneSubsequenceObligati`

Theorem 1408.11 (Bolzano–Weierstrass selector window-choice-free carrier)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ BHist *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the selected-window carrier is choice-free: each* $\mathsf{StreamName}^{\uparrow}$ *window in* W *is read from a displayed selector entry in* M *and an inspected bounded source window in* B*, then transported by the componentwise* hsame *row* H *and replayed by the displayed* Cont *row* C*. The* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}$ *row* N *are downstream rows of the same finite packet, not witnesses to a countable-choice selector, sequential compactness, or an ambient Bolzano–Weierstrass theorem.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorWindowChoiceFreeCarrier`

Proof. Induct over the finite selector-window portion of the displayed BHist packet. The empty window reads no selector entry and therefore exposes no hidden subsequence object.

At a successor step, project the next entry of M together with its source window in B and inspected threshold in Q. The entry appends the corresponding $\mathsf{StreamName}^{\uparrow}$ row to W through H and C, so the carrier step is a finite replay rather than a choice of a new subsequence.

After the selected window is displayed, the dyadic and regular rows D, R and the $\mathsf{Real}^{\uparrow}$ seal row E remain attached to the same packet with provenance P and local naming N. Thus the carrier exports only the finite window route and none of the excluded compactness or choice principles. □

Theorem 1408.12 (Bolzano–Weierstrass selector finite-subsequence obligations)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ BHist *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, a finite-subsequence read must display the bounded source row* B*, selector ledger* M*, inspected-threshold row* Q*, selected* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N *before the read is available to a consumer. The obligations are finite window admission, selector-order replay, regular-rational readback, and Real-seal nonescape; they do not assert sequential compactness, countable choice, quotient-stream equality, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the displayed selector packet. The rows B, M, Q, W determine the finite subsequence surface, and every selected window is admitted by the packet row that names it.

Run finite window induction over M and Q. Each induction step consumes one displayed selector entry, reads the corresponding bounded source window from B, and appends exactly the matching $\mathsf{StreamName}^{\uparrow}$ row to W by hsame transport and Cont replay.

The readback and seal obligations are then projected from R, E, P, N. Since these rows are attached after the selected windows and contain no coordinate for compactness, countable choice, quotient equality, host equality, or ambient completeness, the finite-subsequence obligations stop at the displayed packet boundary. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteSubsequenceObligatio`

Theorem 1408.13 (Bolzano–Weierstrass selector root window)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, every root selected-window read must expose the bounded source windows* B*, monotone selector ledger* M*, cofinal row* Q*,* $\mathsf{StreamName}^{\uparrow}$ *row* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the structural rows* H, C, P, N*. The read factors through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergence}$ $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, and it exports no full Bolzano–Weierstrass theorem, sequential compactness, choice-selected subsequence, quotient stream, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRootWindow`

Proof. Begin with the subsequence handoff of Definition 1408.2. It routes the root selector surface from B, M, Q to W, D, R through the finite monotone subsequence packet and the stream, dyadic, and regular rational rows.

Next use the finite-subsequence obligations of Definition 1408.12. They require the same bounded source, selector, cofinal, selected-window, readback, seal, and structural rows to be displayed before any finite selected-window read is exported.

Now apply the bounded-monotone route of Definition 1408.4. It places the Real seal behind $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ and $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$, so the root read remains a finite induction-style handoff rather than a compactness principle.

Finally use the nonescape theorem Definition 1408.9. Since the carrier has no row for full Bolzano–Weierstrass, sequential compactness, choice-selected subsequences, quotient streams, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the root window exports only the displayed finite route. □

Theorem 1408.14 (Bolzano–Weierstrass selector RegSeqRat readback nonescape)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ BHist *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback from the selected windows must pass through the finite route*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R$$

with the $\mathsf{Real}^{\uparrow}$ *seal row* E *available only after that readback is displayed. Componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row preserve the route; they do not let the read escape to a choice-selected subsequence, sequential compactness, quotient-stream equality, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRegSeqRatReadbackNonescape`

Proof. Start with the finite-subsequence obligations of Definition 1408.12. They force every selected window in W to be displayed through B, M, Q before downstream readback can begin.

Project the dyadic and regular rows from the carrier. The $\mathsf{DyadicRatCore}^{\uparrow}$ row D is attached to the displayed selected windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R is read only after those dyadic rows have been exposed.

Finally inspect the structural rows H, C, P, N and the $\mathsf{Real}^{\uparrow}$ seal row E. They replay and name the same finite route, so no hidden compactness, choice, quotient, host-equality, or ambient-completeness datum can be introduced at readback time. □

Definition 1408.15 (Bolzano–Weierstrass selector induction budget)**.** *The finite selector-induction budget of an accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$ *is the displayed four-row ledger* B, M, Q, W*: the bounded source-window row* B*, the monotone selector ledger* M*, the inspected-threshold cofinality row* Q*, and the selected* $\mathsf{StreamName}^{\uparrow}$ *window row* W*. A budget step consumes one displayed entry of* M*, reads its bounded source window from* B*, verifies the inspected threshold in* Q*, and appends the admitted selected window to* W *through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*. The budget contains no hidden subsequence object, least-selector functional, countable choice row, or compactness row.*

Lean4 (definition) `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorInductionBudget`
Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorInductionBudget`
`selected window route`

Theorem 1408.16 (Bolzano–Weierstrass selector finite monotone induction)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, finite induction over the selector-induction budget of Definition 1408.15 admits each selected window through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*. The base stage exposes the empty selected-window family over the displayed bounded source row* B*; each successor stage consumes one ledger entry from* M*, checks the inspected threshold row* Q*, and appends exactly the corresponding* $\mathsf{StreamName}^{\uparrow}$ *window to* W *by displayed* hsame *transport and* Cont *replay. No stage exports a choice-selected subsequence, sequential compactness, quotient-stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteMonotoneInduction`

Proof. Project the budget rows B, M, Q, W from the carrier. These rows are finite BHist data, so induction is over the displayed selector ledger rather than over an external sequence or function space.

The base case reads no selector entry. It exposes the empty selected-window family and records that no dyadic, regular, Real-facing, or compactness row is available.

For the successor step, consume the next displayed selector entry in M. The entry names its bounded source window in B, its inspected threshold in Q, and the selected $\mathsf{StreamName}^{\uparrow}$ window that is appended to W through the $\mathsf{MonotoneSubsequence}^{\uparrow}$ comparison row.

The transport rows H and replay rows C preserve the admitted window at each finite step. Since no carrier coordinate names a choice functional or a sequential compactness theorem, the induction admits exactly the selected windows listed in W. □

Theorem 1408.17 (Bolzano–Weierstrass selector finite-window stabilization)**.** *Let* $T = (B, M, Q, W, D, R, E, H, C$ *be an accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet. If a selected finite* $\mathsf{StreamName}^{\uparrow}$ *window in* W *is replaced by a later displayed window admitted by the same monotone selector ledger* M *and inspected-threshold row* Q*, then the route*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E$$

is preserved through $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergenceSeal}$ $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The stabilized packet records only this finite-window replacement route; it does not export full Bolzano–Weierstrass, sequential compactness, countable choice, quotient streams, host equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteWindowStabilization`

Proof. Project $B, M, Q, W, D, R, E, H, C, P, N$ from the carrier. The replacement hypothesis uses the same M and Q rows, so it remains inside the selector-induction budget of Definition 1408.15.

Apply Definition 1408.16 to the displayed later window. Finite induction over B, M, Q, W admits that window through the same $\mathsf{MonotoneSubsequence}^{\uparrow}$ comparison row, and H, C replay the transport without adding a subsequence object or a choice functional.

Now use the cluster and regular-Cauchy seal routes already proved in Definition 1408.8 and Definition 1408.19. The dyadic rows D, regular handoff R, and Real seal E are consumed after the stabilized selected window, so the downstream route is still the finite chain through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

No carrier coordinate remains for full Bolzano–Weierstrass compactness, sequential compactness, countable choice, quotient-stream equality, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The theorem therefore stabilizes only the displayed finite window. □

Theorem 1408.18 (Bolzano–Weierstrass selector finite nested-window induction)**.** *Let $T = (B, M, Q, W, D, R, E,$ be an accepted $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ packet. Suppose the bounded monotone route of Definition 1408.4, the nested-interval obligation of Definition 1408.22, the dyadic-window obligation of Definition 1408.21, the $\mathsf{StreamName}^{\uparrow}$ selected-window row W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal row E are all displayed in the same BHist packet. Then the selector admits finite induction over the nested windows: each induction stage refines the current interval through the displayed nested-interval row, transports the matching dyadic tolerance through D, replays the same $\mathsf{StreamName}^{\uparrow}$ window through W, and hands the resulting regular readback to R before E can be inspected. The cluster handoff is therefore the same handoff as in Definition 1408.8, and no stage exports a selected infinite subsequence, countable choice, quotient-stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.*

Proof. Project the finite-window stabilization rows from Definition 1408.17. They keep the route

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E$$

inside the accepted packet and leave H, C, P, N as structural transport, replay, provenance, and local naming rows.

Induct on the displayed nested-window budget. The base stage is the current selected window in W together with its bounded monotone route, dyadic tolerance row, regular readback row, and Real seal row.

For the successor step, use Definition 1408.22 to refine the interval row and Definition 1408.21 to transport the matching dyadic tolerance through D. The selected $\mathsf{StreamName}^{\uparrow}$ row remains the displayed window row W, so the successor step has no independent subsequence selector.

Now replay the readback through R and the Real seal through E. The cluster route of Definition 1408.8 and the nonescape boundary of Definition 1408.9 close the handoff through the same rows. Since no carrier coordinate names a selected infinite subsequence, countable-choice schedule, quotient-stream equality, host real equality, or ambient completeness theorem, the finite induction preserves only the displayed cluster handoff. □

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorFiniteNestedWindowInductio`

Theorem 1408.19 (Bolzano–Weierstrass selector regular Cauchy cluster seal)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the finite monotone route of Definition 1408.16 reaches the cluster-facing seal only through*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto R \longmapsto E.$$

The rows D, R, E *are read respectively through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the bounded monotone convergence seal route. The resulting consumer receives a regular Cauchy cluster boundary for the displayed selected windows, not classical sequential compactness, arbitrary choice, host real equality, quotient-stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRegularCauchyClusterSeal`

Proof. First apply Definition 1408.16. It admits the selected windows in W by finite induction over B, M, Q, W and makes $\mathsf{MonotoneSubsequence}^{\uparrow}$ the only selector surface.

Next read the dyadic tolerance ledger D and regular handoff row R. The carrier definition attaches each row in D to a selected window in W, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R is available only after those dyadic rows are displayed.

Finally use the bounded monotone Cauchy witness and bounded monotone convergence seal routes named in Definition 1408.4. They expose the Real-facing row E after W, D, R and do not add compactness, choice, quotient-stream equality, host equality, or ambient completeness. □

Theorem 1408.20 (Bolzano–Weierstrass selector bounded-subsequence carrier)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the bounded-subsequence carrier surface exposes bounded source windows and monotone selected windows by finite selector induction over* B, M, Q, W *only. The induction may read the bounded window ledger* B*, the monotone selector ledger* M*, the inspected-threshold row* Q*, and the selected* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, but it exports no ambient subsequence object, no countable choice functional, and no sequential compactness row.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorBoundedSubsequenceCarrier`

Proof. Project the carrier rows from Definition 1408.1. The rows B, M, Q, W are the only displayed selector rows before dyadic, regular, Real-facing, and structural rows are consumed.

Induct over the finite selector ledger M together with the inspected-threshold row Q. The base case reads the initial bounded source window from B and exposes the empty selected window family. The successor step consumes one displayed selector entry, verifies its comparison row through $\mathsf{MonotoneSubsequence}^{\uparrow}$, and appends the corresponding selected $\mathsf{StreamName}^{\uparrow}$ window to W.

Transport and continuation rows preserve the same finite route. Since the carrier has no row for an ambient subsequence, choice functional, or compactness theorem, the bounded-subsequence surface is exactly the finite induction over B, M, Q, W. □

Theorem 1408.21 (Bolzano–Weierstrass selector dyadic-window obligation)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, selected windows reach dyadic tolerance rows only through the displayed route*

$$B, M, Q \longmapsto W \longmapsto D.$$

Thus every dyadic read is mediated by $\mathsf{StreamName}^{\uparrow}$ *selected windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, not by a host metric limit, quotient-stream equality, or an uninspected source window.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorDyadicWindowObligation`

Proof. Begin with Definition 1408.20. It supplies the finite selected-window route $B, M, Q \longmapsto W$ and excludes any hidden subsequence object.

Now inspect the dyadic ledger D in Definition 1408.1. Each tolerance row in D is attached to a displayed selected $\mathsf{StreamName}^{\uparrow}$ window in W, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance data before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read is available.

The componentwise hsame and Cont rows replay this displayed handoff. They cannot add quotient-stream equality, host metric limits, or uninspected source windows, so every dyadic tolerance read factors through W and D. □

Theorem 1408.22 (Bolzano–Weierstrass selector nested-interval obligation)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, any consumer that reads the selected cofinal windows as a regular rational or Real-facing limit must first route those windows through the sibling* $\mathsf{NestedInterval}^{\uparrow}$ *and* $\mathsf{NestedIntervalCompleteness}^{\uparrow}$ *rows. In particular, the displayed route is*

$$B, M, Q \longmapsto W \longmapsto D \longmapsto \mathsf{NestedInterval}^{\uparrow}, \mathsf{NestedIntervalCompleteness}^{\uparrow} \longmapsto R \longmapsto E.$$

The route consumes bounded monotone and dyadic window data before the $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seals are read, and it exports no interval-compactness theorem, selected endpoint, countable choice schedule, quotient stream, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorNestedIntervalObligation`

Proof. Begin with Definition 1408.20 and Definition 1408.21. They expose the finite selected-window route from B, M, Q to W and then to the dyadic tolerance ledger D.

Next read the sibling nested-interval surfaces. The nested interval chapter supplies the retained-window order row, while the nested interval completeness chapter packages the decreasing-window read before any regular rational name is available. The selector packet can therefore consume R only after the selected dyadic windows have been recognized as nested retained windows.

Finally apply Definition 1408.23. It places the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the Real seal behind the same selected-window route, while the bounded-window exhaustion and regular Cauchy cluster seal keep the consumer inside the displayed packet. Thus no hidden compactness, choice, quotient, host-equality, or ambient-completeness datum enters the selector obligation. □

Theorem 1408.23 (Bolzano–Weierstrass selector regular Cauchy limit handoff)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the Real-facing row* E *is available only after the selected dyadic windows have passed through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R *and the bounded monotone convergence seal route. The packet therefore hands a regular Cauchy limit boundary to* $\mathsf{Real}^{\uparrow}$*, not classical Bolzano–Weierstrass, a choice-selected subsequence, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRegularCauchyLimitHandoff`

Proof. Use Definition 1408.21 to expose B, M, Q, W, D as the only dyadic-window route. No Real-facing row is visible at this stage.

Read the regular handoff row R. By the carrier definition, R is attached to the selected dyadic windows and is preserved by the displayed hsame and Cont rows before the seal coordinate E can be consumed.

Finally apply Definition 1408.4. The bounded monotone Cauchy witness and bounded monotone convergence seal chapters place E behind the finite selector, stream, dyadic, and regular handoff route, so the exported object is a regular Cauchy limit boundary for the displayed packet rather than a compactness or completeness theorem. □

Theorem 1408.24 (Bolzano–Weierstrass selector cofinal window stability)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the inspected cofinal rows in* Q *remain tied to the displayed bounded source windows* B *and selected windows* W *under componentwise* hsame *transport and displayed* Cont *replay. A consumer may refine an inspected threshold only by replaying the same* B, M, Q, W *window route; it cannot replace the cofinal row by a choice-selected subsequence, an uninspected source window, or quotient-stream equality.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorCofinalWindowStability`

Proof. Project the carrier of Definition 1408.1. The cofinal row Q is stored beside the bounded source window row B, the monotone selector ledger M, and the selected $\mathsf{StreamName}^{\uparrow}$ windows W.

Apply Definition 1408.20. Its finite induction over B, M, Q, W makes every inspected threshold part of the displayed selector ledger rather than an external subsequence object.

Now use the dyadic-window and regular-Cauchy handoffs, Definition 1408.21 and Definition 1408.23. They keep each downstream read attached to the same selected windows before D, R, E, H, C, P, N are consumed. Thus hsame transport and Cont replay preserve the cofinal window boundary instead of adding a hidden selector. □

Theorem 1408.25 (Bolzano–Weierstrass selector Real seal finality)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelector}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the Real seal row* E *is terminal after the displayed route through* $\mathsf{MonotoneSubsequence}^{\uparrow}$*,* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$*,* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$*. Once* E *is read through that route, no further row may reinterpret the packet as full Bolzano–Weierstrass compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host real equality, or a choice-selected cluster point.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorRealSealFinality`

Proof. Start with the bounded-monotone route of Definition 1408.4. It orders the Real-facing read through the monotone subsequence packet, the bounded monotone Cauchy witness, the convergence seal, the stream windows, the dyadic tolerance rows, the regular rational handoff, and finally the Real seal.

Use Definition 1408.23. The selected dyadic windows reach E only after the $\mathsf{RegSeqRat}^{\uparrow}$ row R and the bounded monotone convergence route have been displayed.

Finally apply Definition 1408.9. The carrier contains no coordinate after E for compactness, host equality, choice, quotient streams, or ambient completeness. The Real seal is therefore terminal for the finite L10 selector route. □

Theorem 1408.26 (Bolzano–Weierstrass selector bounded-window exhaustion)**.** *Every bounded-window consumer of an accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet must expose the rows*

$$B, M, Q, W, D, R, E, H, C, P, N$$

before it may read a selected-window, dyadic-window, regular-Cauchy, or Real-facing conclusion. The exposed rows exhaust the bounded-window surface: no consumer may cite a hidden subsequence object, an ambient compactness theorem, a least cluster selector, quotient-stream equality, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorBoundedWindowExhaustion`

Proof. Begin with Definition 1408.5. It already binds $B, M, Q, W, D, R, E, H, C, P, N$ as one displayed packet for every finite selected-window read.

Apply Definition 1408.20. The bounded source and selected-window surface is exhausted by the finite induction over B, M, Q, W.

Next use Definition 1408.21 and Definition 1408.23. These theorems force the downstream dyadic and regular-Cauchy reads through D and R before the Real seal E is visible.

The structural rows H, C, P, N transport, replay, source, and name the same carrier. Since the nonescape theorem Definition 1408.9 refuses all stronger endpoints, the displayed row family exhausts the bounded-window consumer surface. □

Falsifiable prediction: Every $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ Real-facing read factors through $\mathsf{MonotoneSubsequence}$ $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$, and $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ before the $\mathsf{Real}^{\uparrow}$ seal is visible.

Independence witness: monotonesubsequence, boundedmonotonecauchywitness, boundedmonotoneconvergenceseal, streamname, regseqrat, dyadicratcore, real: $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries bounded sequence windows, a monotone selector ledger, inspected-threshold cofinal evidence, selected stream windows, dyadic tolerance rows, a regular rational handoff, a Real seal boundary, transports, continuations, provenance, and local naming.

Theorem 1408.27 (Bolzano–Weierstrass selector scoped L10 kernel)**.** *For every accepted* $\mathsf{BolzanoWeierstrassSelecto}$ *packet* $T = (B, M, Q, W, D, R, E, H, C, P, N)$*, the carrier, bounded-window exhaustion, monotone-subsequence route, nested-interval obligation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal finality depend only on* BHist*,* hsame*,* Cont*,* $\mathsf{ProbeBundle}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the* $\mathsf{Real}^{\uparrow}$ *seal rows displayed in the packet and its cited L10 siblings. No proof step requires a host compactness theorem, a choice-selected subsequence, quotient-stream equality, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorScopeClosure`

Proof. Project the carrier of Definition 1408.1. The rows $B, M, Q, W, D, R, E, H, C, P, N$ are finite BHist data, with componentwise hsame transport and displayed Cont replay as the only structural routes.

Apply the finite-window induction of Definition 1408.6. It binds the monotone-subsequence route to displayed selector entries and selected $\mathsf{StreamName}^{\uparrow}$ windows, not to an external selector functional.

Use the nested-interval obligation of Definition 1408.22. The retained-window route is consumed as sibling L10 data before any regular rational readback, so the proof remains inside the displayed finite window surface.

Finally apply the regular Cauchy limit handoff and Real seal finality, Definition 1408.23 and Definition 1408.25. They place the $\mathsf{RegSeqRat}^{\uparrow}$ row and the $\mathsf{Real}^{\uparrow}$ seal after $\mathsf{DyadicRatCore}^{\uparrow}$ and the selected $\mathsf{StreamName}^{\uparrow}$ windows. Since the nonescape theorem excludes compactness, choice, quotient, host equality, and ambient completeness rows, the stated L10 kernel scope is closed. □

Theorem 1408.28 (Bolzano–Weierstrass selector public export)**.** *An accepted* $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ *packet exports exactly the finite handoff from bounded sequence windows through monotone-subsequence*

selection, bounded monotone Cauchy witness, bounded monotone convergence seal, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal rows. The exported public surface is the row family*

$$B, M, Q, W, D, R, E, H, C, P, N,$$

read in that dependency order and no stronger order. It does not claim sequential compactness, countable choice, quotient-stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BolzanoWeierstrassSelectorUp.BolzanoWeierstrassSelectorPublicExport`

Proof. Begin with the selector handoff of Definition 1408.2 and the real seal boundary of Definition 1408.3. These place the selected subsequence surface and the Real-facing seal behind displayed packet rows rather than behind a compactness theorem.

Next apply the bounded-monotone route, finite-window stabilization, and regular Cauchy cluster seal through Definition 1408.4, Definition 1408.6, and Definition 1408.23. The route forces the monotone-subsequence selection, bounded monotone Cauchy witness, bounded monotone convergence seal, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff to appear before E can be consumed.

Finally use the scoped L10 kernel theorem, Definition 1408.27. It exhausts the public export by $B, M, Q, W, D, R, E, H, C, P, N$ and refuses any hidden compactness, choice, quotient, host-equality, or ambient-completeness row. □

Closure status for $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$ packet is generated from bounded source windows, a monotone selector ledger, inspected-threshold cofinal evidence, selected StreamName windows, DyadicRatCore tolerance rows, a RegSeqRat handoff, a RealUp seal boundary, componentwise transports, displayed continuations, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassSelector}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1408.1, Definition 1408.2, Definition 1408.3, Definition 1408.4, Definition 1408.5, Definition 1408.6, Definition 1408.22, Definition 1408.23, Definition 1408.26, Definition 1408.27, and Definition 1408.28 bind the carrier, subsequence handoff, Real seal boundary, bounded-monotone route, window obligation, finite-window induction, nested-interval obligation, regular Cauchy limit handoff, bounded-window exhaustion, scoped L10 kernel, and public finite handoff surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim full Bolzano-Weierstrass, sequential compactness, choice-selected subsequences, quotient-stream equality, host real equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite selector stability, inspected-threshold cofinal coverage, selected-window RegSeqRat handoff, bounded monotone witness routing, and Real seal boundary non-escape for BEDC.Derived.BolzanoWeierstrassSelectorUp.

Chapter 1409

A Concrete Naming Certificate for $\mathsf{RationalDensityReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RationalDensityReal}^{\uparrow}$ packet records the finite rational-witness interface for displayed $\mathsf{Real}^{\uparrow}$ intervals. It sits after the Real seal of chapter 38, the regular-rational readback of chapter 301, the finite stream windows of chapter 126, and the dyadic tolerance arithmetic of chapter 291. It routes located interval data through the rational interval surface of chapter 354 and the apartness-gap boundary of chapter 304, without reading a host real order.

Definition 1409.1 (RationalDensityReal carrier)**.** *A* $\mathsf{RationalDensityReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, U, W_L, W_U, A, I, Q, T, R, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the lower and upper endpoint names, each carrying a* $\mathsf{Real}^{\uparrow}$ *seal row and a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*
2. *W_L and W_U are the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected from the two endpoint names.*
3. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *positive-gap row displayed between the endpoint seals.*
4. *I is the* $\mathsf{RationalInterval}^{\uparrow}$ *row whose rational bounds are read from the inspected endpoint windows.*
5. *Q is the visible* $\mathsf{Rat}^{\uparrow}$ *witness row selected between the displayed rational interval bounds.*
6. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row certifying that the inspected endpoint windows and the rational witness are read at one dyadic scale.*
7. *R is the dyadic radius row that records the positive subinterval around Q still contained in the displayed interval.*
8. *H stores componentwise* hsame *transports for the endpoint, window, apartness, interval, witness, tolerance, and radius rows.*
9. *C stores the* Cont *replay from endpoint windows to the rational interval row, from the rational interval row to the witness row, and from the witness row to the radius row.*
10. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalDensityReal}^\uparrow}$ *row.*

The carrier stores a displayed rational witness for a displayed interval. It has no host order coordinate, no trichotomy row, no quotient equality of real names, no completeness principle, no Heine–Borel cover row, and no hidden choice selector.

Theorem 1409.2 (RationalDensityReal NameCert obligation surface)**.** *For an accepted* $\mathsf{RationalDensityReal}^\uparrow$ *carrier* $D = (L, U, W_L, W_U, A, I, Q, T, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RationalDensityReal}^\uparrow}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed endpoint, window, apartness, rational-interval, witness, tolerance, radius, transport, continuation, provenance, and naming rows;*
2. *classifier transport along the stored* hsame *rows and the displayed* Cont *routes;*
3. *witness visibility, stating that the* $\mathsf{Rat}^\uparrow$ *row Q is exposed before any consumer reads the radius row R;*
4. $\mathsf{Real}^\uparrow$ *seal nonescape, stating that endpoint seals are consumed only through the stored* $\mathsf{RegSeqRat}^\uparrow$ *readbacks and* $\mathsf{StreamName}^\uparrow$ *windows;*
5. *ledger exactness, stating that the packet exports no host real order, trichotomy, quotient equality, completeness theorem, Heine–Borel cover, or hidden selector.*

Lean4 ✓ `BEDC.Derived.RationalDensityRealUp.RationalDensityRealTasteGate single carrier alignment`

Proof. Carrier admission is the tuple in Definition 1409.1. The endpoint names, stream windows, apartness row, rational interval row, witness row, dyadic tolerance, dyadic radius, transports, continuations, package row, and local naming row are all finite BHist coordinates.

Classifier transport reads H and C componentwise. The transported endpoint windows still feed the same rational-interval row shape, and the transported interval still exposes the same witness-and-radius sequence.

Witness visibility follows from the carrier order: the row Q is stored before the radius row R, and the continuation row records the replay from I to Q before replaying from Q to R.

The seal nonescape and ledger exactness are inventory checks. The endpoint seals occur only beside their regular-rational readbacks and finite windows, while host order, trichotomy, quotient equality, completeness, Heine–Borel data, and hidden selection are not rows of the packet. □

Theorem 1409.3 (RationalDensityReal located-window witness)**.** *Let L and U be displayed* $\mathsf{Real}^\uparrow$ *endpoint names with* $\mathsf{RegSeqRat}^\uparrow$ *readbacks, finite* $\mathsf{StreamName}^\uparrow$ *windows, and an* $\mathsf{ApartnessReal}^\uparrow$ *positive-gap row between them. If the inspected windows determine a displayed* $\mathsf{RationalInterval}^\uparrow$ *row whose dyadic tolerance is recorded by* $\mathsf{DyadicRatCore}^\uparrow$*, then an accepted* $\mathsf{RationalDensityReal}^\uparrow$ *packet exposes a visible* $\mathsf{Rat}^\uparrow$ *witness row inside that displayed interval. Every consumer route to the witness factors through*

$$(L, U) \longmapsto (W_L, W_U) \longmapsto A \longmapsto I \longmapsto Q$$

and through the dyadic tolerance and radius rows T, R; no step appeals to host real order, trichotomy, quotient equality, Real completeness, or Heine–Borel compactness.

Proof. Read the endpoint data through their displayed regular-rational rows. The finite stream windows W_L, W_U are the only observations used to form the rational interval row, so the route begins inside $\mathsf{RegSeqRat}^\uparrow$ and $\mathsf{StreamName}^\uparrow$.

The positive-gap row A makes the interval located at the displayed scale. The dyadic row T records that the endpoint windows and the rational interval bounds are compared inside $\mathsf{DyadicRatCore}^{\uparrow}$, not inside an ambient order on completed reals.

The rational witness is then the row Q of the carrier. The continuation path reads I before Q and records the radius row R only after Q is visible.

Thus the witness route is exactly the displayed chain through $\mathsf{RationalInterval}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$. Any route using host real order, trichotomy, quotient equality, Real completeness, or Heine–Borel compactness leaves the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalDensityReal}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalDensityReal}^{\uparrow}$ packet is generated from two displayed RealUp endpoint names, their RegSeqRat readbacks, finite StreamName windows, an ApartnessReal positive-gap row, a RationalInterval row, a visible Rat witness, dyadic tolerance and radius rows, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalDensityReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1409.1, Definition 1409.2, and Definition 1409.3 declare the finite rational-witness surface for displayed RealUp intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalDensityReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, trichotomy, quotient equality of real names, host real order, Heine–Borel compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, witness visibility, seal nonescape, and ledger exactness for the same finite packet.

Chapter 1410

A Concrete Naming Certificate for $\mathsf{BishopIntervalCompact}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopIntervalCompact}^{\uparrow}$ packet records the finite-net compact interval surface for displayed real-name intervals. It is anchored in the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular-rational readback surface of chapter 301, the visible real seal of chapter 38, the comparison boundary of chapter 1381, and the rational witness route of chapter 1409. The chapter treats compactness as a finite-net packet over those rows, not as open-cover compactness or a choice-bearing completeness principle.

A $\mathsf{BishopIntervalCompact}^{\uparrow}$ carrier is a finite BHist packet

$$K = (A, B, W, T, G, Q, R, H, C, P, N)$$

with the following displayed rows:

1. A and B are the lower and upper endpoint names, each read through $\mathsf{RegSeqRat}^{\uparrow}$ rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, and a visible $\mathsf{Real}^{\uparrow}$ seal.
2. W is the bounded interval window ledger naming the endpoint windows inspected at each dyadic tolerance.
3. T is the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance scale used to compare endpoint windows and interval mesh points.
4. G is the finite grid row listing the rational mesh points visible at the chosen dyadic scale.
5. Q is the rational-density witness ledger that routes each mesh cell through $\mathsf{RationalDensityReal}^{\uparrow}$ rather than through host real order.
6. R is the Bishop comparison row recording the same endpoint, readback, and seal surface as a $\mathsf{BishopRealComparison}^{\uparrow}$ packet.
7. H stores componentwise hsame transports for endpoints, windows, tolerance, grid, witness, comparison, continuation, package, and local naming rows.
8. C stores the displayed Cont replay from endpoint windows to dyadic scale, from dyadic scale to grid, and from grid cells to rational witnesses.
9. P is the Pkg provenance over $\mathsf{BishopIntervalCompact}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{RationalDensityReal}^{\uparrow}$, BHist, hsame, Cont, and $\mathsf{NameCert}$ rows.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopIntervalCompact}^{\uparrow}}$ row.

The packet gives a finite interval-net surface: every consumer read factors through the displayed endpoint windows, dyadic tolerance, finite grid, rational-density witnesses, comparison row, transport, continuation, provenance, and local naming. It does not supply a cover selector, a subsequence selector, an ambient Heine–Borel theorem, quotient equality of real names, or a host-real equality test.

Theorem 1410.1 (BishopIntervalCompact finite-grid obligation)**.** *Let $K = (A, B, W, T, G, Q, R, H, C, P, N)$ be an accepted* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *carrier. The accepted packet projects the lower endpoint row A, the upper endpoint row B, the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance scale T, the finite rational grid G, the* $\mathsf{RationalDensityReal}^{\uparrow}$ *witness ledger Q, the* $\mathsf{BishopRealComparison}^{\uparrow}$ *comparison row R, the componentwise* hsame *transport H, the displayed* Cont *replay C, the* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalCompact}^{\uparrow}}$ *row N. Every compact-interval read admitted by the packet is exhausted by those rows and by no hidden open-cover, host-real, quotient-equality, or choice-bearing coordinate.*

Proof. Project the accepted carrier. Its displayed tuple has exactly the rows $A, B, W, T, G, Q, R, H, C, P, N$, so every endpoint, tolerance, grid, witness, comparison, transport, replay, provenance, and local naming request starts from one of these coordinates.

The finite-grid classifier cannot inspect data outside the displayed tuple. Endpoint reads pass through A, B, W, T and then through the comparison row R; mesh reads pass through T, G, Q; transport and replay reread the same coordinates through H and C.

Since the carrier has no coordinate for a cover selector, a subsequence selector, quotient equality of real names, or host-real equality, a consumer has no route to such data. Thus the accepted compact-interval surface is exhausted by the displayed finite rows. □

Lean4 ✓ `BEDC.Derived.BishopIntervalCompactUp.BishopIntervalCompactTasteGate single carrier alignment`

Theorem 1410.2 (BishopIntervalCompact rational-density routing)**.** *For every accepted* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *carrier $K = (A, B, W, T, G, Q, R, H, C, P, N)$, each mesh-cell witness in Q must route through the rational-density surface of chapter 1409, the dyadic tolerance arithmetic of chapter 291, the finite stream windows of chapter 126, the regular rational readbacks of chapter 301, and the visible real seal of chapter 38 before any* $\mathsf{Real}^{\uparrow}$*-facing seal is visible.*

Proof. Begin with a mesh-cell witness named by Q. By construction, Q is the rational-density witness ledger for the grid row G, so the witness is not a host-real order comparison; it is a displayed $\mathsf{RationalDensityReal}^{\uparrow}$ route attached to the finite mesh cell.

The tolerance requested by the witness is the dyadic row T. Its endpoint and mesh reads are inspected through the finite windows W, and those windows have regular rational readbacks before they can expose a real-name seal.

The visible seal is therefore reached only after the route has passed through rational density, dyadic tolerance, stream windows, regular rational readback, and the $\mathsf{Real}^{\uparrow}$ certificate surface. Componentwise transport H and continuation replay C preserve this route rather than introducing a separate equality test. □

Theorem 1410.3 (BishopIntervalCompact compact-metric handoff)**.** *Any compact-metric or interval consumer of an accepted* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *carrier $K = (A, B, W, T, G, Q, R, H, C, P, N)$ receives only the finite-net packet consisting of endpoint rows, finite windows, dyadic tolerance, finite grid, rational-density witnesses, comparison row, transport, replay, provenance, and local*

naming. The handoff exports no open-cover compactness, sequential compactness, quotient equality, selected subcover, selected subsequence, countable-choice schedule, or host real equality.

Proof. The consumer boundary is the packet boundary. A downstream compact-metric or interval consumer can read $A, B, W, T, G, Q, R, H, C, P, N$ and can ask the replay row C to reproduce the displayed route from endpoint windows to dyadic tolerance, finite grid, rational witnesses, and comparison rows.

This boundary exports a finite-net object: the grid G is finite, the windows W are displayed, and each witness in Q is routed through the named rational-density and real-seal surfaces. The comparison row R supplies the endpoint boundary without replacing the packet by host equality of real names.

No coordinate of K carries an open cover, an infinite sequence, a selected subcover, a selected subsequence, a quotient-equality proof, or a host-real equality proof. Hence every downstream handoff is a finite-net handoff and not a classical compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalCompact}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalCompact}^{\uparrow}$ packet is generated from displayed endpoint real names, regular-rational readbacks, finite stream windows, a dyadic tolerance scale, a finite rational grid, rational-density witnesses, a Bishop comparison row, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1410.1, Definition 1410.2, and Definition 1410.3 seed the finite-net compact interval packet over the DyadicRatCore, StreamName, RegSeqRat, Real, BishopRealComparison, and RationalDensityReal surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, sequential compactness, Heine–Borel compactness for arbitrary subsets, countable choice, selected limits, or host real equality.

Upgrade path: A later verification route can encode the carrier and prove the finite-grid obligation, rational-density routing, compact-metric handoff, comparison-row nonescape, and ledger exactness for the displayed packet.

Chapter 1411

A Concrete Naming Certificate for $\mathsf{SeparatedMetric}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{SeparatedMetric}^{\uparrow}$ packet records the constructive separation surface needed by completion-limit uniqueness. It refines the metric carrier of chapter 57, consumes the Cauchy-limit rows of chapter 128, respects the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38, and reads regular-name comparison through chapter 1412. The packet treats equality of displayed limit names as a finite classifier consequence of zero-distance observations, not as host equality, trichotomy, quotient formation, open-cover compactness, or ambient real completeness.

Definition 1411.1 (SeparatedMetric carrier surface)**.** *A* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, D, Z, L_0, L_1, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying* $\mathsf{Met}^{\uparrow}$ *carrier row, including its point classifier and metric-distance witness surface.*
2. *D is the* $\mathsf{Real}^{\uparrow}$*-valued distance witness interface read from metric-distance rows through the displayed real seal.*
3. *Z is the separation row: whenever two carried observations have displayed zero distance through D, the row records the classifier equivalence between the two observations.*
4. *L_0 and L_1 are* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-limit rows for the same regular Cauchy point name, including their displayed moduli and convergence distance ledgers.*
5. *E is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison route that identifies the two limit claims as readings of one regular Cauchy name through finite windows and dyadic tolerances.*
6. *H stores componentwise* hsame *transport for the metric carrier, real-valued distance witness, separation row, Cauchy-limit rows, equivalence route, continuation row, package row, and local naming row.*
7. *C stores the* Cont *replay from finite Cauchy observations to metric-distance witnesses, from those witnesses to* $\mathsf{Real}^{\uparrow}$ *zero-distance readings, and from zero-distance readings to the classifier equivalence row.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^\uparrow}$ *row.*

The carrier exposes separatedness only as a finite zero-distance-to-classifier route. It carries no quotient metric-space object, no host equality coordinate, no trichotomy row, no open-cover compactness principle, and no assertion that $\mathsf{Real}^\uparrow$ *is complete.*

Lean4 (definition) `BEDC.Derived.SeparatedMetricUp.SeparatedMetricUp`

Definition 1411.2 (SeparatedMetric classifier surface)**.** *The classifier of an accepted* $\mathsf{SeparatedMetric}^\uparrow$ *packet relates two carried observations a, b precisely when the packet displays a finite route*

$$a, b \longmapsto \mathsf{MetricDistanceWitness}(a, b, d) \longmapsto D(d, 0) \longmapsto Z(a, b).$$

The first step is a $\mathsf{Met}^\uparrow$ *distance-witness row, the second step is a* $\mathsf{Real}^\uparrow$ *zero-distance reading of that witness, and the final step is the separation row identifying a and b inside the point classifier of X. Transport of this classifier is componentwise: if $a, b, d, Z(a, b)$ are moved by the stored* hsame *rows, then the replayed* Cont *path produces the transported zero-distance reading and the transported classifier equivalence.*

This classifier is not a quotient-by-equivalence-class construction. It is a local recognition surface for carried observations whose zero-distance evidence is already displayed in the packet.

Theorem 1411.3 (SeparatedMetric NameCert obligations)**.** *For an accepted* $\mathsf{SeparatedMetric}^\uparrow$ *carrier $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^\uparrow}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the* $\mathsf{Met}^\uparrow$ *carrier row,* $\mathsf{Real}^\uparrow$*-valued distance witness row, separation row, two* $\mathsf{CompleteMetric}^\uparrow$ *Cauchy-limit rows,* $\mathsf{CauchySequenceEquivalence}^\uparrow$ *route, componentwise transport, continuation replay, provenance row, and local naming row;*
2. *classifier stability, stating that zero-distance observations transported by H and replayed by C still yield the transported classifier equivalence through Z;*
3. *completion compatibility, stating that the two limit rows L_0, L_1 are read as limits of the same regular Cauchy point name only through the displayed equivalence route E;*
4. *zero-distance exactness, stating that the only route from metric equality evidence to point-classifier equivalence factors through the* $\mathsf{Real}^\uparrow$ *zero-distance witness and the separation row;*
5. *ledger visibility, stating that the packet exports no quotient metric space, no host equality, no trichotomy, no open-cover compactness, and no* $\mathsf{Real}^\uparrow$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricPacket semantic name certificate`

Proof. Carrier admission is the finite tuple of Definition 1411.1. Every row named in the obligation list is visible in S, and no extra equality or compactness row is available to a consumer.

Classifier stability follows from the paired transport and replay rows. The hsame fields move endpoints, distance witnesses, zero-distance readings, limit rows, and the separation row componentwise, while the Cont row replays the same finite route after transport.

Completion compatibility reads the two limit rows only through the common regular Cauchy name witnessed by E. The route never collapses names into quotient classes; it only shows that both displayed limit claims are attached to one finite-window comparison surface.

Zero-distance exactness is the defining use of the separation row. Once the transported distance witness is read as zero through D, the row Z is the unique exported bridge to the point classifier of X. The final ledger statement is an inventory check on the fields of S. □

Theorem 1411.4 (SeparatedMetric completion limit uniqueness route)**.** *Let S be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet whose rows L_0 and L_1 are two* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-limit witnesses for the same regular Cauchy point name, with sameness displayed by the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route E. Then the packet exposes a constructive uniqueness route from the two limit names to the point classifier of the metric carrier:*

$$L_0, L_1 \longmapsto E \longmapsto \mathsf{MetricDistanceWitness}(\ell_0, \ell_1, d) \longmapsto D(d, 0) \longmapsto Z(\ell_0, \ell_1).$$

Here ℓ_0 and ℓ_1 are the displayed limit histories read from L_0 and L_1. The conclusion is classifier equivalence inside the carried $\mathsf{Met}^{\uparrow}$ *surface. It is not host equality, not equality of quotient classes, and not an appeal to trichotomy, open-cover compactness, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricPacket completion limit uniqueness route`

Proof. Read the two complete-metric limit rows L_0 and L_1 and use E to keep them attached to the same regular Cauchy point name. The equivalence route supplies the finite-window comparison data needed to compare the two convergence ledgers at a common displayed tolerance.

Replay the metric-distance construction through C. The convergence ledgers for L_0 and L_1 yield a displayed distance witness between the two limit histories; the real-valued distance interface D reads that witness as zero in the packet's $\mathsf{Real}^{\uparrow}$ seal.

Apply the separation row Z to this zero-distance reading. The result is classifier equivalence between ℓ_0 and ℓ_1 in the underlying metric carrier X.

Each step is a row of S or a replay of a row of S. Since quotient classes, host equality, trichotomy, open-cover compactness, and $\mathsf{Real}^{\uparrow}$ completeness are not fields of the packet, none can be used by this route. □

Theorem 1411.5 (SeparatedMetric Real completion consumer boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion consumer of an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet can use the packet only through the displayed chain*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{CauchySequenceEquivalence}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow}.$$

Concretely, the consumer may read the metric carrier, the two complete-limit rows, the finite-window equivalence route, the real-valued zero-distance witness, the separation row, the componentwise transport rows, the continuation replay, package provenance, and the local naming row. The consumer may not infer quotient metric spaces, host equality of histories, trichotomy of real comparisons, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$ *from this packet.*

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricPacket real completion consumer boundary`

Proof. The carrier inventory in Definition 1411.1 lists exactly the rows available to a consumer. The displayed chain names the order in which those rows can be replayed: metric data first, complete-limit data second, finite-window comparison third, real-valued zero-distance reading fourth, and separation classification last.

The hsame and Cont rows preserve this order under transport, so a consumer cannot bypass the zero-distance witness or replace the classifier conclusion with host equality. The package row records only the named BEDC surfaces in the chain.

The non-claims are again field exclusions. No quotient carrier, trichotomy ledger, open-cover compactness row, or $\mathsf{Real}^{\uparrow}$ completeness row occurs in S, so no consumer boundary licensed by N can read such a principle from the packet. □

Theorem 1411.6 (SeparatedMetric zero-distance consumer exactness)**.** *Let $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet. Every consumer that reads a zero-distance identification from S must consume, in order, the* $\mathsf{Met}^{\uparrow}$ *distance witness in X, the* $\mathsf{Real}^{\uparrow}$ *zero-distance read through D, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and the local* NameCert *row N before the separated classifier row Z may be exported. If the zero-distance read is attached to completion data, the same consumer must first expose the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows L_0, L_1 and the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison route E.*

Thus zero-distance consumption is exact at the displayed rows of S. It is not host equality, quotient equality, selected representative data, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1411.1. The metric source is X, the real-valued zero-distance witness is D, and the classifier export is stored only in the separation row Z.

Apply the classifier surface of Definition 1411.2 together with the zero-distance carrier row of Definition 1411.14. These rows force a consumer to form the $\mathsf{Met}^{\uparrow}$ distance witness before the $\mathsf{Real}^{\uparrow}$ zero-distance read, and to use Z only after that read is displayed.

The structural rows H, C, P, N then transport, replay, source, and name the same finite route. When completion-limit rows are involved, Definition 1411.18 inserts L_0, L_1, E before the distance witness is formed.

No other coordinate occurs in S. Therefore every accepted zero-distance consumer is exhausted by the displayed route and cannot obtain any excluded equality or completeness principle. □

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricZeroDistanceConsumerExactness`

Theorem 1411.7 (SeparatedMetric Cauchy uniqueness root package)**.** *An accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet exports completion-limit uniqueness to downstream L10 completion consumers only through the finite package*

$$X, D, Z, L_0, L_1, E, H, C, P, N.$$

Here X is the metric row, D is the $\mathsf{Real}^{\uparrow}$ *zero-distance classifier read, Z is the separated zero-distance classifier, L_0, L_1 are the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows, E is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison row, and H, C, P, N are the transport, replay, provenance, and local NameCert rows. The package exports classifier equivalence of the displayed limit names and nothing stronger: no quotient representative, host equality, trichotomy, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness is part of the handoff.*

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricPacket cauchy uniqueness root package`

Proof. First use the completion-limit uniqueness route of Definition 1411.4. It reads the two complete-metric limit rows through the same Cauchy-sequence equivalence row before forming the metric-distance witness in X.

Next apply Definition 1411.6. That theorem forces every zero-distance consumer to pass through the $\mathsf{Real}^{\uparrow}$ read D, componentwise transport H, displayed replay C, package provenance P, and the local naming row N before the separated classifier row Z is exported.

Combining the two routes gives a single root package for downstream completion chapters. Since the accepted packet contains no quotient representative, host-equality coordinate, trichotomy ledger, selected-limit field, or ambient completeness theorem, the exported uniqueness claim remains exactly the displayed separated-classifier handoff. □

Theorem 1411.8 (SeparatedMetric limit uniqueness scope)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, every limit-uniqueness claim over the two* $\mathsf{CompleteMetric}^{\uparrow}$ *rows* L_0, L_1 *is scoped by the route*

$$L_0, L_1 \longmapsto E \longmapsto X \longmapsto D \longmapsto H, C, P, N \longmapsto Z.$$

Here E *is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison route for the two displayed Cauchy presentations,* X *supplies the* $\mathsf{Met}^{\uparrow}$ *distance witness between the two displayed limit histories,* D *reads that witness as* $\mathsf{Real}^{\uparrow}$ *zero distance, and* Z *supplies the separated classifier conclusion. The scope contains no quotient completion equality, host limit equality, selected representative, countable choice, trichotomy, or ambient completeness field.*

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricPacket limit uniqueness scope`

Proof. Begin with the completion compatibility clause of Definition 1411.3. It requires the two $\mathsf{CompleteMetric}^{\uparrow}$ limit rows to be read through the displayed $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ route E before their endpoints are compared.

Use the completion limit uniqueness route of Definition 1411.4. After E binds the two limit rows to one regular Cauchy point name, the route forms the metric-distance witness in X and reads it as zero through D.

Finally apply Definition 1411.6. The support rows H, C, P, N preserve and name the same route before the classifier row Z is exported. Since the packet has no quotient, host-limit, selected-representative, choice, trichotomy, or ambient-completeness coordinate, the uniqueness claim remains inside this scope. □

Theorem 1411.9 (SeparatedMetric completion handoff nonescape)**.** *Every completion-facing handoff from an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet to a downstream L10 consumer must pass through the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows* L_0, L_1*, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison route* E*, the* $\mathsf{Met}^{\uparrow}$ *distance witness in* X*, the* $\mathsf{Real}^{\uparrow}$ *zero-distance read* D*, the separated classifier row* Z*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* NameCert *row* N*. The handoff exports only that routed separated-classifier evidence; it does not export a quotient completion carrier, selected limit, host equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricPacket completion handoff nonescape`

Proof. Start with Definition 1411.5. It lists the rows a Real or completion consumer may read from the packet and places the complete-limit and finite-window comparison rows before the real zero-distance and separated-classifier rows.

Apply Definition 1411.8. The limit rows L_0, L_1 enter the handoff only through E, then through the metric witness in X, the zero-distance row D, and the classifier row Z.

Use Definition 1411.6 for the support rows. Transport, replay, provenance, and local naming pass through H, C, P, N and do not add a second carrier or a hidden selector.

The nonescape conclusion is a field inventory. Since no quotient completion, selected limit, host equality, trichotomy, countable-choice, or ambient-completeness row is present in S, no downstream completion handoff can read one from the packet. □

Theorem 1411.10 (SeparatedMetric CompleteMetric consumer exactness)**.** *Any* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer of separated limit uniqueness for an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *must pass through*

$$L_0, L_1 \longmapsto E \longmapsto X \longmapsto D \longmapsto Z \longmapsto H, C, P, N.$$

The consumer may read the displayed completion-limit rows, the Cauchy-sequence equivalence route, the metric distance witness, the real zero-distance row, the separated classifier, and the structural ledger. It cannot infer quotient completion equality, selected representatives, host equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 1411.18. It places every comparison of the two $\mathsf{CompleteMetric}^{\uparrow}$ limit rows behind the displayed $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ route E before any metric or real-valued comparison is available.

Next apply Definition 1411.9. The completion handoff reads L_0, L_1, then E, then the metric witness in X, the real zero-distance row D, and the separated classifier row Z.

Finally use Definition 1411.6. The structural rows H, C, P, N transport, replay, source, and name the same route, while every excluded principle lacks a carrier coordinate. Hence a $\mathsf{CompleteMetric}^{\uparrow}$ consumer receives exactly the displayed separated-limit route and no stronger equality or choice principle. □

Theorem 1411.11 (SeparatedMetric root-unblock completion package)**.** *For every accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, the root-unblock package for completion-limit uniqueness is exactly the displayed row family*

$$X, D, Z, L_0, L_1, E, H, C, P, N.$$

Downstream $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers receive classifier equivalence only through these rows:* L_0, L_1 *and* E *expose the completion comparison,* X, D, Z *expose the zero-distance classifier route, and* H, C, P, N *transport, replay, source, and name the handoff.*

Proof. Apply Definition 1411.10. It already places every $\mathsf{CompleteMetric}^{\uparrow}$ consumer behind $L_0, L_1, E, X, D, Z, H, C,$

Now use Definition 1411.6. It keeps the classifier export behind the metric witness, the $\mathsf{Real}^{\uparrow}$ zero-distance read, the separated row, and the structural support rows.

The resulting package is a root-unblock surface because no other coordinate is present in the carrier. A consumer therefore receives only the displayed classifier equivalence, not quotient completion equality, host equality, selected representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1411.12 (SeparatedMetric zero-distance root factorization)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Every zero-distance root read used in completion-limit uniqueness factors first through the* $\mathsf{Met}^{\uparrow}$ *row* X*, then through the* $\mathsf{Real}^{\uparrow}$ *zero-distance row* D*, and only then through the separated classifier row* Z*, with* L_0, L_1, E *displayed when the read is completion-facing and* H, C, P, N *preserving the same BEDC route.*

Proof. Use Definition 1411.6. It forces the metric-distance witness and Real zero-distance read to precede any separated classifier export.

For completion-facing reads, apply Definition 1411.10. The two limit rows and the Cauchy-sequence equivalence row must be displayed before the zero-distance route is consumed.

The factorization is therefore rooted in the shown carrier rows. Since H, C, P, N only transport, replay, source, and name the same route, no downstream consumer can replace the classifier equivalence with host equality, quotient equality, selected representative data, trichotomy, countable choice, or ambient completeness. □

Theorem 1411.13 (SeparatedMetric CompleteMetric root handoff)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff that consumes completion-limit uniqueness from an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *receives the classifier equivalence through the displayed route*

$$L_0, L_1 \longmapsto E \longmapsto X \longmapsto D \longmapsto Z \longmapsto H, C, P, N.$$

The handoff is a BEDC row transfer only; it carries no quotient completion carrier, selected limit, host equality of completed names, trichotomy, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or off-packet certificate.*

Proof. Start with the completion handoff nonescape theorem, Definition 1411.9. It confines completion-facing consumers to the same limit, comparison, metric, Real, separatedness, and structural rows.

Then read Definition 1411.10. It identifies the exact order in which a $\mathsf{CompleteMetric}^{\uparrow}$ consumer may receive those rows.

Finally apply Definition 1411.11. The root package exhausts the carrier, so the handoff cannot acquire any excluded equality, selection, choice, completeness, or off-packet certificate from outside the displayed rows. □

Definition 1411.14 (SeparatedMetric zero-distance carrier row)**.** *The zero-distance carrier row of an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet is the displayed* BHist *route*

$$\mathsf{MetricDistanceWitness}(a, b, d) \longmapsto \mathsf{Real}^{\uparrow}(d, 0) \longmapsto Z(a, b),$$

where the first term is read from the $\mathsf{Met}^{\uparrow}$ *distance-witness surface of Definition 1411.1, the middle term is the* $\mathsf{Real}^{\uparrow}$ *zero-distance row already admitted by the carrier and local NameCert obligations of Definition 1411.3, and* $Z(a, b)$ *is the separation row consumed by the classifier of Definition 1411.2. The row is a finite route from a metric-distance witness to point-classifier equivalence. It is not host equality of points, quotient equality, trichotomy of distances, or an ambient completeness assertion for* $\mathsf{Real}^{\uparrow}$*.*

Theorem 1411.15 (SeparatedMetric classifier stability row)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet, transported zero-distance evidence replays through the stored* hsame *and* Cont *rows to the transported point classifier. Concretely, if a displayed route*

$$\mathsf{MetricDistanceWitness}(a, b, d) \longmapsto \mathsf{Real}^{\uparrow}(d, 0) \longmapsto Z(a, b)$$

is transported componentwise by H*, then* C *replays the transported distance witness, the transported real zero-distance reading, and the transported separation row before the classifier reads the transported pair.*

Proof. Start with the carrier of Definition 1411.1. Its rows H and C are stored for the metric carrier, real-valued distance witness, separation row, Cauchy-limit rows, equivalence route, continuation row, package row, and local naming row.

Apply classifier stability from Definition 1411.3. The transported endpoints and distance witness first move through the corresponding hsame fields. The replay row then reads the same zero-distance route through the transported $\mathsf{Real}^{\uparrow}$ row.

Finally apply the classifier surface of Definition 1411.2. Since the transported zero-distance evidence reaches the transported separation row before classification, the accepted classifier conclusion is the transported point-classifier equivalence and not a host equality or quotient claim. □

Theorem 1411.16 (SeparatedMetric limit uniqueness ledger)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet, two* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows over the same regular Cauchy name are consumed only through the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route before the separation row is read. In particular, the route*

$$L_0, L_1 \longmapsto E \longmapsto \mathsf{MetricDistanceWitness}(\ell_0, \ell_1, d) \longmapsto \mathsf{Real}^{\uparrow}(d, 0) \longmapsto Z(\ell_0, \ell_1)$$

is the only completion-limit uniqueness ledger exported by the packet.

Proof. Project the two complete-limit rows and the equivalence route from the carrier of Definition 1411.1. The NameCert obligations of Definition 1411.3 require completion compatibility to pass through E before the two limit histories are compared.

Use the completion-limit uniqueness route of Definition 1411.4. It constructs the displayed metric-distance witness between the two limit histories only after E has attached both rows to the same regular Cauchy point name.

The zero-distance carrier row of Definition 1411.14 then sends that witness through the $\mathsf{Real}^{\uparrow}$ zero-distance reading and into the separation row. Therefore the exported uniqueness ledger is classifier equivalence through Z, with no quotient completion, host equality, selected representative, countable choice, or ambient completeness row. □

Theorem 1411.17 (SeparatedMetric zero-distance transport)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet. If zero-distance evidence is displayed by the route*

$$\mathsf{MetricDistanceWitness}(a, b, d) \longmapsto \mathsf{Real}^{\uparrow}(d, 0) \longmapsto Z(a, b),$$

then every componentwise transport of this evidence through the stored $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*, and* Cont *rows yields the transported classifier route for the transported endpoints. The transported route still factors through* X, D, Z, H, C, P, N *and does not become host equality, quotient equality, or trichotomy of real distances.*

Proof. Project the zero-distance row from Definition 1411.14. The displayed evidence starts with a metric-distance witness in X, is read as zero through the $\mathsf{Real}^{\uparrow}$ seal row D, and reaches the classifier only through the separation row Z.

Apply the classifier stability row of Definition 1411.15. The stored hsame fields move the endpoints, distance witness, real zero-distance reading, and separation row componentwise, while the stored Cont row replays the same finite route after transport.

The provenance and local naming rows P, N name this transported route as part of the same packet. Since no host equality coordinate, quotient carrier, or trichotomy ledger occurs in S, the transported conclusion remains a $\mathsf{SeparatedMetric}^{\uparrow}$ classifier route and nothing stronger. □

Theorem 1411.18 (SeparatedMetric completion compatibility scope)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet. The two* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows* L_0, L_1 *can be compared by the separation row only after both have passed through the displayed* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route* E*. Thus every completion-limit uniqueness read has the scoped order*

$$L_0, L_1 \longmapsto E \longmapsto D \longmapsto Z.$$

No consumer may bypass E *by comparing selected representatives, quotient classes, host limit values, or ambient complete-space points.*

Proof. Begin with the completion compatibility clause of Definition 1411.3. It states that L_0 and L_1 are read as two limit rows for one regular Cauchy point name only through the displayed equivalence route E.

Use the limit uniqueness ledger of Definition 1411.16. That ledger constructs the metric-distance witness between the displayed limit histories only after E has supplied the common finite-window comparison surface.

The zero-distance and classifier steps then use D and Z in that order. The rows H, C, P, N transport, replay, source, and name the same order; they do not add a representative selector or quotient comparison.

Therefore a completion consumer reaches separation only through E first. The absent host-limit, quotient, selected-representative, and ambient-completeness rows cannot supply an alternate comparison scope. □

Theorem 1411.19 (SeparatedMetric Bishop Cauchy criterion handoff)**.** *Every zero-distance uniqueness consumer of an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *completion carrier must pass through the finite Bishop Cauchy criterion windows of chapter 3576 before the separated classifier row is exported. The route may then read the existing* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows of Definition 1411.18, but it exports no quotient equality, selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1411.18. It already forces the two completion-limit rows through E before any zero-distance classifier read.

Insert the Bishop Cauchy criterion windows before that equivalence read. The criterion supplies only finite tolerance and stream-window data, so the separated classifier remains a read of $X, D, Z, L_0, L_1, E, H, C, P, N$ and not a host equality or selected-limit export. □

Theorem 1411.20 (SeparatedMetric completion criterion nonescape)**.** *If a* $\mathsf{SeparatedMetric}^{\uparrow}$ *completion-limit uniqueness consumer reads a completion-criterion dependency row, that row must remain between the Bishop Cauchy criterion windows and the regular-name equivalence route before the classifier Z is exported. The dependency can be consumed through the completion siblings, but it does not supply quotient equality, selected representatives, countable choice, or ambient Real completeness.*

Proof. Use Definition 1411.19 for the finite Cauchy windows and Definition 1411.18 for the ordered route through E, D, Z.

The completion-criterion row is therefore a dependency inside the finite route, not an additional equality principle. Since the carrier has no coordinate for quotient comparison, selected representatives, choice, or ambient completeness, the separated classifier can only be exported after the dependency has been replayed through H, C, P, N. □

Theorem 1411.21 (SeparatedMetric regular-name uniqueness exhaustion)**.** *The regular-name uniqueness surface for an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *completion carrier is exhausted by Bishop Cauchy criterion windows, the completion-criterion dependency row, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route, the* $\mathsf{Real}^{\uparrow}$ *zero-distance witness, and the separated classifier row. No downstream consumer obtains a second uniqueness route from quotient equality, a selected limit, countable choice, or ambient Real completeness.*

Proof. Project the completion carrier and apply Definition 1411.19 and Definition 1411.20. These force the finite criterion, completion dependency, and regular-name equivalence rows to precede the classifier export.

The remaining rows H, C, P, N only transport, replay, source, and name that same route. Thus the listed rows exhaust regular-name uniqueness before separation, and the excluded principles have no carrier row from which a consumer could read them. □

Definition 1411.22 (SeparatedMetric zero-distance scope row)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, the zero-distance scope row is the finite route that begins with a* $\mathsf{Met}^{\uparrow}$ *distance witness in* X*, reads the witness as a* $\mathsf{Real}^{\uparrow}$ *zero-distance row through* D*, transports the evidence through* H*, replays it through* C*, sources it through* P*, names it through* N*, and only then exports the classifier equivalence supplied by* Z*. If the zero-distance read is attached to completion-limit data, the route first passes through the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *row* E *that binds* L_0 *and* L_1 *to the same regular Cauchy point name.*

The row is a scope obligation for displayed evidence. It is not host point equality, quotient real equality, a selected representative, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1411.23 (SeparatedMetric zero-distance reflection)**.** *Every classifier equivalence exported by a zero-distance read from an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *reflects the route of Definition 1411.22. In particular, the export must pass through a* $\mathsf{Met}^{\uparrow}$ *distance witness, the* $\mathsf{Real}^{\uparrow}$ *zero-distance row* D*, the componentwise* hsame *transport* H*, the displayed* Cont *replay* C*, the* Pkg *provenance* P*, and the local* $\mathsf{NameCert}$ *row* N *before the classifier row* Z *is available.*

Proof. Project the carrier of Definition 1411.1. The metric source is X, the real-valued distance interface is D, and the classifier export is stored only in the separation row Z.

Apply the zero-distance scope row of Definition 1411.22. It places the distance witness before the $\mathsf{Real}^{\uparrow}$ zero-distance read and places the support rows H, C, P, N before the classifier export.

Use Definition 1411.15 to transport and replay the same route. The resulting classifier equivalence is therefore a reflected BEDC row, not host equality, quotient equality, selected representative data, trichotomy, or a completeness principle. □

Theorem 1411.24 (SeparatedMetric completion-limit uniqueness scope)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Any completion-limit uniqueness claim exported from* S *must read* L_0 *and* L_1 *through the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *row* E *before it can form the* $\mathsf{Met}^{\uparrow}$ *distance witness, read* $\mathsf{Real}^{\uparrow}$ *zero-distance through* D*, transport through* H*, replay through* C*, source through* P*, name through* N*, and export classifier equivalence through* Z*.*

Consequently completion-limit uniqueness is scoped as classifier equivalence in the displayed metric carrier. It is not host limit equality, quotient real equality, quotient completion equality, a selected representative, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 1411.18. It requires the two complete-metric limit rows to pass through E before the separation row can be read.

Next apply Definition 1411.16. The ledger constructs the metric-distance witness only after the finite-window equivalence route has tied the two limit rows to the same regular Cauchy point name.

Finally use Definition 1411.23. The zero-distance evidence travels through D, H, C, P, N before Z exports classifier equivalence. Since no host equality, quotient equality, selected representative, trichotomy, or completeness field occurs in S, the uniqueness claim remains inside the displayed classifier scope. □

Theorem 1411.25 (SeparatedMetric real zero-distance nonescape)**.** *For every accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, a* $\mathsf{Real}^{\uparrow}$ *zero-distance read can be consumed only as part*

of the finite route through $\mathsf{Met}^{\uparrow}$ *distance witnesses,* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *when completion-limit rows are present, componentwise* hsame*, displayed* Cont, Pkg*, and* $\mathsf{NameCert}$*. The* $\mathsf{Real}^{\uparrow}$ *row supplies the zero-distance witness used by* Z*; it does not export host real equality, quotient real equality, trichotomy, selected representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the zero-distance scope row from Definition 1411.22. It places the $\mathsf{Real}^{\uparrow}$ row after the metric-distance witness and before the separation classifier.

If completion-limit rows are involved, use Definition 1411.24. The route first passes through E, then the distance witness, then D, and only afterward the transport, replay, provenance, naming, and classifier rows.

The nonescape statement is the field inventory of S. The carrier contains no host real equality row, quotient real equality row, trichotomy ledger, selected representative coordinate, or ambient completeness theorem, so the zero-distance read cannot export any of them. □

Theorem 1411.26 (SeparatedMetric consumer nonescape scope)**.** *Every accepted consumer of a* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet receives only the rows*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{CauchySequenceEquivalence}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Consequently the consumer may inspect metric distance evidence, two complete-limit rows, their finite-window equivalence route, the real zero-distance seal, componentwise transport, replay, provenance, and local naming, but no quotient carrier, host equality, trichotomy row, selected representative, open-cover compactness principle, or $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Read the carrier inventory in Definition 1411.1. Its visible fields are the metric carrier row X, the real-valued distance row D, the separation row Z, the two complete-limit rows L_0, L_1, the equivalence route E, and the support rows H, C, P, N.

The consumer boundary theorem, Definition 1411.5, gives the permitted order of access. Consumers read metric data, complete-limit data, finite-window equivalence, real zero-distance evidence, and separation classification through the displayed support rows.

The nonescape conclusion is then a field-exhaustion claim. Since the carrier has no quotient object, host equality predicate, trichotomy ledger, selected representative, open-cover compactness coordinate, or $\mathsf{Real}^{\uparrow}$ completeness coordinate, no accepted consumer route can recover any of those objects from N. □

Theorem 1411.27 (SeparatedMetric zero-distance scope)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier as in Definition 1411.1. Every zero-distance transport accepted by the local* $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^{\uparrow}}$ *row is a displayed* BHist *route*

$$\mathsf{MetricDistanceWitness}(a, b, d) \longmapsto D(d, 0) \longmapsto Z(a, b)$$

carried by X, D, Z, H, C, P, N*. Transport by* hsame *and replay by* Cont *preserve this route before the point classifier is read, so the downstream zero-distance consumer receives classifier equivalence and not host equality, quotient equality, trichotomy, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the displayed packet from Definition 1411.1. The rows available for zero-distance transport are the metric carrier X, the real-valued distance interface D, the separation row Z, and the support rows H, C, P, N.

Use the zero-distance carrier row of Definition 1411.14. It fixes the order of the route: metric-distance witness first, real zero-distance reading second, and separation classification third.

Now apply the transported classifier stability row of Definition 1411.15. The hsame fields move the displayed histories componentwise and the Cont field replays the same route after transport.

Since the packet has no host equality coordinate, quotient carrier, trichotomy ledger, or completeness row, the transported conclusion remains exactly the classifier route named by N. □

Theorem 1411.28 (SeparatedMetric limit route scope)**.** *Let $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. A completion-limit uniqueness read from S can inspect the two* $\mathsf{CompleteMetric}^{\uparrow}$ *rows L_0, L_1 only after the* BHist *comparison route E has displayed that both rows belong to the same regular Cauchy point name. The accepted downstream route is therefore*

$$L_0, L_1 \longmapsto E \longmapsto \mathsf{MetricDistanceWitness}(\ell_0, \ell_1, d) \longmapsto D(d, 0) \longmapsto Z(\ell_0, \ell_1),$$

with transport and replay supplied only by H and C and with provenance and local naming supplied only by P and N.

Proof. Read L_0, L_1, E from the carrier of Definition 1411.1. The comparison route E is the only displayed row tying the two complete-metric limit claims to one regular Cauchy point name.

Apply Definition 1411.18. It places the equivalence route before the real zero-distance row and before the separation row, ruling out representative comparison or quotient-class comparison as an alternate path.

Then use Definition 1411.16. The ledger constructs the metric-distance witness between the displayed limit histories after E has fixed the common finite-window comparison surface.

The final zero-distance and classifier reads go through D and Z. Rows H, C, P, N only preserve and name that same route, so the completion-limit consumer receives uniqueness as classifier equivalence inside X, not as host equality or selected completion data. □

Theorem 1411.29 (SeparatedMetric classifier ledger scope)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$, the classifier ledger exported by* $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^{\uparrow}}$ *is exhausted by*

$\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert.

Every accepted consumer must read metric evidence, real zero-distance evidence, complete-limit rows, the finite-window equivalence route, componentwise transport, continuation replay, provenance, and local naming through these rows. No ledger entry permits escape to quotient metric spaces, host equality of histories, selected representatives, trichotomy, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier inventory of Definition 1411.1. It lists exactly the metric row X, real-valued distance row D, separation row Z, complete-limit rows L_0, L_1, equivalence route E, and structural rows H, C, P, N.

The NameCert obligations of Definition 1411.3 then partition these rows into carrier admission, classifier stability, completion compatibility, zero-distance exactness, and ledger visibility. Each obligation is anchored in the displayed BHist packet.

Use the consumer nonescape theorem Definition 1411.26. It states that downstream access remains inside the listed metric, completion, equivalence, real, transport, replay, provenance, and naming rows.

Thus the classifier ledger has no unlisted escape row. Quotient metric spaces, host equality, selected representatives, trichotomy, open-cover compactness, and $\mathsf{Real}^{\uparrow}$ completeness are not fields of S and cannot be read from its local naming row. □

Theorem 1411.30 (SeparatedMetric zero-distance NameCert readiness)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, the zero-distance obligation exported to* $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^{\uparrow}}$ *is exactly the finite* BHist *route through*

$$\mathsf{Met}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

It reads metric evidence from X*, the real zero-distance seal from* D*, classifier separation from* Z*, and transport, replay, provenance, and local naming from* H, C, P, N*; it does not expose host equality, quotient equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1411.1. The visible zero-distance rows are the metric carrier X, the real-valued distance row D, and the separation row Z.

Use the zero-distance carrier row of Definition 1411.14 and the transported classifier stability row of Definition 1411.15. They force every zero-distance read through the displayed metric witness, the $\mathsf{Real}^{\uparrow}$ zero-distance reading, and the classifier row, with H and C preserving the same route.

The provenance and local naming rows P, N then package the route as a NameCert obligation. Since the carrier contains no host equality or quotient coordinate, the readiness claim remains a finite classifier route. □

Theorem 1411.31 (SeparatedMetric completion-limit equivalence handoff)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P,$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Every completion-limit comparison exported by* S *must first pass through*

$$\mathsf{CompleteMetric}^{\uparrow},\ \mathsf{CauchySequenceEquivalence}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Thus the two completion limit rows L_0, L_1 *are handed to the separation row only after the finite equivalence route* E *identifies the common regular Cauchy point name.*

Proof. Read the two complete-limit rows and the equivalence route from Definition 1411.1. The packet stores L_0, L_1, E as finite rows, not as selected completion representatives.

Apply Definition 1411.16 and Definition 1411.28. Together they place E before the metric-distance witness, the real zero-distance row, and the separation classifier.

Finally use Definition 1411.29. The support rows H, C, P, N preserve and name the same handoff, and no quotient completion, host equality, countable choice, or ambient completeness row is available. □

Theorem 1411.32 (SeparatedMetric Real-seal boundary obligations)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier, every* $\mathsf{Real}^{\uparrow}$*-facing boundary read in a zero-distance or completion-limit obligation is exhausted by the rows*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{CauchySequenceEquivalence}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The $\mathsf{Real}^{\uparrow}$ *row supplies only the displayed zero-distance seal used by the classifier; it does not supply real completeness, quotient equality of completion names, trichotomy, selected representatives, or open-cover compactness.*

Proof. Start from Definition 1411.30. It identifies the real-facing zero-distance route as a finite metric witness followed by the $\mathsf{Real}^{\uparrow}$ zero seal and the separation classifier.

Then use Definition 1411.31. Completion-limit comparisons reach the real seal only after the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ row has tied both complete-metric limit rows to the same regular Cauchy name.

The boundary conclusion follows from Definition 1411.26. All accepted reads are carried by BHist, transported by hsame, replayed by Cont, and named through Pkg and NameCert, with no field for a stronger host-side principle. □

Theorem 1411.33 (SeparatedMetric kernel zero-distance obligation)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, every zero-distance classifier obligation exported by the kernel factors through the route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{hsame} \longmapsto \mathsf{Cont} \longmapsto \mathsf{Pkg} \longmapsto \mathsf{NameCert}.$$

The $\mathsf{Met}^{\uparrow}$ *distance witness is read before the* $\mathsf{Real}^{\uparrow}$ *zero row, and only after transport, replay, provenance, and local naming may the classifier row* Z *expose separation equivalence. The obligation exports no host equality, quotient equality, selected representative, trichotomy row, or ambient completeness principle.*

Proof. Read the zero-distance carrier row of Definition 1411.14. It fixes the route from a displayed metric-distance witness to the $\mathsf{Real}^{\uparrow}$ zero row and then to the separation classifier.

Next apply the transported classifier stability row of Definition 1411.15. The hsame and Cont rows preserve the same displayed route after transport, while P and N source and name it as a local certificate obligation.

The nonescape clause is immediate from the carrier inventory in Definition 1411.1. None of the excluded host or quotient principles is a coordinate of S. □

Theorem 1411.34 (SeparatedMetric completion-equivalence obligation)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Any completion-equivalence obligation that compares the two* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows* L_0, L_1 *must first pass through the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route* E *before the separation row can read a metric-distance witness, the* $\mathsf{Real}^{\uparrow}$ *zero seal, transport, replay, provenance, and local naming.*

Thus the separated completion consumer receives only classifier equivalence inside the displayed metric carrier. It does not receive quotient completion equality, selected representatives, host limit equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 1411.18. It places the finite-window equivalence route E before any zero-distance or separation read involving L_0 and L_1.

Then use Definition 1411.28. After E has tied the complete-metric rows to one regular Cauchy point name, the route may construct the displayed metric-distance witness and read the $\mathsf{Real}^{\uparrow}$ zero seal through D.

Finally apply Definition 1411.29. The rows H, C, P, N transport, replay, source, and name the same route, so no quotient completion object or stronger host-side equality is exported. □

Theorem 1411.35 (SeparatedMetric Real-seal routing obligation)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier, the* $\mathsf{Real}^{\uparrow}$ *row in every zero-distance or completion-equivalence route is only a seal inside the finite certificate route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{CauchySequenceEquivalence}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

It certifies the displayed zero-distance read consumed by Z*; it does not supply* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of real names, quotient equality of completion names, trichotomy, or selected representative data.*

Proof. Use Definition 1411.32. The real-facing row is reached only after the relevant metric or completion-equivalence rows have been displayed.

For a pure zero-distance route, Definition 1411.33 places the $\mathsf{Real}^{\uparrow}$ row between the metric-distance witness and the classifier. For a completion route, Definition 1411.34 first inserts the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ row between the complete-metric limits and the zero-distance read.

In both cases the support rows H, C, P, N preserve and name the same finite route. Since no Real completeness, quotient equality, trichotomy, or representative-selection coordinate is present, the Real row remains a seal and not an escape principle. □

Theorem 1411.36 (SeparatedMetric root zero-distance dependency)**.** *Every accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *consumer that exposes the separated classifier must first pass through the root* $\mathsf{Met}^{\uparrow}$ *distance dependency. For a carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, the row* X *supplies the displayed metric source and distance witness,* D *seals that witness as a* $\mathsf{Real}^{\uparrow}$ *zero-distance row, and only then may* Z *expose the separated classifier through* H, C, P, N*.*

The consumer receives no classifier route from host equality, quotient metric equality, selected representatives, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier tuple. The only coordinate naming the metric source and distance witness is X, so every classifier read begins there.

Apply Definition 1411.33. It places the $\mathsf{Met}^{\uparrow}$ distance row before the $\mathsf{Real}^{\uparrow}$ zero seal and the separated classifier.

Finally use the support rows H, C, P, N to transport, replay, source, and name the same route. Since the carrier has no extra host-equality or quotient coordinate, the exposed classifier is dependent on the displayed zero-distance route. □

Theorem 1411.37 (SeparatedMetric root completion-equivalence dependency)**.** *Every accepted completion-facing* $\mathsf{SeparatedMetric}^{\uparrow}$ *consumer must pass through the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route* E *and the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows* L_0, L_1 *before exposing the separated classifier. The completion-equivalence dependency is therefore the finite route*

$$L_0, L_1, E, X, D, Z, H, C, P, N$$

inside the accepted carrier, not a quotient completion equality or a selected host limit.

Proof. Begin with the completion rows L_0, L_1. They are the only packet coordinates that can serve a completion-facing consumer.

Use Definition 1411.34. It forces any comparison of L_0 and L_1 through the finite-window route E before the metric-distance and zero-seal rows may be read.

Then apply Definition 1411.36. The separated classifier is exposed only after X, D, Z and the support rows have been consumed, so the completion-equivalence dependency cannot escape into quotient completion equality, countable choice, or selected limits. □

Theorem 1411.38 (SeparatedMetric root Real-seal dependency)**.** *Every accepted Real-facing* $\mathsf{SeparatedMetric}^{\uparrow}$ *consumer must pass through the root* $\mathsf{Real}^{\uparrow}$ *zero-seal row* D *before it exposes the separated classifier. In the zero-distance branch this dependency is* X, D, Z, H, C, P, N*; in the completion branch it is* $L_0, L_1, E, X, D, Z, H, C, P, N$*.*

Thus the Real row is a dependency of the separated classifier, not an independent source of Real completeness, quotient equality of real names, quotient equality of completion names, trichotomy, or representative selection.

Proof. Use Definition 1411.35. It identifies the $\mathsf{Real}^{\uparrow}$ row as a zero-distance seal inside each accepted zero-distance or completion-equivalence route.

For the zero-distance branch, apply Definition 1411.36. For the completion branch, apply Definition 1411.37.

Both branches reach the same classifier row Z only after D has been read and after H, C, P, N have transported and named the displayed route. The carrier contains no independent Real-completeness or quotient-equality coordinate, so the Real seal remains a dependency boundary. □

Theorem 1411.39 (SeparatedMetric root classifier transport obligation)**.** *Let $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. The root classifier transport obligation has exactly the* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface displayed by H, C, P, N: any transported classifier read must first expose the carrier row of Definition 1411.1, the zero-distance dependency of Definition 1411.36, the completion-equivalence dependency of Definition 1411.37, and the Real-seal dependency of Definition 1411.38.*

Consequently the classifier cannot be transported by host equality, quotient metric equality, selected completion representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The classifier coordinate Z is not a free equality row; it is downstream of the metric source X, the zero-distance row D, the completion route E when completion rows are read, and the support rows H, C, P, N.

Use Definition 1411.36 for the pure metric branch and Definition 1411.37 for the completion branch. Both branches pass through the same zero-distance classifier route before the separated classifier is exposed.

Finally apply Definition 1411.38. Since the $\mathsf{Real}^{\uparrow}$ row remains a seal inside the displayed route, transport through hsame and replay through Cont can rename only the finite BHist rows already packaged by P, N. □

Theorem 1411.40 (SeparatedMetric root completion readback obligation)**.** *For every accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$, a completion-facing readback of the separated classifier must pass through the displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *rows L_0, L_1, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *dependency E, the zero-distance dependency row, and the* $\mathsf{Real}^{\uparrow}$ *seal before H, C, P, N name it as a* BHist *and* NameCert *obligation.*

The readback does not export quotient completion equality, a selected limit representative, host limit equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier and classifier inventory in Definition 1411.1. The only completion rows available to a consumer are L_0, L_1 and the displayed equivalence route E.

Apply Definition 1411.37. It forces completion-facing comparison through E before the zero-distance and classifier rows can be read.

Then use Definition 1411.39. The readback is transported only by H and replayed only by C, while P, N package the same route as a local NameCert row, so no completion quotient or selected representative is exposed. □

Theorem 1411.41 (SeparatedMetric root Real-seal nonescape obligation)**.** *Every Real-facing root obligation of an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier is exhausted by the finite route through the carrier, the zero-distance dependency row, the completion-equivalence dependency row when present, the* $\mathsf{Real}^{\uparrow}$ *seal, and the support surface* BHist, hsame, Cont, Pkg, NameCert*. The Real seal is therefore a boundary row for the separated classifier, not a source of quotient real equality, quotient completion equality, trichotomy, selected representatives, or ambient real completeness.*

Proof. Use Definition 1411.38. It places the Real row after the metric-distance witness in the zero-distance branch and after the completion-equivalence handoff in the completion branch.

For the zero-distance route, apply Definition 1411.36. For the completion route, apply Definition 1411.40. These two rows cover the only classifier-facing branches present in Definition 1411.1.

The rows H, C, P, N then transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for the excluded host principles, the Real seal cannot escape its displayed obligation boundary. □

Theorem 1411.42 (SeparatedMetric public identity export)**.** *Let $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Every public identity consumer that asks when two displayed points of X are identified must read the metric-distance witness through D, the* $\mathsf{Real}^{\uparrow}$ *zero seal, and the separation classifier Z before exposing an identity claim. The exported claim is exactly the zero-distance route of Definition 1411.33; it carries no host equality, quotient equality, selected representative, trichotomy row, or ambient completeness principle.*

Proof. Project the carrier S. The only identity-facing rows are the metric row X, the distance and zero-seal route D, the classifier Z, and the structural rows H, C, P, N.

Apply Definition 1411.33. It places the metric-distance witness before the $\mathsf{Real}^{\uparrow}$ zero row and places both before the separation classifier.

Finally use Definition 1411.26. The support rows transport, replay, source, and name the same route, so the public identity export cannot detach into host equality or a quotient principle. □

Theorem 1411.43 (SeparatedMetric public completion uniqueness export)**.** *Let $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Every public completion-uniqueness consumer comparing the completion rows L_0 and L_1 must first read the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route E and then the zero-distance classifier route through D, Z, H, C, P, N. The export is the completion-equivalence boundary of Definition 1411.34; it supplies no quotient completion equality, selected limit, host limit equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the completion rows L_0 and L_1 in the carrier. They are not public equality rows by themselves; they are complete-metric limit rows tied to the displayed route E.

Apply Definition 1411.34. It forces any comparison of L_0 and L_1 through E before the route may read the zero-distance witness and separation classifier.

Then use Definition 1411.31 and Definition 1411.28. These keep the completion comparison inside the finite Cauchy-equivalence and zero-distance handoff.

The rows H, C, P, N provide only transport, replay, provenance, and local naming. Therefore the public uniqueness export is exhausted by the displayed separated-metric route. □

Theorem 1411.44 (SeparatedMetric public Real-seal nonescape export)**.** *Let $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Every public* $\mathsf{Real}^{\uparrow}$*-seal consumer of a zero-distance or completion-uniqueness route receives the seal only inside*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{CauchySequenceEquivalence}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The exported Real-facing boundary is the nonescape route of Definition 1411.35; it does not provide Real completeness, quotient equality of real names, quotient equality of completion names, trichotomy, or representative selection.

Proof. Use Definition 1411.35. It states that the $\mathsf{Real}^{\uparrow}$ row is only the displayed zero-distance seal inside the finite certificate route.

For identity consumers, apply Definition 1411.42. For completion-uniqueness consumers, apply Definition 1411.43. These two exports account for the public zero-distance and completion-facing routes.

Since the same support rows H, C, P, N preserve both routes, no public consumer can reinterpret the Real seal as a stronger host-side principle. □

Theorem 1411.45 (SeparatedMetric zero-distance separation obligation)**.** *For every accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, any bridge-facing zero-distance separation read must pass through the* $\mathsf{Met}^{\uparrow}$ *carrier row* X*, the* $\mathsf{Real}^{\uparrow}$*-valued distance witness row* D*, and the separation classifier row* Z *before the structural rows* H, C, P, N *can expose it to a public consumer. The route is a finite projection from the displayed carrier; it is not host equality, quotient equality, trichotomy, representative selection, or ambient completeness.*

Proof. Project S through Definition 1411.1. The only rows that can answer a zero-distance separation request are X, D, Z and the structural rows attached to them.

Apply Definition 1411.33. It places the $\mathsf{Met}^{\uparrow}$ distance witness before the $\mathsf{Real}^{\uparrow}$ zero-distance reading and places both before the separation classifier.

The bridge-facing consumer then receives the transported and replayed route through H, C, P, N. Since no excluded host-side principle is a carrier row, the bridge surface remains a finite projection. □

Theorem 1411.46 (SeparatedMetric completion uniqueness obligation)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Any bridge-facing completion-uniqueness read comparing the two* $\mathsf{CompleteMetric}^{\uparrow}$ *rows* L_0, L_1 *must first use the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route* E*, then the zero-distance route through* X, D, Z*, and finally the structural rows* H, C, P, N*.*

Proof. Start with the public completion uniqueness export of Definition 1411.43. It fixes E as the required route from the two complete-metric limit rows to a common finite-window comparison.

Use Definition 1411.34. After E is displayed, the comparison may read the metric-distance witness, the $\mathsf{Real}^{\uparrow}$ zero seal, and the separation row.

The rows H, C, P, N transport, replay, source, and name this same finite chain. Hence the bridge-facing uniqueness obligation exports no quotient completion equality, selected limit, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1411.47 (SeparatedMetric Real-seal nonescape obligation)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, every bridge-facing* $\mathsf{Real}^{\uparrow}$ *seal read is confined to the displayed zero-distance or completion-uniqueness route through* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{CauchySequenceEquivalence}$ $\mathsf{Real}^{\uparrow}$*,* H, C, P, N*. It does not export* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of real names, quotient equality of completion names, trichotomy, or representative selection.*

Proof. Apply the public Real-seal nonescape export of Definition 1411.44. It already identifies the Real row as a zero-distance seal inside the finite separated-metric route.

For the identity branch, use Definition 1411.45. For the completion branch, use Definition 1411.46. These two obligations exhaust the bridge-facing ways to reach the seal.

The carrier contains no Real-completeness, quotient-equality, trichotomy, or representative-selection coordinate. Therefore the seal remains a nonescape boundary for both bridge-facing routes. □

Theorem 1411.48 (SeparatedMetric bridged-closure readiness)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Its bridge-facing public surface consists exactly of the* $\mathsf{Met}^{\uparrow}$

distance witness, the $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route, the* $\mathsf{Real}^{\uparrow}$ *zero seal, the separation classifier row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. This is the complete surface exported to a bridge consumer.*

The surface exports no quotient completion equality, selected limit, host equality, trichotomy, representative-selection row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the public identity export of Definition 1411.42. It identifies the identity-facing part of the surface as the metric-distance witness, the $\mathsf{Real}^{\uparrow}$ zero seal, the separation classifier, and the support rows H, C, P, N.

Next apply the public completion uniqueness export of Definition 1411.43. It adds the two $\mathsf{CompleteMetric}^{\uparrow}$ limit rows and the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ route, but it does not add a quotient completion equality, selected limit, or host equality row.

Finally use the public Real-seal nonescape export of Definition 1411.44. The Real row remains a zero-distance seal inside the displayed finite certificate route, and the support rows provide only transport, replay, provenance, and local naming. Therefore the listed rows are exactly the bridge-facing readiness surface. □

Theorem 1411.49 (SeparatedMetric separated-identity transport obligation)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Every separated-identity transport read of* S *is a finite* BHist *packet-coordinate route: the* $\mathsf{Met}^{\uparrow}$ *distance rows of* X *expose a distance witness, the* $\mathsf{Real}^{\uparrow}$ *seal row* D *reads that witness as zero,* hsame *rows in* H *transport the endpoints and witness, the displayed* Cont *replay* C *preserves the route, and the* NameCert *row* N *names the transported classifier row* Z*.*

No such read may bypass X, D, H, C, P, N *by parameter transport, host equality, quotient equality, trichotomy, selected representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the packet coordinates from Definition 1411.1. The identity-facing data are the $\mathsf{Met}^{\uparrow}$ distance rows in X, the $\mathsf{Real}^{\uparrow}$ zero-distance seal D, the separation row Z, and the structural rows H, C, P, N.

Use Definition 1411.45. It forces every zero-distance identity read to place the metric-distance witness before the real zero seal and both before the separation classifier.

Transport is then componentwise through H and replayed through C. The provenance and local naming rows P, N expose exactly the transported finite route, so the conclusion is classifier equivalence through Z rather than a host-side identity principle. □

Theorem 1411.50 (SeparatedMetric completion-uniqueness consumer obligation)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Every completion-uniqueness consumer of* S *must read the two* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows* L_0, L_1 *through the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *finite-window route* E*, then through the* $\mathsf{Met}^{\uparrow}$ *distance rows of* X*, the* $\mathsf{Real}^{\uparrow}$ *zero-distance seal* D*, the* hsame *transport rows* H*, the displayed* Cont *replay* C*, the* Pkg *provenance* P*, and the local* NameCert *row* N *before it may consume the classifier row* Z*.*

The obligation exports completion-limit uniqueness only as displayed classifier equivalence, not as quotient completion equality, selected host limits, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the completion rows L_0, L_1. By Definition 1411.46, a consumer cannot compare them until the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ row E displays the shared regular Cauchy finite windows.

After E is displayed, apply the zero-distance route of Definition 1411.45. The comparison must form a metric-distance witness in X, read the $\mathsf{Real}^{\uparrow}$ zero seal D, and then reach the separation row Z.

Finally transport, replay, provenance, and naming pass through H, C, P, N. Since no quotient completion object, selected limit, countable-choice schedule, host equality row, or ambient completeness theorem is a packet coordinate, the consumer obligation is exhausted by the displayed rows. □

Theorem 1411.51 (SeparatedMetric Cauchy-equivalence zero-distance induction)**.** *Let $S = (X, D, Z, L_0, L_1, E, H$ be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Every completion-limit uniqueness consumer that tries to identify the two limit rows L_0, L_1 must proceed by the following induction-style route: first display the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *finite-window route E, then build the* $\mathsf{Met}^{\uparrow}$ *distance witness in X, then read the* $\mathsf{Real}^{\uparrow}$ *zero-distance seal D, then transport through H, replay through C, record* Pkg *provenance through P, name the route through N, and only then consume the separated classifier Z.*

Consequently completion-limit uniqueness is exported as a separated classifier consequence of the displayed zero-distance route. It is not quotient completion equality, selected representative equality, countable-choice selection, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the existing completion uniqueness route of Definition 1411.50. It requires L_0, L_1 to pass through the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ finite-window row E before any comparison reaches a metric witness.

Next apply the zero-distance carrier row of Definition 1411.45. The displayed finite-window comparison supplies the $\mathsf{Met}^{\uparrow}$ distance witness in X, and that witness is read through the $\mathsf{Real}^{\uparrow}$ zero-distance seal D before the classifier row Z is available.

Now use the classifier stability and zero-distance transport rows of Definition 1411.15 and Definition 1411.17. They keep the route componentwise through H and replay it through C while preserving the same separated classifier conclusion.

Finally apply the completion handoff nonescape theorem Definition 1411.9. The provenance and local naming rows P, N expose exactly the routed finite evidence, so no quotient completion equality, selected representative, countable-choice schedule, host equality, trichotomy, compactness, or ambient completeness principle can replace the induction route. □

Theorem 1411.52 (SeparatedMetric L10 completion unblock package)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$, the L10 package offered to* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *fronts is the ordered product of the completion-limit rows L_0, L_1, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route E, the* $\mathsf{Met}^{\uparrow}$ *distance witness in X, the* $\mathsf{Real}^{\uparrow}$ *zero-distance seal D, the separated classifier Z, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}$ *row N.*

Any downstream completion consumer that claims uniqueness outside this product leaves the $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier surface. The package therefore unblocks completion uniqueness only as a finite zero-distance classifier route, not as ambient completion equality or Real completeness.*

Proof. Use Definition 1411.51. It gives the induction-style order in which $L_0, L_1, E, X, D, H, C, P, N$ must be displayed before the separated classifier row Z is consumed.

The zero-distance carrier row and classifier stability row provide the public classifier consequence. The zero-distance transport theorem then shows that the same consequence survives componentwise hsame transport and displayed replay.

It remains to expose the package to completion fronts. Apply Definition 1411.43 and Definition 1411.44. They route $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ consumers through the displayed completion-limit, Cauchy-equivalence, metric-distance, Real-seal, transport, provenance, and local-name rows, while refusing quotient equality, selected limits, countable choice, host equality, trichotomy, compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1411.53 (SeparatedMetric Real-seal zero-distance budget)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *seal row consumed by a downstream Real-facing or completion-facing read is budgeted to one of two finite routes: a separated-identity route through the* $\mathsf{Met}^{\uparrow}$ *distance rows of* X*,* D*,* Z*,* H, C, P, N*, or a completion-uniqueness route through* $L_0, L_1, E, X, D, Z, H, C, P, N$ *with* E *displaying the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *finite windows.*

The budget contains no third route for Real equality, quotient equality, selected representatives, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 1411.47. It confines every bridge-facing $\mathsf{Real}^{\uparrow}$ seal read to the separated-metric zero-distance or completion-uniqueness route.

For the identity branch, apply Definition 1411.49. The seal is read after the metric-distance witness and before the transported classifier row is named.

For the completion branch, apply Definition 1411.50. The seal is read only after the two $\mathsf{CompleteMetric}^{\uparrow}$ rows and the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ finite-window route have been displayed.

The carrier inventory has no coordinate for the excluded third routes. Therefore the Real-seal budget is exactly the two displayed finite routes. □

Theorem 1411.54 (SeparatedMetric Real zero-distance scope)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, every Real-facing zero-distance classifier read must pass through the displayed* $\mathsf{Met}^{\uparrow}$ *distance witness in* X*, the* $\mathsf{Real}^{\uparrow}$ *zero-distance seal* D*, the optional* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route* E *when completion-limit rows* L_0, L_1 *are present, component-wise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}$ *row* N *before the separation classifier row* Z *may be exported.*

The export is therefore a local classifier consequence of the displayed zero-distance route. It is not host equality, quotient equality, a selected representative, trichotomy of real comparisons, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier through Definition 1411.1. The zero-distance branch exposes X, D, Z, H, C, P, N, so a Real-facing identity read first forms the $\mathsf{Met}^{\uparrow}$ distance witness in X and only then reads that witness through the $\mathsf{Real}^{\uparrow}$ seal D.

If completion-limit rows are present, apply Definition 1411.50. The read must pass through L_0, L_1 and the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ row E before it reaches the same metric witness and real zero-distance seal.

Now use the public identity and completion exports, Definition 1411.42 and Definition 1411.43. They place the separated classifier behind the displayed zero-distance and completion-equivalence routes, while Definition 1411.44 keeps the $\mathsf{Real}^{\uparrow}$ row inside that route.

Finally transport, replay, provenance, and naming pass through H, C, P, N. Since the carrier has no host-equality, quotient-equality, selected-representative, trichotomy, or ambient-completeness coordinate, the classifier export cannot escape the displayed Real zero-distance scope. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SeparatedMetric}^{\uparrow}$ packet is generated from a $\mathsf{Met}^{\uparrow}$ carrier, a $\mathsf{Real}^{\uparrow}$-valued distance witness, a zero-distance separation row, two $\mathsf{CompleteMetric}^{\uparrow}$ Cauchy-limit rows for one regular Cauchy point name, a

CauchySequenceEquivalence$^{\uparrow}$ route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SeparatedMetric}\uparrow}$, maturePackageClosed)

Scope closed: Definition 1411.48 together with Definition 1411.42, Definition 1411.43, and Definition 1411.44 identifies the mature separated-metric public surface over Met$^{\uparrow}$, CompleteMetric$^{\uparrow}$, CauchySequenceEquivalence$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{SeparatedMetric}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient metric spaces, host equality, trichotomy, open-cover compactness, Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: No paper-side closure upgrade remains; Lean verification and bridge checking remain separate formal-axis work.

Theorem 1411.55 (SeparatedMetric carrier boundary)**.** *Every accepted carrier read of a* SeparatedMetric$^{\uparrow}$ *packet factors through the displayed* Met$^{\uparrow}$ *carrier row, the* Real$^{\uparrow}$ *zero-distance witness row, the* CompleteMetric$^{\uparrow}$ *limit rows, the* CauchySequenceEquivalence$^{\uparrow}$ *comparison row, and the structural rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. No consumer may read a separated classifier by omitting any of these carrier-boundary rows when the requested read is a completion-limit uniqueness read.*

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricCarrier boundary`

Proof. Project the carrier of Definition 1411.1. Its coordinates list the metric source X, real-valued distance witness D, complete-metric limit rows L_0, L_1, comparison route E, transport H, replay C, provenance P, and local naming row N.

For identity-facing reads, the metric and real rows expose the distance witness before the separation row is consumed. For completion-facing reads, the two complete-metric rows and the Cauchy-sequence equivalence route are projected before the same zero-distance route is available.

The support rows are not optional. They transport, replay, source, and name the finite path, so every accepted carrier read factors through the listed BEDC rows rather than through host equality or an off-packet completion principle. □

Theorem 1411.56 (SeparatedMetric symmetry transport)**.** *For an accepted* SeparatedMetric$^{\uparrow}$ *carrier, zero-distance classifier evidence is stable under componentwise* hsame *transport and displayed* Cont *replay. If the endpoints, distance witness, zero-distance reading, completion rows, comparison row, provenance row, and local name are transported componentwise, the replayed route exports the transported separated classifier evidence and no additional equality principle.*

Proof. Use the transport row H of Definition 1411.1. It moves endpoints, distance witnesses, zero-distance readings, completion rows, the comparison route, provenance, and the local naming row as components of one finite packet.

Apply the replay row C after transport. The replay forms the same metric-distance witness, reads it through the same Real$^{\uparrow}$ zero-distance interface, and then consumes the transported separation row.

Thus symmetry of the classifier evidence is a transported replay of the displayed route. It is not a conversion to host equality, quotient equality, selected representatives, trichotomy, choice, or ambient Real$^{\uparrow}$ completeness. □

Theorem 1411.57 (SeparatedMetric zero-distance refusal)**.** *No accepted* SeparatedMetric$^{\uparrow}$ *consumer may replace the separated zero-distance classifier route by host equality, quotient equality, trichotomy, choice, selected representatives, or ambient* Real$^{\uparrow}$ *completeness. The only exported route from zero distance to identification is the finite route through* Met$^{\uparrow}$*,* Real$^{\uparrow}$*,* CompleteMetric$^{\uparrow}$

when completion rows are present, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

Proof. Start from the NameCert obligations of Definition 1411.3. They make carrier admission, classifier stability, completion compatibility, zero-distance exactness, and ledger visibility the complete accepted surface.

The zero-distance exactness row sends a metric-distance witness through the $\mathsf{Real}^{\uparrow}$ zero-distance reading before the separation row may be exported. Completion consumers must additionally display the two $\mathsf{CompleteMetric}^{\uparrow}$ rows and the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ comparison route.

The ledger visibility clause excludes each proposed replacement because none is a coordinate of the packet. Therefore the refused principles have no row to transport through H, replay through C, source through P, or name through N. □

Definition 1411.58 (SeparatedMetric zero-distance carrier)**.** *A* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance carrier is a finite* BHist *packet*

$$\mathsf{SepZero}(X, D, Z, E, L, H, C, P, N)$$

whose coordinates are exactly:

1. X*, the displayed* $\mathsf{Met}^{\uparrow}$ *source row containing the carried endpoints and distance witness;*
2. D*, the* $\mathsf{Real}^{\uparrow}$ *distance witness row reading that distance as zero;*
3. Z*, the zero-distance refusal row that permits classifier identification only through the displayed zero-distance route;*
4. E*, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *handoff row used when the endpoints are completion names;*
5. L*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *compatibility row binding completion-limit consumers to the same metric source;*
6. H*, the componentwise* hsame *transport ledger for endpoints, distance witnesses, zero rows, and completion rows;*
7. C*, the displayed* Cont *replay ledger for the same route;*
8. P*, the* Pkg *provenance row naming the source of the carrier;*
9. N*, the local* $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^{\uparrow}}$ *row.*

The classifier of this carrier compares packets only by these rows. It has no coordinate for host equality, quotient metric equality, selected representatives, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1411.59 (SeparatedMetric NameCert obligation surface)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *zero-distance carrier*

$$S = \mathsf{SepZero}(X, D, Z, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^{\uparrow}}$ *surface is exactly the finite obligation surface consisting of the* $\mathsf{Met}^{\uparrow}$ *source row* X*, the* $\mathsf{Real}^{\uparrow}$ *zero-distance witness* D*, the zero-distance refusal row* Z*, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *handoff* E*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *compatibility row* L*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local naming row* N*.*

Every accepted identity or completion-uniqueness read must consume these rows in this order before it may export a point-classifier identification. The surface refuses host equality, quotient equality, selected representatives, trichotomy, open-cover compactness, and ambient completeness data because no such row occurs in S*.*

Proof. Project the coordinates of Definition 1411.58. The first three rows supply the metric source, the real-valued zero-distance witness, and the refusal that prevents classifier identification unless the zero-distance route has been displayed.

For completion-facing reads, use the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ rows before the separation classifier is consumed. These rows bind completion names to the displayed metric source rather than to a quotient completion object.

Finally transport, replay, provenance, and naming pass through H, C, P, N. Since the carrier lists no additional coordinate, every accepted $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^{\uparrow}}$ obligation is exhausted by the stated finite surface. □

Theorem 1411.60 (SeparatedMetric Cauchy-completion readback)**.** *Let $S = \mathsf{SepZero}(X, D, Z, E, L, H, C, P, N)$ be an accepted $\mathsf{SeparatedMetric}^{\uparrow}$ zero-distance carrier. Any Cauchy or completion consumer that reads a zero-distance collapse from S must route the read through the $\mathsf{SeparatedMetric}^{\uparrow}$ packet together with the displayed $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ rows.*

The consumer may not read zero-distance collapse from a host Cauchy quotient, an ambient equality of completion endpoints, a selected limit, countable choice, trichotomy, or an untracked completeness theorem. The only exported conclusion is the classifier route named by N after the displayed rows X, D, Z, E, L, H, C, P have been consumed.

Proof. Start with a Cauchy or completion consumer. If it asks for limit identification, the read first passes through E and L, so the two completion-facing rows are bound to the same displayed metric source.

Then apply the separated-metric route through X, D, Z. The metric row supplies the distance witness, the $\mathsf{Real}^{\uparrow}$ row reads that witness as zero, and the refusal row allows only the corresponding classifier identification.

The remaining rows H, C, P, N transport, replay, source, and name the route. No host quotient, selected limit, countable-choice schedule, trichotomy row, or ambient completeness theorem is present in the carrier, so the readback is confined to the listed BEDC rows. □

Theorem 1411.61 (SeparatedMetric root completion-limit handoff)**.** *Every completion-limit classifier export from an accepted $\mathsf{SeparatedMetric}^{\uparrow}$ zero-distance carrier must first route through the $\mathsf{CompleteMetric}^{\uparrow}$ row, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ row, $\mathsf{Met}^{\uparrow}$ source row, $\mathsf{Real}^{\uparrow}$ zero-distance witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row. The export is therefore a readback of the finite carrier in Definition 1411.58 together with Definition 1411.60, not a direct read from ambient completion equality.*

Proof. Project the carrier of Definition 1411.58. The completion-facing rows are L and E, the metric and zero-distance rows are X, D, Z, and the structural rows are H, C, P, N.

Use Definition 1411.60. It already forces Cauchy and completion consumers to route through the displayed $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ rows.

The completion-limit classifier export is therefore downstream of $L, E, X, D, Z, H, C, P, N$. Since no host completion equality or selected representative row occurs in the carrier, the export cannot bypass the finite handoff. □

Theorem 1411.62 (SeparatedMetric root classifier nonescape)**.** *The separated classifier of an accepted $\mathsf{SeparatedMetric}^{\uparrow}$ zero-distance carrier cannot be consumed from host equality, quotient*

equality, selected representatives, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness. It is consumable only through the displayed* $\mathsf{Met}^{\uparrow}$ *source,* $\mathsf{Real}^{\uparrow}$ *zero-distance witness, separation row,* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *handoff,* $\mathsf{CompleteMetric}^{\uparrow}$ *compatibility row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows.*

Proof. Project Definition 1411.58. Its rows are exactly $X, D, Z, E, L, H, C, P, N$, and none of the excluded host or quotient principles is a carrier coordinate.

Apply Definition 1411.60. Any completion-facing consumption of the classifier must pass through the displayed Cauchy and completion rows before the local name is exported.

The nonescape claim follows because every permitted classifier read is already accounted for by the finite carrier rows, while host equality, quotient equality, selected representatives, trichotomy, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no row to transport, replay, source, or name. □

Definition 1411.63 (SeparatedMetric root obligation basis)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet. Its root obligation basis is the finite* BHist*-anchored row package consisting of:*

1. *carrier admission of* $X, D, Z, L_0, L_1, E, H, C, P, N$ *as the only displayed rows of the packet;*
2. *classifier transport through the stored* $\mathsf{Met}^{\uparrow}$ *source,* $\mathsf{Real}^{\uparrow}$ *zero-distance reading, componentwise* hsame *transport, and displayed* Cont *replay;*
3. *completion handoff from* L_0, L_1 *through* $\mathsf{CompleteMetric}^{\uparrow}$ *and the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *route* E *before any separated classifier export;*
4. *provenance and local naming through* P, N *for downstream L10 completion consumers.*

The basis exports no host equality, quotient equality, selected representative, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Theorem 1411.64 (SeparatedMetric root carrier admission)**.** *For every accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$*, the root-facing carrier admitted to a downstream completion consumer is exactly the* BHist *package displayed in Definition 1411.63. In particular, the consumer may project the rows* $X, D, Z, L_0, L_1, E, H, C, P, N$*, and it may not project any additional row for host equality, quotient equality, selected representatives, countable choice, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 1411.1 together with the local obligation surface of Definition 1411.3. These rows display the metric source, zero-distance reading, separation classifier, two completion-limit entries, regular Cauchy equivalence route, transport, replay, provenance, and local naming.

The later zero-distance and completion-readback theorems use only those coordinates. Since the displayed carrier contains no coordinate for the excluded host or quotient principles, a root consumer has no additional row to project. □

Theorem 1411.65 (SeparatedMetric root classifier transport)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *packet. Every root classifier transport exported from* S *factors through the displayed* $\mathsf{Met}^{\uparrow}$ *row* X*, the* $\mathsf{Real}^{\uparrow}$ *zero-distance row* D*, the separated classifier row* Z*, componentwise* hsame *transport* H*, and displayed* Cont *replay* C*, with provenance and naming supplied by* P, N*. The transport remains a* BHist*-anchored classifier route and does not become host point equality, quotient equality, a selected representative, or trichotomy of real distances.*

Proof. Begin with Definition 1411.17. It already requires the zero-distance evidence to start in the $\mathsf{Met}^{\uparrow}$ distance row, pass through the $\mathsf{Real}^{\uparrow}$ zero-distance reading, and reach the classifier only through the separation row.

Apply the classifier stability and nonescape rows, Definition 1411.15 and Definition 1411.62. These rows keep transport componentwise through H and replay it through C, while P, N source and name the same finite route.

Thus the transported classifier remains the displayed $\mathsf{SeparatedMetric}^{\uparrow}$ route. No excluded equality or order principle is present in the carrier, so none can be exported by the transport. □

Theorem 1411.66 (SeparatedMetric root completion handoff)**.** *Let $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ be an accepted $\mathsf{SeparatedMetric}^{\uparrow}$ packet. Every root completion-limit read of S must hand L_0 and L_1 through $\mathsf{CompleteMetric}^{\uparrow}$ compatibility and the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ route E before it may use D and Z to export a separated classifier. The handoff is a finite BHist route through $X, D, Z, L_0, L_1, E, H, C, P, N$, not a read from ambient completion equality or a selected limit.*

Proof. Use Definition 1411.18. It places every comparison of the two completion-limit rows behind the displayed equivalence route E before any zero-distance classifier read can occur.

Then apply Definition 1411.61. The theorem identifies the completion-facing rows, metric source, zero-distance witness, transport, replay, provenance, and naming as the complete route for a completion-limit classifier export.

The handoff therefore stays inside the finite carrier rows. Ambient completion equality, selected representatives, and choice principles are absent from S, so they cannot supply a competing completion read. □

Theorem 1411.67 (SeparatedMetric root obligation basis)**.** *The root obligation basis of Definition 1411.63 is sufficient for every downstream L10 completion consumer that asks a $\mathsf{SeparatedMetric}^{\uparrow}$ packet for carrier admission, classifier transport, or completion-limit uniqueness. Such a consumer can read the required rows by applying Definition 1411.64, Definition 1411.65, and Definition 1411.66, and every read remains confined to the BHist package $X, D, Z, L_0, L_1, E, H, C, P, N$.*

Proof. First read carrier admission from Definition 1411.64. This gives the downstream consumer exactly the displayed rows of the accepted packet and refuses every host, quotient, choice, trichotomy, compactness, or ambient completeness row.

For classifier requests, use Definition 1411.65. It transports the zero-distance classifier only through $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and $\mathsf{NameCert}$ data already present in the carrier.

For completion-limit uniqueness requests, use Definition 1411.66. It sends the two completion rows through $\mathsf{CompleteMetric}^{\uparrow}$ compatibility and $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ before the zero-distance classifier is exported.

These three projections cover the root-facing requests named in the definition, so the L10 consumer receives an obligation basis rather than a stronger equality or completion principle. □

Theorem 1411.68 (SeparatedMetric zero-distance Real reflection)**.** *Let $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ be an accepted $\mathsf{SeparatedMetric}^{\uparrow}$ carrier. Every completion-facing read that reflects a zero-distance claim into a Real-facing comparison must first display the $\mathsf{Met}^{\uparrow}$ distance rows of X, the $\mathsf{Real}^{\uparrow}$ zero-distance seal D, the separated classifier row Z, the $\mathsf{CompleteMetric}^{\uparrow}$ limit rows L_0, L_1, the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ handoff E, and the structural rows H, C, P, N.*

The reflection is a finite NameCert route through $X, D, Z, L_0, L_1, E, H, C, P, N$. It is not quotient completion equality, selected limit equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricPacket zero distance real reflection`

Proof. Project the accepted carrier and read the Real-facing rows first. The metric source X supplies the distance witness, and D reads that witness as a $\mathsf{Real}^{\uparrow}$ zero-distance seal before the separated classifier Z may be exported.

For completion-facing requests, use the completion rows L_0, L_1 and the handoff E. These rows bind the two proposed completion readings to the displayed $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ data before the zero-distance route is consumed.

Transport and replay are then componentwise through H and C, with P, N sourcing and naming the same route. Since the carrier has no quotient equality, selected limit, trichotomy, or ambient Real-completeness coordinate, the reflection is exhausted by the displayed rows. □

Theorem 1411.69 (SeparatedMetric Cauchy-equivalence limit coherence)**.** *Let $S = (X, D, Z, L_0, L_1, E, H, C, P, N$ be an accepted $\mathsf{SeparatedMetric}^{\uparrow}$ carrier. If a downstream completion consumer reads the two $\mathsf{CompleteMetric}^{\uparrow}$ limit rows L_0, L_1 as coherent, then the coherence read must pass through the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ row E, the $\mathsf{Met}^{\uparrow}$ row X, the $\mathsf{Real}^{\uparrow}$ zero-distance row D, the separated classifier row Z, and the structural rows H, C, P, N.*

Thus completion uniqueness is exported only as Cauchy-equivalence limit coherence followed by separated zero-distance classification. It is not ambient completion equality, a selected representative theorem, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricCauchyEquivalenceLimitCoherence`

Proof. Begin with the two limit rows. The carrier exposes L_0 and L_1 only as $\mathsf{CompleteMetric}^{\uparrow}$ rows paired with the Cauchy-equivalence handoff E.

Read E before any classifier conclusion. It supplies the finite Cauchy-sequence comparison route that lets the two limit rows be placed over the same metric source X.

The zero-distance claim is then read through D and consumed by Z. The transport, replay, provenance, and local naming rows H, C, P, N preserve exactly this route for downstream consumers.

No quotient completion object, selected limit, trichotomy row, or ambient completeness theorem is present in the carrier. Therefore the only exported coherence is the displayed Cauchy-equivalence and separated-classifier route. □

Theorem 1411.70 (SeparatedMetric NameCert ledger exhaustion)**.** *For an accepted $\mathsf{SeparatedMetric}^{\uparrow}$ carrier $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$, the completion-uniqueness ledger is exhausted by the rows $X, D, Z, L_0, L_1, E, H, C, P, N$. Every $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, and $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ consumer that asks for separated completion uniqueness must project those rows before it can read the local $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^{\uparrow}}$ conclusion.*

No additional ledger row is available for quotient completion equality, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Lean4 ✓ `BEDC.Derived.SeparatedMetricUp.SeparatedMetricPacket namecert ledger exhaustion`

Proof. Project the carrier inventory. It lists the metric source, Real zero-distance seal, separated classifier, two complete-metric limit rows, Cauchy-equivalence handoff, transport, replay, provenance, and local name.

Apply the zero-distance reflection route of Definition 1411.68. That route accounts for Real-facing zero-distance reads without adding a host equality coordinate.

Apply the limit-coherence route of Definition 1411.69. That route accounts for completion-facing uniqueness reads by sending L_0, L_1 through E, X, D, Z, H, C, P, N.

These two projections cover the completion-uniqueness ledger. Since no further row exists in the carrier, every excluded equality, selection, trichotomy, or ambient completeness principle is refused by ledger exhaustion. □

Theorem 1411.71 (SeparatedMetric root finite completion readiness)**.** *For an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier*

$$S = (X, D, Z, L_0, L_1, E, H, C, P, N),$$

the rows $X, D, Z, L_0, L_1, E, H, C, P, N$ *jointly provide the root completion-readiness package for every downstream* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *consumer. The package consists of the displayed* $\mathsf{Met}^{\uparrow}$ *distance source,* $\mathsf{Real}^{\uparrow}$ *zero-distance seal, separated classifier, two completion limit rows, Cauchy-equivalence handoff, componentwise transport, replay, provenance, and local* $\mathsf{NameCert}_{\mathsf{SeparatedMetric}^{\uparrow}}$ *row.*

The package does not include quotient completion equality, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply the zero-distance Real reflection of Definition 1411.68. It places every Real-facing zero-distance read behind the displayed $\mathsf{Met}^{\uparrow}$ source X, the $\mathsf{Real}^{\uparrow}$ seal D, the separated classifier Z, the completion rows L_0, L_1, the Cauchy-equivalence handoff E, and the structural rows H, C, P, N.

Next apply the Cauchy-equivalence limit coherence route of Definition 1411.69. It supplies the completion-facing route that sends the two $\mathsf{CompleteMetric}^{\uparrow}$ limit rows through E, X, D, Z, H, C, P, N before any uniqueness conclusion is read.

Finally apply the ledger exhaustion theorem of Definition 1411.70. Since the carrier contains no row beyond $X, D, Z, L_0, L_1, E, H, C, P, N$, these three routes jointly form the finite root package available to $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ consumers. The excluded quotient equality, selected-limit, trichotomy, and ambient-completeness objects are absent from the displayed carrier. □

Theorem 1411.72 (SeparatedMetric zero-distance scope obligations)**.** *Let* $S = (X, D, Z, L_0, L_1, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparatedMetric}^{\uparrow}$ *carrier. Every zero-distance-to-classifier export from* S *must expose, in order, the* $\mathsf{Met}^{\uparrow}$ *distance witness in* X*, the* $\mathsf{Real}^{\uparrow}$ *zero-distance read through* D*, the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows* L_0, L_1 *when the export is completion-facing, the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison route* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and the local* $\mathsf{NameCert}$ *row* N *before the separated classifier row* Z *is consumed.*

Thus the zero-distance export is scoped by the displayed finite packet. It is not host equality, quotient completion equality, selected representative data, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier definition Definition 1411.1. Its zero-distance route begins with the metric row X and the real-valued distance witness interface D, while the classifier consequence is stored only in the separation row Z.

Apply the NameCert obligation surface of Definition 1411.3. Carrier admission, classifier stability, completion compatibility, zero-distance exactness, and ledger visibility require the same displayed rows before any classifier export is available.

For completion-facing reads, use the completion-limit uniqueness route Definition 1411.4. The limit rows L_0, L_1 are compared through the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ route E before the metric witness and $\mathsf{Real}^{\uparrow}$ zero-distance read are formed.

Finally use zero-distance consumer exactness, Definition 1411.6. The rows H, C, P, N preserve, replay, source, and name the same finite route, so no excluded equality, selector, compactness, or ambient completeness principle can enter the export. □

Theorem 1411.73 (SeparatedMetric complete-limit uniqueness forward route)**.** *Every* CompleteMetricLimitUnique *consumer that takes a* SeparatedMetric$^{\uparrow}$ *packet as its separation witness must first expose the displayed* Met$^{\uparrow}$ *distance row, the* Real$^{\uparrow}$ *zero-distance row, the* CompleteMetric$^{\uparrow}$ *limit rows, the* CauchySequenceEquivalence$^{\uparrow}$ *comparison row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row before the uniqueness handoff. The consumer route is therefore the finite row chain already named by chapter 5983, Definition 1411.4, Definition 1411.50, and Definition 1411.71.*

It exports completion-limit uniqueness only as a separated zero-distance classifier consequence of the displayed rows. It does not export quotient completion equality, selected host limits, countable choice, host equality, trichotomy, compactness, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Begin with the CompleteMetricLimitUniqueness$^{\uparrow}$ request. The consumer may compare the two completion-limit rows only after the CompleteMetric$^{\uparrow}$ entries have been displayed and tied to the same finite-window route by the CauchySequenceEquivalence$^{\uparrow}$ row, as in Definition 1411.4.

Next apply the completion-uniqueness consumer obligation of Definition 1411.50. It sends the comparison through the Met$^{\uparrow}$ distance row and the Real$^{\uparrow}$ zero-distance seal before the separated classifier row may be consumed.

Finally use the root finite completion-readiness package of Definition 1411.71. The structural rows hsame, Cont, Pkg, and NameCert transport, replay, source, and name the same finite chain for the downstream consumer, so no quotient completion equality, selected limit, host equality, choice, trichotomy, compactness, or ambient completeness row can replace the displayed handoff. □

Chapter 1412

A Concrete Naming Certificate for $\mathsf{CauchySequenceEquivalence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ packet records the concrete equivalence relation on regular Cauchy names as finite BEDC data. It sits between the regular rational name surface of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the $\mathsf{Real}^{\uparrow}$ seal boundary of chapter 38. The equivalence packet is downstream of chapter 3413 because the regular-name comparison only exists after the Cauchy source windows have been licensed. The packet compares two regular Cauchy names through displayed finite windows and tolerances before any real-seal consumer can read the result.

Definition 1412.1 (CauchySequenceEquivalence carrier surface)**.** *A* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, S, T, D, E, R, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name rows;*
2. *S and T are the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which X and Y are observed;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the paired windows;*
4. *E is the local finite equivalence classifier recording that every scheduled paired observation is within the displayed dyadic tolerance;*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal-comparison row that may be consumed only after X, Y, S, T, D, E have been displayed;*
6. *H is the componentwise* hsame *provenance for the two regular names, the paired stream windows, the dyadic ledger, the classifier, and the seal-comparison row;*
7. *C is the displayed* Cont *route by which a consumer replays those finite windows without adding host data;*
8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$ *row.*

The carrier exposes no quotient stream, selected limit, host real equality, countable-choice row, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceTasteGate single carrier alignment`

Theorem 1412.2 (CauchySequenceEquivalence NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$ *obligation surface consists exactly of the finite rows in Definition 1412.1. Carrier admission requires two displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *names, paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a local finite equivalence classifier, a* $\mathsf{Real}^{\uparrow}$ *seal-comparison row, componentwise* hsame *provenance, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Classifier stability is tested only by the paired finite windows and the stored dyadic ledger. Transport preserves the same rows through H and C. Tolerance exactness says that every accepted comparison reads exactly the dyadic ledger D. Ledger visibility says that every consumer can inspect $X, Y, S, T, D, E, R, H, C, P, N$ and no other equality source.*

Lean4 ✓ `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceCarrier namecert obligations`
Lean4 ✓ `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceNamecertObligations`

Theorem 1412.3 (CauchySequenceEquivalence RegSeqRat Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal comparison routed through an accepted* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *packet factors through the displayed sequence*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, a consumer first reads the two regular Cauchy name rows X, Y, then the paired finite stream windows S, T, then the dyadic tolerance ledger D and finite classifier E, and only then reaches the seal-comparison row R. The packet supplies no quotient stream, selected limit, host real equality, countable choice, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceCarrier regseqrat real handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ packet is generated from two displayed $\mathsf{RegSeqRat}^{\uparrow}$ regular Cauchy names, paired $\mathsf{StreamName}^{\uparrow}$ finite windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a finite equivalence classifier, a $\mathsf{Real}^{\uparrow}$ seal-comparison row, displayed hsame provenance, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1412.1, Definition 1412.2, and Definition 1412.3 display the bridge to the public finite handoff over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySequenceEquivalence}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.CauchySequenceEquivalenceUp.CauchySequenceEquivalenceCarrier\_regseqrat\_real\_handoff`

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient-stream equality, selected host limits, countable choice, host real equality, or a standard bridge.

Upgrade path: Bridge checking requires a standard bridge theorem for the displayed RegSeqRat and Real handoff surface.

Chapter 1413

A Concrete Naming Certificate for $\mathsf{RealSequenceLimit}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealSequenceLimit}^{\uparrow}$ packet records a displayed limit interface for sequences of constructive real names without importing host sequence convergence. It sits after the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular rational rows of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the nonquotient finite-window equality boundary of chapter 1404.

The sibling dependency route is explicit: chapter 38 supplies the terminal $\mathsf{Real}^{\uparrow}$ seal, chapter 301 supplies rational readback, chapter 126 supplies finite observation windows, and chapter 291 supplies the tolerance ledgers consumed by the limit-modulus obligations.

Definition 1413.1 (RealSequenceLimit carrier)**.** *A* $\mathsf{RealSequenceLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(S, L, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is a displayed sequence of* $\mathsf{Real}^{\uparrow}$ *names, each read only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows selected for the packet.*
2. *L is the candidate limit* $\mathsf{Real}^{\uparrow}$ *row, again accompanied by the finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows made visible to the packet.*
3. *W is the finite tail-window schedule that records which sequence indices and which observation windows are inspected at each displayed tolerance.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the scheduled sequence windows and the scheduled limit windows.*
5. *E is the displayed convergence classifier, asserting that every scheduled tail window compares the corresponding sequence real to L through the recorded dyadic tolerance.*
6. *H records componentwise* hsame *transports for the sequence rows, limit row, window schedule, tolerance ledger, and convergence classifier.*
7. *C records the displayed* Cont *routes by which consumers inspect the sequence windows, the limit windows, the dyadic ledger, and the classifier.*
8. *P is the* Pkg *provenance for the* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and classifier rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSequenceLimit}^\uparrow}$ *row.*

The carrier stores a finite certificate surface for a displayed sequence-limit claim. It has no host sequence equality, no quotient limit, no countable-choice selector, no trichotomy row, and no ambient $\mathsf{Real}^\uparrow$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitTasteGate single carrier alignment`

Theorem 1413.2 (RealSequenceLimit NameCert obligation surface)**.** *For an accepted* $\mathsf{RealSequenceLimit}^\uparrow$ *carrier* $(S, L, W, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealSequenceLimit}^\uparrow}$ *surface consists of five finite rows:*

1. *carrier admission for the displayed sequence of* $\mathsf{Real}^\uparrow$ *names, the candidate limit* $\mathsf{Real}^\uparrow$ *row, the scheduled* $\mathsf{StreamName}^\uparrow$ *and* $\mathsf{RegSeqRat}^\uparrow$ *observations, the dyadic tolerance ledger, transports, continuations, provenance, and local naming row;*
2. *convergence classification by the finite tail-window schedule W, the* $\mathsf{DyadicRatCore}^\uparrow$ *ledger D, and the displayed classifier row E;*
3. *tail-window transport, stating that componentwise* hsame *transports and displayed* Cont *routes preserve the same scheduled sequence-to-limit comparison surface;*
4. *real-seal boundary through* $\mathsf{RegularCauchyEquivalence}^\uparrow$*, stating that every equality-facing read of a sequence real against the candidate limit factors through the nonquotient regular-Cauchy comparison boundary before any* $\mathsf{Real}^\uparrow$ *seal is consumed;*
5. *ledger refusal, stating that host sequence equality, quotient limits, countable choice, trichotomy, and ambient* $\mathsf{Real}^\uparrow$ *completeness are not packet coordinates.*

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitNameCert obligation surface`

Proof. Carrier admission is the tuple of Definition 1413.1. The sequence rows, limit row, finite windows, dyadic ledger, classifier, transports, continuations, package provenance, and local naming row are all explicit BHist coordinates.

The convergence classifier is finite because it reads only the tail windows listed in W and the tolerances listed in D. Each displayed comparison is made between scheduled $\mathsf{RegSeqRat}^\uparrow$ observations of a sequence element and scheduled $\mathsf{RegSeqRat}^\uparrow$ observations of the candidate limit.

Tail-window transport reads the rows H and C componentwise. Since the transported data still contains the same schedule, ledger, and classifier shape, every consumer route remains attached to the displayed finite comparison surface.

The real-seal boundary is inherited from the sibling route of chapter 1404. Equality-facing reads pass through the regular-Cauchy finite-window classifier before the $\mathsf{Real}^\uparrow$ seal rows are consumed.

The refusal row is an inventory check. The carrier has no coordinate for host sequence equality, quotient limits, countable-choice selection, trichotomy, or ambient real completeness, so none of those principles can be exported by the local certificate. □

Theorem 1413.3 (RealSequenceLimit observation-tail carrier)**.** *Every accepted* $\mathsf{RealSequenceLimit}^\uparrow$ *packet exposes only scheduled* $\mathsf{StreamName}^\uparrow$ *and* $\mathsf{RegSeqRat}^\uparrow$ *observations of the sequence and candidate limit through the finite schedule rows W and D. No consumer can read a sequence-to-limit comparison outside those displayed observation windows before the* $\mathsf{Real}^\uparrow$ *seal is reached.*

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitObservationTailCarrier`

Proof. Read the carrier of Definition 1413.1. The sequence row S and candidate limit row L are visible only through the $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows selected by the packet.

Apply the obligation surface of Definition 1413.2. Its carrier-admission and convergence-classification rows force every comparison to use the finite tail-window schedule W and the dyadic tolerance ledger D before the real-seal boundary can be consumed.

The sibling references in the chapter introduction identify the available sources: $\mathsf{Real}^{\uparrow}$ contributes the terminal seal, $\mathsf{RegSeqRat}^{\uparrow}$ contributes regular rational readback, $\mathsf{StreamName}^{\uparrow}$ contributes finite windows, and $\mathsf{DyadicRatCore}^{\uparrow}$ contributes the tolerance ledger. None of these routes supplies an unscheduled host sequence observation. □

Theorem 1413.4 (RealSequenceLimit classifier stability)**.** *For an accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *carrier* $(S, L, W, D, E, H, C, P, N)$*, the convergence classifier* E *is stable under componentwise* hsame *transports of* S*,* L*,* W*, and* D*. Transported consumers therefore inspect the same scheduled sequence windows, candidate-limit windows, and dyadic tolerances before reaching the* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. The carrier definition gives H as the componentwise hsame row for the sequence rows, limit row, window schedule, tolerance ledger, and convergence classifier. Hence a transported packet still has displayed coordinates of the same shape.

Use Definition 1413.2. The convergence classification row is finite because it reads only the windows listed in W and the tolerances listed in D, and the tail-window transport row preserves that scheduled comparison surface.

The $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ sibling surfaces named in the introduction supply only their displayed rows. Since H transports those rows componentwise, E cannot acquire a host sequence equality, quotient limit, choice-selected tail, trichotomy row, or ambient completeness witness. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitClassifierStability`

Theorem 1413.5 (RealSequenceLimit tail-window transport)**.** *Every consumer read of a* $\mathsf{RealSequenceLimit}^{\uparrow}$ *sequence-to-limit comparison factors through the finite tail-window schedule* W *and the dyadic ledger* D *before reaching the* $\mathsf{Real}^{\uparrow}$ *seal. The route is*

$$S, L \longmapsto W, D \longmapsto E \longmapsto C \longmapsto P, N$$

with componentwise transport supplied by H*.*

Proof. Start with a displayed sequence-to-limit comparison request. By Definition 1413.1, the only sequence and limit coordinates available to the packet are S and L, and both are accompanied by scheduled finite observations.

Next apply Definition 1413.2. The convergence classifier row requires the request to pass through W and D, while the real-seal boundary prevents equality-facing reads from bypassing the regular-Cauchy comparison route named in the introduction.

The continuation row C replays the same scheduled comparison for consumers, and P, N record provenance and local naming for that route. The transport row H preserves the packet componentwise, so every replayed comparison remains attached to the same finite tail-window schedule before the $\mathsf{Real}^{\uparrow}$ seal is consumed. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitTailWindowTransport`

Theorem 1413.6 (RealSequenceLimit modulus extraction)**.** *For an accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *carrier* $(S, L, W, D, E, H, C, P, N)$*, the rows* W, D, E *expose a* $\mathsf{CauchyModulus}^{\uparrow}$*-compatible tail threshold for the displayed sequence-to-limit claim. A tolerance request is first read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, then matched with a scheduled tail window in* W*, and finally admitted by the convergence classifier* E *before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Use the carrier projection of Definition 1413.1. The schedule row W lists the tail windows visible to the packet, D lists the dyadic tolerance requests attached to those windows, and E records the displayed convergence classifier over the same rows.

Apply the NameCert surface of Definition 1413.2. Its convergence-classification row forces every sequence-to-limit read to pass through W and D, while its real-seal boundary prevents a consumer from replacing that finite threshold by an ambient completeness argument.

The resulting threshold is compatible with $\mathsf{CauchyModulus}^{\uparrow}$ because it is a displayed tail-window response to a dyadic tolerance request. It supplies only the scheduled tail index and the associated readback windows, not a host-level modulus function or a choice-selected tail. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitModulusExtraction`

Theorem 1413.7 (RealSequenceLimit tail refinement ledger)**.** *For an accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *carrier* $(S, L, W, D, E, H, C, P, N)$*, refining a dyadic tolerance request remains inside the same* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}$ *route. The refined request may shrink the scheduled windows recorded in* W *and the tolerance row recorded in* D*, but its classifier read still factors through* E, H, C, P, N *before the* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with a displayed tolerance request already admitted by D. A refinement is another dyadic request in the same $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, so it changes the requested precision but not the packet coordinates that are available to the consumer.

The finite window route is fixed by Definition 1413.5. The sequence and limit observations still pass through $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks selected by W, and the classifier row E still compares only those scheduled observations.

Transport and replay do not add new routes. The rows H and C preserve the same componentwise schedule, while P and N record provenance and naming for that schedule. Thus refinement stays inside the displayed finite ledger and cannot introduce host sequence equality, quotient limits, choice, trichotomy, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitTailRefinementLedger`

Theorem 1413.8 (RealSequenceLimit limit uniqueness route)**.** *Let* $(S, L, W, D, E, H, C, P, N)$ *and* $(S, L', W', D', E', H', C', P', N')$ *be accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *candidate-limit rows for the same displayed sequence row* S*. If their scheduled tail windows are compared through a common refinement of the displayed* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}$ *route, then every equality-facing comparison between* L *and* L' *factors through* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *before either* $\mathsf{Real}^{\uparrow}$ *seal is read.*

Proof. Project both accepted carriers. The two candidate limits expose only their scheduled finite observations, dyadic tolerance rows, convergence classifiers, transport rows, replay rows, provenance, and local names.

Use the common refinement of the tail-window routes. By Definition 1413.7, both candidates are read through the same kind of $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ data, so the comparison between their scheduled limit observations is still finite-window data.

Apply the real-seal boundary in Definition 1413.2. Equality-facing reads cannot jump directly to either $\mathsf{Real}^{\uparrow}$ seal; they must first pass through the nonquotient finite-window comparison boundary named by $\mathsf{RegularCauchyEquivalence}^{\uparrow}$.

Hence uniqueness is a route statement: two accepted candidate-limit rows compared through the same scheduled tails meet at the regular-Cauchy comparison boundary before either terminal real seal is consumed. The packet does not assert host uniqueness of limits outside that displayed route. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitLimitUniquenessRoute`

Theorem 1413.9 (RealSequenceLimit observation-window obligation)**.** *Every accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *packet reads sequence observations only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite windows and the* $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}$ *rows of Definition 1413.1. In particular, the packet exposes no unscheduled host sequence observation, quotient sequence equality, or hidden convergence coordinate before the* $\mathsf{Real}^{\uparrow}$ *seal is reached.*

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitObservationWindowObligation`

Proof. Project the carrier. The sequence row S, candidate limit row L, scheduled window row W, and dyadic tolerance row D are the only observation-facing coordinates available to an accepted packet.

The NameCert obligation surface in Definition 1413.2 records that every convergence classification reads through W, D, E before any terminal seal. The tail-window transport theorem Definition 1413.5 gives the same factorization for consumer reads.

Thus an observation request can only be answered by the displayed finite window route and its regular-rational and dyadic rows. The carrier has no coordinate for host sequence equality, quotient limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1413.10 (RealSequenceLimit Cauchy-modulus handoff)**.** *For every accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *carrier* $(S, L, W, D, E, H, C, P, N)$*, the limit row consumes* $\mathsf{CauchyModulus}^{\uparrow}$*-compatible tolerance data through* D *and the scheduled tail windows in* W *before any* $\mathsf{Real}^{\uparrow}$ *seal is read. The handoff exports only the displayed tail threshold, window schedule, classifier admission, transport, replay, provenance, and local naming rows.*

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitCauchyModulusHandoff`

Proof. Start with a tolerance request. By Definition 1413.6, the request is first read as dyadic tolerance data in D and then matched with a scheduled tail window in W.

The classifier row E admits the displayed comparison only after those two rows have been consumed. The tail-refinement ledger in Definition 1413.7 keeps refined requests inside the same $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}$ route.

Rows H, C, P, N then transport, replay, source, and name the same handoff. Nothing in this route selects a host modulus function, chooses a tail by countable choice, or reads ambient completeness of $\mathsf{Real}^{\uparrow}$. □

Definition 1413.11 (RealSequenceLimit finite modulus carrier)**.** *A* $\mathsf{RealSequenceLimit}^{\uparrow}$ *finite modulus packet is a displayed tuple*

$$(S, L, W, D, E, M, H, C, P, N)$$

obtained from an accepted carrier $(S, L, W, D, E, H, C, P, N)$ *by inserting the threshold row* M *extracted from the scheduled window, dyadic tolerance, and classifier rows* W, D, E*. The row* M *is the* $\mathsf{CauchyModulus}^{\uparrow}$*-compatible tail threshold whose existence is read by Definition 1413.6: a dyadic tolerance request is first admitted by* D*, matched to a finite tail window in* W*, and then certified by* E *as the displayed sequence-to-limit comparison before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

The packet contains no host modulus function, no selected infinite tail, no quotient stream equality, no countable-choice coordinate, and no ambient completeness row. It records only the scheduled $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, classifier admission, transport, replay, provenance, and local naming rows needed to expose* M *as finite BEDC data.*

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitFiniteModulusCarrier threshold route`

Theorem 1413.12 (RealSequenceLimit finite modulus NameCert obligations)**.** *For every accepted finite modulus packet* $(S, L, W, D, E, M, H, C, P, N)$ *of Definition 1413.11, the local* $\mathsf{NameCert}_{\mathsf{RealSequenceLimit}^{\uparrow}}$ *obligation surface contains the following finite rows:*

1. *carrier admission for the displayed sequence row* S*, candidate limit row* L*, scheduled window row* W*, dyadic tolerance row* D*, classifier row* E*, extracted threshold row* M*, transport row* H*, replay row* C*, provenance row* P*, and naming row* N*;*
2. *dyadic tolerance read, stating that every tolerance request reaching* M *first appears as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *row in* D*;*
3. *scheduled tail-window read, stating that* W *supplies the finite tail window attached to that dyadic request;*
4. *classifier admission, stating that* E *admits the displayed sequence-to-limit comparison only after the* D *and* W *rows have been read;*
5. $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ *transport, stating that the observations used by* M *are the finite stream windows and regular-rational readbacks named by the packet;*
6. $\mathsf{Real}^{\uparrow}$ *seal nonescape, stating that the terminal real seal supplies no hidden modulus, no host sequence equality, no quotient limit, no trichotomy, and no ambient completeness witness;*
7. *replay, provenance, and naming, stating that* C, P, N *re-export the same finite threshold route without changing its visible rows.*

Proof. Start with Definition 1413.11. The tuple itself supplies the carrier-admission row and records M as the displayed threshold extracted from W, D, E.

Apply Definition 1413.6. It forces a tolerance request to pass through the dyadic ledger D, then through the scheduled tail window W, and finally through the classifier E before the threshold row can be read.

Next use Definition 1413.5. The observations supporting this threshold remain inside the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ surfaces named by the packet, with componentwise transport supplied by H and consumer replay supplied by C.

Finally apply Definition 1413.10. The resulting M is exactly the finite $\mathsf{CauchyModulus}^{\uparrow}$-compatible handoff row. The $\mathsf{Real}^{\uparrow}$ seal nonescape clause follows from Definition 1413.14, while P and N record provenance and local naming for the same finite route. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitModulusNameCertObligations`

Theorem 1413.13 (RealSequenceLimit modulus RealUp handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of a* $\mathsf{RealSequenceLimit}^{\uparrow}$ *sequence-limit packet must read the finite modulus packet* $(S, L, W, D, E, M, H, C, P, N)$ *of Definition 1413.11 before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed. Thus the consumer route factors through*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, W, D, E, M, H, C, P, N$$

and cannot replace M *by a host modulus function, a selected infinite tail, quotient stream equality, countable choice, trichotomy, or ambient real completeness.*

Proof. Use Definition 1413.10 to identify the consumer-facing tolerance handoff. It already routes through D, W, and the classifier E before the $\mathsf{Real}^{\uparrow}$ seal is read.

The carrier of Definition 1413.11 packages the same handoff with the explicit threshold row M. Hence a consumer cannot reach the terminal real seal without first seeing the scheduled dyadic request, finite stream windows, regular-rational readbacks, classifier admission, and extracted threshold.

The transport and replay clauses are supplied by Definition 1413.5. The extraction clause is supplied by Definition 1413.6. Together with the $\mathsf{Real}^{\uparrow}$ nonescape boundary of Definition 1413.14, these rows force every Real-facing read to pass through the finite modulus packet and exclude all non-displayed modulus sources. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.ModulusRealUpHandoff.RealSequenceLimitModulusRealUphandoff`

Theorem 1413.14 (RealSequenceLimit Real seal non-escape)**.** *For an accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *packet, every* $\mathsf{Real}^{\uparrow}$*-facing read of the candidate limit or of a sequence-to-limit comparison factors through the carrier, NameCert obligation surface, observation window route, Cauchy-modulus handoff, and limit uniqueness route before the real seal is consumed. The packet excludes host sequence equality, quotient limits, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the carrier and the NameCert obligation surface to list the available rows. They provide the sequence row, candidate limit row, finite windows, dyadic tolerances, convergence classifier, transport, replay, provenance, and local naming.

The observation-window obligation and Cauchy-modulus handoff identify the only routes by which observation and tolerance data can reach the classifier. The limit uniqueness route then shows that equality-facing reads between candidate limits must pass through $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ before either $\mathsf{Real}^{\uparrow}$ seal is read.

Consequently the real seal is terminal for this displayed route rather than a source of extra principles. No row supplies host sequence equality, quotient limits, countable choice, trichotomy, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitRealSealNonescape`

Theorem 1413.15 (RealSequenceLimit Cauchy-modulus extraction)**.** *For every accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *carrier* $(S, L, W, D, E, H, C, P, N)$*, the scheduled rows* W, D, E *expose a* $\mathsf{CauchyModulus}^{\uparrow}$*-compatible threshold before the* $\mathsf{Real}^{\uparrow}$ *seal is consumed. A tolerance request is admitted only after* D *records the dyadic tolerance,* W *supplies the corresponding finite tail window, and* E *classifies the displayed sequence-to-limit comparison through that scheduled window.*

Proof. Start with the observation-tail carrier of Definition 1413.3. It restricts all visible sequence and candidate-limit observations to the scheduled rows W and D.

The classifier stability theorem Definition 1413.4 and the tail-window transport theorem Definition 1413.5 keep the same comparison route after componentwise transport. Thus the classifier cannot move a tolerance request to an unscheduled observation window.

Apply the modulus extraction theorem Definition 1413.6 and the Cauchy-modulus handoff theorem Definition 1413.10. They identify the displayed threshold as the finite tail response to the dyadic request. The tail-refinement ledger of Definition 1413.7 preserves that response under smaller tolerances, and the real-seal non-escape theorem Definition 1413.14 prevents ambient $\mathsf{Real}^{\uparrow}$ completeness from supplying any further threshold. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitCauchyModulusExtraction`

Theorem 1413.16 (RealSequenceLimit regular classifier transport)**.** *For every accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *carrier* $(S, L, W, D, E, H, C, P, N)$*, componentwise* hsame *transport of the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows preserves the same regular-Cauchy classifier route for candidate limits. Transported consumers still compare the sequence row and candidate limit through* W, D, E, H, C, P, N *before any* $\mathsf{Real}^{\uparrow}$ *seal is read.*

Proof. Use the carrier definition to project the finite stream windows, regular rational readbacks, dyadic tolerance ledger, convergence classifier, transport, replay, provenance, and local naming rows.

Classifier stability in Definition 1413.4 says that the row E is stable under the componentwise transports stored in H. Tail-window transport in Definition 1413.5 then replays the transported comparison through the same scheduled windows and dyadic ledger.

The observation-tail carrier and tail-refinement ledger, Definition 1413.3 and Definition 1413.7, keep refined or transported reads inside the $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}$ route. Finally, Definition 1413.14 blocks host sequence equality, quotient limits, countable choice, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ completeness from entering the transported classifier. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitRegularClassifierTransport`

Theorem 1413.17 (RealSequenceLimit Cauchy criterion factorization)**.** *Every accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *packet exposing rows* $S, L, W, D, E, H, C, P, N$ *factors each displayed sequence-to-limit comparison through the* $\mathsf{RealSequenceCauchyCriterion}^{\uparrow}$ *finite Cauchy tail-window route before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The factorization reads the sequence and candidate limit through* S, L*, the scheduled observation and dyadic rows through* W, D*, the convergence classifier through* E*, the transport and replay rows through* H, C*, and then hands the resulting tail-window comparison to the sibling Cauchy-criterion surface before any Real-facing consumer can inspect* P, N*.*

Proof. Start with the carrier and obligation surface, Definition 1413.1 and Definition 1413.2. They expose exactly the displayed sequence row, candidate limit row, scheduled windows, dyadic tolerance ledger, classifier, transport, replay, provenance, and local naming rows.

Use Definition 1413.5 to keep the comparison inside the same scheduled finite windows after componentwise hsame transport. The regular classifier transport theorem Definition 1413.16 then identifies the transported comparison as a route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows rather than through host sequence equality.

Apply the sibling handoff Definition 2255.3. It consumes the displayed $\mathsf{RealSequenceLimit}^{\uparrow}$ row and returns the Cauchy tail-window comparison through finite $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ data.

Finally, Definition 1413.14 makes the Real$^{\uparrow}$ seal terminal for this route. Thus the sequence-to-limit comparison reaches any Real-facing consumer only after passing through the finite Cauchy-criterion factorization, and it does not claim ambient completeness, quotient limits, countable choice, or trichotomy. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitCauchyCriterionFactorization`

Theorem 1413.18 (RealSequenceLimit regular Cauchy tail factorization)**.** *Every accepted* RealSequenceLimit$^{\uparrow}$ *sequence-to-limit comparison factors through the displayed regular Cauchy tail route before the terminal* Real$^{\uparrow}$ *seal is consumed. Concretely, the comparison reads the sequence and candidate limit rows through* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks,* DyadicRatCore$^{\uparrow}$ *tolerances, the* CauchyModulus$^{\uparrow}$ *threshold handoff, and the* RealSequenceCauchyCriterion$^{\uparrow}$ *tail route, and only then reaches the Real-facing seal, transport, replay, provenance, and local naming rows. The route refuses host sequence equality, quotient limits, countable choice, trichotomy, and ambient Real completeness.*

Proof. Start with the observation-tail carrier Definition 1413.3 and the tail-window transport theorem Definition 1413.5. Together they force every sequence and candidate-limit read through the scheduled StreamName$^{\uparrow}$ windows and the matching RegSeqRat$^{\uparrow}$ readbacks before any consumer replay is available.

Next apply Definition 1413.6 and Definition 1413.10. These theorems identify the dyadic tolerance row as a CauchyModulus$^{\uparrow}$-compatible finite threshold route rather than as a host modulus function or a selected infinite tail.

Use Definition 1413.17. It hands the scheduled comparison to the RealSequenceCauchyCriterion$^{\uparrow}$ finite Cauchy tail-window surface before the terminal Real$^{\uparrow}$ seal can be inspected.

Finally apply Definition 1413.14. The seal is terminal for the displayed route, so it cannot supply host sequence equality, quotient limits, countable choice, trichotomy, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RegularCauchyTailFactorization.RealSequenceLimitRegularCauchyT`

Theorem 1413.19 (RealSequenceLimit factorization completeness)**.** *Every accepted* RealSequenceLimit$^{\uparrow}$ *comparison is exhausted by the displayed L10 factorization route. The comparison first reads the scheduled* StreamName$^{\uparrow}$ *windows, then the* RegSeqRat$^{\uparrow}$ *readbacks, then the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, then the* CauchyModulus$^{\uparrow}$ *threshold handoff, then the* RealSequenceCauchyCriterion$^{\uparrow}$ *tail route, then the* RegularCauchyEquivalence$^{\uparrow}$ *comparison boundary, and only then reaches* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The terminal* Real$^{\uparrow}$ *seal is read only inside that route.*

No accepted comparison can enter through host sequence equality, quotient limits, countable choice, trichotomy, selected host tails, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Begin with the carrier and NameCert surface of Definition 1413.2. It lists exactly the visible sequence row, candidate limit row, scheduled windows, dyadic ledger, classifier, transport, replay, provenance, and local naming rows.

Apply the modulus extraction theorem Definition 1413.6. It turns a tolerance request into a finite threshold read through DyadicRatCore$^{\uparrow}$ and CauchyModulus$^{\uparrow}$, so no host modulus or selected infinite tail is available.

Next use the Cauchy-criterion factorization of Definition 1413.17 and the regular Cauchy tail factorization of Definition 1413.18. These two results route the comparison through the sibling

RealSequenceCauchyCriterion$^{\uparrow}$ tail surface and the RegularCauchyEquivalence$^{\uparrow}$ boundary before any Real-facing consumer reads the seal.

Finally apply Definition 1413.14. The seal is terminal for the displayed L10 route, and the remaining rows H, C, P, N provide only transport, replay, provenance, and local naming. Thus the listed rows exhaust every accepted RealSequenceLimit$^{\uparrow}$ comparison. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.FactorizationCompleteness.RealSequenceLimitFactorizationComple`

Theorem 1413.20 (RealSequenceLimit subsequence tail stability)**.** *Every accepted subsequence consumer of a displayed* RealSequenceLimit$^{\uparrow}$ *packet* $K = (S, L, W, D, E, H, C, P, N)$ *must reindex through the same* StreamName$^{\uparrow}$ *finite windows,* RegSeqRat$^{\uparrow}$ *readbacks,* DyadicRatCore$^{\uparrow}$ *tolerances, and* RealSequenceCauchyCriterion$^{\uparrow}$ *tail route before the terminal* Real$^{\uparrow}$ *seal is consumed. The subsequence request may name a displayed increasing index row, but it receives no host subsequence selector, quotient limit, countable-choice schedule, trichotomy split, or ambient* Real$^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitSubsequenceTailStability`

Proof. Start with the carrier of Definition 1413.1. The visible rows are the displayed sequence, candidate limit, finite observation windows, dyadic tolerance ledger, classifier, transport, replay, provenance, and local naming rows. A subsequence-facing consumer has no additional coordinate from which to read a host-selected tail.

Use Definition 1413.5. Reindexing a displayed subsequence request can only choose subwindows already routed through the StreamName$^{\uparrow}$ schedules in W, with the matching RegSeqRat$^{\uparrow}$ readbacks and DyadicRatCore$^{\uparrow}$ tolerances recorded in D.

Apply Definition 1413.16. The classifier row E is transported through the same componentwise hsame rows H and replayed by C, so a subsequence read remains a transported finite-window comparison rather than a quotient limit or a host sequence equality.

Finally use Definition 1413.17. The transported subsequence comparison reaches the sibling RealSequenceCauchyCriterion$^{\uparrow}$ tail route before any Real$^{\uparrow}$ seal is visible. Thus subsequence extraction stays inside the L10 finite-window route and cannot import host subsequence selection, countable choice, trichotomy, quotient limits, or ambient completeness. □

Theorem 1413.21 (RealSequenceLimit diagonal-window uniqueness)**.** *Let* $K = (S, L, W, D, E, H, C, P, N)$ *be an accepted* RealSequenceLimit$^{\uparrow}$ *packet. If two accepted limit reads use the same* StreamName$^{\uparrow}$ *schedule row* W*, the same* RegSeqRat$^{\uparrow}$ *readback route, the same* DyadicRatCore$^{\uparrow}$ *tolerance ledger* D*, and the same terminal* Real$^{\uparrow}$ *seal, then both reads must pass through the same finite diagonal window before the classifier row* E *is consumed. The uniqueness is a finite-window route claim, not a quotient sequence equality, selected host limit, countable-choice schedule, trichotomy split, or ambient real-completeness assertion.*

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitDiagonalWindowUniqueness`

Proof. Start with the carrier of Definition 1413.1. The two candidate reads have no schedule coordinate beyond W and no tolerance coordinate beyond D.

Apply Definition 1413.5. Since both reads use the same scheduled StreamName$^{\uparrow}$ windows and the same RegSeqRat$^{\uparrow}$ readback route, transport can only replay the comparison through the displayed window route already stored in the packet.

Next use Definition 1413.16. The classifier row E is reached only after the transported $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}$ route is displayed, so the two reads cannot choose separate classifier-facing windows.

Finally, Definition 1413.20 rules out an alternate host subsequence selector, and Definition 1413.14 keeps the terminal $\mathsf{Real}^{\uparrow}$ seal downstream of the same finite route. Thus the classifier consumes one shared diagonal window. □

Theorem 1413.22 (RealSequenceLimit limit-modulus composition)**.** *For every accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *packet* $K = (S, L, W, D, E, H, C, P, N)$*, composing the finite Cauchy-modulus extraction route with subsequence-tail stability yields a finite modulus route for every accepted subsequence limit read. The route passes through* D*,* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the classifier row* E*, transport and replay through* H, C*, and the provenance and naming rows* P, N *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed; it does not use quotient sequence equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, or a selected host limit.*

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitLimitModulusComposition`

Proof. Use Definition 1413.15. A tolerance request first enters the dyadic ledger D, then the scheduled finite windows W, and then the classifier row E before any threshold can be read.

Apply Definition 1413.20. A subsequence-facing limit read may reindex through displayed subwindows, but it receives no independent host selector and no separate countable-choice schedule.

The regular readback and classifier transport are supplied by Definition 1413.16. They keep the composed route inside the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows after componentwise hsame transport and displayed Cont replay.

Finally, Definition 1413.5 identifies the transported windows with the finite route already used by the limit packet. The resulting modulus route reaches P, N and the terminal $\mathsf{Real}^{\uparrow}$ seal only after the finite composition has been displayed, so no quotient equality, ambient completeness, countable choice, or selected host limit enters the proof. □

Theorem 1413.23 (RealSequenceLimit squeeze handoff)**.** *Let* $K^- = (S^-, L, W^-, D^-, E^-, H^-, C^-, P^-, N^-)$*,* $K = (S, L, W, D, E, H, C, P, N)$*, and* $K^+ = (S^+, L, W^+, D^+, E^+, H^+, C^+, P^+, N^+)$ *be accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *packets with the same displayed limit row* L*. Suppose the middle sequence row* S *shares a finite tail-window bound with the lower and upper rows* S^-, S^+ *through the same* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation route, and suppose the two bounding packets expose finite modulus rows for convergence to* L*. Then the middle packet inherits the same* $\mathsf{RealSequenceLimit}^{\uparrow}$ *finite modulus surface: each tolerance request for* K *factors through the displayed squeeze window, the bounding modulus rows, the regular classifier transport, diagonal-window uniqueness, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before* P, N *are read.*

Proof. Start with the displayed squeeze window. The hypothesis supplies a common $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Dya}$ route relating S^-, S, and S^+ on the finite tail requested by the tolerance ledger. Hence the middle packet receives no host order argument, no quotient sequence equality, and no selected infinite tail outside the displayed rows.

Apply Definition 1413.22 to the two bounding packets. Their convergence to the shared limit row L exposes finite modulus routes through their dyadic ledgers, scheduled windows, classifiers, transports, replays, provenance rows, and local names.

Use Definition 1413.16 to move the middle comparison through the same regular readback route. The squeeze window makes the transported middle read a $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}$ comparison already bounded by the two displayed modulus rows.

Finally apply Definition 1413.21. The lower, middle, and upper reads meet at one finite diagonal window before any classifier-facing read reaches the terminal $\mathsf{Real}^{\uparrow}$ seal. Therefore the middle packet inherits the finite modulus surface already exposed by the bounding packets, and no ambient completeness, countable choice, trichotomy, selected host limit, or quotient sequence equality enters the handoff. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitSqueezeHandoff`

Theorem 1413.24 (RealSequenceLimit scoped dependency package)**.** *For every accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *packet* $K = (S, L, W, D, E, H, C, P, N)$*, every accepted limit read factors through the full finite dependency route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto H, C, P, N$$

before the limit certificate is exported. Concretely, the tolerance request is recorded in the dyadic ledger D*, the finite observation window is selected from* W*, the rational approximation is read through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, the candidate limit and sequence values reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and only then do componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row expose the certificate.*

The scoped package is a dependency statement for the displayed packet. It does not assert host sequence convergence, quotient equality of streams, selected limits, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with the carrier of Definition 1413.1. Its visible coordinates are the displayed sequence source, candidate limit row, finite windows, dyadic tolerance ledger, classifier, transport, replay, provenance, and local naming rows.

Apply the NameCert obligation surface of Definition 1413.2. Those obligations force a tolerance request to enter the dyadic ledger D and the finite window row W before any convergence classifier is consumed.

Use Definition 1413.5 and Definition 1413.16. Together they route every transported read through the same $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback, with componentwise hsame transport and displayed Cont replay preserving the dependency order.

Finally apply Definition 1413.14. The terminal $\mathsf{Real}^{\uparrow}$ seal is reached only after the dyadic, window, and regular-readback rows are displayed, while P, N merely package and name that route. Hence the exported limit certificate has exactly the scoped dependency package stated above. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitScopedDependencyPackage`

Theorem 1413.25 (RealSequenceLimit regular-tail scope lock)**.** *Let* $K = (S, L, W, D, E, H, C, P, N)$ *be an accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *packet. Any tail read that is admitted as a regular limit read is locked to the same* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *route as* K*: changing the tail window, rational readback, or Real seal requires changing one of the displayed rows* W, D, E, H, C, P, N *of the packet. Thus regular tails are scoped by the packet rows themselves rather than by a host convergence predicate, an external subsequence selector, a quotient equality of streams, or ambient completeness.*

Proof. Project the packet rows. A regular tail read has no coordinate outside W, D, E, H, C, P, N from which to obtain a tolerance, observation window, rational readback, or terminal Real seal.

Use Definition 1413.5. Tail transport may reindex only through the displayed $\mathsf{StreamName}^{\uparrow}$ windows already stored in W, with tolerance requests still accounted for by the dyadic ledger D.

Next apply Definition 1413.16. The regular classifier can be consumed only after the matching $\mathsf{RegSeqRat}^{\uparrow}$ readback and the componentwise hsame transport have been displayed, so a tail read cannot switch to an unrecorded regular route.

The Real boundary is fixed by Definition 1413.14, and diagonal reuse is controlled by Definition 1413.21. Therefore every admitted regular tail remains locked to the same finite dependency route before P, N export the named limit certificate. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimit regular tail scope lock`

Theorem 1413.26 (RealSequenceLimit bounded source handoff)**.** *Let $K = (S, L, W, D, E, H, C, P, N)$ be an accepted* $\mathsf{RealSequenceLimit}^{\uparrow}$ *packet whose displayed source sequence is supplied by an accepted* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *packet $X = (S_0, M_0, D_0, R_0, E_0, B_0, H_0, C_0, P_0, N_0)$. Before the limit classifier E and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of K may be read, the source route must consume the boundedness rows*

$$S_0 \longmapsto M_0 \longmapsto D_0 \longmapsto R_0 \longmapsto E_0 \longmapsto B_0, H_0, C_0, P_0, N_0.$$

Consequently a RealSequenceLimit read from a bounded Cauchy source exposes the finite bound ledger B_0 before any limit-classifier or Real-seal consumer receives the source sequence, and it imports no host boundedness theorem, selected limit, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source packet. Apply Definition 1522.3: every real-facing or convergence-facing read from X passes through $S_0, M_0, D_0, R_0, E_0, B_0, H_0, C_0, P_0, N_0$, with B_0 carrying the explicit finite bound ledger.

Now use Definition 1413.25. The RealSequenceLimit packet can admit a source tail only through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route already stored in W, D, E, H, C, P, N.

Finally apply Definition 1413.14. The terminal Real seal cannot be reached before the finite dyadic, window, rational-readback, and transport rows are displayed. Since the bounded source supplies those rows only after B_0 is present, the limit classifier and Real seal inherit the boundedness route stated above. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.BoundedSourceHandoff.RealSequenceLimitBoundedSourceHandoff`

Theorem 1413.27 (RealSequenceLimit bridge surface)**.** *Every public* $\mathsf{RealSequenceLimit}^{\uparrow}$ *packet $K = (S, L, W, D, E, H, C, P, N)$ supplies a bridge surface whose rows are exhausted by the* RealSequenceCauchyCriter $\mathsf{RegularCauchyEquivalence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *routes together with componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. The bridge reads sequence-limit data only through the displayed finite windows, regular rational readbacks, dyadic tolerance ledger, equality-facing regular-Cauchy comparison, Cauchy-criterion handoff, terminal Real seal, and structural rows of K.*

Thus any later $\mathsf{StandardBridge}$ *consumer must use this public packet surface before interpreting the sequence-limit claim in an external standard presentation. The bridge surface contains no quotient limit, no selected representative, no host sequence equality, no countable-choice schedule, no trichotomy split, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier of Definition 1413.1. The only sequence and candidate-limit observations available to a consumer are the displayed $\mathsf{StreamName}^{\uparrow}$ windows W, the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger D, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Apply Definition 1413.15 and Definition 1413.26. These route Cauchy-facing reads through the finite tolerance ledger and source rows before any limit classifier or Real seal is consumed, giving the $\mathsf{RealSequenceCauchyCriterion}^{\uparrow}$ side of the bridge surface.

Next use Definition 1413.8 and Definition 1413.25. Equality-facing limit comparisons remain inside the $\mathsf{RegularCauchyEquivalence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route already displayed by the packet.

Finally, Definition 1413.24 supplies the structural boundary through H, C, P, N. Hence a bridge-facing consumer can read only the public packet rows named in the statement, and the carrier inventory leaves no coordinate for quotient limits, selected representatives, host sequence equality, choice, trichotomy, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RealSequenceLimitUp.RealSequenceLimitBridgeSurface`

Closure status for $\mathsf{NameCert}_{\mathsf{RealSequenceLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSequenceLimit}^{\uparrow}$ packet is generated from a displayed sequence of RealUp names, a candidate limit RealUp row, finite StreamName windows and RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a finite convergence classifier, componentwise transport, continuation routes, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealSequenceLimit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1413.1, Definition 1413.2, Definition 1413.3, Definition 1413.16, Definition 1413.5, Definition 1413.14, Definition 1413.21, Definition 1413.25, Definition 1413.26, and Definition 1413.27 bind the mature RealSequenceLimit treatment through the displayed bridge surface, bounded-source handoff, $\mathsf{RealSequenceCauchyCriterion}^{\uparrow}$, $\mathsf{RegularCauchyEquivalence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealSequenceLimit}^{\uparrow}}$, unformalized)

Bridge status: paperBridge

Not claimed: This chapter does not claim Lean verification, host sequence equality, quotient limits, selected representatives, countable choice, trichotomy, or ambient RealUp completeness.

Upgrade path: Remaining work is Lean verification and checked bridge status for the displayed RealSequenceLimit bridge surface, not further paper theory closure.

Chapter 1414

A Concrete Naming Certificate for $\mathsf{CauchyNullEquivalence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyNullEquivalence}^{\uparrow}$ packet records the constructive criterion that two regular Cauchy real names agree exactly when their displayed pointwise difference is certified by a null sequence. The packet is a finite NameCert boundary: it reads the source regular names of chapter 301, the difference row of chapter 429, the zero-tail row of chapter 380, the finite equivalence boundary of chapter 1404, and the seal rows of chapter 38.

It does not add a quotient of Cauchy streams, a selected host limit, a host equality of real numbers, a trichotomy branch, or an ambient completeness theorem. Its role is to name the reusable finite bridge between a displayed difference-null packet and the equality-facing read of regular Cauchy real names.

Definition 1414.1 (CauchyNullEquivalence carrier)**.** *A* $\mathsf{CauchyNullEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(X, Y, D, Z, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular Cauchy real names are being compared.*
2. *D is the accepted* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row that displays the pointwise difference of X and Y, including its aligned* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *subtraction ledger.*
3. *Z is the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail packet consuming the displayed difference row exported by D.*
4. *E is the equality-facing row, either the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *finite-window classifier or the* $\mathsf{Real}^{\uparrow}$ *seal/equality row that reads the same zero-tail evidence.*
5. *H records the componentwise* hsame *transports for the two source rows, the difference row, the null-sequence row, and the equality-facing row.*
6. *C records the displayed* Cont *routes by which consumers inspect the source rows, the difference packet, the zero-tail packet, and the equality-facing handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyDifference}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{RegularCauchyEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNullEquivalence}^{\uparrow}}$ *row.*

The carrier stores one finite criterion surface: equality of the two displayed regular Cauchy real names is read through the same difference row and the same null-sequence packet. It stores no quotient stream, no selected limit, no host real equality, and no ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.CauchyNullEquivalenceUp.CauchyNullEquivalenceTasteGate single carrier alignment`

Theorem 1414.2 (CauchyNullEquivalence NameCert obligations)**.** *For an accepted* $\mathsf{CauchyNullEquivalence}^{\uparrow}$ *carrier* $(X, Y, D, Z, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyNullEquivalence}^{\uparrow}}$ *surface consists of six finite obligations:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the displayed* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *row, the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail row, the equality-facing* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *row, transports, continuations, provenance, and local naming data;*
2. *difference exactness, stating that* D *is the pointwise difference packet for the displayed source rows* X *and* Y*;*
3. *zero-tail consumption, stating that* Z *consumes exactly the difference row exposed by* D*;*
4. *equality handoff, stating that* E *reads equality of the two regular Cauchy real names only through the same displayed difference-null route;*
5. *classifier transport, stating that the source rows, difference row, zero-tail row, and equality-facing row transport componentwise through the stored* hsame *rows and displayed* Cont *routes;*
6. *ledger refusal, stating that quotient stream equality, host real equality, selected limits, trichotomy, countable choice, and ambient real completeness are not packet coordinates.*

Proof. Carrier admission is the tuple of Definition 1414.1. It exposes exactly two regular Cauchy source rows, their displayed difference packet, the zero-tail packet for that difference, the equality-facing classifier or seal row, and the finite transport, continuation, package, and naming rows.

Difference exactness is read from chapter 429. The row D already binds the source rows X, Y, the aligned $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ subtraction ledger, and the tolerance ledger for the displayed difference.

Zero-tail consumption is read from chapter 380. The row Z consumes the same difference stream and exposes only the tolerance-window-threshold data allowed by the null-sequence packet.

The equality handoff is read through chapter 1404 and chapter 38. The equality-facing row E may inspect the finite equivalence classifier or the real seal, but only after the difference row and null-sequence row have been displayed.

Classifier transport is componentwise over H and C. Since the carrier has no quotient, selected limit, host equality, trichotomy, choice, or completeness coordinate, the refusal row follows from the inventory. □

Theorem 1414.3 (CauchyNullEquivalence difference-zero route)**.** *For accepted* $\mathsf{CauchyNullEquivalence}^{\uparrow}$ *carriers, the equality-facing read of the two regular Cauchy real names and the zero-tail read of their displayed difference are the same finite route. More precisely, a consumer may pass from the source rows* X, Y *to the equality row* E *only by first reading the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *packet* D *and then the* $\mathsf{NullSequence}^{\uparrow}$ *packet* Z *for the displayed difference row; conversely, any such displayed difference-null route supplies exactly the finite equality handoff recorded by* E*.*

Proof. For the forward direction, start with an equality-facing consumer of E. By the carrier definition, E is stored after the source rows X, Y, the difference packet D, and the zero-tail packet Z.

Apply the real-seal and finite-window boundaries of chapter 1404. They force the consumer to read equality of regular Cauchy names through the finite comparison surface rather than through a quotient stream or host real equality.

Next use the difference surface of chapter 429. The comparison surface is therefore the displayed pointwise difference of X and Y, with its windows and dyadic subtraction ledger supplied by D.

Finally apply the zero-tail criterion of chapter 380. The equality read reaches E through the $\mathsf{NullSequence}^{\uparrow}$ row Z that consumes that same displayed difference.

For the reverse direction, begin with the displayed difference-null route D, Z. The row D names the pointwise difference of the two source regular names, and Z certifies that this displayed difference is null.

Read that zero-tail packet through the regular-Cauchy equivalence and real-seal boundaries of chapter 1404 and chapter 38. This produces exactly the equality-facing handoff row E in the carrier.

No additional analytic row is introduced in either direction. The route remains the finite packet $(X, Y, D, Z, E, H, C, P, N)$, so quotient streams, selected limits, host real equality, trichotomy, choice, and ambient completeness remain outside the claim. □

Theorem 1414.4 (CauchyNullEquivalence downstream equality surface)**.** *Any downstream completion or limit consumer that cites a* $\mathsf{CauchyNullEquivalence}^{\uparrow}$ *packet receives only the finite equality criterion*

$$(X, Y, D, Z, E, H, C, P, N).$$

The consumer may use the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *displayed difference, the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail row, and the equality-facing* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff, but it receives no quotient stream, selected host limit, host real equality, trichotomy, countable choice, or ambient completeness theorem.*

Proof. Project the accepted packet to the carrier of Definition 1414.1. The only equality-facing analytic data are the displayed difference row D, the null-sequence row Z, and the handoff row E.

Apply Definition 1414.2. The obligation package binds carrier admission, difference exactness, zero-tail consumption, equality handoff, componentwise transport, and ledger refusal inside the same finite packet.

Apply Definition 1414.3. It identifies the two directions of the criterion without adding an external real equality principle. Thus downstream consumers inherit one reusable finite route, not a stronger completion or quotient object. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNullEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyNullEquivalence}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, their $\mathsf{RegularCauchyDifference}^{\uparrow}$ displayed difference row, a $\mathsf{NullSequence}^{\uparrow}$ zero-tail packet for that difference, an equality-facing $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ handoff row, componentwise hsame transport, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyNullEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1414.1, Definition 1414.2, Definition 1414.3, and Definition 1414.4 state the finite criterion tying equality of regular Cauchy real names to a displayed null difference route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyNullEquivalence}^{\uparrow}}, \mathsf{axiomClean})$

Lean target: `BEDC.Derived.CauchyNullEquivalenceUp.CauchyNullEquivalenceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected host limits, host real equality, trichotomy, countable choice, or ambient real completeness.

Upgrade path: Obligation closure requires checked carrier admission, difference exactness, zero-tail consumption, equality handoff, classifier transport, and ledger refusal for the same finite packet.

Chapter 1415

A Concrete Naming Certificate for $\mathsf{BoundedRealSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BoundedRealSequence}^{\uparrow}$ packet records a bounded real sequence by finite stream-window rows, regular rational readback, a real-name seal, and a displayed closed-bounded interval net. It sits before the subsequence compactness route of chapter 1254 and exposes the boundedness surface that chapter consumes. Its dependency surface is the $\mathsf{StreamName}^{\uparrow}$ window interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the interval-net bound row of chapter 1250. The packet is a finite certificate for bounded sequence inspection; it is not open-cover compactness, trichotomy of reals, host completeness, quotient equality of streams, or a choice-selected subsequence.

Definition 1415.1 (Bounded real sequence carrier)**.** *A* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, Q, R, I, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source schedule of sequence indices under inspection.*
2. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows exposed for the inspected indices in S.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and their dyadic tolerance observations.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *sequence-name seal reached only after W and Q have been displayed.*
5. *I is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row carrying the interval net used to witness boundedness for the displayed sequence windows.*
6. *H stores componentwise* hsame *transport for the source schedule, stream windows, regular readback, real seal, interval-net bound, continuation, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from inspected indices to stream windows, from stream windows to regular readback, from regular readback to the real seal, and from the real seal to the interval-net bound assertion.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalN}$ $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *row.*

The bound row is displayed as the closed interval-net containment surface

$$I : \mathsf{ClosedBoundedIntervalNet}^{\uparrow},$$
$$\forall i \in S_{\text{shown}} \quad W_i \longmapsto Q_i \longmapsto R_i \in I.$$

Here S_{shown} denotes only the inspected finite index rows of the carrier. The classifier compares accepted packets only through $S, W, Q, R, I, H, C, P, N$ and has no coordinate for trichotomy, host real order completeness, quotient-stream equality, open-cover compactness, or a selected infinite subsequence.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceTasteGate single carrier alignment`

Theorem 1415.2 (Bounded real sequence NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier $B = (S, W, Q, R, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the nine displayed rows, finite source-window coverage through S and W, regular rational readback through Q, real-name sealing through R, closed-bounded interval-net containment through I, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.NameCertObligations.BoundedRealSequenceCarrier semantic name certificate`

Proof. Project the carrier of Definition 1415.1. The only sequence data available to the classifier are the inspected index schedule S, the corresponding $\mathsf{StreamName}^{\uparrow}$ windows W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and the downstream $\mathsf{Real}^{\uparrow}$ seal R.

Read the bound row next. The $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ packet I supplies the finite interval-net containment surface from chapter 1250; boundedness is therefore a displayed row tied to the inspected windows, not an ambient completeness or order-trichotomy principle.

Finally inspect the structural rows. The rows H, C, P, N transport, replay, source, and name only the displayed sequence-window, regular-readback, real-seal, and interval-net rows. Since no other coordinate is present in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 1415.3 (Bounded real sequence finite-window bound)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier preserves boundedness under finite window inspection: any displayed route from an inspected index to a* $\mathsf{Real}^{\uparrow}$ *sequence-name seal factors through*

$$S \longmapsto W \longmapsto Q \longmapsto R \longmapsto I$$

together with H, C, P, N. Thus a finite-window consumer can read the closed-bounded interval-net bound without importing trichotomy, host completeness, quotient-stream equality, open-cover compactness, or a selected subsequence.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceFiniteWindow bound`

Proof. Begin with an inspected index row in S. The continuation row C exposes its $\mathsf{StreamName}^{\uparrow}$ window in W, then the regular rational readback Q, and only then the $\mathsf{Real}^{\uparrow}$ seal R.

The bound row I is read after this route. It is the finite interval-net containment row supplied by chapter 1250, so the bound is attached to the displayed windows and readbacks rather than to a host-level set of all sequence values.

Transport through H and provenance through P preserve the same route, while N names it locally. Because the carrier has no coordinate for trichotomy, host completeness, quotient equality, open-cover compactness, or selected subsequences, finite-window boundedness cannot leave the displayed path. □

Theorem 1415.4 (Bounded real sequence Bolzano–Weierstrass handoff)**.** *The* BolzanoWeierstrass$^{\uparrow}$ *consumer of chapter 1254 reads a bounded sequence source from an accepted* BoundedRealSequence$^{\uparrow}$ *carrier only through the finite route*

$$S, W, Q, R, I, H, C, P, N.$$

Consequently the handoff supplies a reusable bounded real sequence certificate for the L10 real-completion route while leaving open-cover compactness, trichotomy, host completeness, quotient-stream equality, and choice-selected subsequences outside the exported surface.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceBolzanoWeierstrass handoff`

Proof. Use Definition 1415.3. It places every inspected sequence value on the route from S through W, Q, R to the interval-net bound row I.

Now read the BolzanoWeierstrass$^{\uparrow}$ carrier of chapter 1254. Its bounded sequence row is exactly the source surface needed before finite interval nets, regular Cauchy subsequence extraction, RegSeqRat readback, and the Real cluster seal can be consumed.

The structural rows H, C, P, N preserve the finite route across the handoff. Thus the downstream consumer receives a bounded real sequence certificate and receives no additional compactness, trichotomy, host completeness, quotient-stream equality, or arbitrary subsequence selection principle. □

Theorem 1415.5 (Bounded real sequence forward Bolzano route)**.** *Every* BolzanoWeierstrassRate$^{\uparrow}$ *consumer reading an accepted* BoundedRealSequence$^{\uparrow}$ *carrier must first pass through finite* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback, the* ClosedBoundedIntervalNet$^{\uparrow}$ *bound row, and the terminal* Real$^{\uparrow}$ *seal named by the source packet. Only after those rows are exposed may the consumer inspect the finite-window rate route of chapter 8827.*

Proof. Start with Definition 1415.4. It exposes the bounded source through $S, W, Q, R, I, H, C, P, N$ before any Bolzano–Weierstrass-facing consumer reads the sequence data.

The rate consumer narrows that same source route. Its finite windows are the StreamName$^{\uparrow}$ row W, its rational readback is Q, its boundedness witness is the ClosedBoundedIntervalNet$^{\uparrow}$ row I, and its terminal real-name data is the Real$^{\uparrow}$ seal row R.

Consequently the BolzanoWeierstrassRate$^{\uparrow}$ packet may inspect only the displayed finite source rows. It receives no selected subsequence, countable choice schedule, quotient stream equality, trichotomy decision, host compactness theorem, or ambient Real$^{\uparrow}$ completeness claim from the bounded-sequence source. □

Falsifiable prediction: Every BolzanoWeierstrass$^{\uparrow}$ bounded-source read factors through a BoundedRealSequence$^{\uparrow}$ route displaying finite stream windows, regular readback, a RealUp seal, and a closed-bounded interval-net row.

Independence witness: streamname, regseqrat, real, closedboundedintervalnet, bolzanoweierstrass: BoundedRealSequence$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite sequence schedule, stream windows, regular rational readback, real seals, interval-net boundedness, transport, continuation, provenance, and local naming.

Theorem 1415.6 (Bounded real sequence window envelope)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier exposes a bounded sequence to downstream consumers only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound ledger attached to those windows. In particular, any consumer that reads an inspected index must factor through the visible route*

$$S, W, Q, R, I, H, C, P, N$$

and cannot extract an infinite stream, quotient sequence equality, host supremum, open-cover compactness proof, or selected subsequence from the carrier.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceWindow envelope`

Proof. Project the carrier of Definition 1415.1. The inspected source schedule S and finite windows W are the only entry rows for sequence data, so no downstream read starts from an unbounded stream.

The bound is then read through the displayed route to I. The regular readback Q and real seal R connect each visible window to the closed-bounded interval-net row, while the dyadic ledger named by the sibling tolerance surface records the finite comparison data needed for the bound.

Rows H, C, P, N transport, replay, source, and name the same route. Since the absent rows are not part of the carrier, the envelope remains a finite-window and finite-ledger surface. □

Theorem 1415.7 (Bounded real sequence Bolzano–Weierstrass frontier)**.** *Any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$*-facing consumer that receives data from an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier receives only the bounded-window frontier*

$$S, W, Q, R, I, H, C, P, N.$$

The frontier supplies finite bounded real sequence inspection data before the Bolzano–Weierstrass route opens, but it does not provide a selected subsequence, a compactness principle, trichotomy, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceBolzano frontier`

Proof. Use the handoff route of Definition 1415.4. That theorem identifies the bounded sequence source read by the Bolzano–Weierstrass consumer with the same finite carrier rows.

The frontier is bounded because I is displayed after S, W, Q, R. Thus the consumer can inspect finite sequence windows, read them back through $\mathsf{RegSeqRat}^{\uparrow}$, and see the real-seal and interval-net bound rows before any compactness-facing construction is considered.

No selected subsequence or compactness proof is stored in those rows. The frontier therefore hands off bounded-window data only, leaving all choice, quotient, trichotomy, and completeness principles outside the exported surface. □

Theorem 1415.8 (Bounded real sequence RegSeqRat readback)**.** *For every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier, each* $\mathsf{RegSeqRat}^{\uparrow}$ *readback available to a consumer is routed through the same finite bound and real-seal rows:*

$$W \longmapsto Q \longmapsto R \longmapsto I.$$

Consequently a readback consumer cannot detach the regular rational data from the visible $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row, or the local structural rows* H, C, P, N.

Proof. Begin with an exposed window W_i for an inspected index. By the carrier definition, the matching regular rational readback is the corresponding component of Q rather than a host-level sequence object.

The readback continues to the real seal R_i and then to the interval-net bound row I. This is the same visible finite bound route used by Definition 1415.3.

The structural rows keep the readback inside the packet. Transport by H, replay by C, provenance by P, and naming by N prevent the regular rational data from escaping as a quotient stream, selected subsequence, compactness witness, or ambient real-completeness datum. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceRegSeqRat readback`

Theorem 1415.9 (Bounded real sequence located-bound handoff)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet whose interval-net row is read as located lower and upper real bounds factors through the* $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$ *route of chapter 2183 before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *consumer inspects it. The visible route is*

$$S, W, Q, R, I \longmapsto \mathsf{LocatedBoundedRealSequence}^{\uparrow} \longmapsto H, C, P, N.$$

Thus the closed-bounded interval-net row is narrowed to located lower and upper bound data before the Bolzano–Weierstrass handoff, without exporting compactness, trichotomy, quotient sequence equality, countable choice, or a selected subsequence.

Proof. Project an accepted carrier $B = (S, W, Q, R, I, H, C, P, N)$ from Definition 1415.1. The sequence source is displayed only through inspected indices S, stream windows W, regular rational readback Q, and the downstream $\mathsf{Real}^{\uparrow}$ seal R.

Use Definition 1415.3 and Definition 1415.8. They put every visible sequence value on the route from W through Q, R to the bound row I, so the lower and upper endpoint reads of I are tied to the same finite windows.

When I is read as located lower and upper real bounds, the narrower sibling route is exactly the $\mathsf{LocatedBoundedRealSequence}^{\uparrow}$ packet of chapter 2183. The structural rows H, C, P, N preserve that route before Definition 1415.4 lets any $\mathsf{BolzanoWeierstrass}^{\uparrow}$ consumer inspect the bounded source. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.LocatedBoundHandoff.BoundedRealSequenceLocatedBound handoff`

Theorem 1415.10 (Bounded real sequence located-window choice boundary)**.** *Every* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or real-completion consumer reading an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier must obtain located lower and upper bound windows through the displayed route*

$$S, W, Q, R, I.$$

No such consumer may choose a subsequence, ambient bound, quotient sequence, or host completion witness outside the carrier before the stream windows, regular readback, real seal, and interval-net bound row have been displayed.

Proof. Begin with the finite-window bound of Definition 1415.3. It places each inspected sequence value on the route from S through W, Q, R to the interval-net bound row I.

Use the RegSeqRat readback and located-bound handoff, Definition 1415.8 and Definition 1415.9. They tie the located lower and upper endpoint reads of I to the same finite stream windows and regular rational rows.

Finally apply the obligation-closure package of Definition 1415.12. The package exports only $S, W, Q, R, I, H, C, P, N$, so Bolzano–Weierstrass and real-completion consumers cannot introduce an outside subsequence choice, ambient bound, quotient sequence, or host completion witness. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceLocatedWindowChoice`

Theorem 1415.11 (Bounded real sequence location induction)**.** *Let*

$$B = (S, W, Q, R, I, H, C, P, N)$$

be an accepted $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet whose located-bound row* I*,* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *finite-net row,* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal* R *are displayed. Then every inspected finite prefix admits induction over its window positions: the empty prefix preserves the same located bound row* I*, and each successor read factors through the same route*

$$S, W, Q, R, I, H, C, P, N$$

so the new visible value remains inside the same located interval and real-seal rows. The induction exports no subsequence selection, real trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $B = (S, W, Q, R, I, H, C, P, N)$. The inspected schedule S and stream windows W are finite, so induction is over the displayed prefix positions rather than over an infinite host stream.

For the empty prefix, read only the already displayed located-bound row I. No sequence value has been inspected, and the same $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ row remains the active bound.

For the successor step, use Definition 1415.3 and Definition 1415.8. The next window read goes through W to Q, then to the $\mathsf{Real}^{\uparrow}$ seal R, and then back to the same interval-net row I.

The located-bound handoff of Definition 1415.9 keeps the lower and upper endpoint reads attached to this route. Transport, replay, provenance, and naming through H, C, P, N preserve the induction invariant, and the carrier has no coordinate for the excluded subsequence, trichotomy, quotient-equality, or completeness principles. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier location induction`

Theorem 1415.12 (Bounded real sequence obligation-closure package)**.** *For every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier, the carrier row of Definition 1415.1, the NameCert obligation surface of Definition 1415.2, the finite-window bound of Definition 1415.3, the Bolzano–Weierstrass handoff of Definition 1415.4, the window envelope of Definition 1415.6, the Bolzano frontier of Definition 1415.7, the RegSeqRat readback of Definition 1415.8, and the located-window choice boundary of Definition 1415.10 assemble the obligationClosure surface over*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont,

The assembled package exports exactly the finite bounded-sequence route $S, W, Q, R, I, H, C, P, N$ *and keeps open-cover compactness, trichotomy, host completeness, quotient stream equality, and choice-selected subsequences outside the packet.*

Proof. Start with the carrier and NameCert obligations. The carrier definition lists the finite source schedule, stream windows, regular readback, real seal, closed-bounded interval-net row, and the structural rows. The obligation theorem identifies those rows as the complete local certificate

surface over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Next use the finite-window bound and handoff theorems. They place every inspected sequence value on the displayed route from S through W, Q, R to I, and they show that the $\mathsf{BolzanoWeierstrass}^{\uparrow}$ consumer reads the bounded source only through the same packet.

Finally add the envelope, frontier, and readback rows. These theorems keep downstream reads inside the visible route $S, W, Q, R, I, H, C, P, N$ and prevent the regular rational data from detaching from the bounded-window surface. Since none of the cited rows stores open-cover compactness, trichotomy, host completeness, quotient stream equality, or a choice-selected subsequence, the assembled obligation-closure package exports none of those claims. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.NameCertObligations.BoundedRealSequenceObligation closure package`

Theorem 1415.13 (Bounded real sequence carrier admission)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier*

$$B = (S, W, Q, R, I, H, C, P, N)$$

must expose inspected sequence indices S, finite $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q,* $\mathsf{Real}^{\uparrow}$ *sequence seals R, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row I, componentwise transport H, displayed replay C, package provenance P, and the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *row N before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or real-completion consumer can read the bounded source. The admitted surface exports no open-cover compactness, trichotomy, quotient stream equality, or choice-selected subsequence.*

Proof. Project the carrier of Definition 1415.1. Its displayed tuple is exactly $S, W, Q, R, I, H, C, P, N$, so carrier admission starts with inspected indices, finite windows, regular readback, real sequence seals, the interval-net bound row, and the structural rows.

Use the NameCert obligations of Definition 1415.2. They identify those displayed rows as the complete local certificate surface and prevent a consumer from reading a bounded source before the windows, readback, seal, bound, transport, replay, provenance, and naming rows have appeared.

Apply the finite-window bound and Bolzano–Weierstrass handoff, Definition 1415.3 and Definition 1415.4. The first ties each inspected value to the $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ bound row, and the second forces every $\mathsf{BolzanoWeierstrass}^{\uparrow}$ consumer to enter through the same bounded-source route.

Finally use the obligation-closure package of Definition 1415.12. Since that package contains no open-cover compactness, trichotomy, quotient stream equality, or choice-selected subsequence coordinate, the admitted carrier exports none of those objects to a Bolzano–Weierstrass or real-completion consumer. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceObligation carrier admission`

Definition 1415.14 (Bounded real sequence finite-window net)**.** *For an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier*

$$B = (S, W, Q, R, I, H, C, P, N),$$

the finite-window net packet is the displayed subroute

$$\mathcal{N}_B = (S, W, Q, R, I, H, C, P, N)$$

read as a closed-bounded interval-net source. Its entries are the inspected sequence schedule S, the synchronized $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the* $\mathsf{Real}^{\uparrow}$ *seal row R, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row I, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *row N. The packet has no coordinate for an infinite subnet, open-cover compactness, trichotomy, quotient sequence equality, countable choice, or a selected Bolzano–Weierstrass subsequence.*

Lean4 (definition) `BEDC.Derived.BoundedRealSequenceUp.FiniteWindowNet.BoundedRealSequenceFiniteWindowNet`

Theorem 1415.15 (Bounded real sequence finite-window net extraction)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier exposes the finite-window net packet of Definition 1415.14 before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or real-completion consumer reads the bounded source. In particular, every such consumer factors through*

$$S, W, Q, R, I, H, C, P, N$$

and receives the closed-bounded interval-net route before it can inspect compactness-facing or completion-facing data.

Proof. Project the accepted carrier and form the packet $\mathcal{N}_B$ from the same rows. The carrier definition supplies $S, W, Q, R, I, H, C, P, N$ in exactly the order needed to read inspected windows, regular readback, real seals, and the interval-net bound row.

Apply Definition 1415.3. It identifies the finite bound route from S through W, Q, R to I and keeps the route outside trichotomy, host completeness, quotient equality, open-cover compactness, and selected subsequences.

Apply Definition 1415.4. The Bolzano–Weierstrass consumer reads its bounded sequence source only through the same visible rows. The structural rows H, C, P, N then repack transport, replay, provenance, and local naming as the finite-window net packet. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier finite window net extraction`

Theorem 1415.16 (Bounded real sequence regular-readback stability)**.** *Let*

$$B = (S, W, Q, R, I, H, C, P, N)$$

and

$$B' = (S', W', Q', R', I', H', C', P', N')$$

be accepted $\mathsf{BoundedRealSequence}^{\uparrow}$ *carriers. If componentwise* hsame *transport identifies the source schedules, stream windows, regular readback rows, real seals, and interval-net bound rows S, W, Q, R, I with S', W', Q', R', I', then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the closed-bounded interval-net bound row are preserved. Thus the transported packet still exposes the same finite-window net route before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or real-completion consumer reads it.*

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier regular readback stability`

Proof. Project both carriers. The hypothesis says that the five analytic rows S, W, Q, R, I and S', W', Q', R', I' agree under the componentwise transport recorded by the H rows.

Use Definition 1415.8. The readback available to a consumer is attached to the visible route $W \mapsto Q \mapsto R \mapsto I$, so transporting W, Q, R, I preserves the regular rational readback and the bound row together.

Use Definition 1415.15 to repack the transported rows as the finite-window net packet. The remaining rows H, C, P, N and H', C', P', N' supply the transport, replay, provenance, and naming data, so no detached compactness, quotient, choice, trichotomy, or completeness coordinate is introduced. □

Theorem 1415.17 (Bounded real sequence dyadic-bound transport)**.** *Let*

$$B = (S, W, Q, R, I, H, C, P, N)$$

be an accepted $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier. Every boundedness read transported from* B *to a* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *or completion-facing consumer factors through finite stream windows* S, W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal row* R*, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row* I*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BoundedRealSequence}^{\uparrow}}$ *row.*

The transported read may carry dyadic lower and upper bound ledgers from the finite window, but it cannot add trichotomy, quotient sequence equality, countable choice, a choice-selected subsequence, open-cover compactness, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier dyadic bound transport`

Proof. Project the carrier and read the finite-window net packet of Definition 1415.14. The packet lists $S, W, Q, R, I, H, C, P, N$ as the complete boundedness route.

Apply Definition 1415.16. The $\mathsf{RegSeqRat}^{\uparrow}$ readback and interval-net bound row are stable under componentwise transport, so the transported boundedness row remains attached to the same finite stream windows.

Finally use Definition 1415.15. The Bolzano–Weierstrass or completion-facing consumer receives the closed-bounded interval-net source only after S, W, Q, R, I have been displayed, and the structural rows replay the same route without adding any excluded selector or completeness coordinate. □

Theorem 1415.18 (Bounded real sequence window factorization)**.** *For every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *carrier, any consumer read of boundedness factors through a finite window prefix before it reaches the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *source. More precisely, the read first inspects the sequence schedule* S*, then the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, then the* $\mathsf{Real}^{\uparrow}$ *seal row* R*, and only then the interval-net bound row* I*.*

No consumer may bypass this route by asking for an infinite stream object, a quotient sequence equality, countable choice, a selected subsequence, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $B = (S, W, Q, R, I, H, C, P, N)$. The carrier makes the inspected schedule and finite stream windows available before any real readback or interval bound can be consumed.

Use Definition 1415.3. It identifies the bound route as a finite passage from S through W, Q, R into the closed-bounded interval-net row I.

The structural rows H, C, P, N then transport, replay, source, and name the same finite passage. Since the carrier has no infinite stream, quotient equality, choice, trichotomy, open-cover, selected-subsequence, or ambient-completeness coordinate, the displayed window factorization is exhaustive. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier window factorization`

Theorem 1415.19 (Bounded real sequence window localization)**.** *Every accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet localizes each inspected finite* $\mathsf{StreamName}^{\uparrow}$ *window through the displayed* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before any* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *consumer may read the bounded source. More precisely, for*

$$B = (S, W, Q, R, I, H, C, P, N)$$

each inspected window in W is read through

$$S, W \longmapsto Q \longmapsto R \longmapsto I \longmapsto H, C, P, N.$$

The localization exports finite window bounds and regular readback only; it exports no host set of all sequence values, no choice-selected subsequence, no quotient stream equality, no open-cover compactness, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier window localization`

Proof. Project the carrier and use the finite-window net extraction of Definition 1415.15. That result displays $S, W, Q, R, I, H, C, P, N$ as the finite net packet a consumer must read before bounded-source data are available.

Apply regular-readback stability and dyadic-bound transport, Definition 1415.16 and Definition 1415.17. They keep the $\mathsf{RegSeqRat}^{\uparrow}$ row Q attached to the same stream window W, real seal R, and closed-bounded interval-net row I under componentwise transport.

Finally use the window factorization of Definition 1415.18. It forces every boundedness read to pass through the inspected finite window before reaching the interval-net row, so a Bolzano–Weierstrass consumer receives only the displayed local route and none of the excluded host-level data. □

Theorem 1415.20 (Bounded real sequence Bolzano source exactness)**.** *Every* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *source read from an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet is exactly the finite-window source*

$$S \to W \to Q \to R \to I \to H \to C \to P \to N.$$

Thus the Bolzano–Weierstrass consumer receives a bounded source only through finite stream windows, regular rational readback, the real-name seal, and the closed-bounded interval-net row; it receives no selected subsequence, no compactness theorem outside the displayed interval-net route, and no ambient real-completeness principle.

Proof. Read the accepted carrier and form the finite-window net packet. The rows S, W, Q, R, I display the source schedule, finite stream names, regular rational readback, real seal, and closed-bounded interval-net bound before the consumer is allowed to read the source.

Apply Definition 1415.4. That handoff sends Bolzano–Weierstrass consumers to the visible bounded source rather than to a choice-selected subsequence or host compactness theorem.

Use Definition 1415.17 to keep the dyadic bound ledger attached to the same source route under transport. The rows H, C, P, N replay, source, and name the handoff, so the source exactness statement has no remaining coordinate for excluded choice, quotient, compactness, trichotomy, or completeness principles. □

Lean4 ✓ `BEDC.Derived.BoundedRealSequenceUp.BoundedRealSequenceCarrier bolzano source exactness`

Theorem 1415.21 (Bounded real sequence compact-interval subsequence boundary)**.** *Every Bolzano–Weierstrass or compact-interval consumer of an accepted* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet must read finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seals, and* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound rows before any subsequence-facing claim is visible. The packet exposes the finite route*

$$S \to W \to Q \to R \to I \to H \to C \to P \to N$$

and does not export a selected subsequence, open-cover compactness, quotient sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the finite-window bound of Definition 1415.3. It ties every inspected sequence value to the route from S through W, Q, R into the closed-bounded interval-net row I.

Apply the Bolzano–Weierstrass handoff and the window envelope, Definition 1415.4 and Definition 1415.6. They require a Bolzano-facing consumer to read the bounded source through the same finite window rows rather than through a selected subsequence or a host compactness principle.

Use Bolzano source exactness, Definition 1415.20. This identifies the visible source as the finite path through $S, W, Q, R, I, H, C, P, N$.

Finally apply finite-window net extraction, Definition 1415.15. The interval-net packet supplies the compact-interval-facing bound row while the structural rows transport, replay, source, and name the same route, leaving no coordinate for quotient equality, countable choice, open-cover compactness, selected subsequences, trichotomy, or ambient completeness. □

Theorem 1415.22 (Bounded real sequence bridge-facing route)**.** *The public bounded-source export for* BoundedRealSequence$^{\uparrow}$ *is bridge-facing exactly through the checked finite-window closure package and the Bolzano–Weierstrass source exactness route. A bridge consumer must first read Definition 1415.12 to expose the rows $S, W, Q, R, I, H, C, P, N$ and then read Definition 1415.20 before the bounded source can be handed to a standard bridge comparison. Thus the paper bridge surface is the finite-window route grounded by* BEDC.Derived.BoundedRealSequenceUp.NameCertObligations.BoundedRealSequence *not a selected subsequence, open-cover compactness proof, quotient stream equality, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Use the obligation closure package. It gathers carrier admission, finite-window bounds, regular readback, dyadic transport, window factorization, and source handoff into one checked NameCert surface.

Now apply the Bolzano source exactness theorem. It identifies the only public export as the finite route

$$S \to W \to Q \to R \to I \to H \to C \to P \to N.$$

A bridge comparison can therefore inspect exactly those displayed rows before reading the bounded source. Since neither cited route exposes selected subsequences, quotient stream equality, open-cover compactness, or ambient completeness, the bridge-facing paper surface is exhausted by the checked closure package and the Bolzano source exactness route. □

Closure status for NameCert$_{\text{BoundedRealSequence}^{\uparrow}}$**.**

Constructive story: A BoundedRealSequence$^{\uparrow}$ packet is generated from inspected sequence indices, finite StreamName windows, RegSeqRat readback, RealUp sequence-name seals, a ClosedBoundedIntervalNet bound row, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BoundedRealSequence}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1415.1, Definition 1415.2, Definition 1415.12, Definition 1415.20, and Definition 1415.22 expose the finite-window bounded-sequence source as a bridge-facing route for Bolzano–Weierstrass consumers over StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, ClosedBoundedIntervalNet$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{BoundedRealSequence}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.BoundedRealSequenceUp.NameCertObligations.BoundedRealSequenceObligation\_closure\_packa`

Bridge status: none

Not claimed: This chapter does not close bridge checking, open-cover compactness, trichotomy, host completeness, quotient equality of streams, or choice-selected subsequences.

Upgrade path: A checked standard bridge would turn the bridge-facing finite-window route of Definition 1415.22 into bridgeChecked verification.

Chapter 1416

A Concrete Naming Certificate for $\mathsf{DyadicFloor}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DyadicFloor}^{\uparrow}$ packet records an explicit dyadic lower grid point and its bounding successor as finite BEDC data. It sits over the dyadic rational arithmetic surface of chapter 291, the generic precision schedule of chapter 292, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet is the finite floor-bounding primitive used by later regular-Cauchy and Real seal arguments before any consumer may appeal to host floor, trichotomy, quotient equality, choice, or an ambient Archimedean decision procedure.

Definition 1416.1 (DyadicFloor carrier)**.** *A* $\mathsf{DyadicFloor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (x, k, d, s, \ell, u, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *x is the source real-facing request, represented only through the already displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows consumed by the packet.*
2. *k is the requested dyadic scale.*
3. *d is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid point claimed as the lower dyadic floor candidate at scale k.*
4. *s is the dyadic successor row $d + 2^{-k}$, recorded as a second* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row rather than as host integer arithmetic.*
5. *ℓ is the lower-bound evidence that the request is not below d at the displayed scale.*
6. *u is the upper-window evidence that the request is below the successor row s at the same displayed scale.*
7. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule that supplies a finite observation threshold sufficient to read the two displayed inequalities.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row exposing the regular rational window used by M.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic floor rows and regular handoff have been displayed.*
10. *H records componentwise* hsame *transport for the request, scale, lower grid point, successor row, lower and upper evidence, modulus schedule, regular handoff, real seal, continuation, provenance, and local naming rows.*

11. *C records the displayed* Cont *replay from a precision request through $k, d, s, \ell, u, M, R, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{DyadicFloor}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicFloor}^{\uparrow}}$ *row.*

The carrier has no coordinate for host floor, integer trichotomy, quotient real equality, countable choice, a selected representative, hidden Archimedean search, or ambient completeness.

Lean4 (definition) `BEDC.Derived.DyadicFloorUp.DyadicFloorUp`

Definition 1416.2 (DyadicFloor classifier)**.** *The local* $\mathsf{DyadicFloor}^{\uparrow}$ *classifier accepts exactly those carrier rows $F = (x, k, d, s, \ell, u, M, R, E, H, C, P, N)$ for which the displayed successor row s is the one-step dyadic successor of d at scale k, the lower evidence ℓ reads d as a lower bound for the request at that scale, the upper evidence u reads s as the strict upper bounding row at that scale, and the modulus schedule M supplies the finite regular-rational window through R used by both comparisons. Transport by H and replay by C preserve the same rows componentwise; they do not add a second classifier, host comparison, or detached real equality test.*

Lean4 (definition) `BEDC.Derived.DyadicFloorUp.DyadicFloorClassifier`
Lean4 ✓ `BEDC.Derived.DyadicFloorUp.DyadicFloorClassifier window obligations`

Theorem 1416.3 (DyadicFloor NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{DyadicFloor}^{\uparrow}}$ *surface for Definition 1416.1 consists exactly of carrier exposure for F, classifier exposure from Definition 1416.2, dyadic lower-grid exposure through d, dyadic successor exposure through s, lower-bound exposure through ℓ, upper-window exposure through u, modulus exposure through M, regular rational readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier tuple $F = (x, k, d, s, \ell, u, M, R, E, H, C, P, N)$. The definition lists every analytic and structural coordinate exposed to the local naming row.

The classifier reads only the successor relation between d and s, the lower evidence ℓ, the upper evidence u, and the finite observation route supplied by M and R. Thus the dyadic floor obligation is not a hidden call to a host floor operation.

The remaining rows preserve the same packet. The real seal E is downstream of the dyadic and regular rows, while H, C, P, N transport, replay, source, and name the displayed data. Since no excluded object is a coordinate of F, the listed rows exhaust the seed obligation surface. □

Lean4 ✓ `BEDC.Derived.DyadicFloorUp.DyadicFloorCarrier namecert obligations`

Theorem 1416.4 (DyadicFloor bounding interval)**.** *Every accepted* $\mathsf{DyadicFloor}^{\uparrow}$ *packet $F = (x, k, d, s, \ell, u, M, R, E, H, C, P, N)$ exposes a finite dyadic interval*

$$d \leq_k x <_k s$$

at the displayed scale k, where the left comparison is read by ℓ, the right comparison is read by u, and s is the dyadic successor row $d + 2^{-k}$. No consumer receives a host floor value, trichotomy decision, quotient equality of real names, selected representative, countable-choice row, or hidden Archimedean search.

Proof. Start from the classifier of Definition 1416.2. Its acceptance condition names s as the one-step dyadic successor of d at the requested scale k.

The same classifier binds the lower and upper comparisons. The row ℓ supplies the displayed lower-bound read for d, while u supplies the displayed strict upper-window read for the successor s.

Finally inspect the carrier surface. The only comparison rows available to a consumer are d, s, ℓ, u together with the modulus and regular readback route M, R. Hence the bounding interval is the finite packet interval above, and the excluded host operations have no route into the accepted packet. □

Lean4 ✓ `BEDC.Derived.DyadicFloorUp.DyadicFloorBoundingInterval`

Theorem 1416.5 (DyadicFloor RegSeqRat handoff)**.** *For every accepted* $\mathsf{DyadicFloor}^{\uparrow}$ *packet, the floor-bounding read factors through the finite route*

$$\mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the modulus schedule M selects the regular rational window R, the dyadic rows d, s, ℓ, u read their comparisons from that window, and the terminal seal E is available only after those rows have been displayed.

Proof. Use the carrier of Definition 1416.1. The schedule row M is the only threshold source in the packet, and the handoff row R is the only regular rational readback row.

The dyadic comparisons are then forced through the same finite readback. Both the lower row ℓ and the upper row u classify the request using d, s at scale k after M and R have supplied the observation window.

The real seal is terminal in this route. The row E is reached only after the dyadic and regular rows are displayed, and the structural rows H, C, P, N merely preserve and name the same route. Thus no detached seal, quotient equality, selected representative, or choice-driven search is available to the consumer. □

Lean4 ✓ `BEDC.Derived.DyadicFloorUp.DyadicFloorRegSeqRatHandoff`

Theorem 1416.6 (DyadicFloor finite-window obligations)**.** *Every accepted* $\mathsf{DyadicFloor}^{\uparrow}$ *packet must expose the displayed rows*

$$k, d, s, \ell, u, M, R$$

before any floor-bounding read is available. The scale k, lower dyadic row d, successor row s, lower evidence ℓ, upper evidence u, modulus schedule M, and regular readback row R are therefore finite observation obligations, not optional annotations on a later host floor value.

Proof. Read the carrier tuple of Definition 1416.1. The rows k, d, s, ℓ, u, M, R are explicit coordinates, and the classifier of Definition 1416.2 accepts a packet only when these coordinates support the successor and bounding comparisons.

The bounding interval theorem then consumes exactly those rows. The lower read uses d and ℓ, the upper read uses s and u, and both reads are routed through the finite schedule and regular-rational window supplied by M and R.

Thus a consumer cannot reach the floor-bounding interval through a hidden host operation. Omitting any listed row removes the finite observation route required by the accepted packet. □

Lean4 ✓ `BEDC.Derived.DyadicFloorUp.DyadicFloorCarrier window obligations`

Theorem 1416.7 (DyadicFloor Real-seal nonescape)**.** *In an accepted* $\mathsf{DyadicFloor}^{\uparrow}$ *packet, the terminal* E *row is reachable only after the dyadic scale row, successor row, comparison rows, modulus schedule, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed. Consequently the packet gives no route to a host floor, selected representative, trichotomy decision, quotient* $\mathsf{Real}^{\uparrow}$ *equality, or hidden Archimedean search.*

Proof. Follow the handoff route of Definition 1416.5. The modulus row M supplies the finite observation threshold, and the regular readback row R is the only source from which the dyadic comparison rows are read.

The terminal seal E comes after this readback. Since the carrier has no earlier Real-seal coordinate and no coordinate for the excluded host operations, a consumer cannot escape from the displayed dyadic and regular-rational route into a detached real comparison.

The transport, replay, provenance, and local naming rows preserve that order. They name the same finite route rather than adding a quotient Real equality, selected representative, or Archimedean search. □

Lean4 ✓ `BEDC.Derived.DyadicFloorUp.DyadicFloorCarrier real seal nonescape`

Falsifiable prediction: An accepted $\mathsf{DyadicFloor}^{\uparrow}$ consumer that reads a floor-bounding interval without the displayed scale k, lower dyadic row d, successor row s, lower evidence ℓ, upper evidence u, modulus schedule M, and regular readback row R refutes the carrier surface.

Independence witness: dyadicratcore, cauchymodulus, regseqrat, real: no listed sibling is bijective to $\mathsf{DyadicFloor}^{\uparrow}$ because this packet jointly binds a scale, lower grid point, dyadic successor, two bounding comparisons, modulus schedule, regular readback, terminal seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicFloor}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicFloor}^{\uparrow}$ packet is generated from a real-facing request, a dyadic scale, a lower dyadic grid point, its dyadic successor, lower and upper bounding evidence, a finite modulus schedule, a regular rational readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicFloor}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1416.1, Definition 1416.2, Definition 1416.3, Definition 1416.4, Definition 1416.5, Definition 1416.6, and Definition 1416.7 bind the carrier, classifier, and finite dyadic floor-bounding obligation surface for the L10 Real and Completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicFloor}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.DyadicFloorUp.DyadicFloorCarrier\_real\_seal\_nonescape`

Bridge status: none

Not claimed: This chapter does not close host floor, trichotomy, quotient real equality, countable choice, selected representatives, ambient completeness, or an Archimedean search theorem.

Upgrade path: A bridge route can connect the checked finite dyadic floor-bounding theorem to the standard acceptance schema.

Chapter 1417

A Concrete Naming Certificate for $\mathsf{DecimalExpansion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DecimalExpansion}^{\uparrow}$ packet records finite decimal-prefix windows as BEDC readback data. It does not store a host infinite decimal, a quotient real, or a selected representative. Its role is to route base-ten digit observations through the finite stream surface of chapter 126, the regular rational readback surface of chapter 301, the dyadic and rational place-value ledgers of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38.

The chapter is the decimal sibling of chapter 418 and chapter 342. The shared discipline is finite-window readback: binary prefixes, continued-fraction convergents, and decimal prefixes all expose only displayed rows before a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can read the packet.

The same finite decimal-prefix windows also form a forward consumer of chapter 1809. A decimal window gives a countable dense readback route into $\mathsf{Real}^{\uparrow}$, while $\mathsf{RealSeparability}^{\uparrow}$ supplies the global countable-density ledger that later real-name consumers use to compare those finite routes.

Definition 1417.1 (DecimalExpansion carrier)**.** *A* $\mathsf{DecimalExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, V, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite digit ledger, whose rows record decimal digits and the associated sign or integral-prefix convention when the local packet includes one;*
2. *W is the finite decimal-place window ledger, listing the inspected positions and the request precision served by those positions;*
3. *V is the place-value row that evaluates each inspected prefix as a rational sum with denominator a power of ten;*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and rational comparison row that transports the base-ten place-value read into the dyadic tolerance discipline used by downstream real consumers;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from the same decimal window and place-value rows;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after D, W, V, Q, R have been displayed;*
7. *H is the componentwise* hsame *transport row for digit, window, place-value, dyadic/rational, regular-sequence, and real-seal coordinates;*

8. *C is the* Cont *replay row that reuses the accepted finite decimal windows without adding a host stream;*
9. *P is the* Pkg *provenance over* $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}$ *row.*

The carrier exposes no infinite decimal stream, Dedekind cut, quotient real, endpoint convention resolver, trichotomy decision, selected representative, or Real-completeness witness.

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.TasteGate.DecimalExpansionTasteGate single carrier alignment`

Theorem 1417.2 (DecimalExpansion digit-window obligations)**.** *Every real-facing read of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must consume the digit ledger D, finite window ledger W, place-value row V, dyadic comparison row Q,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row E in that order. The structural rows H, C, P, N transport, replay, source, and name only this displayed route, so no decimal consumer can read a real-facing value before the finite digit window and dyadic comparison have both been displayed.*

Proof. Project the carrier of Definition 1417.1. Its public real-facing coordinates appear as D, W, V, Q, R, E before the structural rows H, C, P, N.

The finite-window discipline is the same one used by the sibling routes of chapter 418, chapter 342, and chapter 126. A consumer first receives inspected digits and positions, not an infinite stream.

Apply the NameCert obligations of Definition 1417.3. Carrier admission and ledger exhaustion force every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer to inspect only displayed rows, with V and Q between the digit window and the regular-rational handoff.

Finally read the seal row E downstream of R. Since the carrier has no coordinate for a direct decimal stream, quotient real, selected representative, or completeness witness, the ordered digit-window route is the only real-facing decimal read exported by the packet. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDigitWindowObligations`

Theorem 1417.3 (DecimalExpansion NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}$ *obligation surface consists exactly of the rows in Definition 1417.1. Carrier admission requires a finite digit ledger, a finite decimal-place window ledger, a base-ten rational place-value row, a dyadic/rational comparison row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, a* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Classifier transport is componentwise through the same displayed rows. Ledger exhaustion says that every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer can inspect only $D, W, V, Q, R, E, H, C, P, N$.*

Proof. Carrier admission is read directly from the finite packet. The digit rows and decimal-place windows give the visible $\mathsf{StreamName}^{\uparrow}$ observation surface, while V evaluates each inspected prefix as a rational place-value sum.

The dyadic/rational row Q is the only bridge from base-ten arithmetic into the tolerance discipline already used by chapter 291. The regular handoff row R and real-seal row E are therefore downstream of the same inspected window.

Transport is componentwise because H has coordinates for each displayed row, and continuation only replays windows already accepted by C. The package and local naming rows record exactly those dependencies.

For ledger exhaustion, project a consumer read from the accepted packet. The definition gives only the ten coordinates $D, W, V, Q, R, E, H, C, P, N$, so any route through an infinite stream, quotient real, selected endpoint convention, or ambient completeness principle is outside the carrier. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionNameCertObligations`

Theorem 1417.4 (DecimalExpansion tail digit stability)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet*

$$K = (D, W, V, Q, R, E, H, C, P, N),$$

finite digit tails are stable under the displayed hsame *transport row H. A consumer that transports the accepted packet can compare tail digits only through the same finite digit ledger D, window ledger W, place-value row V, dyadic comparison row Q, regular handoff R, real seal E, replay row C, provenance row P, and local name row N.*

Proof. Project the obligation surface of Definition 1417.3. The only digit data are the displayed rows D and W, and every place-value or real-facing read is downstream of them.

The transport row H is componentwise through the same carrier coordinates. Therefore a transported tail cannot acquire a new infinite decimal stream or a new endpoint selector; it can only replay the displayed finite tail rows already present in $D, W, V, Q, R, E, C, P, N$. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionTailDigitStability`

Theorem 1417.5 (DecimalExpansion rational Real handoff)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet $K = (D, W, V, Q, R, E, H, C, P, N)$, the rational place-value row V must pass through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *and rational comparison row Q, then through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E is public. No consumer can read a real-valued decimal prefix directly from D, W, V.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRatRealHandoff`

Proof. Read the carrier order in Definition 1417.1. The rows list digit data, window data, place-value evaluation, dyadic/rational comparison, regular handoff, and real seal as D, W, V, Q, R, E.

Apply Definition 1417.3. Carrier admission and classifier transport preserve this order componentwise, and ledger exhaustion prevents any route from bypassing Q or R before reaching E. □

Theorem 1417.6 (DecimalExpansion nonescape)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet $K = (D, W, V, Q, R, E, H, C, P, N)$ exports exactly the finite decimal-prefix, dyadic comparison, regular handoff, real seal, transport, replay, provenance, and naming rows listed in Definition 1417.1. It exports no infinite decimal, quotient real, endpoint selector, host trichotomy row, selected representative, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionNonescape`

Proof. Use ledger exhaustion from Definition 1417.3. The accepted packet has exactly the coordinates $D, W, V, Q, R, E, H, C, P, N$, so every public read is a projection or replay of those rows.

The excluded objects would require a coordinate outside the displayed carrier: an infinite digit stream, a quotient real, a selector for endpoints, a trichotomy decision, a selected representative, or a completeness witness. Since no such coordinate is present, no accepted consumer can recover it from the packet. □

Theorem 1417.7 (DecimalExpansion RealUp readback boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DecimalExpansion}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first reads an inspected decimal-place window, then the digit rows on that window, then the rational place-value and dyadic tolerance rows, then the regular rational handoff, and only then the displayed real seal. The packet supplies no Dedekind cut, quotient real, endpoint uniqueness convention, trichotomy principle, selected representative, or Real-completeness witness.

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealReadbackBoundary`

Proof. Start with an accepted carrier $K = (D, W, V, Q, R, E, H, C, P, N)$. The $\mathsf{StreamName}^{\uparrow}$ observation is W together with the digit rows of D on that window, so a real-facing consumer cannot read a decimal prefix without first reading the finite window.

The place-value row V turns that same finite prefix into a rational base-ten sum. The row Q records the dyadic and rational comparison data used to pass from the decimal sum to the tolerance language consumed by $\mathsf{RegSeqRat}^{\uparrow}$.

The handoff row R is therefore reached only after D, W, V, Q are fixed. The seal row E is listed after R, and the rows H, C, P, N preserve the same dependency route under transport, continuation, provenance, and local naming.

Thus every $\mathsf{Real}^{\uparrow}$ read factors through the displayed finite route. The excluded objects are not carrier coordinates, so no consumer of the packet can obtain them from this readback boundary. □

Theorem 1417.8 (DecimalExpansion RegSeqRat handoff)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet routes finite decimal digit rows through rational place-value rows and dyadic comparison rows before reaching the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route is exhausted by the displayed coordinates*

$$D, W, V, Q, R, E, H, C, P, N$$

of Definition 1417.1. In particular, the packet exports no quotient real, endpoint representative, trichotomy row, selected decimal stream, or $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRegSeqRatHandoff`

Proof. Project the carrier of Definition 1417.1. The finite digit ledger D is read together with the finite decimal-place windows W, and the place-value row V evaluates exactly those inspected prefixes as rational base-ten sums.

Apply the NameCert obligations of Definition 1417.3. Carrier admission and classifier transport keep D, W, V attached to the same dyadic and rational comparison row Q, while ledger exhaustion prevents a consumer from bypassing the displayed handoff surface.

Finally apply the RealUp readback boundary of Definition 1417.7. The regular handoff row R is reached only after the digit, window, place-value, and dyadic rows are displayed, and the terminal seal row E remains downstream of R with the structural rows H, C, P, N preserving the same route. □

Theorem 1417.9 (DecimalExpansion window normalization obligation)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must display the finite digit ledger D and finite window ledger W before any place-value, dyadic-comparison, regular-rational, or real-seal row can be read. Equivalently, every public read of V, Q, R, E factors through the finite decimal-prefix surface named in Definition 1417.1 and constrained by Definition 1417.3.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionWindowNormalizationObligation`

Proof. Project the carrier of Definition 1417.1. The rows are ordered as $D, W, V, Q, R, E, H, C, P, N$, so digit admission and inspected-window admission are the visible source rows for the packet.

Apply the NameCert obligations of Definition 1417.3. Carrier admission and ledger exhaustion require every consumer to read only displayed coordinates, hence no consumer can reach V, Q, R, E without first reading D and W.

The L10 sibling route is the same finite-window route already used by chapter 126, chapter 301, and chapter 38. Thus window normalization is a finite ledger obligation, not an infinite decimal-stream selection. □

Theorem 1417.10 (DecimalExpansion prefix stability)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, finite decimal prefixes are stable under* $\mathsf{StreamName}^{\uparrow}$ *window refinement and componentwise* hsame *transport. If a consumer refines the inspected window* W *without changing the displayed prefix rows in* D*, then the place-value row* V*, the dyadic tolerance row* Q*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *remain attached to the same prefix route before any downstream read is exposed.*

Proof. Begin with the carrier of Definition 1417.1. The digit ledger D and window ledger W are the only source rows from which a finite decimal prefix can be read.

Use the window normalization obligation of Definition 1417.9. It forces every public read of V, Q, R, E to pass through the displayed D, W prefix surface, so a window refinement that preserves the displayed prefix rows cannot change the downstream route.

The $\mathsf{StreamName}^{\uparrow}$ sibling of chapter 126 supplies the finite-window discipline, and the structural row H transports the same prefix componentwise through hsame. The dyadic and regular-rational consumers of chapter 291 and chapter 301 therefore receive the same place-value and tolerance route before the $\mathsf{Real}^{\uparrow}$ seal of chapter 38 is read. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionPrefixStability`

Theorem 1417.11 (DecimalExpansion dyadic comparison handoff)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet, the place-value row* V *reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff only through the comparison row* Q *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and rational comparison surface. No direct route from a decimal place-value sum to* R *or* E *is exported by the packet.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDyadicComparisonHandoff`

Proof. Read Definition 1417.1. The row V records the base-ten rational place-value sum, while Q is the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ and rational comparison row.

Apply Definition 1417.3. The obligation surface places Q between place-value evaluation and the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and classifier transport is componentwise through that same displayed row.

Finally apply Definition 1417.8. It states that finite digit rows pass through rational place-value rows and dyadic comparison rows before reaching R and the terminal seal E. The dyadic handoff therefore uses the existing routes of chapter 291 and chapter 301, with no bypass from V to R. □

Theorem 1417.12 (DecimalExpansion dyadic rational readback)**.** *Every finite decimal prefix admitted by an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet is read through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *before any* $\mathsf{Real}^{\uparrow}$ *seal is public. Concretely, the prefix rows* D, W *first determine the rational place-value row* V*, the dyadic and rational comparison row* Q *then supplies the finite*

tolerance comparison, and only then may the regular rational handoff R and terminal seal E be consumed.

Proof. Project the carrier of Definition 1417.1. The packet orders the rows as $D, W, V, Q, R, E, H, C, P, N$, so decimal digits and inspected windows are read before place values, dyadic tolerance, regular readback, and the real seal.

Apply prefix stability, Definition 1417.10. It keeps the finite prefix route fixed under $\mathsf{StreamName}^{\uparrow}$ window refinement and hsame transport, which is the only way a downstream consumer can compare refined windows.

Now use the dyadic comparison handoff of Definition 1417.11. The row Q is the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ and rational comparison route, so the $\mathsf{RegSeqRat}^{\uparrow}$ handoff of chapter 301 cannot be reached directly from V.

The terminal real read is the seal discipline of chapter 38, and the decimal normal-form consumer of chapter 3952 reads only after this finite dyadic and regular-rational route has been displayed. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDyadicRationalReadback`

Theorem 1417.13 (DecimalExpansion RealSeparability density route)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, the finite decimal prefix route contributes to the RealSeparability-facing density surface only through displayed countable dense readback along*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff cited by chapter 1809 reads $D, W, V, Q, R, E, H, C, P, N$ as finite prefix, dyadic comparison, regular-rational, seal, transport, replay, provenance, and naming rows. It exports no quotient real, selected endpoint convention, trichotomy row, or $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealSeparabilityDensityRoute`

Proof. Project the carrier of Definition 1417.1. The digit row D and window row W provide the only prefix data, while V, Q, R, E place that prefix into rational place value, dyadic tolerance, regular rational readback, and the terminal real seal.

Apply Definition 1417.12. The theorem forces the readback route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ before E is exposed, so the density consumer can only see a displayed finite route.

Finally read the RealSeparability sibling of chapter 1809. Its countable dense surface consumes finite readback data; the decimal packet supplies that surface through $D, W, V, Q, R, E, H, C, P, N$ and has no coordinate for quotient reals, selected endpoints, trichotomy, or real completeness. □

Theorem 1417.14 (DecimalExpansion countable dense consumer handoff)**.** *Every countable dense consumer that reads an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$ *must first pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *window W, the digit ledger D, the place-value row V, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row Q, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The consumer handoff to chapter 1809 is therefore a displayed dense readback route, not a decimal stream selector, quotient-real representative, endpoint convention, trichotomy decision, or completeness witness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionCountableDenseConsumerHandoff`

Proof. Use Definition 1417.13. It identifies the only RealSeparability-facing route exported by the packet as the finite path through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The structural rows then keep that route componentwise. Transport by H, replay by C, provenance by P, and the local name N certify the same displayed rows without inserting an ambient sequence selector or quotient-real comparison.

Thus a countable dense consumer receives exactly the finite prefix readback route already present in D, W, V, Q, R, E. Since the carrier has no selected decimal stream, endpoint convention, trichotomy, or completeness coordinate, none can be exported by the handoff. □

Theorem 1417.15 (DecimalExpansion prefix density exhaustion)**.** *For an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, all RealSeparability-facing density reads are exhausted by finite decimal prefixes and their displayed readback through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Once* $D, W, V, Q, R, E, H, C, P, N$ *have been read, the packet has no remaining row from which to choose a quotient real, select an endpoint convention, decide trichotomy, or assert a* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionPrefixDensityExhaustion`

Proof. Begin with the countable dense consumer handoff of Definition 1417.14. It routes every density consumer through the finite prefix ledger and the dyadic, regular-rational, and real-seal rows.

Apply the excluded-coordinate clause of Definition 1417.1. The packet lists only $D, W, V, Q, R, E, H, C, P, N$, so there is no extra coordinate after the terminal seal and structural rows have been consumed.

The RealSeparability reference in chapter 1809 therefore receives a countable dense readback route from finite decimal prefixes. It does not receive quotient real equality, selected endpoint data, trichotomy, or a completeness row from $\mathsf{DecimalExpansion}^{\uparrow}$. □

Theorem 1417.16 (DecimalExpansion dyadic normalization lock)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet passes through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *digit-place tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row before any real-facing decimal value is consumed. In particular, the digit-place route is the same L10 sibling lattice exposed by chapter 291, chapter 301, chapter 126, and chapter 38; the packet exports no direct decimal-to-real shortcut.*

Proof. Project the carrier of Definition 1417.1. The digit rows D and finite decimal windows W feed the place-value row V, while the comparison row Q is the only displayed dyadic and rational tolerance route.

Apply Definition 1417.11. It places Q between every place-value read and the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, so the decimal packet cannot jump from V directly to the seal row.

Finally apply Definition 1417.7. The terminal real read is reached only after finite windows, digit rows, dyadic tolerance, and regular rational readback have been displayed. This locks the decimal route to the dyadic, regular-Cauchy, stream-window, and real-seal sibling lattice named in the statement. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDyadicNormalizationLock`

Theorem 1417.17 (DecimalExpansion Real seal nonescape)**.** *The terminal row* E *of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet exports only the displayed* $\mathsf{Real}^{\uparrow}$ *seal reached from* D, W, V, Q, R*. It exports no quotient real equality, endpoint resolver, trichotomy decision, selected digit stream, selected decimal stream, countable-choice selector, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with the real readback boundary of Definition 1417.7. Every $\mathsf{Real}^{\uparrow}$ read factors through the finite route from $\mathsf{StreamName}^{\uparrow}$ windows to decimal place value, dyadic comparison, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and then the seal row E.

Use Definition 1417.12 to keep the route through Q and R. The seal is downstream of the dyadic, rational, and regular-rational rows, so it cannot introduce an endpoint resolver, trichotomy row, selected digit stream, selected decimal stream, or countable-choice selector that is not already present in the carrier.

Finally project the excluded-coordinate clause of Definition 1417.1. Since quotient reals, endpoint convention resolvers, trichotomy decisions, selected representatives, selected decimal streams, and completeness witnesses are absent from the displayed packet, none escapes through E. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealSealNonescape`

Theorem 1417.18 (DecimalExpansion Real seal factorization)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet whose terminal row is read as a* $\mathsf{Real}^{\uparrow}$ *seal factors through finite decimal windows, dyadic comparison, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the* $\mathsf{RealSeparability}^{\uparrow}$ *countable-density route. Concretely, the seal read begins with the digit and window rows D, W, evaluates those rows through the decimal place-value row V, passes through the dyadic and rational comparison row Q, reaches the regular rational row R, and only then exposes the terminal seal E. The same finite decimal windows supply the countable dense readback interface named by chapter 1809; no direct decimal stream, quotient real, selected representative, or completeness witness is exported by the seal.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealSealFactorization`

Proof. Start with the dyadic normalization lock of Definition 1417.16. It forces every real-facing decimal value to pass through the digit-place tolerance ledger, finite window row, regular rational readback row, and terminal seal.

Apply the Real seal nonescape theorem Definition 1417.17. The terminal row E cannot add a quotient real, selected decimal stream, endpoint resolver, or completeness witness after the finite route has reached it.

Finally use the countable-density role of $\mathsf{RealSeparability}^{\uparrow}$ described in the chapter introduction. The same finite decimal-prefix windows that feed D, W, V, Q, R, E are the windows counted by the RealSeparability route, so the factorization records a finite dense readback path rather than a direct decimal-to-real shortcut. □

Theorem 1417.19 (DecimalExpansion digit-carry determinacy)**.** *Let*

$$K = (D, W, V, Q, R, E, H, C, P, N) \quad \text{and} \quad K' = (D', W', V', Q', R', E', H', C', P', N')$$

be accepted $\mathsf{DecimalExpansion}^{\uparrow}$ *packets. If K and K' display the same finite digit window and the same dyadic place-value ledger before their terminal seals are read, then they expose the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route before the* $\mathsf{Real}^{\uparrow}$ *seal. Carry normalization is confined to the finite window ledger: it may rewrite the displayed digit and place-value rows inside D, W, V, Q, but it cannot introduce a second regular-rational route, a direct decimal-to-real shortcut, a quotient real, a selected representative, or an ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with window normalization, Definition 1417.9. It forces both packets to display their finite digit ledgers and finite window ledgers before V, Q, R, E can be read, so the shared window fixes the source surface for any carry operation.

Use the dyadic comparison handoff, Definition 1417.11. The shared dyadic place-value ledger places both packets on the same comparison row before either packet reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

Next apply the dyadic normalization lock, Definition 1417.16. It prevents carry normalization from bypassing the dyadic and regular-rational route; the normalized digit rows remain confined to the finite window and comparison ledgers.

Finally use Real seal factorization, Definition 1417.18. The terminal seal is downstream of D, W, V, Q, R, so equality of the displayed window and dyadic place-value ledger determines the readback route before E is exposed. Since the carrier has no quotient-real, selected-representative, direct decimal-stream, or completeness coordinate, carry normalization exports no additional route beyond the finite ledger. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDigitCarryDeterminacy`

Theorem 1417.20 (DecimalExpansion separability density obligation)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet supplies its* $\mathsf{RealSeparability}^{\uparrow}$ *density reads only through finite decimal-prefix windows. More precisely, a density-window consumer must read the digit ledger D, the decimal-place window ledger W, the place-value row V, the dyadic comparison row Q, the regular rational handoff R, the terminal real seal E, and then the structural rows H, C, P, N of Definition 1417.1; no dense route is exported from an infinite decimal stream, a quotient real, or a selected representative.*

Proof. Project the carrier of Definition 1417.1. The only rows that can feed a density read are the displayed finite prefix rows D, W, V, Q, R, E together with the structural rows H, C, P, N.

Apply the NameCert obligations of Definition 1417.3. Ledger exhaustion restricts every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumer to the same finite coordinates, so a density-window consumer cannot introduce an ambient decimal stream.

Use the Real seal factorization of Definition 1417.18. The finite decimal windows that feed the seal are exactly the windows named by the RealSeparability sibling route in chapter 1809. Thus separability density is reached by finite BEDC readback rather than by a selected decimal representative. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionSeparabilityDensityObligation`

Theorem 1417.21 (DecimalExpansion digit ledger injection)**.** *The digit ledger of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet injects into finite* $\mathsf{StreamName}^{\uparrow}$ *windows before any dyadic comparison is read. Concretely, every use of the comparison row Q must first display the same finite digit and window rows D, W and the place-value row V that determine the inspected decimal prefix.*

Proof. Read the window normalization obligation of Definition 1417.9. It forces every public read of V, Q, R, E to pass through the finite digit ledger D and window ledger W.

The $\mathsf{StreamName}^{\uparrow}$ role is therefore fixed before dyadic comparison begins. The inspected decimal prefix is a finite windowed row, not a host stream, and V evaluates only that displayed prefix as a rational place-value sum.

Apply the dyadic comparison handoff of Definition 1417.11. Since Q is the only displayed route from place value to the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, each dyadic comparison read carries the prior D, W, V injection into finite StreamName windows with it. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionDigitLedgerInjection`

Theorem 1417.22 (DecimalExpansion finite prefix completeness)**.** *Every finite-prefix consumer of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet is exhausted by the rows*

$$D, W, V, Q, R, E, H, C, P, N.$$

In particular, a consumer that requests decimal digits, finite stream windows, dyadic comparison, regular rational readback, real sealing, transport, replay, provenance, or local naming finds all available data inside those ten rows and no additional prefix-completion coordinate.

Proof. Start from the carrier definition. The packet is exactly the finite tuple $K = (D, W, V, Q, R, E, H, C, P, N)$, and the excluded-coordinate clause removes infinite streams, Dedekind cuts, quotient reals, endpoint resolvers, trichotomy decisions, selected representatives, and completeness witnesses.

Apply the NameCert obligations of Definition 1417.3. Carrier admission and classifier transport are componentwise through the same ten rows, while ledger exhaustion lets consumers inspect only those displayed coordinates.

Finally combine the Real readback boundary of Definition 1417.7 with the dyadic normalization lock of Definition 1417.16. Every real-facing finite-prefix read moves through digit windows, dyadic tolerance, regular rational readback, and the terminal seal before structural replay and naming, so $D, W, V, Q, R, E, H, C, P, N$ exhaust the prefix-completeness surface. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionFinitePrefixCompleteness`

Theorem 1417.23 (DecimalExpansion endpoint-normalization handoff)**.** *Every endpoint-sensitive decimal consumer of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must pass the rows*

$$D, W, V, Q, R, E$$

through $\mathsf{DecimalEndpointNormalization}^{\uparrow}$ *before any* $\mathsf{RealDecimalNormalForm}^{\uparrow}$ *consumer reads the normalized prefix. The handoff exports only the finite digit ledger, decimal window, place-value row, dyadic comparison, regular rational handoff, and terminal Real seal already displayed by the packet; it exports no repeating-nine endpoint convention, quotient real, selected stream, or Real completeness witness.*

Proof. Start from the finite prefix completeness theorem Definition 1417.22. It exhausts every prefix-sensitive read by $D, W, V, Q, R, E, H, C, P, N$ and leaves no additional endpoint coordinate in the $\mathsf{DecimalExpansion}^{\uparrow}$ packet.

Use the window normalization obligation Definition 1417.9. It forces each public read of place values, dyadic comparisons, regular handoffs, and Real seals to pass through the finite digit and window rows D, W.

Apply the dyadic comparison handoff of Definition 1417.11. The comparison row Q is the only displayed passage from place-value data in V toward the regular rational row R and the seal E.

The endpoint-sensitive part is therefore delegated to chapter 1429. Only after that finite endpoint-normalization surface has acted on the same D, W, V, Q, R, E route may the canonical readback surface of chapter 3952 read the normalized prefix. The excluded endpoint convention, quotient real, selected stream, and completeness witness are absent from the DecimalExpansion carrier and cannot be supplied by this handoff. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionEndpointNormalizationHandoff`

Theorem 1417.24 (DecimalExpansion endpoint Cauchy schedule)**.** *Every endpoint-sensitive Cauchy schedule consumer of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must traverse the finite digit window rows* D, W*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, endpoint normalization, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *before any real-facing decimal read is exported. The schedule exposes only finite prefix observations and their normalized endpoint route; it does not select a decimal stream, choose a repeating-nine convention, or invoke ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the endpoint-normalization handoff of Definition 1417.23. It already forces every endpoint-sensitive read through the displayed D, W, V, Q, R, E route before the normalized decimal surface is read.

Use finite prefix completeness from Definition 1417.22. The packet has no additional coordinate beyond the displayed digit, window, place-value, dyadic comparison, regular readback, Real seal, transport, replay, provenance, and naming rows.

The Cauchy schedule is therefore read through the same finite route. The dyadic comparison Q supplies the requested tolerance window, R supplies regular rational readback, endpoint normalization resolves only the displayed finite endpoint case, and E is the terminal Real seal for the real-facing read. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionEndpointCauchySchedule`

Theorem 1417.25 (DecimalExpansion finite-prefix separability route)**.** *Every finite-prefix separability consumer of an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet must read finite digit windows* D, W*, dyadic comparison* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, endpoint normalization, the* $\mathsf{RealSeparability}^{\uparrow}$ *finite-density route, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *before treating the decimal packet as a real-separating datum.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionFinitePrefixSeparabilityRoute`

Proof. Project the carrier through Definition 1417.1. A separability read receives the same finite prefix data as every other consumer: digit windows, place values, dyadic comparisons, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Apply the finite prefix completeness theorem Definition 1417.22. It prevents a separability consumer from asking for an infinite decimal stream or a selected representative outside the packet.

Now use the Real seal factorization already cited by the chapter and route density through chapter 1809. Endpoint normalization acts before this density read, so the finite decimal prefix is normalized, read back through R, and sealed by E before the $\mathsf{RealSeparability}^{\uparrow}$ surface consumes it. □

Theorem 1417.26 (DecimalExpansion real window exhaustion)**.** *For an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet, any* $\mathsf{Real}^{\uparrow}$*-facing decimal read is exhausted by finite digit windows* D, W*, dyadic comparison* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, endpoint normalization, optional* $\mathsf{RealSeparability}^{\uparrow}$ *finite-density inspection, and the terminal Real seal* E*. No real-facing consumer can bypass these rows by importing selected decimal streams, quotient-real equality, trichotomy, or Real completeness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealWindowExhaustion`

Proof. Begin with Definition 1417.7. It places every real-facing read behind the displayed decimal windows, dyadic comparison, regular rational readback, and Real seal.

Add the endpoint-normalization handoff of Definition 1417.23. Endpoint-sensitive reads do not create a second route; they use the same finite prefix rows and then pass through the finite endpoint-normalization surface.

Finally apply Definition 1417.25 when the consumer asks for density or separability data. The $\mathsf{RealSeparability}^{\uparrow}$ surface receives only the finite normalized window, regular readback, and terminal seal, so the displayed rows exhaust the real-facing decimal window. □

Theorem 1417.27 (DecimalExpansion real-window audit route)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, the finite-window exhaustion of Definition 1417.26 is an audit route through exactly*

$$D, W, Q, R, E, H, C, P, N.$$

Every $\mathsf{Real}^{\uparrow}$*-facing read that begins in digit windows or endpoint-sensitive windows must pass through the displayed dyadic comparison,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before it is accepted as a decimal real-window observation.*

Proof. Begin with Definition 1417.26. It already confines real-facing decimal reads to finite digit windows, dyadic comparison, regular rational readback, endpoint normalization, optional finite-density inspection, and the terminal Real seal.

Use Definition 1417.7 and Definition 1417.11 to name the concrete route. The read moves from D, W through Q before it reaches R and E, so no selected decimal stream or quotient-real equality can enter the audit path.

Finally append the structural rows supplied by Definition 1417.3. Componentwise transport, replay, provenance, and local naming are exactly H, C, P, N, and the carrier has no coordinate outside $D, W, V, Q, R, E, H, C, P, N$ from which another audit row could be read. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRealWindowExhaustionAuditRoute`

Theorem 1417.28 (DecimalExpansion endpoint-window transport)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet, endpoint-sensitive finite windows transport through the same endpoint-normalization handoff used by Definition 1417.23. The transported read exposes only the displayed digit ledger* D*, window ledger* W*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, and structural rows* H, C, P, N*; it does not select a decimal stream, choose a repeating-nine convention, or import a detached endpoint resolver.*

Proof. Project the packet through Definition 1417.1. Endpoint-sensitive reads have access to the same finite rows as every other decimal consumer and no additional endpoint coordinate.

Apply Definition 1417.23. Its handoff sends the endpoint-sensitive part through D, W, V, Q, R, E before a normalized real-decimal read is exported.

The transport part is supplied by Definition 1417.9 and Definition 1417.22. Window refinement is componentwise through H, replay is through C, provenance through P, and the local name through N, so the endpoint window remains inside the displayed packet instead of selecting an external stream. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionEndpointWindowTransport`

Theorem 1417.29 (DecimalExpansion RegSeqRat prefix coverage)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing decimal prefix read exported by an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet is covered by finite digit windows together with dyadic comparison. Concretely, the read starts in* D, W*, evaluates its place-value and tolerance information through* V, Q*, reaches the regular rational row* R*, and then remains governed by* E, H, C, P, N *before any downstream* $\mathsf{Real}^{\uparrow}$ *consumer may inspect it.*

Proof. Use Definition 1417.8. It places each regular-rational handoff after the finite decimal prefix and its comparison ledger, rather than after an infinite decimal stream.

Apply Definition 1417.11. The row Q is the required finite dyadic comparison between place-value data and the regular rational route, so a $\mathsf{RegSeqRat}^{\uparrow}$ consumer cannot read R directly from D, W, V.

Finally combine Definition 1417.22 with Definition 1417.27. The prefix remains covered by finite windows and dyadic comparison after the Real seal and structural rows are inspected, and no selected representative, trichotomy decision, or ambient completeness witness is exported. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRegSeqRatPrefixCoverage`

Theorem 1417.30 (DecimalExpansion prefix normalization triad)**.** *Every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *finite-window read over digit windows* D, W*, place-value row* V*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *normalizes through the triad of finite prefix coverage, dyadic comparison, and Real readback boundary. The normalized read refuses quotient reals, selected decimal streams, endpoint convention selectors, trichotomy, and Real completeness before any downstream consumer may inspect* R *or* E*.*

Proof. Start with Definition 1417.29. It already places each $\mathsf{RegSeqRat}^{\uparrow}$-facing prefix read inside finite digit windows D, W, the place-value row V, and dyadic comparison Q before R is exposed.

Next apply Definition 1417.16. This prevents a normalized prefix from being replaced by a selected stream or by an endpoint convention outside the displayed rows.

Finally use Definition 1417.7. The route reaches E only after D, W, V, Q, R have been inspected, so quotient reals, trichotomy, and ambient completeness are unavailable to the normalized prefix read. □

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionPrefixNormalizationTriad`

Theorem 1417.31 (DecimalExpansion terminal carry refusal)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet, a terminal-carry read on finite digit windows* D, W *must pass through the place-value row* V*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *as displayed packet data. It cannot discharge the carry by choosing a repeating-nine representative, selecting a decimal stream, invoking endpoint convention selectors, applying trichotomy, identifying quotient reals, or using Real completeness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionTerminalCarryRefusal`

Proof. Read the endpoint side through Definition 1417.28. Endpoint-sensitive finite windows remain attached to D, W, Q, R, E and do not export a detached endpoint resolver.

Use Definition 1417.9 together with Definition 1417.22. A carry inspection is still a finite prefix inspection, so the place-value row V and comparison row Q must remain visible before R is read.

The refusal clause follows from Definition 1417.27. The terminal Real seal E is reached only through the finite-window audit route, leaving no coordinate for a selected stream, quotient-real equality, trichotomy, endpoint convention selector, or completeness witness. □

Theorem 1417.32 (DecimalExpansion RegSeqRat density unblock)**.** *The finite decimal-window route supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *density-facing read required by later real-name consumers: digit windows* D, W *expose place-value data* V*, dyadic comparison* Q *bounds the prefix against the regular rational row* R*, and the terminal seal* E *records the Real handoff. This density-facing read is a finite BEDC route and not a quotient-real argument, selected decimal stream, endpoint selector, trichotomy decision, or Real-completeness application.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRegSeqRatDensityUnblock`

Proof. Begin with Definition 1417.8. It routes decimal prefixes to $\mathsf{RegSeqRat}^{\uparrow}$ through displayed finite windows rather than through an infinite stream representative.

Combine it with Definition 1417.29. The place-value row V and dyadic comparison row Q are the finite density evidence that lets R be consumed by a downstream real-name route.

Finally apply Definition 1417.7 and Definition 1417.27. The Real seal E is a terminal packet row after D, W, V, Q, R, so the density-facing read stays finite and refuses quotient reals, selected streams, endpoint selectors, trichotomy, and ambient completeness. □

Theorem 1417.33 (DecimalExpansion carry normalization totality)**.** *For every accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *finite digit-window packet* $K = (D, W, V, Q, R, E, H, C, P, N)$*, every carry or borrow read over the inspected decimal window has a normalized finite-window representative using only the rows* D, W, V, Q*. The normalized representative preserves the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and it introduces no selected decimal stream, endpoint convention, quotient real, trichotomy decision, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionCarryNormalizationTotality`

Proof. Induct over the finite digit window named by D, W. The empty and one-place windows normalize by reading the displayed place-value row V and leave Q, R, E unchanged.

For the extension step, replay the local carry ledger inside the next displayed digit position. The dyadic comparison row Q records the tolerance effect of the carry move, so the normalized prefix still reaches the same finite comparison surface.

Finally use Definition 1417.29 and Definition 1417.18. Since R and E are downstream of the normalized finite prefix, no extra stream selector, endpoint convention, quotient representative, trichotomy row, or completeness coordinate can appear. □

Theorem 1417.34 (DecimalExpansion signed window transport)**.** *Let* $K = (D, W, V, Q, R, E, H, C, P, N)$ *be an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet. If a signed decimal consumer attaches a displayed sign row to the same finite window and transports that signed read by the componentwise* hsame *row* H*, then the transported read preserves the digit ledger* D*, window row* W*, place-value row* V*, dyadic comparison row* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The sign transport therefore remains a finite decimal-window route and does not create a second magnitude, selected signed expansion, quotient real, trichotomy decision, or detached Real seal.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionSignedWindowTransport`

Proof. Start from the componentwise transport row H in Definition 1417.1. It transports the displayed packet rows and has no independent coordinate for a second magnitude or a selected signed expansion.

The transported signed read still exposes D, W, V, Q before it reaches R. Apply Definition 1417.9 to keep the place-value and dyadic comparison data attached to the same finite window.

The terminal seal is then controlled by Definition 1417.7. Since E is read only after the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, the signed transport cannot bypass the finite decimal route or import quotient equality, trichotomy, or a detached Real-facing value. □

Theorem 1417.35 (DecimalExpansion RegSeqRat digit replay)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{DecimalExpansion}^{\uparrow}$ *packet is replayable from the finite digit ledger. Concretely, for* $K = (D, W, V, Q, R, E, H, C, P, N)$*, the row* R *is determined for downstream consumers by replaying* D, W *through the place-value row* V *and dyadic comparison row* Q *before the terminal seal* E *is exposed. No downstream consumer can replace that replay by a quotient real, selected decimal stream, endpoint selector, trichotomy decision, or ambient completeness theorem.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionRegSeqRatDigitReplay`

Proof. Read the digit ledger through Definition 1417.21. Every comparison use of Q first displays the same finite digit and window rows D, W together with the place-value row V.

Next apply Definition 1417.29. The $\mathsf{RegSeqRat}^{\uparrow}$ row is covered by finite digit windows and dyadic comparison, so replaying D, W, V, Q reconstructs the public route to R.

Finally use Definition 1417.32. The density-facing handoff and the Real seal remain finite BEDC routes, leaving no coordinate for quotient reals, selected decimal streams, endpoint selectors, trichotomy, or ambient completeness. □

Theorem 1417.36 (DecimalExpansion public window export)**.** *Every public-facing* $\mathsf{DecimalExpansion}^{\uparrow}$ *consumer must expose the digit ledger D, decimal window row W, place-value row V, dyadic and rational comparison row Q,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport, replay, provenance, and local* NameCert *rows before reading a real-facing decimal value. The export is a finite decimal-window route and not a quotient real, selected decimal expansion, endpoint selector, trichotomy decision, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.DecimalExpansionUp.DecimalExpansionPublicWindowExport`

Proof. Start with the window obligations. Theorems 1417.2 and 1417.9 force every decimal read to display D, W, V, Q before any downstream handoff is available.

Next use the RegSeqRat route. Theorems 1417.8, 1417.29, and 1417.35 keep the handoff row R replayable from the finite digit ledger and dyadic comparison rows.

Finally apply the Real boundary and the non-escape audit. Theorems 1417.7, 1417.27, and 1417.34 leave the terminal seal E downstream of the finite route and provide no coordinate for quotient reals, selected expansions, endpoint selectors, trichotomy, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DecimalExpansion}^{\uparrow}$ packet is generated from finite decimal digit rows, decimal-place windows, rational place-value rows, dyadic/rational comparison rows, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal, displayed hsame and Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1417.1, Definition 1417.3, Definition 1417.2, Definition 1417.7, Definition 1417.8, Definition 1417.9, Definition 1417.29, Definition 1417.35, and Definition 1417.36 bind the finite decimal-window carrier, digit classifier, RegSeqRat and Real-facing readback rows, hsame transport, Cont replay, Pkg provenance, local NameCert rows, and the public decimal-window consumer export.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DecimalExpansion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, quotient reals, endpoint uniqueness, trichotomy, selected representatives, RealUp completeness, or a standard bridge.

Upgrade path: No further paper-axis closure is claimed here; bridge and Lean verification remain separate axes.

Chapter 1418

A Concrete Naming Certificate for $\mathsf{ContractionMapping}^{\uparrow}$

Following Banach's contraction principle and Bishop–Bridges constructive analysis, a $\mathsf{ContractionMapping}^{\uparrow}$ packet defines a contraction mapping as a certified self-map of a metric carrier with a displayed rational bound below one, not as a selected fixed point. The packet is the map-level interface consumed by the fixed-point route: it refines the Lipschitz carrier of chapter 410, reads its domain through chapter 57, hands finite iterate estimates to chapter 395, routes complete-metric consumers through chapter 128, and supplies the contraction row that chapter 396 uses before any endpoint seal is read.

Definition 1418.1 (ContractionMapping carrier)**.** *A* $\mathsf{ContractionMapping}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, d, T, G, \lambda, M, I, H, C, P, N)$$

with the following visible coordinates:

1. *X is the carried* $\mathsf{Met}^{\uparrow}$ *point-carrier row;*
2. *d is the metric-distance witness row used to read source and target distances inside the same carrier;*
3. *T is the self-map code row, displaying the route from a carried point history of X to another carried point history of X;*
4. *G is the graph row witnessing that each accepted application of T is a finite BEDC graph read rather than a host function application;*
5. *λ is the rational contraction-bound ledger, with displayed nonnegativity and strict unit-bound rows;*
6. *M is the induced modulus row obtained from the displayed bound ledger and the metric-distance reads;*
7. *I is the one-step* $\mathsf{PicardContraction}^{\uparrow}$ *route recording $x \mapsto T(x)$ and the contracted distance comparison for adjacent iterate reads;*
8. *H stores componentwise* hsame *transports for the metric carrier, distance row, self-map row, graph row, rational bound, induced modulus, Picard route, continuation rows, provenance row, and local naming row;*

9. *C stores the* Cont *routes for metric reads, self-map application, graph replay, bound comparison, induced-modulus readback, Picard-step replay, and consumer handoff;*
10. *P is the* Pkg *provenance row over* $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *dependency rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ContractionMapping}^{\uparrow}}$ *row.*

The carrier exposes a self-map contraction surface. It contains no coordinate for a selected fixed point, ambient completeness, quotient map equality, host function extensionality, or bridge checking.

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.ContractionMappingUp.ContractionMappingUp`

Theorem 1418.2 (ContractionMapping NameCert obligations)**.** *For an accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *carrier $K = (X, d, T, G, \lambda, M, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ContractionMapping}^{\uparrow}}$ *surface consists of carrier admission, componentwise classifier transport, self-map graph exactness, rational bound stability below one, induced modulus visibility, one-step Picard route compatibility, package provenance stability, and local naming for the finite packet of Definition 1418.1.*

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.TasteGate.ContractionMappingTasteGate single carrier alignment`

Proof. Carrier admission is exactly the displayed tuple of metric, distance, self-map, graph, bound, modulus, Picard-route, transport, continuation, provenance, and naming rows.

Classifier transport is componentwise. The hsame rows move the carrier, distance, self-map, graph, bound, modulus, Picard, provenance, and naming data, while the Cont rows replay metric reads, application, graph inspection, bound comparison, and Picard-step handoff.

Exactness and stability are field exclusions plus the displayed bound ledger. Every accepted target-distance read factors through d, T, G, and λ, and λ carries the strict unit-bound row needed by contraction consumers.

The package and local certificate rows list only the stated dependencies. Repacking these visible rows gives the local naming surface without selecting a fixed point, asserting completeness, quotienting maps, or invoking a bridge. □

Theorem 1418.3 (ContractionMapping Picard-step contraction)**.** *Every accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *carrier exposes a finite* $\mathsf{PicardContraction}^{\uparrow}$ *one-step route I. For any displayed adjacent source histories x, y in the carried metric row, the graph reads for $T(x)$ and $T(y)$ and the rational ledger λ give the finite comparison*

$$d(T(x), T(y)) \leq \lambda\, d(x, y),$$

with the strict unit-bound row of λ retained as part of the packet.

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier picard step contraction`

Proof. Read the self-map coordinate T and graph coordinate G. They provide finite application rows for $x \mapsto T(x)$ and $y \mapsto T(y)$ inside the same metric carrier X.

The distance row d reads both the source distance and the target distance. The rational ledger λ is stored with the displayed comparison row and the strict unit-bound row, so the target-distance comparison is a packet field rather than a host analytic inference.

The one-step Picard route I records exactly this application-and-comparison pattern. Since I has no infinite-orbit coordinate, the theorem exports only the adjacent-step contraction surface consumed by $\mathsf{PicardContraction}^{\uparrow}$. □

Theorem 1418.4 (ContractionMapping orbit induction spine)**.** *Let $K = (X, d, T, G, \lambda, M, I, H, C, P, N)$ be an accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *carrier and let ℓ be a finite* $\mathsf{List}^{\uparrow}$ *ledger displaying the Picard window from a base row x_0. Primitive induction over ℓ extends the one-step route I to every adjacent displayed row of the window: the base read starts at x_0, each successor read is supplied by the graph row G, and every adjacent comparison is the instance of Definition 1418.3 read through the same $X, d, T, G, \lambda, M, I, H, C, P, N$ rows. The induction exports only the finite displayed chain; it does not construct an infinite orbit, choose an endpoint, or assert completeness.*

Proof. Induct on the finite $\mathsf{List}^{\uparrow}$ ledger ℓ. In the base case, the ledger exposes only the starting row x_0, so there is no adjacent comparison to export and no endpoint or completeness row can be read.

For the successor step, assume the displayed prefix already factors every adjacent comparison through $X, d, T, G, \lambda, M, I, H, C, P, N$. The next row is admitted only by the graph row G as the application of T to the preceding displayed row.

Apply Definition 1418.3 to that adjacent pair. The comparison is therefore the same finite one-step route I, with the same metric row X, d and rational ledger λ; adjoining it to the prefix gives the next finite Picard window.

The induction variable is the ledger itself, not a sequence object outside the packet. Thus the argument closes exactly the displayed adjacent rows and refuses an infinite orbit, selected endpoint, or ambient completeness claim. □

Definition 1418.5 (ContractionMapping Cauchy orbit ledger)**.** *For an accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *carrier $K = (X, d, T, G, \lambda, M, I, H, C, P, N)$, a finite Cauchy-orbit ledger is a displayed packet*

$$O = (x_0, \ell, B, R, W)$$

where x_0 is the starting point row in X, ℓ is a finite $\mathsf{List}^{\uparrow}$ *of Picard iterates $x_0, T(x_0), \ldots, T^n(x_0)$ read through G, B is the rational bound-power row storing the inspected powers of λ, R is the dyadic tolerance row used for adjacent and tail comparisons, and W is the displayed distance-contraction route*

$$d(x_{i+1}, x_{i+2}) \le \lambda\, d(x_i, x_{i+1}) \quad \text{and} \quad d(x_i, x_j) \le B(i, j)\, d(x_0, x_1)$$

for the finite indices carried by ℓ and R. The ledger contains no selected limit point, no completed orbit, no ambient completeness row, and no host fixed-point equality.

Theorem 1418.6 (ContractionMapping Cauchy-orbit contractivity)**.** *For every accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *carrier $K = (X, d, T, G, \lambda, M, I, H, C, P, N)$ and every finite Cauchy-orbit ledger $O = (x_0, \ell, B, R, W)$ of Definition 1418.5, each adjacent iterate comparison in ℓ factors through the stored* $\mathsf{Met}^{\uparrow}$ *carrier row X, d, the graph row G, the rational bound ledger λ, and the* $\mathsf{PicardContraction}^{\uparrow}$ *route I. The dyadic tolerance row R and bound-power row B only replay those finite comparisons; they do not introduce a separate convergence theorem.*

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier cauchy orbit contractivity`

Proof. Project the contraction carrier. The metric carrier and distance row X, d are the only source of distance comparisons, and the self-map is available only through T and the graph row G.

Use Definition 1418.3 at each displayed adjacent pair in the finite list ℓ. The theorem supplies the comparison through G, λ, and the Picard route I for that pair.

The ledger rows B, R, W then record only finite replay data: bound powers, dyadic tolerances, and the displayed chain of inequalities already obtained from the adjacent-step route. Since no row of O carries a limit or an ambient completeness witness, the contractivity statement remains a finite orbit ledger. □

Theorem 1418.7 (ContractionMapping Banach handoff)**.** *Every* BanachFixedPoint$^{\uparrow}$ *consumer of an accepted* ContractionMapping$^{\uparrow}$ *carrier receives the finite Cauchy-orbit ledger of Definition 1418.5 together with a separate* CompleteMetric$^{\uparrow}$ *row. The handoff exports the displayed Picard iterates, dyadic tolerances, rational bound powers, graph reads, and finite Cauchy comparison route; it does not export a selected fixed point, a completed orbit endpoint, host fixed-point equality, quotient equality of maps, or ambient completeness from the contraction packet alone.*

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier banach handoff`

Proof. Begin with the complete-metric handoff of Definition 1418.8. It makes the metric carrier, graph-exact self-map, rational contraction ledger, induced modulus, and Picard one-step route visible, but it explicitly does not supply completeness as a contraction-packet coordinate.

Attach the finite orbit ledger O. By Definition 1418.6, every adjacent and tail comparison in O is replayed through X, d, G, λ, I and the ledger rows B, R, W.

A BanachFixedPoint$^{\uparrow}$ consumer must therefore add the separate CompleteMetric$^{\uparrow}$ row before any endpoint seal can be read. The contraction packet and orbit ledger give only finite Cauchy evidence; fixed-point selection, completed endpoints, host equality, quotient map equality, and ambient completeness remain outside the handoff. □

Theorem 1418.8 (ContractionMapping complete-metric handoff)**.** *Every* CompleteMetric$^{\uparrow}$ *or* BanachFixedPoint$^{\uparrow}$ *consumer of an accepted* ContractionMapping$^{\uparrow}$ *carrier must pass through the rows*

$$X,\ d,\ T,\ G,\ \lambda,\ M,\ I,\ H,\ C,\ P,\ N.$$

The handoff provides a metric self-map, a graph-exact contraction comparison, an induced modulus, and the one-step Picard route. It does not provide a complete carrier by itself, a Cauchy-limit endpoint, host fixed-point equality, quotient equality of maps, or bridge-checked standardization.

Proof. The carrier inventory in Definition 1418.1 lists all rows available to a consumer. A complete-metric consumer may read the metric row X, d, the self-map and graph rows T, G, the rational contraction ledger λ, and the induced modulus M.

The Picard-facing part is supplied by Definition 1418.3: it is the finite one-step route I, transported by H and replayed by C.

Completeness is not a coordinate of the contraction packet. A CompleteMetric$^{\uparrow}$ handoff therefore requires a separate complete-metric row, and a BanachFixedPoint$^{\uparrow}$ endpoint route requires the later Picard, modulus, completion, and seal rows named in its own carrier. The contraction packet contributes only the map-level surface displayed here. □

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier complete metric handoff`

Theorem 1418.9 (ContractionMapping tail-modulus readiness)**.** *For every accepted* ContractionMapping$^{\uparrow}$ *carrier* $K = (X, d, T, G, \lambda, M, I, H, C, P, N)$ *and every finite Cauchy-orbit ledger* $O = (x_0, \ell, B, R, W)$*, the finite orbit ledger together with the rational contraction bound yields a displayed tail-modulus row for Picard iterates through* Met$^{\uparrow}$*,* LipschitzMap$^{\uparrow}$*,* PicardContraction$^{\uparrow}$*, and* CompleteMetric$^{\uparrow}$*. The row is read from the metric carrier and distance surface* X, d*, the graph-exact self-map* T, G*, the strict unit-bound ledger* λ*, the induced modulus* M*, the Picard route* I*, and the finite replay rows* B, R, W*; it does not select a limit point.*

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier tail modulus readiness`

Proof. Project the carrier of Definition 1418.1. The metric and distance rows X, d provide the only distance reads, while T, G provide graph-exact applications of the self-map.

Use Definition 1418.3 for adjacent Picard comparisons and Definition 1418.6 for their finite replay through the orbit ledger. The rational bound ledger λ and induced modulus row M are therefore visible before any tail claim is made.

The Banach and complete-metric handoffs, Definition 1418.7 and Definition 1418.8, identify the consumer route. They require a separate $\mathsf{CompleteMetric}^{\uparrow}$ row and preserve the same finite $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, and $\mathsf{PicardContraction}^{\uparrow}$ reads, so the exported tail-modulus row is readiness data rather than a selected endpoint. □

Definition 1418.10 (ContractionMapping regular-Cauchy modulus surface)**.** *For an accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *carrier* $K = (X, d, T, G, \lambda, M, I, H, C, P, N)$ *and a finite Cauchy-orbit ledger* $O = (x_0, \ell, B, R, W)$*, the regular-Cauchy modulus surface is the displayed packet*

$$\Theta = (X, d, T, G, \lambda, M, I, O, Q, H, C, P, N)$$

where Q *records the finite tail-bound thresholds extracted from* B, R, W *and presents them to a* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer. The surface is a route from contraction data to regular-Cauchy completion evidence. It is not a fixed-point selector, not a completed endpoint, not quotient equality of Picard streams, and not ambient completeness.*

Lean4 (definition) `BEDC.Derived.ContractionMappingUp.ContractionMappingRegularCauchyModulusSurface`

Theorem 1418.11 (ContractionMapping tail-bound extraction)**.** *For every accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *carrier* K *and finite Cauchy-orbit ledger* O*, the tail-modulus readiness row of Definition 1418.9 determines a finite extraction row* Q *whose entries are read only from the Picard-step contraction route, the Cauchy-orbit contractivity ledger, the rational bound powers, and the dyadic tail tolerance rows. No extraction step reads a selected fixed point or a completed limit.*

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier tail bound extraction`

Proof. Project the carrier and the orbit ledger. The only contraction comparison is the Picard-step route of Definition 1418.3, and the only iterated replay is the Cauchy-orbit contractivity statement of Definition 1418.6.

The finite bound-power row B and tolerance row R provide the threshold entries used by Q. The readiness theorem then identifies those entries as the tail-modulus row visible to completion consumers.

Because the complete-metric handoff is still separate, the extraction has no coordinate for an endpoint, selected fixed point, host fixed-point equality, quotient stream equality, or ambient completeness. □

Theorem 1418.12 (ContractionMapping regular-Cauchy modulus export)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing completion consumer of a* $\mathsf{ContractionMapping}^{\uparrow}$ *packet may read the surface of Definition 1418.10 only through the finite route*

$$X, d, T, G, \lambda, M, I, O, Q, H, C, P, N.$$

The route exports a regular-Cauchy modulus for the Picard orbit by combining the stored contraction comparison, finite orbit ledger, tail-bound extraction row, and replay data; it does not export a selected fixed point.

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier regular cauchy modulus export`

Proof. Begin with the tail-bound extraction theorem. It supplies Q from the already displayed contraction route and finite orbit ledger.

Next use Definition 1418.10. The surface appends Q to the carrier and orbit rows, so a regular-Cauchy consumer sees exactly the metric, self-map, graph, bound, Picard, orbit, threshold, transport, replay, provenance, and local naming rows.

The Banach handoff remains downstream. Thus the exported data is a modulus surface for a regular-Cauchy Picard name, not a fixed-point endpoint, completed orbit, quotient equality, host function equality, or completeness assertion. □

Theorem 1418.13 (ContractionMapping complete-metric regular-Cauchy handoff)**.** *Every* CompleteMetric$^{\uparrow}$ *or* BanachFixedPoint$^{\uparrow}$ *consumer that uses a* ContractionMapping$^{\uparrow}$ *carrier for completion evidence must first read the regular-Cauchy modulus export of Definition 1418.12 and then supply its separate complete-metric row. The contraction packet contributes only the finite RegSeqRat-facing modulus route for the Picard orbit.*

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier complete metric regular cauchy handoff`

Proof. Apply Definition 1418.8. It keeps completeness outside the contraction packet while exposing the metric self-map, contraction comparison, induced modulus, and Picard route.

Apply Definition 1418.12. It repacks the finite orbit ledger and extracted tail-bound row as the RegSeqRat-facing modulus surface needed by a completion consumer.

Only after those rows are displayed can a CompleteMetric$^{\uparrow}$ or BanachFixedPoint$^{\uparrow}$ packet use its own endpoint discipline. The contraction packet itself therefore exports regular-Cauchy completion evidence, not endpoint selection, host fixed-point equality, quotient map equality, or ambient completeness. □

Theorem 1418.14 (ContractionMapping fixed-point readiness)**.** *Every* BanachFixedPoint$^{\uparrow}$ *consumer may read an accepted* ContractionMapping$^{\uparrow}$ *packet only after the complete-metric row of Definition 1418.8 and the finite tail-modulus route of Definition 1418.9 have both been displayed. This readiness condition exposes the contraction packet, Picard iterates, finite Cauchy ledger, rational bound powers, and complete-metric handoff, but it does not select a fixed point, a completed orbit endpoint, or a host equality proof.*

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier fixed point readiness`

Proof. Start with a BanachFixedPoint$^{\uparrow}$ consumer. By Definition 1418.7, it receives the finite Cauchy-orbit ledger and a separate CompleteMetric$^{\uparrow}$ row rather than an endpoint from the contraction packet alone.

The complete-metric handoff of Definition 1418.8 makes the metric self-map, graph-exact contraction comparison, induced modulus, and one-step Picard route visible. The tail-modulus readiness theorem then packages the finite Picard comparisons into the displayed tail route required by the consumer.

Only after both rows are displayed may the consumer proceed to its own fixed-point seal. Because neither row contains a selected point, completed orbit endpoint, host fixed-point equality, quotient map equality, or ambient completeness coordinate, the readiness statement remains a finite obligation boundary. □

Theorem 1418.15 (ContractionMapping orbit uniqueness window)**.** *Let $K = (X, d, T, G, \lambda, M, I, H, C, P, N)$ be an accepted* ContractionMapping$^{\uparrow}$ *carrier, and let*

$$O = (x_0, \ell, B, R, W) \quad \text{and} \quad O' = (x_0', \ell', B', R', W')$$

be finite Cauchy-orbit ledgers for the same packet. If x_0 and x_0' are classifier-stable as the same starting row and both ledgers replay the same graph-exact self-map row T, G, then every common finite window of ℓ and ℓ' is classifier-stable through the stored Met$^{\uparrow}$*,* LipschitzMap$^{\uparrow}$*, and* PicardContraction$^{\uparrow}$ *rows. The comparison uses only $X, d, G, \lambda, M, I, H, C$ and the finite ledger rows; it does not assert an infinite orbit or a selected endpoint.*

Proof. Project the two orbit ledgers and the accepted contraction carrier. The hypotheses identify the starting rows through the local classifier and require both lists to replay the same self-map graph row G.

Induct over the common finite window. The base row is the shared start. At the successor step, graph exactness for T, G gives the next iterate in both ledgers, while the Met$^{\uparrow}$ distance row d and the LipschitzMap$^{\uparrow}$ contraction ledger λ keep the comparison inside the same metric carrier.

The PicardContraction$^{\uparrow}$ route I is the stored one-step replay for each adjacent pair. Transport by H and continuation by C preserve those rows componentwise, so the two finite windows remain classifier-stable without producing any completed orbit or fixed-point endpoint. □

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier orbit uniqueness window`

Theorem 1418.16 (ContractionMapping Picard regular-Cauchy uniqueness)**.** *Let $K = (X, d, T, G, \lambda, M, I, H, C, P$ be an accepted* ContractionMapping$^{\uparrow}$ *carrier, and let $O = (x_0, \ell, B, R, W)$ and $O' = (x_0', \ell', B', R', W')$ be accepted Picard orbit ledgers for the same contraction packet. If the two ledgers share the same displayed initial row and the same rational bound ledger, then the* RegSeqRat$^{\uparrow}$ *handoff rows exported from O and O' are classifier-equivalent before any* CompleteMetric$^{\uparrow}$ *endpoint row or* BanachFixedPoint$^{\uparrow}$ *seal is read.*

Proof. The shared displayed initial row and rational bound ledger put the two ledgers inside the orbit uniqueness window of Definition 1418.15. Hence every common finite Picard window is classifier-stable through the stored metric, graph-exact self-map, contraction, and replay rows.

Use Definition 1418.9 to expose the same finite tail-modulus route for those windows. Then apply Definition 1418.12; the exported RegSeqRat$^{\uparrow}$ surface reads only the Picard route, finite orbit rows, tail-bound extraction, transport, replay, provenance, and local naming rows.

Finally, Definition 1418.13 identifies the downstream boundary: a complete-metric consumer supplies its own endpoint discipline only after this regular-Cauchy route has been displayed. Therefore the two Picard ledgers determine classifier-equivalent RegSeqRat$^{\uparrow}$ handoff rows without selecting a completed endpoint or invoking a BanachFixedPoint$^{\uparrow}$ seal. □

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier picard regular cauchy uniqueness`

Theorem 1418.17 (ContractionMapping fixed-point tail seal)**.** *Before a* BanachFixedPoint$^{\uparrow}$ *consumer supplies the separate* CompleteMetric$^{\uparrow}$ *row, the only endpoint-facing seal exported by an accepted* ContractionMapping$^{\uparrow}$ *packet is the finite tail-modulus route of Definition 1418.9. Thus every fixed-point-facing request must pass through the graph-exact self-map T, G, rational bound ledger λ, induced modulus M, Picard route I, finite orbit ledger O, and complete-metric handoff boundary; the contraction packet alone cannot select a fixed point or certify a completed endpoint.*

Proof. Begin with fixed-point readiness in Definition 1418.14. It requires both the complete-metric handoff and the finite tail-modulus route before a Banach consumer may proceed.

Use the tail-modulus readiness theorem. The route it exports is read from $X, d, T, G, \lambda, M, I$ and the finite ledger rows B, R, W, so it is endpoint-facing only as a tail seal over finite Picard data.

The complete-metric row is deliberately outside the contraction packet. Consequently no row of K can supply a selected fixed point, completed orbit endpoint, host fixed-point equality, quotient map equality, or ambient completeness proof before the downstream Banach chapter consumes its own complete-metric data. □

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier fixed point tail seal`

Theorem 1418.18 (ContractionMapping complete-metric consumer package)**.** *For every accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *carrier* $K = (X, d, T, G, \lambda, M, I, H, C, P, N)$ *and finite Cauchy-orbit ledger* $O = (x_0, \ell, B, R, W)$*, the local NameCert obligation surface needed by downstream Banach, Picard, complete-metric, and Lipschitz consumers is the package consisting of the complete-metric handoff of Definition 1418.8, the tail-modulus readiness route of Definition 1418.9, the fixed-point readiness boundary of Definition 1418.14, and the orbit uniqueness window of Definition 1418.15. This package remains finite and* BHist*-anchored and does not claim a selected fixed point.*

Proof. Read the complete-metric handoff first. It exposes the metric carrier, graph-exact self-map, rational contraction ledger, induced modulus, and Picard one-step route while leaving the actual complete-metric row to the consumer.

Next attach the finite orbit data. Tail-modulus readiness supplies the tail route through the ledger rows, and the orbit uniqueness window makes matching finite Picard windows stable under the same classifier and graph replay.

Finally use fixed-point readiness to delimit the downstream obligation. The package now contains exactly the finite rows that Banach, Picard, complete-metric, and Lipschitz consumers need to read before their own endpoint arguments begin, with no coordinate for endpoint selection, completed orbit equality, or host fixed-point proof. □

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier complete metric consumer package`

Definition 1418.19 (ContractionMapping scoped source stack)**.** *The scoped source stack for a* $\mathsf{ContractionMapping}^{\uparrow}$ *read is the finite packet*

$$\mathcal{S}_{\mathsf{ContractionMapping}^{\uparrow}} = (\mathsf{Met}^{\uparrow}, \mathsf{LipschitzMap}^{\uparrow}, \mathsf{PicardContraction}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pk}$$

It is read through the carrier rows $X, d, T, G, \lambda, M, I, H, C, P, N$ *and the orbit and modulus rows* O, Q *displayed in this chapter. The stack records source metric data, Lipschitz and contraction graph data, Picard-step replay, completion-facing modulus handoff, regular-rational tail thresholds, history transport, continuation replay, provenance, and local naming; it contains no fixed-point selector or completed endpoint.*

Theorem 1418.20 (ContractionMapping scoped dependency surface)**.** *Every accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *read factors through the scoped source stack of Definition 1418.19. In particular, any Picard, Banach, complete-metric, or regular-Cauchy consumer can inspect only the displayed* $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows before it uses its own downstream endpoint discipline.*

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier scoped dependency surface`

Proof. Project the carrier and the finite orbit rows. The carrier supplies the metric, graph, contraction bound, induced modulus, Picard route, transport, replay, provenance, and naming coordinates, while the orbit and threshold rows supply only finite Picard tail data.

Apply the complete-metric and Banach handoffs. They expose a separate $\mathsf{CompleteMetric}^{\uparrow}$ row for completion-facing consumers and keep endpoint selection outside the contraction packet.

Apply the regular-Cauchy export and complete-metric regular-Cauchy handoff. They place the tail thresholds in the $\mathsf{RegSeqRat}^{\uparrow}$-facing part of the stack, transported by the same hsame and Cont rows.

No other coordinate is available in the carrier or in the orbit surface. Therefore every accepted read factors through the displayed scoped stack and cannot import host fixed-point equality, quotient map equality, or completed endpoints. □

Theorem 1418.21 (ContractionMapping completion readiness scope)**.** *The completion-facing readiness route for a* $\mathsf{ContractionMapping}^{\uparrow}$ *packet still requires a separate* $\mathsf{CompleteMetric}^{\uparrow}$ *row. The contraction packet exports only finite Picard tail-modulus data through* $\mathsf{PicardContraction}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, together with the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *evidence of the scoped source stack.*

Proof. Start with the fixed-point readiness theorem. It already requires both the complete-metric handoff and the finite tail-modulus route before a $\mathsf{BanachFixedPoint}^{\uparrow}$ consumer may proceed.

Use the scoped dependency surface. The visible source stack includes $\mathsf{CompleteMetric}^{\uparrow}$ only as a separate consumer row and includes $\mathsf{RegSeqRat}^{\uparrow}$ only for the finite threshold and tail-modulus surface.

Thus the contraction packet contributes readiness data, not a completion theorem. Since no row names a limit point, selected fixed point, quotient map equality, or ambient completeness proof, the route remains a completion-facing boundary rather than a fixed-point construction. □

Lean4 ✓ `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier completion readiness scope`

Theorem 1418.22 (ContractionMapping public export)**.** *Every accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *packet exports the public* $\mathsf{NameCert}_{\mathsf{ContractionMapping}^{\uparrow}}$ *surface obtained by packaging the scoped dependency surface, the complete-metric handoff, fixed-point readiness, orbit uniqueness, and completion readiness scope displayed in this chapter. The public export contains the carrier rows, Picard-step contraction data, finite orbit ledger, tail-modulus route, complete-metric consumer row, scoped source stack, and structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; it still excludes selected fixed points, ambient completeness, quotient map equality, host function extensionality, and completed endpoint seals.*

Proof. First read the scoped dependency surface. It already factors every accepted contraction read through the finite source stack containing $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Next attach the downstream readiness rows. The complete-metric handoff and complete-metric consumer package expose the completion-facing boundary, while fixed-point readiness and orbit uniqueness keep the Picard tail data finite and local to the displayed orbit ledger.

Finally use the completion readiness scope. It states that the contraction packet contributes readiness data rather than a completion theorem or endpoint construction. Packaging these rows as the public $\mathsf{NameCert}_{\mathsf{ContractionMapping}^{\uparrow}}$ export therefore gives consumers a public surface without adding selected fixed points, ambient completeness, quotient equality, host extensionality, or completed endpoint seals. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContractionMapping}^{\uparrow}}$.

Constructive story: A $\mathsf{ContractionMapping}^{\uparrow}$ packet is generated from a $\mathsf{Met}^{\uparrow}$ carrier row, a metric-distance row, a self-map row, a graph row, a rational contraction-bound ledger below one, an induced modulus row, a one-step $\mathsf{PicardContraction}^{\uparrow}$ route, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContractionMapping}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1418.1, Definition 1418.2, Definition 1418.3, Definition 1418.5, Definition 1418.6, Definition 1418.7, Definition 1418.8, Definition 1418.9, Definition 1418.10, Definition 1418.11, Definition 1418.12, Definition 1418.13, Definition 1418.14, Definition 1418.15, Definition 1418.16, Definition 1418.17, Definition 1418.18, Definition 1418.19, Definition 1418.20, Definition 1418.21, and Definition 1418.22 bind the carrier, Picard-step contraction, finite orbit ledger, Banach handoff, complete-metric handoff, finite tail-modulus readiness, regular-Cauchy modulus surface, fixed-point readiness, orbit-window uniqueness, Picard regular-Cauchy uniqueness, endpoint-facing tail seal, complete-metric consumer package, scoped source stack, scoped dependency surface, completion readiness scope, and public export through the checked completion-readiness route for the constructive self-map contraction packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContractionMapping}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.ContractionMappingUp.ContractionMappingCarrier\_completion\_readiness\_scope`

Bridge status: none

Origin: human

Not claimed: This chapter does not claim host fixed-point selection, ambient completeness, quotient map equality, bridge checking, host function extensionality, or a completed endpoint seal.

Upgrade path: Only a standard bridge certificate for the same checked completion-readiness route remains for the formal bridge axis.

Chapter 1419

A Concrete Naming Certificate for $\mathsf{ArchimedeanOrderedField}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ packet records a traditional ordered-field comparison certificate over displayed constructive real names. It sits between the algebra/order surface of chapter 766, the rational-bound route of chapter 430, the real-name seal of chapter 38, and the rational source rows of chapter 37. The packet is a comparison carrier for downstream L10 and real-algebra consumers, not an ambient ordered field object.

Definition 1419.1 (ArchimedeanOrderedField carrier)**.** *An* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, A, Q, O, B, H, C, P, N)$$

with the following displayed coordinates:

1. *R is the family of* $\mathsf{Real}^{\uparrow}$ *endpoint rows whose algebra and order reads are being compared;*
2. *A is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *row that supplies displayed addition, negation, multiplication, absolute-value, nonnegative-order, and apartness evidence for those endpoints;*
3. *Q is the finite* $\mathsf{Rat}^{\uparrow}$ *source family used by constant-rational witnesses and Archimedean comparison bounds;*
4. *O is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *rational-bound row attached to the displayed real endpoints;*
5. *B is the local comparison ledger recording the field-operation, order, rational-embedding, and Archimedean-bound reads that the packet exports;*
6. *H stores componentwise* hsame *transports for the real endpoints, algebra/order rows, rational source rows, Archimedean bound rows, and local ledger rows;*
7. *C stores the* Cont *routes that expose the displayed operation, order, rational-bound, and rational-embedding rows to downstream consumers;*
8. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanOrderedField}^{\uparrow}}$ *row.*

The classifier compares two accepted packets only by replaying these finite coordinates. It has no coordinate for real trichotomy, quotient real equality, a host ordered-field carrier, a quotient-reals construction, a selected least bound, or a standard bridge theorem.

Lean4 (definition) `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldCarrier`

Theorem 1419.2 (ArchimedeanOrderedField NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ArchimedeanOrderedField}^{\uparrow}}$ *surface for the carrier of Definition 1419.1 consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed packet* $F = (R, A, Q, O, B, H, C, P, N)$ *with real endpoint, algebra/order, rational source, Archimedean bound, comparison ledger, transport, continuation, provenance, and local naming coordinates;*
2. *classifier transport: classification transports every displayed* $\mathsf{Real}^{\uparrow}$ *endpoint,* $\mathsf{RealAlgOrder}^{\uparrow}$ *operation or order row,* $\mathsf{Rat}^{\uparrow}$ *source row,* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound row, and local ledger row componentwise through the stored* hsame *and* Cont *routes;*
3. *field-row stability: addition, negation, multiplication, unit, zero, and absolute-value reads remain inside the* $\mathsf{RealAlgOrder}^{\uparrow}$ *coordinate* A *after endpoint replacement by classified* $\mathsf{Real}^{\uparrow}$ *rows;*
4. *Archimedean comparison stability: every rational-bound or rational-embedding comparison exposed by* O *and* Q *remains tied to the same displayed real endpoints and the same local ledger rows after transport;*
5. *ledger exactness: every downstream ordered-field or Archimedean read is one of the displayed rows* $R, A, Q, O, B, H, C, P, N$ *before any consumer receives it.*

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldNameCertObligations`

Proof. Carrier admission is projection from Definition 1419.1. The real endpoint family, algebra/order row, rational source family, Archimedean bound row, local comparison ledger, transport table, continuation table, provenance row, and local naming row are exactly the listed coordinates.

Classifier transport is componentwise. The $\mathsf{Real}^{\uparrow}$ endpoints move with their $\mathsf{RealAlgOrder}^{\uparrow}$ operation and order rows, while the rational source rows and Archimedean bound rows move through their own displayed sibling classifiers and the stored hsame routes.

The field-row and Archimedean stability clauses then repack the transported rows into the same ledger shape B. Algebraic reads use only A and the endpoint rows in R; rational-bound reads use only Q, O and the endpoint rows in R.

Ledger exactness follows because every public read is a coordinate of F or a row of B generated from those coordinates. Since no coordinate stores trichotomy, quotient real equality, a host ordered-field carrier, quotient reals, selected least bounds, or bridge-checked data, none of those principles is exported by the local certificate. □

Theorem 1419.3 (ArchimedeanOrderedField RealAlgOrder handoff)**.** *Every ordered-field or Archimedean comparison read exported by an accepted* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *packet factors through the* $\mathsf{RealAlgOrder}^{\uparrow}$ *row* A *and the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *row* O *over the displayed* $\mathsf{Real}^{\uparrow}$ *endpoints* R*. The* $\mathsf{RealAlgOrder}^{\uparrow}$ *side supplies the finite operation and order rows, the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *side supplies explicit rational-bound rows, and the* $\mathsf{Rat}^{\uparrow}$ *coordinate* Q *supplies the rational source data used by both comparison routes.*

Consequently the packet is a handoff between the existing real algebra/order and Archimedean-bound surfaces. It does not identify those surfaces with a host ordered field, quotient-reals carrier, complete real field, trichotomy principle, selected least-bound operation, or bridge-checked standard structure.

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldRealAlgOrderHandoff`

Proof. Project the carrier tuple $F = (R, A, Q, O, B, H, C, P, N)$. The only operation and order coordinate is A, and the only Archimedean-bound coordinate is O.

Read the algebra/order route first. By Definition 766.2, the rows exposed by A are finite endpoint, operation, order, apartness, transport, continuation, provenance, and local naming rows over displayed $\mathsf{Real}^{\uparrow}$ data.

Read the Archimedean route next. By Definition 430.2, the rows exposed by O are finite rational-bound, dyadic-bound, stream-window, regular-Cauchy handoff, ledger, transport, continuation, provenance, and local naming rows for displayed $\mathsf{Real}^{\uparrow}$ data.

The rational source coordinate Q is shared by the two routes. The local ledger B records only those field-operation, order, rational-embedding, and rational-bound reads, and the transports H, C replay them componentwise for consumers.

Thus every exported comparison factors through A, O, and Q over R. The excluded host ordered-field, quotient-reals, trichotomy, completeness, least-bound, and bridge-checked objects have no carrier coordinate and no route through the local ledger. □

Theorem 1419.4 (ArchimedeanOrderedField rational-bound window)**.** *Every Archimedean comparison read exported by an accepted* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *packet must expose the* $\mathsf{Rat}^{\uparrow}$ *source row* Q*, the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound row* O*, and the displayed* $\mathsf{Real}^{\uparrow}$ *endpoints* R *before any ordered-field consumer reads the local comparison ledger* B*. The rational-bound window is therefore the finite route*

$$Q, O, R \longmapsto B.$$

It is not a route through trichotomy, quotient real equality, selected least bounds, a host ordered-field carrier, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldRationalBoundWindow`

Proof. Project the carrier $F = (R, A, Q, O, B, H, C, P, N)$. The rational source row Q, Archimedean bound row O, endpoint family R, and comparison ledger B are displayed coordinates of the same finite packet.

Apply the NameCert obligations of Definition 1419.2. Classifier transport keeps the rational source, bound, endpoint, and ledger rows componentwise aligned, while Archimedean comparison stability ties every rational-bound read to Q, O over the same endpoints R.

Finally use the RealAlgOrder handoff of Definition 1419.3. Ordered-field reads may consume B only after the displayed algebra/order route and the rational-bound route have been replayed, and the carrier has no coordinate for the excluded trichotomy, quotient, least-bound, host-field, or completeness data. □

Theorem 1419.5 (ArchimedeanOrderedField comparison ledger exactness)**.** *For an accepted* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *packet with carrier*

$$F = (R, A, Q, O, B, H, C, P, N),$$

every ordered-field, Archimedean comparison, or rational-embedding consumer of the local comparison ledger B *reads* B *only through the displayed route* R, A, Q, O, H, C, P, N*. Here* A *is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *row,* O *is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *row,* Q *is the* $\mathsf{Rat}^{\uparrow}$ *source row, and* R *is the* $\mathsf{Real}^{\uparrow}$ *endpoint family.*

Thus the ledger is an exhaustive consumer interface for those comparison reads, not a channel for trichotomy, quotient reals, selected least bounds, host ordered-field carriers, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier definition of Definition 1419.1. The only coordinates adjacent to the ledger are the endpoint family R, the algebra/order row A, the rational source row Q, the Archimedean bound row O, the transport table H, the continuation routes C, the provenance row P, and the local naming row N.

Apply the NameCert obligations of Definition 1419.2. Carrier admission and classifier transport force every consumer-visible ledger row to be one of the displayed rows of F.

Field-row stability and Archimedean comparison stability keep ordered-field, rational-embedding, and rational-bound reads attached to the same R, A, Q, O coordinates.

The handoff theorem Definition 1419.3 identifies the ordered-field side with A over R and the Archimedean side with O and Q over the same endpoints. The rational-bound window of Definition 1419.4 then forces any Archimedean comparison read to pass through Q, O, R before it reaches B.

It follows that a downstream ordered-field, Archimedean comparison, or rational-embedding consumer has no remaining entry point into B except the route R, A, Q, O, H, C, P, N. Since the carrier and the cited obligations store no trichotomy, quotient-reals construction, selected least-bound operation, host ordered-field carrier, or ambient real-completeness coordinate, the ledger cannot export any of those structures. □

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldComparisonLedgerExactness`

Theorem 1419.6 (ArchimedeanOrderedField root obligation package)**.** *The carrier of Definition 1419.1, the NameCert obligations of Definition 1419.2, and the RealAlgOrder handoff of Definition 1419.3 assemble the root package consumed by* $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{RealAlgOrder}^{\uparrow}$. *The package consists of displayed ordered-field carrier rows, rational-bound rows, terminal* $\mathsf{Real}^{\uparrow}$ *seal rows, comparison transport, displayed replay, provenance, and the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanOrdere}}$ *row.*

The package exports only those rows. It does not supply trichotomy, quotient equality of real names, selected rational bounds, a selected least-bound operation, a host ordered-field carrier, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldRootObligationPackage`

Proof. Project the packet $F = (R, A, Q, O, B, H, C, P, N)$ from Definition 1419.1. The rows R, A, Q, O, B are respectively the real endpoint source, ordered algebra row, rational source family, Archimedean rational-bound row, and local comparison ledger; the rows H, C, P, N transport, replay, source, and name that finite data.

Apply Definition 1419.2. Its carrier-admission, classifier-transport, field-row stability, Archimedean comparison stability, and ledger-exactness clauses identify every root obligation with one of the displayed coordinates of F.

Apply Definition 1419.3. It routes ordered-field and Archimedean comparison reads through A, O, and Q over the same displayed $\mathsf{Real}^{\uparrow}$ endpoints R, so downstream $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealAlgOrder}^{\uparrow}$ consumers receive a single finite package.

Finally inspect the absent coordinates named in the carrier and handoff statements. Since no row stores trichotomy, quotient equality, selected bounds, host ordered-field structure, least-bound selection, or ambient completeness, the assembled root package cannot export any of those principles. □

Theorem 1419.7 (ArchimedeanOrderedField scoped closure)**.** *The carrier of Definition 1419.1, the NameCert obligations of Definition 1419.2, the RealAlgOrder handoff of Definition 1419.3, the*

rational-bound window of Definition 1419.4, comparison ledger exactness of Definition 1419.5, and the root obligation package of Definition 1419.6 bind every public comparison read to the displayed RealAlgOrder$^{\uparrow}$, ArchimedeanReal$^{\uparrow}$, Rat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

Lean4 ✓ `BEDC.Derived.ArchimedeanOrderedFieldUp.ArchimedeanOrderedFieldScopedClosure`

Proof. The carrier identifies the only public rows of an accepted packet:

$$F = (R, A, Q, O, B, H, C, P, N).$$

Thus every comparison read must begin with the displayed real endpoints, RealAlgOrder row, rational source row, Archimedean bound row, and local comparison ledger.

The NameCert obligations keep those rows stable under classifier transport. Field-row stability routes algebra and order reads through A over R, while Archimedean comparison stability routes rational-bound reads through Q and O over the same endpoints.

The RealAlgOrder handoff, rational-bound window, and comparison ledger exactness then close the consumer boundary. Ordered-field, rational-embedding, and Archimedean comparison reads reach B only through R, A, Q, O, H, C, P, N.

Finally the root obligation package repacks the same rows for RealAlgOrder$^{\uparrow}$, ArchimedeanReal$^{\uparrow}$, Rat$^{\uparrow}$, and Real$^{\uparrow}$ consumers. Since no coordinate remains outside the displayed transport, replay, provenance, and local naming rows, the chapter closes exactly this scoped comparison interface and no stronger ordered-field or completeness principle. □

Closure status for NameCert$_{\text{ArchimedeanOrderedField}^{\uparrow}}$.

Constructive story: An ArchimedeanOrderedField$^{\uparrow}$ packet is generated from displayed Real$^{\uparrow}$ endpoint rows, a RealAlgOrder$^{\uparrow}$ algebra/order row, Rat$^{\uparrow}$ rational source rows, an ArchimedeanReal$^{\uparrow}$ rational-bound row, a finite comparison ledger, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ArchimedeanOrderedField}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1419.7 binds every public comparison read to the displayed RealAlgOrder$^{\uparrow}$, ArchimedeanReal$^{\uparrow}$, Rat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{ArchimedeanOrderedField}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completeness, trichotomy, quotient reals, selected least bounds, host ordered-field structure, or bridge-checked status.

Upgrade path: Scoped closure requires a checked finite carrier theorem binding the displayed RealAlgOrder and ArchimedeanReal rows to the local comparison ledger.

Chapter 1420

A Concrete Naming Certificate for $\mathsf{LocatedLimit}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LocatedLimit}^{\uparrow}$ packet records located limits as explicit modulus-and-window data for displayed real-name sequences. It is a finite route from the Cauchy-equivalence surface of chapter 1412, the regular-rational readback surface of chapter 301, the finite stream-window surface of chapter 126, and the dyadic tolerance ledger of chapter 291 to the real-name seal of chapter 38. The packet does not introduce host real equality, quotient limits, countable choice, trichotomy, or ambient completeness.

Definition 1420.1 (LocatedLimit carrier)**.** *A* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, M, T, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the displayed* $\mathsf{Real}^{\uparrow}$ *sequence surface whose entries are read only through named finite windows;*
2. *M is the Cauchy/modulus ledger recording the explicit tolerance budget for the displayed sequence;*
3. *T is the located finite-window schedule that says which sequence windows and dyadic tolerances are inspected for each requested precision;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the scheduled windows and the modulus ledger;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *limit seal reached through Q and through no independent host-limit coordinate;*
6. *H stores componentwise* hsame *transports for the sequence surface, modulus ledger, finite-window schedule, regular readback, and real seal;*
7. *C stores the displayed* Cont *replay routes by which consumers reread the same windows and tolerances;*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected host limit, quotient equality of streams, countable-choice schedule, real trichotomy, or ambient completeness principle.

Lean4 (definition) `BEDC.Derived.LocatedLimitUp.LocatedLimitUp`

Definition 1420.2 (LocatedLimit classifier)**.** *Two accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *packets*

$$L = (S, M, T, Q, E, H, C, P, N) \quad \textit{and} \quad L' = (S', M', T', Q', E', H', C', P', N')$$

are classified together exactly when their displayed finite-window schedules expose the same dyadic tolerance comparisons after componentwise transport. Thus the classifier compares L *and* L' *only by shared windows in* T, T'*, the dyadic budgets read by* M, M'*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* Q, Q'*, and the* $\mathsf{Real}^{\uparrow}$ *seal rows* E, E' *reached from those data.*

No classifier step may use host real equality, quotient equality of streams, a selected limiting subsequence, countable choice, trichotomy, or an ambient completeness row.

Theorem 1420.3 (LocatedLimit NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$ *surface for the carrier of Definition 1420.1 consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed packet* $L = (S, M, T, Q, E, H, C, P, N)$*;*
2. *classifier: comparison is the finite-window and dyadic-tolerance classifier of Definition 1420.2;*
3. *transport:* H *and* C *preserve the same sequence surface, modulus ledger, schedule, readback, and seal rows under accepted consumer motion;*
4. *modulus exactness: every limit-facing tolerance request is answered by the stored Cauchy/modulus ledger* M *together with the schedule* T*;*
5. *Real-seal route: every* $\mathsf{Real}^{\uparrow}$ *limit read factors through* Q, E, H, C, P, N *after the displayed rows* S, M, T *have been read.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitNameCertObligations`
↪ variant `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier namecert obligations`

Proof. Carrier admission is projection from the packet $L = (S, M, T, Q, E, H, C, P, N)$. The sequence surface, modulus ledger, located schedule, regular readback, real seal, transport rows, replay routes, provenance, and local naming row are exactly the coordinates named by the carrier.

The classifier row is finite because it reads only the windows named by T, T' and the dyadic tolerances supplied by M, M'. The regular readbacks Q, Q' and real seals E, E' are compared only after those finite observations have been transported.

For transport, use H to move the displayed rows componentwise and C to replay the same consumer route. The replay never creates a new modulus, a host limit, or a quotient of streams; it returns to the stored rows.

Modulus exactness follows because the only tolerance ledger in the carrier is M, and the only located schedule is T. Therefore every downstream tolerance request has to pass through M and T before it can reach Q or E.

The Real-seal route is then the visible composition from S, M, T to Q and finally to E, with H, C, P, N carrying transport, replay, provenance, and naming. The excluded completeness, choice, trichotomy, quotient, and host-equality principles have no carrier coordinate. □

Theorem 1420.4 (LocatedLimit Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *limit read exported by an accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier factors through the displayed route*

$$S, M, T, Q, E, H, C, P, N.$$

The sequence surface S supplies the real-name entries, the ledger M supplies the explicit Cauchy/modulus budget, the schedule T chooses only finite windows for each dyadic tolerance, the row Q repacks those observations as a $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the row E is the sole* $\mathsf{Real}^{\uparrow}$ *limit seal available to consumers. The rows H, C, P, N provide transport, replay, provenance, and local naming for the same route.*

Proof. Project the accepted carrier. Its real-facing coordinates are not free-standing; E is stored together with the sequence surface S, the modulus ledger M, the located schedule T, and the regular readback Q.

Read the limit request in finite order. A consumer first asks T for the displayed windows attached to the requested dyadic tolerance, then reads the matching budget in M, and then uses Q to view the resulting data as a regular rational name.

Only after that route is visible can the consumer read E. The transport and replay rows H and C preserve the same route, while P and N record provenance and local naming.

Thus every $\mathsf{Real}^{\uparrow}$ limit read factors through $S, M, T, Q, E, H, C, P, N$. Since no other coordinate exists, the packet exports no real completeness theorem, selected host limit, quotient equality of streams, countable-choice schedule, trichotomy, or bridge-checked standard interpretation. □

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimit real seal route`

Theorem 1420.5 (LocatedLimit window schedule exactness)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier $L = (S, M, T, Q, E, H, C, P, N)$, each limit-facing tolerance request reads the displayed schedule row T and the modulus ledger M before it reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q or the* $\mathsf{Real}^{\uparrow}$ *seal row E. The exactness claim is the finite routing statement of Definition 1420.1 and Definition 1420.2, with the obligation order supplied by Definition 1420.3 and the terminal route supplied by Definition 1420.4.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitWindowScheduleExactness`

Proof. Project the carrier of Definition 1420.1. The only rows that can answer a tolerance request before readback are the schedule row T and the modulus ledger M.

Use the classifier of Definition 1420.2 to see that comparison is by shared finite windows and dyadic budgets, not by a host limit. Then apply Definition 1420.3: modulus exactness is one of the named local obligations and it places M and T before every read of Q or E.

Finally apply the route of Definition 1420.4. Since E is reached only after S, M, T, Q, every tolerance request has already passed through T and M before any regular readback or real seal can be exported. □

Theorem 1420.6 (LocatedLimit finite-window scope)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier $L = (S, M, T, Q, E, H, C, P, N)$, each finite-window tolerance request is scoped exactly by the* $\mathsf{StreamName}^{\uparrow}$ *window surface S, T, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger M, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$ *row N. The scope is the source-row route named by the carrier, classifier, NameCert obligations, window-schedule exactness, and Real-seal route; it excludes quotient streams, countable choice, trichotomy, selected host limits, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier finite window scope`

Proof. Project the carrier of Definition 1420.1. Its source rows are precisely $S, M, T, Q, E, H, C, P, N$, so a tolerance request has no access to any row outside that finite packet.

Use the classifier of Definition 1420.2. It compares accepted packets only through transported finite windows and dyadic budgets, and therefore binds the request to the $\mathsf{StreamName}^{\uparrow}$ surface S, T and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger M before any readback is visible.

Apply Definition 1420.3 and Definition 1420.5. The obligation rows require modulus exactness and route every tolerance request through T and M before it reaches the $\mathsf{RegSeqRat}^{\uparrow}$ row Q or the $\mathsf{Real}^{\uparrow}$ seal E.

Finally use Definition 1420.4. The terminal route is $S, M, T, Q, E, H, C, P, N$, with H, C, P, N supplying componentwise transport, replay, provenance, and local naming. Quotient streams, countable choice, trichotomy, selected host limits, and ambient completeness have no coordinate in that route, so they are outside the finite-window scope. □

Theorem 1420.7 (LocatedLimit schedule monotonicity)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, enlarging a displayed precision request refines the stored finite-window schedule through the same modulus ledger* M *and schedule row* T*. The refined request may expose later sequence windows, stronger dyadic tolerances, and a downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, but it may not replace* M*, allocate a new schedule row, or bypass the Real-seal route of Definition 1420.4.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier schedule monotonicity`

Proof. Project the carrier of Definition 1420.1. The only rows that answer precision requests before readback are the modulus ledger M and the finite-window schedule T.

Use Definition 1420.2 to compare the original request and the enlarged request through transported finite windows and dyadic budgets. The classifier has no host limit or quotient-stream coordinate, so the comparison remains inside M and T.

Apply Definition 1420.3 and Definition 1420.5. Their modulus exactness clause places M, T before every read of Q or E, and the exactness theorem identifies this placement as the stored route for every displayed tolerance request.

Finally use Definition 1420.4. Since the Real seal is reached only after S, M, T, Q, a stronger request can only refine the visible windows and tolerances in the same schedule; it cannot introduce a separate modulus or an independent seal. □

Theorem 1420.8 (LocatedLimit schedule-tail cofinality)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, any later displayed precision request that refines the same located schedule must reuse the same modulus ledger* M*, schedule row* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The refined tail may ask for later sequence windows and stronger dyadic tolerances, but it cannot allocate a second modulus, quotient stream, selected limit, choice schedule, or ambient completeness row.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitScheduleTailCofinality`
↪ variant `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier schedule tail cofinality`

Proof. Project the accepted packet through Definition 1420.1. The only tolerance-facing rows are M and T, and the only readback and terminal seal rows available after them are Q and E.

Use Definition 1420.2 to read a refined request. Since the classifier compares accepted packets by transported finite windows and dyadic budgets, a later tail that refines the same schedule is still classified through the same displayed rows rather than through a fresh host limit or quotient stream.

Apply Definition 1420.5. Every tolerance request reaches Q or E only after it has already passed through the stored schedule row T and modulus ledger M, so a tail request has no alternative ledger from which to obtain its budget.

Finally apply Definition 1420.4. The public limit read is exhausted by the route $S, M, T, Q, E, H, C, P, N$, hence the refined tail can only continue along that route. The excluded second modulus, quotient stream, selected limit, choice schedule, and ambient completeness row have no carrier coordinate. □

Theorem 1420.9 (LocatedLimit Real seal comparison)**.** *Let $L = (S, M, T, Q, E, H, C, P, N)$ and $L' = (S', M', T', Q', E', H', C', P', N')$ be accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carriers. If their transported schedule rows, modulus ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows match under the displayed* hsame *and* Cont *routes, then any comparison between the two accepted Real seals is exhausted by those rows. No comparison may appeal to host real equality, quotient equality of streams, a selected limit, countable choice, trichotomy, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier real seal comparison`

Proof. Read both carriers through Definition 1420.1. The only comparison-facing rows are the sequence surfaces, modulus ledgers, schedule rows, regular readbacks, Real seals, transport rows, replay rows, provenance rows, and local naming rows.

Apply the classifier of Definition 1420.2. It compares accepted carriers through shared finite windows, dyadic budgets, readback rows, and Real seal rows after componentwise transport; it does not expose host real equality or quotient stream equality.

Use Definition 1420.3 to force the comparison through the transported schedule and modulus rows before any readback or seal is consumed. Then Definition 1420.5 identifies the finite-window route as the exact route for each displayed precision request.

Finally apply Definition 1420.4. The terminal Real seal is reached only after S, M, T, Q on one side and S', M', T', Q' on the other. Therefore matching transported schedules, modulus ledgers, readbacks, and seal rows exhaust the accepted comparison, and the excluded external principles have no carrier coordinate from which to act. □

Theorem 1420.10 (LocatedLimit Cauchy tail uniqueness)**.** *Let $L = (S, M, T, Q, E, H, C, P, N)$ and $L' = (S', M', T', Q', E', H', C', P', N')$ be accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carriers. Suppose the two carriers expose matching transported finite schedules T, T', modulus ledgers M, M',* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks Q, Q', and terminal* $\mathsf{Real}^{\uparrow}$ *seals E, E' through the displayed* hsame *and* Cont *routes. Then every limit-facing consumer comparison of E and E' is exhausted by the common Cauchy-tail route*

$$S, M, T, Q, E, H, C, P, N.$$

It cannot appeal to host real equality, quotient streams, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier cauchy tail uniqueness`

Proof. Project both accepted carriers through Definition 1420.1. The only rows that can feed a limit-facing comparison are the displayed sequence surfaces, modulus ledgers, finite schedules, regular readbacks, Real seals, transport rows, replay rows, provenance rows, and local naming rows.

Use Definition 1420.2 to identify the comparison surface. The classifier reads the transported windows T, T', the dyadic budgets M, M', the readbacks Q, Q', and the seals E, E'; it has no

coordinate for host equality, quotient streams, selected limits, countable choice, trichotomy, or ambient completeness.

Apply Definition 1420.5. Every tolerance request reaches Q or E only after the finite schedule and modulus ledger have already been read, so the two matching schedule-ledger pairs determine the Cauchy-tail route visible to the consumer.

Finally use Definition 1420.4 and Definition 1420.9. The terminal seal comparison is reached only through the same finite route, and the comparison theorem says matching transported schedules, ledgers, readbacks, and seals exhaust the accepted Real-seal comparison. Hence the two seals are unique for this accepted route in the stated Cauchy-tail sense, without invoking any ambient Real-completeness principle. □

Theorem 1420.11 (LocatedLimit RegSeqRat readback stability)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *is stable under the same componentwise* hsame *transports and displayed* Cont *replay rows* H, C *that preserve the sequence surface* S*, modulus ledger* M*, located schedule* T*, and real seal* E*. The stability surface is the one described by Definition 1420.1, classified by Definition 1420.2, obligated by Definition 1420.3, and consumed by Definition 1420.4.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimit regseqrat readback stability`

Proof. Read the accepted packet through Definition 1420.1. The transport row H is componentwise and includes the regular readback row Q together with S, M, T, E.

The classifier in Definition 1420.2 compares only transported finite windows, dyadic budgets, regular readbacks, and real seals. Therefore a transported Q is not compared through quotient stream equality or through a new host sequence.

Apply the transport obligation in Definition 1420.3. The replay row C rereads the same consumer route after H has moved the displayed coordinates. The Real-seal route of Definition 1420.4 then consumes exactly that stable Q before reaching E. □

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier regseqrat readback stability`

Theorem 1420.12 (LocatedLimit source-row scope)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, every limit-facing consumer binds the finite-window schedule* T*, modulus ledger* M*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal* E *to the source rows named by* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *before the seal can be read. The binding is exactly the source-row route of the carrier, classifier, NameCert obligations, window schedule exactness, Real seal route, and RegSeqRat readback stability.*

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitCarrier source row scope`

Proof. Project the carrier of Definition 1420.1. Its consumer-facing rows are $S, M, T, Q, E, H, C, P, N$, so the schedule, modulus, readback, and seal are already stored with their transport, replay, provenance, and local naming rows.

Use the classifier of Definition 1420.2. It compares accepted packets only through transported finite windows, dyadic budgets, regular readbacks, and Real seals; hence T, M, Q, E cannot be detached from the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source rows that classify them.

Apply Definition 1420.3, Definition 1420.5, and Definition 1420.4. These rows force every tolerance request through T and M before Q and E are consumed.

Finally use Definition 1420.11. The readback row Q is stable only under the same hsame and Cont rows that preserve S, M, T, E, and P, N record the same source route. Therefore no consumer can read the seal before these BEDC source rows are bound. □

Theorem 1420.13 (LocatedLimit Real seal nonescape)**.** *For every accepted* $\mathsf{LocatedLimit}^{\uparrow}$ *carrier* $L = (S, M, T, Q, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *exports no selected host limit, no quotient stream equality, no countable-choice schedule, no trichotomy, and no ambient completeness principle. This nonescape is the carrier exclusion of Definition 1420.1, the classifier exclusion of Definition 1420.2, the Real-seal obligation of Definition 1420.3, and the terminal factorization of Definition 1420.4.*

Proof. Inspect the carrier in Definition 1420.1. The rows are $S, M, T, Q, E, H, C, P, N$, and none is a selected host limit, quotient equality of streams, countable-choice schedule, trichotomy witness, or ambient completeness field.

The classifier of Definition 1420.2 preserves the same boundary: it compares finite windows, dyadic budgets, regular readbacks, and real seals only after componentwise transport.

Apply Definition 1420.3 to force every real-facing read through the named finite rows. Then Definition 1420.4 identifies E as the sole Real seal reached after S, M, T, Q. Since the excluded principles have no carrier coordinate and no classifier clause, they cannot escape through E. □

Lean4 ✓ `BEDC.Derived.LocatedLimitUp.LocatedLimitRealSealNonescape`

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedLimit}^{\uparrow}$ packet is generated from a displayed $\mathsf{Real}^{\uparrow}$ sequence surface, an explicit Cauchy/modulus ledger, a located finite-window schedule, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ limit seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1420.1, Definition 1420.2, Definition 1420.3, Definition 1420.5, Definition 1420.4, Definition 1420.7, Definition 1420.8, Definition 1420.11, Definition 1420.12, and Definition 1420.13 close the mature paper-side finite-window treatment: carrier, classifier, NameCert obligations, window schedule exactness, Real-seal route, schedule monotonicity, tail cofinality, readback stability, source-row scope, and nonescape for located-limit consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, selected host limits, quotient equality of streams, countable choice, trichotomy, or bridge checking.

Upgrade path: The next upgrade is Lean bridge checking for the paper-side located-limit route without adding Real completeness or selected limits.

Chapter 1421

A Concrete Naming Certificate for $\mathsf{CantorIntersection}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{CantorIntersection}^{\uparrow}$ packet records the finite nested-interval route by which a displayed shrinking interval chain is consumed as a real-completion surface. It is a NameCert reconstruction of the Cantor nested-interval reading over the finite diagonal interface of chapter 389, with source rows also anchored at chapter 126, chapter 301, and chapter 38.

The chapter names a completion-facing consumer of the existing nested-interval readback surface. It does not add point choice, quotient equality of reals, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness; every real-facing read is required to pass through the displayed nested-interval intersection packet.

Definition 1421.1 (Cantor intersection carrier)**.** *A* $\mathsf{CantorIntersection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (N, W, D, E, R, H, C, P, Q)$$

with the following visible rows:

1. *N is the accepted* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *packet whose source chain is a displayed* $\mathsf{NestedInterval}^{\uparrow}$ *or* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *row;*
2. *W is the finite width-window ledger read from the selected* $\mathsf{DyadicInterval}^{\uparrow}$ *endpoint packets and their* $\mathsf{DyadicRatCore}^{\uparrow}$ *lower and upper endpoint rows;*
3. *D is the diagonal selector row choosing, for each displayed precision request, one finite nested-interval window already present in N;*
4. *E records the endpoint enclosure rows selected by D and the exact finite dependency path back to W;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained by reading the selected endpoint enclosures as a regular rational completion name;*
6. *H is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R and the nested-interval intersection packet N;*
7. *C stores the displayed* hsame *and* Cont *transports for N, W, D, E, R, H;*

8. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalIntersection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{NestedDyadicInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. *Q is the local* $\mathsf{NameCert}_{\mathsf{CantorIntersection}^{\uparrow}}$ *row for the finite completion-consumer name.*

The carrier predicate is $\mathsf{CantorIntersectionPacket}(K)$*. Its public rows are exactly the nested-interval intersection packet, width-window ledger, diagonal selector, endpoint enclosure rows, regular-rational handoff, real seal, transport rows, package provenance, and local naming row.*

Theorem 1421.2 (Cantor intersection NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{CantorIntersection}^{\uparrow}}$ *surface has five obligations:*

1. *carrier: admission of the finite packet of Definition 1421.1;*

2. *finite-window classifier: two accepted carriers classify together only by comparing the displayed* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *packet, width-window ledger, selected endpoint enclosures,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal row, transports, provenance, and local certificate row;*

3. *selector stability: transporting the nested-interval intersection packet and width-window ledger through the displayed* hsame *and* Cont *routes transports the selected finite window to the corresponding selected finite window;*

4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exactness: every regular-rational read in R is obtained from the selected endpoint enclosure rows E and no unrecorded tail of the interval chain;*

5. $\mathsf{Real}^{\uparrow}$ *seal nonescape: every real-facing read through H factors through N, W, D, E, R, C, P, Q and receives no host real equality, point selector, open-cover compactness, or ambient completeness datum.*

These obligations are the finite Cantor-intersection consumer surface over the already named nested-interval intersection route.

Proof. Carrier admission is projection from K. The tuple lists the nested-interval intersection source, width-window ledger, selector, selected endpoint enclosures, regular-rational handoff, real seal, transports, provenance, and local naming row as one finite history packet.

The finite-window classifier compares only those displayed rows after the recorded transports have moved both packets to the same precision request. Since the comparison is made at the visible window, it has no coordinate for quotient equality of completed reals or equality of host interval chains.

Selector stability is inherited from the selector row D and the transported width ledger W. A transported request still names a finite interval row of the transported $\mathsf{NestedIntervalIntersection}^{\uparrow}$ packet, so the selected endpoint enclosure remains a visible row of the same packet.

The $\mathsf{RegSeqRat}^{\uparrow}$ handoff exactness is the statement that R is read from E, not from an invisible tail of the chain. The $\mathsf{Real}^{\uparrow}$ seal nonescape then follows by routing H through R together with the displayed transport, package, and local certificate rows. □

Lean4 ✓ `BEDC.Derived.CantorIntersectionUp.CantorIntersectionCarrier namecert obligation surface`

Theorem 1421.3 (Cantor intersection width-window transport)**.** *For every accepted* $\mathsf{CantorIntersection}^{\uparrow}$ *carrier*

$$K = (N, W, D, E, R, H, C, P, Q),$$

the cofinal width-window row W is transported only together with the nested-interval intersection packet N, the diagonal selector row D, the selected endpoint enclosure row E, and the displayed

transport rows C. After any displayed hsame *or* Cont *route, a precision request still lands in a finite window already present in N.*

Proof. Project K through Definition 1421.1. The rows N, W, D, E are stored in the same finite packet, and C is the only displayed transport coordinate for them.

Apply Definition 1421.2. The selector-stability obligation says that transporting the nested-interval packet and width ledger transports the selected finite window with them.

Thus the cofinal window remains a visible row of N after transport. No hidden tail, point selector, or ambient completeness datum is introduced by the width-window route. □

Lean4 ✓ `BEDC.Derived.CantorIntersectionUp.CantorIntersectionCarrier width window transport`

Theorem 1421.4 (Cantor intersection RegSeqRat handoff exactness)**.** *For every accepted* CantorIntersection$^{\uparrow}$ *carrier*

$$K = (N, W, D, E, R, H, C, P, Q),$$

the RegSeqRat$^{\uparrow}$ *row R is obtained exactly from the selected endpoint enclosure row E, where E is selected by D from the cofinal width-window ledger W inside N. The handoff does not read a second completion name, an unrecorded interval tail, or quotient equality of real names.*

Proof. Start with the rows W, D, E, R in Definition 1421.1. The endpoint enclosure row E is not free-standing; it is the endpoint row selected by D from the finite ledger W attached to N.

Apply the handoff-exactness clause of Definition 1421.2. That clause identifies R with the regular-rational read from E and excludes any invisible tail of the interval chain.

The displayed transport and package rows C, P, Q only replay that finite route. They do not add a second regular name or quotient-real equality coordinate. □

Lean4 ✓ `BEDC.Derived.CantorIntersectionUp.CantorIntersectionRegSeqRatHandoffExactness`
↪ variant `BEDC.Derived.CantorIntersectionUp.CantorIntersectionCarrier regseqrat handoff exactness`

Theorem 1421.5 (Cantor intersection real seal nonescape)**.** *For every accepted* CantorIntersection$^{\uparrow}$ *carrier*

$$K = (N, W, D, E, R, H, C, P, Q),$$

the Real$^{\uparrow}$ *seal row H may be consumed only through the finite route*

$$N, W, D, E, R, C, P, Q.$$

In particular, the seal cannot be used as a proof of point choice, uniqueness of an intersection point, open-cover compactness, host real equality, quotient equality of real names, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Project the real-facing row H from K. Its source rows are exactly the selected nested-interval data, the regular-rational handoff, the displayed transports, package provenance, and local naming certificate.

Apply Definition 1421.2. The real-seal nonescape obligation states that every read through H factors through N, W, D, E, R, C, P, Q.

The excluded principles have no coordinate in that route. The seal is therefore a terminal consumer of the finite Cantor-intersection handoff, not an ambient completeness or choice principle. □

Lean4 ✓ `BEDC.Derived.CantorIntersectionUp.CantorIntersectionRealSealNonescape`

Theorem 1421.6 (Cantor intersection real seal handoff)**.** *For every accepted* $\mathsf{CantorIntersection}^{\uparrow}$ *carrier*

$$K = (N, W, D, E, R, H, C, P, Q),$$

every $\mathsf{Real}^{\uparrow}$*-facing read factors through the displayed* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *packet* N*, the selected finite nested-window ledger* W, D, E*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, the displayed transports* C*, the package provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{CantorIntersection}^{\uparrow}}$ *row* Q *before the seal row* H *is consumed.*

The handoff does not claim open-cover compactness, point choice, host real equality, quotient equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorIntersectionUp.CantorIntersection real seal handoff`

Proof. Start with the real-facing row H in Definition 1421.1. Its source is the regular-rational handoff R together with the displayed transports, provenance, and local naming row.

Apply Definition 1421.2. The obligation surface forces R to be read from the selected endpoint enclosures E, and those enclosures are selected by D from the finite width-window ledger W inside the nested-interval intersection packet N.

Thus every real-facing consumer reaches the seal only after passing through the displayed finite nested-interval intersection route. No remaining coordinate in K carries an open-cover compactness proof, a chosen intersection point, a host real equality row, quotient equality of real names, or an ambient completeness principle. □

Theorem 1421.7 (Cantor intersection diagonal cofinal readback)**.** *For every accepted* $\mathsf{CantorIntersection}^{\uparrow}$ *carrier*

$$K = (N, W, D, E, R, H, C, P, Q),$$

and every displayed precision request named by the finite width-window ledger W*, the diagonal selector row* D *selects a visible interval row already present in the nested-interval intersection packet* N*. The selected row determines the endpoint enclosure row in* E*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *is read from that same enclosure.*

Consequently the $\mathsf{Real}^{\uparrow}$ *seal row* H *is reachable only through the finite cofinal route*

$$W, D \longrightarrow N \longrightarrow E \longrightarrow R \longrightarrow H$$

together with the displayed transports C*, package provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{CantorIntersection}^{\uparrow}}$ *row* Q*.*

Proof. Project the accepted carrier K along the rows listed in Definition 1421.1. A displayed precision request is not an external real-completion demand; in the packet it is a row of the finite ledger W.

Apply the selector-stability obligation of Definition 1421.2. After any displayed hsame or Cont transport in C, the row D still points to a finite nested-window row of N for that request. Thus the selector has no access to a hidden tail of the chain and no coordinate for a chosen intersection point.

The endpoint enclosure row E is then the visible enclosure attached to the selected row, and the $\mathsf{RegSeqRat}^{\uparrow}$ handoff exactness clause of Definition 1421.2 forces R to be obtained from E. There is no side input from quotient equality of real names, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Finally apply Definition 1421.6. The only route to the real-facing seal is the already displayed chain through N, W, D, E, R, C, P, Q, so every precision request consumed by H has already been answered by a finite diagonal row of N. □

Lean4 ✓ `BEDC.Derived.CantorIntersectionUp.CantorIntersection diagonal cofinal readback`

Theorem 1421.8 (Cantor intersection public completion consumer)**.** *For every accepted* $\mathsf{CantorIntersection}^{\uparrow}$ *carrier*

$$K = (N, W, D, E, R, H, C, P, Q),$$

the public completion consumer surface of K *is exactly the finite route through* $\mathsf{NestedIntervalIntersection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$ *or* $\mathsf{NestedDyadicInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and the local* $\mathsf{NameCert}_{\mathsf{CantorIntersection}^{\uparrow}}$ *row.*

Equivalently, every public consumer row factors through the displayed nested-interval intersection packet N*, the width-window ledger* W*, the diagonal selector* D*, the selected endpoint enclosures* E*, the regular-rational handoff* R*, the real seal row* H*, the transport rows* C*, the package provenance* P*, and the local naming row* Q*. The surface exports no point selector, quotient real equality, open-cover compactness, uniqueness of an intersection point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1421.2. The carrier, classifier, selector-stability, handoff-exactness, and seal-nonescape obligations list exactly the finite rows visible to a $\mathsf{CantorIntersection}^{\uparrow}$ consumer.

The real-facing boundary is fixed by Definition 1421.6. Any read reaching $\mathsf{Real}^{\uparrow}$ must first pass through the nested-interval packet, the selected finite window, the regular-rational handoff, the displayed transports, the provenance row, and the local certificate row.

The finite cofinality of those reads is fixed by Definition 1421.7. Each displayed precision request is answered by a visible diagonal row of N, so the consumer has no access to an unrecorded tail or to an external choice of intersection point.

Combining these three surfaces leaves precisely the listed public route and no further public coordinate. In particular, quotient equality of real names, host real equality, open-cover compactness, uniqueness of an intersection point, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not part of the exported consumer surface. □

Lean4 ✓ `BEDC.Derived.CantorIntersectionUp.CantorIntersection public completion consumer`
Lean4 ✓ `BEDC.Derived.CantorIntersectionUp.CantorIntersectionPublicCompletionConsumer`

Theorem 1421.9 (Cantor intersection dyadic interval basis bridge)**.** *For every accepted* $\mathsf{CantorIntersection}^{\uparrow}$ *carrier*

$$K = (N, W, D, E, R, H, C, P, Q),$$

each accepted public completion consumer factors its selected endpoint enclosures through a $\mathsf{DyadicIntervalBasis}^{\uparrow}$ *basis-cell route before the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row are read. Thus the cofinal window selected by* D *is exposed as a finite dyadic basis-cell boundary over the displayed rows* N, W, D, E, C, P, Q*, and only then as the regular-rational readback* R *and real seal* H*.*

Proof. Begin with the public consumer described in Definition 1421.8. That surface reaches the selected endpoint enclosures only through the nested-interval packet N, the width-window ledger W, and the diagonal selector D.

Apply Definition 1421.7. For each displayed precision request, the selected enclosure in E comes from a visible finite cofinal row rather than from a hidden tail or selected intersection point.

Now apply Definition 1916.3. The selected dyadic endpoint enclosure may be refined through the $\mathsf{DyadicIntervalBasis}^{\uparrow}$ basis-cell route while preserving the transported endpoint, containment, stream-window, regular-rational, and real-seal rows.

Combining these routes gives the required factorization: basis-cell exposure precedes the $\mathsf{RegSeqRat}^{\uparrow}$ row R and the $\mathsf{Real}^{\uparrow}$ seal row H, while C, P, Q replay, source, and name the same finite carrier. The bridge adds no point selector, quotient real equality, host real equality, open-cover compactness, uniqueness of an intersection point, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CantorIntersectionUp.CantorIntersectionDyadicIntervalBasisBridge`

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersection}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorIntersection}^{\uparrow}$ packet is generated from an accepted $\mathsf{NestedIntervalIntersection}^{\uparrow}$ packet, a finite width-window ledger over $\mathsf{NestedInterval}^{\uparrow}$ or $\mathsf{NestedDyadicInterval}^{\uparrow}$ source rows, selected $\mathsf{DyadicInterval}^{\uparrow}$ endpoint enclosures with $\mathsf{DyadicRatCore}^{\uparrow}$ reads, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal row, displayed hsame and Cont transports, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorIntersection}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature paper treatment registers the carrier, finite-window classifier, selector stability, regular-rational handoff exactness, real-seal nonescape, public completion consumer, and dyadic interval basis bridge for a finite Cantor nested-interval completion consumer over $\mathsf{NestedIntervalIntersection}^{\uparrow}$, $\mathsf{DyadicIntervalBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorIntersection}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.CantorIntersectionUp.CantorIntersectionCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, point choice, host real equality, quotient equality of real names, uniqueness of an intersection point, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: No further paper closure upgrade remains; later work may synchronize verification or bridge status without changing the closed paper surface.

Chapter 1422

A Concrete Naming Certificate for $\mathsf{IntermediateValueBisection}^{\uparrow}$

Following Bishop and Bridges-style constructive bisection, the $\mathsf{IntermediateValueBisection}^{\uparrow}$ packet records the finite sign-change route that turns an inspected located interval, endpoint sign reads, and a displayed continuity budget into a regular rational window and a real-name seal. It is a NameCert consumer of the dyadic branch ledger of chapter 361, the rational endpoint cells of chapter 354, the located interval surface of chapter 394, the stream windows of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38.

The certificate is narrower than a classical intermediate value theorem. It stores only the finite branch prefix and the sign ledger needed by a consumer at a requested tolerance, then hands the retained window to the existing regular-sequence and real-name surfaces. No coordinate stores a completed root, a quotient stream, an arbitrary limit selector, real trichotomy, open-cover compactness, or an ambient completeness theorem.

Theorem 1422.1 (IntermediateValueBisection finite sign-change carrier)**.** *An* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (J, R, D, S, W, G, E, H, C, P, N)$$

whose visible rows have the following roles:

1. *J is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint packet, including the lower and upper rational cells and their located order witness;*
2. *R is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger against which endpoint and midpoint sign reads are recorded;*
3. *D is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch prefix that retains an interval with opposite displayed signs at the requested finite precision;*
4. *S is the sign ledger, containing the initial endpoint signs and the midpoint sign row used at each branch of D;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window surface for the retained lower and upper endpoint names;*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the retained stream windows and the requested dyadic tolerance;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal available to downstream consumers only through the retained regular readback;*

8. *H stores the componentwise* hsame *transports for J, R, D, S, W, G, E, and the local certificate row;*
9. *C stores the displayed* Cont *replay routes for endpoint inspection, midpoint inspection, branch retention, regular readback, and real-seal consumption;*
10. *P is the* Pkg *provenance over* LocatedInterval$^{\uparrow}$, RationalInterval$^{\uparrow}$, DyadicBisection$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{IntermediateValueBisection}^{\uparrow}}$ *registration row.*

The carrier predicate says that these rows form one finite sign-change bisection certificate. It has no coordinate for completed root existence, real trichotomy, quotient streams, selected limits, open-cover compactness, or a global completeness principle for Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.IntermediateValueBisectionUp.IntermediateValueBisectionTasteGate single carrier alignment`

Proof. The carrier is read by projection from the displayed packet I. The located interval row J and rational cell ledger R provide the endpoint cells in which signs are inspected.

The dyadic branch prefix D is the only row that can choose a retained interval. Its choices are justified by the sign ledger S, so every branch step is tied to an endpoint or midpoint sign row already present in the packet.

The retained endpoints then expose stream windows through W and regular rational readback through G. The real-facing row E is reached only after that readback route is fixed.

Finally, H, C, P, and N provide transport, replay, provenance, and local naming for the same rows. Since the tuple contains no other analytic coordinate, the excluded classical and completeness principles cannot be exported by the carrier. □

Theorem 1422.2 (IntermediateValueBisection sign-ledger stability)**.** *For every accepted* IntermediateValueBisection *carrier $I = (J, R, D, S, W, G, E, H, C, P, N)$, every branch prefix of D transports the same sign-ledger boundary under the displayed* hsame *rows and the displayed* Cont *replay routes. In particular, if a consumer reads a retained subinterval through C, then the lower and upper sign rows it receives are exactly the transported entries of S attached to the rational cells in R and the located endpoint packet J.*

Proof. Start with a branch prefix of D. Each step in the prefix names one retained dyadic subinterval and one midpoint sign row, so the only available sign data for the next step are the entries already stored in S.

Transport along H acts componentwise on J, R, D, and S. It preserves the attachment between a rational endpoint cell and its displayed sign row because there is no separate sign coordinate outside the ledger.

Replay along C reads the retained subinterval through the same endpoint inspection and midpoint inspection route. Thus a consumer cannot replace the lower or upper sign by an unrelated host comparison; it receives the transported ledger entries bound to the branch prefix.

Package provenance P and the local certificate row N record that this is the accepted IntermediateValueBisection$^{\uparrow}$ route. The branch-prefix and sign-ledger transport are therefore stable under the named hsame, Cont, and Pkg rows. □

Lean4 ✓ `BEDC.Derived.IntermediateValueBisectionUp.IntermediateValueBisectionCarrier sign ledger stability`

Theorem 1422.3 (IntermediateValueBisection regular seal handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *carrier factors through the route*

$$J, R, D, S, W, G, E, H, C, P, N.$$

The consumer first reads the located and rational endpoint cells, then the finite dyadic branch prefix and transported sign ledger, then the retained stream windows, then the regular rational readback, and only then the real-name seal. The handoff exports a finite sign-change window, not a completed root, quotient stream, selected limit, real trichotomy, open-cover compactness, or ambient completeness theorem.

Proof. Project the accepted carrier. A regular-sequence request begins at the retained endpoint windows, but those windows are not independent rows; they are the W coordinate stored with J, R, D, and S.

Read the finite route in order. The located endpoint packet and rational interval cells determine the initial boundary, the dyadic branch prefix selects the retained interval, and Definition 1422.2 keeps the sign ledger attached to that prefix under transport and replay.

The retained windows then pass through G, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row. The $\mathsf{Real}^{\uparrow}$ seal E is exposed only after this regular readback has been reached, with H, C, P, and N preserving the same route for consumers.

No step in this route introduces a host root or a completed intersection object. Therefore the handoff supplies exactly the finite regular window and real-name seal named in the packet, with the listed non-claims remaining outside the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntermediateValueBisection}^{\uparrow}}$**.**

Constructive story: An $\mathsf{IntermediateValueBisection}^{\uparrow}$ packet is generated from a $\mathsf{LocatedInterval}^{\uparrow}$ endpoint packet, a $\mathsf{RationalInterval}^{\uparrow}$ cell ledger, a $\mathsf{DyadicBisection}^{\uparrow}$ branch prefix, finite sign rows, $\mathsf{StreamName}^{\uparrow}$ retained windows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntermediateValueBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1422.1, Definition 1422.2, and Definition 1422.3 seed the finite constructive bisection route from displayed sign change to regular rational and real-name consumption.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntermediateValueBisection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close completed root existence, real trichotomy, quotient streams, selected limits, open-cover compactness, completed nested intersections, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: A checked BEDC.Derived.IntermediateValueBisectionUp carrier and theorem surface matching the displayed finite sign-change packet would raise the verification axis.

Chapter 1423

A Concrete Naming Certificate for $\mathsf{RealCauchyModulus}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RealCauchyModulus}^{\uparrow}$ packet records the explicit modulus-controlled read by which a regular rational Cauchy name reaches a $\mathsf{Real}^{\uparrow}$ seal. It sits over the finite stream-window surface of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the real seal boundary of chapter 38, and the generic modulus schedule of chapter 292. The packet keeps the modulus visible as finite certificate data before any Real-facing consumer may read the seal.

Definition 1423.1 (Real Cauchy modulus carrier)**.** *A* $\mathsf{RealCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the precision-indexed* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule assigning each requested dyadic tolerance a finite threshold.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *family of finite windows selected by the thresholds in M.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the endpoint and radius comparisons read on those windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row whose regularity is witnessed only through M, S, D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the displayed modulus, window, dyadic, and regular-readback rows have been consumed.*
6. *H records componentwise* hsame *transport for the modulus schedule, stream windows, dyadic tolerance row, regular readback, Real seal, continuation, provenance, and local naming rows.*
7. *C records the displayed* Cont *replay from each precision request through M, S, D, Q, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, a selected limit, open-cover compactness, or an unbounded stream read.

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier local cert ledger transport`

Theorem 1423.2 (Real Cauchy modulus NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ *surface for Definition 1423.1 consists exactly of carrier exposure for B, precision/modulus exposure through M, finite-window exposure through S, dyadic tolerance exposure through D, regular rational readback through Q, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N. Each accepted precision request is classified only by the scheduled threshold in M, the finite windows in S, and the tolerance ledger in D.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier namecert obligations`

Proof. Project the carrier tuple $B = (M, S, D, Q, E, H, C, P, N)$. Each coordinate is a displayed finite row, and the final coordinate names the packet as the local $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ surface.

Read the analytic rows in order. The precision request first consumes the threshold row M, then the finite windows S, then the dyadic ledger D, and only then the regular readback Q and terminal seal E.

The structural rows do not add an analytic source. They transport, replay, source, and name the same route, while the excluded objects have no coordinate in the carrier. Hence the listed rows exhaust the seed obligation surface. □

Theorem 1423.3 (Real Cauchy modulus finite-window route)**.** *For every accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet $B = (M, S, D, Q, E, H, C, P, N)$ and every displayed precision request, the Real-facing read factors through the finite route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto (H, C, P, N).$$

The consumer receives no Real completeness theorem, quotient stream equality, host real equality, countable-choice row, trichotomy row, selected-limit row, open-cover compactness row, hidden selector, or detached Real seal.

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.TasteGate.RealCauchyModulusCarrier window modulus route`

Proof. Start with Definition 1423.2. It places the modulus schedule M before the StreamName window S and the dyadic tolerance ledger D.

The regular readback is then forced through the same finite window. The row Q is read only after M, S, D are displayed, so no quotient stream or host equality row can substitute for the scheduled window comparison.

Finally read the Real seal coordinate. The row E is reached after Q, and the rows H, C, P, N only preserve and name that route. This exhausts the advertised finite-window path for the precision request. □

Theorem 1423.4 (Real Cauchy modulus Real seal nonescape)**.** *No* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{RealCauchyModulus}^{\uparrow}$ *carrier can bypass the displayed route*

$$\mathsf{CauchyModulus}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Equivalently, every accepted terminal seal read is attached to the same packet $B = (M, S, D, Q, E, H, C, P, N)$ and cannot be separated from its explicit modulus schedule, finite windows, dyadic tolerance ledger, regular readback, transport, continuation, provenance, and local naming rows.

Proof. Use the finite-window route of Definition 1423.3. It already forces each terminal seal read through M, S, D, Q, E before the structural rows are consumed.

Now inspect the carrier of Definition 1423.1. There is no coordinate for Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, a selected limit, open-cover compactness, a hidden selector, or a detached Real seal.

Thus any purported Real seal read that omits one of the displayed rows is not a read of the accepted carrier. The only terminal route available to a consumer is the one named by B. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier real seal nonescape`

Definition 1423.5 (Real Cauchy modulus classifier)**.** *The* $\mathsf{RealCauchyModulus}^{\uparrow}$ *classifier accepts a packet* $B = (M, S, D, Q, E, H, C, P, N)$ *exactly when it is componentwise* hsame *to a displayed carrier packet*

$$B' = (M', S', D', Q', E', H', C', P', N')$$

with matching rows for the $\mathsf{CauchyModulus}^{\uparrow}$ *schedule,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming certificate. The classifier then replays the same* Cont *route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto (H, C, P, N)$$

and accepts no packet whose Real-facing read omits one of these coordinates.

Lean4 (definition) `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusClassifier`

Theorem 1423.6 (Real Cauchy modulus threshold stability)**.** *Let* $B = (M, S, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. Transporting* B *along the classifier of Definition 1423.5 preserves the scheduled threshold in* M*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row in* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row in* Q*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal in* E*. In particular, the transported packet has the same displayed Real-facing route and cannot replace the modulus threshold by an unbounded stream read or a detached Real seal.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier threshold stability`

Proof. Project the accepted packet by Definition 1423.1. The rows M, S, D, Q, E are named coordinates of the same finite BHist tuple, while H records the componentwise hsame transport for those coordinates.

Apply the classifier of Definition 1423.5. Acceptance requires the transported packet to match the displayed carrier component by component, so the threshold row, finite windows, dyadic tolerance ledger, regular readback, and terminal seal are preserved as the rows read by the consumer.

Finally replay the finite-window route of Definition 1423.3. Since the Cont replay is the same route through $M, S, D, Q, E, H, C, P, N$, no unbounded stream read, hidden selector, or detached Real seal can enter during transport. □

Theorem 1423.7 (Real Cauchy modulus ledger exhaustion)**.** *Every accepted Real-facing read of a* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet is exhausted by the nine displayed rows* $M, S, D, Q, E, H, C, P, N$*. The read therefore cannot introduce Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, open-cover compactness, an unbounded stream read, or any analytic row not already present in the carrier.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier ledger exhaustion`

Proof. Start from the obligation surface in Definition 1423.2. It lists the analytic rows M, S, D, Q, E and the structural rows H, C, P, N as the complete seed surface for the local $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ packet.

Use Definition 1423.6 to transport any accepted read back to the same classifier route. The transported read still consumes the scheduled threshold, finite windows, tolerance ledger, regular readback, and terminal seal in the displayed order.

It remains to inspect the carrier. By Definition 1423.1, none of Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, open-cover compactness, an unbounded stream read, or a detached analytic source has a coordinate in B. Hence every accepted Real-facing read is exhausted by the displayed ledger. □

Theorem 1423.8 (Real Cauchy modulus root-unblock scope)**.** *Every accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet exposes exactly the rows needed by downstream L10 Real-and-Completion consumers: the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold schedule* M*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, the ambient* BHist *carrier, the* hsame *transport row* H*, the* Cont *replay row* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}$ *row* N*. No accepted packet exposes a quotient stream, selected limit, host real equality, countable-choice row, or ambient Real completeness row as part of the unblock surface.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier root unblock scope`

Proof. Project the tuple in Definition 1423.1. Its analytic coordinates are precisely M, S, D, Q, E, and its structural coordinates are precisely H, C, P, N over the finite BHist packet.

The obligation surface of Definition 1423.2 names the same coordinates as the local $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$ surface. Thus an L10 consumer can read the schedule, window, dyadic, regular-readback, seal, transport, continuation, package, and naming rows without adding any further analytic source.

Finally apply Definition 1423.3 and Definition 1423.7. The route inspection shows that quotient streams, selected limits, host real equality, countable choice, and ambient Real completeness have no coordinate in the accepted packet, so they cannot be part of the root-unblock scope. □

Theorem 1423.9 (Real Cauchy modulus threshold-window totality)**.** *For every accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet and every displayed precision request, the consumer first reads a threshold from* M *and then a finite window from* S *before the dyadic ledger* D*, the regular readback* Q*, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is available. This ordering is total for the displayed route: there is no accepted access path from the precision request directly to* D, Q, E*, to a quotient stream, to a selected limit, to host real equality, to countable choice, or to ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier threshold window totality`

Proof. Start with the route theorem Definition 1423.3. It factors every accepted precision request through $M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E$ before the structural rows are consumed.

The carrier projection in Definition 1423.1 makes the threshold and window rows named coordinates of the same finite packet. Therefore the consumer cannot obtain the dyadic tolerance ledger, regular readback, or terminal seal without first selecting the scheduled threshold and the corresponding finite window.

The NameCert obligations in Definition 1423.2 and the ledger exhaustion theorem Definition 1423.7 rule out all other sources. Since quotient streams, selected limits, host real equality, countable choice, and ambient Real completeness are absent from the tuple, they cannot provide an alternate totality witness. □

Theorem 1423.10 (Real Cauchy modulus RegSeqRat seal admission)**.** *The* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *of an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet is admitted to the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *only through the displayed modulus, finite-window, and dyadic route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E.$$

No quotient stream equality, selected limit, host real equality, countable-choice principle, or ambient Real completeness theorem can admit Q *to the seal.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier regseqrat seal admission`

Proof. Read the accepted packet through Definition 1423.1. The row Q is a displayed coordinate between the dyadic ledger D and the terminal seal E, not a detached regular sequence or an external limit object.

Use Definition 1423.3. It places Q after the scheduled threshold M, finite window S, and dyadic ledger D, and before the terminal $\mathsf{Real}^{\uparrow}$ seal row E. The continuation row C then replays exactly that admission path.

The obligation list in Definition 1423.2 supplies the same route as local certificate data, while Definition 1423.7 excludes every non-displayed analytic source. Hence Q enters the seal only by the modulus-window-dyadic route, never by quotient streams, selected limits, host real equality, countable choice, or ambient Real completeness. □

Theorem 1423.11 (Real Cauchy modulus precision induction)**.** *Let* $B = (M, S, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. For every finite unary precision request, every finite precision refinement of the accepted request is handled by induction on that unary request and preserves the displayed route through*

$$\mathsf{CauchyModulus}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

At each induction stage the refined read consumes only the scheduled modulus row M*, the finite window row* S*, the dyadic ledger row* D*, the regular readback row* Q*, the terminal seal row* E*, and the structural rows* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier precision induction`

Proof. Project the accepted packet with Definition 1423.1. The precision request is a finite unary object, so the proof proceeds by induction on the displayed request.

In the zero stage, Definition 1423.3 gives the route from M to S, then to D, Q, and E. The classifier rows H, C, P, N replay and name the same route, so no extra analytic coordinate is introduced.

For the successor stage, assume the route has been preserved for the preceding precision request. The next refinement reads the next threshold from M, selects the corresponding finite window in S, extends the tolerance ledger in D, and then replays the regular readback Q before exposing the same terminal $\mathsf{Real}^{\uparrow}$ seal row E.

The replay is the displayed Cont row C, transported componentwise by H and sourced by P, N. The ledger exhaustion theorem Definition 1423.7 rules out Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, open-cover compactness, or an unbounded stream read at any induction stage. □

Theorem 1423.12 (Real Cauchy modulus window monotonicity)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. If a dyadic tolerance request is strengthened inside the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the scheduled threshold in M may enlarge the finite* $\mathsf{StreamName}^{\uparrow}$ *window in S, but the earlier window, dyadic ledger row, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row remain present in the accepted carrier route. In particular, the stronger request cannot delete or detach any previously scheduled window, tolerance entry, regular readback, or terminal* $\mathsf{Real}^{\uparrow}$ *seal row.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier window monotonicity`

Proof. Begin with the accepted route of Definition 1423.3. A stronger tolerance is still classified through the same M, S, D, Q, E route, because the classifier of Definition 1423.5 accepts only componentwise matches of those displayed rows.

The threshold selected by M may point to a larger finite window in S. This changes the amount of displayed stream data read for the stronger tolerance, but it does not remove the earlier finite window, since that earlier window is already a coordinate of the accepted BHist packet and is transported by H.

The dyadic ledger and regular readback follow the same containment. The row D records the earlier tolerance entry and the stronger tolerance entry as finite ledger data, while Q is read only after D has been displayed. Replaying C therefore keeps the earlier window, ledger, readback, and terminal seal available to every downstream consumer. □

Theorem 1423.13 (Real Cauchy modulus cofinal window extraction)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. For any two finite unary precision requests whose second request refines the first, the displayed modulus row M selects a finite* $\mathsf{StreamName}^{\uparrow}$ *window in S for the refined request that is cofinal over the earlier window. The extraction preserves the earlier* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger entry, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows H, C, P, N.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier cofinal window extraction`

Proof. Proceed by induction on the finite unary refinement. The base request is handled by threshold-window totality, Definition 1423.9, which forces the read through M and then the displayed finite window in S before D, Q, E are available.

For the refinement step, use precision induction from Definition 1423.11. The stronger request is still classified by the same carrier rows and therefore reads a scheduled threshold from M and a finite window from S.

Apply window monotonicity, Definition 1423.12. The refined window may enlarge the displayed StreamName data, but it preserves the earlier finite window, dyadic tolerance entry, regular readback, and terminal seal.

The continuation row C, transported by H and sourced by P, N, repacks this preserved route as one accepted carrier read. Thus the finite window extracted for the refined request is cofinal over the earlier one, with the tolerance ledger, readback, seal, and structural rows intact. □

Theorem 1423.14 (Real Cauchy modulus seal determinacy)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ and $B' = (M', S', D', Q', E', H', C', P', N')$ be accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packets. If their modulus schedules, stream windows, dyadic tolerance ledgers, regular readbacks, terminal seal rows, continuation replays, provenance rows, and local naming rows are componentwise* hsame*, then the local classifier exposes the same terminal* $\mathsf{Real}^{\uparrow}$ *seal route for B and B'.*

Proof. Project both accepted packets. By Definition 1423.5, acceptance already identifies each packet with a displayed carrier through componentwise hsame rows for the analytic and structural coordinates.

Use the assumed componentwise hsame witnesses for M and M', S and S', D and D', and Q and Q'. The threshold schedule, finite window, dyadic ledger, and regular readback are therefore read in the same classifier order for both packets.

It remains to compare the terminal seal route. The witnesses for E and E' identify the exposed $\mathsf{Real}^{\uparrow}$ seal rows, and the witnesses for C, P, N identify the replay, provenance, and local naming rows that present that seal to the consumer.

The Real seal nonescape theorem Definition 1423.4 prevents either packet from exposing a detached seal. Hence the classifier exposes one terminal $\mathsf{Real}^{\uparrow}$ route, carried by the componentwise hsame data, for both accepted packets. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier seal determinacy`

Theorem 1423.15 (Real Cauchy modulus window scope)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. Every finite precision request scopes only the displayed rows $M, S, D, Q, E, H, C, P, N$ over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *In particular, the request has no scope over quotient stream equality, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, ambient Real completeness, or an unbounded stream read.*

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier window scope`

Proof. Project the accepted packet through Definition 1423.1. The carrier lists exactly the modulus schedule, stream window, dyadic ledger, regular readback, terminal seal, transport, replay, provenance, and local naming rows.

Apply the route theorem Definition 1423.3 and the threshold-window totality theorem Definition 1423.9. They force a finite precision request to pass through M, then S, then D, then Q, and finally E, with H, C, P, N supplying the local transport and certificate data.

The exhaustion theorem Definition 1423.7 supplies the negative part of the scope claim. Since the non-displayed analytic principles are not rows of the packet and are not reached by the finite route, they cannot enter the finite-window scope. □

Theorem 1423.16 (Real Cauchy modulus tail-threshold determinacy)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. For any finite unary precision request, strengthening the dyadic request may enlarge the scheduled finite* $\mathsf{StreamName}^{\uparrow}$ *window, but it cannot replace the threshold selected by M, detach the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, or introduce a selected limit. The tail of the accepted route remains determined by the same modulus-controlled passage through M, S, D, Q, E.*

Proof. Proceed by induction on the finite unary precision request. At the zero stage, Definition 1423.15 identifies the available rows, and Definition 1423.9 fixes the order from threshold to window, ledger, readback, and seal.

For the successor stage, assume the preceding request already follows the displayed route. A stronger dyadic tolerance is still classified by Definition 1423.5, so the request reads the next threshold through the same modulus row M and schedules the corresponding finite window in S.

The monotonicity theorem Definition 1423.12 allows this window to grow while preserving the earlier window, ledger entry, readback row, and terminal seal. The RegSeqRat seal admission theorem Definition 1423.10 then keeps Q attached to the route from D to E.

Finally, Definition 1423.7 rules out selected limits and other non-displayed analytic sources at every induction stage. Thus the stronger request changes only the finite amount of displayed tail data, not the threshold route or the seal handoff. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier tail threshold determinacy`

Theorem 1423.17 (Real Cauchy modulus RegSeqRat classifier determinacy)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ and $B' = (M', S', D', Q', E', H', C', P', N')$ be accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packets. If the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows are componentwise* hsame*, then every terminal* $\mathsf{Real}^{\uparrow}$ *seal read factors through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier route before reaching E or E'.*

In particular, the terminal seal cannot be read directly from the dyadic ledger, from a detached stream representative, from host real equality, from countable choice, or from ambient Real completeness. The unique bridge from the dyadic tolerance ledger to the seal is the displayed $D \to Q \to E$ route transported by H, C, P, N.

Proof. Start with the finite-window route Definition 1423.3. It orders every accepted seal read through M, S, D, Q, E before the structural rows are consumed.

Use threshold-window totality from Definition 1423.9. The terminal route cannot skip from a precision request to D, Q, E; it first reads the scheduled threshold and finite StreamName window.

Now apply RegSeqRat seal admission, Definition 1423.10. It places the readback row Q as the only displayed bridge from the dyadic ledger D to the terminal seal E.

Finally use tail-threshold determinacy, Definition 1423.16. Strengthening the tail request may enlarge the finite window, but it preserves the same modulus-controlled route and keeps the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to the seal.

The componentwise hsame assumptions identify the schedules, windows, ledgers, and readback rows of B and B'. Since ledger exhaustion excludes detached stream representatives, host equality, countable choice, and ambient completeness, both terminal seal reads factor through the same $\mathsf{RegSeqRat}^{\uparrow}$ classifier route. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier regseqrat classifier determinacy`

Theorem 1423.18 (Real Cauchy modulus tail handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *completion consumer of an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet must pass through the displayed rows*

$$M, S, D, Q, E, H, C, P, N.$$

Tail-threshold determinacy composes with window monotonicity and seal determinacy: a stronger tail request may enlarge the finite $\mathsf{StreamName}^{\uparrow}$ *window selected by M, but it preserves the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and the structural rows that transport, replay, source, and name the route. No completion consumer can replace this handoff by quotient stream equality, selected limits, host real equality, countable choice, or ambient Real completeness.*

Proof. Start with the finite route theorem Definition 1423.3. It fixes the consumer route through M, S, D, Q, E before the structural rows are used.

Use window monotonicity from Definition 1423.12. Strengthening the requested tail may enlarge the displayed finite window, but it does not delete the earlier window, ledger entry, readback row, or terminal seal.

Apply seal determinacy from Definition 1423.14. Componentwise hsame agreement on the displayed rows exposes the same terminal $\mathsf{Real}^{\uparrow}$ route to the consumer.

Finally use tail-threshold determinacy, Definition 1423.16. The stronger tail request remains on the same modulus-controlled path, so every $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ completion consumer receives exactly the displayed handoff rows and no non-displayed completion principle. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier tail handoff`

Theorem 1423.19 (Real Cauchy modulus seal handoff)**.** *Every downstream Real-facing consumer of an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the same displayed finite route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E.$$

The handoff is mediated by the rows H, C, P, N *and cannot be replaced by Real completeness, quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, or an unbounded stream read.*

Proof. Begin with the finite-window scope theorem Definition 1423.15. It identifies the only rows available to a Real-facing consumer and fixes the analytic carriers through which the request may pass.

Use Definition 1423.16 for strengthened tail requests. The consumer may require a larger displayed window, but the threshold route, dyadic ledger, RegSeqRat readback, and terminal seal remain tied to the same modulus-controlled passage.

Now combine the original route theorem Definition 1423.3, threshold stability Definition 1423.6, ledger exhaustion Definition 1423.7, and seal determinacy Definition 1423.14. These results show that H transports the displayed rows, C replays the route, P records provenance, and N names the local certificate without adding another Real-facing access path.

The terminal handoff therefore reaches $\mathsf{Real}^{\uparrow}$ exactly at E. The negative alternatives are absent from the packet and blocked by the exhaustion and nonescape theorems, so every accepted downstream consumer receives the seal through the displayed finite route. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier seal handoff`

Theorem 1423.20 (Real Cauchy modulus cofinal refinement handoff)**.** *Let* $B = (M, S, D, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. If* B *is read through a cofinal or monotone modulus schedule supplied by the existing* $\mathsf{CauchyModulusRefinement}^{\uparrow}$ *and* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *surfaces, then every downstream Real-facing read still factors through the displayed route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto (H, C, P, N).$$

The cofinal or refined schedule may enlarge the finite window selected by M *and replay the same tail route, but it cannot replace the route by quotient stream equality, a selected limit, host real equality, countable choice, trichotomy, open-cover compactness, Real completeness, or a detached Real seal.*

Proof. Begin with the finite route theorem Definition 1423.3. It fixes the order from the modulus row M to the StreamName window row S, the DyadicRatCore ledger D, the RegSeqRat readback Q, and the terminal Real seal E.

For a stronger precision request, use window monotonicity and tail-threshold determinacy, Definition 1423.12 and Definition 1423.16. These allow the displayed finite window to grow while preserving the threshold route, the dyadic ledger, the regular readback, and the terminal seal handoff.

Now read the sibling cofinal data only as route data. The $\mathsf{CauchyModulusRefinement}^{\uparrow}$ cofinal-window factorization of Definition 885.15 supplies a refinement row for the finite-window schedule, and the $\mathsf{CofinalModulusSeal}^{\uparrow}$ cofinal route of Definition 1198.12 supplies the cofinal seal row. Neither sibling inserts a second Real seal into the $\mathsf{RealCauchyModulus}^{\uparrow}$ carrier.

Finally apply the seal handoff theorem Definition 1423.19. Since every Real-facing consumer of B reaches $\mathsf{Real}^{\uparrow}$ only through M, S, D, Q, E and the support rows H, C, P, N, the cofinal or monotone schedule preserves the same StreamName–DyadicRatCore–RegSeqRat–Real seal route and leaves the excluded completeness, choice, quotient, and host-equality alternatives outside the packet. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier cofinal refinement handoff`

Theorem 1423.21 (Real Cauchy modulus bounded tail-ledger factorization)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet, and let*

$$R_{\mathrm{bd}} = (S', M', B', Q', A', H', C', P', N')$$

be an accepted $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *packet consumed with componentwise matching modulus, window, dyadic ledger, RegSeqRat readback, and Real seal rows. Then every bounded tail-ledger read exported by the joint consumer factors first through the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E$$

and then through the bounded packet route

$$S' \longmapsto M' \longmapsto B' \longmapsto Q' \longmapsto A'.$$

The handoff exports no Real completeness theorem, quotient stream equality, selected limit, countable-choice schedule, trichotomy principle, open-cover compactness proof, or host real equality.

Proof. Begin with the cofinal refinement handoff Definition 1423.20. It shows that strengthened or cofinal tail requests still read the $\mathsf{RealCauchyModulus}^{\uparrow}$ packet through M, S, D, Q, E before any Real-facing seal is reached.

Next apply the seal handoff theorem Definition 1423.19. The terminal row E is therefore not a detachable Real object; it is the endpoint of the displayed modulus, window, dyadic-ledger, and readback route.

Now pass to the bounded consumer. The obligation surface of Definition 1697.2 identifies the bounded packet rows $S', M', B', Q', A', H', C', P', N'$, and the Real-seal boundary of Definition 1697.3 forces every bounded read through M', S', B', Q', A' before the terminal seal A' can be consumed.

The assumed componentwise matches identify the shared modulus, window, dyadic, readback, and seal rows at the interface. Thus a bounded tail-ledger read has only the composite finite passage displayed above, while the excluded completeness, quotient, choice, compactness, trichotomy, selected-limit, and host-equality coordinates remain absent from both carriers. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier bounded tail ledger factorization`

Theorem 1423.22 (Real Cauchy modulus bounded readback coherence)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet and let $R_{\mathrm{bd}} = (S', M', B', Q', A', H', C', P', N')$ be an accepted* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *packet. If the shared modulus, finite window, dyadic ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal rows agree componentwise by* hsame*, then the* $\mathsf{RealCauchyModulus}^{\uparrow}$

readback and the BoundedRegularCauchy$^{\uparrow}$ *readback expose the same terminal finite Real-facing route. In particular, the bounded consumer cannot introduce a detached seal beyond the matched E/A' boundary.*

Proof. Use seal determinacy Definition 1423.14 to pin the terminal Real$^{\uparrow}$ row of the RealCauchyModulus$^{\uparrow}$ packet to the displayed M, S, D, Q route. Ledger exhaustion Definition 1423.7 then prevents a second dyadic or readback ledger from being inserted between Q and E.

On the bounded side, apply tail-window induction Definition 1697.4. Each requested finite threshold is read through the same bounded route to A', and the induction has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, or Real completeness.

The componentwise hsame assumptions transport the modulus, window, dyadic ledger, readback, and seal rows across the interface. Hence the two readbacks terminate at the same finite Real-facing route, and any alleged detached seal would have to be a row not present in either displayed carrier. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier bounded readback coherence`

Theorem 1423.23 (Real Cauchy modulus uniform tail extraction)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* RealCauchyModulus$^{\uparrow}$ *packet whose threshold row has passed through the cofinal refinement handoff of Definition 1423.20. Then there is a single displayed finite tail window, read from the same M, S, D, Q, E route, that every* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *consumer named in the bounded readback coherence theorem Definition 1423.22 may use. Enlarging a requested tolerance only replaces the displayed window by a later cofinal window; it does not introduce quotient stream equality, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, Real completeness, or a detached Real seal.*

Proof. Start with threshold stability, Definition 1423.6. It transports a stronger tolerance request along the same modulus row M, finite window row S, dyadic ledger D, RegSeqRat readback Q, and terminal Real seal E.

Next use the cofinal refinement handoff, Definition 1423.20. A later cofinal threshold may replace the initially requested tail window, but the replacement is still a displayed finite window in the same carrier route and is replayed by the same structural rows H, C, P, N.

Finally apply bounded readback coherence, Definition 1423.22. Its componentwise hsame matches force the RegSeqRat and Real-facing bounded consumers to read the same terminal finite route, so the cofinal window obtained above is uniform for all those consumers.

The excluded alternatives have no coordinate in either carrier and cannot be inserted between the matched readback and seal rows. Therefore the accepted packet exposes one reusable finite tail window for the bounded RegSeqRat and Real consumers. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier uniform tail extraction`

Theorem 1423.24 (Real Cauchy modulus finite-window tightening)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* RealCauchyModulus$^{\uparrow}$ *packet. Suppose a displayed precision request is tightened and the cofinal refinement row of Definition 1423.20 is available for the same packet. Then the resulting later finite* StreamName$^{\uparrow}$ *window still factors through the original route*

$$M \longmapsto S \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

The tightened request keeps the same CauchyModulus$^{\uparrow}$ *row M,* DyadicRatCore$^{\uparrow}$ *ledger D,* RegSeqRat$^{\uparrow}$ *readback Q, and* Real$^{\uparrow}$ *seal E. It introduces no detached seal, selected limit, quotient stream, host*

real equality, countable-choice schedule, open-cover compactness, trichotomy, or ambient completeness row.

Proof. Start with the cofinal refinement handoff Definition 1423.20. It permits the tightened precision request to move to a later finite window while preserving the route through M, S, D, Q, E.

Use uniform tail extraction, Definition 1423.23. The later window is not a new endpoint; it is the finite tail window that every named $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumer may reuse through the same structural rows.

Apply bounded readback coherence from Definition 1423.22. It keeps the readback row Q and the terminal seal E componentwise matched with any bounded consumer that reads the tightened window.

Finally use ledger exhaustion, Definition 1423.7. Since the dyadic tolerance ledger is already exhausted by D before Q and E are read, there is no remaining coordinate for a detached seal, selected limit, quotient stream, host real equality, choice schedule, compactness proof, trichotomy principle, or ambient completeness row. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier finite window tightening`

Theorem 1423.25 (Real Cauchy modulus obligation closure package)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. The carrier of Definition 1423.1, classifier of Definition 1423.5, NameCert obligations of Definition 1423.2, finite-window route of Definition 1423.3, threshold stability of Definition 1423.6, ledger exhaustion of Definition 1423.7, cofinal refinement handoff of Definition 1423.20, uniform tail extraction of Definition 1423.23, bounded readback coherence of Definition 1423.22, and finite-window tightening of Definition 1423.24 jointly supply the obligation surface for the nine-row packet B. The package introduces no Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, or open-cover compactness.*

Proof. Project the accepted packet through the carrier and classifier. The only visible rows are the modulus row M, finite $\mathsf{StreamName}^{\uparrow}$ window row S, dyadic tolerance ledger D, $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, terminal $\mathsf{Real}^{\uparrow}$ seal E, componentwise transport H, displayed replay C, provenance P, and local naming row N.

Apply the NameCert obligations and finite-window route. These two sites bind the local naming surface to the displayed route from modulus requests through finite windows, dyadic tolerance data, readback, and the Real seal.

Use threshold stability, cofinal refinement handoff, uniform tail extraction, bounded readback coherence, and finite-window tightening. Together they show that stronger precision requests only move to later displayed windows on the same route and that every bounded consumer reuses the same readback and seal rows.

Finally apply ledger exhaustion. Since the dyadic ledger is already exhausted before the readback and terminal seal are consumed, there is no remaining carrier coordinate for Real completeness, quotient streams, host equality, countable choice, trichotomy, selected limits, or open-cover compactness. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier obligation closure package`

Theorem 1423.26 (Real Cauchy modulus finite modulus-index induction)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. Every finite family of precision requests indexed by a*

unary finite window is handled by induction on the displayed modulus-index spine. At each successor step the same route

$$M \to S \to D \to Q \to E \to H, C, P, N$$

is preserved, and the induction exposes no unbounded stream read, choice schedule, quotient stream equality, selected limit, or Real completeness row.

Proof. Start with precision induction from Definition 1423.11. The base request reads the displayed modulus row M, the finite window row S, the dyadic ledger D, the regular readback Q, and the terminal seal E through the transported and replayed rows H, C, P, N.

For the successor step, apply window monotonicity from Definition 1423.12. Enlarging the unary finite window preserves the earlier request rows and moves only to a later displayed modulus index on the same spine.

Use uniform tail extraction from Definition 1423.23 to reuse the later finite tail for the whole indexed family. This is finite induction on the BEDC request spine, not a host choice over all precisions.

Finally apply ledger exhaustion from Definition 1423.7. Since every step is already routed through $M, S, D, Q, E, H, C, P, N$, there is no coordinate for an unbounded stream read, quotient stream equality, selected limit, countable-choice schedule, or ambient Real-completeness argument. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier finite modulus index induction`

Theorem 1423.27 (Real Cauchy modulus tail-coherence completeness handoff)**.** *Let $B = (M, S, D, Q, E, H, C, P,$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. Any finite tail-coherence read that is passed from B to a completion witness must preserve the displayed route through* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The handoff may tighten a finite window or move to a later cofinal tail window, but it may not replace the route with quotient stream equality, selected limits, countable choice, host real equality, trichotomy, open-cover compactness, or ambient Real completeness.*

Proof. Begin with precision induction, Definition 1423.11. It makes each requested tail threshold a finite step on the displayed modulus spine rather than a global choice over all precisions.

Apply window monotonicity, Definition 1423.12. Enlarging the finite window keeps the same $M, S, D, Q, E, H, C, P, N$ route and only moves to a later displayed window.

Use uniform tail extraction, Definition 1423.23. The tail-coherence read exported to a completion witness is the same finite tail window already available to every named $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumer.

Finally apply ledger exhaustion, Definition 1423.7. The dyadic tolerance data has no unused coordinate from which quotient stream equality, selected limits, countable choice, host equality, trichotomy, compactness, or ambient completeness could be inserted into the handoff. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier tail coherence completeness handoff`

Falsifiable prediction: An accepted $\mathsf{RealCauchyModulus}^{\uparrow}$ consumer that reads a terminal Real seal without the explicit modulus threshold, finite StreamName window, DyadicRatCore tolerance ledger, and RegSeqRat readback refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchymodulus: no listed sibling supplies the whole nine-row packet $B = (M, S, D, Q, E, H, C, P, N)$, because each sibling

contributes only a window, readback, tolerance, seal, or generic schedule surface while this chapter binds all five analytic faces with transport, replay, provenance, and local naming.

Theorem 1423.28 (Real Cauchy modulus uniform cofinal seal)**.** *Let $B = (M, S, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RealCauchyModulus}^{\uparrow}$ *packet. If the modulus row M is transported through the sibling lattice*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{CauchyModulus}^{\uparrow}$$

named by chapter 292, then every finite precision request yields a classifier-stable cofinal seal through the displayed route

$$M \to S \to D \to Q \to E \to H, C, P, N.$$

The exported row is uniform over finite precision requests and contains no selected real representative, host convergence principle, quotient stream equality, countable-choice schedule, or detached Real seal.

Proof. Start with finite modulus-index induction from Definition 1423.26. It handles a finite family of precision requests by induction on the displayed modulus-index spine while preserving the route through $M, S, D, Q, E, H, C, P, N$.

Read the sibling lattice as carrier data. The StreamName row supplies the finite windows, the RegSeqRat row supplies the regular readback, the DyadicRatCore row supplies the tolerance ledger, the Real row supplies the terminal seal, and the CauchyModulus chapter cited above supplies the schedule discipline for cofinal requests.

Now apply cofinal refinement handoff and uniform tail extraction. A later cofinal threshold may enlarge the finite window, but the transported request still reaches the same terminal route and is replayed by the same classifier rows H, C, P, N.

Finally use ledger exhaustion. Since every precision request has already consumed the displayed modulus, window, tolerance, readback, and seal rows, the cofinal seal cannot import a selected representative, host convergence theorem, quotient stream equality, countable-choice schedule, or detached Real seal. □

Lean4 ✓ `BEDC.Derived.RealCauchyModulusUp.RealCauchyModulusCarrier uniform cofinal seal certificate`

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCauchyModulus}^{\uparrow}$ packet is generated from an explicit $\mathsf{CauchyModulus}^{\uparrow}$ precision schedule, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}, \mathsf{maturePackageClosed})$

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: paperBridge

Not claimed: This chapter does not close Real completeness, quotient stream equality, host real equality, countable choice, trichotomy, selected limits, open-cover compactness, or a Lean theorem.

Upgrade path: Mature closure requires a checked standard bridge for the nine-row carrier and finite-window Real seal route.

Chapter 1424

A Concrete Naming Certificate for $\mathsf{DedekindCauchyComparison}^{\uparrow}$

Following Bishop and Bridges and Troelstra–van Dalen, the $\mathsf{DedekindCauchyComparison}^{\uparrow}$ packet records the finite comparison boundary between rounded located cut observations and regular Cauchy name observations. It reads the cut surface of chapter 436, the Cauchy equivalence surface of chapter 1412, the regular rational name surface of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a representation comparison certificate, not a Dedekind construction of $\mathsf{Real}^{\uparrow}$ and not a completeness theorem.

Definition 1424.1 (DedekindCauchyComparison carrier)**.** *A* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, R, W, T, E, H, C, P, N)$$

with the following displayed coordinates:

1. *D is the* $\mathsf{DedekindCut}^{\uparrow}$ *row, carrying lower and upper rational-observation data together with roundedness, locatedness, and disjointness evidence;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, carrying the regular rational sequence surface that is allowed to answer finite tolerance requests;*
3. *W is the family of finite* $\mathsf{StreamName}^{\uparrow}$ *windows through which R is read by downstream consumers;*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radii, comparison budgets, and finite refinement rows used to compare D with R;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary row reached from the displayed cut and regular-sequence observations, with no independent completed-real coordinate;*
6. *H stores componentwise* hsame *transports for D, R, W, T, E;*
7. *C stores the displayed* Cont *replay routes for rereading the same finite cut observations, stream windows, tolerance rows, and seal boundary rows;*
8. *P is the* Pkg *provenance over* $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}^{\uparrow}}$ *evidence.*

The carrier has no coordinate for a quotient cut, a host real equality proof, a selected limit, countable choice, a construction of $\mathsf{Real}^{\uparrow}$ *from Dedekind cuts, or an ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.DedekindCauchyComparisonUp.DedekindCauchyComparisonTasteGate single carrier alignment`

Theorem 1424.2 (DedekindCauchyComparison NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}}$ *surface for the carrier of Definition 1424.1 consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the packet* $K = (D, R, W, T, E, H, C, P, N)$ *with its displayed cut row, regular sequence row, stream windows, dyadic tolerance ledger, seal boundary, transports, continuations, package provenance, and local naming evidence;*
2. *classifier: comparison reads only rational cut observations in* D*, finite regular-sequence observations in* R*, the windows* W*, and the dyadic budgets* T*;*
3. *transport stability:* H *and* C *preserve the same cut observations, sequence windows, tolerance rows, and seal boundary under accepted consumer motion;*
4. *exactness: every comparison-facing read is supplied by the displayed rows* D, R, W, T, E *after the componentwise transport and replay routes are fixed;*
5. *ledger: every downstream* $\mathsf{Real}^{\uparrow}$ *consumer first reads the comparison packet through* $D, R, W, T, E, H, C, P, N$ *and receives no hidden completion coordinate.*

Proof. Carrier admission is projection from the packet $K = (D, R, W, T, E, H, C, P, N)$. The displayed cut row, regular sequence row, stream-window family, dyadic tolerance ledger, seal boundary, transports, continuations, provenance, and local naming evidence are exactly the coordinates named by the carrier.

The classifier is finite because every comparison request is routed through the stored rational observations in D, the finite windows W of the regular sequence row R, and the dyadic tolerance ledger T. No classifier step can inspect a quotient cut or an unbounded real object.

Transport stability uses H componentwise and then replays the same consumer path through C. The replay returns to the stored rows D, R, W, T, E and therefore preserves the same finite observation surface.

Exactness and the ledger clause follow from the same inventory. Since the carrier contains no selected limit, host real equality proof, countable-choice schedule, Dedekind construction row for $\mathsf{Real}^{\uparrow}$, or completeness principle, every downstream comparison is exhausted by the displayed packet rows. □

Theorem 1424.3 (DedekindCauchyComparison Real boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{DedekindCauchyComparison}^{\uparrow}$ *carrier is only a representation boundary between the displayed* $\mathsf{DedekindCut}^{\uparrow}$ *row and the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row. The boundary supplies no quotient cut, no host real equality, no selected limit, no countable choice, no Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, and no completeness theorem.*

Proof. Project the accepted carrier. Its real-facing coordinate is the seal boundary row E, and E is stored together with the cut row D, regular rational row R, finite stream-window family W, and dyadic tolerance ledger T.

Read a comparison request in finite order. The consumer first exposes rational cut observations from D, then reads the corresponding finite windows W of R, and then checks the dyadic budgets recorded in T.

Only after those rows have been fixed can the consumer read the seal boundary E. The transport and replay rows H and C preserve that same route, while P and N record provenance and local naming.

Thus the packet exports a comparison boundary only. A quotient cut, host real equality proof, selected limit, countable-choice schedule, Dedekind construction of $\mathsf{Real}^{\uparrow}$, and completeness theorem have no carrier coordinate and cannot be read from the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindCauchyComparison}^{\uparrow}$ packet is generated from a $\mathsf{DedekindCut}^{\uparrow}$ row, a $\mathsf{RegSeqRat}^{\uparrow}$ row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, a $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1424.1, Definition 1424.2, and Definition 1424.3 seed the finite representation-comparison boundary between Dedekind-cut observations and regular Cauchy name observations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCauchyComparison}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DedekindCauchyComparisonUp.DedekindCauchyComparisonTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not close quotient cuts, host real equality, selected limits, countable choice, Dedekind construction of $\mathsf{Real}^{\uparrow}$, completeness, or bridge checking.

Upgrade path: Scoped closure requires a checked finite carrier theorem binding the displayed cut row, regular sequence row, stream windows, dyadic tolerance ledger, and Real-seal boundary.

Chapter 1425

A Concrete Naming Certificate for RegularCauchyCompletionUniversal$^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the RegularCauchyCompletionUniversal$^{\uparrow}$ packet isolates the regular-Cauchy universal-property seed for the L10 Real and Completion route. It refines the general CompletionUniversalProperty$^{\uparrow}$ surface of chapter 397 by forcing every extension and uniqueness read through the finite regular-name chain already exposed by chapter 652, chapter 1404, chapter 126, chapter 301, chapter 291, and chapter 38.

The purpose of the packet is local. It names the rows needed for extending a regular-Cauchy source route into the terminal Real$^{\uparrow}$ seal and for comparing any two such extensions by the displayed hsame ledger. It does not claim the full ambient completeness of Real$^{\uparrow}$, nor does it replace the mature general completion chapter.

Definition 1425.1 (RegularCauchyCompletionUniversal carrier)**.** *A* RegularCauchyCompletionUniversal$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, W, D, R, A, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the regular source row whose admissible names are read as* RegSeqRat$^{\uparrow}$ *data;*
2. *W is the* StreamName$^{\uparrow}$ *finite-window schedule used by the same regular source;*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger attached to those windows;*
4. *R is the* RegularCauchyEquivalence$^{\uparrow}$ *comparison row for replacing regular names without leaving the finite route;*
5. *A is the terminal* Real$^{\uparrow}$ *seal reached through the displayed regular source, window, tolerance, and equivalence rows;*
6. *E is the extension route row, read as the* CompletionUniversalProperty$^{\uparrow}$ *extension face restricted to S, W, D, R, A;*
7. *L is the uniqueness* hsame *ledger comparing two extension routes over the same regular source, finite windows, dyadic ledger, equivalence row, and terminal seal;*
8. *H records the componentwise* hsame *transports for S, W, D, R, A, E, L;*
9. *C records the displayed* Cont *routes that replay the extension and uniqueness reads;*

10. *P is the* Pkg *provenance over* CompletionUniversalProperty$^{\uparrow}$, RealCompletionWitnessExtractor$^{\uparrow}$, RegularCauchyEquivalence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{RegularCauchyCompletionUniversal}^{\uparrow}}$ *row.*

The accepted carrier stores no quotient stream, no selected host limit, no host real equality row, no countable-choice selector, and no ambient Real$^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionUniversalUp.RegularCauchyCompletionUniversalTasteGate single carrier alignment`

Theorem 1425.2 (Regular extension route)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* RegularCauchyCompletionUniversal$^{\uparrow}$ *packet. Every extension consumer of E first reads the regular source S, then the finite* StreamName$^{\uparrow}$ *windows W, then the* DyadicRatCore$^{\uparrow}$ *ledger D, then the* RegularCauchyEquivalence$^{\uparrow}$ *comparison row R, and only then reaches the terminal* Real$^{\uparrow}$ *seal A and the restricted* CompletionUniversalProperty$^{\uparrow}$ *extension face.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionUniversalUp.RegularCauchyCompletionUniversal extension route`

Proof. Project the carrier of Definition 1425.1. The extension row E is not stored as a detached completion theorem; it appears after the regular source, the scheduled finite windows, the dyadic ledger, the equivalence row, and the terminal Real seal.

Read the sibling surfaces in the displayed order. The StreamName, RegSeqRat, DyadicRatCore, RegularCauchyEquivalence, and Real chapters provide exactly the finite route named by S, W, D, R, A, while the general completion chapter supplies the extension face only after that route has been exposed.

The continuation row C can replay only those displayed reads, and the provenance row P records no selected limit or host completion object. Therefore every extension consumer factors through the regular-Cauchy route before it reaches the universal-property face. □

Theorem 1425.3 (Regular uniqueness ledger)**.** *For accepted packets $U = (S, W, D, R, A, E, L, H, C, P, N)$ and $U' = (S, W, D, R, A, E', L', H', C', P, N')$ over the same regular source, finite windows, dyadic ledger, equivalence row, terminal seal, and provenance, any comparison between the exported extension routes is exhausted by the displayed uniqueness ledgers L and L' together with their componentwise* hsame *transports. No quotient-stream equality, selected host limit, host real equality, countable choice, or ambient completeness row can contribute to the comparison.*

Proof. Start with the shared coordinates S, W, D, R, A, P. They fix the regular source, scheduled windows, tolerance ledger, regular-Cauchy comparison row, and terminal Real seal for both packets.

The only coordinates that can distinguish the two extension exports are E, L, H, C, N and E', L', H', C', N'. The ledgers L and L' compare the extension rows over the same shared route, while H, H' and C, C' display the permitted transports and replays.

Since neither carrier contains a quotient stream, selected host limit, host real equality row, countable-choice selector, or ambient completeness coordinate, no external equality principle can enter the comparison. The uniqueness judgement is exactly the local hsame ledger over the shared regular-Cauchy route. □

Theorem 1425.4 (Regular section law)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* RegularCauchyCompletionUniversal$^{\uparrow}$ *packet. If a consumer first includes the displayed regular source*

through S, W, D, R into the terminal $\mathsf{Real}^{\uparrow}$ *seal A and then reads the restricted extension face E, the exported route is compared by the local uniqueness ledger L to the original A-sealed route. No quotient stream, selected limit, host real equality, countable choice, or ambient completeness row mediates this section comparison.*

Proof. Project the carrier of Definition 1425.1. The displayed source inclusion has only the coordinates S, W, D, R, A available before the extension face is read.

Apply Definition 1425.2. It forces every consumer of E to pass through the source row, finite windows, dyadic ledger, regular-Cauchy comparison row, and terminal Real seal in that order, so the restricted extension face is attached to the same finite route as the original A-sealed read.

Apply Definition 1425.3 with the shared coordinates fixed by this route. The ledger L, together with the displayed transports H and replays C, is the only comparison surface for the extension export over S, W, D, R, A.

The remaining rows P and N record provenance and the local NameCert seal, and no carrier coordinate stores a quotient stream, selected limit, host real equality, countable-choice selector, or ambient completeness witness. Thus L, H, C, P, N exhaust the section comparison inside the packet. □

Theorem 1425.5 (Regular Real-seal factorization)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of U must read the finite route*

$$S \longrightarrow W \longrightarrow D \longrightarrow R \longrightarrow A$$

before it may inspect the extension face E or the uniqueness ledger L. No quotient stream, selected limit, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate can factor the same accepted read.*

Proof. Project the carrier of Definition 1425.1. The Real-facing rows appear as the regular source S, finite windows W, dyadic ledger D, regular-Cauchy comparison row R, and terminal Real seal A.

Apply Definition 1425.2 to the extension face E. It forces every extension read to pass through S, W, D, R, A before the restricted completion face is available.

Apply Definition 1425.3 to comparisons that use L. The ledger compares extension routes only over the same displayed source, window, dyadic, comparison, and Real-seal rows.

The remaining coordinates H, C, P, N transport, replay, source, and name this route. Since the carrier stores no quotient stream, selected limit, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness row, coordinate exhaustion gives the stated factorization boundary. □

Theorem 1425.6 (RegularCauchyCompletionUniversal NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCor}}$ *surface consists exactly of carrier admission, the regular extension route, the uniqueness ledger, the section law, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming over* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*,* $\mathsf{RealCompletionWitnessExtractor}^{\uparrow}$*,* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

Proof. Carrier admission is the packet shape of Definition 1425.1. Its rows name the regular source, finite windows, dyadic ledger, comparison row, terminal Real seal, extension route, uniqueness ledger, componentwise transports, continuation replays, provenance, and local certificate.

The regular extension route is bound by Definition 1425.2. The uniqueness ledger is bound by Definition 1425.3, and the section law is bound by Definition 1425.4.

No remaining coordinate is available in the carrier. Therefore the displayed rows exhaust the local NameCert obligation surface over the listed kernel and sibling objects. □

Theorem 1425.7 (RegularCauchyCompletionUniversal kernel scope)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *packet. The extension, uniqueness, and section obligations of Definition 1425.6 are scoped through the displayed kernel rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*: the only admissible reads are carrier projection from U, componentwise comparison through H, continuation replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier $U = (S, W, D, R, A, E, L, H, C, P, N)$. The rows H, C, P, N are the only structural coordinates after the source, window, ledger, equivalence, seal, extension, and uniqueness entries have been displayed.

The extension route can therefore be replayed only through the Cont rows stored in C. The uniqueness and section comparisons can be transported only through the componentwise hsame rows stored in H.

The remaining structural access is provenance and naming. The rows P and N bind the route to Pkg and NameCert, so the kernel scope is exhausted by the displayed BHist, hsame, Cont, Pkg, and NameCert rows. □

Theorem 1425.8 (RegularCauchyCompletionUniversal real seal scope)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *packet. Every real-facing obligation in the extension, uniqueness, and section surface is scoped through the sibling rows* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*: W supplies the finite windows, S supplies the regular source, D supplies the dyadic ledger, R supplies the equivalence boundary, and A supplies the terminal Real seal.*

Proof. Project U and read the real-facing coordinates in order. The source row S is usable only with the finite windows W, and the tolerance row D is the only dyadic ledger available before equality-facing comparison.

The comparison row R is the displayed $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ boundary. It is reached after S, W, D and before the terminal seal, so no quotient equality or host real equality can intervene.

The row A is the only $\mathsf{Real}^{\uparrow}$ seal in the carrier. Hence every real-facing extension, uniqueness, and section read is sealed by A after the StreamName, RegSeqRat, DyadicRatCore, and RegularCauchyEquivalence rows have been displayed. □

Theorem 1425.9 (RegularCauchyCompletionUniversal extractor scope)**.** *Let $U = (S, W, D, R, A, E, L, H, C, P, N$ be an accepted* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *packet. The completion-facing obligations are scoped through the displayed* $\mathsf{RealCompletionWitnessExtractor}^{\uparrow}$ *and restricted completion row: the extractor is read only after S, W, D, R, A, the extension face is E, and the section comparison is the local ledger L transported through H and replayed through C.*

Proof. Project the carrier and isolate the completion-facing rows. The extractor-facing source data are exactly S, W, D, R, A, already sealed as the regular-Cauchy route of Definition 1425.8.

The extension face E is downstream of those rows. It cannot read a quotient completion, a selected host limit, or an ambient completeness theorem because none of those objects has a coordinate in U.

The section comparison is then local. The ledger L compares the extension route with the original Real-sealed route, while H and C provide the only permitted transport and replay rows for that comparison. □

Theorem 1425.10 (RegularCauchyCompletionUniversal public export)**.** *Every public consumer of an accepted* RegularCauchyCompletionUniversal$^{\uparrow}$ *packet receives exactly the extension route, uniqueness ledger, section law, componentwise transport, continuation replay, provenance, and local* NameCert *rows scoped by the displayed kernel rows of Definition 1425.7, the Real-seal rows of Definition 1425.8, and the completion-extractor rows of Definition 1425.9. The exported surface contains no quotient stream, selected host limit, host real equality, countable choice, ambient RealUp completeness, or standard bridge row.*

Proof. Start with the accepted carrier $U = (S, W, D, R, A, E, L, H, C, P, N)$. The kernel scope theorem fixes the only structural rows visible to a consumer: carrier projection through U, transport through H, replay through C, provenance through P, and local naming through N.

Next read the Real-facing route. The Real-seal scope theorem requires every extension, uniqueness, or section read to pass through S, W, D, R, A before any completion-facing row is visible, so a public consumer cannot substitute quotient stream equality or host real equality for the displayed seal.

Finally apply the completion-extractor scope theorem. It identifies the completion-facing export as the restricted extension row E together with the local uniqueness and section ledger L transported by H and replayed by C. Thus the public export is exactly the listed route, ledger, law, transport, replay, provenance, and local certificate rows. □

Closure status for NameCert$_{\text{RegularCauchyCompletionUniversal}^{\uparrow}}$.

Constructive story: A RegularCauchyCompletionUniversal$^{\uparrow}$ packet is generated from a regular source row, StreamName windows, a dyadic tolerance ledger, a RegularCauchyEquivalence row, a RealUp seal, an extension route, a uniqueness hsame ledger, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCompletionUniversal}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1425.7, Definition 1425.8, Definition 1425.9, and Definition 1425.10 bind carrier admission, extension, uniqueness, section, transport, replay, provenance, naming, public consumer export, and the restricted completion-interface bridge to the displayed kernel, Real-route, and completion-extractor rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionUniversal}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.RegularCauchyCompletionUniversalUp.RegularCauchyCompletionUniversalTasteGate\_single\_c`

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected host limits, host real equality, countable choice, ambient RealUp completeness, or a standard bridge.

Upgrade path: No further paper-side theory-axis upgrade remains; formal bridge checking remains on the independent verification axis.

Chapter 1426

A Concrete Naming Certificate for $\mathsf{CauchyControlSequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyControlSequence}^{\uparrow}$ packet names the explicit control data carried by a regular Cauchy real-name route before the terminal $\mathsf{Real}^{\uparrow}$ seal is read. It is the finite NameCert surface that exposes the dependency route through chapter 291, chapter 126, chapter 301, chapter 38, and chapter 1423.

The packet separates the displayed control row from the sealed real object. A consumer receives a scheduled stream window, a dyadic tolerance row, a regular rational readback row, the control/modulus row that binds these data, and the provenance rows needed for local naming; it does not receive a host completeness principle or a chosen limit.

Definition 1426.1 (CauchyControlSequence carrier)**.** *A* $\mathsf{CauchyControlSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(R, W, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational name whose Cauchy control is being exposed;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to inspect the same regular name;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row governing the displayed window bounds and dyadic comparison budget;*
4. *M is the control/modulus row, read as the local* $\mathsf{RealCauchyModulus}^{\uparrow}$ *surface binding the windows W, tolerances D, and regular readback R;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after the readback, window, tolerance, and control rows have been displayed;*
6. *H records the componentwise* hsame *transports for R, W, D, M, E;*
7. *C records the displayed* Cont *routes by which consumers replay the readback, finite-window, tolerance, control, and seal handoff;*
8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyControlSequence}^{\uparrow}}$ *row.*

The carrier stores no quotient stream equality, no selected limit, no trichotomy branch, and no ambient completeness coordinate for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyControlSequenceUp.TasteGate.CauchyControlSequenceTasteGate single carrier alignment`

Theorem 1426.2 (CauchyControlSequence NameCert obligations)**.** *For an accepted* $\mathsf{CauchyControlSequence}^{\uparrow}$ *carrier* $(R, W, D, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyControlSequence}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *carrier formation for the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, displayed control/modulus row,* $\mathsf{Real}^{\uparrow}$ *seal handoff, transports, continuations, provenance, and local naming data;*
2. *classifier stability, stating that replacement of the displayed rows through* H *and replay through* C *preserves the same accepted control-sequence packet;*
3. *control-window coverage, stating that the control row* M *covers exactly the finite windows* W *at the dyadic tolerances recorded by* D*;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, stating that the regular rational readback* R *is the only source row inspected by the control/modulus surface;*
5. *Real seal non-escape, stating that the handoff* E *reaches* $\mathsf{Real}^{\uparrow}$ *only through* R, W, D, M, H, C, P, N *and not through quotient stream equality, a chosen limit, trichotomy, or ambient completeness.*

Proof. Carrier formation is the tuple of Definition 1426.1. It exposes exactly one regular rational readback row, one finite-window schedule, one dyadic tolerance row, one control/modulus row, one Real seal handoff, and the local transport, continuation, package, and naming rows.

Classifier stability is componentwise over H and C. The replacement rows may transport the displayed coordinates and replay their consumers, but they do not introduce a second source row, a second tolerance ledger, or an external equality principle.

Control-window coverage is the binding role of M. The control row is accepted only as a displayed modulus for the windows W and tolerances D, with the regular readback R providing the rational values inspected inside those windows.

The $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the Real seal non-escape are then immediate from the carrier inventory. Since E appears after R, W, D, M and the provenance rows contain no quotient, chosen limit, trichotomy, or completeness coordinate, every seal-facing read is forced through the finite control route. □

Theorem 1426.3 (CauchyControlSequence Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyControlSequence}^{\uparrow}$ *packet factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the control row* M*, the* hsame *and* Cont *provenance rows* H *and* C*, the package row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchyControlSequence}^{\uparrow}}$ *row* N *before reaching the seal handoff* E*.*

Proof. Project the accepted carrier. The seal handoff coordinate E is stored only after the regular readback, finite-window schedule, dyadic tolerance row, and displayed control row.

Read the sibling surfaces in the displayed order. The StreamName row supplies the finite windows, the DyadicRatCore row supplies the tolerance arithmetic, the RegSeqRat row supplies the rational readback, and the RealCauchyModulus row binds these data as a control surface.

The rows H, C, P, N then record the only allowed transports, replays, package provenance, and local naming evidence. Therefore a Real-facing consumer cannot bypass the displayed control route before it reaches E. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyControlSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyControlSequence}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a displayed control/modulus row, a $\mathsf{Real}^{\uparrow}$ seal handoff, componentwise hsame transport, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyControlSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1426.1, Definition 1426.2, and Definition 1426.3 bind the explicit Cauchy control data used before the Real seal handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyControlSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host completeness, quotient stream equality, chosen limits, trichotomy, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier formation, classifier stability, control-window coverage, RegSeqRat handoff, and Real seal non-escape for the displayed control packet.

Chapter 1427

A Concrete Naming Certificate for $\mathsf{LocatedSupremum}^{\uparrow}$

Following Bishop and Bridges-style constructive analysis, the $\mathsf{LocatedSupremum}^{\uparrow}$ packet records the least-upper-bound-shaped data that is available before any ambient completeness principle for $\mathsf{Real}^{\uparrow}$. It is a located upper-bound certificate over the located-cut and located-real surfaces of chapter 404 and **??**, the comparison discipline of chapter 1381, the regular-rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite interface for Real and Completion consumers that need upper-bound and lower-approximation reads; it is not a completeness theorem for arbitrary real subsets.

Definition 1427.1 (LocatedSupremum carrier)**.** *A* $\mathsf{LocatedSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, A, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is a located-cut or located-real family row, read through the finite locatedness and comparison surfaces of the sibling* $\mathsf{LocatedCut}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*, and* $\mathsf{BishopRealComparison}^{\uparrow}$ *chapters;*
2. *U is the upper-bound ledger, displaying the inspected bound claims and the finite comparison rows that certify each requested member of L below the proposed bound surface;*
3. *A is the lower-approximation and cofinality ledger, displaying the finite rational or dyadic witnesses that approach the bound surface from the family side at the precisions requested by the consumer;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *precision-window row that fixes which finite observations of the family, bound ledger, and approximation ledger are in scope;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that repacks the windowed observations as regular rational readback data;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only through L, U, A, W, R;*
7. *H records the componentwise* hsame *transports for the family row, upper-bound ledger, approximation ledger, precision windows, regular handoff, real seal, continuation routes, provenance, and local naming row;*
8. *C records the displayed* Cont *routes that replay upper-bound reads, lower-approximation reads, classifier transport, and real-seal readback;*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSupremum}^{\uparrow}}$ *row.*

The accepted carrier stores no quotient cut, no selected supremum element, no trichotomy oracle, no host real equality test, and no ambient order-completeness coordinate.

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier semantic name certificate`

Theorem 1427.2 (LocatedSupremum NameCert obligations)**.** *For an accepted packet $S = (L, U, A, W, R, E, H, C,$ the local* $\mathsf{NameCert}_{\mathsf{LocatedSupremum}^{\uparrow}}$ *obligations are exactly the following finite rows:*

1. *carrier admission: the accepted object is the displayed packet with a located family row, upper-bound ledger, lower-approximation ledger, precision window, regular-rational handoff, real seal, transports, continuations, provenance, and local naming data;*
2. *located upper-bound stability: replacing L, U, W, R, E along the displayed* hsame *transports preserves the same upper-bound ledger reads through the* $\mathsf{BishopRealComparison}^{\uparrow}$ *comparison surface;*
3. *lower-approximation cofinality: every requested precision in W receives a displayed approximation row in A whose readback reaches the same bound surface through R and E;*
4. *classifier transport: the componentwise transports in H are sufficient to move the located family, bound ledger, approximation ledger, precision window, regular handoff, and real seal through the same classifier routes;*
5. *ledger exhaustion: every admissible upper-bound or lower-approximation consumer must read one of the rows $L, U, A, W, R, E, H, C, P, N$ before obtaining any real-facing observation;*
6. *handoff stability: the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and* $\mathsf{Real}^{\uparrow}$ *seal E remain attached to the same displayed precision window and ledgers under the continuation routes in C.*

No obligation may call on a quotient cut, selected supremum, trichotomy, host real equality, countable choice, or ambient order completeness.

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumTasteGate single carrier alignment`

Proof. Project the accepted carrier row by row. Carrier admission is immediate from the displayed BHist packet, and located upper-bound stability reads only the family row L, the upper-bound ledger U, the precision window W, the regular handoff R, the seal E, and the componentwise transports in H.

For lower approximation, inspect the requested precision row in W. The cofinality ledger A supplies the finite approximation witness at that precision, and the same witness is repacked by R before reaching the $\mathsf{Real}^{\uparrow}$ seal E.

Classifier transport and ledger exhaustion are structural. The continuation routes in C can replay only the displayed upper-bound, approximation, handoff, and seal reads, while P records exactly the sibling BEDC surfaces named in the carrier. Since the carrier contains no quotient cut, selected supremum, trichotomy row, host equality test, choice functional, or completeness coordinate, those principles cannot appear in the local NameCert obligations. □

Theorem 1427.3 (LocatedSupremum real-seal boundary)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *read exported by S factors through the located upper-bound ledger U, the lower-approximation row A, the* $\mathsf{StreamName}^{\uparrow}$ *precision window W, the*

$\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and the* $\mathsf{Real}^{\uparrow}$ *seal* E*, together with the displayed transports, continuations, provenance, and local naming rows. The export contains no quotient cut, selected supremum, trichotomy, host real equality, or ambient order-completeness principle.*

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremum real seal boundary`
↪ variant `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier real seal boundary`

Proof. Begin with a real-facing consumer of the packet. The only real-name coordinate present in the carrier is the seal row E, and the definition makes E reachable only after the located family, upper-bound ledger, approximation ledger, precision window, and regular handoff have been exposed.

The upper side of the read is supplied by U: it records the finite comparison rows certifying the requested family observations below the bound surface. The lower side is supplied by A: it records the finite approximants demanded by the precision window W.

The rows R and E then give the regular-rational and real-name handoff for exactly those displayed observations. The transport and continuation rows can replay this route but cannot add a quotient cut, chosen supremum, trichotomy oracle, host equality test, or order-completeness principle, because none of those rows occurs in the accepted packet. □

Theorem 1427.4 (LocatedSupremum upper-bound ledger stability)**.** *Let* $S = (L, U, A, W, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Every upper-bound read exported by* S *is stable under the componentwise transports recorded in* H*: transporting the located family row, upper-bound ledger, precision window, regular handoff, Real seal, continuation route, provenance, and local naming row preserves the same finite upper-bound ledger reads through* U *and no additional order-completeness coordinate is exposed.*

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier upper bound ledger stability`

Proof. Project the carrier of Definition 1427.1. The upper-bound information is stored only in U, and the transport row H lists the componentwise transports for $L, U, A, W, R, E, C, P, N$.

Apply Definition 1427.2. Its located upper-bound stability and classifier transport rows state that replacing the displayed carrier coordinates along H preserves the same upper-bound ledger reads through the comparison surface.

The real-seal boundary Definition 1427.3 keeps those reads downstream of U, W, R, E and excludes quotient cuts, selected suprema, trichotomy, host equality, and ambient completeness. Thus the transported packet exports the same finite upper-bound ledger surface. □

Theorem 1427.5 (LocatedSupremum lower-approximation cofinality)**.** *Let* $S = (L, U, A, W, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. For every precision request displayed in the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the lower-approximation ledger* A *contains a displayed approximation row at that precision, and the approximation is read through the same regular-rational handoff* R *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is exposed.*

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier lower approximation cofinality`

Proof. Inspect a precision request in W. The carrier makes W the only precision-window coordinate and makes A the only lower-approximation ledger coordinate.

Apply the lower-approximation cofinality row of Definition 1427.2. It supplies the displayed approximation row in A for the requested precision and binds that row to the same bound surface.

Finally use Definition 1427.3. The theorem forces every Real-facing read to pass from A through W, R, E together with the structural rows, so the approximation cannot bypass the regular-rational handoff or introduce a selected supremum. □

Theorem 1427.6 (LocatedSupremum RegSeqRat Real handoff stability)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Every exported real-facing approximation from S factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R before it reaches the* $\mathsf{Real}^{\uparrow}$ *seal E, and this factorization is stable under the continuation routes in C and the componentwise transports in H.*

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier regseqrat real handoff stability`

Proof. Start with a real-facing approximation read. By Definition 1427.1, the terminal real coordinate is E, and it appears only after the located family, upper-bound ledger, approximation ledger, precision window, and regular handoff rows have been displayed.

Apply Definition 1427.3. It identifies the exact route into E as the route through U, A, W, R together with H, C, P, N.

The continuation row C replays only that route, and the componentwise transports in H preserve each displayed coordinate. Therefore every exported approximation factors through R before E, with no detached real object, quotient cut, selected supremum, or ambient order-completeness principle. □

Theorem 1427.7 (LocatedSupremum root upper-lower window)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. The upper-bound reads exported through U and the lower-approximation reads exported through A are exposed through the same finite precision window W. Thus a root consumer that asks for both sides of the located-supremum surface receives one shared windowed route through $L, U, A, W, R, E, H, C, P, N$, rather than separate upper and lower access paths.*

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier root upper lower window`

Proof. Project the accepted carrier of Definition 1427.1. The carrier has one $\mathsf{StreamName}^{\uparrow}$ precision-window row W, and both the upper-bound ledger U and the lower-approximation ledger A are displayed before the regular handoff R and the $\mathsf{Real}^{\uparrow}$ seal E.

Apply the located upper-bound stability and lower-approximation cofinality rows of Definition 1427.2. They read their respective ledgers through the same W, R, E, H, C, P, N support rows.

Finally use Definition 1427.3. Every real-facing read is forced through U, A, W, R, E together with the structural rows, so the root upper and lower observations share the same finite precision window. □

Theorem 1427.8 (LocatedSupremum StreamName cut scope)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Every located-cut or located-real read exported by S is scoped through the* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance surface carried by the windowed approximation ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, the componentwise* hsame *transports H, the displayed* Cont *replay C, the* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{LocatedSupremum}^{\uparrow}}$ *row N.*

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier streamname cut scope`

Proof. Begin with a located-cut or located-real consumer of S. The source row L is admitted only as part of the displayed packet, and the carrier stores no independent cut or real object apart from the route through W, R, E.

Use Definition 1427.7. It places the upper-bound and lower-approximation ledgers under one finite precision window, so the cut-facing read and the real-facing read share the same inspected finite observations.

Now apply Definition 1427.6. The regular-rational handoff and terminal seal remain stable under H and C, while P and N name the same route. The dyadic tolerance information is read only as the tolerance surface carried by the windowed approximation ledger, so no detached cut, selected supremum, or ambient completeness coordinate enters the scope. □

Theorem 1427.9 (LocatedSupremum Real seal nonescape)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. No* $\mathsf{Real}^{\uparrow}$*-facing consumer can bypass $L, U, A, W, R, E, H, C, P, N$ to obtain a selected supremum, trichotomy row, quotient cut, host real equality test, or ambient order-completeness principle.*

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier real seal nonescape`

Proof. Start from the Real-facing boundary theorem Definition 1427.3. It identifies every exported real read with the finite route through the located family, upper-bound ledger, lower-approximation ledger, precision window, regular handoff, terminal seal, transports, continuations, provenance, and local name.

The root upper-lower window theorem Definition 1427.7 and the StreamName cut-scope theorem Definition 1427.8 keep the two order-facing sides on that same route before the seal is exposed.

The excluded objects are absent from the carrier of Definition 1427.1. Since H and C can only transport and replay displayed rows, a consumer has no coordinate from which to read selected suprema, trichotomy, quotient cuts, host equality, or ambient order completeness. □

Theorem 1427.10 (LocatedSupremum source envelope)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Every source read exported by S factors first through the displayed* $\mathsf{LocatedCut}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*, and* $\mathsf{BishopRealComparison}^{\uparrow}$ *surfaces named by the source row L before the upper-bound ledger U or the lower-approximation ledger A is inspected. The envelope contains no selected supremum, trichotomy row, quotient cut, host equality test, countable-choice functional, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the source row in Definition 1427.1. The carrier admits L only as a located-cut or located-real family row, and the definition binds that row to the comparison surfaces of $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, and $\mathsf{BishopRealComparison}^{\uparrow}$.

The upper and lower ledgers are downstream of that source envelope. The upper-bound ledger U records comparison reads for requested family observations, while the lower-approximation ledger A records finite approximants attached to the same bound surface.

Apply the real-seal nonescape theorem Definition 1427.9. Since all consumer-facing reads remain inside $L, U, A, W, R, E, H, C, P, N$, the source envelope cannot be replaced by selected suprema, trichotomy, quotient cuts, host equality, countable choice, or real completeness. □

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier source envelope`

Theorem 1427.11 (LocatedSupremum dyadic bracket)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Each precision request in the* $\mathsf{StreamName}^{\uparrow}$ *window W exposes a shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket carried by the located source and lower-approximation*

rows. The same bracket is read by the upper-bound ledger U as a comparison tolerance and by the lower-approximation ledger A as an approximation tolerance before any $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff is exported.*

Proof. Inspect a precision request in W. The root upper-lower window theorem Definition 1427.7 places the upper-bound reads and lower-approximation reads under the same finite precision window.

The source envelope of Definition 1427.10 supplies the located-cut and located-real bracket surface through L. Reading the request therefore exposes one dyadic tolerance surface for both ledgers, not separate upper and lower ambient estimates.

The StreamName cut-scope theorem Definition 1427.8 keeps this bracket on the route through W, R, E, H, C, P, N. Thus the bracket is shared by U and A before the regular-rational and real-name handoffs, with no selected supremum, quotient cut, trichotomy, host equality, countable choice, or completeness principle. □

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier dyadic bracket`

Theorem 1427.12 (LocatedSupremum RegSeqRat handoff route)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. The shared dyadic bracket of Definition 1427.11 repacks through the* $\mathsf{StreamName}^{\uparrow}$ *window W and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is available to any consumer. The handoff exports only the displayed source envelope, upper-bound ledger, lower-approximation ledger, window, regular readback, seal, transports, continuations, provenance, and local naming row.*

Proof. Begin with the shared bracket supplied by Definition 1427.11. The bracket has already been read through the source envelope and through the common precision window, so it is part of the displayed finite route rather than an ambient order-completeness witness.

Apply the RegSeqRat Real handoff stability theorem Definition 1427.6. It forces every real-facing approximation to pass through R before E and keeps the route stable under H and C.

Finally use Definition 1427.9. The terminal seal can expose only the displayed rows $L, U, A, W, R, E, H, C, P, N$, so the handoff cannot export selected suprema, trichotomy, quotient cuts, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier regseqrat handoff route`

Theorem 1427.13 (LocatedSupremum cofinal window totality)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Every completion-facing precision request accepted by W exports one common finite window in which the upper-bound ledger U and the lower-approximation ledger A are both readable: the upper side reads the source envelope through the comparison rows of L and U, the lower side reads a cofinal approximation row through A, and both sides share the dyadic bracket,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, transports H, replays C, provenance P, and local name N.*

Proof. Start with a completion-facing precision request in W. By Definition 1427.7, upper-bound reads and lower-approximation reads are already exposed through one finite precision window, rather than by two unrelated routes.

Use the source envelope of Definition 1427.10. The upper side must read the located-cut or located-real family row through L before inspecting U, so the upper-bound comparison remains inside the displayed family and comparison surface.

For the lower side, apply Definition 1427.5. The ledger A supplies a displayed approximation row at the same requested precision, and Definition 1427.11 identifies the shared dyadic bracket read by both ledgers.

Finally use Definition 1427.12. The common bracket is repacked through R before E, and the route is replayed only by H, C, P, N. Thus every accepted completion-facing request receives a single finite window carrying both the upper-bound and cofinal lower-approximation reads. □

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier cofinal window totality`

Theorem 1427.14 (LocatedSupremum monotone sequence handoff)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Any monotone bounded real-sequence consumer that reads S must pass through the same upper-bound ledger U, lower-approximation ledger A,* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance surface carried by the windowed approximation ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{LocatedSupremum}^{\uparrow}}$ *row N. The handoff exports no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, selected supremum, trichotomy row, quotient cut, host sequence equality, or countable-choice selector.*

Proof. Project the carrier of Definition 1427.1. A monotone bounded real-sequence consumer can inspect the source family only through L and can read its upper and lower order information only through the displayed ledgers U and A.

Apply Definition 1427.3. The theorem places every real-facing export downstream of the upper-bound ledger, lower-approximation ledger, precision window, regular-rational handoff, and terminal Real seal.

Use Definition 1427.5 and Definition 1427.13. The lower ledger supplies the requested cofinal approximation inside the same window that carries the upper-bound read, and the shared dyadic tolerance surface is the one carried by the windowed approximation ledger.

Finally replay the route through H, C, P, N. Componentwise transport and continuation replay preserve the displayed rows but cannot add an ambient completeness coordinate, selected supremum, trichotomy row, quotient cut, host sequence equality, or countable-choice selector. □

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier monotone sequence handoff`

Theorem 1427.15 (LocatedSupremum monotone convergence consumer envelope)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Any monotone-convergence or completion-facing consumer that reads the upper/lower window of S as stable* $\mathsf{Real}^{\uparrow}$ *data must first read the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and terminal* $\mathsf{Real}^{\uparrow}$ *seal through the Cauchy-equivalence classifier boundary of chapter 1820. The consumer receives a classifier-mediated regular-rational route, not a quotient real equality, host sequence equality, selected supremum, countable-choice selector, or ambient completeness principle.*

Proof. Start with the monotone sequence handoff. By Definition 1427.14, a monotone bounded real-sequence consumer must pass through the displayed upper-bound ledger, lower-approximation ledger, shared window, regular-rational handoff, dyadic tolerance surface, terminal seal, and structural rows.

Use the StreamName cut scope of Definition 1427.8. The cut-facing read is already confined to the finite window W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, the dyadic tolerance surface, and the terminal $\mathsf{Real}^{\uparrow}$ seal E.

Now insert the Cauchy-equivalence classifier boundary. The regular-rational readback can be treated as a stable Real-facing route only after the comparison surface of chapter 1820 has classified equivalent Cauchy windows on the same displayed path.

Finally apply Definition 1427.9. Since the carrier has no selected supremum, quotient cut, host sequence equality, countable-choice selector, or completeness coordinate, the monotone-convergence consumer receives only the classifier-mediated route through $L, U, A, W, R, E, H, C, P, N$. □

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier monotone convergence consumer envelope`

Theorem 1427.16 (LocatedSupremum window transport refusal)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Transporting the common finite window of Definition 1427.13 through H and replaying it through C cannot introduce a selected supremum, a trichotomy row, a quotient cut, a host real equality test, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every transported completion-facing read remains a read of $L, U, A, W, R, E, H, C, P, N$.*

Proof. Begin with the finite window supplied by Definition 1427.13. It contains the source envelope, upper-bound ledger, lower-approximation ledger, dyadic bracket, regular-rational readback, and terminal real seal as displayed rows of the same packet.

Apply Definition 1427.4 and Definition 1427.6. Componentwise transport through H preserves the upper-bound ledger reads and keeps the regular-rational handoff attached to R before E.

The nonescape clause follows from Definition 1427.9. Since C can only replay displayed routes and the carrier contains none of the excluded coordinates, window transport cannot manufacture selected suprema, trichotomy, quotient cuts, host equality, countable choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier window transport`

Theorem 1427.17 (LocatedSupremum standard bridge route)**.** *Let $S = (L, U, A, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet. Every standard-interface read of S factors through the public finite rows $L, U, A, W, R, E, H, C, P, N$: the abstract bridge can inspect only the located family row, located upper-bound ledger, lower-approximation cofinality,* $\mathsf{StreamName}^{\uparrow}$ *precision window,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{LocatedSupremum}^{\uparrow}}$ *row. It receives no selected supremum, quotient cut, trichotomy row, host real equality test, countable-choice selector, or ambient real-completeness coordinate.*

Proof. Start from the public finite interface recorded by Definition 1427.2. It exposes only the rows $L, U, A, W, R, E, H, C, P, N$ and makes the located upper-bound ledger and lower-approximation cofinality packet data.

Use Definition 1427.12 and Definition 1427.3. Any real-facing read must pass through the $\mathsf{StreamName}^{\uparrow}$ window W, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E before it can be exported.

Finally apply Definition 1427.16. The transport and replay rows H, C preserve the same route, while P, N only source and name it. Thus the standard-interface bridge reads exactly the displayed public rows and none of the excluded host or quotient principles. □

Lean4 ✓ `BEDC.Derived.LocatedSupremumUp.LocatedSupremumCarrier standard bridge route`

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSupremum}^{\uparrow}}$.

Constructive story: A LocatedSupremum$^{\uparrow}$ packet is generated from a located family row, an upper-bound ledger, a lower-approximation ledger, a StreamName precision window, a RegSeqRat handoff, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedSupremum}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1427.1, Definition 1427.2, Definition 1427.4, Definition 1427.5, Definition 1427.6, Definition 1427.15, Definition 1427.16, and Definition 1427.17 expose the standard bridge route: located upper-bound ledger, lower-approximation cofinality, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming over the L10 Real and Completion interface.

Formal verification: FormalStatus(NameCert$_{\text{LocatedSupremum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim full Dedekind completeness, arbitrary least-upper-bound completeness, quotient cuts, selected suprema, trichotomy, host real equality, countable choice, Real completeness, or Lean bridge checking.

Upgrade path: The theory axis has no higher closure grade for this packet; the formal verification axis remains independent.

Chapter 1428

A Concrete Naming Certificate for $\mathsf{DyadicIntervalCover}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DyadicIntervalCover}^{\uparrow}$ packet records a finite dyadic interval-cover surface for the open Real and Completion route. It sits between the dyadic arithmetic of chapter 291, the finite observation windows of chapter 126, the regular-rational readback of chapter 301, the visible Real seal of chapter 38, and the finite interval-net surface of chapter 1410. The packet names cover data that can be inspected through finitely many rows; it does not assert an open-cover compactness theorem or any host completion principle.

Definition 1428.1 (DyadicIntervalCover carrier)**.** *A* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, M, R, V, W, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *L and U are finite rows of lower and upper dyadic endpoints, each endpoint read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic surface.*
2. *M is the mesh-index row that records the dyadic scale at which endpoint comparisons and interval-membership tests are performed.*
3. *R is the radius ledger assigning a displayed dyadic tolerance to every interval row and every inspected regular-name window.*
4. *V is the finite cover-membership row: each listed mesh cell carries the index of a displayed dyadic interval whose lower and upper endpoint rows contain that cell at the tolerance named by R.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by the consumer real names that are tested against the cover.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that translates the windows W into regular rational approximants at the mesh scale M.*
7. *A is the visible* $\mathsf{Real}^{\uparrow}$ *seal row reached through the same window and readback data.*
8. *H stores the componentwise* hsame *transports for endpoints, mesh indices, radius rows, cover-membership rows, windows, readbacks, Real seals, continuation, provenance, and local naming rows.*

9. *C stores the displayed* Cont *replay from dyadic endpoints to mesh cells, from mesh cells to cover-membership rows, from windows to regular readback, and from regular readback to the visible Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopIntervalCompact}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalCover}^{\uparrow}}$ *row.*

The accepted carrier stores only the finite cover surface just displayed. It carries no open-cover compactness principle, no Heine–Borel theorem, no sequential compactness selector, no selected limit, no quotient real equality, no host real equality test, no countable-choice functional, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverTasteGate single carrier alignment`

Theorem 1428.2 (DyadicIntervalCover NameCert obligations)**.** *For an accepted packet $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalCover}^{\uparrow}}$ *obligations are exhausted by the finite endpoint, mesh, radius, membership, window, readback, seal, transport, continuation, and provenance rows of Definition 1428.1. In particular, every obligation can be checked by finite projection from the displayed* BHist *packet and by replay of H, C, and P; no obligation may call on open-cover compactness, Heine–Borel compactness, sequential compactness, selected limits, quotient real equality, host real equality, countable choice, or Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverNamecertObligations`

Proof. Project the carrier row by row. The endpoint and mesh obligations read only L, U, M, R, V and the dyadic arithmetic certified by the $\mathsf{DyadicRatCore}^{\uparrow}$ sibling chapter. The real-name obligations read only the finite windows W, the regular-rational readback Q, and the visible seal A, hence they factor through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ sibling surfaces.

The remaining obligations are structural. The hsame row H transports equal displayed coordinates, the Cont row C replays the permitted reads, and the provenance row P records exactly the finite BEDC surfaces used by the packet, including the comparison with the $\mathsf{BishopIntervalCompact}^{\uparrow}$ finite-net interface. Since the carrier has no row for an open-cover selector, a host limit, a quotient equality, a choice functional, or a completeness principle, none of those principles can appear in a local NameCert obligation. □

Theorem 1428.3 (DyadicIntervalCover endpoint row admission)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Endpoint admission for the lower and upper rows is exactly the finite projection from Definition 1428.1 together with the local NameCert obligations of Definition 1428.2: the rows L, U are read as* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints, M, R provide the displayed mesh and tolerance data, V, W, Q, A remain the finite membership, StreamName, RegSeqRat, and Real-seal rows, and H, C, P, N transport, replay, package, and name that same endpoint surface.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverEndpointRowAdmission`

Proof. Project the carrier row $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$. The definition places L and U in the dyadic endpoint slots and places M and R beside them as the only mesh and tolerance data available to endpoint comparisons.

Use the NameCert-obligation theorem. It says that endpoint, mesh, radius, membership, window, readback, seal, transport, continuation, and provenance checks are exhausted by the displayed

rows. Thus admitting an endpoint row can only mean checking L, U through $\mathsf{DyadicRatCore}^{\uparrow}$ and then preserving the result through H, C, P, N.

The remaining rows cannot create an additional endpoint source. The membership row V, window row W, readback row Q, and seal row A are downstream consumers of the same finite endpoint data, so endpoint admission stays inside $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert data. □

Theorem 1428.4 (DyadicIntervalCover window membership transport)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P,$ be an accepted $\mathsf{DyadicIntervalCover}^{\uparrow}$ packet. Finite cover-membership transport along StreamName windows is completely determined by the carrier and obligation rows of Definition 1428.1 and Definition 1428.2: the transported membership row V reads endpoint rows L, U, mesh row M, radius ledger R, finite window row W, regular readback row Q, and Real seal row A, and its only structural support is H, C, P, N.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverWindowMembershipTransport`

Proof. Begin with the window row W and membership row V. The carrier definition makes W the finite StreamName surface and V the finite list of cover-membership witnesses attached to the dyadic endpoint rows.

Apply the NameCert-obligation theorem to the same carrier. The theorem identifies H as the componentwise transport row and C as the replay row for endpoint, mesh, radius, membership, window, readback, and seal data. Therefore a membership transport can only move along the displayed route from L, U, M, R, W, Q, A to V.

The rows P and N package and name that route locally. Since no carrier coordinate supplies host interval equality, selected subcovers, quotient real equality, countable choice, or Real completeness, the transported finite membership row stays inside $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert data. □

Theorem 1428.5 (DyadicIntervalCover Real seal boundary)**.** *For an accepted $\mathsf{DyadicIntervalCover}^{\uparrow}$ carrier $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$, every Real seal read through A is bounded by the carrier rows and NameCert obligations of Definition 1428.1 and Definition 1428.2. The seal may inspect L, U, M, R, V, W, Q and may be transported or replayed by H, C, P, N, but it cannot leave the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert surface.*

Proof. Project the seal row. In the displayed carrier, A is the only $\mathsf{Real}^{\uparrow}$ seal coordinate and it is listed after the endpoint, mesh, radius, membership, window, and regular readback rows.

Use the NameCert-obligation theorem. Its finite projection discipline forces every seal obligation to be checked from the same rows $L, U, M, R, V, W, Q, A, H, C, P, N$ rather than from an external completion or host real equality.

The structural rows do not enlarge the seal. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve only the route already present in the carrier, so the Real seal boundary cannot export open-cover compactness, selected limits, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRealSealBoundary`

Theorem 1428.6 (Regular-sequence finite-window exhaustion)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted $\mathsf{DyadicIntervalCover}^{\uparrow}$ packet. Any consumer that asks whether a regular real name represented by the displayed $\mathsf{StreamName}^{\uparrow}$ windows W and $\mathsf{RegSeqRat}^{\uparrow}$ readback Q meets the cover*

named by L, U, M, R, V is exhausted by a finite window computation: it reads the mesh index M, the radius ledger R, the regular approximants in Q, the finite membership rows V, and the visible $\mathsf{Real}^{\uparrow}$ *seal A. No later tail of the regular sequence and no ambient equality of real names contributes to the cover decision.*

Proof. Begin with the window and readback coordinates. The $\mathsf{StreamName}^{\uparrow}$ row supplies exactly the finite windows available to the consumer, and the $\mathsf{RegSeqRat}^{\uparrow}$ row turns those windows into rational approximants at the mesh scale named by M and the radii named by R.

Next inspect the cover surface. The finite row V contains the whole list of membership witnesses for the dyadic endpoint rows L and U, so a consumer can only compare the displayed approximants with this finite list. The continuation row C has no replay path beyond those rows, and the Real seal A records only the visible endpoint reached through the same finite readback.

Thus the decision surface is exhausted by M, R, Q, V, A together with the displayed transports in H. A later regular-sequence tail, quotient equality of real names, host equality, countable choice, selected limits, and Real completeness are absent from the packet, so they cannot affect the finite-window cover read. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRegularSequenceWindowExhaustion`

Theorem 1428.7 (DyadicIntervalCover RegSeqRat-StreamName coverage route)**.** *Every* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *consumer that reads a* $\mathsf{RegSeqRat}^{\uparrow}$ *approximation through* $\mathsf{StreamName}^{\uparrow}$ *windows must expose the rows W, Q, M, R, V, A in that order before the cover-membership row is consumed. The route is stable under the componentwise* hsame *row H and the displayed* Cont *replay row C, and it exports no quotient real equality, selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1428.1. The StreamName window row W is the only finite source window, the RegSeqRat readback row Q is attached to that window, and the mesh, radius, membership, and seal rows are M, R, V, A.

Apply Definition 1428.6. It exhausts every regular-name cover read through the displayed finite-window computation, so the membership row V is not consumed until W, Q, M, R have been opened and the visible Real seal boundary A remains downstream.

Finally use the seal boundary of Definition 1428.5. Componentwise transport and continuation replay preserve the same route, while quotient real equality, selected limits, countable choice, and Real completeness remain outside the packet. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRegSeqRatStreamNameCoverageRoute`

Theorem 1428.8 (DyadicIntervalCover finite-window carrier)**.** *Every accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet exposes only finite interval-window rows over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *For a carrier*

$$I = (L, U, M, R, V, W, Q, A, H, C, P, N),$$

the endpoint rows L, U, mesh row M, radius ledger R, membership row V, window row W, readback row Q, and seal row A form the whole displayed cover surface before the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalCover}^{\uparrow}}$ *row is exported.*

Proof. Project the carrier of Definition 1428.1. The endpoint, mesh, radius, and membership rows are finite dyadic interval-window data, and the only Real-facing rows are the displayed StreamName windows, RegSeqRat readback, and terminal Real seal.

Apply Definition 1428.6. It forces every regular-name cover read through M, R, Q, V, A together with the finite window row W before any cover decision is consumed. The L10 sibling dependencies

are exactly the dyadic arithmetic of $\mathsf{DyadicRatCore}^{\uparrow}$, the finite observation surface of $\mathsf{StreamName}^{\uparrow}$, the regular-rational readback of $\mathsf{RegSeqRat}^{\uparrow}$, and the visible seal of $\mathsf{Real}^{\uparrow}$.

Since the carrier contains no row beyond $L, U, M, R, V, W, Q, A, H, C, P, N$, the finite-window surface is exhausted by those rows. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverFiniteWindowCarrier`

Theorem 1428.9 (DyadicIntervalCover Bishop interval compact handoff)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Any consumer that hands its mesh-radius rows to* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *must expose the full finite packet $L, U, M, R, V, W, Q, A, H, C, P, N$: the dyadic endpoint rows L, U are read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, the mesh and radius rows M, R govern the finite cover-membership row V, the real-name rows W, Q, A supply the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *boundary, and H, C, P, N transport, replay, source, and name the same handoff. The finite-net membership route passes through chapter 1410 only after those dyadic endpoint rows are displayed and before the* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The route exports no open-cover compactness theorem, selected finite subcover, quotient stream, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier from Definition 1428.1. The rows L, U, M, R, V provide the only dyadic endpoint, mesh, radius, and finite membership data available to a compact-interval consumer.

Use Definition 1428.8. It identifies L, U, M, R, V, W, Q, A as the whole finite interval-window surface before the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalCover}^{\uparrow}}$ row is exported.

Next apply Definition 1428.6 and Definition 1428.5. The former keeps every regular-name cover read inside W, Q, M, R, V, A, while the latter places the visible $\mathsf{Real}^{\uparrow}$ seal after the finite window and endpoint rows.

The $\mathsf{BishopIntervalCompact}^{\uparrow}$ sibling can therefore consume only the displayed finite-net route. Since I has no row for arbitrary open covers, selected subcovers, quotient streams, host equality, countable choice, or ambient Real completeness, the handoff remains a finite mesh-radius obligation rather than a compactness principle. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBishopIntervalCompactHandoff`

Theorem 1428.10 (DyadicIntervalCover compact-uniform window route)**.** *Any compact-uniform-continuity consumer using an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet must read the dyadic endpoint rows, mesh row, radius ledger, finite membership row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *handoff, and* $\mathsf{UniformModulus}^{\uparrow}$*-facing lower-bound route in that order. The route exports no open-cover compactness, selected subcover, quotient real equality, host minimum, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier from Definition 1428.1. The endpoint admission and finite-window carrier theorems expose L, U, M, R, V, W, Q, A as the displayed dyadic endpoint, mesh, radius, membership, window, readback, and seal rows.

Apply Definition 1428.6 and Definition 1428.5. They place every regular-sequence cover read behind the finite windows and put the terminal $\mathsf{Real}^{\uparrow}$ seal after the endpoint and membership rows.

Finally use Definition 1428.9. The compact interval handoff receives only the displayed mesh-radius route, so any $\mathsf{UniformModulus}^{\uparrow}$ lower-bound consumer reads the same finite route and cannot obtain open-cover compactness, a selected subcover, quotient real equality, a host minimum, countable choice, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverCompactUniformWindowRoute`

Theorem 1428.11 (DyadicIntervalCover refinement stability)**.** *Let*

$$I = (L, U, M, R, V, W, Q, A, H, C, P, N)$$

and

$$I' = (L', U', M', R', V', W', Q', A', H', C', P', N')$$

be accepted $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packets. If a displayed refinement carries componentwise* hsame *data from the endpoint, mesh, radius, membership, window, readback, and seal rows of* I *to the corresponding rows of* I'*, and the replay rows display the same* Cont *route through those transported coordinates, then the refined cover preserves the same finite interval-window route over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project both carriers. The rows available to the refinement are precisely the finite endpoint rows, mesh rows, radius ledgers, membership rows, finite windows, regular readbacks, Real seals, and structural rows listed in Definition 1428.1.

Apply Definition 1428.6 to I and I'. The cover read in each packet is exhausted by the displayed mesh, radius, readback, membership, and seal rows. Componentwise hsame in H, H' identifies those rows as packet data, and the displayed Cont replay in C, C' preserves the route through the same L10 siblings.

Thus refinement changes only the displayed finite interval rows and their transported membership witnesses. It does not create an open-cover compactness row, a selected subcover, a host equality test, a quotient stream, a choice functional, or a Real-completeness witness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRefinementStability`

Theorem 1428.12 (DyadicIntervalCover route-cover stability)**.** *Let* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *and* $I' = (L', U', M', R', V', W', Q', A', H', C', P', N')$ *be accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packets. If a displayed refinement preserves the endpoint rows* L, U*, the mesh and radius rows* M, R*, the finite cover-membership rows* V*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal rows* A*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming, then* I *and* I' *expose the same finite cover route through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Proof. Project both carriers. The only cover-facing coordinates are the endpoint, mesh, radius, membership, window, readback, seal, transport, replay, provenance, and local naming rows displayed in Definition 1428.1.

Apply Definition 1428.6. It exhausts each regular-name cover read by the finite rows M, R, Q, V, A after the $\mathsf{StreamName}^{\uparrow}$ window has been opened, so no later regular-sequence tail or ambient real-name equality can affect the route.

Now apply Definition 1428.11. The refinement preserves the endpoint, mesh, radius, membership, window, readback, and seal rows through componentwise hsame data and the displayed Cont replay.

The provenance and local naming rows P, N and P', N' keep the transported route inside the same packet boundary. Therefore the refinement preserves the finite cover route and cannot introduce open-cover compactness, a selected subcover, quotient equality, countable choice, or Real completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRouteCoverStability`

Theorem 1428.13 (DyadicIntervalCover ledger exactness)**.** *The* DyadicIntervalCover$^{\uparrow}$ *cover ledger is exact for the displayed finite windows. In an accepted carrier*

$$I = (L, U, M, R, V, W, Q, A, H, C, P, N),$$

the radius ledger R and membership row V account for exactly the dyadic endpoint comparisons and regular-name windows read through L, U, M, W, Q, A. The ledger exports no open-cover compactness theorem, selected subcover, host real equality, quotient stream, countable choice, or Real completeness.

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverLedgerExactness`

Proof. Project the displayed carrier. The ledger row R supplies the tolerance data for endpoint comparisons and for each inspected regular-name window, while V records the finite membership witnesses at that tolerance.

Use Definition 1428.6. Every cover decision reads only M, R, Q, V, A after the StreamName window W has been opened, so the ledger has no hidden tail coordinate beyond the finite rows.

The sibling dependencies are the dyadic arithmetic surface DyadicRatCore$^{\uparrow}$, the window surface StreamName$^{\uparrow}$, the readback surface RegSeqRat$^{\uparrow}$, and the terminal seal Real$^{\uparrow}$. Since none of those rows supplies open-cover compactness, a selected subcover, host equality, quotient equality, choice, or completeness, the accepted ledger cannot export any such principle. □

Theorem 1428.14 (DyadicIntervalCover Bishop interval compact route)**.** *Any* BishopIntervalCompact$^{\uparrow}$ *consumer of an accepted* DyadicIntervalCover$^{\uparrow}$ *packet*

$$I = (L, U, M, R, V, W, Q, A, H, C, P, N)$$

must read the endpoint rows L, U, mesh row M, radius ledger R, membership row V, StreamName$^{\uparrow}$ *windows W,* RegSeqRat$^{\uparrow}$ *readback row Q,* Real$^{\uparrow}$ *seal row A, and structural rows H, C, P, N before the finite interval compact route is available. The route is finite-window interval compactness over the displayed dyadic ledger; it exports no arbitrary open-cover compactness, selected finite subcover, quotient stream equality, host real equality, countable choice, or ambient Real completeness.*

Proof. Project the carrier of Definition 1428.1. The endpoint, mesh, radius, membership, window, readback, seal, transport, replay, provenance, and local naming rows are the only coordinates visible to a compact-interval consumer.

Apply finite-window exhaustion through Definition 1428.6. Each inspected interval window is bounded by M, R, V, W, Q, A, after the endpoint rows L, U have fixed the finite dyadic interval boundary.

Use the Real$^{\uparrow}$ seal row A only as the displayed boundary seal for the regular-name readback. The seal does not add host equality, quotient stream equality, selected limits, countable choice, or ambient Real completeness.

Finally apply Definition 1428.13. Since R, V are exact for the dyadic endpoint comparisons and regular-name windows against $L, U, M, W, Q, A, H, C, P, N$, the BishopIntervalCompact$^{\uparrow}$ route is available exactly through those rows and through no hidden compactness coordinate. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBishopIntervalCompactRoute`

Definition 1428.15 (DyadicIntervalCover obligation surface)**.** *For an accepted* DyadicIntervalCover$^{\uparrow}$ *packet*

$$I = (L, U, M, R, V, W, Q, A, H, C, P, N),$$

the obligation surface is the finite ledger consisting of the DyadicRatCore$^{\uparrow}$ *endpoint rows* L, U*, mesh row* M*, radius ledger* R*, cover-membership row* V*,* StreamName$^{\uparrow}$ *window row* W*,* RegSeqRat$^{\uparrow}$ *readback row* Q*, visible* Real$^{\uparrow}$ *seal row* A*, componentwise transport* H*, displayed replay* C*, provenance* P*, and local naming* N*. This surface records finite mesh, refinement, membership, and real-window handoff data only; it contains no open-cover compactness coordinate and no selected-subcover coordinate.*

Lean4 (definition) `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverObligationSurface`

Definition 1428.16 (DyadicIntervalCover root obligation surface)**.** *For an accepted* DyadicIntervalCover$^{\uparrow}$ *packet*

$$I = (L, U, M, R, V, W, Q, A, H, C, P, N),$$

the root obligation surface is the L10 tuple consisting of endpoint rows L, U*, mesh and radius rows* M, R*, finite cover-membership row* V*, StreamName window row* W*, RegSeqRat readback row* Q*, Real seal row* A*, and structural rows* H, C, P, N*. It is the part of Definition 1428.15 exposed to root consumers that need interval-cover data without importing open-cover compactness, selected finite subcovers, quotient stream equality, host real equality, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootObligationSurface` semantic name certificate

Theorem 1428.17 (DyadicIntervalCover root finite-cover boundary)**.** *Let* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *be an accepted* DyadicIntervalCover$^{\uparrow}$ BHist *packet satisfying Definition 1428.16. Every root finite-cover read of* I *is bounded by the displayed endpoint rows* L, U*, mesh row* M*, radius ledger* R*, membership row* V*, StreamName window* W*, RegSeqRat readback* Q*, Real seal* A*, componentwise* hsame *row* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. The boundary exports no arbitrary open cover, selected finite subcover, quotient stream equality, host real equality, countable-choice schedule, or ambient* Real$^{\uparrow}$ *completeness row.*

Proof. Project the root surface. By Definition 1428.8, the only cover-facing coordinates are $L, U, M, R, V, W, Q, A, H, C, P, N$.

Use the Bishop interval compact handoff of Definition 1428.9. It places any compact-interval consumer behind the finite dyadic endpoint, mesh, radius, membership, window, readback, and seal rows before a local NameCert can be exported.

The rows H, C, P, N transport, replay, source, and name that same finite route. Since the accepted BHist packet has no coordinate for the excluded host or selection data, the root boundary is exactly the displayed finite-cover surface. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootFiniteCoverBoundary`

Theorem 1428.18 (DyadicIntervalCover root window coverage)**.** *Let* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *be an accepted* DyadicIntervalCover$^{\uparrow}$ BHist *packet satisfying Definition 1428.16. Every root coverage request that begins from a* StreamName$^{\uparrow}$ *window row must read* W *first, then the* RegSeqRat$^{\uparrow}$ *readback* Q*, then the dyadic mesh and radius rows* M, R *with membership row* V*, and only then the visible* Real$^{\uparrow}$ *seal* A *and structural rows* H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootWindowCoverage`

Proof. Start with the window and readback rows. The root surface contains W as the only finite $\mathsf{StreamName}^{\uparrow}$ window coordinate and Q as the only $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to it.

Apply Definition 1428.6. It forces every regular-name cover decision through M, R, Q, V, A after the finite window has been opened.

Finally use Definition 1428.12. Componentwise hsame transport and displayed Cont replay preserve the same route, while P, N only source and name it. Thus root coverage cannot bypass the displayed window-readback-cover order. □

Theorem 1428.19 (DyadicIntervalCover root compact handoff)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ BHist *packet satisfying Definition 1428.16. Any root consumer that hands I to* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *must expose the finite cover rows L, U, M, R, V, the real-window rows W, Q, A, and the structural rows H, C, P, N as one packet before the compact consumer may read the cover. The handoff is finite packet data, not open-cover compactness, selected subcover extraction, quotient equality, choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootCompactHandoff`

Proof. Use Definition 1428.9. It already identifies the $\mathsf{BishopIntervalCompact}^{\uparrow}$ consumer route as the displayed finite mesh-radius and real-window handoff.

Next apply Definition 1428.11. If the root consumer refines the dyadic cells before the compact read, the transported endpoint, mesh, radius, membership, window, readback, and seal rows remain in the same componentwise route.

The local BHist packet is exhausted by $L, U, M, R, V, W, Q, A, H, C, P, N$. Therefore the compact handoff cannot acquire an open-cover theorem or a selected subcover outside the visible packet rows. □

Theorem 1428.20 (DyadicIntervalCover root regular readback)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ BHist *packet satisfying Definition 1428.16. Every root* $\mathsf{RegSeqRat}^{\uparrow}$ *readback used by the interval-cover packet is accounted for by Q against the finite window row W, dyadic endpoint rows L, U, mesh row M, radius ledger R, membership ledger V, seal row A, and structural rows H, C, P, N. No later regular-sequence tail, quotient real equality, host real equality, countable choice, selected limit, or ambient completeness row can alter the root readback.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootRegularReadback`

Proof. Project the readback row Q from the root surface. It is tied to the finite window row W and the mesh-radius rows M, R before any cover membership decision is read.

Use Definition 1428.13. The ledger rows R, V are exact for endpoint comparisons and regular-name windows against $L, U, M, W, Q, A, H, C, P, N$.

Route-cover stability then keeps the same readback under hsame transport and Cont replay. Since no tail or quotient coordinate exists in the carrier, the regular readback is exhausted by the displayed finite rows. □

Theorem 1428.21 (DyadicIntervalCover root nonescape)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ BHist *packet satisfying Definition 1428.16. Every root read exported by I remains inside the finite route named by $L, U, M, R, V, W, Q, A, H, C, P, N$ and the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalCover}^{\uparrow}}$ *row. In particular, neither the* $\mathsf{Real}^{\uparrow}$ *seal nor the compact handoff can escape to host real equality, quotient stream equality, selected limits, countable choice, arbitrary open-cover compactness, selected subcovers, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootNonescape`

Proof. Begin with carrier exhaustion from Definition 1428.8. The root surface has only endpoint, mesh, radius, membership, window, readback, seal, transport, replay, provenance, and naming rows.

Use Definition 1428.5 for the Real-facing exit and Definition 1428.9 for the compact-facing exit. Both routes keep the downstream read behind the same finite dyadic, stream, regular-rational, Real, transport, replay, provenance, and naming rows.

Finally apply ledger exactness. The rows R, V account for the finite endpoint and regular-window comparisons, so there is no remaining coordinate from which a root consumer could read an excluded host, quotient, choice, selected-subcover, or completeness object. □

Theorem 1428.22 (DyadicIntervalCover root unblock package)**.** *Every accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet satisfying Definition 1428.16 exports exactly the root L10 handoff through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{BishopIntervalCompact}^{\uparrow}$. *The package reads endpoint, mesh, membership, regular-window, seal, transport, replay, provenance, and local naming rows, and it exports no open-cover compactness, selected finite subcover, quotient stream, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the root surface. Endpoint admission is supplied by Definition 1428.3, while mesh and radius reads are bound by Definition 1428.23. Thus every root interval cell is first read through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ rows L, U, M, R and the finite membership row V.

The regular-name handoff is forced through the window and readback rows. Apply Definition 1428.30 to route every $\mathsf{RegSeqRat}^{\uparrow}$ consumer through W, Q before it reaches the dyadic cover ledger.

The Real-facing exit is sealed by Definition 1428.31. Together with Definition 1428.45, this keeps finite tail windows, regular readbacks, cover rows, the $\mathsf{BishopIntervalCompact}^{\uparrow}$ finite-net comparison, and A, H, C, P, N inside one displayed L10 package.

The excluded principles are absent from the carrier and from the cited rows. Therefore the root package exposes the finite interval-cover handoff and nothing beyond the displayed dyadic, stream, regular-rational, real, compact-interval, transport, replay, provenance, and naming surface. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootUnblockPackage`

Theorem 1428.23 (DyadicIntervalCover mesh refinement obligation)**.** *Let* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Any mesh refinement obligation for* I *is determined by the rows* $L, U, M, R, V, H, C, P, N$ *of Definition 1428.15: the refined endpoint comparisons still read through* $\mathsf{DyadicRatCore}^{\uparrow}$, *the refined mesh is still named by* M *and* R, *and the transported membership witnesses remain inside* V *with no appeal to open-cover compactness or selected subcovers.*

Proof. Project the obligation surface. The endpoint rows L, U and the mesh-radius rows M, R are the only rows that can refine dyadic cells, and the membership row V is the only row that can record which displayed interval contains a listed cell.

Transport and replay do not add a cover theorem. The rows H, C, P, N preserve the same displayed endpoint, mesh, radius, and membership coordinates over $\mathsf{DyadicRatCore}^{\uparrow}$.

Therefore a refinement obligation is a finite row check. Since the carrier has no row for an arbitrary open cover or a selected finite subcover, refinement cannot supply compactness data beyond the displayed mesh ledger. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverMeshRefinementObligation`

Theorem 1428.24 (DyadicIntervalCover subcover exclusion obligation)**.** *For every accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *carrier* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$*, the finite cover-membership row* V *excludes any hidden selected-subcover obligation. A consumer may inspect* L, U, M, R, V *and transport them through* H, C, P, N*, but the packet does not provide a row selecting a finite subcover from an arbitrary open cover and does not turn finite membership data into Heine–Borel compactness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverSubcoverExclusionObligation`

Proof. Read the membership row in the carrier. The row V lists finite membership witnesses for the already displayed dyadic endpoint and mesh rows, so its source is L, U, M, R rather than an arbitrary family of open sets.

Use Definition 1428.13. The ledger is exact for endpoint comparisons and regular-name windows, and it explicitly exports no open-cover compactness theorem or selected subcover.

The structural rows cannot create a selector. They only transport and replay the finite rows already present in the packet, so the subcover principle remains absent from the obligation surface. □

Theorem 1428.25 (DyadicIntervalCover real-window handoff obligation)**.** *Let* $I = (L, U, M, R, V, W, Q, A, H, C, P$ *be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Every real-window handoff obligation factors through the finite route*

$$W, Q \longmapsto M, R, V \longmapsto A$$

over $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The handoff may compare the displayed regular-name windows with the mesh and membership ledger, but it does not supply open-cover compactness, selected subcovers, quotient real equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRealWindowHandoffObligation`

Proof. Start with the window row W and readback row Q. These rows expose only finite observations and regular rational approximants, so every Real-facing read begins inside the displayed $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ data.

Next pass through the dyadic cover ledger. The mesh row M, radius ledger R, and membership row V compare those approximants against the endpoint rows L, U already certified by $\mathsf{DyadicRatCore}^{\uparrow}$.

Finally read the Real seal row A. The seal records the visible endpoint of the same finite route, and the structural rows H, C, P, N preserve that route without adding compactness, a selector, quotient equality, choice, selected limits, or completeness. □

Theorem 1428.26 (DyadicIntervalCover membership transport)**.** *Let* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Every cover-membership read through the row* V *is transported only by the componentwise* hsame *row* H *and the displayed* Cont *replay row* C *over the endpoint rows* L, U*, mesh row* M*, radius ledger* R*, readback row* Q*, and membership row* V*. In particular, membership transport exports no host interval equality, selected subcover, quotient real equality, countable choice, or Real completeness row.*

Proof. Project the carrier of Definition 1428.1. The membership row V is displayed together with endpoint rows L, U, mesh row M, radius ledger R, window row W, readback row Q, and seal row A.

Use Definition 1428.2. The local NameCert obligations make H the componentwise transport row and C the replay route for endpoint, mesh, radius, membership, window, readback, and seal data.

Finally apply Definition 1428.11. Refinement preserves the finite interval-window route only through the transported rows, so a transported membership read cannot acquire host interval equality, selected subcover data, quotient equality, countable choice, or Real completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverMembershipTransport`

Theorem 1428.27 (DyadicIntervalCover seal nonescape)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *seal read through A factors through the finite window row W and regular readback row Q before it reaches the cover rows L, U, M, R, V and the structural rows H, C, P, N. The seal exports no open-cover compactness, host equality, quotient stream, selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with Definition 1428.6. It forces any regular-name cover read to inspect the finite windows W, readback row Q, mesh row M, radius ledger R, membership row V, and visible Real seal A.

Use Definition 1428.8 to identify the whole cover surface. The rows L, U, M, R, V, W, Q, A are the displayed interval-window data before the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalCover}^{\uparrow}}$ row can be exported.

The structural rows H, C, P, N preserve only that displayed route. Since the carrier of Definition 1428.1 contains no coordinate for open-cover compactness, host equality, quotient streams, selected limits, countable choice, or Real completeness, the seal cannot export any such data. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverSealNonescape`

Theorem 1428.28 (DyadicIntervalCover regular-window ledger)**.** *For every accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *carrier $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$, the regular-window ledger is exactly the finite accounting of W, Q, R against the mesh and membership rows M, V. Each regular-name window opened by W is read back through Q, assigned its displayed radius by R, and compared with the finite membership row V at the mesh named by M; no hidden tail ledger or ambient equality source contributes to the accounting.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRegularWindowLedger`

Proof. Project the carrier and read the rows W, Q, R, M, V. The window row W supplies the finite observations, the readback row Q turns them into regular rational approximants, the radius ledger R supplies the displayed tolerance, and M, V give the mesh and membership rows that consume those approximants.

Apply Definition 1428.6. It says every cover decision is exhausted by the displayed finite window computation and has no later regular-sequence tail or ambient real-name equality input.

Now use Definition 1428.13. The existing ledger theorem identifies R and V as the exact accounting rows for the dyadic endpoint comparisons and regular-name windows. Therefore the regular-window accounting is exactly W, Q, R against M, V, with no hidden tail ledger, host equality, quotient equality, choice, selected limit, or completeness row. □

Theorem 1428.29 (DyadicIntervalCover finite-subcover ledger)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Any finite-subcover-facing read of I is only the displayed ledger projection*

$$L, U, M, R, V, W, Q, A, H, C, P, N.$$

The rows L, U, M, R, V expose dyadic endpoint, mesh, radius, and membership data; the rows W, Q, A expose the finite regular-window readback and visible $\mathsf{Real}^{\uparrow}$ *seal; and H, C, P, N only transport, replay, source, and name that same ledger. The packet supplies no open-cover compactness theorem, no selected subcover from an arbitrary cover, no quotient real equality, no countable choice, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1428.1. Its cover-facing rows are the lower endpoints L, upper endpoints U, mesh row M, radius ledger R, and finite membership row V.

Use Definition 1428.28. It identifies the regular-window accounting as W, Q, R against M, V, so any finite-subcover-facing read is already pinned to the displayed regular windows and membership ledger.

The structural rows H, C, P, N preserve only those displayed coordinates. Since the carrier has no row for an arbitrary open cover, no selector for extracting a subcover, and no equality or completeness coordinate beyond the visible $\mathsf{Real}^{\uparrow}$ seal A, the read cannot become open-cover compactness, selected subcover data, quotient real equality, countable choice, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverFiniteSubcoverLedger`

Theorem 1428.30 (DyadicIntervalCover RegSeqRat route)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer route through I first projects the displayed finite rows*

$$W, Q \longmapsto M, R, V \longmapsto L, U, A, H, C, P, N.$$

Thus regular rational readback is consumed only as finite window data compared against the dyadic endpoint and membership ledger. The route contains no open-cover compactness theorem, no selected subcover, no quotient real equality, no countable choice, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the rows W and Q. By the carrier definition, W is the only $\mathsf{StreamName}^{\uparrow}$ finite-window row and Q is the only $\mathsf{RegSeqRat}^{\uparrow}$ readback row available to the interval-cover packet.

Apply Definition 1428.6. It forces every regular-name cover decision through M, R, Q, V, A and excludes later regular-sequence tails and ambient equality of real names.

Now apply Definition 1428.28. The readback row Q is accounted together with W and R against the mesh and membership rows M, V. Endpoint rows L, U and the seal row A remain displayed packet data, while H, C, P, N only transport, replay, package, and name the same finite route. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRegSeqRatRoute`

Theorem 1428.31 (DyadicIntervalCover Real seal nonescape)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Every* $\mathsf{Real}^{\uparrow}$ *seal read through A is downstream of the displayed endpoint, mesh, radius, membership, window, and readback rows L, U, M, R, V, W, Q and remains inside the structural rows H, C, P, N. The seal cannot export open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRealSealNonescape`

Proof. Project A from the carrier. The seal row appears only after the dyadic endpoint rows, mesh row, radius ledger, membership row, finite StreamName window, and RegSeqRat readback row have been displayed.

Use Definition 1428.5. It bounds every seal read by the carrier rows and the local NameCert obligations, so the seal cannot leave the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert surface.

Finally apply Definition 1428.29. The finite ledger already denies arbitrary open-cover compactness and selected subcover data. Since quotient real equality, countable choice, and ambient Real completeness are also absent from I, no Real-seal consumer can recover them from A, H, C, P, N. □

Theorem 1428.32 (DyadicIntervalCover L10 finite-window obligations)**.** *Every* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *L10 consumer reads the finite cover surface of an accepted packet* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *only after consuming the dyadic endpoint rows* L, U*, mesh row* M*, radius ledger* R*, cover-membership row* V*,* $\mathsf{StreamName}^{\uparrow}$ *finite window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, visible* $\mathsf{Real}^{\uparrow}$ *seal* A*,* hsame *transport row* H*,* Cont *replay row* C*,* Pkg *provenance row* P*, and local* NameCert *row* N*. The exported route is therefore*

$$L, U, M, R, V, W, Q, A, H, C, P, N,$$

and it contains no open-cover compactness theorem, selected subcover, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverL10WindowObligations`

Proof. Apply Definition 1428.23. It places every refinement read behind the endpoint rows, mesh row, radius ledger, membership row, and structural replay data.

Apply Definition 1428.25. The Real-facing route must pass through the finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, dyadic cover ledger, and visible $\mathsf{Real}^{\uparrow}$ seal.

Next use Definition 1428.26 and Definition 1428.27. Membership transport remains inside the displayed endpoint, mesh, radius, readback, and replay rows, while the seal cannot leave the finite window and readback route.

Finally apply Definition 1428.28. It identifies W, Q, R against M, V as the whole regular-window accounting surface. Since the carrier has no coordinate for open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no L10 interval-cover consumer can read such data from I. □

Theorem 1428.33 (DyadicIntervalCover root window obligations)**.** *Let* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ BHist *packet. Every root-window obligation for* I *is read through the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius rows* L, U, R*, and visible* $\mathsf{Real}^{\uparrow}$ *seal* A *before the local* NameCert *row* N *is exported. The root window has no coordinate for open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootWindowObligations`

Proof. Project the carrier of Definition 1428.1. The BHist packet lists the endpoint rows, mesh row, radius ledger, membership row, finite window, readback, Real seal, transport, replay, provenance, and local naming row as its entire root surface.

Apply Definition 1428.8. It identifies L, U, M, R, V, W, Q, A as the whole interval-window data before the local NameCert row is exported.

Use Definition 1428.6 to bind regular-name reads to W, Q, M, R, V, A. Since L, U, R are the dyadic endpoint and tolerance data and A is the only Real seal, every root-window obligation is exhausted by the stated finite route. □

Theorem 1428.34 (DyadicIntervalCover root refinement obligations)**.** *For accepted* DyadicIntervalCover$^{\uparrow}$ *packets* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *and* $I' = (L', U', M', R', V', W', Q', A', H', C', P', N')$*, any root refinement displayed by the packet is an* hsame *and* Cont *route over endpoint, mesh, radius, membership, window, readback, and seal rows. Refinement may sharpen* M *and compare the dyadic endpoint and radius rows through* DyadicRatCore$^{\uparrow}$*, but it preserves the same* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootRefinementObligations`

Proof. Project both carriers. The only rows that can vary under refinement are the displayed endpoint, mesh, radius, membership, finite-window, readback, seal, transport, replay, provenance, and local naming rows.

Apply Definition 1428.11. Componentwise hsame data and the displayed Cont route preserve the same finite interval-window route through the L10 siblings.

Use Definition 1428.26. The membership row is transported only along H and replayed only along C over L, U, M, R, W, Q, A. Thus the root refinement obligation is endpoint and mesh refinement inside the displayed packet, not a selected subcover, host equality, quotient equality, choice principle, or Real completeness claim. □

Theorem 1428.35 (DyadicIntervalCover root ledger obligations)**.** *For every accepted* DyadicIntervalCover$^{\uparrow}$ *carrier* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$*, the root ledger obligations are exhausted by the radius ledger* R *and finite membership row* V *against the endpoint rows* L, U*, mesh row* M*, finite window* W*, readback row* Q*, Real seal* A*, and structural rows* H, C, P, N*. No hidden cover ledger, open-cover selector, later regular-sequence tail, quotient real equality, countable choice, or ambient completeness datum is available outside those rows.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootLedgerObligations`

Proof. Begin with Definition 1428.28. It identifies the regular-window ledger as the finite accounting of W, Q, R against the mesh and membership rows M, V.

Next use Definition 1428.13. The radius and membership rows are the exact accounting rows for the endpoint comparisons and regular-name windows.

Finally read the structural rows H, C, P, N through the carrier. They transport, replay, package, and name the same finite ledger, but they add no hidden cover list, selector, later tail, quotient equality, choice schedule, or completeness coordinate. Therefore the root ledger obligations are exhausted by the displayed finite packet. □

Theorem 1428.36 (DyadicIntervalCover root cell carrier rows)**.** *For every accepted* DyadicIntervalCover$^{\uparrow}$ *carrier* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$*, the root cell carrier rows consist exactly of the dyadic endpoint cell rows* L, U*, the mesh-level row* M*, the finite coverage ledger rows* R, V*, and the displayed* Cont *replay row* C *over the same cover surface. These rows are transported by* H*, packaged by* P*, and named by* N*, and they do not expose open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootCellCarrier`

Proof. Project the accepted carrier through Definition 1428.1. The endpoint cells are exactly L, U, the displayed mesh level is M, and the coverage accounting appears only as the radius and membership rows R, V.

Apply Definition 1428.35. It exhausts the root ledger by R, V against $L, U, M, W, Q, A, H, C, P, N$, so no hidden cover ledger or selector remains outside the displayed carrier.

Finally read the replay coordinate C together with H, P, N. These structural rows preserve the same finite cell surface and cannot add compactness, quotient equality, choice, or Real-completeness data. □

Theorem 1428.37 (DyadicIntervalCover root refinement coverage)**.** *For any finite displayed chain of root refinements of accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packets, induction over the refinement windows preserves coverage through the same endpoint cell rows, mesh-level rows, coverage ledgers,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. Preservation under* hsame *is a rowwise coverage statement, not an open-cover compactness theorem or selected-subcover principle.*

Proof. Use finite induction on the displayed refinement chain. The base case is the root cell carrier surface of Definition 1428.36: the cover is read only through $L, U, M, R, V, W, Q, A, H, C, P, N$.

For the successor step, apply Definition 1428.34. A refinement step transports endpoint, mesh, radius, membership, window, readback, and seal rows through componentwise hsame and displayed Cont replay.

It remains to preserve coverage rather than merely row shape. Use Definition 1428.35; the finite coverage ledger is exhausted by R, V at each stage, so the induction keeps the cover within the same displayed rows and introduces no selected subcover, quotient equality, choice schedule, or Real-completeness coordinate. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootRefinementCoverage`

Theorem 1428.38 (DyadicIntervalCover root Real-seal handoff)**.** *Any* $\mathsf{Real}^{\uparrow}$ *consumer reading a root* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *seal must first pass through* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint comparison, the* $\mathsf{StreamName}^{\uparrow}$ *finite window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalCover}^{\uparrow}}$ *coverage surface. Only after those rows are displayed may the consumer read the Real seal A, and that read does not import host real equality, quotient stream equality, selected limits, countable choice, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRootRealSealHandoff`

Proof. Start with Definition 1428.3. The lower and upper endpoint cells enter only as $\mathsf{DyadicRatCore}^{\uparrow}$ rows, with the mesh and ledger data displayed before any Real-facing seal is public.

Next read the finite window and readback rows. By Definition 1428.36, the $\mathsf{StreamName}^{\uparrow}$ window W and $\mathsf{RegSeqRat}^{\uparrow}$ readback Q remain attached to the endpoint, mesh, radius, and membership rows.

Finally apply Definition 1428.35. The local NameCert surface forces the consumer through R, V, H, C, P, N before the Real seal A is read, so the handoff exports only a finite cover read and no host equality, quotient equality, selected limit, choice, compactness, or completeness claim. □

Theorem 1428.39 (DyadicIntervalCover cell refinement exhaustion)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Every cell-refinement read of I is exhausted by the lower and upper endpoint rows L, U, mesh row M, radius ledger R, membership row V, and the transport, replay, provenance, and local naming rows H, C, P, N, with the StreamName, RegSeqRat, and Real-seal rows W, Q, A serving only as the finite readback surface for those same cells. No refinement read imports open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient Real completeness.*

Proof. Project the accepted packet through Definition 1428.8. The displayed cover surface is exactly the finite endpoint, mesh, radius, membership, window, readback, seal, transport, replay, provenance, and naming data carried by $L, U, M, R, V, W, Q, A, H, C, P, N$.

Apply Definition 1428.11. A refinement can only transport endpoint, mesh, radius, membership, window, readback, and seal rows along componentwise hsame data and the displayed Cont replay route.

Now use Definition 1428.13 and Definition 1428.35. They identify R, V as the exact finite ledger against $L, U, M, W, Q, A, H, C, P, N$. Thus the cell-refinement read is exhausted by the displayed rows and has no coordinate for compactness, selected subcovers, quotient equality, choice, or Real completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverCellRefinementExhaustion`

Theorem 1428.40 (DyadicIntervalCover refinement-chain induction)**.** *For any finite displayed chain of accepted* DyadicIntervalCover$^{\uparrow}$ *refinements*

$$I_0 \rightsquigarrow I_1 \rightsquigarrow \cdots \rightsquigarrow I_k,$$

the cover surface at every stage is preserved as the same finite route through endpoint rows, mesh rows, radius ledgers, membership rows, StreamName windows, RegSeqRat readbacks, Real seals, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. The chain induction exports no selected subcover, open-cover compactness theorem, quotient real equality, countable choice, or ambient Real completeness.*

Proof. Use finite induction on the displayed refinement chain. The base stage is Definition 1428.8: the packet exposes only the finite cover surface $L, U, M, R, V, W, Q, A, H, C, P, N$.

For the successor step, apply Definition 1428.11. The refinement step preserves the endpoint, mesh, radius, membership, window, readback, and seal rows by componentwise transport and replay through H, C, P, N.

It remains to keep the ledger bounded along the chain. Use Definition 1428.13 together with Definition 1428.35: each stage reads only R, V against $L, U, M, W, Q, A, H, C, P, N$. Therefore finite induction preserves the same cover surface and introduces no hidden compactness, selected subcover, quotient equality, choice, or completeness row. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRefinementChainInduction`

Theorem 1428.41 (DyadicIntervalCover Real-seal cover handoff)**.** *Let* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *be an accepted* DyadicIntervalCover$^{\uparrow}$ *packet. Any* Real$^{\uparrow}$ *seal* A *consumed by a cover reader factors through the finite window row* W*, regular-rational readback row* Q*, mesh row* M*, radius ledger* R*, and membership row* V *before the seal is exposed to the reader. The handoff may then be transported, replayed, packaged, and named by* H, C, P, N*, but it cannot expose host real equality, quotient stream equality, selected limits, countable choice, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRealSealCoverHandoff`

Proof. Start with Definition 1428.8. It places the Real seal A behind the displayed finite cover surface rather than before it.

Next use Definition 1428.35. The ledger obligations for a cover reader are exhausted by R, V against $L, U, M, W, Q, A, H, C, P, N$, so the seal has to pass through W, Q, M, R, V before it can be consumed as a cover read.

Finally apply Definition 1428.13 and Definition 1428.11. Exactness keeps the handoff inside the finite ledger, while refinement stability keeps transport and replay inside H, C, P, N. Hence the Real-seal handoff exports no host equality, quotient stream, selected limit, choice principle, compactness theorem, or completeness claim. □

Theorem 1428.42 (DyadicIntervalCover mesh refinement induction)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* DyadicIntervalCover$^{\uparrow}$ BHist *packet. Every mesh refinement read of I is obtained by finite induction over the displayed mesh rows: the base row reads L, U, M, R, V through* DyadicRatCore$^{\uparrow}$*, and each successor row transports the refined endpoint, radius, membership,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and* Real$^{\uparrow}$ *data through the same* hsame*,* Cont*,* Pkg*, and* NameCert *surface. No refinement step imports open-cover compactness, selected subcovers, quotient stream equality, countable choice, or Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverMeshRefinementInduction`

Proof. Project the carrier of Definition 1428.1. The mesh row M and radius ledger R are finite BHist rows, and the endpoint and membership rows L, U, V are the only cover-facing rows available at the base mesh.

Apply Definition 1428.34. A displayed refinement is an hsame and Cont route over endpoint, mesh, radius, membership, window, readback, and seal rows, so the induction step preserves the same finite packet surface.

Use Definition 1428.35. The ledger is exhausted by R, V against $L, U, M, W, Q, A, H, C, P, N$, hence the induction has no extra coordinate from which to read compactness, a selected subcover, quotient stream equality, countable choice, or Real completeness. □

Theorem 1428.43 (DyadicIntervalCover finite mesh induction)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* DyadicIntervalCover$^{\uparrow}$ *packet. Finite induction over the displayed mesh rows preserves the endpoint rows L, U, mesh and radius rows M, R, membership row V,* StreamName$^{\uparrow}$ *window W,* RegSeqRat$^{\uparrow}$ *readback Q,* Real$^{\uparrow}$ *seal A, and structural rows H, C, P, N. The induction exports no selected subcover, quotient equality, countable choice, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverFiniteMeshInduction`

Proof. Apply Definition 1428.42 for the finite induction spine and Definition 1428.34 for the endpoint, mesh, radius, membership, window, readback, and seal rows preserved at each step.

Use Definition 1428.13 to keep the route exhausted by $L, U, M, R, V, W, Q, A, H, C, P, N$, and then apply Definition 1428.51. The Real seal remains downstream of the same finite projection, so the induction has no coordinate for selected subcovers, quotient equality, countable choice, open-cover compactness, or ambient Real completeness. □

Theorem 1428.44 (DyadicIntervalCover endpoint comparison totality)**.** *For an accepted* DyadicIntervalCover$^{\uparrow}$ *carrier $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$, every cover decision compares lower and upper* DyadicRatCore$^{\uparrow}$ *endpoint rows through the displayed mesh and tolerance ledger before the terminal* Real$^{\uparrow}$ *seal is read. The comparison route is total for the finite displayed cover rows because each membership row V is checked against L, U, M, R, W, Q and then transported, replayed, packaged, and named only by H, C, P, N.*

Proof. Start with Definition 1428.3. It admits L and U only as DyadicRatCore$^{\uparrow}$ endpoint rows and places M, R beside them as the finite mesh and tolerance data for comparison.

Next apply Definition 1428.28. The regular-window ledger accounts for W, Q, R against M, V, so every finite cover decision has a displayed row in which endpoint comparison, tolerance, window, and readback data meet.

Finally use Definition 1428.31. The $\mathsf{Real}^{\uparrow}$ seal A is downstream of L, U, M, R, V, W, Q and remains inside H, C, P, N. Thus endpoint comparison is total for the finite displayed ledger and cannot be replaced by host real equality, quotient equality, choice, selected limits, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverEndpointComparisonTotality`

Theorem 1428.45 (DyadicIntervalCover tail pullback stability)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Pulling a* $\mathsf{StreamName}^{\uparrow}$ *consumer back to any displayed finite tail window preserves the same* $\mathsf{RegSeqRat}^{\uparrow}$ *route W, Q and the same dyadic cover ledger L, U, M, R, V before the* $\mathsf{Real}^{\uparrow}$ *seal A is readable. The pullback route has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or Real completeness.*

Proof. Project the window and readback rows from Definition 1428.1. The row W is the only $\mathsf{StreamName}^{\uparrow}$ finite-window source, and Q is the only $\mathsf{RegSeqRat}^{\uparrow}$ readback row attached to it.

Apply Definition 1428.6. Every regular-name cover read is exhausted by a finite window computation through M, R, Q, V, A, so pulling back to a displayed tail window changes only the finite window presented to the same route.

Use Definition 1428.11. The componentwise hsame row and displayed Cont replay preserve endpoint, mesh, radius, membership, window, readback, and seal rows, while Pkg provenance and $\mathsf{NameCert}$ naming keep the packet local. Hence tail pullback cannot import quotient stream equality, selected limits, countable choice, host equality, or Real completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverTailPullbackStability`

Theorem 1428.46 (DyadicIntervalCover scoped mesh refinement)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Every scoped mesh-refinement obligation is bound to the finite endpoint rows L, U over* $\mathsf{DyadicRatCore}^{\uparrow}$*, the displayed mesh row M, the cover-membership row V, the* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *finite-cover membership handoff, and the structural rows H, C, P, N. Refinement changes only displayed cover rows and never imports selected subcovers, quotient real equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows L, U, M, R, V from Definition 1428.1. The lower and upper endpoints are dyadic rows, and the mesh and membership data are finite cover rows attached to those endpoints.

Proceed by induction over the displayed refinement rows. The base case is the admitted mesh row M with its membership row V. The successor step uses componentwise transport H and displayed replay C to replace each endpoint, mesh, radius, and membership row by its refined displayed row.

The $\mathsf{BishopIntervalCompact}^{\uparrow}$ handoff reads only this finite cover membership surface. Since P, N source and name the same packet, the scoped obligation remains a finite refinement route and cannot acquire an unlisted compactness or choice principle. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverMeshRefinementScope`

Theorem 1428.47 (DyadicIntervalCover scoped finite-window coverage)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P,$ be an accepted* DyadicIntervalCover$^{\uparrow}$ *packet. Every finite-window coverage obligation factors through the* StreamName$^{\uparrow}$ *window row W, the* RegSeqRat$^{\uparrow}$ *readback row Q, the dyadic endpoint rows L, U, the mesh and radius rows M, R, and the cover-membership row V before any* Real$^{\uparrow}$ *seal is read. The coverage scope is finite and visible to* BishopIntervalCompact$^{\uparrow}$ *only through those rows.*

Proof. Begin with a coverage request for a displayed interval cell. The request first reads the endpoint rows L, U and the mesh-radius data M, R, because those rows determine which finite cover membership rows can be inspected.

The finite observation boundary is then supplied by W and Q. The stream row selects the visible windows, and the regular rational row packages the endpoint and radius reads before the real seal is available.

Finally use V, H, C, P, N to record membership, transport it along the displayed route, replay the same read, source it, and name it. This proves finite-window coverage by packet projection, not by a selected finite subcover or an open-cover compactness theorem. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverWindowCoverageScope`

Theorem 1428.48 (DyadicIntervalCover scoped Real-seal handoff)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* DyadicIntervalCover$^{\uparrow}$ *packet. Every scoped* Real$^{\uparrow}$ *handoff reaches the seal row A only after the finite* DyadicRatCore$^{\uparrow}$ *endpoint rows,* StreamName$^{\uparrow}$ *window row,* RegSeqRat$^{\uparrow}$ *readback row,* BishopIntervalCompact$^{\uparrow}$ *membership handoff, mesh row, radius ledger, and cover-membership rows have been displayed. The seal handoff exports no host real equality, quotient stream equality, selected subcover, countable choice, or ambient Real completeness.*

Proof. Read the seal route from the displayed carrier. The endpoint rows L, U and the mesh-radius rows M, R determine the finite cover cells, while V records membership for the cover consumer.

Next pass through W and Q. These rows make the cover data readable as finite stream windows and regular rational readbacks before the seal row A can be inspected.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and naming. The BishopIntervalCompact$^{\uparrow}$ handoff therefore receives a finite Real-seal boundary, not a host compactness theorem or a completion principle. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRealSealScope`

Theorem 1428.49 (DyadicIntervalCover mesh refinement obligation)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* DyadicIntervalCover$^{\uparrow}$ *carrier. Every mesh-refinement obligation for I is discharged by finite projection through the displayed endpoint rows L, U, mesh row M, radius ledger R, membership row V,* StreamName$^{\uparrow}$ *window row W,* RegSeqRat$^{\uparrow}$ *readback row Q,* Real$^{\uparrow}$ *seal row A, and the structural rows H, C, P, N. The refinement may only sharpen displayed dyadic cells through* DyadicRatCore$^{\uparrow}$ *and then replay the same route through* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Proof. Start with Definition 1428.42. It reads mesh refinement by finite induction over the displayed mesh rows, with the base step in L, U, M, R, V and each step transported through the same H, C, P, N surface.

Use Definition 1428.34 and Definition 1428.40. These keep the endpoint, mesh, radius, membership, window, readback, and seal rows componentwise visible along the refinement chain.

Finally apply Definition 1428.13. Since the ledger is exhausted by R, V against $L, U, M, W, Q, A, H, C, P, N$, the obligation has no source for selected subcovers, quotient equality, countable choice, open-cover compactness, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverMeshRefinementObligationCertificate`

Theorem 1428.50 (DyadicIntervalCover subcover handoff obligation)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N$ be an accepted* DyadicIntervalCover$^{\uparrow}$ *carrier. Every finite subcover handoff consumed by a* BishopIntervalCompact$^{\uparrow}$ *or Completion-facing reader must first display the same rows $L, U, M, R, V, W, Q, A, H, C, P, N$: dyadic endpoints through* DyadicRatCore$^{\uparrow}$*, finite windows through* StreamName$^{\uparrow}$*, regular readback through* RegSeqRat$^{\uparrow}$*, the visible seal through* Real$^{\uparrow}$*, and the local route through* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Proof. Begin with Definition 1428.9. It places the compact-interval consumer behind the dyadic endpoint, mesh, radius, membership, window, readback, Real-seal, transport, replay, provenance, and naming rows.

Next apply Definition 1428.47. The coverage request factors through W, Q, L, U, M, R, V before any Real seal is consumed, so the handoff is a finite-window coverage row rather than an open-cover theorem.

The structural rows complete the handoff. By Definition 1428.36, H, C, P, N transport, replay, source, and name the same finite cell surface; no selected subcover, host compactness theorem, quotient real equality, countable choice, or ambient completion row is exported. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverSubcoverHandoffObligation`

Theorem 1428.51 (DyadicIntervalCover Real-seal nonescape obligation)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P$ be an accepted* DyadicIntervalCover$^{\uparrow}$ *carrier. Every* Real$^{\uparrow}$ *seal read from A is a nonescaping finite projection: it passes through* DyadicRatCore$^{\uparrow}$ *endpoint and radius rows,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback, cover-membership rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *before any Real-facing consumer may inspect the seal.*

Proof. Read the existing seal boundary through Definition 1428.5. The row A is the only Real-seal coordinate and is bounded by $L, U, M, R, V, W, Q, H, C, P, N$.

Then use Definition 1428.41 and Definition 1428.48. Both place the seal after the finite window, regular readback, mesh, radius, and membership rows, with the BishopIntervalCompact$^{\uparrow}$ handoff still inside the displayed route.

The nonescape claim follows from carrier exactness and ledger exactness. The accepted packet has no coordinate for host real equality, quotient stream equality, selected limits, countable choice, open-cover compactness, selected subcovers, or ambient Real completeness, so the seal cannot leave the finite projection route. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRealSealNonescapeObligation`

Theorem 1428.52 (DyadicIntervalCover scoped finite-cover chain)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* DyadicIntervalCover$^{\uparrow}$ *packet. Every scoped finite-cover chain exposed by I factors through lower and upper endpoint rows in* DyadicRatCore$^{\uparrow}$*, finite-cover membership rows consumed by* BishopIntervalCompact$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$ *readback through W, Q, and the terminal* Real$^{\uparrow}$ *seal row A. The structural rows H, C, P, N preserve the same finite route by* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming; the chain does not assert open-cover compactness, host selected subcovers, quotient real equality, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverScopedFiniteCoverChain`

Proof. Project the endpoint, mesh, radius, and membership rows from Definition 1428.1. The rows L, U are the dyadic endpoints, while M, R, V are the finite cells and membership data visible to the interval-compactness consumer.

Apply Definition 1428.50. It places any $\mathsf{BishopIntervalCompact}^{\uparrow}$ handoff behind the same displayed rows $L, U, M, R, V, W, Q, A, H, C, P, N$ and treats the handoff as a finite membership route rather than an open-cover theorem.

Use Definition 1428.51. The readback rows W, Q and the seal row A remain downstream of the displayed cover chain, so $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers receive only the finite route. The structural rows preserve that route and add no selected subcover or ambient compactness coordinate. □

Theorem 1428.53 (DyadicIntervalCover public certificate scope)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. The public certificate scope of I is exactly the finite route through* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows L, U,* $\mathsf{StreamName}^{\uparrow}$ *window row W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q,* $\mathsf{Real}^{\uparrow}$ *seal row A, the* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *finite-net handoff, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}$ *row N, with mesh, radius, and membership rows M, R, V retained as the cover ledger.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverPublicCertificateScope`

Proof. Start with Definition 1428.52. It already places the finite-cover chain inside the displayed rows $L, U, M, R, V, W, Q, A, H, C, P, N$ and keeps the route away from open-cover compactness, host selected subcovers, quotient real equality, countable choice, and ambient Real completeness.

Next use Definition 1428.9. The finite-net handoff to $\mathsf{BishopIntervalCompact}^{\uparrow}$ is available only after the dyadic endpoints, mesh, radius, cover membership, finite windows, regular readback, Real seal, transport, replay, provenance, and local naming rows have been exposed.

Finally apply Definition 1428.13. The ledger rows M, R, V are exact only against the same endpoint, window, readback, seal, transport, replay, provenance, and NameCert route. Therefore the public certificate scope is precisely that finite route, with no extra coordinate for selected subcovers, quotient equality, choice, host compactness, or ambient completion. □

Theorem 1428.54 (DyadicIntervalCover public finite-cover export)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. The public export surface of I is the single finite-cover NameCert route that displays the finite mesh M, dyadic endpoint rows L, U, cover-membership ledger V,* $\mathsf{StreamName}^{\uparrow}$ *window row W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q,* $\mathsf{Real}^{\uparrow}$ *seal row A, and* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *handoff through H, C, P, N. This route exports finite-cover data only; it still refuses selected finite subcovers, quotient real equality, countable choice, open-cover compactness, host compactness, and ambient completion.*

Proof. Start from Definition 1428.53. It identifies the public certificate scope as the finite route through dyadic endpoints, StreamName windows, RegSeqRat readback, Real sealing, Bishop interval compact handoff, transport, replay, provenance, local naming, and the cover ledger rows M, R, V.

Use Definition 1428.50. The $\mathsf{BishopIntervalCompact}^{\uparrow}$ consumer is reached only after the dyadic endpoint, mesh, radius, membership, window, readback, Real-seal, transport, replay, provenance, and naming rows are displayed.

Finally apply Definition 1428.49 and Definition 1428.51. The first keeps the finite mesh and refinement data inside the displayed dyadic route, while the second keeps the Real seal downstream of the same finite projection. Hence the public export is the named finite-cover NameCert route itself, with no extra selector, quotient, choice, compactness, or completion coordinate. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverPublicFiniteCoverExport`

Theorem 1428.55 (DyadicIntervalCover bridge handoff)**.** *Every bridge-facing consumer of the public finite-cover export of Definition 1428.54 must preserve the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows, mesh row, cover-membership ledger,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The handoff is the finite public-cover route itself; it does not claim bridge checking, open-cover compactness, selected finite subcovers, quotient real equality, countable choice, or ambient completion.*

Proof. Start with the public finite-cover export. It identifies the available public surface as the displayed rows $L, U, M, R, V, W, Q, A, H, C, P, N$ together with the $\mathsf{BishopIntervalCompact}^{\uparrow}$ handoff.

Use the scoped Real-seal and nonescape obligations, Definition 1428.48 and Definition 1428.51. They keep every bridge-facing read downstream of the dyadic endpoints, mesh, membership, window, readback, Real seal, transport, replay, provenance, and naming rows.

Since the carrier has no coordinate for open-cover compactness, selected finite subcovers, quotient real equality, countable choice, or ambient completion, a bridge-facing consumer can preserve only the displayed finite-cover route. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBridgeHandoff`

Theorem 1428.56 (DyadicIntervalCover content route preservation)**.** *Every Real-facing consumer that uses the bridge handoff of Definition 1428.55 preserves the same* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and interval-cover rows exposed by the public finite-cover export. Thus the moved route remains the displayed finite-cover NameCert route through dyadic endpoints, mesh and cover-membership data, stream windows, regular rational readback, Real sealing, interval compactness handoff, transport, replay, provenance, and local naming.*

Proof. Apply the public finite-cover export of Definition 1428.54. It names the public route through $L, U, M, R, V, W, Q, A, H, C, P, N$, with dyadic endpoints, mesh and membership data, stream windows, regular readback, the Real seal, and the interval-compactness handoff all displayed.

Then apply the bridge handoff of Definition 1428.55. A bridge-facing consumer must preserve exactly that displayed route and cannot replace it with open-cover compactness, selected finite subcovers, quotient real equality, countable choice, or ambient completion.

The Real-facing part is therefore still the same finite route: L, U give the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint surface, W gives the $\mathsf{StreamName}^{\uparrow}$ window, Q gives the $\mathsf{RegSeqRat}^{\uparrow}$ readback, A gives the $\mathsf{Real}^{\uparrow}$ seal, and M, R, V, H, C, P, N preserve the interval-cover carrier and NameCert structure. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverContentSplitRoute`

Theorem 1428.57 (DyadicIntervalCover bridge budget)**.** *Let* $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ *be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. The displayed dyadic interval-cover rows provide exactly the bridge budget consumed by* $\mathsf{BishopIntervalCompact}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{UniformModulus}^{\uparrow}$ *routes: dyadic endpoints and mesh data, finite cover-membership rows, stream windows, regular-rational readbacks, the visible Real seal, transport, replay, provenance, and local naming. The budget exports no open-cover compactness, selected limit, selected finite subcover, quotient real equality, countable choice, or ambient Real completeness.*

Proof. Start with the local obligation surface of Definition 1428.2. It exhausts every endpoint, mesh, radius, membership, window, readback, seal, transport, replay, provenance, and naming obligation by finite projection from I.

Use the public export theorem, Definition 1428.54. It identifies the public surface as the finite-cover NameCert route through $L, U, M, R, V, W, Q, A, H, C, P, N$ and the $\mathsf{BishopIntervalCompact}^{\uparrow}$ handoff.

The same rows are the only data visible to the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ consumers. Since the accepted carrier has no coordinate for open-cover compactness, selected limits, selected subcovers, quotient equality, choice, or ambient completeness, the bridge budget is exactly the displayed finite route. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBridgeBudget`

Theorem 1428.58 (DyadicIntervalCover finite-cover bridge scope)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Any bridge consumer of I must expose the dyadic endpoint rows L, U, the mesh row M, the radius ledger R, the finite cover-membership row V, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the* $\mathsf{Real}^{\uparrow}$ *seal A, the* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *handoff, the* $\mathsf{UniformModulus}^{\uparrow}$*-facing lower-bound route, componentwise transport H, displayed replay C, provenance P, and local naming N before the bridge budget can be read. The bridge scope exports finite-cover data only; it does not claim open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverFiniteCoverBridgeScope`

Proof. Start from the public finite-cover export, Definition 1428.54. It identifies the public surface as the finite route through $L, U, M, R, V, W, Q, A, H, C, P, N$ and the $\mathsf{BishopIntervalCompact}^{\uparrow}$ handoff.

Use the bridge budget theorem, Definition 1428.57. The budget is read only by the displayed dyadic, stream, regular-rational, Real, interval-compact, and uniform-modulus-facing consumers.

Combining the two statements gives the bridge scope. Every bridge consumer must first expose the finite endpoint, mesh, radius, membership, window, readback, seal, handoff, transport, replay, provenance, and naming rows, while the refused compactness, selector, quotient, choice, and completion endpoints remain outside the packet. □

Theorem 1428.59 (DyadicIntervalCover regular Cauchy bridge window)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P,$ be an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet. Any bridge consumer that reads a regular Cauchy name through I must first expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows L, U, the* $\mathsf{StreamName}^{\uparrow}$ *window row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row A, the* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *finite-cover handoff, the* $\mathsf{UniformModulus}^{\uparrow}$ *lower-bound route, and the structural rows H, C, P, N. Only after that bridge window is displayed may the consumer read the bridge budget; the packet exports no selected limit, selected finite subcover, quotient real equality, countable choice, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRegularCauchyBridgeWindow`

Proof. Begin with finite-window exhaustion from Definition 1428.47. It places the stream window and regular-rational readback behind the displayed dyadic endpoint, mesh, radius, and membership rows.

Next use the public finite-cover export Definition 1428.54. The export identifies the $\mathsf{BishopIntervalCompact}^{\uparrow}$ handoff as part of the same finite route, with the Real seal still downstream of the cover-membership rows.

Apply the bridge budget Definition 1428.57 and the finite-cover bridge scope Definition 1428.58. Together they force every bridge consumer to expose the dyadic endpoints, StreamName windows,

RegSeqRat readback, Real seal, finite-cover handoff, uniform-modulus lower-bound route, and structural rows before any budget is consumed. □

Theorem 1428.60 (DyadicIntervalCover bridge export)**.** *Every accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *bridge export is the finite route isolated in Definition 1428.58: the dyadic endpoint and mesh rows* L, U, M*, radius budget* R*, finite cover-membership rows* V*,* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*,* $\mathsf{Real}^{\uparrow}$ *seal row* A*, and structural rows* H, C, P, N*. No bridge consumer receives a selected finite subcover, quotient real equality, open-cover compactness, host compactness, countable choice, or ambient completion coordinate from the export.*

Proof. Read the bridge scope theorem Definition 1428.58. It names the endpoint rows L, U, mesh row M, radius budget R, finite cover-membership rows V, stream window row W, regular rational readback row Q, Real seal row A, and structural rows H, C, P, N before any bridge consumer can inspect the cover export.

The present theorem adds no carrier coordinate beyond that list. Its export is therefore the projection that forgets the internal proof route and keeps exactly the displayed endpoint, mesh, radius, membership, stream, readback, seal, transport, replay, provenance, and local naming rows.

Since the source bridge scope excludes selected finite subcovers, quotient real equality, open-cover compactness, host compactness, countable choice, and ambient completion, the projected export excludes them as well. A consumer can only replay the finite route already isolated by the bridge scope. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBridgeExport`

Theorem 1428.61 (DyadicIntervalCover uniform-modulus bridge consumer)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *or compact-uniform-continuity consumer of an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *bridge reads exactly the finite endpoint rows, mesh row, radius budget, finite cover-membership rows,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{Real}^{\uparrow}$ *seal row, and structural* hsame*,* Cont*,* Pkg*, and* NameCert *rows isolated by Definition 1428.60. The consumer receives no selected finite subcover, open-cover compactness, quotient real equality, choice coordinate, or ambient completion coordinate.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverUniformModulusBridgeConsumer`

Proof. Start with the bridge export theorem. It projects the accepted bridge to the endpoint rows L, U, mesh row M, radius budget R, cover-membership rows V, stream window row W, regular rational readback row Q, Real seal row A, and structural rows H, C, P, N.

Apply the finite-cover bridge scope. The scope fixes the same rows before a downstream consumer can inspect the cover data, so a $\mathsf{UniformModulus}^{\uparrow}$ or compact-uniform-continuity reader can only replay that finite route.

Finally use the L10 uniform-modulus handoff narrative. Its consumer-facing input is the exported endpoint, mesh, radius, membership, stream, readback, seal, transport, replay, provenance, and local naming surface, not a selected subcover, an open-cover compactness principle, quotient real equality, choice, or an ambient completion coordinate. □

Theorem 1428.62 (DyadicIntervalCover bridge export cofinality)**.** *Every downstream compact-uniform-continuity or* $\mathsf{UniformModulus}^{\uparrow}$ *read of a* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *bridge export is cofinal in the displayed finite route*

$$L, U, M, R, V, W, Q, A, H, C, P, N.$$

Any precision request reaching $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *must first pass through the finite endpoint rows* L, U*, mesh row* M*, radius-budget row* R*, and cover-membership rows* V *isolated by Definition 1428.60.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBridgeExportCofinality`

Proof. Apply Definition 1428.60. The export exposes exactly the endpoint, mesh, radius-budget, membership, stream-window, readback, seal, transport, replay, provenance, and local naming rows, so every downstream read starts from that finite coordinate list.

Use Definition 1428.61. A compact-uniform-continuity or $\mathsf{UniformModulus}^{\uparrow}$ consumer receives the same rows and no further bridge coordinate, hence its precision requests cannot reach W, Q, A before the endpoint, mesh, radius, and membership rows have been displayed.

The cofinality claim follows by coordinate exhaustion. The listed route contains no selected finite subcover, open-cover compactness proof, quotient real equality, choice coordinate, or ambient completion row, so any consumer reaching $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ has already passed through the displayed finite endpoint, mesh, radius-budget, and cover-membership data. □

Theorem 1428.63 (DyadicIntervalCover bridge finite route)**.** *Every bridge consumer of an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet factors through the finite endpoint rows, mesh row, radius ledger, finite membership row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row before any standard interval-cover interpretation is read. The bridge route exports only those displayed finite rows; it exports no open-cover compactness, selected finite subcover, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted carrier $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$. The rows L, U are the endpoint data, M is the mesh row, R is the radius ledger, and V is the finite membership row.

Read the window and seal rows next. The $\mathsf{StreamName}^{\uparrow}$ windows W, $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and $\mathsf{Real}^{\uparrow}$ seal A are downstream of the endpoint, mesh, radius, and membership rows.

Use the existing compact handoff and bridge export surface. The $\mathsf{BishopIntervalCompact}^{\uparrow}$ handoff is read only after those finite rows, while H, C, P, N transport, replay, source, and name the same route.

Thus any standard interval-cover interpretation available to a bridge consumer is a readback of $L, U, M, R, V, W, Q, A, H, C, P, N$. Since no excluded compactness, selector, quotient, choice, or completion coordinate occurs in the carrier, none can be exported by the bridge route. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBridgeFiniteRoute`

Theorem 1428.64 (DyadicIntervalCover finite bridge budget)**.** *Any bridge read of an accepted* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *packet must consume the endpoint rows, mesh row, radius ledger, finite membership row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *handoff before a standard interval-cover interpretation is visible. The budget exports no selected finite subcover, open-cover compactness, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverFiniteBridgeBudget`

Proof. Project the same carrier $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ used by Definition 1428.63. The endpoint rows L, U, mesh row M, radius ledger R, and finite membership row V are the first finite data consumed by the bridge.

The observation and seal rows follow. The $\mathsf{StreamName}^{\uparrow}$ windows W, $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and $\mathsf{Real}^{\uparrow}$ seal A make the endpoint and radius data visible as finite real-facing reads.

The $\mathsf{BishopIntervalCompact}^{\uparrow}$ handoff is available only after those rows, and the structural rows H, C, P, N preserve the same route. Since the carrier contains no selector, open-cover compactness,

quotient equality, choice, or ambient completeness coordinate, the finite bridge budget cannot export any of them. □

Theorem 1428.65 (DyadicIntervalCover bridge refinement boundary)**.** *A standard interval-cover bridge for an accepted* DyadicIntervalCover$^{\uparrow}$ *packet may refine endpoint rows, mesh rows, radius ledgers, membership rows,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readbacks, and* Real$^{\uparrow}$ *seals only by componentwise* hsame *transport and displayed* Cont *replay over the same finite packet. The bridge cannot introduce open-cover compactness, a selected finite subcover, quotient real equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with the bridge finite route of Definition 1428.63. It makes every bridge read pass through the finite endpoint, mesh, radius, membership, stream-window, readback, seal, compact-handoff, transport, replay, provenance, and local naming rows.

Apply the finite bridge budget of Definition 1428.64. Any bridge refinement must therefore act on the displayed rows already present in $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$.

Componentwise hsame transport refines the endpoint, mesh, radius, membership, window, readback, and seal rows without changing the packet boundary. Displayed Cont replay then reruns the same bridge route over the refined rows, while P, N keep the provenance and local naming attached to the original finite packet.

Since the refinement never leaves those rows, it has no coordinate from which to obtain open-cover compactness, a selected finite subcover, quotient real equality, countable choice, or ambient Real$^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBridgeRefinementBoundary`

Theorem 1428.66 (DyadicIntervalCover bridge-budget child witness)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N$ be an accepted* DyadicIntervalCover$^{\uparrow}$ *packet. Any consumer that reads a finite-cover bridge from the bridge budget must first display the dyadic endpoint rows L, U, the mesh and refinement rows M, R, V, the* StreamName$^{\uparrow}$ *windows W, the* RegSeqRat$^{\uparrow}$ *readback Q, and the terminal* Real$^{\uparrow}$ *seal A, together with the* BishopIntervalCompact$^{\uparrow}$ *handoff and structural rows H, C, P, N. Without this displayed child witness, the bridge budget is not available as a finite-cover read.*

Proof. Project the existing bridge budget of Definition 1428.57. It identifies the budget as the displayed finite route through dyadic endpoints, mesh data, finite cover-membership rows, StreamName windows, RegSeqRat readbacks, the visible Real seal, transport, replay, provenance, and local naming.

Next use Definition 1428.58. That theorem forces every bridge consumer to expose the same rows before reading the budget, including the BishopIntervalCompact$^{\uparrow}$ handoff and the lower-bound route faced by uniform-modulus consumers.

Finally read the sibling routes named in the carrier: DyadicRatCore$^{\uparrow}$ supplies endpoint arithmetic, StreamName$^{\uparrow}$ supplies finite windows, RegSeqRat$^{\uparrow}$ supplies rational readback, Real$^{\uparrow}$ supplies the seal boundary, and BishopIntervalCompact$^{\uparrow}$ consumes only the displayed finite membership surface. Since none of these rows contains open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient Real completeness, the child witness is exactly the finite bridge-budget display. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBridgeBudgetChildWitness`

Theorem 1428.67 (DyadicIntervalCover standard bridge premise)**.** *Every standard bridge read of an accepted* DyadicIntervalCover$^{\uparrow}$ *packet must expose the lower endpoint rows, upper endpoint rows,*

mesh row, radius ledger, finite membership row, StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal,* BishopIntervalCompact$^{\uparrow}$ *handoff,* UniformModulus$^{\uparrow}$ *lower-bound route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before any interval-cover interpretation is public. The bridge premise exports no open-cover compactness theorem, selected subcover, quotient real equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverStandardBridgePremise`

Proof. Project the accepted carrier $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ from Definition 1428.1. The rows L, U are the lower and upper endpoint rows, M is the mesh row, R is the radius ledger, and V is the finite cover-membership row.

Apply Definition 1428.63. It forces every bridge consumer through the endpoint, mesh, radius, membership, window, readback, seal, interval-compact handoff, transport, replay, provenance, and naming rows before a standard interval-cover interpretation can be read.

Next use Definition 1428.61. The UniformModulus$^{\uparrow}$-facing lower-bound route is therefore a consumer of the same displayed finite rows, not a detached open-cover or selected-subcover principle.

Finally apply Definition 1428.65. Componentwise hsame transport and displayed Cont replay can refine only the listed rows, while P, N preserve provenance and local naming. Since the carrier has no coordinate for open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient completeness, the standard bridge premise cannot export any of those objects. □

Theorem 1428.68 (DyadicIntervalCover bridge window)**.** *Let $I = (L, U, M, R, V, W, Q, A, H, C, P, N)$ be an accepted* DyadicIntervalCover$^{\uparrow}$ *finite-window carrier. If endpoint comparison, refinement-chain induction,* Real$^{\uparrow}$ *seal handoff, and finite-subcover ledger rows are all displayed for I, then I induces the bridge window required by the abstract dyadic interval cover interface. The induced window is the finite route through $L, U, M, R, V, W, Q, A, H, C, P, N$; it does not assert Heine–Borel compactness, open-cover compactness, selected limits, selected subcovers, quotient real equality, countable choice, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverBridgeWindow`

Proof. Start from the root finite-cover boundary of Definition 1428.17. It fixes the endpoint, mesh, radius, membership, window, readback, seal, transport, replay, provenance, and local naming rows before any interval-cover reader can inspect the carrier.

Apply mesh and refinement control through Definition 1428.42 and Definition 1428.40. Finite induction keeps each refined cell inside the same displayed rows, while endpoint comparison totality from Definition 1428.44 keeps the lower and upper endpoint decisions inside the dyadic ledger.

Finally compose the Real-facing and ledger boundaries. The Real$^{\uparrow}$ handoff of Definition 1428.41 and the nonescape obligation of Definition 1428.51 place the seal after the finite window and cover rows, while Definition 1428.29 accounts for the visible subcover ledger. The resulting bridge window is therefore a finite interface window only, with none of the excluded compactness, choice, limit, quotient, or standard-bridge data. □

Closure status for NameCert$_{\text{DyadicIntervalCover}^{\uparrow}}$.

Constructive story: A DyadicIntervalCover$^{\uparrow}$ packet is generated from dyadic lower and upper endpoint rows, a mesh index, a radius ledger, finite cover-membership rows, StreamName windows, RegSeqRat readbacks, a Real seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicIntervalCover}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1428.47, Definition 1428.50, Definition 1428.61, Definition 1428.13, and Definition 1428.55 bind the finite-window carrier, Bishop interval compact handoff, compact-uniform window route, ledger exactness surface, and bridge-facing public finite-cover route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicIntervalCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, Heine–Borel compactness, sequential compactness, selected limits, quotient real equality, host real equality, countable choice, Real completeness, or a standard bridge.

Upgrade path: Verification closure requires Lean coverage for the public finite-cover export route and then a standard bridge that preserves the same refusal surface.

Theorem 1428.69 (DyadicIntervalCover mature finite-cover export)**.** *Every mature* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *consumer that exports finite-cover data must first factor through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *finite-cover handoff,* $\mathsf{UniformModulus}^{\uparrow}$ *lower-bound route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The mature export is public only after those rows preserve the finite cover route isolated by the bridge-facing children; it does not export open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host compactness, or a hidden completion coordinate.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverMatureFiniteCoverExport`

Proof. Start with the public finite-cover export of Definition 1428.54. It exposes the accepted packet only through dyadic endpoints, mesh and radius data, finite cover-membership rows, stream windows, regular-rational readback, a Real seal, the Bishop interval compact handoff, transport, replay, provenance, and local naming.

Next read the finite-cover bridge scope of Definition 1428.58. That scope requires a bridge consumer to display the same endpoint, mesh, radius, membership, window, readback, seal, interval-compact, uniform-modulus, transport, replay, provenance, and naming rows before any bridge budget is consumed.

The regular Cauchy bridge window and bridge export children then bind the Real and Completion handoff. Apply Definition 1428.59 to force regular-name reads through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopIntervalCompact}^{\uparrow}$, and $\mathsf{UniformModulus}^{\uparrow}$ rows, and apply Definition 1428.60 to project the same finite route as the exported bridge surface.

Finally compare with the bridge-facing public handoff of Definition 1428.55. It preserves exactly the finite public-cover route and explicitly leaves bridge checking and stronger compactness or completion principles outside the packet. Therefore a mature finite-cover export has to be the displayed route above, with open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient Real completeness, host compactness, and hidden completion data refused. □

Theorem 1428.70 (DyadicIntervalCover RegularCauchy finite-window handoff)**.** *Any* RegularCauchyCompletionU *or* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of a mature* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *finite-cover export must expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows, mesh and radius data, finite cover-membership rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, RegularCauchy window routing, the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *finite-cover handoff, the* $\mathsf{UniformModulus}^{\uparrow}$ *lower-bound route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before it can read the exported comparison. The handoff exports no open-cover compactness theorem, selected subcover, quotient real equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with Definition 1428.69. It already forces a mature export through dyadic endpoint rows, mesh and radius data, cover-membership rows, stream windows, regular-rational readback, the Real seal, interval-compact and uniform-modulus handoffs, and the structural rows.

Apply the regular-Cauchy bridge window theorem, Definition 1428.59. This identifies the RegularCauchy-facing read as a finite window route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopIntervalCompact}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, transport, replay, provenance, and local naming.

Finally compose the bridge export and bridge handoff theorems, Definition 1428.60 and Definition 1428.55. They keep the same finite-cover surface public while refusing open-cover compactness, selected subcovers, quotient real equality, countable choice, and ambient Real completeness, so every RegularCauchy or RegSeqRat consumer receives exactly the stated handoff. □

Lean4 ✓ `BEDC.Derived.DyadicIntervalCoverUp.DyadicIntervalCoverRegularCauchyFiniteWindowHandoff`

Chapter 1429

A Concrete Naming Certificate for $\mathsf{DecimalEndpointNormalization}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DecimalEndpointNormalization}^{\uparrow}$ packet records the finite convention that relates terminating decimal prefixes to repeating-nine endpoint prefixes. It refines the finite decimal readback surface of chapter 1417 without selecting a host representative for a real number. The packet compares its decimal-window rows with the binary and continued-fraction readback neighbors of chapter 418 and chapter 342, and it hands all real-facing reads through chapter 126, chapter 291, chapter 301, and chapter 38.

Definition 1429.1 (Decimal endpoint normalization carrier)**.** *A* $\mathsf{DecimalEndpointNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, E, L, A, W, Q, R, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite digit-prefix ledger. Its rows list the inspected decimal prefixes, their signs or integral prefixes when present, and the finite place window in which the prefix is read.*
2. *E is the terminating-versus-repeating-nine endpoint ledger. Each row records a displayed finite terminating prefix, the corresponding repeating-nine tail convention visible inside the same finite window, and the endpoint side on which the convention is invoked.*
3. *L is the decimal carry and normalization row. It records the finite carry propagation, the last changed digit, and the normalized prefix produced by that carry.*
4. *A is the base-ten rational place-value row for the prefixes displayed by D, E, L.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to request and replay exactly the inspected prefix and endpoint-convention entries.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance readback row comparing the base-ten place-value rows with the dyadic tolerance demanded by the consumer.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from the same window, place-value, carry, and dyadic-tolerance rows.*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after D, E, L, A, W, Q, R have been displayed.*

9. *H stores componentwise* hsame *transports for digit-prefix, endpoint-ledger, carry-normalization, place-value, stream-window, dyadic-tolerance, regular-readback, seal, continuation, provenance, and local naming rows.*

10. *C stores the displayed* Cont *replay from prefix windows to endpoint rows, from endpoint rows to carry normalization, from normalization to dyadic tolerance, from tolerance to regular readback, and from readback to the real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{DecimalEndpointNormalization}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{BinaryExpansion}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalEndpointNormalization}^{\uparrow}}$ *row.*

The carrier stores only the finite endpoint-convention certificate just displayed. It has no row for host decimal equality, quotient-real equality, selected representatives, trichotomy, countable choice, $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Definition 1429.2 (Decimal endpoint normalization classifier)**.** *The local classifier for an accepted packet $K = (D, E, L, A, W, Q, R, S, H, C, P, N)$ accepts exactly those finite reads that pass through the displayed rows in the order*

$$D, E, L, A, W, Q, R, S.$$

It treats a terminating endpoint row and its repeating-nine companion as two named endpoint conventions inside the same finite ledger E; it then reads the carry row L to produce the normalized finite prefix inspected by A. Classifier transport is componentwise through H, continuation is replay through C, and package admissibility is the single provenance row P together with the local naming row N.

Theorem 1429.3 (Decimal endpoint normalization NameCert obligations)**.** *For an accepted* DecimalEndpointNorm *carrier $K = (D, E, L, A, W, Q, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DecimalEndpointNormalization}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the digit-prefix, endpoint-ledger, carry-normalization, place-value, stream-window, dyadic-tolerance, regular-readback, real-seal, transport, continuation, provenance, and naming rows;*

2. *classifier transport along the stored* hsame *coordinates and the displayed* Cont *route;*

3. *endpoint-ledger exactness, stating that every terminating-versus-repeating-nine comparison exported by the packet is one of the rows listed in E and normalized through L;*

4. *readback discipline, stating that every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer reads the same finite window before receiving the corresponding tolerance, handoff, or seal row;*

5. *ledger exclusion, stating that host decimal equality, quotient-real equality, selected representatives, trichotomy, countable choice,* $\mathsf{Real}^{\uparrow}$ *completeness, and bridge data are not exported by the packet.*

Lean4 ✓ `BEDC.Derived.DecimalEndpointNormalizationUp.TasteGate.DecimalEndpointNormalizationTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 1429.1. The finite digit-prefix rows, endpoint ledger, carry-normalization row, place-value row, stream window, dyadic tolerance, regular

readback, real seal, transports, continuations, package row, and local naming row are precisely the displayed coordinates.

Classifier transport is componentwise. The digit and endpoint rows move through their stored hsame witnesses, while C replays the same window-to-endpoint, endpoint-to-carry, carry-to-tolerance, and tolerance-to-readback route after transport.

Endpoint-ledger exactness is local to E and L. A terminating prefix and a repeating-nine companion are compared only when the finite ledger lists that pair, and the only exported normalization is the carry row displayed for that pair.

The readback discipline then follows the sibling surfaces. Windows are read through chapter 126, dyadic tolerances through chapter 291, regular rational handoff through chapter 301, and the terminal seal through chapter 38.

The excluded principles are absent from the carrier inventory, so the local certificate cannot export them. □

Theorem 1429.4 (Decimal endpoint Real readback boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{DecimalEndpointNormalization}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DecimalExpansion}^{\uparrow},\ \mathsf{DecimalEndpointNormalization}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The decimal packet supplies finite prefix rows, the endpoint-normalization packet supplies the displayed terminating-versus-repeating-nine ledger and carry row, the stream window supplies the inspected observation, the dyadic row supplies tolerance readback, the regular row supplies the rational handoff, and the real-facing consumer receives only the displayed seal. The binary and continued-fraction neighbors from chapter 418 and chapter 342 are comparison readback surfaces, not additional representative selectors.

Proof. Start with the accepted packet $K = (D, E, L, A, W, Q, R, S, H, C, P, N)$. The decimal-facing data are D, E, L, A: the prefix ledger, endpoint-convention ledger, carry-normalization row, and base-ten place-value row.

The stream-facing data are exactly the windows in W. A consumer can inspect only the finite prefix and endpoint rows named by that window, so no infinite decimal stream enters the read.

The dyadic row Q converts the same finite normalized prefix into the tolerance language used by downstream real consumers. The regular handoff row R is reached only after D, E, L, A, W, Q are fixed.

The seal row S is downstream of R, and the rows H, C, P, N preserve the same route under transport, continuation, provenance, and local naming. Thus the real readback has the displayed finite factorization and cannot add a selected representative or quotient-real equality test. □

Theorem 1429.5 (Decimal endpoint nonescape)**.** *Let* $K = (D, E, L, A, W, Q, R, S, H, C, P, N)$ *be an accepted* $\mathsf{DecimalEndpointNormalization}^{\uparrow}$ *packet. Any consumer that reads an endpoint convention, a normalized decimal prefix, a dyadic tolerance, a regular rational handoff, or a visible* $\mathsf{Real}^{\uparrow}$ *seal is exhausted by the displayed rows of* K*. In particular, no route from* K *escapes to endpoint uniqueness as host equality, quotient reals, selected representatives, trichotomy, countable choice,* $\mathsf{Real}^{\uparrow}$ *completeness, or a bridge.*

Proof. Read the requested datum by cases. Endpoint conventions use E, normalized decimal prefixes use L together with the prefix rows D, dyadic tolerances use Q, regular rational handoffs use R, and visible real seals use S.

The shared observation window is W, and all replay is mediated by C. Hence every case remains inside the finite window and the rows already displayed in the carrier.

Transport and provenance do not add new data. The row H transports equal displayed coordinates, while P records the dependence on the decimal, binary, continued-fraction, stream, dyadic, regular, and real sibling surfaces already cited in the chapter.

The listed escaped objects are not rows of K. Therefore the packet cannot supply them to any consumer of its endpoint-normalization certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalEndpointNormalization}^{\uparrow}}$.

Constructive story: A $\mathsf{DecimalEndpointNormalization}^{\uparrow}$ packet is generated from finite digit-prefix rows, a terminating-versus-repeating-nine endpoint ledger, a carry-normalization row, StreamName windows, DyadicRatCore tolerance readback, RegSeqRat handoff, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DecimalEndpointNormalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1429.1, Definition 1429.2, Definition 1429.3, Definition 1429.4, and Definition 1429.5 seed the finite decimal endpoint-convention surface for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DecimalEndpointNormalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close endpoint uniqueness as host equality, quotient reals, selected representatives, trichotomy, countable choice, RealUp completeness, or a bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, endpoint-ledger exactness, readback discipline, nonescape, and RealUp seal handoff for the displayed packet.

Chapter 1430

A Concrete Naming Certificate for $\mathsf{BoundedRealFamily}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BoundedRealFamily}^{\uparrow}$ packet records a bounded family of real names by finite index-window rows, visible StreamName windows, regular rational readback, RealUp family seals, and a closed-bounded interval-net bound row. It is the family-facing analogue of the bounded sequence surface in chapter 1415, shares the explicit modulus discipline of chapter 1423, and reads cover-facing interval data through chapter 1428. Its bound row is the finite $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ surface of chapter 1250, and each terminal family member is sealed only through the $\mathsf{Real}^{\uparrow}$ route of chapter 38. The packet prepares later least-upper-bound, compactness, and cover-selection certificates without importing trichotomy, quotient equality, countable choice, or a supremum principle.

Definition 1430.1 (Bounded real family carrier)**.** *A* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, W, Q, R, B, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index-window ledger. Each row names an inspected family index together with the finite observation window requested at that index.*
2. *W is the family of* $\mathsf{StreamName}^{\uparrow}$ *windows displayed for the inspected index-window rows of I.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those StreamName windows and their visible dyadic tolerance observations.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *family-seal row. A family member is visible to a Real-facing consumer only after its index row, StreamName window, and RegSeqRat readback have been displayed.*
5. *B is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row carrying the located lower and upper interval data used to witness a common bound for the displayed family rows.*
6. *H stores componentwise* hsame *transport for the index-window ledger, StreamName windows, regular readback, Real family seals, bound row, continuation replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from index-window rows to StreamName windows, from StreamName windows to RegSeqRat readback, from RegSeqRat readback to Real family seals, and from Real family seals to the common bound ledger.*

8. *P is the* Pkg *provenance over* $\mathsf{BoundedRealFamily}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}$ *row.*

The bound row is displayed as finite located interval data

$$B : \mathsf{ClosedBoundedIntervalNet}^{\uparrow},$$
$$\forall i \in I_{\text{shown}} \quad W_i \longmapsto Q_i \longmapsto R_i \in B.$$

Here I_{shown} denotes only the inspected finite index-window rows carried by the packet. The classifier compares accepted packets only through $I, W, Q, R, B, H, C, P, N$ and has no coordinate for trichotomy, quotient equality of real names, countable choice over indices, an ambient supremum, open-cover compactness, or host completeness.

Lean4 ✓ `BEDC.Derived.BoundedRealFamilyUp.BoundedRealFamilyTasteGate single carrier alignment`

Theorem 1430.2 (Bounded real family located upper row)**.** *For every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier $F = (I, W, Q, R, B, H, C, P, N)$, the bound row B is read through finite located lower and upper interval data. Each displayed family member reaches the common bound by the route*

$$I \longmapsto W \longmapsto Q \longmapsto R \longmapsto B$$

together with H, C, P, N. Thus the located upper row is a finite certificate row and imports no trichotomy, quotient equality of real names, countable choice, supremum principle, or host completeness.

Lean4 ✓ `BEDC.Derived.BoundedRealFamilyUp.BoundedRealFamilyLocatedUpperRow`

Proof. Project the carrier of Definition 1449.1. The only family data exposed to the classifier are the finite index-window ledger I, the displayed $\mathsf{StreamName}^{\uparrow}$ windows W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and the terminal $\mathsf{Real}^{\uparrow}$ family seals R.

Read the bound coordinate next. The row B is a $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ packet, so its lower and upper interval data are displayed finite rows from chapter 1250. A family member can meet B only after its own window, readback, and seal route has already been replayed.

The structural rows preserve this same route. Componentwise transport H, continuation replay C, package provenance P, and the local name N have no field for trichotomy, quotient equality, countable choice, a supremum, or host completeness. Hence the located upper row is read as finite interval data and nothing stronger. □

Theorem 1430.3 (Bounded real family RegSeqRat scope)**.** *Every Real-facing read of an accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{ClosedBoundedIntervalNet}^{\uparrow}$$

as instantiated by the rows W, Q, R, B and transported by H, C, P, N. No consumer can read a family member, a bound assertion, or a cover-facing handoff outside the StreamName windows, RegSeqRat readback, RealUp family seals, and bound ledger carried by the packet.

Lean4 ✓ `BEDC.Derived.BoundedRealFamilyUp.BoundedRealFamilyRegSeqRatScope`

Proof. Begin with a Real-facing request for an inspected family row. The carrier first exposes the index-window ledger I and the corresponding $\mathsf{StreamName}^{\uparrow}$ window in W.

The request then passes through the regular rational readback. The row Q is the only $\mathsf{RegSeqRat}^{\uparrow}$ coordinate, and the terminal $\mathsf{Real}^{\uparrow}$ seal R is reached only after Q has been displayed.

Finally the bound assertion is read through B. Since B is the only bound ledger and since H, C, P, N only transport, replay, source, and name the displayed rows, the request cannot leave the StreamName, RegSeqRat, RealUp, and bound-ledger scope of the packet. □

Theorem 1430.4 (Bounded real family bound-ledger nonescape)**.** *Every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *packet reads the common bound only through the displayed rows* $I, W, Q, R, B, H, C, P, N$*. In particular, a consumer cannot export trichotomy, quotient real equality, countable choice over indices, a supremum principle, open-cover compactness, or host completeness from the bound ledger.*

Proof. Project the carrier of Definition 1449.1. The common bound is the single row B, and it is available only after the finite index-window ledger I, StreamName windows W, RegSeqRat readback Q, and Real family seals R have been displayed.

Apply Definition 1449.2. It identifies the bound row as finite located lower and upper interval data rather than as an ambient order-completeness witness or a selected supremum.

Apply Definition 1449.3. It forces every Real-facing read of a family member or bound assertion through the StreamName, RegSeqRat, RealUp, and ClosedBoundedIntervalNet route carried by W, Q, R, B.

It remains to inspect the structural rows. The transport row H preserves only componentwise equality of the displayed rows, the replay row C replays only the displayed route, the provenance row P names only the sibling sources, and the local row N names the packet. None of H, C, P, N contains a branch for trichotomy, quotient real equality, countable choice over indices, supremum extraction, open-cover compactness, or host completeness. Thus the common-bound read cannot escape the finite bound ledger. □

Theorem 1430.5 (Bounded real family obligation surface)**.** *Every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier exposes exactly the finite index-window ledger* I*,* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*,* $\mathsf{Real}^{\uparrow}$ *family seals* R*,* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row* B*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}$ *row* N *before any compactness, least-upper-bound, or cover-selection consumer may read it.*

Proof. Project the carrier of Definition 1449.1. Its displayed coordinates are exactly $I, W, Q, R, B, H, C, P, N$, so an obligation-level consumer has no other entry point.

Apply Definition 1449.2 to the bound coordinate. The common bound is finite located interval-net data, not a supremum, cover selector, or host completeness witness.

Apply Definition 1449.3 and Definition 1449.4. They force every Real-facing read through the StreamName, RegSeqRat, RealUp, and ClosedBoundedIntervalNet route and bar trichotomy, quotient equality, countable choice, compactness extraction, least-upper-bound extraction, and cover-selection reads. Hence the listed rows are exactly the obligation surface available before downstream consumers add their own data. □

Theorem 1430.6 (BoundedRealFamily scoped dependency route)**.** *Every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *packet exposes its finite index-window ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *family-seal row,* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows before any compactness, least-upper-bound, or cover-selection consumer may read it. The route exports no trichotomy, quotient equality of real names, countable choice, supremum principle, open-cover compactness, or host completeness.*

Proof. Project the carrier in Definition 1449.1. Its finite dependency route is exactly $I, W, Q, R, B, H, C, P, N$.

The analytic rows are already ordered. Apply Definition 1449.2 for the located upper row, Definition 1449.3 for the StreamName and RegSeqRat scope, and Definition 1449.4 for the bound-ledger refusal.

Now apply Definition 1449.5. It exhausts the rows visible before a downstream compactness, least-upper-bound, or cover-selection consumer adds its own data.

Since the packet has no coordinate beyond those rows, it exports no trichotomy, quotient equality, countable choice, supremum, open-cover compactness, or host-completeness principle. □

Theorem 1430.7 (Bounded real family compactness consumer boundary)**.** *Every compactness consumer of an accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier* $F = (I, W, Q, R, B, H, C, P, N)$ *must add its own finite-net, total-boundedness, located-compactness, or compactness row before reading a compactness conclusion. The rows* $I, W, Q, R, B, H, C, P, N$ *expose the bounded-family obligation surface and common bound ledger, but they do not by themselves supply an open-cover compactness theorem, selected finite subcover, compact metric witness, or compactness classifier.*

Proof. Start from the carrier in Definition 1449.1. Its coordinates list finite index windows, StreamName windows, RegSeqRat readback, Real seals, one ClosedBoundedIntervalNet bound row, transport, replay, provenance, and the local NameCert row.

Apply Definition 1449.2 and Definition 1449.3. These route every Real-facing read through the displayed windows, readback, seals, and bound row, so a compactness consumer can only see the bounded-family route already named by $I, W, Q, R, B, H, C, P, N$.

Finally apply Definition 1449.4 and Definition 1449.5. The bound ledger refuses compactness extraction, and the obligation surface is exhausted before any downstream compactness consumer reads the packet. Therefore compactness requires an explicit downstream finite-net or compactness row. □

Theorem 1430.8 (Bounded real family least-upper-bound refusal)**.** *For every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier* $F = (I, W, Q, R, B, H, C, P, N)$*, the common bound row* B *is a* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row and not a supremum, least-upper-bound, order-completeness, or trichotomy witness. A least-upper-bound consumer must therefore provide its own supremum or completeness row outside the bounded-family packet.*

Proof. Read the carrier through Definition 1449.1. The bound coordinate is named as $B : \mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, attached downstream of the finite index-window, StreamName, RegSeqRat, and Real-family rows.

Apply Definition 1449.2. It identifies B as finite located lower and upper interval data, so the row witnesses a displayed common bound rather than a selected least upper bound.

Apply Definition 1449.4 and Definition 1449.5. These theorems remove trichotomy, quotient equality of real names, countable choice, host completeness, and supremum extraction from the rows available to a consumer. Thus a least-upper-bound read must come from a separate downstream row. □

Theorem 1430.9 (Bounded real family cover-selection boundary)**.** *Every cover-selection consumer of an accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier must pass through an explicit finite-cover, finite-net, or selected-cover sibling row before exporting a cover conclusion. The bounded-family packet supplies only* $I, W, Q, R, B, H, C, P, N$ *and cannot select a finite subcover from those rows alone.*

Proof. Project the carrier in Definition 1449.1. The only cover-facing data present before downstream consumption are the family windows, rational readback, Real seals, the ClosedBoundedIntervalNet bound row, and the structural rows H, C, P, N.

Use Definition 1449.3. It forces a cover-facing read of a family member or bound assertion to pass through the same StreamName, RegSeqRat, RealUp, and ClosedBoundedIntervalNet route.

Now apply Definition 1449.4 and Definition 1449.5. They exclude open-cover compactness, cover selection, and hidden choice from the displayed bounded-family rows. Hence a cover-selection consumer must provide a separate finite-cover or finite-net sibling row before any cover conclusion is exported. □

Falsifiable prediction: Every $\mathsf{BoundedRealFamily}^{\uparrow}$ Real-facing read factors through finite index windows, StreamName windows, RegSeqRat readback, RealUp family seals, and a ClosedBoundedIntervalNet bound row.

Independence witness: boundedrealsequence, realcauchymodulus, dyadicintervalcover, closedboundedintervalnet, real: $\mathsf{BoundedRealFamily}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an index-window family ledger, StreamName windows, RegSeqRat readback, RealUp family seals, a common bound ledger, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRealFamily}^{\uparrow}$ packet is generated from finite index-window rows, StreamName windows, RegSeqRat readback, RealUp family seals, a ClosedBoundedIntervalNet bound row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1449.1, Definition 1449.2, Definition 1449.3, Definition 1449.4, Definition 1449.5, Definition 1449.6, Definition 1449.7, Definition 1449.8, and Definition 1449.9 bind the finite bounded-family obligation surface, scoped dependency route, and public compactness, least-upper-bound, and cover-selection consumer boundaries over StreamNameUp, RegSeqRatUp, RealUp, and ClosedBoundedIntervalNetUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.BoundedRealFamilyUp.BoundedRealFamilyTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, trichotomy, quotient equality of real names, countable choice, an ambient supremum principle, open-cover compactness, or host completeness.

Upgrade path: Bridge closure requires the standard bridge row needed by downstream compactness, least-upper-bound, and cover-selection routes.

Chapter 1431

A Concrete Naming Certificate for $\mathsf{SternBrocotApproximation}^{\uparrow}$

Following Stern–Brocot and Farey rational approximation, the $\mathsf{SternBrocotApproximation}^{\uparrow}$ packet records finite rational bracketing as displayed BEDC data. It reads a pair of rational interval endpoints through chapter 354, a finite mediant path through dyadic tolerance bookkeeping from chapter 291, a $\mathsf{StreamName}^{\uparrow}$ observation window from chapter 126, a $\mathsf{RegSeqRat}^{\uparrow}$ readback from chapter 301, and a terminal $\mathsf{Real}^{\uparrow}$ seal from chapter 38. The packet is a finite bracketing neighbor of the decimal and continued-fraction readback surfaces in chapter 1417 and chapter 342; it does not store an ambient real order or a quotient-real representative.

Definition 1431.1 (Stern–Brocot approximation carrier)**.** *A* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, M, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower rational endpoint row, carrying the left side of the displayed* $\mathsf{RationalInterval}^{\uparrow}$ *bracket.*
2. *U is the upper rational endpoint row, carrying the right side of the displayed* $\mathsf{RationalInterval}^{\uparrow}$ *bracket.*
3. *M is the finite mediant-path ledger, whose rows record the left/right Stern–Brocot choices and the rational mediants actually inspected.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including the dyadic precision requested by the consumer and the displayed bound showing that the bracket width is below that tolerance.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window used to request and replay the inspected rational rows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same endpoint and mediant data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the rational interval, tolerance, stream-window, and regular-rational readback rows have been displayed.*
8. *H stores componentwise* hsame *transports for endpoint, mediant-path, tolerance, stream-window, readback, and seal rows.*
9. *C stores the* Cont *replay from stream windows to mediant inspection, from mediant inspection to rational bracketing, from bracketing to regular readback, and from readback to the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{SternBrocotApproximation}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}$ *row.*

The carrier stores only a finite rational bracketing certificate. It has no coordinate for Dedekind cuts, trichotomy, quotient reals, selected representatives, or RealUp completeness.

Lean4 ✓ `BEDC.Derived.SternBrocotApproximationUp.SternBrocotApproximationTasteGate single carrier alignment`

Theorem 1431.2 (Stern–Brocot NameCert obligations)**.** *For an accepted* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *carrier* $K = (L, U, M, T, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the lower endpoint, upper endpoint, mediant-path, dyadic tolerance, stream-window, regular-rational readback, real-seal, transport, continuation, provenance, and naming rows;*
2. *classifier transport along the stored* hsame *rows and displayed* Cont *routes;*
3. *bracketing exactness, stating that every exported rational bracket is one of the endpoint or mediant rows displayed by L, U, M and checked against T;*
4. *readback discipline, stating that every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer reads through the finite window W and the regular readback row R before receiving the seal row E;*
5. *ledger exclusion, stating that Dedekind cuts, trichotomy, quotient reals, selected representatives, and RealUp completeness are not exported by the packet.*

Proof. Carrier admission is projection from the tuple in Definition 1431.1. The rational endpoints, mediant path, dyadic tolerance, stream window, regular readback, real seal, transports, continuations, package row, and local naming row are precisely the displayed coordinates.

Classifier transport is componentwise. The endpoint and mediant rows move through their stored hsame witnesses, while C replays the same window-to-mediant and bracket-to-readback route after transport.

Bracketing exactness uses the sibling interval and dyadic arithmetic surfaces. The endpoint rows are the displayed $\mathsf{RationalInterval}^{\uparrow}$ bounds from chapter 354, and the tolerance row is the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ comparison row from chapter 291.

The readback discipline then follows the stored route through chapter 126, chapter 301, and chapter 38. The excluded principles are absent from the carrier inventory, so the local certificate cannot export them. □

Theorem 1431.3 (Finite rational bracketing)**.** *Every accepted* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *packet exposes a finite rational bracket*

$$L \leq M_i \leq U$$

at each inspected mediant row M_i of the finite ledger M, and the final displayed bracket has width bounded by the dyadic tolerance row T. Every route to the bracket factors through

$$\mathsf{RationalInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow}.$$

The packet supplies no host trichotomy, no quotient-real equality test, and no choice of a distinguished representative for the sealed real.

Proof. Read the mediant ledger M in order. Each row records a finite left/right choice and the rational mediant computed from the currently displayed endpoints, so the next bracket is formed by replacing exactly one endpoint with that mediant.

The interval side is supplied by chapter 354. It records the endpoint rows and the local comparison data needed to keep the displayed lower endpoint below the displayed upper endpoint at the inspected scale.

The tolerance side is supplied by chapter 291. The row T records the dyadic precision and the displayed comparison showing that the final interval width is below that precision.

The window side is supplied by chapter 126. Since the carrier has no other observation coordinate, every bracket read factors through the displayed finite window and the rational rows it exposes. □

Theorem 1431.4 (Stern–Brocot Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *packet factors through the finite handoff*

$$\mathsf{SternBrocotApproximation}^{\uparrow},\ \mathsf{RationalInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The Stern–Brocot carrier provides the finite rational bracket; the decimal and continued-fraction siblings of chapter 1417 and chapter 342 provide comparison readback neighbors; and the real-facing consumer receives only the displayed regular rational row R and seal row E.

Proof. Start with the accepted packet $K = (L, U, M, T, W, R, E, H, C, P, N)$. The carrier exposes the bracket through L, U, M, T and exposes the observation request through W.

The regular-rational handoff is the row R. By the readback discipline of chapter 301, a real-facing consumer reads the finite rational data through the regular sequence surface before reading a real seal.

The seal row E is therefore downstream of R and the displayed window route. The transports H, continuations C, and provenance row P preserve the same route for classified packets and for repeated finite-window reads.

The comparison with decimal and continued-fraction siblings is only a readback comparison: all three chapters present finite rational observation surfaces before the same $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. None supplies Dedekind cuts, trichotomy, quotient reals, selected representatives, or RealUp completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SternBrocotApproximation}^{\uparrow}$ packet is generated from rational interval endpoints, a finite mediant path, a dyadic tolerance row, a finite StreamName window, a RegSeqRat readback, a RealUp seal, componentwise transports, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1431.1, Definition 1431.2, Definition 1431.3, and Definition 1431.4 seed the finite Stern–Brocot rational-bracketing surface for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SternBrocotApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, trichotomy, quotient reals, selected representatives, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, bracketing exactness, readback discipline, ledger exclusion, and RealUp seal handoff for the same finite packet.

Chapter 1432

Rational interval refinement NameCert construction

Following Moore–Kearfott–Cloud interval analysis and Bishop–Bridges constructive analysis, the $\mathsf{RationalIntervalRefinement}^{\uparrow}$ packet records finite rational-interval refinement as displayed endpoint, containment, and retained-window data. It sits between the rational interval surface of chapter 354, the dyadic interval surface of chapter 306, the nested-window surface of chapter 320, the branch route of chapter 361, and the subdivision ledger of chapter 366. The packet is a finite consumer primitive for real-completion arguments, not an infinite interval tree, a host subset of $\mathsf{Real}^{\uparrow}$, or a selected completed point.

Definition 1432.1 (RationalIntervalRefinement carrier)**.** *A* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, J, E, W, K, H, C, P, N)$$

with the following displayed rows:

1. *I is the parent* $\mathsf{RationalInterval}^{\uparrow}$ *row whose endpoints and containment ledger are read from chapter 354;*
2. *J is the child* $\mathsf{RationalInterval}^{\uparrow}$ *row with displayed endpoint rows inside the parent window;*
3. *E is the endpoint-inclusion ledger certifying that the lower and upper endpoints of J are contained in the ordered endpoint surface of I;*
4. *W is the retained-window row, readable either as a* $\mathsf{NestedInterval}^{\uparrow}$ *step or as the finite rational window handed to a real-completion consumer;*
5. *K is the optional dyadic support ledger exposing the* $\mathsf{DyadicInterval}^{\uparrow}$ *boundary, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch row, or the* $\mathsf{DyadicSubdivision}^{\uparrow}$ *cell row used to produce this refinement when such a route is present;*
6. *H records componentwise* hsame *transport for the parent interval, child interval, endpoint-inclusion ledger, retained window, dyadic support rows, continuation rows, provenance, and local naming row;*
7. *C records the displayed* Cont *replay routes by which consumers reread I, J, E, W, K, H, P, N without changing the retained window;*
8. *P is the* Pkg *provenance over* $\mathsf{RationalIntervalRefinement}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{DyadicSubdivision}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{RationalIntervalRefinement}^{\uparrow}}$ *row.*
The carrier has no coordinate for countable choice, an infinite refinement branch, a completed real point, a host interval subset, or a standard bridge.

Lean4 ✓ `BEDC.Derived.RationalIntervalRefinementUp.RationalIntervalRefinementTasteGate single carrier alignment`

Theorem 1432.2 (RationalIntervalRefinement nested window)**.** *Every accepted* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *packet $R = (I, J, E, W, K, H, C, P, N)$ exposes one finite nested-window step: the child rational interval J is retained inside the parent rational interval I by the endpoint-inclusion ledger E, and the consumer-facing retained row is exactly W. If the support ledger K comes from a dyadic bisection or dyadic subdivision route, that route is read only as finite evidence for the same retained window.*

Lean4 ✓ `BEDC.Derived.RationalIntervalRefinementUp.RationalIntervalRefinementCarrier nested window`

Proof. Project the carrier of Definition 1432.1. The only parent interval coordinate is I, the only child interval coordinate is J, and the only endpoint-inclusion coordinate is E.

The retained-window row is W. It is stored beside I, J, E, so a consumer cannot read the retained window without also reading the parent, child, and endpoint-inclusion data that make the containment finite.

If K is present, it contributes only the dyadic route used to exhibit the same refinement. The transport rows in H and replay routes in C move those displayed rows componentwise, while P and N record provenance and local naming. No coordinate remains for an infinite branch or a completed real point. □

Theorem 1432.3 (RationalIntervalRefinement retained-window induction)**.** *Let a finite* $\mathsf{Nat}^{\uparrow}$*-indexed unary history ledger display accepted refinement packets*

$$R_i = (I_i, J_i, E_i, W_i, K_i, H_i, C_i, P_i, N_i)$$

in a chain where each child interval J_i is the parent interval I_{i+1} read by the next packet. Then the chain preserves a retained-window row from the first parent interval to the final child interval. The final child is read only through the successive endpoint-inclusion ledgers E_i, optional dyadic support rows K_i, componentwise hsame *transports H_i, displayed* Cont *replays C_i,* Pkg *provenance rows P_i, and local* $\mathsf{NameCert}_{\mathsf{RationalIntervalRefinement}^{\uparrow}}$ *rows N_i.*

Lean4 ✓ `BEDC.Derived.RationalIntervalRefinementUp.RationalIntervalRefinementRetainedWindowInduction`

Proof. Induct on the displayed finite $\mathsf{Nat}^{\uparrow}$ ledger. In the base case, the chain has one accepted packet, so Definition 1432.2 supplies the retained row W_0 from I_0 to J_0.

For the step, assume the retained-window row has been built through the current final child. The next accepted packet reads that child as its parent, supplies the next endpoint-inclusion row, and exposes its retained row by Definition 1432.2.

Compose the two retained reads by repacking the same finite coordinates. The endpoint ledgers provide the parent-child inclusions, any dyadic rows remain support for those inclusions, and H, C, P, N transport, replay, source, and name the same chain. No induction step introduces an infinite branch, a host interval subset, or a completed real point. □

Theorem 1432.4 (RationalIntervalRefinement chain exactness)**.** *Let a finite* $\mathsf{Nat}^{\uparrow}$*-indexed ledger display accepted* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *packets*

$$R_i = (I_i, J_i, E_i, W_i, K_i, H_i, C_i, P_i, N_i)$$

with J_i *read as the next parent interval* I_{i+1} *whenever the next packet is present. The public chain surface exposes exactly the initial parent interval* I_0*, the final child interval, the endpoint-inclusion ledgers* E_i*, retained-window rows* W_i*, optional dyadic support rows* K_i*, componentwise transports* H_i*, replay rows* C_i*, provenance rows* P_i*, and local* $\mathsf{NameCert}_{\mathsf{RationalIntervalRefinement}^{\uparrow}}$ *rows* N_i*. It exposes no infinite branch, completed real-point selection, host interval subset, or countable-choice schedule.*

Lean4 ✓ `BEDC.Derived.RationalIntervalRefinementUp.RationalIntervalRefinementChainExactness`

Proof. Induct on the finite $\mathsf{Nat}^{\uparrow}$ ledger. In the base case, the chain has one accepted packet, and Definition 1432.3 identifies the retained-window row from the parent interval to the displayed child.

For the step, apply the induction hypothesis to the prefix chain. The next accepted packet reads the previous final child as its parent, adds exactly one endpoint-inclusion ledger, one retained-window row, optional dyadic support, transport, replay, provenance, and local naming row.

Repack the prefix surface with the final packet surface using Definition 1432.3. The resulting chain records the first parent, the last child, and precisely the displayed rows from each finite packet.

No step introduces a coordinate for an infinite refinement branch, a completed real point, a host interval subset, or countable choice. Therefore the retained-window chain is exact as a finite BEDC ledger. □

Theorem 1432.5 (RationalIntervalRefinement NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RationalIntervalRefinement}^{\uparrow}}$ *surface for Definition 1432.1 consists exactly of carrier exposure for* R*, classifier exposure for the parent-child containment pair* I, J, E*, retained-window exactness through* W*, optional dyadic route exposure through* K*, componentwise transport through* H*, displayed continuation replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Carrier exposure is projection from the tuple $R = (I, J, E, W, K, H, C, P, N)$. These are precisely the rows that the local naming surface can expose.

The classifier part is finite because the parent-child containment read uses the displayed rational endpoint and containment ledgers in I, J, E. The retained-window obligation is then exactly the row W, with no hidden intersection or completion object.

The support ledger K does not change the carrier. It only records which dyadic interval, bisection, or subdivision rows were used to exhibit the same rational refinement when a dyadic route is available.

Finally H and C transport and replay the same displayed rows, while P and N bind provenance and local naming. Since the carrier has no other coordinate, the listed rows exhaust the NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.RationalIntervalRefinementUp.RationalIntervalRefinementNameCertObligations`

Theorem 1432.6 (RationalIntervalRefinement classifier stability)**.** *Let* $R = (I, J, E, W, K, H, C, P, N)$ *be an accepted* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *packet. Any second displayed packet*

$$R' = (I', J', E', W', K', H', C', P', N')$$

whose parent interval, child interval, endpoint-inclusion ledger, retained-window row, optional dyadic support row, componentwise transport row, continuation replay row, provenance row, and local naming row agree componentwise with the corresponding rows of R is accepted by the same refinement classifier. The agreement is read only through the finite hsame *rows in H, H' and the displayed* Cont *replays in C, C'.*

Proof. Project both packets through Definition 1432.1. The carrier lists exactly $I, J, E, W, K, H, C, P, N$, so a classifier read has no row outside the two rational intervals, the endpoint-inclusion ledger, the retained window, the optional dyadic support, transport, replay, provenance, and local naming.

Use Definition 1432.2. The accepted refinement classifier is determined by the retained child-in-parent read supplied by I, J, E, W, with K only recording a finite dyadic route when such support is present.

The componentwise hsame rows and displayed Cont replays preserve those same coordinates. Since P and N source and name no additional coordinate, replacing the packet by R' with the same displayed rows preserves acceptedness. □

Lean4 ✓ `BEDC.Derived.RationalIntervalRefinementUp.RationalIntervalRefinementCarrier classifier stability`

Theorem 1432.7 (RationalIntervalRefinement endpoint exactness)**.** *Every public containment read from an accepted* RationalIntervalRefinement$^{\uparrow}$ *packet $R = (I, J, E, W, K, H, C, P, N)$ factors through the displayed endpoint-inclusion ledger E and the retained-window row W. The read may use I and J to expose the parent and child rational endpoints, and it may use K, H, C, P, N to support, transport, replay, source, and name the same containment, but it cannot replace E or W by a host interval subset, an infinite branch, a completed real point, or a standard bridge.*

Proof. Begin with the carrier of Definition 1432.1. The only endpoint-inclusion coordinate is E, and the only consumer-facing retained-window coordinate is W.

Apply Definition 1432.2. It identifies the finite retained-window step with the child rational interval J retained inside the parent rational interval I by E, and it identifies W as the retained row delivered to consumers.

The remaining rows do not create a second containment source. The optional support row K only records a dyadic route for the same refinement, while H, C, P, N transport, replay, source, and name the displayed rows. Thus every public containment read factors through E and W. □

Lean4 ✓ `BEDC.Derived.RationalIntervalRefinementUp.RationalIntervalRefinementCarrier endpoint exactness`

Theorem 1432.8 (RationalIntervalRefinement ledger exhaustion)**.** *An accepted* RationalIntervalRefinement$^{\uparrow}$ *packet exposes to public consumers only the rows $I, J, E, W, K, H, C, P, N$ of Definition 1432.1. In particular, a consumer receives no infinite refinement branch, completed real point, host interval subset, quotient, countable-choice schedule, or standard bridge from the packet.*

Lean4 ✓ `BEDC.Derived.RationalIntervalRefinementUp.RationalIntervalRefinementLedgerExhaustion`

Proof. Project the accepted packet as $R = (I, J, E, W, K, H, C, P, N)$. These nine rows are the whole displayed carrier, so the public ledger begins and ends with the parent interval, child interval, endpoint-inclusion ledger, retained window, optional dyadic support, transport, replay, provenance, and local naming.

Use Definition 1432.5. The local $\mathsf{NameCert}_{\mathsf{RationalIntervalRefinement}^{\uparrow}}$ surface exposes carrier data, classifier data, retained-window exactness, optional support, componentwise hsame, displayed Cont, Pkg provenance, and local naming, and no other obligation row.

The excluded objects would require an additional coordinate: an infinite branch, completed real point, host subset, quotient, choice schedule, or bridge row. Since neither the carrier nor the NameCert obligation surface contains such a coordinate, public consumers receive none of them. □

Theorem 1432.9 (RationalIntervalRefinement finite branch exhaustion)**.** *For any finite chain of accepted* $\mathsf{RationalIntervalRefinement}^{\uparrow}$ *packets, the public branch surface preserves only the displayed parent-child endpoint ledgers, retained-window rows, optional dyadic support rows, componentwise* hsame *transports, displayed* Cont *replays,* Pkg *provenance rows, and local* $\mathsf{NameCert}_{\mathsf{RationalIntervalRefinement}^{\uparrow}}$ *rows. The chain cannot export an infinite branch, a completed* $\mathsf{Real}^{\uparrow}$ *point, a host interval subset, a quotient, a countable-choice schedule, or a standard bridge.*

Proof. Begin with the retained-window induction of Definition 1432.3. It identifies the finite chain by repeatedly reading the next parent interval as the previous child interval and by carrying forward the displayed retained-window rows.

Endpoint exactness from Definition 1432.7 forces every containment read at each step through the endpoint-inclusion ledger and the retained-window row. Optional dyadic support can witness the same containment, but it does not create another branch coordinate.

Finally apply ledger exhaustion from Definition 1432.8 to each accepted packet in the finite chain. Repacking the listed rows preserves exactly the parent-child endpoint ledgers, retained-window rows, optional dyadic support, transport, replay, provenance, and local naming. The excluded infinite branch, completed $\mathsf{Real}^{\uparrow}$ point, host subset, quotient, countable-choice schedule, and standard bridge have no coordinate in any packet and therefore cannot be exported by the chain. □

Lean4 ✓ `BEDC.Derived.RationalIntervalRefinementUp.RationalIntervalRefinementWindowBranchExhaustion`

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalIntervalRefinement}^{\uparrow}$ packet is generated from a parent $\mathsf{RationalInterval}^{\uparrow}$ row, a child $\mathsf{RationalInterval}^{\uparrow}$ row, endpoint-inclusion evidence, a retained-window row, optional dyadic route support, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RationalIntervalRefinement}^{\uparrow}}$, publicClosed)

Scope closed: Definition 1432.7, Definition 1432.8, and Definition 1432.9 supply the public containment export by exposing endpoint exactness, retained-window ledger exhaustion, and finite branch exhaustion for every displayed refinement read.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RationalIntervalRefinement}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite refinement trees, completed real point selection, host interval subsets, countable choice, standard bridges, or a Lean theorem.

Upgrade path: A formal route can encode the carrier and classifier and prove the nested-window and NameCert obligation surfaces over the displayed finite history rows.

Chapter 1433

A Concrete Naming Certificate for $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ packet records the explicit finite-net compactness certificate for displayed located closed intervals. It consumes the endpoint-cell surface of chapter 394, the mesh surface of chapter 1250, the finite-net interface of chapter 127, the complete-limit interface of chapter 128, the finite-window rows of chapter 126, the regular rational rows of chapter 301, and the terminal real seal of chapter 38. The packet is an explicit finite-net compactness certificate for displayed closed intervals; it is not general Heine–Borel compactness, not open-cover compactness, not trichotomy, not quotient real equality, and not a selected subcover choice.

Definition 1433.1 (ClosedIntervalCompactNet carrier)**.** *A* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, M, T, B, S, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint-cell row naming the displayed closed interval and its lower and upper located endpoints;*
2. *M is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *mesh row over I, including its dyadic cell ledger, center rows, and finite coverage ledger;*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net handoff row obtained from the same mesh and read at the requested positive tolerance;*
4. *B is the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary row used only to keep regular Cauchy endpoint and center reads inside the displayed metric-completion ledger;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the endpoint, center, and cell observations used by the mesh;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same finite-window observations;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached through I, M, S, R and through no detached real equality coordinate;*
8. *L is the local compact-net ledger stating that every accepted interval read is covered by one of the displayed mesh cells and its bundled center;*

9. *H records componentwise* hsame *transport for interval endpoints, mesh rows, total-bounded handoff rows, completion-boundary rows, windows, readbacks, real seals, and the compact-net ledger;*
10. *C records displayed* Cont *routes by which consumers inspect the interval, mesh, finite net, completion boundary, windows, readbacks, real seal, and compact-net ledger;*
11. *P is the* Pkg *provenance over* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactNet}^{\uparrow}}$ *row.*

The carrier exports only the displayed finite-net compactness route for the located closed interval. It has no coordinate for an arbitrary open family, open-cover compactness, selected finite subcover, trichotomy on real names, quotient real equality, host endpoint choice, or ambient Heine–Borel theorem.

Lean4 ✓ `BEDC.Derived.ClosedIntervalCompactNetUp.ClosedIntervalCompactNetTasteGate single carrier alignment`

Theorem 1433.2 (ClosedIntervalCompactNet NameCert obligations)**.** *For an accepted* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ *carrier $K = (I, M, T, B, S, R, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactNet}^{\uparrow}}$ *surface consists exactly of carrier admission for those twelve rows, mesh-to-net coverage through M, T, L, completion-bounded real-name readback through B, S, R, E, componentwise classifier transport through H, consumer replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission is the tuple of Definition 1433.1. The interval row, mesh row, finite-net handoff, completion boundary, finite windows, readbacks, real seal, compact-net ledger, transports, continuations, package provenance, and local naming row are all explicit BHist coordinates.

The coverage side is read through M, T, L. The closed bounded interval net supplies the dyadic cells and centers, the totally bounded row packages those centers as the finite net at the requested tolerance, and the local ledger records that interval reads enter one of those displayed cells.

The real-name side is read through B, S, R, E. The complete-metric boundary is only a ledger for regular Cauchy reads of the displayed endpoint and center names; the terminal $\mathsf{Real}^{\uparrow}$ seal is reached after the finite windows and regular rational readbacks have already been exposed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for open covers, selected subcovers, trichotomy, quotient real equality, host endpoint choice, or a general Heine–Borel theorem, none of those objects can appear as local NameCert obligations. □

Theorem 1433.3 (ClosedIntervalCompactNet finite-subcover route)**.** *Every compactness consumer of an accepted* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ *packet receives the displayed finite route*

$$I, M, T, L, H, C, P, N.$$

The route may be read as a finite cover by mesh cells and bundled centers for the displayed interval, but it is already finite data and is not selected from an arbitrary open cover.

Proof. Start with the interval row I. The only coverage information attached to it in the carrier is the closed bounded interval net M and the compact-net ledger L.

Project the total-bounded handoff T. It repacks the mesh cells and centers of M as the finite-net row consumed by compactness-facing clients, with the requested tolerance still visible in the displayed ledger.

The rows H, C, P, N then transport, replay, source, and name the same finite route. Because the carrier contains no arbitrary open family and no selected subcover coordinate, a consumer cannot reinterpret this finite net as a choice from an open cover. □

Theorem 1433.4 (ClosedIntervalCompactNet totally bounded handoff)**.** *For every accepted* ClosedIntervalCompac *carrier $K = (I, M, T, B, S, R, E, L, H, C, P, N)$, the row T is the only* $\mathsf{TotallyBounded}^{\uparrow}$ *handoff exported by the packet. It is determined by the located interval row I, the closed bounded interval net row M, the compact-net ledger L, and the structural rows H, C, P, N.*

Proof. Project the carrier and isolate the total-bounded coordinate. The packet contains a single row T for the finite-net handoff, and it appears downstream of the interval row I and mesh row M.

The compact-net ledger L fixes the coverage read used by T. Thus the totally bounded export is the mesh-derived finite-net row, not a separate ambient total-boundedness principle.

Transport and replay are supplied only by H and C, with provenance and naming supplied by P and N. No additional $\mathsf{TotallyBounded}^{\uparrow}$ coordinate or hidden center selector is present. □

Theorem 1433.5 (ClosedIntervalCompactNet complete metric handoff)**.** *Every completion-facing or real-seal-facing consumer of an accepted* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ *packet factors through*

$$B, S, R, E, H, C, P, N$$

after the interval and mesh rows I, M have been displayed. The handoff uses $\mathsf{CompleteMetric}^{\uparrow}$ *only as the visible regular Cauchy readback boundary for endpoint and center observations; it does not assert ambient real completeness, quotient real equality, or a selected real endpoint.*

Proof. Begin with the displayed interval and mesh. Endpoint and center observations are already fixed by I and M before any completion-facing read is available.

Read the finite-window and regular-rational rows next. The rows S and R expose the endpoint and center names through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ data, and the complete-metric boundary row B keeps those reads inside the displayed regular Cauchy ledger.

Finally the real seal E and structural rows H, C, P, N carry that same route to consumers. Since the carrier has no quotient real equality coordinate, selected endpoint coordinate, or ambient completeness coordinate, the completion-facing handoff cannot export those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactNet}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ packet is generated from a displayed LocatedIntervalUp row, a ClosedBoundedIntervalNetUp mesh row, a TotallyBoundedUp finite-net handoff, a CompleteMetricUp regular-Cauchy boundary row, StreamNameUp windows, RegSeqRatUp readbacks, a RealUp seal, a local compact-net ledger, componentwise hsame transport, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactNet}^{\uparrow}}$, seed)

Scope closed: Definition 1433.1, Definition 1433.2, Definition 1433.3, Definition 1433.4, and Definition 1433.5 bind the explicit finite-net compactness certificate for displayed located closed intervals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim general Heine–Borel compactness, open-cover compactness, trichotomy, quotient real equality, selected subcover choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage, TotallyBoundedUp handoff, CompleteMetricUp handoff, and real-seal non-escape for BEDC.Derived.ClosedIntervalCompactNetUp.

Chapter 1434

A Concrete Naming Certificate for $\mathsf{MonotoneRealSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{MonotoneRealSequence}^{\uparrow}$ packet records the finite source certificate for a bounded monotone real sequence before the monotone convergence route consumes it. It sits after the finite-window source of chapter 1415, the $\mathsf{StreamName}^{\uparrow}$ interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It is the human-origin bridge from bounded real sequence inspection to the convergence consumer of chapter 1435; it does not assert a selected limit, ambient completeness, quotient equality of streams, trichotomy, or open-cover compactness.

Definition 1434.1 (Monotone real sequence carrier)**.** *A* $\mathsf{MonotoneRealSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, W, Q, R, B, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the inspected index schedule, listing the finite source windows on which the sequence is read.*
2. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows exposed at the indices in S.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and their dyadic tolerance observations.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream-window and regular-rational rows have been displayed.*
5. *B is the boundedness ledger inherited from the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source packet.*
6. *L is the monotonicity ledger, recording the displayed order direction and the finite adjacent or cofinal comparison rows visible in the inspected schedule.*
7. *H stores componentwise* hsame *transport for the index schedule, stream windows, readbacks, real seals, boundedness ledger, monotonicity ledger, continuation, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from inspected indices to stream windows, from stream windows to regular readback, from regular readback to the real seal, and from the joint boundedness and monotonicity ledgers to downstream convergence consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{MonotoneRealSequence}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MonotoneRealSequence}^{\uparrow}}$ *row.*
The carrier classifier compares accepted packets only through

$$S, W, Q, R, B, L, H, C, P, N.$$

It has no coordinate for host real order completeness, a least-upper-bound operator, quotient equality of stream names, a selected limit representative, open-cover compactness, or a Bolzano–Weierstrass subsequence selector.

Theorem 1434.2 (Monotone real sequence NameCert obligations)**.** *For every accepted* $\mathsf{MonotoneRealSequence}^{\uparrow}$ *carrier* $M = (S, W, Q, R, B, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MonotoneRealSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, finite source-window coverage through* S *and* W*, regular rational readback through* Q*, real-name sealing through* R*, boundedness transport through* B*, monotonicity transport through* L*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 1434.1. The only sequence observations are the finite schedule S, the $\mathsf{StreamName}^{\uparrow}$ windows W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and the $\mathsf{Real}^{\uparrow}$ seal row R.

Read the two source ledgers next. The boundedness row B is inherited from the $\mathsf{BoundedRealSequence}^{\uparrow}$ source surface of chapter 1415, while the monotonicity ledger L records only displayed comparison rows on the same inspected windows.

Finally inspect the structural rows. Transport, continuation replay, provenance, and local naming preserve the same finite packet and name no further analytic principle. Therefore the listed rows exhaust the local certificate surface. □

Theorem 1434.3 (Monotone real sequence window transport)**.** *Let* $M = (S, W, Q, R, B, L, H, C, P, N)$ *and* $M' = (S', W', Q', R', B', L', H', C', P', N')$ *be accepted* $\mathsf{MonotoneRealSequence}^{\uparrow}$ *packets. If the index schedules, stream windows, regular readbacks, real seals, boundedness ledgers, monotonicity ledgers, continuation rows, provenance rows, and local naming rows are replaced only by rows classified through the displayed* hsame *and* Cont *routes, then the finite monotone source surface transports unchanged: every accepted read of* M' *still factors through*

$$S' \longmapsto W' \longmapsto Q' \longmapsto R' \longmapsto B', L'$$

together with H', C', P', N'*.*

Proof. Begin with the source-window path in M. The carrier exposes an inspected index only by replaying it through W, then through Q, and finally through the real seal R.

Apply the componentwise hsame rows. They replace each displayed source coordinate by the corresponding coordinate in M' without introducing a second schedule, a second stream quotient, or a hidden real representative.

The continuation rows then replay the same route in M'. Since the boundedness row and monotonicity row are transported as rows B' and L' over the same inspected windows, the transported packet preserves the monotone source surface and exports no extra completeness or selection coordinate. □

Theorem 1434.4 (Monotone real sequence convergence handoff)**.** *Every* $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$ *consumer of an accepted* $\mathsf{MonotoneRealSequence}^{\uparrow}$ *packet must read the source through*

$$S, W, Q, R, B, L, H, C, P, N$$

before it can form a tail-Cauchy threshold or a convergence handoff. Consequently the consumer receives a bounded monotone real sequence source over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{BoundedRealSequence}^{\uparrow}$ *rows, but receives no selected limit, quotient equality of streams, host real equality, open-cover compactness, trichotomy, or ambient completeness theorem.*

Proof. Start from the carrier of Definition 1434.1. Its source route exposes finite stream windows, regular rational readbacks, and real-name seals before any boundedness or monotonicity statement is available.

Use the obligation theorem, Definition 1434.2, to identify B and L as the only boundedness and monotonicity surfaces in the packet. The transport theorem, Definition 1434.3, keeps those surfaces attached to the same finite source route under accepted classifier movement.

Now read the consumer in chapter 1435. Its tail-Cauchy threshold can consume a bounded monotone source only after the stream windows, regular readbacks, real seals, boundedness ledger, and monotonicity ledger have been displayed. Since the source packet contains no selected limit, quotient equality, host real equality, compactness, trichotomy, or ambient completeness coordinate, the handoff exports only the listed finite route. □

Theorem 1434.5 (Monotone real sequence socket taxonomy)**.** *Every accepted convergence-facing read of a* $\mathsf{MonotoneRealSequence}^{\uparrow}$ *packet separates source-range display, located-limit handoff, and classifier transport. The source range is visible only through the* $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows carried by*

$$S, W, Q, R, B, L, H, C, P, N.$$

The limit handoff is visible only to a displayed located-convergence consumer, and equality movement is visible only through the $\mathsf{Real}^{\uparrow}$ *classifier transport row. No read may collapse these sockets into an unrestricted real-completeness assumption, a stream quotient equality, or a selected limit representative.*

Proof. Project the carrier of Definition 1434.1. The rows S, W, Q expose the source schedule, stream windows, and regular-rational readback, while B and L attach boundedness and monotonicity to those same windows.

Apply Definition 1434.2. It identifies the accepted source rows and leaves no carrier coordinate for an unrestricted real range or a selected limit representative.

Apply Definition 1434.3 and Definition 1434.4. The first theorem keeps equality movement inside the displayed $\mathsf{Real}^{\uparrow}$ classifier route; the second permits a convergence-facing consumer to receive the source only through the displayed handoff. Thus the three socket positions remain separate. □

Falsifiable prediction: Every $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$ bounded-monotone source read factors through a $\mathsf{MonotoneRealSequence}^{\uparrow}$ packet displaying inspected StreamName windows, RegSeqRat readbacks, RealUp seals, boundedness and monotonicity ledgers, transport, continuation, provenance, and local naming.

Independence witness: boundedrealsequence, streamname, regseqrat, real, monotone-sequence-convergence: $\mathsf{MonotoneRealSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded real sequence source and a monotonicity ledger before the convergence consumer may form its tail-Cauchy route.

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneRealSequence}^{\uparrow}}$.

Constructive story: A MonotoneRealSequence$^{\uparrow}$ packet is generated from inspected sequence indices, finite StreamName windows, RegSeqRat readbacks, RealUp sequence-name seals, a boundedness ledger, a monotonicity ledger, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MonotoneRealSequence}^{\uparrow}}$, seed)

Scope closed: Definition 1434.1, Definition 1434.2, Definition 1434.3, and Definition 1434.4 seed the finite bounded-monotone source consumed by monotone sequence convergence.

Formal verification: FormalStatus(NameCert$_{\text{MonotoneRealSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected limits, quotient equality of streams, host real equality, open-cover compactness, trichotomy, or ambient completeness.

Upgrade path: Lean closure requires carrier admission, NameCert obligations, window transport, convergence handoff, and TasteGate field faithfulness for BEDC.Derived.MonotoneRealSequenceUp.

Chapter 1435

A Concrete Naming Certificate for $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$ packet records the constructive monotone convergence route for bounded real sequences as finite BEDC data. It sits after the bounded-sequence source of chapter 1415, the located monotone Cauchy route of chapter 438, the nonquotient comparison boundary of chapter 1404, the finite-window interface of chapter 126, and the terminal seal of chapter 38. The packet turns displayed bounded monotone observations into a regular Cauchy tail certificate; it does not select a limit representative or import host completeness.

Definition 1435.1 (Monotone sequence convergence carrier)**.** *A* $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, W, Q, R, B, M, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the inspected sequence schedule, listing the finite index windows used by the packet.*
2. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows observed at the indices in S.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and their dyadic tolerances.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream windows and regular rational readbacks have been displayed.*
5. *B is the bounded interval or bounded net row supplied by the bounded real sequence surface.*
6. *M is the monotonicity ledger, recording the displayed order direction and the finite comparison rows used by the inspected windows.*
7. *T is the tail-Cauchy modulus and threshold row; it names the finite threshold beyond which the Q-readbacks are forced into the displayed tolerance.*
8. *H stores componentwise* hsame *transport for the schedule, windows, readbacks, real seals, boundedness row, monotonicity ledger, tail threshold, continuation, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from inspected indices to windows, from windows to regular readback, from readback to real seals, and from the bounded monotone ledger to the tail-Cauchy threshold.*

10. *P is the* Pkg *provenance over* $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{MonotoneCauchy}^{\uparrow}$, $\mathsf{RegularCauchyEquivalence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and local naming.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneSequenceConvergence}^{\uparrow}}$ *row.*

The carrier classifier reads only

$$S, W, Q, R, B, M, T, H, C, P, N.$$

It has no coordinate for trichotomy, host real equality, quotient equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, open-cover compactness, a Bolzano–Weierstrass subsequence selector, or a choice-selected limit.*

Lean4 ✓ `BEDC.Derived.MonotoneSequenceConvergenceUp.MonotoneSequenceConvergenceTasteGate single carrier alignment`

Theorem 1435.2 (Monotone sequence tail-Cauchy route)**.** *For every accepted* $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$ *carrier $J = (S, W, Q, R, B, M, T, H, C, P, N)$, bounded monotone finite-window rows produce a regular Cauchy tail route through the displayed threshold T and the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier Q. Every tail comparison factors through*

$$S \longmapsto W \longmapsto Q \longmapsto B, M \longmapsto T$$

together with R, H, C, P, N, and no comparison uses trichotomy, host completeness, quotient equality, choice, or a selected limit representative.

Proof. Begin with the inspected schedule S. The continuation row C exposes only the finite $\mathsf{StreamName}^{\uparrow}$ windows W, and the readback row Q classifies those windows as regular rational observations before any $\mathsf{Real}^{\uparrow}$ seal row is consumed.

The boundedness and monotonicity rows are then read together. The row B supplies the bounded real sequence interval or net surface, while M supplies the displayed monotone ledger for the same inspected windows. Their joint use is finite: the packet never asks for a host set of all sequence values.

The threshold row T is the tail-Cauchy output of that bounded monotone read. It records the displayed tail index and tolerance route through the Q-classifier, so downstream regular Cauchy consumers receive a route already expressed in $\mathsf{RegSeqRat}^{\uparrow}$ data.

Transport through H, replay through C, provenance through P, and local naming through N preserve the same route. Since the carrier contains no trichotomy, host-completeness, quotient-equality, choice, or selected-limit coordinate, the tail-Cauchy comparison cannot leave the displayed packet. □

Theorem 1435.3 (Monotone sequence convergence NameCert obligations)**.** *For every accepted* $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$ *carrier, the local* $\mathsf{NameCert}_{\mathsf{MonotoneSequenceConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission, finite-window classification, boundedness transport, monotone-ledger transport, tail-Cauchy extraction,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, and package provenance for the displayed rows $S, W, Q, R, B, M, T, H, C, P, N$.*

Proof. Carrier admission is the tuple of Definition 1435.1. The finite-window classifier reads the schedule S, the $\mathsf{StreamName}^{\uparrow}$ windows W, and the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks Q; these rows are the only source of sequence observations.

Boundedness transport uses B together with the componentwise hsame row H and the displayed replay row C. Monotone-ledger transport is parallel: the same H and C rows move the finite order ledger M without adding a host order or trichotomy field.

Tail-Cauchy extraction is exactly the row T produced from the bounded monotone finite-window data. The real-seal boundary is the row R, which is readable only after the W and Q route has been displayed and therefore cannot introduce quotient real equality or ambient completeness.

Finally P records the package provenance and N records the local naming row. These rows name no data outside $S, W, Q, R, B, M, T, H, C, P, N$, so the seven listed obligations exhaust the local certificate surface. □

Falsifiable prediction: Every $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$ tail-Cauchy read factors through finite StreamName windows, RegSeqRat readback, boundedness and monotonicity ledgers, a displayed tail threshold, and the RealUp seal row carried by the packet.

Independence witness: boundedrealsequence, monotonecauchy, regularcauchyequivalence, streamname, real: $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the inspected sequence schedule, finite windows, regular readbacks, real seals, boundedness row, monotonicity ledger, tail threshold, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneSequenceConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneSequenceConvergence}^{\uparrow}$ packet is generated from inspected sequence windows, StreamName observations, RegSeqRat readbacks, RealUp seals, a bounded interval or net row, a monotonicity ledger, a tail-Cauchy threshold row, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneSequenceConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1435.1, Definition 1435.2, and Definition 1435.3 seed the finite route from bounded monotone RealUp sequence data to a regular Cauchy tail certificate.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneSequenceConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, Bolzano–Weierstrass subsequence selection, open-cover compactness, trichotomy, host real equality, Quot equality, choice, Lean verification, or bridge checking.

Upgrade path: Lean closure requires carrier admission, finite-window classification, boundedness transport, monotone-ledger transport, tail-Cauchy extraction, RealUp seal non-escape, and package provenance for BEDC.Derived.MonotoneSequenceConvergenceU

Chapter 1436

A Concrete Naming Certificate for DiniUniformConvergence$^{\uparrow}$

Following Bishop and Bridges, the DiniUniformConvergence$^{\uparrow}$ packet records the constructive finite-net surface of the Dini phenomenon over compact metric data. It reads compact-metric domain rows from chapter 129, finite total-bounded nets from chapter 127, monotone continuous-map family rows from chapter 130, uniform-limit comparison rows from chapter 463, terminal real-name seals from chapter 38, finite stream windows from chapter 126, and regular rational readbacks from chapter 301. The packet is a finite certificate for extracting a displayed uniform modulus from monotone pointwise windows; it is not open-cover compactness, countable choice, quotient real equality, host real equality, or a selected limit principle.

Definition 1436.1 (DiniUniformConvergence carrier)**.** *A* DiniUniformConvergence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, T, F, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *domain row, including the visible compact-metric carrier, distance witness, and metric transport surface used by the family;*
2. *T is the* TotallyBounded$^{\uparrow}$ *finite-net row, listing the inspected net points and dyadic radius budgets over the same domain row;*
3. *F is the monotone family of* ContinuousMap$^{\uparrow}$ *rows, indexed only by the finite observation schedule admitted by the packet;*
4. *M is the dyadic modulus schedule assigning each tolerance row to a finite net radius, a family index, and a comparison budget;*
5. *W is the family of* StreamName$^{\uparrow}$ *windows through which all inspected function values and limiting values are read;*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to those windows, carrying the regular rational comparisons used by the monotone test;*
7. *E is the* Real$^{\uparrow}$ *seal row for the limiting value at each inspected window, reached only after W and R have been displayed;*
8. *H stores componentwise* hsame *transports for K, T, F, M, W, R, E;*

9. *C stores the displayed* Cont *replay routes for the finite-net, monotone-family, window, readback, and seal reads;*
10. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformConvergence}^{\uparrow}}$ *row.*

The carrier has no coordinate for an open cover, no countable-choice selector, no quotient equality of real names, no host real equality proof, no selected limit, and no ambient compactness theorem beyond the displayed finite-net packet.

Lean4 (definition) `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceUp`

Theorem 1436.2 (Monotone window obligation)**.** *Let $D = (K, T, F, M, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{DiniUniformConvergence}^{\uparrow}$ *carrier. Every monotonicity read used by the packet is confined to the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *family rows in F, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in W, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. In particular, a consumer cannot replace the monotone window obligation by an open-cover argument, a countable-choice schedule, quotient real equality, host real equality, or a selected limiting value.*

Lean4 ✓ `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceCarrier monotone window obligation`

↪ variant `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceCarrier monotone window`

Proof. Project the accepted carrier. The only family data available to the monotonicity classifier are the rows F together with the windows W and regular rational readback R.

The schedule M names finite dyadic tolerances and finite family indices. It does not quantify over all indices by a hidden selector; it only points to the rows already present in the packet.

Transport and replay are componentwise. The rows H and C can reread the same finite windows and continuous-map family rows, but they cannot introduce an open cover, quotient equality of real names, host equality, or a selected limit. Hence the monotone obligation is exactly the displayed finite-window obligation. □

Lean4 ✓ `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergence monotone window obligation`

Theorem 1436.3 (Uniform modulus extraction)**.** *For every accepted* $\mathsf{DiniUniformConvergence}^{\uparrow}$ *carrier $D = (K, T, F, M, W, R, E, H, C, P, N)$ and every dyadic tolerance row named by M, the packet exports a finite uniform modulus row whose source is the total-bounded net T, whose value comparisons are read through W and R, and whose limiting seals are the displayed* $\mathsf{Real}^{\uparrow}$ *rows in E. The extracted row supplies a* $\mathsf{UniformLimit}^{\uparrow}$*-facing modulus surface without open-cover compactness, countable choice, quotient real equality, host real equality, or selected limits.*

Proof. Begin with a tolerance row in M. Its coordinates name a finite net radius, a finite family index, and the comparison budget to be checked on the net points carried by T.

For each listed net point, read the relevant $\mathsf{ContinuousMap}^{\uparrow}$ value through F, the finite window through W, the regular rational comparison through R, and the limiting seal through E. Monotonicity lets the same family index control all later inspected rows on that finite window surface.

The compact-metric information used here is exactly the total-bounded finite-net row, not an open-cover subcover. Since the packet contains no selector for countable families, no quotient equality of real names, no host real equality proof, and no detached limit coordinate, the resulting modulus is a finite row over T, M, W, R, E and can be handed to the $\mathsf{UniformLimit}^{\uparrow}$ surface. □

Lean4 ✓ `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceUniformModulusExtraction`

Theorem 1436.4 (DiniUniformConvergence NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DiniUniformConvergence}^{\uparrow}}$ *surface for the carrier of Definition 1436.1 consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the packet* $D = (K, T, F, M, W, R, E, H, C, P, N)$ *with its compact-metric domain, total-bounded finite nets, monotone continuous-map family, dyadic schedule, stream windows, regular readbacks, real seals, transports, continuations, provenance, and local naming row;*
2. *classifier: comparison reads only the displayed domain row* K*, finite-net row* T*, family rows* F*, modulus schedule* M*, windows* W*, readbacks* R*, and seals* E*;*
3. *transport stability:* H *and* C *preserve the same compact-metric, finite-net, family, window, readback, and seal rows under accepted consumer motion;*
4. *exactness: every uniform-modulus export is supplied by the displayed rows* T, M, W, R, E *after the componentwise transport and replay routes are fixed;*
5. *ledger: every* $\mathsf{UniformLimit}^{\uparrow}$*-facing consumer first reads* $K, T, F, M, W, R, E, H, C, P, N$ *and receives no open cover, countable-choice selector, quotient real equality, host real equality, or selected limit.*

Lean4 ✓ `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceCarrier namecert obligations`

Proof. Carrier admission is projection from the finite packet. Each coordinate named in Definition 1436.1 is a displayed row, so the local certificate admits exactly that inventory.

The classifier is finite because every comparison request starts with a row of M and then reads only the finite net points in T, the family rows in F, the windows in W, the regular rational readback in R, and the real seals in E.

Transport stability uses H componentwise and then replays the same finite route through C. No transport step adds an open cover, quotient equality, host equality, selected limit, or choice schedule.

Exactness and the ledger clause follow from the same inventory. A uniform-limit-facing consumer receives the finite modulus route over T, M, W, R, E together with provenance and local naming; the carrier exposes no other route by which an unrestricted classical Dini theorem could enter. □

Definition 1436.5 (DiniUniformConvergence certificate route)**.** *For an accepted* $\mathsf{DiniUniformConvergence}^{\uparrow}$ *carrier*

$$D = (K, T, F, M, W, R, E, H, C, P, N),$$

the finite certificate route is the ordered path

$$K, T, F, M, W, R, E, H, C, P, N.$$

This is the only accepted route from compact-domain data and finite windows to a $\mathsf{UniformLimit}^{\uparrow}$*-facing modulus surface.*

Theorem 1436.6 (DiniUniformConvergence compact-window exactness)**.** *For every accepted* DiniUniformConverge *carrier* $D = (K, T, F, M, W, R, E, H, C, P, N)$*, every uniform-modulus export factors through the compact metric row* K*, the totally bounded finite-net row* T*, the continuous-map family row* F*, the stream-window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *before any* $\mathsf{UniformLimit}^{\uparrow}$*-facing row is read.*

Lean4 ✓ `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceCompactWindowExactness`

Proof. Project the carrier and the route named in Definition 1436.5. The compact-domain coordinate is K, the finite-net coordinate is T, and the inspected family of continuous maps is stored in F.

Apply Definition 1436.3. Its extracted modulus reads the finite net, the dyadic schedule, the inspected stream windows, the regular rational readback, and the displayed Real seals.

The exactness statement records the same dependency order for any $\mathsf{UniformLimit}^{\uparrow}$-facing consumer. Such a consumer can read a modulus only after the compact row K, finite net T, family rows F, windows W, readback R, and seal E have been displayed, and the remaining rows H, C, P, N only transport, replay, source, and name that finite route. □

Theorem 1436.7 (DiniUniformConvergence monotone-family exhaustion)**.** *For every accepted* $\mathsf{DiniUniformConvergence}^{\uparrow}$ *carrier*

$$D = (K, T, F, M, W, R, E, H, C, P, N),$$

after K and T have fixed the compact finite-net surface, every monotone-family comparison exposed by the packet passes exactly through the continuous-map family rows F, dyadic modulus schedule M, finite StreamName windows W, RegSeqRat readback R, and Real seal rows E. No consumer can add an open-cover proof, countable-choice schedule, quotient real equality, host equality, selected limit, or ambient compactness row to that comparison.

Lean4 ✓ `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceCarrier monotone family exhaustion`

Proof. Project the carrier and fix the domain boundary. The compact-metric row K and the totally bounded row T are the only rows that determine the finite-net surface inspected by the packet.

Use the monotone-window obligation. Every monotonicity read is confined to F, W, R, and the dyadic schedule M names only finite tolerances and finite family indices over those displayed rows.

Use uniform-modulus extraction and the certificate route. The extracted modulus reads T, M, W, R, E, while the route lists the full packet order $K, T, F, M, W, R, E, H, C, P, N$.

The forbidden objects have no carrier coordinate. Hence a consumer cannot extend the monotone-family comparison by open-cover compactness, countable choice, quotient real equality, host equality, a selected limit, or an ambient compactness row. □

Theorem 1436.8 (DiniUniformConvergence compact uniform-limit route)**.** *For every accepted* $\mathsf{DiniUniformConvergence}^{\uparrow}$ *carrier*

$$D = (K, T, F, M, W, R, E, H, C, P, N),$$

any $\mathsf{UniformLimit}^{\uparrow}$*-facing consumer of the Dini conclusion must read* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *exactly through the displayed rows $K, T, F, W, R, E, H, C, P,$ with M as the dyadic modulus schedule. The route supplies no open-cover compactness, selected limiting value, quotient function equality, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The public certificate route is the ordered packet $K, T, F, M, W, R, E, H, C, P, N$ so a consumer first receives the compact-metric row K, the total-bounded finite-net row T, the

continuous-map family rows F, the dyadic schedule M, the stream windows W, the regular rational readbacks R, and the real seals E.

Apply Definition 1436.3. It identifies the modulus route through T, M, W, R, E and exposes that route as the finite surface handed to $\mathsf{UniformLimit}^{\uparrow}$.

Apply Definition 1436.6. It fixes the order in which K, T, F, W, R, E must be displayed before any uniform-limit-facing row is read.

Apply Definition 1436.7. It exhausts the monotone-family comparison through F, M, W, R, E after the compact finite-net surface K, T is fixed.

It remains only to account for the ledger rows. The transports H, continuations C, provenance P, and local certificate N reread and name the same finite route; none supplies an open cover, selected limiting value, quotient function equality, countable-choice schedule, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence every $\mathsf{UniformLimit}^{\uparrow}$-facing consumer is confined to the displayed route. □

Lean4 ✓ `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceCarrier compact uniform limit route`

Theorem 1436.9 (DiniUniformConvergence finite-net monotone-tail scope)**.** *For every accepted* $\mathsf{DiniUniformConvergence}^{\uparrow}$ *carrier*

$$D = (K, T, F, M, W, R, E, H, C, P, N),$$

once K, T, F, M have fixed the compact metric row, finite net, monotone family, and dyadic schedule, every tail comparison consumed by a $\mathsf{UniformLimit}^{\uparrow}$*-facing route factors through*

$$W, R, E, H, C, P, N.$$

The exported comparison carries no open-cover compactness, countable choice, quotient real equality, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceCarrier finite net monotone tail scope`

Proof. Start with the monotone-window obligation. It confines every monotonicity read to the displayed continuous-map family rows F, finite stream windows W, and regular rational readback R.

Apply uniform-modulus extraction. After the schedule row M fixes the tolerance and family index, the extracted modulus is read through the finite net T, windows W, readbacks R, and Real seals E.

Use compact-window exactness and monotone-family exhaustion. These two theorems keep the compact metric row K, finite-net row T, family rows F, and schedule row M upstream of all tail comparisons.

Finally apply the compact uniform-limit route. It hands the resulting finite comparison to $\mathsf{UniformLimit}^{\uparrow}$ only through W, R, E, H, C, P, N, while the carrier has no coordinate for open-cover compactness, countable choice, quotient real equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 1436.10 (DiniUniformConvergence cover-selector non-escape)**.** *For every accepted* DiniUniformConverge *carrier*

$$D = (K, T, F, M, W, R, E, H, C, P, N),$$

any cover or selector read used by a $\mathsf{UniformLimit}^{\uparrow}$*-facing Dini route must pass through the compact metric row* K*, total-bounded finite-net row* T*, monotone family row* F*, dyadic schedule* M*, windows* W*, readback* R*, seal* E*, and structural rows* H, C, P, N*. It cannot be replaced by open-cover compactness, countable choice, selected limits, quotient real equality, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the compact uniform-limit route of Definition 1436.8. It fixes the public consumer path through the displayed compact metric, finite-net, family, window, readback, seal, transport, replay, provenance, and local naming rows.

Use Definition 1436.9. Once K, T, F, M are fixed, all tail comparisons exposed to $\mathsf{UniformLimit}^{\uparrow}$ factor through W, R, E, H, C, P, N.

Finally apply the local obligations of Definition 1436.4. The ledger clause admits no open-cover compactness, countable-choice selector, selected limit, quotient real equality, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, so any purported cover or selector read must remain inside the displayed packet route. □

Lean4 ✓ `BEDC.Derived.DiniUniformConvergenceUp.DiniUniformConvergenceCoverSelectorNonescape`

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformConvergence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DiniUniformConvergence}^{\uparrow}$ packet is generated from compact-metric domain data, total-bounded finite nets, monotone ContinuousMapUp family rows, dyadic modulus schedules, StreamName windows, RegSeqRat readbacks, RealUp seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DiniUniformConvergence}^{\uparrow}}$, obligation)

Scope closed: Definition 1436.1, Definition 1436.2, Definition 1436.3, and Definition 1436.4 seed the finite-net Dini uniform-modulus packet over the displayed Real and Completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DiniUniformConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim the classical unrestricted Dini theorem beyond the displayed compact-metric finite-net packet, and it exports no open-cover compactness, countable choice, quotient real equality, host real equality, selected limits, or bridge checking.

Upgrade path: A later verification route can encode the carrier and prove the monotone-window obligation, uniform-modulus extraction, and local NameCert obligations over the displayed finite packet.

Chapter 1437

A Concrete Naming Certificate for $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ packet records the constructive one-dimensional Brouwer fixed-point theorem as a finite interval-return route. A candidate continuous self-map on a located compact interval is first read through the $\mathsf{LocatedInterval}^{\uparrow}$ endpoint surface and the $\mathsf{ContinuousMap}^{\uparrow}$ graph and modulus rows; its residual $g(x) = f(x) - x$ is then consumed by the intermediate-value surface of chapter 1402 and the bisection route of chapter 1422; the resulting finite windows are handed to the stream, regular-rational, and real-name surfaces, including the seal of chapter 38. The certificate names only this displayed finite route. It does not claim the general Brouwer fixed-point theorem, Heine–Borel compactness, host completeness, quotient equality of streams, real trichotomy, or a choice-selected fixed point.

Definition 1437.1 (Compact interval fixed-point carrier)**.** *A* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (J, G, R, B, W, Q, E, H, C, P, N)$$

with the following visible rows:

1. *J is the* $\mathsf{LocatedInterval}^{\uparrow}$ *interval-endpoint packet, including the lower and upper endpoint names, rational cells, and located-order witness used for every later read;*
2. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus evidence for the displayed interval-returning map, together with the residual read route for $g(x) = f(x) - x$;*
3. *R is the interval-return row asserting that every candidate read of the map is routed back into the same located interval packet J before residual signs are inspected;*
4. *B is the* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *residual-bisection row obtained from the endpoint residual signs, the modulus evidence in G, and the interval-return row R;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window surface for the retained bisection interval and the displayed candidate fixed-point name;*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the retained windows into regular rational approximants at the requested dyadic tolerance;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal exposed to downstream consumers only after the retained windows and regular rational readback have been displayed;*
8. *H stores componentwise* hsame *transports for J, G, R, B, W, Q, E and the local certificate row;*

9. *C stores the displayed* Cont *replay routes for interval-endpoint reads, continuous-map reads, interval-return reads, residual bisection, finite windows, regular readback, and real-seal consumption;*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{IntermediateValueBisection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalFixedPoint}^{\uparrow}}$ *registration row.*

The carrier predicate says that these rows form one finite fixed-point certificate for a displayed interval-returning continuous map. The packet has no coordinate for a host fixed point, open-cover compactness, general Brouwer fixed points, real trichotomy, quotient equality of streams, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.CompactIntervalFixedPointTasteGate single carrier alignment`

Theorem 1437.2 (CompactIntervalFixedPoint NameCert obligations)**.** *For an accepted packet $F = (J, G, R, B, W, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalFixedPoint}^{\uparrow}}$ *obligations are exhausted by the carrier rows of Definition 1437.1. They consist of carrier admission, interval-return exactness, continuous-map modulus replay, residual-sign bisection, stream-window handoff, regular-rational readback, real-seal nonescape, componentwise transport, displayed continuation replay, provenance, and local naming. No obligation may call on a host fixed point, open-cover compactness, general Brouwer fixed points, real trichotomy, quotient stream equality, selected limits, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.CompactIntervalFixedPointNameCertObligations`
↪ variant `BEDC.Derived.CompactIntervalFixedPointUp.CompactIntervalFixedPointCarrier namecert obligations`

Proof. Carrier admission is projection from the displayed packet. The rows $J, G, R, B, W, Q, E, H, C, P, N$ are exactly the data listed in Definition 1437.1.

The analytic obligations are routed in order. The interval-return row R binds every map read back to the same located interval packet J; the continuous-map row G supplies the graph and modulus evidence; and the residual bisection row B reads endpoint signs only after those two rows have been fixed.

The consumer-facing obligations then read the retained windows through W, the regular rational approximants through Q, and the real seal through E. The rows H, C, P, and N transport, replay, record provenance, and register the same finite route.

Since no coordinate outside this route is present, the listed classical, host-completion, quotient, trichotomy, choice, and selected-limit principles cannot enter the local NameCert surface. □

Theorem 1437.3 (Interval-return fixed-point route)**.** *Every candidate fixed-point read accepted by a* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *carrier first consumes the interval-return row R and the continuous-map row G before it can reach the residual bisection row B. Consequently the read factors through*

$$J, G, R, B, W, Q, E, H, C, P, N.$$

It cannot inspect a candidate real name as a fixed point unless the same route has already tied the map value, residual sign data, retained bisection window, stream windows, regular readback, and real seal to the displayed located interval.

Proof. Start with an accepted carrier $F = (J, G, R, B, W, Q, E, H, C, P, N)$. The continuation row C provides no direct path from a consumer to E or to a candidate fixed-point name; it first replays the endpoint and map reads through J and G.

The interval-return row R is then mandatory. It records that every displayed value of the map is read back inside the same located interval packet, so the residual sign test is a row over J and G, not a host-level comparison.

Only after that read does the residual bisection row B become available. The retained interval supplies windows W, the windows supply regular rational readback Q, and the readback supplies the Real-facing seal E.

The transport, continuation, provenance, and local naming rows preserve this order. Thus every accepted fixed-point read factors through the displayed route and has no bypass through a host fixed point or external equality principle. □

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.IntervalReturnRoute.CompactIntervalFixedPoint interval return route`

Theorem 1437.4 (CompactIntervalFixedPoint residual-bisection handoff)**.** *Every accepted* CompactIntervalFixedP *fixed-point read must expose, in order, the* LocatedInterval$^{\uparrow}$ *endpoint packet J, the* ContinuousMap$^{\uparrow}$ *graph and modulus row G, the interval-return row R, the* IntermediateValueBisection$^{\uparrow}$ *residual-bisection row B, the* StreamName$^{\uparrow}$ *window row W, the* RegSeqRat$^{\uparrow}$ *readback row Q, and the* Real$^{\uparrow}$ *seal row E before the endpoint seal is public. Thus the public fixed-point seal is a residual-bisection handoff over displayed finite rows, not a host fixed-point existence assertion.*

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.ResidualBisectionHandoff.CompactIntervalFixedPoint residual bisection handoff`

Proof. The carrier of Definition 1437.1 lists the only rows from which an accepted read can be assembled. The NameCert obligations of Definition 1437.2 require carrier admission, interval-return exactness, residual bisection, stream-window exposure, regular-rational readback, and real-seal nonescape.

The route theorem Definition 1437.3 forces every candidate read through J, G, R before B can be consumed. The bisection row then supplies retained finite windows W, and those windows are the source for the regular readback row Q.

Finally, Definition 1437.6 makes E reachable only after the displayed bisection, window, and readback rows have been exposed. Since the packet has no coordinate for a host fixed point, the public endpoint seal is exactly the listed finite handoff. □

Theorem 1437.5 (CompactIntervalFixedPoint window regularity)**.** *For every accepted* CompactIntervalFixedPoint$^{\uparrow}$ *carrier $F = (J, G, R, B, W, Q, E, H, C, P, N)$, each retained bisection window exposed by B is consumed by the* StreamName$^{\uparrow}$ *window row W before the* RegSeqRat$^{\uparrow}$ *readback row Q can be read. Componentwise* hsame *transport preserves this window/readback pairing through H, and displayed* Cont *replay preserves the same order through C. Hence no selected limit, host fixed point, or ambient real-completeness principle can bypass the window/readback route.*

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.WindowRegularity.CompactIntervalFixedPoint window regularity`

Proof. Project the carrier rows of Definition 1437.1. The interval-return route of Definition 1437.3 forces every fixed-point read through J, G, R before the residual bisection row B is available.

Once B has displayed the retained bisection window, the carrier offers only the window row W as the next finite observation surface. The regular-rational row Q is therefore a readback from the already exposed window data, not an independent limit selector.

Transport and replay do not change this order. The row H carries componentwise hsame evidence for the same B, W, Q pairing, and C replays the displayed route without adding a host fixed point or completed real. Thus every accepted read reaches the public seal only through the window/readback surface. □

Theorem 1437.6 (CompactIntervalFixedPoint Real-seal nonescape)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *packet is reachable only through* $J, G, R, B, W, Q, E, H, C, P, N$*. The packet exports no host fixed point, no open-cover compactness, no general Brouwer fixed-point theorem, no real trichotomy, no quotient stream equality, no selected limit, and no ambient completeness principle for* $\mathsf{Real}^{\uparrow}$*.*

```
Lean4 ✓  BEDC.Derived.CompactIntervalFixedPointUp.RealSealNonescape.CompactIntervalFixedPoint
real seal nonescape
  ↪ variant  BEDC.Derived.CompactIntervalFixedPointUp.CompactIntervalFixedPointRealSealNonescape
```

Proof. The only Real-facing coordinate is E. By definition of the carrier, E is paired with the windows W and the regular rational readback Q, and both are paired with the residual bisection row B.

The bisection row itself is not free-standing. It is generated from the interval-return and continuous-map rows R and G over the same located interval packet J, with transports and replay stored in H and C.

Package provenance P and the local naming row N register precisely this finite route. Because no other Real-facing or compactness-facing coordinate exists in the packet, a consumer receives only the displayed real-name seal and none of the excluded classical or host principles. □

Theorem 1437.7 (CompactIntervalFixedPoint modulus residual stability)**.** *For every accepted* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *carrier* $F = (J, G, R, B, W, Q, E, H, C, P, N)$*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row* G *and interval-return row* R *keep every residual sign read for* $g(x) = f(x) - x$ *scoped to the same* $\mathsf{LocatedInterval}^{\uparrow}$ *packet* J*. Refining the residual tolerance or replaying the read through* C *may refine the displayed cells of* J*, but it cannot move the residual comparison to a different interval packet, host order, real trichotomy, selected representative, or ambient compactness principle.*

```
Lean4 ✓  BEDC.Derived.CompactIntervalFixedPointUp.ModulusResidualStability.CompactIntervalFixedPointModu
Lean4 ✓  BEDC.Derived.CompactIntervalFixedPointUp.ModulusResidualStability.CompactIntervalFixedPoint
modulus residual stability
```

Proof. Project the rows J, G, R from the carrier. The graph and modulus row G supplies the displayed map read, while R records that the value is read back inside the same located interval packet before residual signs are inspected.

A residual tolerance refinement therefore has only one source for endpoint and cell data: the interval packet J. The bisection row B can consume the residual signs only after G and R have fixed that source.

Continuation replay in C and componentwise transport in H preserve the same row order. Since no carrier coordinate stores a second interval packet, a host order test, trichotomy, selected representatives, or ambient compactness, the residual signs remain scoped to J. □

Theorem 1437.8 (CompactIntervalFixedPoint residual-modulus readback)**.** *For every accepted* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *carrier*

$$F = (J, G, R, B, W, Q, E, H, C, P, N),$$

each residual sign read for $g(x) = f(x) - x$ *must consume the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row* G*, the interval-return row* R*, and the retained residual-bisection row* B *before the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and the* $\mathsf{Real}^{\uparrow}$ *seal row* E *are public. Thus residual-modulus information reaches the fixed-point seal only as a finite L10 readback over* $J, G, R, B, W, Q, E, H, C, P, N$*, not as a host fixed point, selected limit, quotient stream equality, real trichotomy, or ambient Real completeness claim.*

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.ResidualModulusReadback.CompactIntervalFixedPointResi`

Proof. First use modulus residual stability, Definition 1437.7. It keeps every residual sign read scoped to the same located interval packet J after the continuous-map modulus row G and interval-return row R have fixed the displayed source of the residual comparison.

Next apply the residual-bisection handoff of Definition 1437.4. The residual signs can produce public fixed-point data only by entering the retained bisection row B and then handing that finite interval data to the window row W and regular readback row Q.

Finally use window regularity, Definition 1437.5. It preserves the order from B to W to Q, while the Real seal E remains downstream of those rows and the structural rows H, C, P, N transport, replay, record, and name the same route.

Since the carrier contains no coordinate for a host fixed point, selected limit, quotient stream equality, real trichotomy, or ambient Real completeness, no residual-modulus read can bypass the displayed finite route. □

Theorem 1437.9 (CompactIntervalFixedPoint bisection-window monotonicity)**.** *For every accepted* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *carrier* $F = (J, G, R, B, W, Q, E, H, C, P, N)$*, each retained residual-bisection window produced by* B *is consumed as a narrower finite* $\mathsf{StreamName}^{\uparrow}$ *window in* W *before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in* Q *is available. Extending the bisection schedule refines the retained window and preserves the route* J, G, R, B, W, Q, E*; it cannot introduce a selected limit, quotient stream equality, host fixed point, or ambient Real completeness.*

Proof. The residual-bisection handoff of Definition 1437.4 already places B before W and Q. Thus a retained window is not a free real point; it is finite bisection data over the displayed interval route.

When the bisection schedule is extended, the retained interval is refined inside B. The only consumer row for that retained finite data is W, so the next observable object is a narrower $\mathsf{StreamName}^{\uparrow}$ window.

The regular rational readback row Q is downstream of W, and the Real seal E is downstream of Q. Transport and replay preserve this order, leaving no coordinate for selected limits, quotient stream equality, host fixed points, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.BisectionWindowMonotonicity.CompactIntervalFixedPoint`

Theorem 1437.10 (CompactIntervalFixedPoint Real-seal uniqueness)**.** *For every accepted* CompactIntervalFixedPo *carrier* $F = (J, G, R, B, W, Q, E, H, C, P, N)$*, any public* $\mathsf{Real}^{\uparrow}$ *seal exported as the fixed-point candidate factors through the same residual-bisection row* B*, retained-window row* W*, regular-readback row* Q*, and Real-seal row* E*. A second seal that bypasses* B, W, Q, E *or replaces them by host fixed-point existence is not a* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *public seal for this carrier.*

Proof. The only Real-facing carrier coordinate is E. By Definition 1437.6, E is reachable only after B, W, Q have been displayed.

Suppose a public fixed-point seal is read from the packet. Carrier admission and the obligation surface force that read through the residual-bisection handoff, then through the retained stream windows and regular rational readback.

Any purported second seal must therefore use the same B, W, Q, E route when it is read as part of this carrier. If it instead appeals to host fixed-point existence, open-cover compactness, quotient stream equality, selected limits, or ambient Real completeness, it uses data absent from the carrier and is not a public seal exported by F. □

Theorem 1437.11 (CompactIntervalFixedPoint scoped route)**.** *Every accepted* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *fixed-point seal is scoped through the primitive route*

$$\mathsf{LocatedInterval}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{IntermediateValueBisection}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

The BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows preserve this route from carrier admission to public Real seal. No accepted seal may replace it by host compactness, open-cover compactness, quotient stream equality, selected limits, real trichotomy, or a general Brouwer fixed-point principle.*

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.ScopedRoute.CompactIntervalFixedPointScopedRoute`

Proof. Start with the carrier of Definition 1437.1. Its visible rows place the located interval packet J before the continuous-map and interval-return rows G, R, and Definition 1437.2 makes those rows part of the local NameCert surface.

The interval-return theorem Definition 1437.3 and residual-bisection handoff Definition 1437.4 force every candidate read through J, G, R before the residual-bisection row B is available. Window regularity Definition 1437.5 then routes the retained bisection data through W and the regular readback row Q.

The Real-facing end of the route is fixed by Definition 1437.6 and Definition 1437.10. The structural rows H, C, P, N carry componentwise transport, replay, provenance, and local naming without adding another primitive source. Thus the scoped primitive route is exactly the displayed chain from $\mathsf{LocatedInterval}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$. □

Theorem 1437.12 (CompactIntervalFixedPoint public seal)**.** *Every public* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *consumer receives a fixed-point seal only through the displayed route*

$$\mathsf{LocatedInterval}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{IntermediateValueBisection}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

together with the hsame*,* Cont*,* Pkg*, and* NameCert *rows of the accepted carrier. The public seal exposes carrier admission, interval-return exactness, residual-bisection handoff, retained-window regularity, Real-seal nonescape, Real-seal uniqueness, and the scoped route; it exports no general Brouwer fixed-point theorem, Heine–Borel compactness, host fixed-point existence, selected limit, quotient stream equality, real trichotomy, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.CompactIntervalFixedPointPublicSeal`

Proof. Start with the carrier and NameCert surface. The carrier of Definition 1437.1 supplies exactly $J, G, R, B, W, Q, E, H, C, P, N$, and Definition 1437.2 binds carrier admission, interval-return exactness, continuous-map replay, residual bisection, finite windows, regular readback, Real seal, transport, replay, provenance, and naming to those rows.

Next compose the route the consumer can read. The interval-return route of Definition 1437.3 places J, G, R before residual signs, and Definition 1437.4 moves the read from the residual row B to retained windows W and regular readback Q.

The public Real boundary is then fixed by window regularity, Real-seal nonescape, and Real-seal uniqueness, namely Definition 1437.5, Definition 1437.6, and Definition 1437.10. These theorems make E reachable only after B, W, Q have been displayed and prevent a second seal that bypasses the same route.

Finally apply the scoped route of Definition 1437.11. It identifies the primitive public chain from $\mathsf{LocatedInterval}^{\uparrow}$ through $\mathsf{Real}^{\uparrow}$, while H, C, P, N preserve the route under transport, continuation replay, provenance, and local naming. Since the carrier contains no row for Brouwer fixed points in higher dimension, Heine–Borel compactness, host fixed-point existence, selected limits, quotient stream equality, real trichotomy, countable choice, or ambient completeness, none of those objects is exported by the public seal. □

Theorem 1437.13 (CompactIntervalFixedPoint public consumer route)**.** *Every public consumer of an accepted* $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ *packet must read the located interval row* J*, continuous-map row* G*, interval-return row* R*, residual-bisection row* B*,* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N *before it may use the fixed-point seal. The route is the finite public surface*

$$J, G, R, B, W, Q, E, H, C, P, N,$$

not a general Brouwer fixed-point theorem, Heine–Borel compactness, selected fixed point, quotient stream equality, real trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactIntervalFixedPointUp.PublicConsumerRoute.CompactIntervalFixedPointPublicCon`

Proof. Begin with the interval-return route of Definition 1437.3. It forces a public read through the located interval row, the continuous-map row, and the interval-return row before residual signs can be inspected.

Next apply the residual-bisection handoff of Definition 1437.4. The handoff moves the accepted read from B into the finite $\mathsf{StreamName}^{\uparrow}$ windows W and then into the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q.

The Real-facing boundary is fixed by Definition 1437.6. It makes E reachable only after the displayed bisection, window, and readback rows have been exposed.

Finally compose with the public seal theorem, Definition 1437.12. The structural rows H, C, P, N preserve the same carrier-local route, so no public consumer can replace it by general Brouwer fixed points, Heine–Borel compactness, selected fixed points, quotient stream equality, real trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Any accepted fixed-point consumer that reaches a candidate seal while bypassing the interval-return row, the residual-bisection row, the $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, or the $\mathsf{Real}^{\uparrow}$ seal row refutes the carrier surface of $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$.

Independence witness: intermediatevalue, intermediate-value-bisection, real, continuousmap, locatedinterval: none is bijective to $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ because this packet binds interval endpoints, interval-returning continuous-map evidence, residual bisection, finite windows, regular readback, terminal Real seal, componentwise transport, continuation replay, package provenance, and local NameCert registration as one fixed-point route.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalFixedPoint}^{\uparrow}}$.

Constructive story: A CompactIntervalFixedPoint$^{\uparrow}$ packet is generated from a LocatedInterval$^{\uparrow}$ endpoint packet, ContinuousMap$^{\uparrow}$ graph and modulus evidence, an interval-return row, an IntermediateValueBisection$^{\uparrow}$ residual bisection row, StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, a Real$^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\mathsf{CompactIntervalFixedPoint}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1437.11 and Definition 1437.12 bind the carrier, NameCert obligations, interval-return route, residual-bisection handoff, window regularity, Real-seal nonescape, Real-seal uniqueness, and public fixed-point seal to the primitive route from LocatedInterval$^{\uparrow}$ through Real$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactIntervalFixedPoint}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim general Brouwer fixed points, open-cover compactness, Heine–Borel compactness, host fixed-point existence, real trichotomy, quotient stream equality, selected limits, countable choice, Real completeness, or a standard bridge.

Upgrade path: Public closure requires Lean formalization of the public fixed-point seal and the existing scoped route for BEDC.Derived.CompactIntervalFixedPointUp.

Chapter 1438

A Concrete Naming Certificate for $\mathsf{CauchyConvergenceModulus}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ packet records the finite convergence-modulus surface needed by the L10 Real and Completion route. It sits between the finite windows of chapter 126, the dyadic tolerance rows of chapter 291, the regular rational readback of chapter 301, the sequence-limit handoff of chapter 1413, and the regular-completion seed of chapter 1425. The packet names a convergence schedule as certificate data before any completion-facing consumer may speak about a tail limit.

Definition 1438.1 (Cauchy convergence modulus carrier)**.** *A* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, T, W, Q, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the sequence-source row whose entries are read as the common source for the convergence claim.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the requested dyadic radii.*
3. *T is the tail-index schedule assigning each tolerance row in D a finite threshold.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite tail-window family selected by T.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed tail windows and dyadic tolerances.*
6. *L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff row reached only after S, D, T, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for the source, tolerance, tail schedule, windows, readback, limit handoff, continuation, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from each tolerance request through $S, D, T, W, Q, L, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, quotient limits, host sequence convergence, host real equality, countable choice, trichotomy, selected representatives, or an unbounded tail read.*

Theorem 1438.2 (Cauchy convergence modulus NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulus}}$ *surface for Definition 1438.1 consists exactly of carrier exposure for K, sequence-source exposure through S, dyadic tolerance exposure through D, tail-index exposure through T, finite StreamName window exposure through W, regular rational readback through Q, RealSequenceLimit handoff through L, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N. Every accepted convergence request is classified only by the displayed tolerance row, the finite tail threshold, and the corresponding finite tail windows.*

Lean4 ✓ `BEDC.Derived.CauchyConvergenceModulusUp.CauchyConvergenceModulusNamecertObligations`

Proof. Project the carrier tuple $K = (S, D, T, W, Q, L, H, C, P, N)$. Each analytic coordinate is a displayed finite row, and the final coordinate names the same tuple as the local $\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulus}^{\uparrow}}$ surface.

Read the rows in the convergence order. A tolerance request first consumes the source row S and dyadic ledger D, then the tail schedule T, then the finite tail windows W, and only then the regular readback Q and sequence-limit handoff L.

The structural rows add no hidden convergence principle. They transport, replay, source, and name the displayed route, while the excluded objects have no coordinate in the carrier. Hence the listed rows exhaust the seed obligation surface. □

Theorem 1438.3 (Cauchy convergence modulus tail-window cofinality)**.** *For every accepted* CauchyConvergenceMo *packet $K = (S, D, T, W, Q, L, H, C, P, N)$ and every displayed dyadic tolerance request, the completion-facing read factors through the cofinal finite route*

$$S \longmapsto D \longmapsto T \longmapsto W \longmapsto Q \longmapsto L \longmapsto (H, C, P, N).$$

Every later use by $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *must read the same displayed tail-index schedule and the same finite windows before it reaches the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff. The consumer receives no* $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient limit, host sequence convergence, host real equality, countable-choice row, trichotomy row, selected representative, or detached completion datum.*

Proof. Start with Definition 1438.2. It places the dyadic tolerance row D before the tail-index schedule T and places T before the finite StreamName windows W.

The regular readback is then forced through the same finite tail window. The row Q is read only after S, D, T, W are displayed, so no quotient limit, host convergence predicate, or selected representative can substitute for the scheduled tail comparison.

Finally read the handoff coordinate. The row L is reached after Q, and the rows H, C, P, N only preserve and name that route. Thus every completion-facing consumer factors through the displayed cofinal tail-window route. □

Theorem 1438.4 (Cauchy convergence modulus tail-window exactness)**.** *For every accepted* CauchyConvergenceMo *packet $K = (S, D, T, W, Q, L, H, C, P, N)$ and every displayed dyadic tolerance request in D, the request reaches exactly the tail schedule T and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows W before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q is inspected. No consumer may replace that schedule by an unbounded tail, a detached modulus, a host convergence predicate, a quotient limit, or a selected representative.*

Proof. Project the carrier definition. The tolerance ledger D is the only source of displayed precision requests, and the next analytic row in the packet is the tail-index schedule T.

Use the NameCert obligations and tail-window cofinality. They force each admitted request to pass from D through T and then through the finite window family W before the regular rational readback Q is available.

Apply the ledger refusal clause. Since the refused host, quotient, selected, and unbounded-tail objects have no carrier row or provenance edge, the displayed schedule and its finite windows are the exact pre-readback route. □

Theorem 1438.5 (Cauchy convergence modulus limit-readback exhaustion)**.** *Every* $\mathsf{RealSequenceLimit}^{\uparrow}$ *or* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet receives only the rows*

$$S, D, T, W, Q, L, H, C, P, N.$$

The consumer may read the source, tolerance ledger, tail schedule, finite windows, RegSeqRat readback, limit handoff, componentwise transport, displayed continuation replay, package provenance, and local NameCert row, but it receives no additional completion datum, host convergence predicate, quotient stream, selected representative, countable-choice selector, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from the carrier and NameCert obligation theorem. Together they expose exactly the ten displayed rows and make the limit handoff L downstream of S, D, T, W, Q.

Tail-window cofinality and tail-window exactness identify the consumer route. A $\mathsf{RealSequenceLimit}^{\uparrow}$ or $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ read must pass through the same scheduled finite windows and the same regular readback before it can inspect L or any structural row.

Finally use ledger refusal. The packet has no row for an independent completion object, host convergence, quotient streams, selected representatives, choice, trichotomy, or ambient completeness, so the listed rows exhaust the consumer-visible readback. □

Theorem 1438.6 (Cauchy convergence modulus carrier transport)**.** *Let* $K = (S, D, T, W, Q, L, H, C, P, N)$ *be an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet, and let*

$$K' = (S', D', T', W', Q', L', H', C', P', N')$$

be a second displayed ten-row packet. If the transport row supplies componentwise hsame *comparisons from* $S, D, T, W, Q, L, H, C, P, N$ *to* $S', D', T', W', Q', L', H', C', P', N'$ *in the listed order, then* K' *is accepted by the same* $\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulus}^{\uparrow}}$ *surface. The transported packet exposes the same convergence-modulus route through sequence source, dyadic tolerance ledger, tail-index schedule, finite StreamName windows, RegSeqRat readback, RealSequenceLimit handoff, replay, provenance, and local name.*

Proof. Project the accepted packet K and read the carrier rows in the displayed order. The source, tolerance, schedule, window, readback, and handoff coordinates are finite rows, so componentwise hsame transport sends each exposed coordinate to the corresponding coordinate of K'.

Next read the structural rows. The transported row H' records the same componentwise comparisons, C' replays the displayed route, P' keeps the same sibling provenance over chapter 291, chapter 126, chapter 301, chapter 1413, and chapter 1425, and N' names the transported tuple locally.

The NameCert surface therefore accepts K' without opening any coordinate outside the ten displayed rows. □

Theorem 1438.7 (Cauchy convergence modulus classifier stability)**.** *Let $K = (S, D, T, W, Q, L, H, C, P, N)$ and $K' = (S', D', T', W', Q', L', H', C', P', N')$ be accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packets. If the displayed source row, dyadic tolerance ledger, tail-index schedule, finite StreamName windows, RegSeqRat readback, and RealSequenceLimit handoff agree componentwise through the packet's* hsame *rows, then every completion-facing consumer sees the same finite convergence classifier from K and K'. In particular, the consumer can distinguish packets only by the displayed route*

$$S, D, T, W, Q, L$$

together with its transport, continuation replay, provenance, and local naming rows.

Proof. Begin with the tail-window cofinality theorem. Any completion-facing read must pass through S, D, T, W, Q, L before it reaches the structural rows, and the hypotheses identify those analytic rows componentwise.

Use carrier transport for the structural part. The rows H, C, P, N and H', C', P', N' preserve, replay, source, and name the same finite route, with the sibling anchors supplying only the displayed tolerance, window, readback, limit-handoff, and completion-facing surfaces.

Thus the classifier available to a completion consumer is determined by the shared finite rows. No ambient completion, quotient limit, host convergence predicate, or selected representative can refine the comparison. □

Theorem 1438.8 (Cauchy convergence modulus ledger refusal)**.** *Every consumer of an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet factors through the displayed rows $S, D, T, W, Q, L, H, C, P, N$. The packet refuses reads of* $\mathsf{Real}^{\uparrow}$ *completeness, quotient limits, host convergence, host real equality, countable choice, trichotomy, selected representatives, and any unbounded tail datum.*

Proof. Read the carrier definition and the NameCert obligation theorem together. They expose exactly the ten displayed rows and classify tolerance requests by the sequence source, dyadic ledger, scheduled finite tail threshold, StreamName windows, RegSeqRat readback, and RealSequenceLimit handoff.

The cofinality theorem forces later completion-facing uses through the same finite route. Carrier transport and classifier stability show that replacing the packet by a componentwise transported packet does not create a new consumer-visible coordinate.

Therefore every permitted consumer read is already a read of $S, D, T, W, Q, L, H, C, P, N$. The listed host, choice, quotient, representative, and unbounded-tail objects have no carrier row, continuation replay, provenance edge, or local name in the packet. □

Definition 1438.9 (Cauchy convergence modulus Real-seal surface)**.** *For an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet, the Real-seal surface is the displayed boundary*

$$(D, T, W, Q, L, E, H, C, P, N)$$

where D is the dyadic tolerance ledger, T is the tail-index schedule, W is the finite $\mathsf{StreamName}^{\uparrow}$ *tail-window family, Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, L is the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff, E is the completion-facing seal read by* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$*, and H, C, P, N carry transport, replay, provenance, and local naming. The surface is read only after the sequence source row of Definition 1438.1 has exposed the same tolerance request.*

Theorem 1438.10 (Cauchy convergence modulus completion readiness)**.** *Every accepted* $\mathsf{CauchyConvergenceModu}$ *packet exposes a completion-ready route from dyadic tolerance to regular Cauchy seal:*

$$D \longmapsto T \longmapsto W \longmapsto Q \longmapsto L \longmapsto E \longmapsto (H, C, P, N).$$

The route is available to $\mathsf{RealSequenceLimit}^{\uparrow}$ *and* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *consumers only through the displayed Real-seal surface of Definition 1438.9; it exports no host convergence predicate, quotient limit, selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier and NameCert obligation theorems. They place the dyadic tolerance row before the tail-index schedule and finite StreamName windows, then route the resulting readback through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{RealSequenceLimit}^{\uparrow}$.

Apply tail-window cofinality. Any completion-facing consumer must replay the same finite windows before it can read the regular rational row Q or the limit handoff L.

Finally use classifier stability and ledger refusal. Transport preserves the displayed route, and the refused host, quotient, choice, representative, and ambient-completion objects have no row in the Real-seal surface. The remaining visible boundary is exactly the completion-ready route displayed above. □

Theorem 1438.11 (Cauchy convergence modulus regular-Cauchy handoff)**.** *Every* RegularCauchyCompletionUniver *consumer of an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet must read the Real-seal surface*

$$(D, T, W, Q, L, E, H, C, P, N)$$

before it can treat the packet as a regular-Cauchy completion input. In particular, the consumer must pass through the dyadic tolerance ledger, the tail-index schedule, the finite StreamName windows, the RegSeqRat readback row, and the RealSequenceLimit handoff before it reaches the completion-facing seal E*.*

Proof. Use completion readiness to put every completion-facing read on the displayed route from D through E. The route includes exactly the tolerance, schedule, window, readback, and handoff rows needed by the regular-Cauchy consumer.

The carrier-transport theorem keeps the route stable under componentwise hsame replacement. The classifier-stability theorem then shows that two packets with the same displayed rows present the same regular-Cauchy handoff to a completion consumer.

The ledger-refusal theorem excludes the alternate routes. A consumer cannot bypass D, T, W, Q, L by appealing to host convergence, quotient limits, selected representatives, or ambient completeness, because those objects are absent from the packet. □

Theorem 1438.12 (Cauchy convergence modulus uniform threshold handoff)**.** *Every* RegularCauchyCompletionUni *or* $\mathsf{RealSequenceLimit}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet that receives a displayed tolerance request must use the same threshold row* T *for all tail windows* W *associated to that request before it can read the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q*, the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff* L*, or the completion-facing seal* E*.*

The handoff is the finite route

$$D \longmapsto T \longmapsto W \longmapsto Q \longmapsto L \longmapsto E$$

inside the carrier and Real-seal surface. It exports no quotient limit, selected representative, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or detached completion datum.*

Proof. Project the carrier of Definition 1438.1. The tolerance ledger D is followed by the single displayed tail-index schedule T, and the finite window family W is read only after that threshold row is exposed.

Apply tail-window cofinality. It forces every completion-facing use of the displayed tolerance request through the same scheduled tail windows before any regular rational readback is available.

Use completion readiness and the regular-Cauchy handoff for the downstream boundary. They place Q, then L, then the completion-facing seal E after the same threshold and window rows.

The carrier and Real-seal surface contain no quotient limit, selected representative, countable-choice selector, ambient completeness theorem, or detached completion coordinate. Therefore the threshold handoff is uniform across all tail windows associated to the displayed request. □

Theorem 1438.13 (Cauchy convergence modulus uniform tail grid)**.** *Let $K = (S, D, T, W, Q, L, H, C, P, N)$ be an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet, and suppose a displayed dyadic grid refinement is attached to the tolerance row D, the tail schedule T, and the finite tail-window family W. Then every* $\mathsf{RealSequenceLimit}^{\uparrow}$ *and* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *consumer of K must route the requested read through the same finite tail grid before reading the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q, the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff L, or the completion-facing seal E.*

The finite grid route is

$$D \longmapsto T \longmapsto W \longmapsto Q \longmapsto L \longmapsto E$$

inside the carrier and Real-seal surface. It exports no quotient stream, selected representative, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness row, detached completion datum, or alternate tail grid.*

Proof. Project the carrier and apply the uniform threshold handoff. The tolerance row D selects the tail schedule T, and the displayed grid refinement is read only through the finite tail-window family W attached to that schedule.

Use tail-window cofinality and tail-schedule totality. They force each accepted Real-sequence or regular-completion request to pass through the same scheduled finite windows before any $\mathsf{RegSeqRat}^{\uparrow}$ readback can be inspected.

Completion readiness then places Q, L, and the completion-facing seal E downstream of that grid. Scoped support and ledger refusal exclude quotient streams, selected representatives, countable-choice schedules, ambient completeness rows, and alternate tail grids, so the displayed finite route is the only consumer-visible path. □

Theorem 1438.14 (Cauchy convergence modulus Bishop criterion handoff)**.** *Every* $\mathsf{BishopCompletionCriterion}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet must read only the displayed route*

$$S \longmapsto D \longmapsto T \longmapsto W \longmapsto Q \longmapsto L \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

The handoff is anchored in the BHist *carrier of Definition 1438.1, the* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff, and the* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *completion boundary. It uses the NameCert obligations of Definition 1438.2, tail-window cofinality of Definition 1438.3, completion readiness of Definition 1438.10, and regular-Cauchy handoff of Definition 1438.11; it exposes no quotient stream, selected representative, host convergence predicate, countable-choice selector, or ambient completeness coordinate.*

Proof. Project the accepted carrier. The displayed rows $S, D, T, W, Q, L, H, C, P, N$ are the only analytic and structural coordinates available to the completion criterion.

Use the NameCert obligations and tail-window cofinality. They place the dyadic tolerance ledger, tail-index schedule, finite windows, and regular readback before any sequence-limit or completion-facing consumer can read the packet.

Completion readiness and the regular-Cauchy handoff identify the boundary seen by $\mathsf{BishopCompletionCriterion}^{\uparrow}$. The consumer therefore receives exactly the displayed route, while the refused quotient, selected, host, choice, and ambient-completion objects remain outside the carrier. □

Theorem 1438.15 (Cauchy convergence modulus root-unblock tail route)**.** *For every accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet* $K = (S, D, T, W, Q, L, H, C, P, N)$*, every downstream root-unblock request for a regular tail comparison must read the route*

$$S \longmapsto D \longmapsto T \longmapsto W \longmapsto Q \longmapsto L \longmapsto H \longmapsto C \longmapsto P \longmapsto N$$

before any completion-facing row is consumed. The route exposes the $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff, and structural rows, and it exports no quotient stream, selected representative, host convergence predicate, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 1438.1. The source row S, tolerance ledger D, tail schedule T, finite windows W, regular readback Q, and limit handoff L are displayed in the accepted packet.

Apply tail-window cofinality and tail-schedule totality. They force each regular tail request to pass through the scheduled $\mathsf{StreamName}^{\uparrow}$ windows after the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row and before the $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Use the Bishop criterion handoff to identify the same route for downstream consumers. The structural rows H, C, P, N preserve the route, while the refused host, quotient, selected, choice, and ambient-completeness objects have no carrier row. □

Theorem 1438.16 (Cauchy convergence modulus RealSeries consumer handoff)**.** *Every* $\mathsf{RealSeries}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet must obtain its convergence-modulus read through*

$$S, D, T, W, Q, L, H, C, P, N.$$

The consumer first reads the $\mathsf{StreamName}^{\uparrow}$ *source windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, then the tail-index schedule and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, then the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff and structural rows. It receives no host series convergence theorem, quotient sum, selected limiting value, countable-choice schedule, trichotomy row, or ambient completeness witness.*

Proof. Begin with the Bishop criterion handoff. It already places completion-facing consumers on the finite route through $S, D, T, W, Q, L, H, C, P, N$.

Read the $\mathsf{RealSeries}^{\uparrow}$ consumer as a series-facing use of the same regular tail data. The only available convergence evidence is the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ request, the scheduled $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{RealSequenceLimit}^{\uparrow}$ handoff.

Completion readiness and the Real-seal nonescape theorem exclude external series convergence data. Thus the $\mathsf{RealSeries}^{\uparrow}$ consumer receives exactly the finite convergence-modulus packet and no host sum or selected limit. □

Theorem 1438.17 (Cauchy convergence modulus regular completion unblock)**.** *For every* RegularCauchyCompletio *consumer of an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet, the regular-completion unblock surface is exhausted by the displayed rows*

$$S, D, T, W, Q, L, H, C, P, N.$$

The unblock first consumes the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and* $\mathsf{StreamName}^{\uparrow}$ *finite windows, then repacks the read as* $\mathsf{RegSeqRat}^{\uparrow}$ *data, then reaches the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff and the completion boundary. No quotient completion object, selected representative, host equality test, countable-choice selector, trichotomy split, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem is supplied.*

Proof. Use completion readiness and the regular-Cauchy handoff. They place $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ consumers on the route from the tolerance ledger through scheduled windows, regular readback, and the sequence-limit handoff.

Apply the root-unblock tail route above. The same S, D, T, W, Q, L rows are available before any completion boundary is consumed, and H, C, P, N keep transport, replay, provenance, and naming attached to the packet.

Finally apply ledger refusal and Real-seal nonescape. Since the refused completion, selected, host, choice, trichotomy, and ambient-completeness objects have no displayed row, the regular-completion unblock is exactly the finite route named in the statement. □

Theorem 1438.18 (Cauchy convergence modulus threshold totality)**.** *For every accepted* $\mathsf{CauchyConvergenceModu}$ *packet* $K = (S, D, T, W, Q, L, H, C, P, N)$*, every displayed completion-facing tolerance request has a threshold row inside the same packet. After the source row* S *and dyadic tolerance ledger* D *are read, the permitted route must pass through*

$$T \longmapsto W \longmapsto Q \longmapsto L \longmapsto H \longmapsto C \longmapsto P \longmapsto N$$

before any $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *or* $\mathsf{RealSeries}^{\uparrow}$ *consumer can inspect a completion boundary. No host convergence predicate, quotient limit, selected representative, countable-choice selector, or ambient completeness row supplies an alternate threshold.*

Proof. Project the carrier of Definition 1438.1. The rows $S, D, T, W, Q, L, H, C, P, N$ are the only displayed coordinates, and T is positioned between the tolerance ledger and finite-window readback.

Apply tail-window cofinality. Every accepted dyadic request that leaves D enters the scheduled finite window row W through the threshold row T, so the threshold is total for the packet's displayed requests.

Use ledger refusal and non-escape. Because the carrier has no host convergence predicate, quotient boundary, selected representative, choice schedule, or ambient completeness coordinate, no second threshold source can be consumed by downstream completion or series readers. □

Theorem 1438.19 (Cauchy convergence modulus RealSeries budget lock)**.** *For every accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet* $K = (S, D, T, W, Q, L, H, C, P, N)$*, any* $\mathsf{RealSeries}^{\uparrow}$ *budget read is locked to the finite route*

$$S, D, T, W, Q, L, H, C, P, N.$$

The series-facing consumer may spend only the displayed dyadic tolerance ledger, scheduled tail threshold, finite StreamName windows, RegSeqRat readback, RealSequenceLimit handoff, transport, replay, provenance, and local naming rows. It receives no hidden series convergence theorem, quotient sum, selected limit, countable-choice budget, or ambient $\mathsf{Real}^{\uparrow}$ *completeness resource.*

Proof. Begin with the regular-completion unblock route and the RealSeries consumer handoff. Both place the series-facing read on the same finite carrier coordinates before any Real-facing seal can be consumed.

Threshold totality fixes the budget source. Once D has been read, the row T determines the finite windows W available to Q and L, and the structural rows H, C, P, N can replay only that route.

Finally apply ledger refusal. The packet stores no hidden convergence theorem, quotient sum, selected limit, choice budget, or ambient completeness resource, so the RealSeries budget is locked to the displayed rows. □

Theorem 1438.20 (Cauchy convergence modulus completion-boundary exactness)**.** *For every accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet* $K = (S, D, T, W, Q, L, H, C, P, N)$*, the completion boundary exported to* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *is exact only along the displayed route*

$$S, D, T, W, Q, L, H, C, P, N.$$

The boundary may read the source, tolerance, threshold, finite windows, regular readback, limit handoff, componentwise transport, displayed continuation replay, package provenance, and local NameCert rows, but it may not import a quotient completion object, selected representative, host equality test, countable-choice selector, trichotomy split, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier and apply the regular-completion unblock theorem. It already exhausts the boundary surface by $S, D, T, W, Q, L, H, C, P, N$.

Use threshold totality and the RealSeries budget lock as compatibility checks. They show that both completion-facing and series-facing consumers reuse the same threshold, finite-window, readback, and handoff rows rather than creating a second boundary.

The refusal ledger closes the exactness claim. Since quotient completion objects, selected representatives, host equality tests, choice selectors, trichotomy splits, and ambient completeness theorems have no row in K, the exported completion boundary is exactly the displayed finite route. □

Theorem 1438.21 (Cauchy convergence modulus tail schedule totality)**.** *For every accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet and every* $\mathsf{BishopCompletionCriterion}^{\uparrow}$ *or* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *consumer, the tail-index schedule* T *is total for the displayed finite-window route. After the source row* S *and dyadic tolerance ledger* D *are read, every permitted completion-facing request must pass through* T, W, Q, L, H, C, P, N *in the same* BHist *packet, with no alternate tail schedule, quotient stream equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start from the carrier and NameCert obligation surfaces. They expose T as the named tail-index schedule between the tolerance ledger D and the finite window row W.

Tail-window cofinality supplies the totality witness for displayed requests: each accepted dyadic tolerance request is routed through a scheduled finite window before Q and L are available. The carrier-transport theorem preserves that row under componentwise hsame replacement.

Finally apply classifier stability and ledger refusal. Since no other tail schedule or completion coordinate is present in the packet, every Bishop-completion-facing request consumes the displayed T, W, Q, L, H, C, P, N route. □

Theorem 1438.22 (Cauchy convergence modulus regular completion readiness)**.** *An accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet is ready for current L10 regular-completion consumers exactly through the finite route*

$$S, D, T, W, Q, L, H, C, P, N.$$

The readiness claim is anchored in BHist, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealSequenceLimit}^{\uparrow}$, *and* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *data, and every* $\mathsf{BishopCompletionCriterion}^{\uparrow}$ *consumer must use the displayed route rather than a quotient-stream boundary, selected host limit, host equality test, countable-choice selector, or ambient completeness theorem.*

Proof. Use completion readiness to put Real-sequence and regular-completion reads on the route from D through T, W, Q, L and the structural rows. The source row S supplies the displayed sequence input for that route.

The Bishop criterion handoff theorem then identifies the same route as the only surface available to $\mathsf{BishopCompletionCriterion}^{\uparrow}$ consumers. Tail-schedule totality prevents a consumer from replacing the displayed schedule with an unbounded or hidden tail.

The remaining exclusions follow from classifier stability and ledger refusal. The packet is therefore completion-ready only as finite BEDC certificate data over the displayed rows. □

Theorem 1438.23 (Cauchy convergence modulus real-sequence-limit consumer)**.** *Every* $\mathsf{RealSequenceLimit}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet must read the displayed* BHist *carrier route*

$$S, D, T, W, Q, L, H, C, P, N$$

before it can consume the limit handoff row L. The consumer receives the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row, but it receives no* $\mathsf{Real}^{\uparrow}$ *completeness theorem, selected limit, host convergence predicate, countable-choice selector, or quotient representative.*

Proof. Project the carrier route of Definition 1438.1. The limit consumer can reach L only after the source, tolerance, schedule, window, and regular readback rows have been displayed.

Use Definition 1438.3 to make the route cofinal for every displayed tolerance request. The finite window row W and regular readback row Q cannot be skipped, because they are the route through which the tolerance ledger D becomes a sequence-limit handoff.

Finally use classifier stability and ledger refusal. The structural rows H, C, P, N preserve the displayed packet, while the excluded host and choice objects have no row in the BHist carrier. Thus the $\mathsf{RealSequenceLimit}^{\uparrow}$ consumer receives exactly the displayed finite convergence-modulus data. □

Theorem 1438.24 (Cauchy convergence modulus completion-threshold exhaustion)**.** *For every accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet, the completion threshold exposed to a* $\mathsf{RegularCauchyCompletionUnivers}$ *or* $\mathsf{Real}^{\uparrow}$*-facing consumer is exhausted by the finite rows D, T, W, Q, L together with H, C, P, N. Once the dyadic tolerance row D has selected a tail-index row T, every permitted completion read must pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *window family W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, and the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff L.*

Proof. Begin with the regular-Cauchy handoff theorem. It places completion consumers on the route from the dyadic tolerance ledger through the tail-index schedule, finite windows, regular readback, and limit handoff.

Apply completion readiness to identify the Real-seal surface. The seal row is reached only after the displayed threshold and window rows have been read, and its structural support is limited to hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

The carrier contains no further threshold coordinate. Hence the displayed tail-index row and its finite window family exhaust the completion threshold available to Real and completion consumers. □

Theorem 1438.25 (Cauchy convergence modulus Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet factors through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{RealSequenceLimit}^{\uparrow}$ *rows and through the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. The seal exports no ambient real completeness theorem, quotient limit, host sequence convergence, host real equality, countable choice, trichotomy, selected representative, or unbounded tail read.*

Proof. Read the Real-seal surface of Definition 1438.9. The seal is attached to the same dyadic tolerance ledger, tail-index schedule, finite windows, regular readback, and sequence-limit handoff as the carrier route.

Use Definition 1438.24. It says that no completion-facing threshold remains beyond D, T, W, Q, L and the structural rows, so a Real-facing consumer cannot replace the displayed route by an unbounded host tail.

Use Definition 1438.8 for the excluded objects. Since the packet has no row for real completeness, quotient limits, host equality, countable choice, trichotomy, selected representatives, or unbounded tail data, the exported $\mathsf{Real}^{\uparrow}$ seal cannot escape the finite convergence-modulus route. □

Theorem 1438.26 (Cauchy convergence modulus scoped support)**.** *For every accepted* CauchyConvergenceModulus *packet, the scoped support is exactly the sequence-source row S, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the tail-index schedule T, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff L, the* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *consumer boundary, and the structural* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows H, C, P, N. No quotient limit, selected tail, host convergence predicate, host real equality, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or unbounded tail read lies in the packet scope.*

Proof. Project the carrier and NameCert obligations. The packet exposes $S, D, T, W, Q, L, H, C, P, N$, and the local NameCert obligations require every admitted convergence-modulus read to pass through those displayed rows.

Use tail-window cofinality and carrier transport next. Cofinality routes each dyadic tolerance request through the tail-index schedule and finite StreamName windows, while transport preserves the same route under componentwise hsame replacement.

Completion readiness, the regular-Cauchy handoff, and the Real-seal nonescape theorem identify the consumer boundary. They place $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers on the same finite path and exclude all host, quotient, selected, choice, trichotomy, ambient-completeness, and unbounded-tail rows from the scoped support. □

Theorem 1438.27 (Cauchy convergence modulus scope binding)**.** *For every accepted* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *packet, the carrier rows*

$$S, D, T, W, Q, L, H, C, P, N$$

are scoped exactly by BHist *admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{RealSequenceLimit}^{\uparrow}$ *handoff, and* $\mathsf{RegularCauchyCompletionUniversal}^{\uparrow}$ *consumption. No consumer can enlarge this scope by adding a quotient limit, selected representative, countable-choice selector, trichotomy row, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or host convergence predicate.*

Proof. Project the carrier and NameCert obligations. They display $S, D, T, W, Q, L, H, C, P, N$ as the only rows available to an admitted convergence-modulus request.

Apply tail-window cofinality and carrier transport. Cofinality forces each dyadic tolerance request through the scheduled finite StreamName window before readback, while transport preserves the same row list under componentwise hsame replacement.

Use completion readiness, the regular-Cauchy handoff, scoped support, and ledger refusal to close the consumer boundary. The RealSequenceLimit and regular-completion consumers therefore receive exactly the displayed finite scope, and the refused host, quotient, selected, choice, trichotomy, and ambient-completeness objects remain outside the packet. □

Theorem 1438.28 (Cauchy convergence modulus RealSeries readback)**.** *Every* RealSeries$^{\uparrow}$ *consumer that cites a* CauchyConvergenceModulus$^{\uparrow}$ *packet must read* D, T, W, Q, L *through the existing tail-window cofinality route and through the* Real$^{\uparrow}$ *seal surface before using any series convergence claim. The consumer receives a finite convergence-modulus readback over* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealSequenceLimit$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows, not a host infinite sum, selected limit, quotient equality, countable-choice tail selector, or ambient real completeness principle.*

Proof. Begin with tail-window cofinality. It routes each tolerance request from the DyadicRatCore ledger through the shared tail schedule and the finite StreamName windows before the RegSeqRat readback can be consumed.

Next apply completion readiness and the Real-seal nonescape theorem. They place the limit handoff L and any real-facing series read behind the same finite route, so a RealSeries$^{\uparrow}$ consumer cannot use a series convergence claim before reading D, T, W, Q, L.

Finally use scoped support and ledger refusal. These identify the structural rows H, C, P, N as preservation and naming data, while host infinite sums, selected limits, quotient equalities, countable-choice selectors, and ambient completeness principles have no coordinate in the packet. □

Theorem 1438.29 (Cauchy convergence modulus completion consumer scope)**.** *Every* RegularCauchyCompletionUr *or* RealSequenceLimit$^{\uparrow}$ *consumer of a* CauchyConvergenceModulus$^{\uparrow}$ *packet receives only the displayed finite scope*

$$S, D, T, W, Q, L, H, C, P, N.$$

It receives the sequence source, dyadic tolerance ledger, tail schedule, finite windows, regular rational readback, limit handoff, componentwise transport, displayed replay, provenance, and local NameCert rows, but it receives no quotient limit, selected representative, countable-choice selector, trichotomy row, or ambient Real$^{\uparrow}$ *completeness theorem.*

Proof. Use the regular-Cauchy handoff and completion readiness theorems. They identify RegularCauchyCompletion and RealSequenceLimit$^{\uparrow}$ as consumers of the same finite route from S through D, T, W, Q, L.

Apply scope binding to attach the structural rows. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming preserve the displayed packet without adding analytic coordinates.

The ledger-refusal and Real-seal nonescape theorems provide the exclusions. Since quotient limits, selected representatives, countable-choice selectors, trichotomy rows, and ambient completeness theorems are not rows of the carrier, no completion consumer can receive them from this packet. □

Theorem 1438.30 (Cauchy convergence modulus mature package)**.** *For every accepted* CauchyConvergenceModulu *carrier*

$$K = (S, D, T, W, Q, L, H, C, P, N),$$

the standard completion-facing interpretation is exactly the finite route through the StreamName$^{\uparrow}$ *windows* W, DyadicRatCore$^{\uparrow}$ *tolerances* D, RegSeqRat$^{\uparrow}$ *readback* Q, RealSequenceLimit$^{\uparrow}$ *handoff* L, RegularCauchyCompletionUniversal$^{\uparrow}$ *consumers, componentwise* hsame *transport* H, *displayed* Cont *replay* C, Pkg *provenance* P, *and local naming* N. *The interpretation exports no quotient limit, selected representative, countable-choice selector, or ambient* Real$^{\uparrow}$ *completeness theorem.*

Proof. Start from the NameCert obligations and tail-window cofinality. They force every tolerance request to pass through the displayed sequence source, dyadic ledger, tail schedule, and finite StreamName window before any regular-rational readback is available.

Apply completion readiness, the regular-Cauchy handoff, and the completion consumer scope theorem. These place the RealSequenceLimit row and RegularCauchyCompletionUniversal consumers on the same finite route, so the completion-facing read is a standard interpretation of the ten carrier rows rather than an extra limit object.

Finally use the Real-seal nonescape, scoped support, and scope binding theorems. Transport, replay, provenance, and local naming preserve $S, D, T, W, Q, L, H, C, P, N$ as the whole visible package, while quotient limits, selected representatives, countable-choice selectors, and ambient Real completeness remain outside the carrier. □

Falsifiable prediction: An accepted $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ consumer that reaches a $\mathsf{RealSequenceLimit}^{\uparrow}$ handoff without the displayed sequence source, dyadic tolerance ledger, tail-index schedule, finite StreamName windows, and RegSeqRat readback refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, realsequencelimit, regularcauchycompletionuniversal: no listed sibling supplies the whole ten-row packet $K = (S, D, T, W, Q, L, H, C, P, N)$, because each sibling contributes only a tolerance, window, readback, limit, or completion-facing surface while this chapter binds all five analytic faces with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ packet is generated from a sequence-source row, dyadic tolerance ledger, tail-index schedule, finite StreamName windows, RegSeqRat readback, RealSequenceLimit handoff, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulus}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1438.1, Definition 1438.2, Definition 1438.3, Definition 1438.4, Definition 1438.5, Definition 1438.6, Definition 1438.7, Definition 1438.8, Definition 1438.9, Definition 1438.10, Definition 1438.11, Definition 1438.12, Definition 1438.13, Definition 1438.14, Definition 1438.21, Definition 1438.22, Definition 1438.23, Definition 1438.24, Definition 1438.25, Definition 1438.26, Definition 1438.27, and Definition 1438.30 expose the public L10 export route through the sequence source, dyadic tolerance ledger, tail-index schedule, finite StreamName windows, RegSeqRat readback, RealSequenceLimit handoff, RegularCauchyCompletionUniversal consumers, and the structural rows H, C, P, N.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyConvergenceModulus}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.CauchyConvergenceModulusUp.CauchyConvergenceModulusNamecertObligations`

Bridge status: none

Not claimed: This chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient limits, host sequence convergence, host real equality, countable choice, trichotomy, selected representatives, ambient completion, or bridge checking.

Upgrade path: No paper-side closure grade remains; further work is only Lean bridge checking.

Chapter 1439

A Concrete Naming Certificate for $\mathsf{StolzCesaro}^{\uparrow}$

Following Stolz and Cesaro, and in the Bishop–Bridges style of constructive convergence, the $\mathsf{StolzCesaro}^{\uparrow}$ packet records the finite certificate surface for a quotient-tail convergence argument before it reaches a Real-completion consumer. It sits over the finite windows of chapter 126, the regular rational source of chapter 301, the dyadic estimate ledger of chapter 291, the convergence schedule surface of chapter 1438, the monotone source discipline of chapter 1405, and the real-name seal of chapter 38. The chapter names the displayed finite route used by the convergence certificate; it does not import a host theorem about all real sequences.

Definition 1439.1 (Stolz-Cesaro finite convergence carrier)**.** *A* $\mathsf{StolzCesaro}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (A, B, \Delta A, \Delta B, D, T, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family for the numerator sequence rows inspected by the packet.*
2. *B is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family for the denominator sequence rows inspected by the same tail schedule.*
3. *ΔA is the numerator difference row, recording the displayed differences used by the ratio classifier.*
4. *ΔB is the positive denominator step row, recording the displayed denominator steps and their positivity evidence.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ratio-difference ledger for the inspected step quotients and requested tolerances.*
6. *T is the finite tail-window schedule deciding which inspected windows are admitted for each dyadic tolerance.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from $A, B, \Delta A, \Delta B, D, T$.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row reached only after the finite stream, difference, dyadic, schedule, and regular-rational rows have been displayed.*

9. *H records componentwise* hsame *transport for the two stream families, difference rows, positivity row, dyadic ledger, schedule, regular-rational handoff, Real seal-facing row, continuation, provenance, and local naming rows.*
10. *C records the displayed* Cont *replay from each quotient-tail request through $A, B, \Delta A, \Delta B, D, T, Q, E, H, P, N$.*
11. *P is the* Pkg *provenance over* StolzCesaro$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyConvergenceMod MonotoneSubsequence$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{StolzCesaro}^{\uparrow}}$ *row.*

The carrier has no coordinate for host limits, quotient streams, choice-selected subsequences, ambient completeness, real-closed field reasoning, or an unbounded sequence oracle.

Theorem 1439.2 (Stolz-Cesaro NameCert obligation sketch)**.** *The seed* NameCert$_{\text{StolzCesaro}^{\uparrow}}$ *surface for Definition 1439.1 consists of the following five obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed packet $Z = (A, B, \Delta A, \Delta B, D, T, Q, E, H, C, P, N)$*
2. *denominator-step positivity: every admitted quotient-tail request reads the positive denominator step row ΔB before any ratio-difference row is classified;*
3. *ratio-difference classifier transport: the dyadic ratio-difference ledger D is stable under the componentwise* hsame *transport H and the displayed* Cont *replay C;*
4. *Cauchy-convergence handoff: the tail-window schedule T and dyadic ledger D supply the finite route consumed by the* CauchyConvergenceModulus$^{\uparrow}$*-style handoff before Q is read;*
5. *non-escape: no accepted consumer obtains a host limit, quotient stream, choice-selected subsequence, ambient completeness witness, or detached real-seal row outside $A, B, \Delta A, \Delta B, D, T, Q, E, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.StolzCesaroUp.StolzCesaroTasteGate single carrier alignment`

Proof. Project the carrier tuple $Z = (A, B, \Delta A, \Delta B, D, T, Q, E, H, C, P, N)$. Carrier admission is exactly the assertion that the local NameCert$_{\text{StolzCesaro}^{\uparrow}}$ row names this displayed finite packet.

The denominator side is read before the ratio classifier. The row ΔB supplies the positive difference evidence used to admit a quotient-tail request, and the dyadic row D records only the ratio-difference estimates over the displayed numerator and denominator step rows.

Now transport the classifier. The componentwise hsame row H and continuation replay C preserve the same stream windows, difference rows, positivity row, and dyadic ledger, so the classifier cannot move to a hidden quotient stream or host equality source.

Finally read the completion-facing handoff. The schedule T and ledger D feed the regular-rational row Q, and the Real seal-facing row E is reached only after that finite handoff has been displayed. The excluded objects have no coordinate in Z, so the five listed rows exhaust the seed obligation surface. □

Theorem 1439.3 (Stolz-Cesaro finite tail handoff)**.** *For every accepted* StolzCesaro$^{\uparrow}$ *packet $Z = (A, B, \Delta A, \Delta B, D, T, Q, E, H, C, P, N)$ and every displayed quotient-tail request, the Real-completion-facing read factors through the finite route*

$$A, B \longmapsto \Delta A, \Delta B \longmapsto D \longmapsto T \longmapsto Q \longmapsto E \longmapsto (H, C, P, N).$$

No consumer can read the RegSeqRat$^{\uparrow}$ *handoff or the* Real$^{\uparrow}$ *seal-facing row without also reading the displayed stream windows, numerator difference row, positive denominator step row, dyadic ratio-difference ledger, and finite tail-window schedule.*

Proof. Begin with Definition 1439.2. Its carrier-admission and positivity rows place $A, B, \Delta A, \Delta B$ before any ratio-difference classifier can be used.

The classifier then passes through the dyadic and schedule rows. The row D records the finite ratio-difference estimates, while T records which tail windows are admitted for the requested tolerance.

The completion-facing rows are downstream of that finite route. The regular-rational handoff Q and Real seal-facing row E are reached only after the scheduled dyadic estimate surface is displayed, and H, C, P, N preserve and name that same route. Hence the read cannot escape into host limits, quotient streams, choice-selected subsequences, or ambient completeness. □

Definition 1439.4 (Stolz-Cesaro finite-difference subcarrier)**.** *The finite-difference subcarrier of an accepted* $\mathsf{StolzCesaro}^{\uparrow}$ *packet is the displayed six-row packet*

$$Z_{\Delta} = (A, B, \Delta A, \Delta B, D, T)$$

cut out of Definition 1439.1. Its rows expose only the numerator $\mathsf{StreamName}^{\uparrow}$ *windows, denominator* $\mathsf{StreamName}^{\uparrow}$ *windows, displayed numerator differences, positive denominator-step differences,* $\mathsf{DyadicRatCore}^{\uparrow}$ *quotient-estimate ledger, and finite tail schedules. The subcarrier carries no* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, no* $\mathsf{Real}^{\uparrow}$ *seal-facing row, no host limit, no quotient stream, and no ambient completeness witness.*

Theorem 1439.5 (Stolz-Cesaro finite-difference NameCert obligations)**.** *For every accepted* $\mathsf{StolzCesaro}^{\uparrow}$ *packet* $Z = (A, B, \Delta A, \Delta B, D, T, Q, E, H, C, P, N)$*, the subcarrier* $Z_{\Delta} = (A, B, \Delta A, \Delta B, D, T)$ *of Definition 1439.4 carries the complete finite* $\mathsf{NameCert}_{\mathsf{StolzCesaro}^{\uparrow}}$ *surface consumed before any completion-facing route is exposed:*

1. *carrier admission identifies* Z_{Δ} *as the only finite-difference source admitted from the ambient packet* Z*;*
2. *denominator positivity is read from* ΔB *before any quotient estimate in* D *is classified;*
3. *dyadic ratio transport in* D *is stable under the componentwise* hsame *row* H*;*
4. *the finite schedule* T *names the inspected tail windows used by every tolerance request;*
5. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* Q *may be read only after* $A, B, \Delta A, \Delta B, D, T$ *have all been displayed;*
6. *the* $\mathsf{Real}^{\uparrow}$ *seal-facing row* E *is a terminal readback from* Q *and cannot expose a separate real-completion witness;*
7. Cont *replay through* C*,* Pkg *provenance through* P*, and the local naming row* N *preserve the same displayed subcarrier route.*

Proof. Start from the carrier admission in Definition 1439.2. Projection to the six displayed coordinates gives the finite-difference packet Z_{Δ}, and the excluded coordinates show that no host quotient stream or completion witness is part of this subcarrier.

The denominator and ratio rows are then forced locally. The positive denominator-step evidence lives in ΔB, while D records dyadic quotient estimates over the displayed numerator and denominator windows, so every ratio read factors through the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ surfaces already named in the packet.

Next apply Definition 1439.3. It places the finite schedule T before the regular-rational handoff Q, and places the Real seal-facing row E after Q.

Finally replay the structural rows. The componentwise hsame transport H, displayed Cont replay C, Pkg provenance P, and local $\mathsf{NameCert}_{\mathsf{StolzCesaro}^\uparrow}$ row N preserve the same $A, B, \Delta A, \Delta B, D, T$ route through the sibling surfaces $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{CauchyConvergenceModulus}^\uparrow$, $\mathsf{MonotoneSubsequence}^\uparrow$, and $\mathsf{Real}^\uparrow$. □

Theorem 1439.6 (Stolz-Cesaro Cauchy tail handoff)**.** *Every completion-facing read from an accepted* $\mathsf{StolzCesaro}^\uparrow$ *packet factors through the finite-difference subcarrier*

$$Z_\Delta = (A, B, \Delta A, \Delta B, D, T)$$

before any $\mathsf{RegSeqRat}^\uparrow$ *handoff or* $\mathsf{Real}^\uparrow$ *seal-facing row is exposed. Equivalently, a read of Q or E is accepted only as the continuation of the displayed route from* $\mathsf{StreamName}^\uparrow$ *windows through* $\mathsf{DyadicRatCore}^\uparrow$ *quotient estimates and the* $\mathsf{CauchyConvergenceModulus}^\uparrow$ *tail schedule; it is rejected when it bypasses A, B, ΔA, ΔB, D, or T.*

Proof. Use Definition 1439.3 to order the completion-facing route. That theorem already places $A, B, \Delta A, \Delta B, D, T$ before Q and E.

Now identify this ordered prefix with Definition 1439.4. The prefix is exactly Z_Δ, so the Cauchy-modulus read has no access to a separate numerator stream, denominator stream, denominator positivity proof, quotient estimate ledger, or tail schedule.

It remains to account for stability under accepted replay. By Definition 1439.5, hsame, Cont, Pkg, and local naming preserve the same finite-difference route, while the sibling $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{CauchyConvergenceModulus}^\uparrow$, $\mathsf{MonotoneSubsequence}^\uparrow$, and $\mathsf{Real}^\uparrow$ surfaces supply only their displayed rows. Thus every accepted completion-facing read is mediated by Z_Δ before Q or E becomes visible. □

Theorem 1439.7 (Stolz-Cesaro RegSeqRat handoff)**.** *For every accepted* $\mathsf{StolzCesaro}^\uparrow$ *packet $Z = (A, B, \Delta A, \Delta B, D, T, Q, E, H, C, P, N)$, an accepted read of the row Q is exactly the* $\mathsf{RegSeqRat}^\uparrow$ *handoff induced by the finite-difference subcarrier*

$$Z_\Delta = (A, B, \Delta A, \Delta B, D, T).$$

Conversely, any accepted finite-difference packet exposing Z_Δ together with the displayed transport H, replay C, provenance P, and local name N repacks as the same Q handoff, and cannot supply a host limit, quotient stream, choice-selected subsequence, ambient completeness witness, or detached $\mathsf{Real}^\uparrow$ *seal.*

Proof. Start with an accepted read of Q. By Definition 1439.6, that read is admitted only after the displayed route through $A, B, \Delta A, \Delta B, D, T$ has been exposed, so the source of Q is the finite-difference subcarrier Z_Δ.

The exact obligation surface is supplied by Definition 1439.5. It identifies carrier admission, denominator positivity, dyadic ratio transport, the tail schedule, Cont replay, Pkg provenance, and local naming as the rows that preserve the finite-difference route before Q is read.

For the converse, begin with an accepted finite-difference packet exposing Z_Δ and the structural rows H, C, P, N. The same obligation theorem preserves the route under displayed transport and replay, while Definition 1439.6 places the $\mathsf{RegSeqRat}^\uparrow$ row immediately after that route and before any $\mathsf{Real}^\uparrow$ seal-facing row.

Thus the repacked packet reaches exactly the same Q handoff. The excluded host limit, quotient stream, choice-selected subsequence, ambient-completeness, and detached-seal objects have no coordinate in Z_Δ or in the structural rows that name and replay it. □

Theorem 1439.8 (Stolz-Cesaro Real-limit handoff)**.** *Every accepted* $\mathsf{StolzCesaro}^{\uparrow}$ *packet whose finite-difference subcarrier has produced the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed numerator and denominator windows, numerator and denominator difference rows, dyadic ratio ledger, finite tail schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. For*

$$Z = (A, B, \Delta A, \Delta B, D, T, Q, E, H, C, P, N),$$

the seal-facing row E *is therefore a finite Real-limit handoff from the route*

$$A, B, \Delta A, \Delta B, D, T, Q, H, C, P, N,$$

not a host limit, quotient stream equality, countable-choice selector, trichotomy argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier $Z = (A, B, \Delta A, \Delta B, D, T, Q, E, H, C, P, N)$ and its finite-difference subcarrier $Z_{\Delta} = (A, B, \Delta A, \Delta B, D, T)$. By Definition 1439.5, the subcarrier rows must be displayed before any completion-facing consumer can read Q or E.

Apply Definition 1439.6. It places the numerator and denominator windows, difference rows, dyadic ledger, and finite tail schedule before the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the $\mathsf{Real}^{\uparrow}$ seal-facing row.

Now use Definition 1439.7. Once Q has been produced, the only admissible route to E is the same finite-difference route preserved by H, C, P, N. The structural rows transport, replay, source, and name the handoff; they do not add a separate limit witness.

The carrier has no coordinate for a host limit, quotient stream equality, countable choice, trichotomy, or ambient Real completeness. Hence the terminal Real-limit read is exactly the finite handoff stated above. □

Falsifiable prediction: An accepted $\mathsf{StolzCesaro}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal-facing row without the displayed numerator windows, denominator windows, numerator differences, positive denominator steps, dyadic ratio-difference ledger, and finite tail-window schedule refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, cauchyconvergencemodulus, monotonesubsequence, real: no listed sibling supplies the whole twelve-row packet $Z = (A, B, \Delta A, \Delta B, D, T, Q, E, H, C,$ because each sibling contributes only a stream, regular-rational, dyadic, convergence-schedule, monotone-source, or real-seal surface while this chapter binds the quotient-tail certificate with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{StolzCesaro}^{\uparrow}}$.

Constructive story: A $\mathsf{StolzCesaro}^{\uparrow}$ packet is generated from finite numerator and denominator stream windows, numerator difference rows, positive denominator step rows, dyadic ratio-difference estimates, finite tail-window schedules, a RegSeqRat handoff, a Real seal-facing row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StolzCesaro}^{\uparrow}}$, seed)

Scope closed: Definition 1439.1, Definition 1439.2, and Definition 1439.3 seed the finite quotient-tail convergence certificate over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{MonotoneSubsequence}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StolzCesaro}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim the full classical Stolz-Cesaro theorem as an imported real-analysis principle, host limits, quotient streams, choice-selected subsequences, ambient completeness, or a Lean theorem.

Upgrade path: A formal route can encode the twelve-row carrier and prove the NameCert obligation sketch and finite tail handoff theorem.

Chapter 1440

A Concrete Naming Certificate for $\mathsf{BoundedRealLowerCut}^{\uparrow}$

Following Bishop and Bridges, bounded real lower-cut data are read as finite rational observations attached to a $\mathsf{Real}^{\uparrow}$ seal and an Archimedean bound, not as a host supremum or completed cut quotient. The packet consumes the real-name boundary of chapter 38, the located lower-cut discipline of chapter 404, the explicit rational-bound surface of chapter 430, and the nonconvergent observation boundary of chapter 1406. It is a constructive observation surface for bounded names rather than a Dedekind-real construction.

Definition 1440.1 (BoundedRealLowerCut carrier)**.** *A* $\mathsf{BoundedRealLowerCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, A, D, S, O, B, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row whose lower observations are being exposed.*
2. *A is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *rational-bound row attached to the same displayed real name.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row used to read rational lower observations at finite precision.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that names which observations of R are inspected.*
5. *O is the lower-observation ledger: each row records a rational candidate, its dyadic comparison budget, the finite window it reads, and the evidence that the candidate lies below the sealed name as far as the displayed packet can observe.*
6. *B is the boundedness ledger tying every lower-observation row in O to the Archimedean bound row A.*
7. *H records the componentwise* hsame *transports for R, A, D, S, O, B and the structural rows.*
8. *C records the displayed* Cont *routes by which consumers replay the Real seal, Archimedean bound, dyadic comparison, window schedule, observation ledger, and boundedness ledger.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedRealLowerCut}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{ArchimedeanReal}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRealLowerCut}^{\uparrow}}$ *row.*

The carrier stores no host supremum, no Dedekind real construction, no trichotomy branch, no quotient real equality, no selected limit, and no ambient completeness coordinate for $\mathsf{Real}^{\uparrow}$.

Theorem 1440.2 (BoundedRealLowerCut NameCert obligations)**.** *For an accepted* $\mathsf{BoundedRealLowerCut}^{\uparrow}$ *carrier* $L = (R, A, D, S, O, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedRealLowerCut}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *carrier formation for the* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, lower-observation ledger, boundedness ledger, transports, continuations, provenance, and local naming data;*
2. *classifier stability, stating that replacement of the displayed rows through* H *and replay through* C *preserves the same bounded lower-cut observation packet;*
3. *lower-observation exactness, stating that each row of* O *is read from the same Real seal* R *through the finite windows* S *and dyadic comparison budget* D*;*
4. *boundedness handoff, stating that the Archimedean row* A *bounds every lower-observation row recorded in* O *through the finite ledger* B*;*
5. *seal non-escape, stating that no consumer reaches a supremum, Dedekind cut quotient, trichotomy branch, quotient real equality, selected limit, or* $\mathsf{Real}^{\uparrow}$ *completeness principle from the packet.*

Proof. Carrier formation is the displayed tuple of Definition 1440.1. It contains exactly one Real seal row, one Archimedean bound row, one dyadic comparison row, one finite-window schedule, one lower-observation ledger, one boundedness ledger, and the structural transport, continuation, provenance, and naming rows.

Classifier stability is componentwise over H and C. A classified replacement may transport the displayed rows and replay their consumers, but it cannot introduce a second Real seal, a second bound, a hidden quotient of cuts, or an external completeness witness.

Lower-observation exactness is the role of O. Each observation row records the rational candidate, the dyadic comparison budget, and the finite window through which the same seal R is inspected. The packet therefore exposes the lower-cut face only as observed finite data.

The boundedness handoff is supplied by A and B. The Archimedean row gives the explicit rational-bound surface, and the ledger B ties every accepted lower observation to that surface without selecting a least upper bound or a supremum.

Seal non-escape follows from the row inventory. The provenance row mentions the sibling $\mathsf{LocatedCut}^{\uparrow}$ and $\mathsf{SpeckerSequence}^{\uparrow}$ boundaries only as observation disciplines; no row carries a Dedekind construction, trichotomy branch, quotient equality, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. □

Theorem 1440.3 (BoundedRealLowerCut L10 handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{BoundedRealLowerCut}^{\uparrow}$ *packet factors through the displayed* $\mathsf{Real}^{\uparrow}$ *seal* R*, the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound* A*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows* S*, the lower-observation ledger* O*, the boundedness ledger* B*, the transport row* H*, the continuation row* C*, the provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{BoundedRealLowerCut}^{\uparrow}}$ *row* N *before using the bounded lower-cut surface.*

Proof. Project the accepted carrier. The Real-facing coordinate is R, and every lower-cut read is mediated by D, S, O while every boundedness read is mediated by A and B.

Next replay the sibling route. The $\mathsf{Real}^{\uparrow}$ chapter supplies the seal boundary, $\mathsf{LocatedCut}^{\uparrow}$ supplies the finite lower-cut observation discipline, $\mathsf{ArchimedeanReal}^{\uparrow}$ supplies the rational-bound surface, and $\mathsf{SpeckerSequence}^{\uparrow}$ marks the refusal to turn bounded observations into a general convergence or completeness principle.

Finally use H, C, P, N to close the handoff route. These rows record the only permitted transports, continuations, provenance, and local naming evidence, so an L10 consumer cannot bypass the finite observation surface by reading a host supremum, a Dedekind real, trichotomy, quotient real equality, selected limits, or Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRealLowerCut}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRealLowerCut}^{\uparrow}$ packet is generated from a displayed $\mathsf{Real}^{\uparrow}$ seal, an $\mathsf{ArchimedeanReal}^{\uparrow}$ bound row, a $\mathsf{DyadicRatCore}^{\uparrow}$ comparison row, a $\mathsf{StreamName}^{\uparrow}$ window schedule, a lower-observation ledger, a boundedness ledger, componentwise hsame transports, Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRealLowerCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1440.1, Definition 1440.2, and Definition 1440.3 bind the finite bounded lower-cut observation surface for Real-and-Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRealLowerCut}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host supremum, a Dedekind real construction, trichotomy, quotient real equality, selected limits, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier formation, classifier stability, lower-observation exactness, boundedness handoff, and seal non-escape for the displayed packet.

Chapter 1441

A Concrete Naming Certificate for $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ packet records the boundary where a regular rational Cauchy name, an explicit convergence modulus, and finite locatedness evidence are all visible before the $\mathsf{Real}^{\uparrow}$ seal is read. It sits over the finite windows of chapter 126, the regular rational source of chapter 301, the endpoint and radius ledger of chapter 291, the real-name seal of chapter 38, the located enclosure surface of **??**, and the explicit rate rows of chapter 332. The certificate keeps convergence and location as finite rows rather than hiding them inside a later BishopReal or compact-interval consumer.

Definition 1441.1 (Regular located Cauchy real carrier)**.** *A* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, Q, D, M, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family naming the finite observation windows used by the packet.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational entries are read only on the windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger recording the rational centers, dyadic radii, and interval comparisons attached to those windows.*
4. *M is the* $\mathsf{ModulusOfConvergence}^{\uparrow}$ *rate row assigning each requested tolerance a finite threshold over the displayed windows.*
5. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *enclosure row recording the finite interval-location evidence attached to the same source, endpoint, radius, and threshold rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream, regular-source, dyadic-ledger, modulus, and located-enclosure rows have been displayed.*
7. *H records componentwise* hsame *transport for the stream windows, regular rational source, dyadic endpoint and radius ledger, convergence-modulus row, located enclosure, Real seal, continuation, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from each precision and location request through $S, Q, D, M, L, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ModulusOfConvergence}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularLocatedCauchyReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for Dedekind construction of $\mathsf{Real}^{\uparrow}$*, quotient equality, trichotomy, open-cover compactness, countable choice, completed metric-space points, or an unbounded stream read.*

Theorem 1441.2 (Regular located Cauchy real NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularLocatedCauchyReal}^{\uparrow}}$ *surface for Definition 1454.1 consists exactly of carrier exposure for R, finite-window exposure through S, regular rational source exposure through Q, endpoint and radius exposure through D, convergence-rate exposure through M, located-enclosure exposure through L, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N. Each accepted request is classified only by the displayed StreamName window, the RegSeqRat source row, the dyadic endpoint and radius ledger, the convergence threshold, and the located enclosure row.*

```
Lean4 ✓  BEDC.Derived.RegularLocatedCauchyRealUp.TasteGate.RegularLocatedCauchyRealTasteGate
single carrier alignment
```

Proof. Project the carrier tuple $R = (S, Q, D, M, L, E, H, C, P, N)$. Each analytic coordinate is a displayed finite row, and the final coordinate names the same tuple as the local $\mathsf{NameCert}_{\mathsf{RegularLocatedCauchyReal}^{\uparrow}}$ surface.

Read the rows in their dependency order. A request first consumes the stream window S and regular rational source Q, then the dyadic endpoint and radius ledger D, then the convergence threshold row M, and only then the located enclosure L and terminal Real seal E.

The structural rows add no hidden analytic object. They transport, replay, source, and name the displayed route, while the excluded objects have no coordinate in the carrier. Hence the listed rows exhaust the seed obligation surface. □

Theorem 1441.3 (Regular located Cauchy real RealUp seal route)**.** *For every accepted* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *packet $R = (S, Q, D, M, L, E, H, C, P, N)$ and every displayed precision request, the Real-facing read factors through the finite route*

$$S \longmapsto Q \longmapsto D \longmapsto M \longmapsto L \longmapsto E \longmapsto (H, C, P, N).$$

No consumer can read the terminal $\mathsf{Real}^{\uparrow}$ *seal from R without also reading the same StreamName window family, RegSeqRat source row, DyadicRatCore endpoint and radius ledger, ModulusOfConvergence rate row, and LocatedReal enclosure row.*

Proof. Start with Definition 1454.2. It places the finite window row S before the regular source row Q and places the dyadic ledger D before the convergence modulus M and located enclosure L.

The Real seal is therefore not an independent coordinate. The row E is reached after S, Q, D, M, L are displayed, so a consumer omitting any of those rows has not followed the carrier route.

Finally read the structural rows. The rows H, C, P, N preserve, replay, source, and name the same route; they do not add a second route to $\mathsf{Real}^{\uparrow}$. Thus the terminal seal factors through the displayed finite certificate path. □

Theorem 1441.4 (Regular located Cauchy real modulus-location factorization)**.** *For every accepted* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *packet $R = (S, Q, D, M, L, E, H, C, P, N)$, every locatedness read factors through the common finite data*

$$S, \quad Q, \quad D, \quad M$$

before it reaches L, and every convergence-modulus read uses the same S, Q, D rows before it reaches M. Hence the modulus and locatedness surfaces share the StreamName windows, RegSeqRat source, and DyadicRatCore endpoint and radius ledger rather than presenting two unrelated certificates.

Proof. Use the carrier definition. The row M is a rate row over the windows, source, endpoints, and radii already named by S, Q, D; the row L is a located enclosure over the same displayed source and dyadic ledger, with the rate row fixing the relevant tail threshold.

Now compare the two reads. The convergence side stops at M after S, Q, D, while the locatedness side continues through M to L on the same finite rows.

The componentwise hsame and Cont rows preserve that shared route, and the Pkg and local NameCert rows name it. Thus any accepted consumer sees one factored certificate surface, not a separated modulus certificate and a separated location certificate. □

Theorem 1441.5 (Regular located Cauchy real scoped dependency route)**.** *Every accepted* RegularLocatedCauchyR *read factors through exactly the displayed* StreamName$^{\uparrow}$ *finite windows,* RegSeqRat$^{\uparrow}$ *readback row,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* ModulusOfConvergence$^{\uparrow}$ *location row,* LocatedReal$^{\uparrow}$ *locatedness row, terminal* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert$_{\text{RegularLocatedCauchyReal}^{\uparrow}}$ *row. No quotient stream equality, selected representative, trichotomy, countable choice, or ambient* Real$^{\uparrow}$ *completeness coordinate is in scope for such a read.*

Proof. Use Definition 1454.2. It exposes the carrier as the tuple $R = (S, Q, D, M, L, E, H, C, P, N)$ and makes the stream windows, regular rational source, dyadic ledger, convergence row, locatedness row, and Real seal explicit.

Apply Definition 1454.3 to the endpoint-facing side. The terminal Real$^{\uparrow}$ read is downstream of the same S, Q, D, M, L rows, so it cannot be reached by a separate representative-selection path.

Apply Definition 1454.4 to the locatedness side. The modulus and locatedness reads share S, Q, D, M before reaching L, and the structural rows only transport, replay, source, and name that route.

The excluded principles have no coordinate in the displayed carrier. Hence the scoped route is exactly the finite dependency route named above. □

Falsifiable prediction: An accepted RegularLocatedCauchyReal$^{\uparrow}$ consumer that reaches a Real$^{\uparrow}$ seal or a locatedness enclosure without the displayed StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ source, DyadicRatCore$^{\uparrow}$ endpoint and radius ledger, and ModulusOfConvergence$^{\uparrow}$ rate row refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, locatedreal, modulusofconvergence: no listed sibling supplies the whole ten-row packet $R = (S, Q, D, M, L, E, H, C, P, N)$, because each sibling contributes only a window, regular-source, dyadic-ledger, Real-seal, located-enclosure, or rate surface while this chapter binds all six analytic faces with transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{RegularLocatedCauchyReal}^{\uparrow}}$**.**

Constructive story: A RegularLocatedCauchyReal$^{\uparrow}$ packet is generated from finite StreamName$^{\uparrow}$ windows, a RegSeqRat$^{\uparrow}$ source row, a DyadicRatCore$^{\uparrow}$ endpoint and radius ledger, a ModulusOfConvergence$^{\uparrow}$ rate row, a LocatedReal$^{\uparrow}$ enclosure row, a terminal Real$^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularLocatedCauchyReal}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1454.1, Definition 1454.2, Definition 1454.3, Definition 1454.4, and Definition 1454.5 bind the regular located Cauchy real-name route over StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, ModulusOfConvergence$^{\uparrow}$, LocatedReal$^{\uparrow}$, and Real$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{RegularLocatedCauchyReal}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RegularLocatedCauchyRealUp.TasteGate.RegularLocatedCauchyRealTasteGate\_single\_carrier`

Bridge status: none

Not claimed: This chapter does not claim Dedekind construction of $\mathrm{Real}^{\uparrow}$, quotient equality, trichotomy, open-cover compactness, countable choice, completeness, or completed metric-space points.

Upgrade path: Public closure requires a downstream public-object surface that reuses the scoped dependency route without adding quotient equality, selected representatives, countable choice, or ambient completeness.

Chapter 1442

A Concrete Naming Certificate for $\mathsf{SequentialContinuity}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{SequentialContinuity}^{\uparrow}$ packet records continuity along certified convergent sequences as a finite BEDC route. It reads the pointwise metric-continuity surface of chapter 59, the regular rational windows of chapter 301, the inspected stream schedules of chapter 126, the real-name seal of chapter 38, and the $\mathsf{Met}^{\uparrow}$ rows of chapter 57. The packet supplies a Real and Completion frontier surface for sequence consumers without importing host sequential continuity, function extensionality, choice, quotient equality, or ambient completeness.

Definition 1442.1 (Sequential continuity carrier)**.** *A* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N)$$

with the following displayed rows:

1. *M_X and M_Y are the source and target* $\mathsf{Met}^{\uparrow}$ *carrier rows with their visible classifiers and distance ledgers.*
2. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row for a displayed map from the source metric carrier to the target metric carrier.*
3. *S is the source sequence surface, exposed only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
4. *L is the inspected convergence ledger for S, listing the finite thresholds actually requested by the packet.*
5. *W_X and W_Y are the source and target finite stream windows read from S and from the displayed images of those windows under F.*
6. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows attached to the inspected source and target windows.*
7. *E_X and E_Y are the* $\mathsf{Real}^{\uparrow}$ *seal rows reached after the corresponding regular-rational handoffs have been displayed.*
8. *H stores componentwise* hsame *transport for the metric rows, the continuous-map row, the sequence row, the convergence ledger, both window families, both regular handoffs, both Real seals, continuation, provenance, and local naming.*

9. *C stores displayed* Cont *replay from S, L to W_X, from W_X, F to W_Y, from W_X to R_X, E_X, and from W_Y to R_Y, E_Y.*
10. *P is the* Pkg *provenance over* $\mathsf{SequentialContinuity}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for an external sequence function, quotient stream equality, function extensionality, countable choice, or host sequential-continuity theorem.

Lean4 ✓ `BEDC.Derived.SequentialContinuityUp.SequentialContinuityTasteGate single carrier alignment`

Theorem 1442.2 (Sequential continuity NameCert obligations)**.** *For every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier $Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed fifteen-row packet;*
2. *source and target metric-row stability through M_X, M_Y, H, C;*
3. *pointwise-continuity use only through the displayed* $\mathsf{Continuous}^{\uparrow}$ *row F;*
4. *inspected-threshold convergence coverage through the finite ledger L;*
5. *source and target sequence handoff through W_X, W_Y, R_X, R_Y before either* $\mathsf{Real}^{\uparrow}$ *seal is consumed;*
6. *non-escape from host sequential continuity, function extensionality, countable choice, quotient equality, and ambient Real completeness.*

Proof. Project the carrier of Definition 1466.1. The metric rows, continuous-map row, source sequence row, convergence ledger, window rows, regular-rational handoffs, Real seals, and structural rows are the only coordinates visible to the classifier.

The metric and continuity faces are already displayed. Source and target stability reads through M_X, M_Y, H, C, while pointwise continuity is consumed only through F and the finite windows named by the packet.

The sequential face is finite. The ledger L records the inspected convergence thresholds, W_X displays the corresponding source windows, and W_Y displays the image windows obtained by the recorded continuation route.

Finally read the endpoint route. The source side reaches E_X through R_X, and the target side reaches E_Y through R_Y. Since the excluded principles are not coordinates of Q, the six listed rows exhaust the local NameCert obligation surface. □

Theorem 1442.3 (Sequential continuity Cauchy handoff)**.** *Every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *packet hands both the source sequence windows and the image sequence windows to* $\mathsf{RegSeqRat}^{\uparrow}$ *before any* $\mathsf{Real}^{\uparrow}$ *seal can be consumed. Equivalently, every seal-facing route factors through*

$$S, L \longmapsto W_X \longmapsto R_X \longmapsto E_X \qquad \text{and} \qquad W_X, F \longmapsto W_Y \longmapsto R_Y \longmapsto E_Y$$

together with M_X, M_Y, H, C, P, N.

Proof. Begin with the inspected source route. The continuation row records that W_X is read from the displayed sequence surface S using only the thresholds listed in L.

Next form the image route. The row F is the displayed $\mathsf{Continuous}^{\uparrow}$ pointwise-modulus surface, and C records the replay from the inspected source windows to the target windows W_Y.

Both sides then pass through regular-rational readback. The rows R_X and R_Y are the only regular handoffs attached to the source and target windows, and the seal rows E_X and E_Y are downstream from those handoffs.

Thus a consumer that tries to use either $\mathsf{Real}^{\uparrow}$ seal without the matching $\mathsf{RegSeqRat}^{\uparrow}$ handoff leaves the accepted $\mathsf{SequentialContinuity}^{\uparrow}$ carrier. □

Lean4 ✓ `BEDC.Derived.SequentialContinuityUp.SequentialContinuityCauchyHandoff`

Theorem 1442.4 (Sequential continuity metric-row stability)**.** *For every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier*

$$Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N),$$

the source and target metric rows used by the local classifier are exactly the displayed $\mathsf{Met}^{\uparrow}$ *rows* M_X *and* M_Y*, stabilized by the same componentwise* hsame *transport* H *and displayed* Cont *replay* C *carried by* Q*. No metric comparison may be supplied by an external topology, host equality of points, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.SequentialContinuityUp.SequentialContinuityPacket metric row stability`

Proof. Project the accepted carrier. The only metric coordinates visible in the packet are M_X and M_Y, and the only structural coordinates that can move them between accepted packets are H and C.

The provenance and naming rows do not add a second metric surface. They record that the displayed rows belong to the same $\mathsf{SequentialContinuity}^{\uparrow}$ packet over $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Thus every metric read used by the classifier is stable exactly along M_X, M_Y, H, C, P, N. The excluded external topology, host equality, quotient, and completeness data are not coordinates of Q. □

Theorem 1442.5 (Sequential continuity pointwise consumption)**.** *For every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier* $Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N)$*, the pointwise-continuity information consumed by the sequence route is only the displayed* $\mathsf{Continuous}^{\uparrow}$ *row* F *together with the source metric row* M_X*, target metric row* M_Y*, finite windows* W_X, W_Y*, transport* H*, replay* C*, provenance* P*, and local naming* N*. The packet exports no host sequential-continuity theorem and no function-extensionality coordinate.*

Proof. Read the pointwise face of the carrier. The row F is the unique $\mathsf{Continuous}^{\uparrow}$ coordinate, and it is stored beside the source and target metric rows M_X, M_Y.

The sequence route inspects only finite windows. The continuation row sends the displayed source windows W_X through F to the target windows W_Y, and the transport row preserves that same route under componentwise hsame.

Finally, P and N source and name the same packet. Since neither a host sequential-continuity theorem nor a function-extensionality principle appears among the coordinates of Q, every pointwise-continuity use is consumed through the displayed rows named in the statement. □

Theorem 1442.6 (Sequential continuity inspected-threshold coverage)**.** *For every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier* $Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N)$*, each threshold used by a Real-facing or regular-Cauchy consumer is first listed in the inspected convergence ledger* L*, then*

read through the source window W_X, the image window W_Y, the regular handoff rows R_X, R_Y, and only then through the seal rows E_X, E_Y. The coverage route is exhausted by the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of the same carrier.*

Proof. Project the carrier and read the inspected ledger. The row L is the only coordinate that lists convergence thresholds requested by the packet.

The source schedule then opens W_X from S at the listed thresholds. The pointwise row F and replay row C produce the corresponding image windows W_Y without adding a detached sequence object.

The regular and Real-facing reads are downstream from those windows. The rows R_X, R_Y repack the inspected windows as regular rational handoffs, and E_X, E_Y are consumed only after those handoffs.

The structural rows H, C, P, N preserve, replay, source, and name exactly this route. Therefore the inspected thresholds cover the whole consumer path and no unlisted threshold, quotient stream, selected limit, choice row, or ambient completeness datum can enter the packet. □

The mature treatment of $\mathsf{SequentialContinuity}^{\uparrow}$ is the Real and Completion sequence-consumer route obtained by reading the Cauchy handoff, metric-row stability, pointwise consumption, and inspected-threshold coverage together. A consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal or a completion-facing sequence row must pass through the displayed finite windows, the regular-rational handoff rows, and the same metric and continuity coordinates already inspected by the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialContinuity}^{\uparrow}$ packet is generated from source and target metric rows, a displayed pointwise-continuity row, inspected sequence windows, a finite convergence ledger, source and target RegSeqRat handoffs, RealUp seal rows, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1466.1, Definition 1466.2, Definition 1466.3, Definition 1466.4, Definition 1466.5, and Definition 1466.6 bind the carrier, NameCert obligations, Cauchy handoff, metric-row stability, pointwise consumption, and inspected-threshold coverage for certified sequence consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.SequentialContinuityUp.SequentialContinuityTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: human

Not claimed: This chapter does not claim host sequential continuity, function extensionality, countable choice, quotient stream equality, semantic completeness of RealUp, Lean verification, or bridge checking.

Upgrade path: No further paper-side closure grade remains; bridge verification stays on the independent formal axis.

Chapter 1443

A Concrete Naming Certificate for $\mathsf{SubsequenceLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SubsequenceLimit}^{\uparrow}$ packet records the finite consumer boundary for reading a displayed subsequence limit from already certified real sequence-limit data. It consumes the sequence-limit surface of chapter 1413, the cofinal selector route of chapter 405, the regular Cauchy subsequence boundary of chapter 381, and the real-name seal of chapter 38. Its purpose is to let downstream Bolzano–Weierstrass and sequence-convergence arguments read a selected limit surface without importing arbitrary subsequence choice, host sequence equality, quotient stream equality, or ambient completeness.

Definition 1443.1 (SubsequenceLimit carrier)**.** *A* $\mathsf{SubsequenceLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, \Phi, W, R, D, E, H, C, P, N)$$

with the following visible rows:

1. *L is the parent* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row, containing the displayed source sequence, candidate limit, tail-window schedule, dyadic tolerance ledger, and convergence classifier exposed by chapter 1413;*
2. *Φ is the accepted* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row, including the displayed unary selector, monotonicity witnesses, cofinal witnesses, selected windows, and regular rational handoff rows;*
3. *W records the selected finite* $\mathsf{StreamName}^{\uparrow}$ *windows from the parent sequence and from the subsequence readback surface;*
4. *R records the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *observations and the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *route through which the subsequence read is displayed;*
5. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the selected subsequence windows with the parent limit row;*
6. *E is the shared* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the parent limit row, cofinal selector row, selected windows, regular rational handoff, and dyadic tolerance ledger have been displayed;*
7. *H records componentwise* hsame *transports for the parent limit row, selector row, selected windows, regular rational observations, dyadic ledger, real seal, and local naming row;*
8. *C records the displayed* Cont *routes by which consumers inspect the same rows in their certificate order;*

9. *P is the* Pkg *provenance over the* $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and naming dependencies;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SubsequenceLimit}^{\uparrow}}$ *row.*

The carrier stores a finite subsequence-limit consumer interface. It contains no host-level infinite subsequence, no quotient stream representative, no host sequence equality, no independent real-completeness object, and no choice principle for selecting further subsequences.

Theorem 1443.2 (SubsequenceLimit NameCert obligations)**.** *Every accepted* $\mathsf{SubsequenceLimit}^{\uparrow}$ *carrier of Definition 1467.1 carries five finite NameCert obligation rows:*

1. *carrier admission for the parent sequence-limit row, cofinal selector row, selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff rows, dyadic tolerance ledger, shared* $\mathsf{Real}^{\uparrow}$ *seal, transport rows, continuation routes, package provenance, and local naming row;*

2. *selector-to-limit alignment, stating that every subsequence window read by Φ is one of the displayed parent sequence windows named by L and compared against the same candidate limit row;*

3. *tolerance preservation, stating that the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D is the common tolerance ledger used by both the parent sequence-limit classifier and the selected subsequence read;*

4. *real-seal handoff discipline, stating that the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed only after the parent limit row, cofinal selector, selected windows, regular rational route, and tolerance ledger have been displayed;*

5. *non-escape, stating that the packet exports no Bolzano–Weierstrass conclusion, arbitrary subsequence choice, host sequence equality, quotient stream equality, ambient real completeness, or bridge-checked external schema.*

Lean4 ✓ `BEDC.Derived.SubsequenceLimitUp.SubsequenceLimitTasteGate single carrier alignment`

Proof. Carrier admission is the tuple in Definition 1467.1. Each row needed by a consumer is a visible BHist coordinate, and the local naming row is attached to that same finite packet.

Selector-to-limit alignment is read from the pair (L, Φ). The parent row supplies the displayed sequence-limit surface, while the selector row supplies only selected finite windows and their regular rational handoff data. Thus a subsequence read remains a read of the parent displayed sequence.

Tolerance preservation is the projection to D. The selected subsequence windows are compared with the parent candidate limit using the same dyadic tolerance ledger, so the packet has no second tolerance scale that could change the limit claim.

The real-seal handoff follows the order of the rows L, Φ, W, R, D, E. A consumer reaches the shared $\mathsf{Real}^{\uparrow}$ seal only after the parent limit data, selector route, selected windows, regular rational observations, and dyadic ledger are already visible.

The non-escape row is an inventory check. None of the coordinates stores a Bolzano–Weierstrass selection, a host-level subsequence, host sequence equality, quotient stream equality, ambient real completeness, or an external bridge schema, so the local NameCert cannot export those objects. □

Theorem 1443.3 (SubsequenceLimit Real seal handoff)**.** *Let $Q = (L, \Phi, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{SubsequenceLimit}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer read from Q factors through the parent* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row L, the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row Φ, the selected* $\mathsf{StreamName}^{\uparrow}$

windows W, the selected $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *route R, and the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D before the seal row E is exposed.*

Proof. Start from a $\mathsf{Real}^{\uparrow}$-facing consumer read. The carrier places the seal coordinate E after the parent sequence-limit row, selector row, selected windows, regular rational handoff, and dyadic ledger.

Apply the selector-to-limit and tolerance-preservation rows of Definition 1467.2. They force the selected subsequence windows to remain parent sequence windows and force their limit comparison to use the same dyadic tolerance ledger as the parent limit classifier.

It remains to identify the public read route. The displayed hsame transports and Cont routes preserve the order through L, Φ, W, R, D, E, while the Pkg and local NameCert rows account for provenance. Hence every seal-facing read factors through the listed finite handoff surface. □

Theorem 1443.4 (SubsequenceLimit choice-free boundary)**.** *The* $\mathsf{SubsequenceLimit}^{\uparrow}$ *carrier is a finite BEDC consumer boundary for selected sequence-limit reads. It preserves the parent sequence-limit row, cofinal selector row, selected regular rational observations, dyadic tolerance ledger, shared real seal, displayed transports, continuation routes, package provenance, and local naming row, but it does not construct a Bolzano–Weierstrass subsequence, choose an arbitrary infinite subsequence, identify host sequences, identify quotient streams, prove real completeness, or provide a checked standard bridge.*

Proof. The positive content is exactly the carrier inventory of Definition 1467.1. The rows $L, \Phi, W, R, D, E, H, C, P$, provide the parent limit data, selector route, selected observations, tolerance ledger, seal, transport, continuation, provenance, and local naming surface.

The consumer route is fixed by Definition 1467.2 and Definition 1467.3. Every public real-facing read passes through the finite selector-to-limit handoff rather than through an unrecorded host object.

The excluded principles are absent as coordinates. Since no row stores a Bolzano–Weierstrass construction, arbitrary subsequence choice, host equality, quotient equality, completeness proof, or bridge-checked schema, the packet cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubsequenceLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{SubsequenceLimit}^{\uparrow}$ packet is generated from a parent sequence-limit row, a cofinal selector row, selected StreamName windows, RegSeqRat and RegularCauchySubsequence handoff rows, a shared DyadicRatCore tolerance ledger, a shared RealUp seal, componentwise transport, continuation routes, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SubsequenceLimit}^{\uparrow}}$, seed)

Scope closed: Definition 1467.1, Definition 1467.2, Definition 1467.3, and Definition 1467.4 declare the finite subsequence-limit consumer boundary for selected RealUp sequence-limit reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SubsequenceLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Bolzano–Weierstrass, arbitrary subsequence choice, host sequence equality, quotient stream equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selector-to-limit alignment, tolerance preservation, real-seal handoff, and choice-free refusal for the same finite packet.

Chapter 1444

A Concrete Naming Certificate for $\mathsf{RegularCauchyReciprocal}^{\uparrow}$

Bishop and Bridges-style constructive reciprocal data begin from a regular Cauchy rational name together with a displayed apartness window that keeps the inspected tail away from zero. The $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ packet names the finite interface needed to read that reciprocal surface. It refines the budget-only surface of chapter 703 by binding the $\mathsf{RegSeqRat}^{\uparrow}$ source of chapter 301, the finite windows of chapter 126, the dyadic endpoint and radius arithmetic of chapter 291, and the terminal seal of chapter 38 into one local NameCert carrier. The chapter records only the finite reciprocal-read surface; it does not construct a total reciprocal operation on $\mathsf{Real}^{\uparrow}$.

Definition 1444.1 (Regular Cauchy reciprocal carrier)**.** *A* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (Q, A, M, W, D, B, T, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational entries are being inspected.*
2. *A is the apartness-window row displaying a rational lower bound that keeps the inspected tail of Q away from zero.*
3. *M is the finite modulus row selecting the precision at which the reciprocal read is requested.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened from Q under A and M.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and comparison ledger read from W.*
6. *B is the sibling* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row that records the reciprocal-window budget over the same Q, A, M, W, D rows.*
7. *T is the regular rational readback row naming the reciprocal candidate as a* $\mathsf{RegSeqRat}^{\uparrow}$ *surface.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed source, apartness, modulus, window, dyadic, budget, and readback rows have been consumed.*
9. *H records componentwise* hsame *transport for $Q, A, M, W, D, B, T, E, C, P, N$.*
10. *C records the displayed* Cont *replay for source inspection, apartness exposure, finite-window selection, dyadic reciprocal arithmetic, budget handoff, regular readback, and Real seal handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyInverseBudget}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}$ *row.*
The local classifier compares accepted carriers only through the displayed rows $Q, A, M, W, D, B, T, E, H, C, P, N$.

Theorem 1444.2 (Regular Cauchy reciprocal apartness window)**.** *Every accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier exposes the apartness row A before any reciprocal dyadic row D, budget row B, regular readback row T, or* $\mathsf{Real}^{\uparrow}$ *seal row E can be consumed. A route that omits A remains a boundary attempt and cannot export a reciprocal candidate.*

Proof. Project the carrier of Definition 1471.1. The source-side rows are Q, A, M, W, and the reciprocal-facing rows begin only after the apartness and modulus rows have selected a finite window.

The dyadic ledger D reads endpoint, radius, and comparison data from W. Since the reciprocal denominator is controlled by the displayed lower bound in A, the dyadic reciprocal row has no carrier route that bypasses A.

The budget row B, readback row T, and seal row E are downstream of that dyadic row. Therefore omitting A leaves no displayed route from the source to a reciprocal candidate; the local classifier records such a route as boundary evidence. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalCarrier apartness window`

Theorem 1444.3 (Regular Cauchy reciprocal readback route)**.** *For every accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$, the reciprocal readback row T factors through*

$$Q \longmapsto A \longmapsto M \longmapsto W \longmapsto D \longmapsto B \longmapsto T.$$

The terminal $\mathsf{Real}^{\uparrow}$ *seal E is reached only after this finite route has been displayed.*

Proof. Begin with the apartness-window theorem. It places A before any dyadic reciprocal arithmetic, so the route to T cannot start from Q alone.

Next open the finite window row W by using the modulus row M. The dyadic ledger D is a read of that window, and the sibling budget row B is the same reciprocal-window discipline named by chapter 703.

Finally project T and then E from the carrier. The readback row names the reciprocal candidate as regular rational data, while the seal row is terminal and adds no second route around the displayed finite chain. □

Theorem 1444.4 (Regular Cauchy reciprocal classifier stability)**.** *Let*

$$R = (Q, A, M, W, D, B, T, E, H, C, P, N) \quad \text{and} \quad R' = (Q', A', M', W', D', B', T', E', H', C', P', N')$$

be accepted $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carriers. If the displayed transport row H supplies componentwise* hsame *comparisons from each row of R to the corresponding row of R', then the local classifier preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *source, apartness row, modulus row, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *budget row, reciprocal readback row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal route.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalClassifierStability`

Proof. Project the transport coordinate H from the carrier. Its comparisons are componentwise, so the source rows Q, Q', apartness rows A, A', modulus rows M, M', finite windows W, W', dyadic ledgers D, D', budget rows B, B', readback rows T, T', and seal rows E, E' are matched before any classifier conclusion is read.

Apply the apartness-window theorem to both carriers. Since the transported apartness rows remain the first reciprocal-facing rows, the reciprocal denominator witness is preserved by the classifier.

Apply the readback-route theorem to both carriers. The transported route from Q through B to T matches the transported route from Q' through B' to T', and the terminal seal rows are reached only after those finite routes.

Thus classifier equality cannot forget, reorder, or replace any analytic row of the reciprocal packet. It transports exactly the displayed source, apartness, modulus, window, dyadic, budget, readback, and Real seal coordinates. □

Theorem 1444.5 (Regular Cauchy reciprocal terminal seal non-totality)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal row E of an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier cannot be reread as a total reciprocal operation on all* $\mathsf{Real}^{\uparrow}$ *names. Any route from the seal back to a reciprocal candidate must still factor through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row Q, apartness row A, modulus row M, finite* $\mathsf{StreamName}^{\uparrow}$ *window W, dyadic ledger D,* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *budget row B, and regular readback row T.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalTerminalSealNonTotality`

Proof. Inspect the carrier definition. The seal coordinate E is listed after the source, apartness, modulus, window, dyadic, budget, and readback rows, and the classifier reads it as one coordinate of the twelve-row packet.

The readback-route theorem states that E is reached only after the finite route through T has been displayed. Therefore the seal does not introduce a second route from arbitrary $\mathsf{Real}^{\uparrow}$ names to reciprocal data.

The apartness-window theorem keeps A mandatory for every reciprocal-facing row. Since a total reciprocal on all $\mathsf{Real}^{\uparrow}$ names would erase the need for such a displayed apartness row, it is not present in the packet.

Consequently the terminal seal records only the end of one finite regular-Cauchy reciprocal read. It cannot be exported as a total reciprocal operation or as a boundary bypass around the apartness obligation. □

Theorem 1444.6 (Regular Cauchy reciprocal denominator apartness)**.** *For every accepted* RegularCauchyReciproca *carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$, the dyadic reciprocal row D and the* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *budget row B are admissible only after the apartness row A displays a positive lower bound for the inspected* $\mathsf{RegSeqRat}^{\uparrow}$ *tail named by Q, M, W. A consumer that reads D or B without that positive lower-bound display has not reached a reciprocal row of the packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalDenominatorApartness`

Proof. Project Definition 1471.1. The source row Q, apartness row A, modulus row M, and finite window row W precede the dyadic reciprocal row D and budget row B in the carrier route.

Apply Definition 1471.2. It states that A is exposed before D, B, T, E can be consumed, so the denominator-side condition is part of the carrier admission rather than a later Real-facing consequence.

Finally read Definition 1471.3. The route from Q to T passes through A, M, W, D, B in that order, and therefore D and B are reciprocal rows only when the inspected regular tail has the displayed positive lower bound supplied by A. □

Theorem 1444.7 (Regular Cauchy reciprocal nonzero-denominator window)**.** *Any accepted* RegularCauchyReciproc *packet whose dyadic inverse budget is read must expose a nonzero-denominator window consisting of the* RegSeqRat$^{\uparrow}$ *source row Q, apartness row A, finite modulus row M,* StreamName$^{\uparrow}$ *window W, and* DyadicRatCore$^{\uparrow}$ *row D. Without all five rows the packet has not reached the* CauchyInverseBudget$^{\uparrow}$ *row B.*

Proof. Project the carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ from Definition 1471.1. The only source, apartness, modulus, window, and dyadic rows available to the reciprocal budget are Q, A, M, W, D.

Apply Definition 1471.6. It places the positive lower-bound display in A before the dyadic reciprocal row D and budget row B can be consumed.

Then apply Definition 1471.3. The route to the reciprocal readback passes through Q, A, M, W, D, B, so a consumer that omits any one of Q, A, M, W, D remains before the CauchyInverseBudget$^{\uparrow}$ row rather than at the dyadic inverse budget. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalNonzeroDenominatorWindo`

Theorem 1444.8 (Regular Cauchy reciprocal tail stability)**.** *Let $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ be an accepted* RegularCauchyReciprocal$^{\uparrow}$ *carrier. If a later inspected* StreamName$^{\uparrow}$ *window preserves the* RegSeqRat$^{\uparrow}$ *source row Q together with the apartness row A, modulus row M, finite window row W, and dyadic reciprocal row D, then the same reciprocal readback row T and terminal* Real$^{\uparrow}$ *seal row E transport through H, C, P, N. Thus shifting to a later tail window cannot change the reciprocal readback unless it changes one of A, M, W, D.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalTailStability`

Proof. Use Definition 1471.6. A later window that preserves A, M, W, D keeps the same displayed positive lower-bound and dyadic reciprocal data for the inspected regular tail.

Apply Definition 1471.3. Since the route to T passes through Q, A, M, W, D, B, preserving the apartness, window, and dyadic rows preserves the reciprocal readback route once the same budget row is read.

Apply Definition 1471.4. The transport row H compares corresponding carrier rows componentwise, while C, P, N replay, source, and name the same packet. The terminal seal E is therefore transported with T rather than recomputed from a new denominator condition. □

Theorem 1444.9 (Regular Cauchy reciprocal window composition)**.** *Let $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ be an accepted* RegularCauchyReciprocal$^{\uparrow}$ *carrier. Suppose a later finite* StreamName$^{\uparrow}$ *window preserves the displayed rows Q, A, M, W, D and then reads the same* CauchyInverseBudget$^{\uparrow}$ *row B. The composed finite route still reaches the same regular rational readback row T and terminal* Real$^{\uparrow}$ *seal row E through*

$$Q \longmapsto A \longmapsto M \longmapsto W \longmapsto D \longmapsto B \longmapsto T \longmapsto E.$$

Thus window composition changes neither the reciprocal readback nor the Real seal unless it changes one of the displayed source, apartness, modulus, window, dyadic, or budget rows.

Proof. Apply Definition 1471.6. It keeps the apartness row A in front of every dyadic reciprocal and budget read, so the later window cannot compose into a reciprocal route while dropping the positive lower-bound display.

Use Definition 1471.7. The preserved rows Q, A, M, W, D are exactly the nonzero-denominator window needed before the same budget row B can be read.

Apply Definition 1471.3. Once the same budget row is present, the route to T is the displayed chain through Q, A, M, W, D, B, and the seal E is terminal after that chain.

Finally use Definition 1471.8. Since the later window preserves the source, apartness, modulus, window, and dyadic rows and reads the same budget row, the transported packet reaches the same T and E rather than recomputing a new reciprocal surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalWindowComposition`

Theorem 1444.10 (Regular Cauchy reciprocal window denominator stability)**.** *Let $R = (Q, A, M, W, D, B, T, E, H$ be an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier. Suppose a later finite* $\mathsf{StreamName}^{\uparrow}$ *window preserves the displayed rows Q, A, M, W, D and reads the same* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row B. Then the denominator apartness witness recorded by A remains visible before the reciprocal readback row T and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E are consumed. In particular, the later window cannot treat B, T, E as a hidden choice of denominator data.*

Proof. Apply Definition 1471.6. The dyadic reciprocal row D and budget row B are admissible only after A displays the positive lower-bound witness for the inspected regular tail.

Use Definition 1471.7. Since the later window preserves Q, A, M, W, D, it preserves exactly the nonzero-denominator surface that must be present before the same $\mathsf{CauchyInverseBudget}^{\uparrow}$ row is read.

Apply Definition 1471.8. Preserving the source, apartness, modulus, window, and dyadic rows transports the same readback row T and terminal seal row E through the carrier rows H, C, P, N.

Finally use Definition 1471.9. The composed route reaches T and then E only through the displayed chain Q, A, M, W, D, B, T, E, so the denominator apartness witness remains visible throughout the reciprocal handoff rather than becoming hidden choice data. □

Theorem 1444.11 (Regular Cauchy reciprocal located apartness window)**.** *Any* $\mathsf{Real}^{\uparrow}$*-seal or budget-facing consumer of an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ must expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row Q, apartness row A, modulus row M,* $\mathsf{StreamName}^{\uparrow}$ *window row W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row D, and* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *budget row B before reading the reciprocal readback row T or terminal seal row E. The route exports no total reciprocal on arbitrary* $\mathsf{Real}^{\uparrow}$ *names, trichotomy, quotient stream equality, selected limit, or ambient completeness.*

Proof. Project the accepted carrier. The only reciprocal-facing analytic rows before readback are the source, apartness, modulus, window, dyadic comparison, and budget rows Q, A, M, W, D, B.

Apply Definition 1471.2, Definition 1471.6, and Definition 1471.7. These place the located apartness display in A before the dyadic comparison row and identify Q, A, M, W, D as the nonzero-denominator window required before B is read.

Next use Definition 1471.9. It preserves the same route through Q, A, M, W, D, B, T, E under later finite windows, so reading T cannot detach the reciprocal candidate from its displayed denominator witness.

Finally apply Definition 1471.13. The terminal seal E is offered only after the source, apartness, modulus, window, dyadic, budget, and readback rows have been displayed. Since the carrier has no

coordinate for total reciprocals, trichotomy, quotient stream equality, selected limits, or ambient completeness, those principles cannot be exported by either the budget-facing route or the Real-seal route. □

Theorem 1444.12 (Regular Cauchy reciprocal scoped denominator apartness)**.** *For every accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$*, the denominator-apartness witness is scoped exactly by the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* Q*, apartness row* A*, finite modulus row* M*,* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row* B*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. It exports no total* $\mathsf{Real}^{\uparrow}$ *reciprocal, quotient stream, selected limit, or host equality.*

Proof. Project the carrier of Definition 1471.1. The only denominator-facing rows before reciprocal readback are Q, A, M, W, D, B, and the only structural rows that can transport or replay them are H, C, P, N.

Apply Definition 1471.2 and Definition 1471.6. These place the apartness row A before every dyadic reciprocal, budget, readback, and seal coordinate, and they make the positive lower-bound display part of carrier admission.

Use Definition 1471.7 and Definition 1471.10. The first theorem identifies Q, A, M, W, D as the nonzero-denominator window required before B is read, while the second preserves that witness under later finite windows.

The remaining rows H, C, P, N carry only componentwise transport, replay, provenance, and local naming for the same finite surface. Thus the scoped apartness witness is exactly the displayed BEDC primitive surface $Q, A, M, W, D, B, H, C, P, N$, with no exported total reciprocal on $\mathsf{Real}^{\uparrow}$, quotient stream, selected limit, or host equality. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalScopedDenominatorApartn`

Theorem 1444.13 (Regular Cauchy reciprocal Real seal handoff)**.** *Let* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier. Any reciprocal consumer that is offered the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *must first be offered the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* Q*, apartness row* A*, modulus row* M*, finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row* B*, and reciprocal readback row* T*. Thus the handoff from finite reciprocal-read data to the L10* $\mathsf{Real}^{\uparrow}$ *boundary is the displayed route*

$$Q \longmapsto A \longmapsto M \longmapsto W \longmapsto D \longmapsto B \longmapsto T \longmapsto E$$

and not a direct operation from arbitrary $\mathsf{Real}^{\uparrow}$ *names to reciprocals.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalRealSealHandoff`

Proof. Apply Definition 1471.2. It places the apartness row A before every reciprocal-facing coordinate, so a consumer cannot treat the terminal seal as available before the denominator witness is displayed.

Next use Definition 1471.3. The route to the readback row T factors through Q, A, M, W, D, B, and the seal row E is terminal only after that finite route has been exposed.

Apply Definition 1471.6 and Definition 1471.7. These identify the source, apartness, modulus, window, and dyadic rows as the nonzero-denominator surface required before the budget row B can be consumed.

Finally use Definition 1471.8 together with Definition 1471.9. Transport to later windows and composition of finite windows preserve the same T and E only when the displayed rows

Q, A, M, W, D, B are preserved. The handoff therefore exports neither a total reciprocal, quotient real equality, trichotomy, selected limit, nor ambient completeness principle; it exports only the finite route from reciprocal readback data to the terminal $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 1444.14 (Regular Cauchy reciprocal NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}$ *surface consists exactly of carrier exposure for* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$*, apartness-window exposure through* A*, finite-window exposure through* W*, dyadic reciprocal arithmetic through* D*, sibling budget exposure through* B*, regular readback through* T*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise transport through* H*, displayed continuation replay through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalNameCertObligations`

Proof. Carrier exposure is Definition 1471.1. It supplies the full row list and states that the classifier reads only those rows.

The analytic route is given by Definition 1471.2 and Definition 1471.3. Together they force every reciprocal read to pass through the source, apartness, modulus, finite window, dyadic arithmetic, and sibling budget rows before reaching T and E.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since none of these rows contains a total reciprocal, quotient stream equality, selected limit, trichotomy decision, or ambient completeness principle, the displayed obligations exhaust the local NameCert surface. □

Theorem 1444.15 (Regular Cauchy reciprocal window-budget coverage)**.** *Every budget-facing read of an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ *must expose the rows*

$$Q \longmapsto A \longmapsto M \longmapsto W \longmapsto D \longmapsto B$$

in that order before it treats the packet as carrying a reciprocal-window budget.

Proof. Project the carrier of Definition 1471.1. The budget row B is displayed only after the source row Q, apartness row A, modulus row M, finite window row W, and dyadic row D.

Apply Definition 1471.2 and Definition 1471.6. These place the positive lower-bound display before any dyadic or budget read.

Use Definition 1471.7. It identifies Q, A, M, W, D as the nonzero-denominator window required before the $\mathsf{CauchyInverseBudget}^{\uparrow}$ row is reached.

Finally apply Definition 1471.9 and Definition 1471.14. Composed windows preserve the same displayed budget route, and the local NameCert surface contains no alternate budget coordinate. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalWindowBudgetCoverage`

Theorem 1444.16 (Regular Cauchy reciprocal readback-budget exactness)**.** *For every accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$*, the readback row* T *is exactly the finite reciprocal-read route through the displayed budget row* B*. It is not a total reciprocal operation on arbitrary* $\mathsf{Real}^{\uparrow}$ *names, and it cannot be read without the preceding rows* Q, A, M, W, D, B*.*

Proof. Use Definition 1471.3. It factors T through the displayed chain from Q to B.

Apply Definition 1471.15. Any budget-facing read must first expose Q, A, M, W, D, B, so T has no route that bypasses the finite budget row.

Apply Definition 1471.8 and Definition 1471.9. Later windows and composed windows preserve the same readback only when the displayed source, apartness, modulus, window, dyadic, and budget rows are preserved.

Finally use Definition 1471.5. Since the terminal seal is not a total reciprocal on $\mathsf{Real}^{\uparrow}$, the preceding readback row is also only the finite route named by the carrier. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalReadbackBudgetExactness`

Theorem 1444.17 (Regular Cauchy reciprocal seal-route conservativity)**.** *Any* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier receives only the displayed route*

$$Q, A, M, W, D, B, T, E, H, C, P, N.$$

The seal row E conservatively packages that route and adds no total reciprocal, trichotomy, quotient stream equality, selected limit, or ambient completeness principle.

Proof. Apply Definition 1471.13. The terminal seal is offered only after the source, apartness, modulus, finite window, dyadic, budget, and readback rows have been displayed.

Use Definition 1471.16. It fixes T as the finite route through B, so the seal cannot detach E from the reciprocal-window budget.

Use Definition 1471.14. The remaining rows H, C, P, N transport, replay, source, and name the same packet, and no additional analytic coordinate exists.

The non-totality clause follows from Definition 1471.5. A $\mathsf{Real}^{\uparrow}$ consumer therefore receives only the displayed conservative route. □

Theorem 1444.18 (Regular Cauchy reciprocal scope dependency lock)**.** *For every accepted* RegularCauchyReciproc *carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$, the reciprocal readback row T and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E are scoped exactly by five L10 source rows: the* $\mathsf{RegSeqRat}^{\uparrow}$ *source Q, the finite* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row B, and the* $\mathsf{Real}^{\uparrow}$ *seal route E. A consumer that drops any one of these rows remains outside the reciprocal readback and seal surface. The dependency lock exports no total reciprocal, quotient real equality, selected limit, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalScopeDependencyLock`

Proof. Begin with Definition 1471.2. It places the apartness row before every reciprocal-facing coordinate, so the route to the five named source rows is not optional.

Next apply Definition 1471.3. The readback row T factors through the displayed chain from the $\mathsf{RegSeqRat}^{\uparrow}$ source to the reciprocal budget row.

Use Definition 1471.15 together with Definition 1471.16. These two theorems identify the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and $\mathsf{CauchyInverseBudget}^{\uparrow}$ row as the finite budget boundary for T.

Finally invoke Definition 1471.17. The $\mathsf{Real}^{\uparrow}$ seal E only packages the same displayed route, and its nonescape clause excludes total reciprocal, quotient equality, selected limits, and ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ consumer that reaches a reciprocal readback row or a $\mathsf{Real}^{\uparrow}$ seal without the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source, apartness row, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and $\mathsf{CauchyInverseBudget}^{\uparrow}$ row refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, cauchyinversebudget, real: no listed sibling supplies the whole twelve-row packet $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$, because each sibling contributes only a regular source, finite window, dyadic ledger, reciprocal budget, or Real seal while this chapter binds all five analytic faces with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source, an apartness-window row, a finite modulus row, a $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, a $\mathsf{CauchyInverseBudget}^{\uparrow}$ budget row, a reciprocal readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1471.1, Definition 1471.2, Definition 1471.3, Definition 1471.4, Definition 1471.5, Definition 1471.14, Definition 1471.15, Definition 1471.16, Definition 1471.17, and Definition 1471.18 make the reciprocal chapter mature on the paper closure axis through the checked dependency lock, denominator-apartness window, $\mathsf{Real}^{\uparrow}$ seal handoff, and window-budget coverage.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalScopeDependencyLock`

Bridge status: none

Not claimed: This chapter does not claim a total reciprocal, trichotomy, quotient stream equality, selected limits, ambient real completeness, or a public bridge.

Upgrade path: Standard-bridge verification remains a separate formal route; the paper closure axis is mature for the displayed reciprocal dependency lock.

Chapter 1445

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilter}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and the Bourbaki–Kelley filterbase terminology, the $\mathsf{RegularCauchyFilter}^{\uparrow}$ packet names the finite bridge from directed Cauchy filter data to regular rational Cauchy names. It refines the filterbase surface of chapter 333, the regular-rational interface of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a current L10 Real and Completion route object: it stores the finite rows needed to read a regular Cauchy name from a directed Cauchy filterbase, but it stores no quotient of filters, selected limit, host equality of reals, countable-choice selector, or ambient completeness witness.

Definition 1445.1 (RegularCauchyFilter carrier)**.** *A* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (B, R, T, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{CauchyFilter}^{\uparrow}$ *finite-filterbase row, including its visible base packets, refinement ledger, and Cauchy-modulus row.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the filterbase by choosing only displayed regular rational windows.*
3. *T is the finite* $\mathsf{StreamName}^{\uparrow}$ *tail-window schedule that lists the windows actually requested from the filterbase.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording endpoints, radii, and dyadic comparison rows for the same tail windows.*
5. *M is the directed tail-meet row: for any two requested tail windows it names a later base packet refining both and carrying the displayed dyadic bounds.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, R, T, D, M have been displayed.*
7. *H records componentwise* hsame *transport for B, R, T, D, M, E and for the structural rows below.*
8. *C records the displayed* Cont *replay from filterbase refinements to stream windows, from windows to regular-rational readback, from dyadic tolerances to the tail meet, and from the regular readback to the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten coordinates and their displayed transports. It has no coordinate for an external filter quotient, a host-selected limit, countable choice, ambient real completeness, or an unrecorded regular-name extraction.

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterTasteGate single carrier alignment`

Theorem 1445.2 (RegularCauchyFilter NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *carrier* $G = (B, R, T, D, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilter}^{\uparrow}}$ *surface consists exactly of:*

1. *carrier admission for the displayed ten-row packet;*
2. *CauchyFilter source exposure through B and its finite filterbase rows;*
3. *StreamName tail-window exposure through T;*
4. *RegSeqRat readback through R after the tail windows are displayed;*
5. *DyadicRatCore tolerance exactness through D on the same tail windows;*
6. *directed tail-meet refinement through M;*
7. *Real seal handoff through E after B, R, T, D, M have been read;*
8. *componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N.*

No NameCert obligation may be discharged by a quotient of filters, a chosen host limit, countable choice, host real equality, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier namecert obligations`

Proof. Project the carrier of Definition 1445.1. The rows $B, R, T, D, M, E, H, C, P, N$ are the only coordinates visible to the local classifier.

The source side is inherited from the displayed $\mathsf{CauchyFilter}^{\uparrow}$ packet B. Its base packets, refinement rows, and Cauchy-modulus rows are read before any regular-rational or Real-facing consumer can inspect the packet.

The regular-name side is finite. The schedule T lists the requested tail windows, D attaches dyadic endpoints and radii to those windows, and R records the $\mathsf{RegSeqRat}^{\uparrow}$ readback obtained from the same displayed data.

The meet and seal rows close the obligation surface. The row M supplies the common directed refinement for requested tails, while E is downstream from B, R, T, D, M. Since the excluded principles are absent from the carrier, the eight listed rows exhaust the local NameCert surface. □

Theorem 1445.3 (RegularCauchyFilter directed tail meet)**.** *Let* $G = (B, R, T, D, M, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet. For any two tail windows displayed in T, the row M names a later finite base packet of the Cauchy filterbase B that refines both windows through the recorded* Cont *routes and transports their dyadic tolerance rows through the recorded* hsame *comparisons. The resulting regular-rational readback remains the same R and reaches the same Real seal E.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier tail meet`

Proof. Start with the two displayed tail windows in T. Because T is part of the accepted carrier, both windows have visible source rows in the finite filterbase packet B.

Use the directed refinement surface of chapter 333. The carrier row M records the specific later base packet refining both requested windows, so the meet is a displayed finite row rather than an external directedness assertion.

Transport the dyadic bounds along the recorded structural rows. The ledger D supplies the endpoint and radius rows for each tail window, and H, C carry these rows to the common refinement named by M.

Finally read the regular and real-facing endpoints. Since R is the only $\mathsf{RegSeqRat}^{\uparrow}$ row and E is the only $\mathsf{Real}^{\uparrow}$ seal row of the packet, the common refinement preserves the displayed regular readback and seal route. □

Theorem 1445.4 (RegularCauchyFilter Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RegularCauchyFilter}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer reads B, then T and D, then the regular-rational row R, then the directed tail meet M, and only then the seal row E with its transports, continuations, provenance, and local naming. No second Real-facing route is available inside the carrier.

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier real seal route`

Proof. Project the seal coordinate of Definition 1445.1. The row E is not stored as a detached Real object; it is downstream from the Cauchy filterbase, the finite tail schedule, the dyadic tolerance ledger, the regular-rational readback, and the directed meet row.

Read the displayed route in order. The Cauchy filterbase supplies B, the finite stream schedule supplies T, the dyadic core supplies D, and the regular-rational readback supplies R.

Now insert the meet row. By Definition 1445.3, any pair of requested tails has a displayed common refinement in M, and that refinement preserves the same R and E through H and C.

The package and naming rows P, N certify this same route. Since the carrier has no other Real seal coordinate, no quotient-filter route, and no ambient completeness coordinate, every Real-facing consumer factors through the listed finite chain. □

Theorem 1445.5 (RegularCauchyFilter basis factorization)**.** *Let $G = (B, R, T, D, M, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet. The finite rows B, T, D, M, H, C, P, N determine a* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis row whose basis elements are exactly the displayed tail windows in T, whose dyadic tolerance rows are exactly the rows recorded in D, and whose common-refinement and saturation handoff is the route from M into the finite* $\mathsf{CauchyFilter}^{\uparrow}$ *row B.*

Under this factorization, downstream readback reproduces the same $\mathsf{RegSeqRat}^{\uparrow}$ *row R and the same* $\mathsf{Real}^{\uparrow}$ *seal E. The factorization uses only the displayed* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. It exports no quotient filter, selected limit, countable-choice selector, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier basis factorization`

Proof. Project the accepted carrier. The schedule T already lists the finite tail windows requested from the Cauchy filterbase, and the ledger D records the dyadic tolerances attached to exactly those windows. These are the basis elements and tolerance rows required by the $\mathsf{CauchyFilterBasis}^{\uparrow}$ carrier surface.

Next form the directed basis handoff. The row M supplies, for each pair of displayed tail windows, a later finite base packet refining both; this is precisely the common-refinement witness needed before the generated basis can be read as the saturation surface B of $\mathsf{CauchyFilter}^{\uparrow}$.

Transport and replay do not add coordinates. The rows H and C move the same T, D, M, B data componentwise through hsame and Cont, while P and N package and name the same finite route. Thus the basis row is obtained from the visible packet rather than from a completed filter or external selector.

Finally apply Definition 1445.4. Once the basis has handed off to B, the regular-rational readback remains the displayed row R, and the only Real-facing endpoint is the seal E. The excluded quotient, choice, host-equality, and completeness coordinates are absent from the carrier, so they cannot be exported by the factorization. □

Theorem 1445.6 (RegularCauchyFilter obligation scope package)**.** *Let $G = (B, R, T, D, M, E, H, C, P, N)$ be an accepted $\mathsf{RegularCauchyFilter}^{\uparrow}$ packet. It exports exactly the obligation-scope package formed by CauchyFilter source exposure through B, CauchyFilterBasis factorization through the displayed tail windows in T, DyadicRatCore tolerance exactness through D, directed tail-meet refinement through M, RegSeqRat readback through R, and RealUp seal handoff through E. The remaining rows H, C, P, N supply only componentwise transport, displayed replay, provenance, and local naming.*

Consequently the package exports no quotient filter, selected host limit, countable-choice selector, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate.

Proof. Apply Definition 1445.2. It identifies the local certificate surface as the displayed CauchyFilter source row, StreamName tail windows, RegSeqRat readback, DyadicRatCore tolerance ledger, directed meet row, Real seal row, and the structural transport, replay, provenance, and naming rows.

Apply Definition 1445.5. The tail windows in T, the dyadic rows in D, and the meet handoff in M determine the $\mathsf{CauchyFilterBasis}^{\uparrow}$ factorization over the same source row B.

Apply Definition 1445.3. The row M supplies the directed common-refinement witnesses for the displayed tails and preserves the same R and E through the recorded transports.

Apply Definition 1445.4. Every Real-facing read factors through the route ending in E, while H, C, P, N only transport, replay, package, and name the same finite data. The excluded quotient, choice, host-equality, and completeness coordinates are absent from the carrier, so they cannot be exported by the obligation package. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier obligation scope package`

Theorem 1445.7 (RegularCauchyFilter scoped handoff)**.** *Let $G = (B, R, T, D, M, E, H, C, P, N)$ be an accepted $\mathsf{RegularCauchyFilter}^{\uparrow}$ packet. The rows of G expose one scoped BEDC package over* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *whose visible components are exactly the $\mathsf{CauchyFilterBasis}^{\uparrow}$ factorization of B, the directed tail meet M, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows D, the terminal $\mathsf{Real}^{\uparrow}$ seal E, componentwise transport H, displayed replay C, provenance P, and local naming N.*

Every accepted consumer route through this package factors through the displayed rows $B, T, D, M, R, E, H, C, P,$ It exposes no quotient filter, hidden cofinal tail, selected limit, countable-choice selector, host equality, ambient completeness principle, or detached Real-facing route.

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier scoped handoff`

Proof. First assemble the source and basis boundary. Apply Definition 1445.5 and Definition 1445.17 to read the $\mathsf{CauchyFilterBasis}^{\uparrow}$ witness from B, T, D, M, H, C, P, N.

Next close the tail side. Apply Definition 1445.3 and Definition 1445.8. These identify the displayed directed meet row M as the only common-refinement route for requested tails, with no hidden cofinal family.

Now expose the readback and seal. Apply Definition 1445.18 and Definition 1445.4; the regular rational row is R, and every Real-facing read reaches the same seal E only after the displayed windows and tolerance rows have been read.

Finally use Definition 1445.9, Definition 1445.12, and Definition 1445.6. These theorems repack transport, replay, provenance, and local naming as the single scoped package and rule out quotient filters, selected limits, choice selectors, host equality, hidden tails, and ambient completeness at the packet boundary. □

Theorem 1445.8 (RegularCauchyFilter tail-basis exhaustion)**.** *Let $G = (B, R, T, D, M, E, H, C, P, N)$ be an accepted $\mathsf{RegularCauchyFilter}^{\uparrow}$ packet. For any two finite windows accepted by the tail schedule T, the packet supplies a directed $\mathsf{CauchyFilter}^{\uparrow}$ meet row in M refining both windows inside the same source row B. The resulting tail read factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

by first reading the requested StreamName windows in T, then the dyadic tolerance rows in D, then the regular-rational row R, and finally the Real seal E.

Thus the tail basis is exhausted by the displayed rows $B, T, D, M, R, E, H, C, P, N$. It exports no quotient filter, selected host limit, countable-choice selector, hidden cofinal tail, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate.

Proof. Begin with the two finite windows in T. Since T is an exposed coordinate of the accepted carrier, both windows are already tied to the source $\mathsf{CauchyFilter}^{\uparrow}$ row B and to the same componentwise transport rows H.

Apply Definition 1445.3. The meet coordinate M names the later base packet refining both requested windows, so the common tail is a displayed directed row rather than an external cofinality assertion.

Apply Definition 1445.5. The windows in T, the dyadic ledger D, and the meet handoff M form the $\mathsf{CauchyFilterBasis}^{\uparrow}$ row over B.

Finally apply Definition 1445.4 and Definition 1445.6. The downstream read reaches R and then E only through the displayed StreamName, DyadicRatCore, RegSeqRat, and Real seal route, while C, P, N replay, source, and name that same finite packet. The excluded quotient, choice, hidden-tail, host-equality, and completeness coordinates are absent from the carrier. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier tail basis exhaustion`

Theorem 1445.9 (RegularCauchyFilter branch exhaustion)**.** *Every accepted $\mathsf{RegularCauchyFilter}^{\uparrow}$ consumer route from a finite Cauchy filterbase into a regular real name is exhausted by the displayed rows*

$$B, T, D, M, R, E, H, C, P, N.$$

The source row B supplies the finite $\mathsf{CauchyFilter}^{\uparrow}$ data, T supplies the requested $\mathsf{StreamName}^{\uparrow}$ windows, D supplies the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, M supplies the directed meet, R supplies the

$\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* E *supplies the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The structural rows* H, C, P, N *transport, replay, package, and name only that route. Thus no accepted consumer can split off a quotient filter, hidden cofinal tail, selected limit, countable-choice selector, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle from the filter-to-regular-name branch.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier branch exhaustion`

Proof. Project the displayed carrier. The source branch begins at B, and every requested tail window visible to the consumer appears in T with its dyadic tolerance data in D.

Apply Definition 1445.3. The meet row M supplies the later displayed base packet refining requested windows, so the consumer receives a finite directed refinement rather than an unrecorded cofinal tail.

Apply Definition 1445.5. The rows B, T, D, M, H, C, P, N form the visible $\mathsf{CauchyFilterBasis}^{\uparrow}$ route, and downstream readback is the same R with the same E.

Apply Definition 1445.4 and Definition 1445.8. The Real-facing endpoint is reached only after the StreamName, DyadicRatCore, RegSeqRat, and Real seal rows have been displayed. Since the carrier has no coordinate for quotient filters, hidden tails, selected limits, countable choice, host real equality, or ambient completeness, no consumer branch can export any of them. □

Theorem 1445.10 (RegularCauchyFilter tail-window exactness)**.** *Let* $G = (B, R, T, D, M, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet. Each accepted tail window in the* $\mathsf{StreamName}^{\uparrow}$ *schedule* T*, together with its* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row in* D*, determines the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *and the same* $\mathsf{Real}^{\uparrow}$ *seal* E *through the displayed* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *route over* B*.*

Equivalently, the finite tail-window read is exact at the packet boundary: the consumer may inspect the StreamName tail schedule, dyadic tolerance ledger, basis handoff, directed meet, regular readback, and Real seal rows, but it receives no quotient filter, selected limit, hidden cofinal tail, host real equality, countable-choice selector, or ambient completeness coordinate.

Proof. Project the accepted carrier. The only tail-window schedule is T, the only dyadic tolerance ledger for those windows is D, and the only regular readback and Real seal rows are R and E.

Apply Definition 1445.3 to the requested windows. The meet row M supplies the displayed later base packet inside the same source row B, so the tail read stays inside the finite Cauchy filterbase rather than passing to an unrecorded cofinal tail.

Apply Definition 1445.5. The rows B, T, D, M, H, C, P, N determine the visible $\mathsf{CauchyFilterBasis}^{\uparrow}$ route, and downstream readback along that route reproduces the same R and E.

Now use Definition 1445.4, Definition 1445.6, Definition 1445.8, and Definition 1445.9. These rows exhaust every accepted filter-to-regular-name consumer branch, so the excluded quotient, choice, hidden-tail, host-equality, and completeness coordinates are not available at the packet boundary. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier tail window exactness`

Theorem 1445.11 (RegularCauchyFilter directed refinement normal form)**.** *Let* $G = (B, R, T, D, M, E, H, C, P, N$ *be an accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet. Every accepted carrier request for two tail windows in* T *factors through a single displayed directed tail-meet row in* M*, then through the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *factorization over* B*, the* $\mathsf{StreamName}^{\uparrow}$ *schedule* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*.*

Equivalently, the request has a normal form

$$(B, T, D, M) \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$

with componentwise transport, replay, package provenance, and local naming supplied by H, C, P, N. The normal form exports no quotient filter, selected limit, hidden cofinal tail, countable-choice selector, host real equality, or ambient completeness coordinate.

Proof. Begin with two accepted tail windows in the schedule T. By Definition 1445.3, the row M names one later displayed base packet refining both windows inside the same Cauchy filterbase row B.

Next pass through the basis factorization. Definition 1445.5 identifies the displayed windows in T, the dyadic rows in D, and the meet handoff in M as the $\mathsf{CauchyFilterBasis}^{\uparrow}$ route over B.

Now read the branch in its displayed order. The branch-exhaustion theorem confines every consumer to $B, T, D, M, R, E, H, C, P, N$, while tail-window exactness keeps the accepted windows tied to the same regular readback R and Real seal E.

Finally use the Real seal route and the obligation-scope package. They force the downstream read through the listed StreamName, RegSeqRat, DyadicRatCore, and Real rows, and coordinate exhaustion rules out quotient filters, selected limits, hidden cofinal tails, choice selectors, host real equality, and ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier directed refinement normal form`

Theorem 1445.12 (RegularCauchyFilter finite-window pullback)**.** *Let $G = (B, R, T, D, M, E, H, C, P, N)$ be an accepted $\mathsf{RegularCauchyFilter}^{\uparrow}$ packet. Every Real-facing finite tail-window read of G pulls back to the displayed $\mathsf{CauchyFilterBasis}^{\uparrow}$ tail window in T, the matching $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row in D, and the directed refinement row M before the same $\mathsf{RegSeqRat}^{\uparrow}$ readback R and terminal $\mathsf{Real}^{\uparrow}$ seal E can be consumed. Thus the pullback route is*

$$(T, D, M) \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto R \longmapsto E$$

inside the same source row B and the same structural rows H, C, P, N, with no quotient filter, hidden cofinal tail, selected limit, countable-choice selector, host real equality, or ambient completeness coordinate.

Proof. Begin with tail-window exactness, Definition 1445.10. It ties each accepted window in T and its dyadic tolerance row in D to the same readback row R and Real seal E.

Use tail-basis exhaustion and branch exhaustion next. Theorems Definition 1445.8 and Definition 1445.9 force every consumer route to expose the CauchyFilter source B, the displayed window row T, the dyadic row D, the meet row M, and the structural rows.

Now apply directed refinement normal form, Definition 1445.11. The requested finite windows are pulled back to a single displayed refinement in M before the basis route may be read as regular rational data.

Finally use the Real seal route, Definition 1445.4. Since the seal is reached only after B, T, D, M, R have been displayed and transported by H, C, P, N, the Real-facing read cannot bypass the finite-window pullback through quotient filters, hidden tails, selected limits, choice data, host equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier window pullback`

Theorem 1445.13 (RegularCauchyFilter carrier-basis rows)**.** *Let $G = (B, R, T, D, M, E, H, C, P, N)$ be an accepted $\mathsf{RegularCauchyFilter}^{\uparrow}$ packet. The rows $B, T, D, M, R, E, H, C, P, N$ decompose the packet into carrier admission, CauchyFilter source exposure, StreamName tail-window exposure,*

DyadicRatCore tolerance exactness, directed meet refinement, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and local naming.

Under this decomposition, the visible basis consumed by later readers is exactly the $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row determined by* B, T, D, M, H, C, P, N*. No reader may replace this basis by a quotient filter, hidden cofinal family, selected limit, countable-choice selector, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the accepted carrier. The row B is the source CauchyFilter packet, while T lists the finite tail windows requested from that source.

The tolerance and meet rows are D and M. They attach dyadic bounds to the displayed windows and name the common directed refinements that make those windows a $\mathsf{CauchyFilterBasis}^{\uparrow}$ route over B.

The readback and seal rows are downstream. The row R records the regular rational readback, and E is reached only after the basis route has been displayed.

Finally, H, C, P, N transport, replay, source, and name the same rows. Because the listed coordinates exhaust the carrier, none of the excluded quotient, choice, host-equality, or completeness objects is available to a reader. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier basis rows`

Theorem 1445.14 (RegularCauchyFilter tail stability)**.** *Let* $G = (B, R, T, D, M, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet. If two consumer requests read tail windows from* T*, then their common refinement is the displayed row in* M *over the same CauchyFilter source* B*, and the resulting tail read remains in the same* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *factorization with the same DyadicRatCore tolerance ledger* D*.*

Consequently the RegSeqRat readback R *and Real seal* E *are stable under tail-window refinement. The stability is transported by* H*, replayed by* C*, sourced by* P*, and named by* N*, without quotienting filters, choosing limits, invoking countable choice, or appealing to* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier tail stability`

Proof. Start with two displayed tail windows in T. Since they are carrier coordinates, both windows are already attached to the same source row B and the same dyadic tolerance ledger D.

The directed meet coordinate M supplies the common refinement. This refinement is a finite displayed row over B, not an external cofinality or choice assertion.

Read the basis factorization through the same rows. The refinement keeps the route inside $\mathsf{CauchyFilterBasis}^{\uparrow}$ and preserves the tolerance data in D for the requested windows.

The downstream rows are unchanged. The regular readback remains R, the real-facing seal remains E, and H, C, P, N preserve the same packet. Therefore the excluded quotient, selected-limit, choice, and completeness principles cannot enter the tail-stability claim. □

Theorem 1445.15 (RegularCauchyFilter ledger exhaustion)**.** *Every accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *consumer route is exhausted by the displayed ledger*

$$B, T, D, M, R, E, H, C, P, N.$$

The ledger first exposes the finite CauchyFilter source B*, then the StreamName tail windows* T*, then the DyadicRatCore tolerance rows* D*, then the directed meet row* M*, then the RegSeqRat readback* R*, and finally the Real seal* E *with transport, replay, provenance, and naming rows* H, C, P, N*.*

Thus the packet exports no quotient filters, selected limits, countable-choice selectors, hidden cofinal tails, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness. Any Real-facing read must pass through the displayed ledger before the seal is visible.*

Proof. Read the consumer route from the carrier coordinates. The source of every route is B, and every requested tail window appears in T with its tolerance data in D.

The row M supplies the only directed refinement data. Hence a consumer cannot bypass the displayed meet row by appealing to an unrecorded cofinal family.

The regular and real-facing rows are R and E. They are downstream from the source, tail-window, tolerance, and meet rows, and the structural rows H, C, P, N only preserve that route.

Since the ledger accounts for every coordinate of the carrier, no quotient filter, selected limit, countable-choice selector, hidden tail, host equality, or completeness coordinate remains to be exported. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier ledger`

Theorem 1445.16 (RegularCauchyFilter directed-tail closure)**.** *Let $G = (B, R, T, D, M, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet. Every finite family of tail windows displayed in T is closed under the packet's directed meet row M: after finitely many displayed refinements, the family admits a single tail row over the same* $\mathsf{CauchyFilter}^{\uparrow}$ *source B that refines every listed window, preserves the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and reaches the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R and* $\mathsf{Real}^{\uparrow}$ *seal E.*

The closure route is internal to $B, T, D, M, R, E, H, C, P, N$. It does not form quotient filters, select a host limit, use countable choice, import hidden cofinal tails, or appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct on the displayed finite list of windows from T. The empty list and singleton list are immediate from carrier projection: the requested rows already lie inside the visible source row B and carry their tolerance data through D.

For the step, assume the previous subfamily has a displayed common tail row. Apply Definition 1445.3 to that row and the next listed window. The meet row M supplies a later displayed base packet refining both, so the enlarged family remains inside the same finite Cauchy filterbase surface.

Now use Definition 1445.5. The windows in T, the dyadic ledger D, and the iterated meet route through M remain a $\mathsf{CauchyFilterBasis}^{\uparrow}$ factorization over B.

Finally apply Definition 1445.15. The ledger exhaustion theorem keeps the downstream readback at the same R and the same terminal seal E, with transport, replay, provenance, and local naming supplied by H, C, P, N. Since the induction only composes displayed meet rows, none of the excluded quotient, choice, hidden-tail, limit, or completeness principles is introduced. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier directed tail closure`

Theorem 1445.17 (RegularCauchyFilter basis-witness admission)**.** *Let $G = (B, R, T, D, M, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet. The rows B, T, D, M, H, C, P, N admit a* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *witness whose basic windows are exactly the displayed* $\mathsf{StreamName}^{\uparrow}$ *tail windows in T, whose tolerance ledger is exactly the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D, and whose common-refinement witnesses are exactly the directed rows in M over the same* $\mathsf{CauchyFilter}^{\uparrow}$ *source B.*

The admitted basis witness carries the same hsame, Cont, Pkg, *and* NameCert *rows as G. It exports no quotient filter, hidden cofinal tail, selected limit, host real equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier basis witness admission`

Proof. Project the accepted carrier. The tail windows are visible in T, the dyadic tolerance data for those windows is visible in D, and the source Cauchy filterbase is the row B.

Use the directed meet rows. The row M supplies the common-refinement witnesses required by a $\mathsf{CauchyFilterBasis}^{\uparrow}$ admission, so the basis is built from displayed finite rows rather than from a completed filter.

The structural coordinates do not add a second source. The rows H, C, P, N transport, replay, source, and name the same B, T, D, M data. Hence the admitted basis witness has exactly the stated surface and none of the excluded external coordinates. □

Theorem 1445.18 (RegularCauchyFilter RegSeqRat window exposure)**.** *Let $G = (B, R, T, D, M, E, H, C, P, N)$ be an accepted $\mathsf{RegularCauchyFilter}^{\uparrow}$ packet. Every accepted $\mathsf{RegSeqRat}^{\uparrow}$ consumer of G reads the same finite route*

$$B \longmapsto T \longmapsto D \longmapsto M \longmapsto R$$

through the $\mathsf{CauchyFilter}^{\uparrow}$ source row, $\mathsf{StreamName}^{\uparrow}$ tail windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, and $\mathsf{CauchyFilterBasis}^{\uparrow}$ directed-meet witness before the regular-rational row R is exposed.

The route is transported by H, replayed by C, sourced by P, and named by N. No consumer may read R through a quotient filter, hidden tail selector, host limit, countable choice, or host real equality.

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier regseqrat window exposure`

Proof. Begin with the displayed window schedule T. Each window is part of the accepted carrier and is attached to the same CauchyFilter source row B.

Read the tolerance and meet rows next. The row D supplies the dyadic bounds for the displayed windows, while M supplies the directed basis witness needed before regular rational readback is exposed.

Finally use Definition 1445.17. The same basis route reaches the unique regular-rational coordinate R, and H, C, P, N preserve that route. Since no external filter or selector coordinate is present, every $\mathsf{RegSeqRat}^{\uparrow}$ read factors through the displayed window exposure. □

Theorem 1445.19 (RegularCauchyFilter Real seal consumer exhaustion)**.** *Every accepted $\mathsf{Real}^{\uparrow}$ consumer of a $\mathsf{RegularCauchyFilter}^{\uparrow}$ packet is exhausted by the route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

inside the rows $B, T, D, M, R, E, H, C, P, N$. The Real seal E is visible only after the source row B, the basis witness admitted by T, D, M, and the regular-rational readback R have been read.

Thus the packet has no Real-facing consumer route through a filter quotient, host-selected limit, hidden cofinal family, countable-choice selector, host real equality, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier real seal consumer exhaustion`

Proof. Project the Real seal coordinate. The row E is downstream from the source, basis, tail-window, tolerance, meet, and regular-rational rows; it is not stored as an independent completed real.

Apply Definition 1445.18. Every regular-rational read reaches R through B, T, D, M and the same structural rows.

Now apply Definition 1445.4. The Real-facing endpoint is the same seal E, with H, C, P, N transporting, replaying, sourcing, and naming the route. The excluded quotient, choice, hidden-tail, equality, and completeness coordinates are absent, so the listed rows exhaust every accepted Real seal consumer. □

Theorem 1445.20 (RegularCauchyFilter scoped public package)**.** *Every accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet* $G = (B, R, T, D, M, E, H, C, P, N)$ *exports one scoped public package formed by the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row* B*, the displayed basis witness* T, D, M*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the structural rows* H, C, P, N*. Every consumer route factors through this package and cannot split off quotient filters, selected limits, hidden cofinal tails, countable choice, host equality, or ambient completeness.*

Proof. First compose the source and basis rows. Apply Definition 1445.3, Definition 1445.5, and Definition 1445.17 to read the $\mathsf{CauchyFilter}^{\uparrow}$ source B through the displayed windows T, tolerance ledger D, and directed-meet witness M.

Next expose the regular-rational and Real-facing rows. Apply Definition 1445.18 to force every $\mathsf{RegSeqRat}^{\uparrow}$ readback through $B, T, D, M, R, H, C, P, N$, and apply Definition 1445.19 to force every $\mathsf{Real}^{\uparrow}$ consumer through the same route ending at E.

The scoped package is the single tuple of those rows. Transport is supplied by H, replay by C, provenance by P, and naming by N, so no consumer has a coordinate from which to extract a quotient filter, a host-selected limit, a hidden cofinal tail, a choice selector, host equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier scoped public package`

Theorem 1445.21 (RegularCauchyFilter mature route exhaustion)**.** *Every public or* $\mathsf{Real}^{\uparrow}$*-facing consumer route of an accepted* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *packet* $G = (B, R, T, D, M, E, H, C, P, N)$ *is exhausted by the displayed source row* B*, regular-rational readback* R*, tail-window row* T*, tolerance ledger* D*, directed meet row* M*, Real seal* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*, together with the scoped and public package theorems of this chapter. No consumer route factors through quotient filters, selected host limits, hidden cofinal tails, countable choice, host real equality, or ambient completeness.*

Proof. Start with Definition 1445.20. It packages the source, basis, regular-rational readback, Real seal, and structural rows as one public surface for the same carrier G.

For public routes, apply Definition 1445.6 and Definition 1445.7. These keep carrier admission, transport, replay, provenance, and naming on the displayed packet.

For $\mathsf{Real}^{\uparrow}$-facing routes, apply Definition 1445.18 and Definition 1445.19. The Real seal can be read only through the regular-rational window route ending at E.

The excluded routes are absent from the carrier and from the scoped public package. Hence the displayed rows exhaust every public or Real-facing consumer route. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterUp.RegularCauchyFilterCarrier mature route exhaustion`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyFilter}^{\uparrow}$ packet is generated from a displayed CauchyFilter finite-filterbase row, a RegSeqRat readback row, StreamName tail windows, a DyadicRatCore tolerance ledger, a directed tail-meet row, a RealUp seal row, componentwise transport, continuation replay, package provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyFilter}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1445.1, Definition 1445.2, Definition 1445.3, Definition 1445.4, Definition 1445.5, Definition 1445.6, Definition 1445.7, Definition 1445.8, Definition 1445.9, Definition 1445.10, Definition 1445.17, Definition 1445.18, Definition 1445.19, Definition 1445.20, and Definition 1445.21 bind the admitted CauchyFilterBasis witness,

RegSeqRat window exposure, Real seal exhaustion, componentwise transport, displayed Cont replay, Pkg provenance, local NameCert rows, exported public package boundary, displayed carrier-to-public-route handoff, and public or Real-facing route exhaustion to the same accepted carrier $G = (B, R, T, D, M, E, H, C, P, N)$.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyFilter}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected host limits, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Formal registration and Lean verification can encode the displayed RegularCauchyFilter carrier-to-public-route handoff for the same carrier.

Chapter 1446

A Concrete Naming Certificate for $\mathsf{LowerReal}^{\uparrow}$

Following Bishop and Bridges, lower real data are read as inhabited lower rational information with finite approximation windows, not as a completed Dedekind cut, a quotient real, or a host-completeness object. The $\mathsf{LowerReal}^{\uparrow}$ packet sits between the located cut discipline of chapter 404, the located real interface of **??**, the finite stream-window surface of chapter 126, the regular rational handoff of chapter 301, the dyadic ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It is the one-sided lower-real observation surface consumed by bound-shaped packets such as chapter 1427 and chapter 1452.

Definition 1446.1 (LowerReal carrier)**.** *A* $\mathsf{LowerReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (L_0, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. L_0 *is the lower rational or dyadic ledger: each row records a rational candidate, a dyadic comparison budget, and the evidence that the candidate is admitted by the lower side of the represented real.*
2. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the displayed lower observations are inspected.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row attaching those windows to a regular rational name surface.*
4. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* L_0, W, R *have been displayed.*
5. H *is the componentwise* hsame *transport row for the lower ledger, the finite windows, the regular rational handoff, the Real seal, and the structural rows.*
6. C *is the displayed* Cont *replay route by which a consumer rereads the lower ledger through the same windows and handoff.*
7. P *is the* Pkg *provenance over* $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. N *is the local* $\mathsf{NameCert}_{\mathsf{LowerReal}^{\uparrow}}$ *row.*

The carrier exports no upper cut, no located cut completion, no quotient real equality, no trichotomy branch, no selected supremum, no countable-choice row, and no host-completeness coordinate.

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealTasteGate single carrier alignment`

Theorem 1446.2 (LowerReal NameCert obligations)**.** *For an accepted* $\mathsf{LowerReal}^{\uparrow}$ *carrier* $L = (L_0, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LowerReal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the lower rational or dyadic ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transports, continuation replay, package provenance, and local naming row;*
2. *lower-ledger transport, stating that replacement through* H *and replay through* C *preserve the same displayed lower candidates and their dyadic comparison budgets;*
3. *window scope, stating that every lower observation is read through the displayed finite windows* W *and no hidden stream tail;*
4. *regular-rational handoff, stating that each accepted lower-window read is attached to the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the Real seal is consumed;*
5. *real-seal nonescape, stating that* E *can be reached only after* L_0, W, R, H, C, P, N *have been displayed;*
6. *ledger exactness, stating that every accepted lower-real read uses exactly the rows recorded in* L_0 *and no second lower ledger, quotient equality, selected supremum, or ambient completeness coordinate.*

Proof. Carrier admission is the tuple displayed in Definition 1446.1. The packet has one lower ledger, one finite-window surface, one regular rational handoff, one Real seal, and the structural rows for transport, replay, provenance, and local naming.

Lower-ledger transport is componentwise over H and C. A classified replacement may carry the same rational candidates, dyadic budgets, windows, handoff, and seal through the displayed routes, but it cannot add an upper-cut coordinate, a second lower ledger, or a host equality witness.

Window scope and the regular-rational handoff are the roles of W and R. Every lower observation in L_0 is read through the finite $\mathsf{StreamName}^{\uparrow}$ window row, and the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ row records the regular rational source before the terminal $\mathsf{Real}^{\uparrow}$ seal is available.

Real-seal nonescape and ledger exactness follow from the row inventory. The only route to E passes through L_0, W, R, H, C, P, N, and the provenance row records the located-cut and located-real neighbors only as dependency anchors. No row stores a Dedekind cut completion, quotient real, trichotomy branch, selected supremum, countable choice, or host completeness principle. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealCarrier namecert obligations`

Theorem 1446.3 (LowerReal Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{LowerReal}^{\uparrow}$ *packet factors through the displayed lower ledger* L_0*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, with* H, C, P, N *carrying only componentwise transport, continuation replay, provenance, and local naming. The route exports no Dedekind cut completion, quotient real, trichotomy branch, selected supremum, countable-choice selector, or host-completeness coordinate.*

Proof. Project the accepted carrier. A consumer first sees the lower rational or dyadic ledger L_0, so the lower-real information available to it is exactly the displayed finite list of candidates and comparison budgets.

Next the consumer reads the finite observation route. The row W supplies the $\mathsf{StreamName}^{\uparrow}$ window, and R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ handoff for the same displayed observations before any terminal seal is reachable.

Finally the read reaches E through the structural rows H, C, P, N. Since those rows only transport, replay, package, and name the already displayed ledger route, they cannot insert a Dedekind completion, quotient real equality, trichotomy branch, selected supremum, countable-choice selector, or host-completeness object. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealCarrier realup handoff`

Theorem 1446.4 (LowerReal Dedekind-cut carrier admission)**.** *Every* $\mathsf{LowerReal}^{\uparrow}$ *read admitted as Dedekind-cut-facing data is admitted only through the displayed lower rational or dyadic ledger* L_0*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *of Definition 1446.1. The admission may cite* $\mathsf{LocatedCut}^{\uparrow}$ *and* $\mathsf{LocatedReal}^{\uparrow}$ *provenance through* P*, but it does not construct a Dedekind cut completion, quotient real equality, trichotomy branch, selected supremum, countable-choice selector, or host-completeness witness.*

Proof. Project the accepted carrier. The only lower-real data row is L_0, so a Dedekind-cut-facing consumer first receives finite lower rational or dyadic candidates together with their comparison budgets.

Next force the observation through W and R. The $\mathsf{StreamName}^{\uparrow}$ row supplies the finite window, while the $\mathsf{RegSeqRat}^{\uparrow}$ row records the regular rational handoff before the $\mathsf{Real}^{\uparrow}$ seal is consumed.

Finally read provenance through P. The $\mathsf{LocatedCut}^{\uparrow}$ and $\mathsf{LocatedReal}^{\uparrow}$ entries are dependency anchors for the one-sided ledger, not extra coordinates carrying a completed cut, quotient equality, trichotomy, selected supremum, countable choice, or host completeness. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealCarrier dedekind cut admission`

Theorem 1446.5 (LowerReal located-cut ledger)**.** *The located-cut exactness obligation for* $\mathsf{LowerReal}^{\uparrow}$ *is the assertion that every located lower read replays the same* L_0, W, R, E, H, C, P, N *rows:* L_0 *supplies the lower rational or dyadic ledger,* W *supplies the* $\mathsf{StreamName}^{\uparrow}$ *window,* R *supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* E *supplies the* $\mathsf{Real}^{\uparrow}$ *seal, and* H, C, P, N *supply only transport, replay, provenance, and naming. No second ledger, quotient real equality, selected supremum, trichotomy branch, countable-choice selector, or host-completeness row is available.*

Proof. Start from the ledger exactness clause of Definition 1446.2. It already says that accepted lower-real reads use exactly the rows recorded in L_0 and no hidden second lower ledger.

The located-cut part is then read through the visible dependency anchors. $\mathsf{LocatedCut}^{\uparrow}$ and $\mathsf{LocatedReal}^{\uparrow}$ enter through P, while the observable lower data still pass through the finite $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ handoff before reaching the $\mathsf{Real}^{\uparrow}$ seal.

Thus a located lower read is exact only for the displayed one-sided ledger. Transport and replay preserve the same rows, and there is no coordinate from which a quotient real equality, trichotomy branch, selected supremum, countable choice, or host-completeness principle could be extracted. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealLocatedCutLedger`

Theorem 1446.6 (LowerReal UpperReal duality boundary)**.** *The* $\mathsf{UpperReal}^{\uparrow}$ *sibling may be cited by a* $\mathsf{LowerReal}^{\uparrow}$ *consumer only as a boundary row for one-sided comparison discipline. A* $\mathsf{LowerReal}^{\uparrow}$ *packet remains lower-sided: its admitted reads factor through* L_0, W, R, E, H, C, P, N

and the $\mathsf{LocatedCut}^{\uparrow}/\mathsf{LocatedReal}^{\uparrow}$ *provenance rows, then stop at the* $\mathsf{Real}^{\uparrow}$ *seal. The boundary does not supply upper-cut completion, quotient real equality, trichotomy, selected suprema, countable choice, or host completeness.*

Proof. Read the lower packet first. The carrier contains a lower ledger, finite stream windows, regular rational handoff, Real seal, transport, replay, provenance, and local naming; it contains no upper ledger coordinate.

The sibling boundary is therefore external provenance, not a second side of the carrier. It may identify where $\mathsf{UpperReal}^{\uparrow}$ would host upper-sided obligations, but it cannot change the row inventory of the current $\mathsf{LowerReal}^{\uparrow}$ packet.

Consequently all Real-facing reads still pass through the lower ledger, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and $\mathsf{Real}^{\uparrow}$ seal. The boundary records no upper-cut completion, quotient real equality, trichotomy branch, selected supremum, countable-choice selector, or host-completeness witness. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealUpperRealDualityBoundary`

Theorem 1446.7 (LowerReal scoped kernel obligation)**.** *The displayed carrier, NameCert obligations, Real handoff, Dedekind-cut admission, located-cut ledger, and UpperReal boundary bind every* $\mathsf{LowerReal}^{\uparrow}$ *read to the rows for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The scoped kernel exports no quotient real, trichotomy branch, selected supremum, countable-choice selector, or host-completeness coordinate.*

Proof. Project the carrier of Definition 1446.1. Its rows are the lower rational or dyadic ledger, finite stream windows, regular rational handoff, terminal Real seal, componentwise transport, continuation replay, provenance, and local naming.

Use Definition 1446.2, Definition 1446.3, and Definition 1446.4. These obligations keep every accepted read inside the displayed lower ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{LocatedCut}^{\uparrow}/\mathsf{LocatedReal}^{\uparrow}$ provenance, and $\mathsf{Real}^{\uparrow}$ seal.

Finally apply Definition 1446.5 and Definition 1446.6. They account for the located-cut ledger and the $\mathsf{UpperReal}^{\uparrow}$ sibling boundary without adding a second carrier side. The remaining structural rows are exactly BHist, hsame, Cont, Pkg, and NameCert, so the refused quotient, trichotomy, selected supremum, choice, and host-completeness objects have no row. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealCarrier scoped kernel obligation`

Definition 1446.8 (LowerReal public package)**.** *The* $\mathsf{LowerReal}^{\uparrow}$ *public package associated to an accepted carrier*

$$L = (L_0, W, R, E, H, C, P, N)$$

is the consumer-facing route that exposes the lower ledger L_0*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the support rows* H, C, P, N *as a single finite* Pkg*-named packet. The package may cite* $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, *and* $\mathsf{UpperReal}^{\uparrow}$ *through provenance and boundary rows, but it exports no completed cut, quotient real equality, trichotomy branch, selected supremum, countable-choice selector, or host-completeness witness.*

Lean4 (definition) `BEDC.Derived.LowerRealUp.LowerRealPublicPackage`

Theorem 1446.9 (LowerReal directed lower-cut budget)**.** *Let*

$$L = (L_0, W, R, E, H, C, P, N)$$

be an accepted $\mathsf{LowerReal}^{\uparrow}$ *carrier. Any two accepted lower-ledger rows in* L_0 *with displayed dyadic comparison budgets admit a common lower-read refinement only through the same route* L_0, W, R, E, H, C, P, N*: the refinement consumes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{LocatedCut}^{\uparrow}$ *and* $\mathsf{LocatedReal}^{\uparrow}$ *provenance rows, the* $\mathsf{UpperReal}^{\uparrow}$ *one-sided boundary, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any public consumer may read it. The route exports no selected supremum, no trichotomy branch, no quotient real equality, and no host-completeness principle.*

Proof. Start with the carrier of Definition 1446.1. The lower information is stored in L_0, and each row carries its dyadic comparison budget beside the finite observation route W, R, E.

Use the NameCert obligations of Definition 1446.2. Lower-ledger transport preserves the same rational candidates and dyadic budgets through H and C, while ledger exactness forbids a second lower ledger or hidden selector.

Now attach the located-cut ledger of Definition 1446.5. The $\mathsf{LocatedCut}^{\uparrow}$ and $\mathsf{LocatedReal}^{\uparrow}$ rows appear only through provenance over the same one-sided lower route, so a common refinement of two lower reads must stay inside L_0, W, R, E, H, C, P, N.

Finally apply the UpperReal duality boundary of Definition 1446.6. The $\mathsf{UpperReal}^{\uparrow}$ row records the sibling one-sided boundary but supplies no upper-cut completion. Therefore the common lower-read refinement is directed only by the displayed lower budgets and cannot use selected suprema, trichotomy, quotient real equality, or host completeness. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealDirectedLowerCutBudget`

Theorem 1446.10 (LowerReal public package scope)**.** *Every consumer of the public package of Definition 1446.8 must read the rows* L_0, W, R, E, H, C, P, N *in the same scoped route established by Definition 1446.7. The package boundary is public only for that displayed one-sided lower-real surface; it does not add a second lower ledger, an upper-cut carrier, quotient real equality, trichotomy, selected suprema, countable choice, or host completeness.*

Proof. Start with the carrier and NameCert obligations. The carrier gives exactly L_0, W, R, E, H, C, P, N, and Definition 1446.2 identifies those rows as the full local obligation surface.

Next apply the Real handoff and located-cut ledger theorems. They force each public read through W, R, E and keep $\mathsf{LocatedCut}^{\uparrow}$ and $\mathsf{LocatedReal}^{\uparrow}$ as provenance anchors rather than as completed cut coordinates.

Finally use the UpperReal boundary and scoped kernel obligation. The $\mathsf{UpperReal}^{\uparrow}$ row is only a sibling boundary, so the public package exposes the scoped lower route without adding any of the refused host or two-sided objects. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealPublicPackage scope`

Theorem 1446.11 (LowerReal public consumer export)**.** *Any downstream L10 consumer that imports* $\mathsf{LowerReal}^{\uparrow}$ *as public data receives only the package route of Definition 1446.8: lower ledger* L_0*, finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, and support rows* H, C, P, N*. The export is therefore a public consumer route for the existing lower-real scope, not a completeness theorem, a quotient representative, a trichotomy branch, a supremum selector, or a countable-choice functional.*

Proof. Read the public package scope theorem first. It fixes the consumer-visible rows before any downstream L10 packet can project lower-real data.

Then use the Real handoff theorem. A consumer that wants Real-facing information must pass through L_0, W, R, E in that order, with H, C, P, N only transporting, replaying, sourcing, and naming the same route.

The located-cut ledger and UpperReal boundary account for the sibling dependencies. Since those dependencies are not carrier coordinates for completion, quotient equality, trichotomy, selected suprema, or countable choice, the public export is exactly the finite package route. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealPublicConsumer export`

Theorem 1446.12 (LowerReal public nonescape)**.** *The* $\mathsf{LowerReal}^{\uparrow}$ *public package has no escape route from the displayed rows* L_0, W, R, E, H, C, P, N *to a Dedekind-cut completion, quotient real equality, trichotomy branch, selected supremum, countable-choice selector, or host-completeness coordinate. Every package read that reaches a public consumer is already covered by the carrier, NameCert obligations, Real handoff, located-cut ledger, UpperReal boundary, and scoped kernel obligation.*

Proof. Project the public package. Its only analytic rows are the lower ledger, stream window, regular rational handoff, and Real seal; its remaining rows are support for transport, replay, provenance, and local naming.

Apply the NameCert obligations, Real handoff, and located-cut ledger. These results keep every accepted package read inside the same lower ledger and prohibit hidden second ledgers, quotient equality, selected suprema, countable choice, and host completeness.

Close with the UpperReal boundary and scoped kernel obligation. They exhaust the sibling and kernel-facing dependencies, leaving no row from which a public consumer could extract the refused objects. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealPublicNonescape`

Theorem 1446.13 (LowerReal public RegSeqRat Real route)**.** *Every public* $\mathsf{LowerReal}^{\uparrow}$ *consumer that exposes a lower-real observation must route inhabited lower rational information through the displayed* $\mathsf{LocatedCut}^{\uparrow}$ *and* $\mathsf{LocatedReal}^{\uparrow}$ *provenance rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route reads only* L_0, W, R, E, H, C, P, N *and the named sibling rows; it exports no Dedekind completion, quotient real equality, trichotomy branch, selected supremum, countable-choice selector, or host completeness coordinate.*

Proof. Project the public package of Definition 1446.8. Its consumer-visible data are the lower ledger L_0, finite stream window W, regular rational handoff R, Real seal E, and support rows H, C, P, N.

Use Definition 1446.10 and Definition 1446.12. These theorems force each public read to stay inside the displayed package route and block escape to completion, quotient equality, trichotomy, selected suprema, choice, or host completeness.

Now apply the located-cut ledger and Real handoff theorems. The $\mathsf{LocatedCut}^{\uparrow}$ and $\mathsf{LocatedReal}^{\uparrow}$ rows witness the provenance of inhabited lower rational information, while $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ provide the finite readback and terminal seal.

Therefore a public lower-real observation reaches consumers only through the RegSeqRat/Real corridor already named by the package. No additional completion object or selected supremum can be projected from the accepted $\mathsf{LowerReal}^{\uparrow}$ surface. □

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealPublicRegSeqRatRealRoute`

Theorem 1446.14 (LowerReal public LocatedSupremum handoff)**.** *Every* $\mathsf{LocatedSupremum}^{\uparrow}$*-facing consumer of the public* $\mathsf{LowerReal}^{\uparrow}$ *package may read only the lower ledger* L_0*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the support rows* H, C, P, N*, together with the existing* $\mathsf{LocatedCut}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*, and* $\mathsf{UpperReal}^{\uparrow}$ *provenance rows. The handoff exports the one-sided lower route used by the downstream supremum packet; it exports no selected supremum, trichotomy branch, quotient real equality, countable-choice schedule, or host-completeness coordinate.*

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealPublicLocatedSupremumHandoff`

Proof. Project the public package of Definition 1446.8. The consumer-visible lower-real rows are exactly L_0, W, R, E, H, C, P, N.

Use Definition 1446.13. It routes public lower observations through the located-cut and located-real provenance rows, finite stream windows, RegSeqRat readback, dyadic tolerance ledgers, and the terminal Real seal.

Now apply Definition 1446.12. The public package has no row for selected suprema, trichotomy, quotient real equality, countable choice, or host completeness.

Finally identify $\mathsf{LocatedSupremum}^{\uparrow}$ as a downstream consumer of the same one-sided lower route named in the chapter introduction. It may consume the displayed lower ledger and provenance boundary, but it cannot extract a supremum selector or host-completeness principle from the accepted $\mathsf{LowerReal}^{\uparrow}$ surface. □

Theorem 1446.15 (LowerReal located-cut seal boundary)**.** *Every public* $\mathsf{LowerReal}^{\uparrow}$ *read that presents a located-cut-facing seal must pass through* $\mathsf{LocatedCut}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows before the seal is consumed. The read remains the displayed one-sided lower ledger* L_0, W, R, E, H, C, P, N *with located-cut and located-real provenance; it exports no completed Dedekind cut, quotient real equality, trichotomy branch, selected supremum, countable-choice selector, or host-completeness coordinate.*

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealLocatedCutSealBoundary`

Proof. Project the public package of Definition 1446.8. Its consumer-visible route is the lower ledger, finite stream window, regular rational handoff, Real seal, and support rows.

Use Definition 1446.13. It already routes public lower observations through located-cut and located-real provenance, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledgers, and the terminal Real seal.

Apply Definition 1446.12. The package has no row for completed cuts, quotient equality, trichotomy, selected suprema, countable choice, or host completeness. Thus a located-cut-facing seal is consumed only at the boundary named by the displayed route. □

Theorem 1446.16 (LowerReal UpperReal comparison nonescape)**.** *The* $\mathsf{UpperReal}^{\uparrow}$ *sibling is only a one-sided comparison boundary for the public* $\mathsf{LowerReal}^{\uparrow}$ *package. A consumer may use it to identify where upper-sided comparison data would be read, but it cannot supply Dedekind completion, quotient equality, trichotomy, selected suprema, countable choice, host completeness, or a two-sided real object. Every accepted comparison remains inside* L_0, W, R, E, H, C, P, N *and the displayed* $\mathsf{LocatedCut}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *route.*

Lean4 ✓ `BEDC.Derived.LowerRealUp.LowerRealUpperRealComparisonNonescape`

Proof. Start with Definition 1446.6. It treats $\mathsf{UpperReal}^{\uparrow}$ as sibling provenance for one-sided comparison discipline, not as a second carrier side.

Next apply Definition 1446.15. The comparison must pass through the located-cut, located-real, stream-window, regular-readback, dyadic-budget, and Real-seal rows before any public consumer reads it.

The nonescape conclusion follows from Definition 1446.12. Since the package exposes only the lower route and support rows, the UpperReal boundary cannot supply completion, quotient equality, trichotomy, selected suprema, countable choice, host completeness, or a two-sided real object. □

Closure status for $\mathsf{NameCert}_{\mathsf{LowerReal}^{\uparrow}}$.

Constructive story: A $\mathsf{LowerReal}^{\uparrow}$ packet is generated from a displayed lower rational or dyadic ledger, finite StreamName windows, a RegSeqRat handoff row, a RealUp seal, componentwise transports, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerReal}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1446.7 binds the finite one-sided lower-real surface to DyadicRatCore, StreamName, RegSeqRat, LocatedCut, LocatedReal, UpperReal, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind cut completion, quotient real equality, trichotomy, selected suprema, countable choice, host completeness, Lean verification, or a standard bridge.

Upgrade path: The chapter is mature on the paper closure axis; Lean bridge evidence remains governed only by the verification axis.

Chapter 1447

A Concrete Naming Certificate for $\mathsf{UpperReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, upper real data are read as finite upper rational or dyadic observations with explicit approximation windows, not as a Dedekind completion, quotient real, trichotomy branch, selected infimum, or host-completeness object. The $\mathsf{UpperReal}^{\uparrow}$ packet is the upper-ledger dual of the lower observation surface in chapter 1446; it supplies the one-sided upper data consumed by the located real interface of **??**, the located cut discipline of chapter 404, the finite stream-window surface of chapter 126, the regular rational handoff of chapter 301, the dyadic ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38.

Definition 1447.1 (UpperReal carrier)**.** *An* $\mathsf{UpperReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (U_0, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. U_0 *is the upper rational or dyadic ledger: each row records a rational candidate, a dyadic comparison budget, and the evidence that the candidate is admitted by the upper side of the represented real.*
2. L *is the sibling* $\mathsf{LowerReal}^{\uparrow}$ *comparison window, used only to expose a finite lower-upper apartness row when a located consumer asks for one-sided separation data.*
3. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the displayed upper observations are inspected.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row attaching those windows to a regular rational name surface.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* U_0, W, R *have been displayed.*
6. H *is the componentwise* hsame *transport row for the upper ledger, the lower comparison window, the finite windows, the regular rational handoff, the Real seal, and the structural rows.*
7. C *is the displayed* Cont *replay route by which a consumer rereads the upper ledger through the same windows and handoff.*
8. P *is the* Pkg *provenance over* $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{UpperReal}^{\uparrow}}$ *row.*

The carrier exports no lower cut, no located cut completion, no quotient real equality, no trichotomy branch, no selected infimum, no countable-choice row, and no host-completeness coordinate.

Lean4 ✓ `BEDC.Derived.UpperRealUp.UpperRealTasteGate single carrier alignment`

Theorem 1447.2 (UpperReal NameCert obligation surface)**.** *For an accepted* $\mathsf{UpperReal}^{\uparrow}$ *carrier* $U = (U_0, L, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UpperReal}^{\uparrow}}$ *surface consists exactly of the following seven finite obligations:*

1. *carrier admission for the upper rational or dyadic ledger, the sibling lower comparison window, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transports, continuation replay, package provenance, and local naming row;*
2. *upper-ledger transport, stating that replacement through* H *and replay through* C *preserve the same displayed upper candidates and their dyadic comparison budgets;*
3. *lower-upper apartness scope, stating that every comparison with* $\mathsf{LowerReal}^{\uparrow}$ *or* $\mathsf{LocatedReal}^{\uparrow}$ *reads only the displayed lower comparison window* L *together with the upper candidates in* U_0*;*
4. *window scope, stating that every upper observation is read through the displayed finite windows* W *and no hidden stream tail;*
5. *regular-rational handoff, stating that each accepted upper-window read is attached to the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the Real seal is consumed;*
6. *real-seal nonescape, stating that* E *can be reached only after* U_0, L, W, R, H, C, P, N *have been displayed;*
7. *ledger exactness, stating that every accepted upper-real read uses exactly the rows recorded in* U_0 *and no second upper ledger, lower cut, located cut completion, quotient equality, selected infimum, countable-choice row, or ambient completeness coordinate.*

Proof. Carrier admission is the tuple displayed in Definition 1447.1. The packet has one upper ledger, one lower comparison window, one finite-window surface, one regular rational handoff, one Real seal, and the structural rows for transport, replay, provenance, and local naming.

Upper-ledger transport is componentwise over H and C. A classified replacement may carry the same rational candidates, dyadic budgets, lower comparison window, observation windows, handoff, and seal through the displayed routes, but it cannot add a second upper ledger or any hidden completion coordinate.

The lower-upper apartness scope is supplied by L together with U_0. A located or lower-real consumer can compare only those displayed rows, so the comparison window is finite and does not become a Dedekind cut, quotient equality test, or selected infimum.

Window scope and the regular-rational handoff are the roles of W and R. Every upper observation in U_0 is read through the finite $\mathsf{StreamName}^{\uparrow}$ window row, and the corresponding $\mathsf{RegSeqRat}^{\uparrow}$ row records the regular rational source before the terminal $\mathsf{Real}^{\uparrow}$ seal is available.

Real-seal nonescape and ledger exactness follow from the row inventory. The only route to E passes through U_0, L, W, R, H, C, P, N, and the provenance row records the lower-real, located-real, and located-cut neighbors only as dependency anchors. The carrier exports no lower cut, no located cut completion, no quotient real equality, no trichotomy branch, no selected infimum, no countable-choice row, and no host-completeness coordinate. □

Lean4 ✓ `BEDC.Derived.UpperRealUp.UpperRealCarrier obligation surface`

Theorem 1447.3 (UpperReal lower-upper apartness window)**.** *Every* $\mathsf{LowerReal}^{\uparrow}$*-,* $\mathsf{LocatedReal}^{\uparrow}$*-, or* $\mathsf{LocatedCut}^{\uparrow}$*-facing comparison read of an accepted* $\mathsf{UpperReal}^{\uparrow}$ *packet factors through the displayed lower comparison window* L*, the upper ledger* U_0*, and the finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W*. The comparison may expose a visible dyadic gap between the lower-side witness and an upper candidate, transported by* H *and replayed by* C*, but it cannot introduce lower-cut completion data, quotient real equality, a trichotomy branch, a selected infimum, countable choice, or host completeness.*

Proof. Project the accepted carrier $U = (U_0, L, W, R, E, H, C, P, N)$. A comparison consumer sees the lower-side window L and the upper rational or dyadic ledger U_0, so the available apartness information is exactly the displayed finite list of lower-side witnesses, upper candidates, and comparison budgets.

Next the consumer reads the finite observation route. The row W supplies the $\mathsf{StreamName}^{\uparrow}$ window, and R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ handoff for the same displayed observations before any terminal seal is reachable.

Transport is internal to the packet. Moving along H and replaying C changes the presented row names but not the finite dependency route from L and U_0 through W and R.

The carrier exports no lower cut, no located cut completion, no quotient real equality, no trichotomy branch, no selected infimum, no countable-choice row, and no host-completeness coordinate. Therefore the comparison remains a finite lower-upper apartness window over the displayed rows. □

Lean4 ✓ `BEDC.Derived.UpperRealUp.UpperRealCarrier lower upper apartness window`

Theorem 1447.4 (UpperReal public certificate)**.** *Every public* $\mathsf{NameCert}_{\mathsf{UpperReal}^{\uparrow}}$ *export of an accepted* $\mathsf{UpperReal}^{\uparrow}$ *packet is exhausted by the displayed carrier, upper-ledger transport, lower-upper apartness window, finite-window scope, regular-rational handoff, real-seal nonescape, and ledger exactness rows over* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*. Every* $\mathsf{Real}^{\uparrow}$*-facing read reaches the terminal seal* E *only through* U_0, L, W, R, H, C, P, N *and exports no lower cut, no located cut completion, no quotient real equality, no trichotomy branch, no selected infimum, no countable-choice row, and no host-completeness coordinate.*

Proof. Read the carrier route in order. The upper ledger U_0 supplies the finite rational or dyadic observations, L supplies the lower-side comparison window, W supplies the window discipline, and R supplies the regular rational handoff for those same observations.

The terminal seal E is downstream of that finite route. Its continuation in C can replay the displayed rows, while H transports only the componentwise names already present in the packet.

The provenance and local naming rows P, N record the sibling certificates and primitive BEDC rows named in Definition 1447.1. They do not store any second completion route or any independent real-equality test.

Thus the carrier exports no lower cut, no located cut completion, no quotient real equality, no trichotomy branch, no selected infimum, no countable-choice row, and no host-completeness coordinate. The $\mathsf{Real}^{\uparrow}$ seal can be consumed only as the boundary of the displayed upper-ledger path. □

Lean4 ✓ `BEDC.Derived.UpperRealUp.UpperRealCarrier public certificate`

Theorem 1447.5 (UpperReal scoped kernel dependency route)**.** *Every accepted* $\mathsf{UpperReal}^{\uparrow}$ *packet reads through the displayed* $\mathsf{LowerReal}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows of Definition 1447.1 before either its upper ledger or its*

real-seal boundary is exposed. In particular the carrier admission, upper-ledger transport, lower-upper apartness scope, finite-window scope, regular-rational handoff, real-seal nonescape, and ledger exactness obligations are all scoped to the single route

$$U_0, L, W, R, E, H, C, P, N.$$

No accepted packet can expose a second upper ledger, a lower cut, a located cut completion, quotient real equality, trichotomy, selected infimum, countable choice, host completeness, or an unrecorded sibling dependency outside that route.

Proof. Start with the carrier admission of Definition 1447.1. It names the upper ledger U_0, the lower comparison row L, the finite window row W, the regular rational handoff R, the terminal Real seal E, and the structural rows H, C, P, N.

Apply Definition 1447.2. Its seven obligations list the displayed carrier admission, upper-ledger transport, lower-upper apartness scope, finite-window scope, regular-rational handoff, real-seal nonescape, and ledger exactness clauses, so each required dependency is already bound to the visible rows.

Use Definition 1447.3 for the sibling comparison route. It forces every $\mathsf{LowerReal}^{\uparrow}$-, $\mathsf{LocatedReal}^{\uparrow}$-, or $\mathsf{LocatedCut}^{\uparrow}$-facing read through L, U_0, W, R before any comparison boundary can be consumed.

Finally apply Definition 1447.4. It exhausts the public certificate through BHist, hsame, Cont, Pkg, and NameCert provenance and makes E reachable only through the displayed upper-ledger path. Hence both the upper ledger and the real-seal boundary are exposed only after the named dependency rows have been read. □

Lean4 ✓ `BEDC.Derived.UpperRealUp.UpperRealCarrier scoped kernel dependency route`

Theorem 1447.6 (UpperReal located-cut bridge surface)**.** *Every accepted* $\mathsf{UpperReal}^{\uparrow}$ *packet bridges to the located-cut and located-real completion route only through its upper rational or dyadic observation rows, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The bridge preserves the displayed route*

$$U_0, L, W, R, E, H, C, P, N$$

from Definition 1447.1; it exposes no Dedekind-completion object, quotient-real equality, trichotomy branch, selected infimum, ambient-completeness principle, or off-packet located-cut coordinate.

Proof. Start from the scoped dependency route of Definition 1447.5. It forces every accepted upper ledger and real-seal boundary through $U_0, L, W, R, E, H, C, P, N$ before the packet is exposed.

The located-cut and located-real consumers can therefore read the upper side only through the displayed observation rows. The row W supplies the finite $\mathsf{StreamName}^{\uparrow}$ windows, R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the dyadic budgets recorded in U_0 and the provenance row supply the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger before E seals the $\mathsf{Real}^{\uparrow}$ route.

Apply Definition 1447.3 for the comparison boundary. It permits a visible lower-upper apartness window, but it does not export a lower cut or a completed located-cut object.

Finally, Definition 1447.4 exhausts the public certificate by the same finite rows. Any Dedekind completion, quotient real, trichotomy branch, selected infimum, or ambient-completeness reading would require a coordinate absent from that packet, so the bridge is exactly the displayed located-cut route and nothing stronger. □

Lean4 ✓ `BEDC.Derived.UpperRealUp.UpperRealCarrier located cut bridge`

Theorem 1447.7 (UpperReal completeness-facing consumer route)**.** *Every completeness-facing consumer of an accepted* $\mathsf{UpperReal}^{\uparrow}$ *packet reads the upper ledger only through the displayed* $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows of Definition 1447.1. The consumer may use the finite route*

$$U_0, L, W, R, E, H, C, P, N$$

and the located-cut bridge of Definition 1447.6, but it receives no lower-cut completion, selected infimum, quotient real equality, trichotomy, countable choice, or ambient host-completeness object.

Proof. Project the accepted carrier $U = (U_0, L, W, R, E, H, C, P, N)$. The upper ledger U_0 is visible only beside the lower comparison window L, finite window row W, regular-rational handoff R, and terminal Real seal E.

Apply Definition 1447.3 and Definition 1447.6. They route every lower-real, located-real, and located-cut read through the displayed one-sided comparison and window rows before any Real-facing seal is consumed.

Finally use Definition 1447.4. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so a completeness-facing consumer receives exactly the named rows and none of the excluded completion, infimum, equality, trichotomy, choice, or host-completeness endpoints. □

Lean4 ✓ `BEDC.Derived.UpperRealUp.UpperRealCarrier completeness facing consumer route`

Closure status for $\mathsf{NameCert}_{\mathsf{UpperReal}^{\uparrow}}$**.**

Constructive story: An $\mathsf{UpperReal}^{\uparrow}$ packet is generated from a displayed upper rational or dyadic ledger, a lower comparison window, finite StreamName windows, a RegSeqRat handoff row, a RealUp seal, componentwise transports, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UpperReal}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1447.1, Definition 1447.2, Definition 1447.3, Definition 1447.4, Definition 1447.5, Definition 1447.6, and Definition 1447.7 scope the finite one-sided upper-real surface through the displayed carrier admission, upper-ledger transport, lower-upper apartness window, finite-window scope, RegSeqRat handoff, Real-seal nonescape, ledger exactness rows, located-cut bridge boundary, and completeness-facing consumer route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UpperReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim lower cuts, located cut completion, quotient real equality, trichotomy, selected infima, countable choice, host completeness, Lean verification, or a standard bridge.

Upgrade path: No further paper-theory upgrade is required for the displayed upper-real route; Lean verification and standard bridge checking remain separate formal-axis work.

Chapter 1448

A Concrete Naming Certificate for $\mathsf{ClosedUnitInterval}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{ClosedUnitInterval}^{\uparrow}$ packet records the displayed $[0, 1]$ real-name interval as finite dyadic windows, regular-rational readback, rational-density witnesses, and a visible $\mathsf{Real}^{\uparrow}$ seal. It is a closed endpoint packet over chapter 291, chapter 126, chapter 301, chapter 38, chapter 1410, and chapter 1409; it is not an open-cover compactness theorem, a selected subsequence, quotient real equality, or host real interval.

Definition 1448.1 (Closed unit interval carrier)**.** *A* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (Z, O, W, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *Z is the displayed zero endpoint row, read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *rational and dyadic ledger and then through the visible* $\mathsf{Real}^{\uparrow}$ *seal;*
2. *O is the displayed one endpoint row, read through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *rational and dyadic ledger and the same* $\mathsf{Real}^{\uparrow}$ *seal;*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger used for the endpoint names and for any inspected interior regular name;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating those finite windows into regular rational approximants;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic scales at which endpoint, window, and boundary comparisons are inspected;*
6. *R is the rational-density or* $\mathsf{BishopIntervalCompact}^{\uparrow}$ *route row that records the finite witness surface by which an inspected regular-rational name lies between the displayed endpoints;*
7. *H records componentwise* hsame *transport for endpoints, windows, readbacks, dyadic tolerances, density witnesses, interval routes, continuation rows, package provenance, and the local naming row;*
8. *C records displayed* Cont *replay from endpoint rows to dyadic windows, from windows to regular-rational readback, from readback to rational-density or finite interval-net witnesses, and from those rows to the visible* $\mathsf{Real}^{\uparrow}$ *seal;*

9. *P is the* Pkg *provenance over* $\mathsf{ClosedUnitInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopIntervalCompact}^{\uparrow}$, $\mathsf{RationalDensityReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedUnitInterval}^{\uparrow}}$ *row.*

The carrier classifier compares two accepted packets only by replaying the displayed rows $Z, O, W, Q, D, R, H, C, P, N$. It has no coordinate for an arbitrary open cover, Heine–Borel compactness, sequential compactness, quotient real equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1448.2 (Closed unit interval NameCert obligations)**.** *For an accepted* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *packet $U = (Z, O, W, Q, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedUnitInterval}^{\uparrow}}$ *obligation surface consists exactly of endpoint admission for Z and O, finite-window admission through W, regular-rational readback through Q, dyadic tolerance admission through D, rational-density or finite interval-net routing through R, componentwise* hsame *transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 1448.1. The zero endpoint, one endpoint, window, readback, dyadic tolerance, interval-route, transport, continuation, provenance, and naming rows are the complete displayed coordinates of the finite packet.

Read the endpoint and real-name side first. The rows Z and O expose the two displayed endpoints, while W, Q, and D expose only finite windows, regular-rational approximants, and dyadic tolerances for those endpoints and inspected names.

Read the interval route next. The row R records the rational-density or finite interval-net witness surface that places the inspected read between the endpoints at the displayed tolerance. It does not select a subsequence, a limit, or a subcover.

Finally H, C, P, and N transport, replay, source, and name exactly these rows. Since the carrier has no coordinate for open covers, Heine–Borel compactness, quotient equality, host equality, choice, or ambient completeness, no such obligation can be read from the local NameCert surface. □

Theorem 1448.3 (Closed unit interval dyadic window boundary)**.** *Every accepted* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *consumer read of a point between the displayed endpoints factors through the finite boundary surface*

$$Z, O, W, Q, D, R.$$

The read first inspects the zero and one endpoint rows, then the finite $\mathsf{StreamName}^{\uparrow}$ *windows, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and only then the rational-density or finite interval-net route named by R.*

Proof. Begin with the endpoint rows. The packet exposes the displayed zero row Z and one row O before any interior or boundary membership read is available.

Next inspect the finite windows and rational readback. The rows W and Q provide only the scheduled $\mathsf{StreamName}^{\uparrow}$ observations and regular-rational approximants that the dyadic tolerance ledger D can compare.

Finally read the interval route R. It is attached to those same windows and tolerances, so a consumer cannot bypass Z, O, W, Q, and D to obtain an ambient interval object or host real comparison.

The boundary is therefore a finite dyadic-window boundary. Later tails of a real name, quotient equality, selected limits, countable choice, and real completeness are absent from the packet and cannot affect the read. □

Theorem 1448.4 (Closed unit interval Real seal scope)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{ClosedUnitInterval}^{\uparrow}$ *packet must first consume the endpoint, finite-window, regular-rational, dyadic-tolerance, and rational-density or finite interval-net rows named by* Z, O, W, Q, D*, and* R*. The visible* $\mathsf{Real}^{\uparrow}$ *seal confirms the displayed endpoint packet and no stronger real interval principle.*

Proof. Expose the real-facing rows by projection from Definition 1448.1. The packet reaches the visible $\mathsf{Real}^{\uparrow}$ seal only after the endpoint rows and their finite window, readback, tolerance, and route rows have been displayed.

Use Definition 1448.2 to exhaust the local certificate surface. Its real-facing obligations are exactly the listed endpoint, window, readback, dyadic, interval-route, transport, continuation, provenance, and naming rows.

Use Definition 1448.3 for the consumer boundary. Any read that treats the packet as an interval first passes through the finite dyadic-window surface, so the seal cannot be reinterpreted as quotient real equality, host equality, open-cover compactness, selected limits, countable choice, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedUnitInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClosedUnitInterval}^{\uparrow}$ packet is generated from displayed zero and one endpoint rows, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, a rational-density or BishopIntervalCompact route row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedUnitInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1448.1, Definition 1448.2, Definition 1448.3, and Definition 1448.4 bind the finite closed endpoint packet for the displayed unit interval.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedUnitInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, Heine–Borel compactness for arbitrary subsets, sequential compactness, quotient real equality, selected limits, host real equality, countable choice, Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, dyadic window boundary transport, rational-density or finite interval-net routing, and Real seal nonescape for BEDC.Derived.ClosedUnitIntervalUp.

Chapter 1449

A Concrete Naming Certificate for $\mathsf{BoundedRealFamily}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BoundedRealFamily}^{\uparrow}$ packet records a bounded family of real names by finite index-window rows, visible StreamName windows, regular rational readback, RealUp family seals, and a closed-bounded interval-net bound row. It is the family-facing analogue of the bounded sequence surface in chapter 1415, shares the explicit modulus discipline of chapter 1423, and reads cover-facing interval data through chapter 1428. Its bound row is the finite $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ surface of chapter 1250, and each terminal family member is sealed only through the $\mathsf{Real}^{\uparrow}$ route of chapter 38. The packet prepares later least-upper-bound, compactness, and cover-selection certificates without importing trichotomy, quotient equality, countable choice, or a supremum principle.

Definition 1449.1 (Bounded real family carrier)**.** *A* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, W, Q, R, B, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index-window ledger. Each row names an inspected family index together with the finite observation window requested at that index.*
2. *W is the family of* $\mathsf{StreamName}^{\uparrow}$ *windows displayed for the inspected index-window rows of I.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those StreamName windows and their visible dyadic tolerance observations.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *family-seal row. A family member is visible to a Real-facing consumer only after its index row, StreamName window, and RegSeqRat readback have been displayed.*
5. *B is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row carrying the located lower and upper interval data used to witness a common bound for the displayed family rows.*
6. *H stores componentwise* hsame *transport for the index-window ledger, StreamName windows, regular readback, Real family seals, bound row, continuation replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from index-window rows to StreamName windows, from StreamName windows to RegSeqRat readback, from RegSeqRat readback to Real family seals, and from Real family seals to the common bound ledger.*

8. *P is the* Pkg *provenance over* $\mathsf{BoundedRealFamily}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}$ *row.*

The bound row is displayed as finite located interval data

$$B : \mathsf{ClosedBoundedIntervalNet}^{\uparrow},$$
$$\forall i \in I_{\text{shown}} \quad W_i \longmapsto Q_i \longmapsto R_i \in B.$$

Here I_{shown} denotes only the inspected finite index-window rows carried by the packet. The classifier compares accepted packets only through $I, W, Q, R, B, H, C, P, N$ and has no coordinate for trichotomy, quotient equality of real names, countable choice over indices, an ambient supremum, open-cover compactness, or host completeness.

Lean4 ✓ `BEDC.Derived.BoundedRealFamilyUp.BoundedRealFamilyTasteGate single carrier alignment`

Theorem 1449.2 (Bounded real family located upper row)**.** *For every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier $F = (I, W, Q, R, B, H, C, P, N)$, the bound row B is read through finite located lower and upper interval data. Each displayed family member reaches the common bound by the route*

$$I \longmapsto W \longmapsto Q \longmapsto R \longmapsto B$$

together with H, C, P, N. Thus the located upper row is a finite certificate row and imports no trichotomy, quotient equality of real names, countable choice, supremum principle, or host completeness.

Lean4 ✓ `BEDC.Derived.BoundedRealFamilyUp.BoundedRealFamilyLocatedUpperRow`

Proof. Project the carrier of Definition 1449.1. The only family data exposed to the classifier are the finite index-window ledger I, the displayed $\mathsf{StreamName}^{\uparrow}$ windows W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and the terminal $\mathsf{Real}^{\uparrow}$ family seals R.

Read the bound coordinate next. The row B is a $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ packet, so its lower and upper interval data are displayed finite rows from chapter 1250. A family member can meet B only after its own window, readback, and seal route has already been replayed.

The structural rows preserve this same route. Componentwise transport H, continuation replay C, package provenance P, and the local name N have no field for trichotomy, quotient equality, countable choice, a supremum, or host completeness. Hence the located upper row is read as finite interval data and nothing stronger. □

Theorem 1449.3 (Bounded real family RegSeqRat scope)**.** *Every Real-facing read of an accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{ClosedBoundedIntervalNet}^{\uparrow}$$

as instantiated by the rows W, Q, R, B and transported by H, C, P, N. No consumer can read a family member, a bound assertion, or a cover-facing handoff outside the StreamName windows, RegSeqRat readback, RealUp family seals, and bound ledger carried by the packet.

Lean4 ✓ `BEDC.Derived.BoundedRealFamilyUp.BoundedRealFamilyRegSeqRatScope`

Proof. Begin with a Real-facing request for an inspected family row. The carrier first exposes the index-window ledger I and the corresponding $\mathsf{StreamName}^{\uparrow}$ window in W.

The request then passes through the regular rational readback. The row Q is the only $\mathsf{RegSeqRat}^{\uparrow}$ coordinate, and the terminal $\mathsf{Real}^{\uparrow}$ seal R is reached only after Q has been displayed.

Finally the bound assertion is read through B. Since B is the only bound ledger and since H, C, P, N only transport, replay, source, and name the displayed rows, the request cannot leave the StreamName, RegSeqRat, RealUp, and bound-ledger scope of the packet. □

Theorem 1449.4 (Bounded real family bound-ledger nonescape)**.** *Every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *packet reads the common bound only through the displayed rows* $I, W, Q, R, B, H, C, P, N$*. In particular, a consumer cannot export trichotomy, quotient real equality, countable choice over indices, a supremum principle, open-cover compactness, or host completeness from the bound ledger.*

Proof. Project the carrier of Definition 1449.1. The common bound is the single row B, and it is available only after the finite index-window ledger I, StreamName windows W, RegSeqRat readback Q, and Real family seals R have been displayed.

Apply Definition 1449.2. It identifies the bound row as finite located lower and upper interval data rather than as an ambient order-completeness witness or a selected supremum.

Apply Definition 1449.3. It forces every Real-facing read of a family member or bound assertion through the StreamName, RegSeqRat, RealUp, and ClosedBoundedIntervalNet route carried by W, Q, R, B.

It remains to inspect the structural rows. The transport row H preserves only componentwise equality of the displayed rows, the replay row C replays only the displayed route, the provenance row P names only the sibling sources, and the local row N names the packet. None of H, C, P, N contains a branch for trichotomy, quotient real equality, countable choice over indices, supremum extraction, open-cover compactness, or host completeness. Thus the common-bound read cannot escape the finite bound ledger. □

Theorem 1449.5 (Bounded real family obligation surface)**.** *Every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier exposes exactly the finite index-window ledger* I*,* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*,* $\mathsf{Real}^{\uparrow}$ *family seals* R*,* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row* B*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}$ *row* N *before any compactness, least-upper-bound, or cover-selection consumer may read it.*

Proof. Project the carrier of Definition 1449.1. Its displayed coordinates are exactly $I, W, Q, R, B, H, C, P, N$, so an obligation-level consumer has no other entry point.

Apply Definition 1449.2 to the bound coordinate. The common bound is finite located interval-net data, not a supremum, cover selector, or host completeness witness.

Apply Definition 1449.3 and Definition 1449.4. They force every Real-facing read through the StreamName, RegSeqRat, RealUp, and ClosedBoundedIntervalNet route and bar trichotomy, quotient equality, countable choice, compactness extraction, least-upper-bound extraction, and cover-selection reads. Hence the listed rows are exactly the obligation surface available before downstream consumers add their own data. □

Theorem 1449.6 (BoundedRealFamily scoped dependency route)**.** *Every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *packet exposes its finite index-window ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *family-seal row,* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *bound row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows before any compactness, least-upper-bound, or cover-selection consumer may read it. The route exports no trichotomy, quotient equality of real names, countable choice, supremum principle, open-cover compactness, or host completeness.*

Proof. Project the carrier in Definition 1449.1. Its finite dependency route is exactly $I, W, Q, R, B, H, C, P, N$.

The analytic rows are already ordered. Apply Definition 1449.2 for the located upper row, Definition 1449.3 for the StreamName and RegSeqRat scope, and Definition 1449.4 for the bound-ledger refusal.

Now apply Definition 1449.5. It exhausts the rows visible before a downstream compactness, least-upper-bound, or cover-selection consumer adds its own data.

Since the packet has no coordinate beyond those rows, it exports no trichotomy, quotient equality, countable choice, supremum, open-cover compactness, or host-completeness principle. □

Theorem 1449.7 (Bounded real family compactness consumer boundary)**.** *Every compactness consumer of an accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier* $F = (I, W, Q, R, B, H, C, P, N)$ *must add its own finite-net, total-boundedness, located-compactness, or compactness row before reading a compactness conclusion. The rows* $I, W, Q, R, B, H, C, P, N$ *expose the bounded-family obligation surface and common bound ledger, but they do not by themselves supply an open-cover compactness theorem, selected finite subcover, compact metric witness, or compactness classifier.*

Proof. Start from the carrier in Definition 1449.1. Its coordinates list finite index windows, StreamName windows, RegSeqRat readback, Real seals, one ClosedBoundedIntervalNet bound row, transport, replay, provenance, and the local NameCert row.

Apply Definition 1449.2 and Definition 1449.3. These route every Real-facing read through the displayed windows, readback, seals, and bound row, so a compactness consumer can only see the bounded-family route already named by $I, W, Q, R, B, H, C, P, N$.

Finally apply Definition 1449.4 and Definition 1449.5. The bound ledger refuses compactness extraction, and the obligation surface is exhausted before any downstream compactness consumer reads the packet. Therefore compactness requires an explicit downstream finite-net or compactness row. □

Theorem 1449.8 (Bounded real family least-upper-bound refusal)**.** *For every accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier* $F = (I, W, Q, R, B, H, C, P, N)$*, the common bound row* B *is a* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row and not a supremum, least-upper-bound, order-completeness, or trichotomy witness. A least-upper-bound consumer must therefore provide its own supremum or completeness row outside the bounded-family packet.*

Proof. Read the carrier through Definition 1449.1. The bound coordinate is named as $B : \mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, attached downstream of the finite index-window, StreamName, RegSeqRat, and Real-family rows.

Apply Definition 1449.2. It identifies B as finite located lower and upper interval data, so the row witnesses a displayed common bound rather than a selected least upper bound.

Apply Definition 1449.4 and Definition 1449.5. These theorems remove trichotomy, quotient equality of real names, countable choice, host completeness, and supremum extraction from the rows available to a consumer. Thus a least-upper-bound read must come from a separate downstream row. □

Theorem 1449.9 (Bounded real family cover-selection boundary)**.** *Every cover-selection consumer of an accepted* $\mathsf{BoundedRealFamily}^{\uparrow}$ *carrier must pass through an explicit finite-cover, finite-net, or selected-cover sibling row before exporting a cover conclusion. The bounded-family packet supplies only* $I, W, Q, R, B, H, C, P, N$ *and cannot select a finite subcover from those rows alone.*

Proof. Project the carrier in Definition 1449.1. The only cover-facing data present before downstream consumption are the family windows, rational readback, Real seals, the ClosedBoundedIntervalNet bound row, and the structural rows H, C, P, N.

Use Definition 1449.3. It forces a cover-facing read of a family member or bound assertion to pass through the same StreamName, RegSeqRat, RealUp, and ClosedBoundedIntervalNet route.

Now apply Definition 1449.4 and Definition 1449.5. They exclude open-cover compactness, cover selection, and hidden choice from the displayed bounded-family rows. Hence a cover-selection consumer must provide a separate finite-cover or finite-net sibling row before any cover conclusion is exported. □

Falsifiable prediction: Every $\mathsf{BoundedRealFamily}^{\uparrow}$ Real-facing read factors through finite index windows, StreamName windows, RegSeqRat readback, RealUp family seals, and a ClosedBoundedIntervalNet bound row.

Independence witness: boundedrealsequence, realcauchymodulus, dyadicintervalcover, closedboundedintervalnet, real: $\mathsf{BoundedRealFamily}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an index-window family ledger, StreamName windows, RegSeqRat readback, RealUp family seals, a common bound ledger, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRealFamily}^{\uparrow}$ packet is generated from finite index-window rows, StreamName windows, RegSeqRat readback, RealUp family seals, a ClosedBoundedIntervalNet bound row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1449.1, Definition 1449.2, Definition 1449.3, Definition 1449.4, Definition 1449.5, Definition 1449.6, Definition 1449.7, Definition 1449.8, and Definition 1449.9 bind the finite bounded-family obligation surface, scoped dependency route, and public compactness, least-upper-bound, and cover-selection consumer boundaries over StreamNameUp, RegSeqRatUp, RealUp, and ClosedBoundedIntervalNetUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRealFamily}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.BoundedRealFamilyUp.BoundedRealFamilyTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, trichotomy, quotient equality of real names, countable choice, an ambient supremum principle, open-cover compactness, or host completeness.

Upgrade path: Bridge closure requires the standard bridge row needed by downstream compactness, least-upper-bound, and cover-selection routes.

Chapter 1450

A Concrete Naming Certificate for $\mathsf{MetricBall}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{MetricBall}^{\uparrow}$ packet records the center-radius open ball used by metric-generated topology, but as finite BEDC NameCert rows rather than as an ambient subset. It extracts the singleton-ball datum used inside $\mathsf{Topology}^{\uparrow}$ into a reusable surface for topology, continuous maps, compact nets, and metric arguments that need the same carrier before generated-open exactness is invoked. The center-radius row is the shared dependency surface read by chapter 57, chapter 88, chapter 1757, and chapter 38; each consumer receives the same displayed distance and positive-radius ledger rather than a host subset.

Definition 1450.1 (MetricBall carrier)**.** *A* $\mathsf{MetricBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, d, c, r, \rho, m, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier row with its point classifier and metric source data.*
2. *d is the* $\mathsf{MetricDistanceWitness}$ *row read from X and valued in the* $\mathsf{Real}^{\uparrow}$ *distance surface.*
3. *c is the center row, classified as a point of the carrier named by X.*
4. *r is a* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *radius row, according to the chosen radius ledger.*
5. *ρ is the positive-radius ledger for r, transported through the ordered-real comparison used by the metric source.*
6. *m is the membership and distance-comparison row. For a displayed point x, it records the comparison $d(c, x) <_{\mathsf{R}} r$ and names this comparison as the* $\mathsf{MetricOpenBall}_d(c, r, \rho)$ *membership read.*
7. *H records the* hsame *transports for the carrier, distance witness, center, radius, positive-radius ledger, and membership-comparison row.*
8. *C records the* Cont *routes that replay distance evaluation, radius comparison, membership transport, finite-base refinement, and singleton-ball handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricBall}^{\uparrow}}$ *row.*

The accepted carrier contains no ambient powerset coordinate, no unindexed open predicate, no quotient equality test on points or radii, and no generated topology closure field.

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallTasteGate single carrier alignment`

Theorem 1450.2 (MetricBall NameCert obligations)**.** *For an accepted packet $B = (X, d, c, r, \rho, m, H, C, P, N)$, the local $\mathsf{NameCert}_{\mathsf{MetricBall}^\uparrow}$ obligation surface consists exactly of carrier admission, classifier transport, radius positivity stability, membership transport, finite refinement and intersection readiness, and ledger non-escape for the displayed rows $X, d, c, r, \rho, m, H, C, P, N$.*

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier namecert obligations`

Proof. Carrier admission reads X as the metric carrier and d as the distance witness over that carrier. The center row c and radius row r are admitted only relative to those source rows, and ρ supplies the displayed positive-radius ledger.

Classifier transport is supplied by H. Transporting the carrier, distance witness, center, radius, and positive-radius rows moves the comparison data in m to the transported copy without introducing a second point classifier or a second radius equality test.

Membership transport is the distance-comparison part of the same ledger. The row m names the predicate $d(c, x) <_{\mathsf{R}} r$, while C replays the route from distance evaluation to ordered-real comparison.

Finite refinement and intersection readiness are only readiness claims. They expose the singleton-ball row and its replayable comparison so that a finite list of such rows can later be concatenated by $\mathsf{Topology}^\uparrow$, but they do not themselves close arbitrary generated opens.

Ledger non-escape follows by inspecting the carrier. Every exported read is one of $X, d, c, r, \rho, m, H, C, P, N$, so no ambient powerset, unindexed open predicate, quotient equality test, or generated topology closure field can be recovered from the packet. □

Theorem 1450.3 (MetricBall refinement obligations)**.** *For an accepted $\mathsf{MetricBall}^\uparrow$ packet $B = (X, d, c, r, \rho, m, H, C, P, N)$, the refinement-facing obligation surface supplies exactly three additional rows. The first row transports positive-radius data through the $\mathsf{Rat}^\uparrow$ or $\mathsf{Real}^\uparrow$ radius ledger before any consumer reads the comparison $d(c, x) <_{\mathsf{R}} r$. The second row refines the finite base into the topology singleton-ball index of Definition 88.10. The third row routes bounded-set containment through $\mathsf{BoundedSet}^\uparrow$ without replacing the center-radius packet by a host subset, selected supremum, compactness proof, or ambient real completeness.*

Proof. Start with the carrier and NameCert obligations of Definition 1450.1 and Definition 1450.2. They expose the carrier row, distance witness, center, radius, positive-radius ledger, membership comparison, transport, replay, provenance, and local name as the only rows of the packet.

The positive-radius row is the transport route of Definition 1450.6. It keeps r, ρ, and m together through the ordered-real comparison used by the metric source, so the $\mathsf{Rat}^\uparrow$ or $\mathsf{Real}^\uparrow$ radius cannot be read independently of its positivity evidence.

The finite-base refinement row is the topology handoff of Definition 1450.4. It sends the center-radius datum to the singleton-ball index in Definition 88.10, and then to the singleton carrying theorem already cited by that handoff.

The bounded containment row is the route of Definition 1450.5. It hands the same transported comparison to $\mathsf{BoundedSet}^\uparrow$ and leaves no coordinate for a host subset, selected maximum, compactness witness, or ambient $\mathsf{Real}^\uparrow$ completeness. □

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier refinement obligations`

Theorem 1450.4 (MetricBall topology handoff)**.** *Every* $\mathsf{Topology}^{\uparrow}$ *metric-generated singleton-ball open read factors through a* $\mathsf{MetricBall}^{\uparrow}$ *packet before it enters generated-open exactness. In particular, the singleton ball datum of Definition 88.10 and the singleton carrying theorem of Definition 88.11 are read as the* $X, d, c, r, \rho, m, H, C, P, N$ *rows of* $\mathsf{MetricBall}^{\uparrow}$ *and only then handed to the indexed topology carrier.*

Proof. Start with a metric-generated singleton-ball open in $\mathsf{Topology}^{\uparrow}$. By Definition 88.10, its datum is a center, a positive radius, and the open-ball predicate obtained from the distance comparison.

Package these entries as X, d, c, r, ρ, m. The metric carrier and distance witness supply X and d, the singleton datum supplies c, r, ρ, and the predicate $\mathsf{MetricOpenBall}_d$ supplies the membership-comparison row m.

Add the structural rows H, C, P, N. They are exactly the transports, continuation replays, provenance, and local name row required by Definition 1450.1.

Now apply Definition 88.11. Its singleton carrying equation reads the same membership row and places the singleton index inside $\mathcal{T}_{d,\mathsf{ball}}$. Thus the generated-open exactness package receives a carried singleton-ball index only after the $\mathsf{MetricBall}^{\uparrow}$ packet has exposed the center-radius NameCert surface. □

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier topology handoff`

Theorem 1450.5 (MetricBall bounded-set containment route)**.** *Every* $\mathsf{BoundedSet}^{\uparrow}$ *membership read that uses a* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger first exposes the* $\mathsf{MetricBall}^{\uparrow}$ *rows* $X, d, c, r, \rho, m, H, C, P, N$*. The bounded-set consumer receives the center-radius comparison only through that packet, not through a host set, supremum, compactness, selected maximum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1450.1. The row m is already the named comparison $d(c, x) <_{\mathsf{R}} r$, and the structural rows H, C, P, N are the only transports, replays, provenance, and local naming data attached to that comparison.

Now read the downstream bounded-set carrier of chapter 1757. Its containment coordinate is a $\mathsf{MetricBall}^{\uparrow}$ ledger, so a membership read reaches bounded-set data only after the center, radius, positive-radius ledger, and comparison row have been opened in the MetricBall packet.

Thus the containment ledger handed to $\mathsf{BoundedSet}^{\uparrow}$ is the same MetricBall row already available to topology, boundedness, diameter, and uniform-space consumers. Since the packet has no coordinate for a host subset, supremum, compactness proof, selected maximum, or ambient real completeness, none of those objects can supply the bounded-set containment route. □

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier boundedset containment route`

Theorem 1450.6 (MetricBall positive-radius transport)**.** *Let* $B = (X, d, c, r, \rho, m, H, C, P, N)$ *be an accepted* $\mathsf{MetricBall}^{\uparrow}$ *packet. If* B *is transported componentwise, then the center row* c*, distance witness* d*, radius row* r*, positive-radius ledger* ρ*, and membership comparison* m *transport together before any* $\mathsf{Topology}^{\uparrow}$ *or* $\mathsf{BoundedSet}^{\uparrow}$ *consumer reads the ball. The dependency route is anchored in the metric source of chapter 57, the topology handoff of chapter 88, the bounded-set containment surface of chapter 1757, and the ordered-real comparison row of chapter 38.*

Proof. Project the carrier of Definition 1450.1. The row H transports exactly the carrier, distance witness, center, radius, positive-radius ledger, and membership-comparison rows named by X, d, c, r, ρ, m.

Apply the NameCert obligations of Definition 1450.2. Classifier transport, radius positivity stability, membership transport, and ledger non-escape all refer to the same displayed rows, so the transported center-radius comparison cannot split into separate topology and bounded-set readings.

For a topology consumer, use Definition 1450.4. The singleton-ball datum enters generated-open exactness only after $X, d, c, r, \rho, m, H, C, P, N$ have been packaged as the $\mathsf{MetricBall}^{\uparrow}$ surface.

For a bounded-set consumer, use Definition 1450.5. The containment ledger likewise reads the transported center, radius, positive-radius ledger, and comparison row before it can serve the downstream $\mathsf{BoundedSet}^{\uparrow}$ membership request. Thus both sibling consumers receive the same transported positive-radius route, with the metric and real dependency anchors still visible. □

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier positive radius transport`

Theorem 1450.7 (MetricBall finite-intersection readiness)**.** *Let*

$$B_0 = (X, d, c_0, r_0, \rho_0, m_0, H_0, C_0, P_0, N_0)$$

and

$$B_1 = (X, d, c_1, r_1, \rho_1, m_1, H_1, C_1, P_1, N_1)$$

be accepted $\mathsf{MetricBall}^{\uparrow}$ *packets over the same* $\mathsf{Met}^{\uparrow}$ *row. If their center, radius, positive-radius, and membership rows have been transported componentwise, then* $\mathsf{Topology}^{\uparrow}$ *may read the pair as a finite-intersection request only through the displayed rows* $X, d, c_i, r_i, \rho_i, m_i, H_i, C_i, P_i, N_i$*, the ordered-real positive-radius ledgers* ρ_i*, and the singleton-ball indexed-open route of Definition 88.10. The request has no coordinate for host powersets, selected radii, compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 1450.2 to each packet. It exposes the carrier, distance witness, center, radius, positive-radius ledger, membership comparison, transport, replay, provenance, and local name as the only available rows.

Apply Definition 1450.3. The finite-base row is already constrained to the topology singleton-ball index, while the bounded-set row remains a separate containment route and supplies no host subset.

Use Definition 1450.4 for the topology consumer. Each singleton-ball datum enters $\mathsf{Topology}^{\uparrow}$ through the indexed-open route of Definition 88.10, so the intersection request is a finite request over two displayed singleton-ball indices rather than a powerset operation.

Finally apply Definition 1450.6 to both packets. The transported rows keep c_i, r_i, ρ_i, m_i together through the ordered-real ledger, so no selected radius, compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle can be read from the finite-intersection request. □

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier finite intersection readiness`

Theorem 1450.8 (MetricBall obligation transport package)**.** *Every topology, bounded-set, finite-intersection, or compact-net consumer of an accepted* $\mathsf{MetricBall}^{\uparrow}$ *packet*

$$B = (X, d, c, r, \rho, m, H, C, P, N)$$

must read the packet through the same displayed $\mathsf{Met}^{\uparrow}$ *source row* X*, metric-distance row* d*, center row* c*, positive* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *radius rows* r, ρ*, membership comparison row* m*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{MetricBall}^{\uparrow}}$ *row* N*. The transport package has no coordinate for an ambient powerset, a selected replacement radius, compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier obligation transport package`

Proof. Start with the carrier of Definition 1450.1. It displays exactly $X, d, c, r, \rho, m, H, C, P, N$, so every consumer first receives the metric source, distance witness, center, radius, positive-radius ledger, and membership comparison before any downstream read is available.

For topology consumers, apply Definition 1450.4. The singleton-ball datum reaches generated-open exactness only after the MetricBall rows have been packaged.

For bounded-set consumers, apply Definition 1450.5. The containment ledger reads the same center-radius comparison and does not introduce a host subset or supremum coordinate.

For finite-intersection and compact-net consumers, use Definition 1450.7 together with Definition 1450.6. These rows keep r, ρ, m attached to the same metric source and ordered-real comparison before any finite request is replayed.

Thus the shared obligation package is the displayed tuple $X, d, c, r, \rho, m, H, C, P, N$. Since the carrier contains no powerset, selected radius, compactness, or ambient completeness coordinate, none can be exported by transport. □

Theorem 1450.9 (MetricBall RegSeqRat Real window boundary)**.** *Every* $\mathsf{MetricBall}^{\uparrow}$ *read over* $\mathsf{Real}^{\uparrow}$*-facing points must display the regular rational readback and real-seal route before any ball-membership answer is exported. Concretely, a consumer receives the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, the* Cont *replay route,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetricBall}^{\uparrow}}$ *rows together with the carrier rows* X, d, c, r, ρ, m *of Definition 1450.1. The boundary is anchored in the finite-window L10 rows of chapter 301, chapter 291, and chapter 38; it exports no host-real equality, unrestricted metric topology, or hidden completion principle.*

Proof. Project the carrier of Definition 1450.1. The membership row m is not a bare subset predicate; it is the named comparison $d(c, x) <_{\mathsf{R}} r$ transported with $X, d, c, r, \rho, H, C, P, N$.

For a real-facing point, the comparison can be consumed only after the finite real-name route has been displayed. The $\mathsf{RegSeqRat}^{\uparrow}$ readback supplies the inspected rational observation, the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance ledger, and the $\mathsf{Real}^{\uparrow}$ row supplies the terminal seal described by the L10 sibling chapters.

Apply Definition 1450.6. It keeps the center, distance witness, radius, positive-radius ledger, and membership comparison together under hsame transport before topology or bounded-set consumers read the ball.

Finally use Definition 1450.2. Ledger non-escape says that every exported read remains inside the displayed rows, so the real-facing ball answer cannot bypass the regular readback, dyadic tolerance, real seal, continuation replay, provenance, or local NameCert boundary. □

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier regseqrat real window boundary`

Theorem 1450.10 (MetricBall Cauchy-filter entry boundary)**.** *Completion and filter consumers may use* $\mathsf{MetricBall}^{\uparrow}$ *only as a finite tolerance-window entry row. The entry row exposes the carrier, distance witness, center, radius, positive-radius ledger, membership comparison,* hsame *transport,* Cont *route,* Pkg *provenance, and local* $\mathsf{NameCert}$ *data of Definition 1450.1, together with the finite-window real readback boundary of Definition 1450.9. It does not provide generated-open topology, arbitrary metric topology, a selected center outside the displayed row, quotient equality, compactness, or any unbounded filter object.*

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier cauchy filter entry boundary`

Proof. Start from the finite-entry view of Definition 1450.9. A completion or filter consumer sees the real-facing membership comparison only after the regular rational readback, dyadic tolerance, real seal, transport, replay, provenance, and local NameCert rows have been displayed.

Use Definition 1450.3 to locate the topology-facing part of the packet. The finite-base row is a singleton-ball index for Definition 88.10; it is not generated-open closure and does not carry arbitrary metric topology.

Use Definition 1450.7 for finite combinations. That theorem permits only a finite request over displayed singleton-ball indices, so a filter consumer may record a tolerance-window entry but cannot extract compactness, quotient equality, selected centers, or an unbounded family of opens.

The bounded-set route of Definition 1450.5 gives the same restriction from the containment side. It hands downstream consumers the transported center-radius comparison and no host subset, selected maximum, compactness witness, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. □

Theorem 1450.11 (MetricBall public export)**.** *The public* $\mathsf{MetricBall}^{\uparrow}$ *export is the center-radius membership packet*

$$B = (X, d, c, r, \rho, m, H, C, P, N)$$

of Definition 1450.1. Topology, bounded-set, finite-intersection, compact-net, and metric consumers may consume the packet only through the displayed distance-comparison row m*, together with its metric source* X, d*, center* c*, radius and positivity rows* r, ρ*, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.MetricBallUp.MetricBallCarrier public export`

Proof. Project the carrier in Definition 1450.1. The only membership-facing coordinate is the comparison row m, and the rows $X, d, c, r, \rho, H, C, P, N$ are precisely the data that make that comparison transportable and replayable.

For topology consumers, apply Definition 1450.4. For bounded-set consumers, apply Definition 1450.5. For finite-intersection and metric-entry consumers, use Definition 1450.7 and Definition 1450.10.

Each route reads the same center-radius comparison before any downstream object is available. Since the carrier has no ambient powerset, selected radius, compactness, host subset, quotient equality, or Real completeness coordinate, the displayed packet is exactly the public export surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricBall}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricBall}^{\uparrow}$ packet is generated from a MetricSpace carrier row, a MetricDistanceWitness row, a center row, a RatUp or RealUp positive-radius row, a membership comparison row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricBall}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1450.11 exports the center-radius membership packet of Definition 1450.1, with Definition 1450.2, Definition 1450.3, Definition 1450.4, and Definition 1450.7 displaying the obligation surface over $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricBall}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a full metric topology, arbitrary generated-open closure, compactness, continuity, quotient equality for metric points, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, metric membership transport, positive-radius stability, finite-base handoff, finite-intersection readiness, and ledger exactness for BEDC.Derived.MetricBallUp.

Chapter 1451

A Concrete Naming Certificate for $\mathsf{MetricClosedBall}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{MetricClosedBall}^{\uparrow}$ packet records center-radius closed balls as finite BEDC NameCert rows. It sits beside the open-ball carrier of chapter 1450, but its membership row is read through non-strict ordered-real comparison over MetricDistanceWitness, Real/Rat order, hsame, Cont, Pkg, and NameCert rows rather than through an ambient closed subset.

Definition 1451.1 (MetricClosedBall carrier)**.** *A* $\mathsf{MetricClosedBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, d, c, r, \rho, m, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier row with its point classifier and metric source data.*
2. *d is the* MetricDistanceWitness *row read from X and valued in the* $\mathsf{Real}^{\uparrow}$ *distance surface.*
3. *c is the center row, classified as a point of the carrier named by X.*
4. *r is a* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *radius row, according to the chosen radius ledger.*
5. *ρ is the radius order ledger for r, recording nonnegativity and, when the packet is handed to an open-ball consumer, the separate positive-radius comparison needed by* $\mathsf{MetricBall}^{\uparrow}$*.*
6. *m is the closed-membership and distance-comparison row. For a displayed point x, it records the comparison $d(c, x) \leq_{\mathsf{R}} r$ and names this comparison as the* $\mathsf{MetricClosedBall}_d(c, r, \rho)$ *membership read.*
7. *H records the* hsame *transports for the carrier, distance witness, center, radius, radius order ledger, and closed-membership comparison row.*
8. *C records the* Cont *routes that replay distance evaluation, non-strict radius comparison, closed-membership transport, and boundary handoff to open-ball rows when a strict comparison is separately supplied.*
9. *P is the* Pkg *provenance over* $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricClosedBall}^{\uparrow}}$ *row.*

The accepted carrier contains no ambient powerset coordinate, no topology-closure predicate, no quotient equality test on points or radii, no compactness witness, and no generated-open field.

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallTasteGate single carrier alignment`

Theorem 1451.2 (MetricClosedBall NameCert obligations)**.** *For an accepted packet $Q = (X, d, c, r, \rho, m, H, C, P, N)$ the local* $\mathsf{NameCert}_{\mathsf{MetricClosedBall}^{\uparrow}}$ *obligation surface consists exactly of carrier admission, classifier transport, radius nonnegativity stability, positive-radius stability for strict-boundary handoff when that handoff is requested, closed-membership transport, boundary comparison with* $\mathsf{MetricBall}^{\uparrow}$*, and ledger non-escape for the displayed rows $X, d, c, r, \rho, m, H, C, P, N$.*

Proof. Carrier admission reads X as the metric carrier and d as the distance witness over that carrier. The center row c and radius row r are admitted only relative to those source rows, while ρ supplies the displayed ordered-real radius ledger.

Classifier transport is supplied by H. Transporting the carrier, distance witness, center, radius, and radius ledger moves the comparison data in m to the transported copy without introducing a second point classifier or a second radius equality test.

Closed-membership transport is the non-strict distance-comparison part of the same ledger. The row m names the predicate $d(c, x) \leq_{\mathsf{R}} r$, while C replays the route from distance evaluation to ordered-real comparison.

Boundary comparison with $\mathsf{MetricBall}^{\uparrow}$ is conditional on a strict comparison row. When an open-ball consumer supplies the positive-radius and strict-membership data required by Definition 1450.1, the route passes through $\mathsf{MetricBall}^{\uparrow}$; otherwise the closed-ball packet exports only its non-strict comparison row.

Ledger non-escape follows by inspecting the carrier. Every exported read is one of $X, d, c, r, \rho, m, H, C, P, N$, so no ambient subset, topology closure, quotient equality test, compactness witness, or generated-open field can be recovered from the packet. □

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier namecert obligations`

Theorem 1451.3 (MetricClosedBall boundary handoff)**.** *Every open-ball consumer of a center-radius strict comparison passes through* $\mathsf{MetricBall}^{\uparrow}$*, while every closed-ball consumer of $Q = (X, d, c, r, \rho, m, H, C, P, N)$ can read only the non-strict comparison row $d(c, x) \leq_{\mathsf{R}} r$ together with its transports and replay routes. The* $\mathsf{MetricClosedBall}^{\uparrow}$ *packet therefore does not recover ambient subsets, quotient point equality, compactness, or topology closure.*

Proof. Start with the accepted closed-ball carrier of Definition 1451.1. Its membership coordinate is m, and m records only the non-strict comparison $d(c, x) \leq_{\mathsf{R}} r$.

If a downstream consumer asks for a strict center-radius ball, the required predicate is not m. It is the open comparison row used by Definition 1450.1, so the request factors through the $\mathsf{MetricBall}^{\uparrow}$ packet and its positive-radius ledger.

If the downstream consumer remains closed-ball facing, the only exported comparison is the non-strict row transported by H and replayed by C. Package provenance P and the local naming row N identify this as the $\mathsf{MetricClosedBall}^{\uparrow}$ surface, not as a topology closure or compactness object.

Thus the handoff is exact at the boundary: strict consumers use $\mathsf{MetricBall}^{\uparrow}$, and closed consumers receive no coordinate from which to reconstruct an ambient subset, quotient point equality, compactness proof, or generated topology closure. □

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier metricball boundary handoff`

Theorem 1451.4 (MetricClosedBall carrier obligations)**.** *For an accepted* $\mathsf{MetricClosedBall}^{\uparrow}$ *packet* $Q = (X, d, c, r, \rho, m, H, C, P, N)$*, carrier admission is exactly the simultaneous admission of the* $\mathsf{Met}^{\uparrow}$ *row* X*, the* MetricDistanceWitness *row* d*, the center row* c*, the radius row* r*, the nonnegative radius ledger* ρ*, the closed-membership comparison row* m*, and the support rows* H, C, P, N*. The packet exports no ambient closed subset, topology-closure predicate, compactness witness, quotient point equality, quotient radius equality, or generated-open field.*

Proof. Read the carrier tuple of Definition 1451.1. The rows X, d, c, r, ρ, m are the only mathematical rows admitted before the structural rows appear.

The support rows do not add a second carrier. The row H transports those displayed coordinates, C replays their distance and comparison route, P records the named provenance, and N gives the local certificate name.

Since no tuple coordinate stores an ambient subset, closure predicate, compactness object, quotient equality test, or generated-open field, none of those objects can be projected from an accepted packet. □

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier obligations`

Theorem 1451.5 (MetricClosedBall radius classifier stability)**.** *Let* $Q = (X, d, c, r, \rho, m, H, C, P, N)$ *and* $Q' = (X', d', c', r', \rho', m', H', C', P', N')$ *be accepted* $\mathsf{MetricClosedBall}^{\uparrow}$ *packets whose carrier, distance, center, radius, and radius-ledger rows are paired by the displayed componentwise* hsame *data in* H *and* H'*. Then the closed-membership classifier transported by* H *and replayed by* C *carries the non-strict comparison row* $d(c, x) \leq_{\mathsf{R}} r$ *to the corresponding row* $d'(c', x') \leq_{\mathsf{R}} r'$*. The transport preserves the radius nonnegativity ledger and the optional positive-radius handoff data used by* $\mathsf{MetricBall}^{\uparrow}$*.*

Proof. Start from the displayed hsame rows. They pair the metric carrier, distance witness, center, radius, and radius ledger componentwise, so the radius classifier is not transported by a host equality of reals or by a quotient radius comparison.

Now replay the closed-membership route. The row C reads distance evaluation first and then the non-strict ordered-real comparison in m, so transporting d, c, r, ρ transports the comparison row itself.

For strict-boundary consumers, the positive-radius data remain a separate part of ρ. Thus the same transport preserves the closed non-strict classifier and, when present, the positive-radius handoff required before the request can pass to $\mathsf{MetricBall}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier radius classifier stability`

Theorem 1451.6 (MetricClosedBall RealAlgOrder boundary)**.** *Every* $\mathsf{RealAlgOrder}^{\uparrow}$ *boundary read made by an accepted* $\mathsf{MetricClosedBall}^{\uparrow}$ *packet factors through the displayed distance witness* d*, the* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Rat}^{\uparrow}$ *radius row* r*, the radius ledger* ρ*, and the closed-membership comparison row* m*. If a downstream consumer asks for a strict boundary comparison, the route first passes through the* $\mathsf{MetricBall}^{\uparrow}$ *handoff of Definition 1451.3; otherwise it remains the non-strict RealAlgOrder comparison* $d(c, x) \leq_{\mathsf{R}} r$ *carried by* m*.*

Proof. Inspect the comparison coordinates of Q. The distance side is the $\mathsf{Real}^{\uparrow}$-valued witness row d, the radius side is r, and the admissible radius facts are exactly those recorded in ρ.

The non-strict order read is m. It routes the displayed distance value and displayed radius through the RealAlgOrder or Rat-order rows named by P, then returns the membership classifier $d(c, x) \leq_{\mathsf{R}} r$.

If a strict comparison is requested, the packet must use the separate positive-radius and strict-membership data described in Definition 1451.3. That request therefore factors through $\mathsf{MetricBall}^{\uparrow}$ and does not create a second closed-ball boundary.

Thus every RealAlgOrder-facing read is either the displayed non-strict comparison row m or the explicit $\mathsf{MetricBall}^{\uparrow}$ strict-boundary handoff. No host closed subset, topology closure, quotient point equality, compactness witness, or generated-open field is exported. □

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier realalgorder boundary`

Theorem 1451.7 (MetricClosedBall boundary classifier transport)**.** *Let $Q = (X, d, c, r, \rho, m, H, C, P, N)$ and $Q' = (X', d', c', r', \rho', m', H', C', P', N')$ be accepted $\mathsf{MetricClosedBall}^{\uparrow}$ packets whose carrier, distance, center, radius, and radius-ledger rows are classified componentwise by the displayed* hsame *data. Then the boundary row m carrying $d(c, x) \leq_{\mathsf{R}} r$ transports through H and replays through C to the boundary row m' carrying $d'(c', x') \leq_{\mathsf{R}} r'$. The transport introduces no topology closure, compactness witness, quotient point equality, or ambient subset data.*

Proof. Project the two packets. The only rows that can affect the closed boundary classifier are the metric carrier, distance witness, center, radius, radius ledger, membership row, and their transport and continuation data.

Use the classifier definition from Definition 1451.1. The row m is precisely the non-strict comparison $d(c, x) \leq_{\mathsf{R}} r$, and the corresponding row in Q' is m'.

Apply radius classifier stability from Definition 1451.5. The componentwise hsame data preserve the radius ledger and the comparison row under transport.

Finally replay the RealAlgOrder boundary route of Definition 1451.6. Since the carrier inventory has no topology-closure, compactness, quotient-point, or ambient-subset coordinate, the transported classifier remains exactly the displayed closed-boundary row. □

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier boundary classifier transport`

Theorem 1451.8 (MetricClosedBall radius source scope)**.** *For an accepted $\mathsf{MetricClosedBall}^{\uparrow}$ packet $Q = (X, d, c, r, \rho, m, H, C, P, N)$, the radius row r is scoped only through the $\mathsf{Rat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ positivity data displayed by ρ. Every closed-membership read must project r, ρ from the same* BHist *carrier, transport them componentwise by H, replay their nonnegative ordered-real route by C, and source the comparison through P, N before using the boundary row m.*

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier radius source scope`

Proof. Project the carrier. The row r is not an ambient real parameter; it is paired with the radius ledger ρ inside the packet.

Use the NameCert obligation theorem to read ρ as the displayed nonnegative radius evidence, with the optional positive-radius handoff remaining separate for strict open-ball consumers.

Transport by H and replay by C. These rows preserve the same RatUp or RealUp positivity source and keep the closed-boundary comparison inside the named carrier rather than inside a quotient radius equality or topology-closure field. □

Theorem 1451.9 (MetricClosedBall center transport scope)**.** *Let $Q = (X, d, c, r, \rho, m, H, C, P, N)$ and $Q' = (X', d', c', r', \rho', m', H', C', P', N')$ be accepted $\mathsf{MetricClosedBall}^{\uparrow}$ packets related by displayed componentwise* hsame *rows. The center row c may be transported only along the $\mathsf{Met}^{\uparrow}$ carrier classifier named by X and X', and the transported boundary read remains stable only after the distance witness, radius ledger,* Cont *replay,* Pkg *provenance, and local* NameCert *rows have been read.*

Proof. Read X and X' first. They are the only carrier rows that classify the centers, so center transport cannot be detached from the underlying $\mathsf{Met}^{\uparrow}$ classifier.

Use the boundary classifier transport theorem. It carries c together with the distance witness, radius row, radius ledger, and membership comparison; H, H' supply the componentwise identifications and C, C' replay the distance route.

The provenance rows P, P' and naming rows N, N' keep the transported center inside the same MetricClosedBall surface. No ambient subset, generated topology, or quotient point equality is introduced. □

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier center transport scope`

Theorem 1451.10 (MetricClosedBall RealAlgOrder boundary scope)**.** *For every accepted* $\mathsf{MetricClosedBall}^{\uparrow}$ *packet* $Q = (X, d, c, r, \rho, m, H, C, P, N)$*, the boundary inequality row* m *is scoped to the RealAlgOrder or Rat-order comparison named by the distance witness* d*, the radius row* r*, and the ledger* ρ*. Apartness-compatible strict comparisons may enter only through the separate* $\mathsf{MetricBall}^{\uparrow}$ *handoff; the closed-ball packet itself exports the non-strict comparison by* BHist *projection,* hsame *transport,* Cont *replay, and* $\mathsf{NameCert}$ *provenance.*

Proof. Inspect m. It records the non-strict boundary comparison $d(c, x) \leq_{\mathsf{R}} r$ and has no coordinate for an ambient closed subset.

Replay the RealAlgOrder boundary theorem. The comparison consumes d, r, ρ and then returns the closed-membership classifier through the same displayed order route.

If an apartness-compatible strict comparison is needed, use the explicit MetricBall boundary handoff. That handoff is separate from m, so the closed-ball scope remains the displayed non-strict boundary route and does not become compactness, topology closure, or quotient equality. □

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier realalgorder boundary scope`

Theorem 1451.11 (MetricClosedBall bridged export)**.** *For every accepted* $\mathsf{MetricClosedBall}^{\uparrow}$ *packet* $Q = (X, d, c, r, \rho, m, H, C, P, N)$*, the public export bridges the non-strict metric boundary row to any abstract closed-ball consumer exactly through* $X, d, c, r, \rho, m, H, C, P, N$*. Strict-radius consumers do not read this export directly: they factor through the sibling* $\mathsf{MetricBall}^{\uparrow}$ *handoff and the displayed RealAlgOrder comparison rows before returning to the closed-ball boundary.*

Proof. Apply Definition 1451.2. It fixes the carrier admission, classifier transport, radius ledger, closed-membership transport, boundary comparison, and ledger non-escape rows of Q.

Apply Definition 1451.3. It separates strict-radius consumers from the non-strict closed-ball export, so the strict route must pass through $\mathsf{MetricBall}^{\uparrow}$ rather than reading the closed boundary as an open ball.

Apply Definition 1451.6. It identifies the closed export as the RealAlgOrder comparison row carried by d, r, ρ, m and transported through H, C, P, N. Thus the bridge-facing consumer receives exactly the displayed packet rows and no ambient closed subset, quotient point equality, compactness witness, or topology closure. □

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallCarrier bridged export`

Definition 1451.12 (MetricClosedBall mature boundary inventory)**.** *The mature* $\mathsf{MetricClosedBall}^{\uparrow}$ *export inventory is exactly the finite list consisting of the* $\mathsf{Met}^{\uparrow}$ *carrier row, the* $\mathsf{MetricDistanceWitness}$ *row, the center row, the radius row, the radius ledger, the non-strict boundary comparison row, the strict-boundary handoff through* $\mathsf{MetricBall}^{\uparrow}$ *when separately supplied, the* $\mathsf{RealAlgOrder}^{\uparrow}$ *or* $\mathsf{Rat}^{\uparrow}$

order source, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetricClosedBall}^{\uparrow}}$ *row. No mature export includes compactness, a full metric topology, topology closure, quotient equality for points or radii, ambient subset data, Lean verification, or bridge checking.*

Lean4 (definition) `BEDC.Derived.MetricClosedBallUp.MetricClosedBallMatureBoundaryInventory`

Lean4 ✓ `BEDC.Derived.MetricClosedBallUp.MetricClosedBallMatureBoundaryInventoryCertificate`

Closure status for $\mathsf{NameCert}_{\mathsf{MetricClosedBall}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricClosedBall}^{\uparrow}$ packet is generated from a MetricSpace carrier row, a MetricDistanceWitness row, a center row, a RatUp or RealUp radius row, a nonnegative radius ledger with optional positive-radius handoff data, a closed-membership comparison row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricClosedBall}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1451.8, Definition 1451.9, Definition 1451.10, Definition 1451.11, and Definition 1451.12 export the mature $\mathsf{MetricClosedBall}^{\uparrow}$ boundary inventory through carrier admission, closed-membership transport, radius nonnegativity, strict-boundary handoff, order-source routing, and ledger non-escape.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricClosedBall}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim compactness, full metric topology, topology closure, quotient equality for metric points or radii, ambient subsets, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode the same carrier admission, closed-membership transport, radius nonnegativity, strict-boundary handoff, and ledger non-escape obligations for BEDC.Derived.MetricClosedBallUp.

Chapter 1452

A Concrete Naming Certificate for $\mathsf{LocatedInfimum}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedInfimum}^{\uparrow}$ packet records greatest-lower-bound data by finite lower-bound ledgers and upper-approximation rows, before any ambient completeness principle for $\mathsf{Real}^{\uparrow}$ is available. It is the lower-bound companion to the $\mathsf{LocatedSupremum}^{\uparrow}$ certificate of chapter 1427 and consumes the bounded-family source supplied by chapter 1449. The carrier therefore gives later interval and bounded-family arguments a finite NameCert target for infimum-shaped reasoning while keeping quotient real equality, trichotomy, countable choice, and host completeness outside the packet.

Definition 1452.1 (LocatedInfimum carrier)**.** *A* $\mathsf{LocatedInfimum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, L, G, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the bounded real family row, read through the finite index-window,* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and common-bound ledgers of* $\mathsf{BoundedRealFamily}^{\uparrow}$.
2. *L is the lower-bound ledger. It records the inspected lower-bound claims and the finite comparison rows that certify each requested member of F above the proposed lower surface.*
3. *G is the greatest-lower-approximation ledger. For each precision request in the displayed window, it stores a finite family-side witness above the proposed lower surface and below every displayed stronger lower-bound candidate at that precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *precision-window row that fixes the finite observations of the family, lower-bound ledger, and greatest-lower-approximation ledger in scope.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that repacks the windowed observations as regular rational readback data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only through F, L, G, W, R.*
7. *H records componentwise* hsame *transports for the family row, lower-bound ledger, greatest-lower-approximation ledger, precision window, regular handoff, real seal, continuation replay, provenance, and local naming row.*
8. *C records displayed* Cont *routes that replay lower-bound reads, greatest-lower-approximation reads, classifier transport, regular-rational handoff, and real-seal readback.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedInfimum}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{BoundedRealFamily}^{\uparrow}$, BishopRealComparison StreamName$^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedInfimum}^{\uparrow}}$ *row.*

The accepted carrier stores no Dedekind cut completion, no arbitrary infimum operator, no quotient real equality test, no trichotomy oracle, no countable-choice functional, and no host-completeness coordinate.

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.TasteGate.LocatedInfimumTasteGate single carrier alignment`

Theorem 1452.2 (LocatedInfimum lower-bound obligation)**.** *For an accepted packet $I = (F, L, G, W, R, E, H, C, P$ every lower-bound read exposed by the local* $\mathsf{NameCert}_{\mathsf{LocatedInfimum}^{\uparrow}}$ *row factors through the bounded-family row F, the lower-bound ledger L, the precision window W, the regular-rational handoff R, and the* $\mathsf{Real}^{\uparrow}$ *seal E, together with the transport, continuation, provenance, and local naming rows. No lower-bound obligation may invoke Dedekind completeness, an arbitrary infimum operator, quotient real equality, trichotomy, countable choice, or host completeness.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumLowerBoundObligation`

Proof. Project the accepted carrier. The only family source is F, and the only lower-bound source is L, so a lower-bound consumer must first inspect the bounded-family row and then one of the displayed comparison entries of L.

The precision window W determines which finite observations are admitted. The handoff row R repacks those observations as regular rational data, and the seal E is reached only after this route has been replayed.

The structural rows cannot enlarge the obligation surface. The transports in H, continuations in C, provenance in P, and name row N preserve the displayed route, but none carries a Dedekind completion, arbitrary infimum operator, quotient equality test, trichotomy oracle, countable-choice functional, or host-completeness field. □

Theorem 1452.3 (LocatedInfimum greatest-lower-bound obligation)**.** *For an accepted packet $I = (F, L, G, W, R, E, H, C, P, N)$, the greatest-lower-bound obligation is exactly the finite demand that each precision row of W receives a displayed witness in G whose readback lies above the proposed lower surface and blocks every displayed stronger lower-bound candidate at that precision. The obligation is local to $F, L, G, W, R, E, H, C, P, N$ and does not assert a global infimum for arbitrary real families.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumGreatestLowerBoundObligation`

Proof. Fix a precision row in W. By definition of the carrier, G is the only ledger that can answer greatest-lower-approximation requests at that precision.

Read the corresponding G entry. It supplies a finite family-side witness, and the route through R and E gives the regular-rational and real-name readback for the same displayed observation.

The comparison is therefore local: the witness is checked against the lower surface and against the stronger lower-bound candidates that are actually present in the window. Since the packet has no coordinate for arbitrary families or an ambient completeness principle, the row proves only the displayed finite greatest-lower-bound obligation. □

Theorem 1452.4 (LocatedInfimum precision-window induction)**.** *For an accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet $I = (F, L, G, W, R, E, H, C, P, N)$, induction over the finite precision-window row W builds*

the displayed witness ledger G from the bounded-family row F, lower-bound ledger L, precision window W, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R,* $\mathsf{Real}^{\uparrow}$ *seal E, transport row H, continuation row C, provenance row P, and local naming row N. The induction uses no Dedekind completeness, arbitrary infimum operator, quotient real equality, trichotomy, countable choice, or host completeness.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumWindowInduction`

Proof. Proceed over the displayed finite window W. The empty window has no precision request, so the witness ledger contributes no greatest-lower-approximation entry.

For a nonempty window, read the next precision request together with the already displayed bounded-family and lower-bound rows F and L. The finite comparison data at that request supplies the corresponding G entry, and the remaining window is handled by the induction hypothesis.

The handoff and seal rows are structural at this stage. The row R repacks the constructed window ledger as regular rational readback, and E seals only that readback. The rows H, C, P, N transport, replay, source, and name the same finite construction, so no completeness, quotient-equality, trichotomy, or choice principle enters the induction. □

Theorem 1452.5 (LocatedInfimum window ledger coverage)**.** *For an accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet $I = (F, L, G, W, R, E, H, C, P, N)$, every precision-window entry admitted by the induction of Definition 1452.4 is consumed by exactly one of the lower-bound ledger L, the greatest-lower-approximation ledger G, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, or the* $\mathsf{Real}^{\uparrow}$ *seal row E, with transport, replay, provenance, and local naming read only through H, C, P, N. The coverage remains internal to $F, L, G, W, R, E, H, C, P, N$ and exports no Dedekind completeness, arbitrary infimum operator, quotient real equality, trichotomy, countable choice, host completeness, or unlisted real-order oracle.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumWindowLedgerCoverage`

Proof. Proceed by induction over the displayed finite precision window W. The empty window has no admitted precision entry, so there is no ledger row to consume.

For a successor window, read the new precision entry and apply the lower-bound obligation of Definition 1452.2. If the entry asks for a lower-bound comparison, it is consumed by the displayed lower-bound ledger L and no other analytic ledger receives that entry.

If the entry asks for a greatest-lower-approximation witness, apply Definition 1452.3. The corresponding row is consumed by G at the same precision, and the induction hypothesis covers the remaining window entries.

The remaining Real-facing reads are structural consequences of the same covered entries. Classifier stability, Definition 1452.6, preserves the assignment under H, C, P, N, while ledger exactness, Definition 1452.7, forces every regular-rational handoff and Real seal read through R and E. Thus each admitted precision-window entry is covered by exactly one displayed analytic row before any handoff or seal is exported, and no forbidden endpoint has a carrier coordinate. □

Theorem 1452.6 (LocatedInfimum classifier stability)**.** *Let $I = (F, L, G, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet. Replacing any displayed component along the corresponding* hsame *transport in H preserves lower-bound reads, greatest-lower-approximation reads,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal access, continuation replay, provenance, and the local* $\mathsf{NameCert}_{\mathsf{LocatedInfimum}^{\uparrow}}$ *classifier. Thus the classifier is stable under componentwise BEDC transport.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumClassifierStability`

Proof. Use the transport ledger H component by component. The family row, lower-bound ledger, greatest-lower-approximation ledger, precision window, regular handoff, real seal, continuation row, provenance row, and name row each have their own displayed hsame transport.

Transport the lower-bound route first. The route still starts at F, reads L inside the same window W, passes through R, and reaches E.

Transport the greatest-lower-approximation route next. The row G is moved with the same precision window and the same handoff and seal rows, so the finite witness relation seen by the classifier is unchanged.

Finally replay C and P after transport. They can only replay and source the transported rows, so the local classifier has no new field through which to distinguish transported copies beyond the displayed hsame data. □

Theorem 1452.7 (LocatedInfimum ledger exactness)**.** *Every Real-facing observation exported by an accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet is obtained from one of the displayed rows* $F, L, G, W, R, E, H, C, P, N$*. In particular, lower-bound, greatest-lower-approximation, handoff, and seal observations are exhausted by the ledger rows, and the packet exports no hidden Dedekind-completeness, arbitrary-infimum, quotient-equality, trichotomy, countable-choice, or host-completeness witness.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumLedgerExactness`

Proof. Begin with a Real-facing observation. The carrier contains only one real seal row, namely E, and the definition makes E reachable only after the bounded-family row, lower-bound ledger, greatest-lower-approximation ledger, precision window, and regular handoff have been displayed.

Inspect the possible observation classes. Lower-bound reads come from L, greatest-lower-approximation reads come from G, window restrictions come from W, and regular rational readback comes from R.

The remaining rows are structural. They transport, replay, source, or name the same finite rows, and therefore cannot create an unlisted completion principle or choice principle. Hence every exported observation is ledger-exact for $F, L, G, W, R, E, H, C, P, N$. □

Theorem 1452.8 (LocatedInfimum lower-cut stability)**.** *For every accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet* $I = (F, L, G, W, R, E, H, C, P, N)$*, the lower-cut boundary determined by the lower-bound row* L *and the greatest-lower-bound approximation row* G *is preserved under the classifier and ledger transport displayed by* H, C, P, N*. In particular, any transported consumer reads the same finite lower-bound comparisons, the same precision-window witnesses, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal before it treats the packet as an infimum boundary.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumLowerCutStability`

Proof. Start with the lower-bound side. By Definition 1452.2, every lower-bound read factors through F, L, W, R, E and the structural rows, so transport cannot move the lower surface to a row outside the carrier.

Now read the greatest-lower-bound side. By Definition 1452.3, every approximation witness is drawn from G at a precision row of W, and by Definition 1452.7 every Real-facing observation is exhausted by $F, L, G, W, R, E, H, C, P, N$.

Finally apply classifier stability from Definition 1452.6. Componentwise hsame transport preserves the lower-bound route, the greatest-lower-approximation route, the regular-rational handoff, the real seal, continuation replay, provenance, and local naming. The transported packet therefore

exposes the same lower-cut boundary and no Dedekind completeness, arbitrary infimum operator, quotient equality test, trichotomy oracle, countable-choice functional, or host-completeness coordinate. □

Theorem 1452.9 (LocatedInfimum supremum-dual route)**.** *Every accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet whose bounded-family row is read through the dual upper-bound presentation first factors through the* $\mathsf{LocatedSupremum}^{\uparrow}$ *sibling of chapter 1427 and the* $\mathsf{BoundedRealFamily}^{\uparrow}$ *row before exposing its lower-bound ledger* L*, greatest-lower-approximation ledger* G*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The resulting route is still the finite carrier route of Definition 1452.1; it does not import a global supremum operator, arbitrary infimum operator, Dedekind completeness, quotient real equality, trichotomy, countable choice, or host completeness.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumSupremumDualRoute`

Proof. Start from the carrier of Definition 1452.1. The bounded-family source is the row F, and the introduction identifies its upper-bound companion as the $\mathsf{LocatedSupremum}^{\uparrow}$ certificate of chapter 1427.

Read the lower-bound side after that dual presentation. By Definition 1452.2, every lower-bound consumer must pass through F, L, W, R, E and the structural rows, so the upper-bound presentation cannot bypass the displayed lower ledger.

Now read the greatest-lower-bound approximation side. Apply Definition 1452.3: the witnesses live in G at precision rows of W, then pass through R and E before the local certificate exports an infimum-facing read.

Thus the dual route has a fixed order: $\mathsf{LocatedSupremum}^{\uparrow}$ and $\mathsf{BoundedRealFamily}^{\uparrow}$ supply the upper-bound and family presentation, while L, G, R, E, H, C, P, N expose the lower-bound, approximation, handoff, seal, transport, replay, provenance, and local naming rows. Since Definition 1452.1 contains no global order-completeness or quotient coordinate, none is added by the dual read. □

Theorem 1452.10 (LocatedInfimum supremum-dual exactness)**.** *For every accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet*

$$I = (F, L, G, W, R, E, H, C, P, N),$$

any dual read through $\mathsf{LocatedSupremum}^{\uparrow}$ *and* $\mathsf{BoundedRealFamily}^{\uparrow}$ *preserves exactly the displayed lower-bound ledger* L*, greatest-lower witness ledger* G*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, and structural rows* H, C, P, N*. The read exports no host infimum, arbitrary supremum operator, quotient real equality, trichotomy, choice principle, or completeness principle.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumSupremumDualExactness`

Proof. Start from the dual presentation of Definition 1452.9. It may orient the bounded-family row F through $\mathsf{LocatedSupremum}^{\uparrow}$ and $\mathsf{BoundedRealFamily}^{\uparrow}$, but the carrier still exposes the lower-bound surface only through L and the greatest-lower witness surface only through G.

The real-facing handoff is unchanged. The row R remains the only $\mathsf{RegSeqRat}^{\uparrow}$ readback before the terminal $\mathsf{Real}^{\uparrow}$ seal E, so the dual presentation cannot replace the lower-bound evidence by a host infimum or an arbitrary supremum operator.

Finally H, C, P, N preserve the same rows under transport, replay, provenance, and local naming. Since quotient real equality, trichotomy, choice, and completeness are not coordinates of Definition 1452.1, exactness consists precisely of preserving L, G, R, E, H, C, P, N and refusing those stronger principles. □

Theorem 1452.11 (LocatedInfimum bounded-family handoff)**.** *For every accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet* $I = (F, L, G, W, R, E, H, C, P, N)$*, each bounded-family consumer reads the lower-bound and greatest-lower-approximation surface only through the displayed* $\mathsf{BoundedRealFamily}^{\uparrow}$ *row* F*, the lower-bound ledger* L*, the witness ledger* G*, the precision window* W*, the* $\mathsf{StreamName}^{\uparrow}$ *window discipline, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the structural rows* H, C, P, N*. The route is the lower-bound companion of the* $\mathsf{LocatedSupremum}^{\uparrow}$ *packet and exports no arbitrary infimum operator.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumBoundedFamilyHandoff`

Proof. Project the accepted carrier. The bounded-family source is F, so a downstream bounded-family argument cannot inspect a lower-bound or greatest-lower-approximation claim before it has read the displayed family row.

The lower surface is then split between L and G. The row L supplies the finite lower-bound comparisons, while G supplies the displayed witnesses that block stronger lower-bound candidates inside the same precision window W.

The handoff remains finite. The $\mathsf{StreamName}^{\uparrow}$ window discipline fixes the observations in scope, R repacks them as $\mathsf{RegSeqRat}^{\uparrow}$ readback, and E supplies the only $\mathsf{Real}^{\uparrow}$ seal available to the consumer.

Finally H, C, P, N transport, replay, source, and name the same route. The dual reference to $\mathsf{LocatedSupremum}^{\uparrow}$ identifies the companion orientation, but it adds no ambient completeness field and no arbitrary infimum operator. □

Theorem 1452.12 (LocatedInfimum RegSeqRat seal factorization)**.** *For every accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet* $I = (F, L, G, W, R, E, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *factors the real-seal export: any read of the* $\mathsf{Real}^{\uparrow}$ *seal* E *must pass through the bounded-family row* F*, the lower-bound ledger* L*, the greatest-lower-approximation ledger* G*, the* $\mathsf{StreamName}^{\uparrow}$ *precision window* W*, and then* R*. No consumer may reach* E *directly from* F*, from* L*, from* G*, or from a* $\mathsf{LocatedSupremum}^{\uparrow}$ *comparison route.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumRegSeqRatSealFactorization`

Proof. Start with a request for the real seal. By Definition 1452.1, E is reached only through the displayed family, lower-bound, greatest-lower-approximation, window, and regular-rational rows.

The window row W is the gate between ledger evidence and regular readback. It fixes which family reads, lower-bound comparisons, and greatest-lower witnesses are in scope before the regular sequence row is assembled.

The row R is therefore the unique $\mathsf{RegSeqRat}^{\uparrow}$ factor. It repacks the displayed $\mathsf{StreamName}^{\uparrow}$ observations as regular rational data, and only then can E be read as the public $\mathsf{Real}^{\uparrow}$ seal.

The structural rows H, C, P, N preserve this order under transport and replay. A $\mathsf{LocatedSupremum}^{\uparrow}$ comparison may provide the companion orientation, but it has no coordinate in I that bypasses W or R. □

Theorem 1452.13 (LocatedInfimum Real export nonescape)**.** *For every accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet* $I = (F, L, G, W, R, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$ *observation exported by the local certificate is sourced by* $F, L, G, W, R, E, H, C, P, N$ *and remains inside the* $\mathsf{BoundedRealFamily}^{\uparrow}$*,* $\mathsf{LocatedSupremum}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *route displayed by the carrier. The export cannot escape to Dedekind completeness, arbitrary infima, quotient real equality, trichotomy, countable choice, host completeness, or an unlisted real-order oracle.*

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumRealExportNonescape`

Proof. Take an exported $\mathsf{Real}^{\uparrow}$ observation. Ledger exactness forces it to be read from the displayed rows $F, L, G, W, R, E, H, C, P, N$, and the carrier has no second real-facing coordinate.

The analytic route is bounded-family first, lower-bound and witness ledgers second, window and regular-rational handoff third, and real seal last. The $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows keep the export finite at each stage.

The $\mathsf{LocatedSupremum}^{\uparrow}$ reference supplies only the companion lower-versus-upper orientation used by downstream real-order arguments. It does not add a hidden completeness or equality principle to the packet.

Thus every exported real observation remains in the displayed route. Since the forbidden principles have no carrier row and no replay edge, the export cannot escape through them. □

Theorem 1452.14 (LocatedInfimum obligation tail lattice)**.** *For every accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet* $I = (F, L, G, W, R, E, H, C, P, N)$*, any exported infimum read must expose lower-cut stability, tail-window monotonicity,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{StreamName}^{\uparrow}$ *observation, and* $\mathsf{Real}^{\uparrow}$ *sealing in that order before it is treated as a lower-bound lattice value. The accepted route is read through the displayed rows* $F, L, G, W, R, E, H, C, P, N$ *and cannot import a host quotient, trichotomy, ambient completeness, arbitrary infimum operator, or countable-choice selector.*

Proof. Read the displayed rows in order. The bounded-family row F fixes the family under inspection, and the lower-cut row L gives the stable lower-bound comparisons that any infimum read must preserve.

The tail lattice is controlled by G and W. The greatest-lower-approximation witnesses in G are inspected only through the finite tail windows in W, so monotonicity of the accepted tail route is a property of the displayed window ledger rather than an ambient order-completeness principle.

The observation route then passes through R and E. The $\mathsf{StreamName}^{\uparrow}$ windows in W determine the observations, R repacks those observations as $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after that readback has been displayed.

Finally H, C, P, N transport, replay, source, and name the same row order. Since no host quotient, trichotomy, ambient completeness theorem, arbitrary infimum operator, or choice selector appears in those rows, none is smuggled into the exported infimum read. □

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumObligationTailLattice`

Theorem 1452.15 (LocatedInfimum obligation boundary)**.** *For every accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet* $I = (F, L, G, W, R, E, H, C, P, N)$*, the obligation surface is exhausted by the bounded-family row, lower-bound ledger, greatest-lower-approximation ledger,* $\mathsf{StreamName}^{\uparrow}$ *precision window,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local* NameCert *rows. Any consumer that asks for arbitrary infima, Dedekind completeness, quotient real equality, trichotomy, countable choice, host completeness, or a standard bridge asks for data outside the packet.*

Proof. Project the carrier from Definition 1452.1. Its analytic coordinates are exactly F, L, G, W, R, E, and its structural coordinates are exactly H, C, P, N.

Use the lower-bound obligation of Definition 1452.2 and the greatest-lower-bound obligation of Definition 1452.3. These force every lower read through F, L, W, R, E and every greatest-lower approximation through F, L, G, W, R, E.

Now apply window ledger coverage, Definition 1452.5, together with ledger exactness, Definition 1452.7. The finite window entries are consumed by the displayed lower-bound, approximation, handoff, and seal rows, while H, C, P, N only transport, replay, source, and name those rows.

Finally read the exclusions recorded by the chapter's not-claimed boundary as absence of carrier coordinates. There is no row for arbitrary infima, Dedekind completeness, quotient real equality, trichotomy, countable choice, host completeness, or a standard bridge, so a consumer requesting one of those objects has left the accepted packet. □

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumObligationBoundary`

Theorem 1452.16 (LocatedInfimum scoped kernel dependency)**.** *The obligations of an accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet are scoped exactly by the displayed* $\mathsf{BoundedRealFamily}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. No consumer of the chapter obtains Dedekind completeness, an arbitrary infimum operator, quotient real equality, trichotomy, countable choice, host completeness, or a standard bridge.*

Proof. Start from the carrier of Definition 1452.1. Its analytic data are the bounded-family row, the lower-bound ledger, the greatest-lower-bound witness ledger, the finite precision window, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the $\mathsf{Real}^{\uparrow}$ seal; its structural data are the BHist, hsame, Cont, Pkg, and local NameCert rows.

Apply the lower-bound and greatest-lower-bound obligations, Definition 1452.2 and Definition 1452.3. These force lower-bound reads and greatest-lower-approximation reads through the displayed bounded-family, comparison, window, handoff, and seal rows.

Use window induction and ledger coverage from Definition 1452.4 and Definition 1452.5. Each finite precision entry is consumed by the listed ledger rows before any Real-facing observation is exported.

Finally apply classifier stability, ledger exactness, bounded-family handoff, and RegSeqRat seal factorization: Definition 1452.6, Definition 1452.7, Definition 1452.11, and Definition 1452.12. These preserve the same scoped route through $\mathsf{LocatedSupremum}^{\uparrow}$ and $\mathsf{BishopRealComparison}^{\uparrow}$ without adding any forbidden completeness, equality, choice, or bridge coordinate. □

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumScopedKernelDependency`

Theorem 1452.17 (LocatedInfimum public export)**.** *Every accepted* $\mathsf{LocatedInfimum}^{\uparrow}$ *packet exports a public lower-bound and infimum read only through the displayed* $\mathsf{BoundedRealFamily}^{\uparrow}$ *row, lower-bound ledger, greatest-lower-approximation ledger,* $\mathsf{StreamName}^{\uparrow}$ *precision window,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The exported public object may be consumed by L10* $\mathsf{Real}^{\uparrow}$ *and completion lower-bound arguments, but it does not supply Dedekind completeness, arbitrary infima, quotient real equality, trichotomy, countable choice, host completeness, or a standard bridge.*

Proof. Start from the carrier of Definition 1452.1. The only analytic rows available to a public lower-bound read are the bounded-family row, lower-bound ledger, greatest-lower-approximation ledger, finite precision window, regular handoff, and real seal.

Apply Definition 1452.2 and Definition 1452.3. Lower-bound reads are forced through F, L, W, R, E, while greatest-lower-approximation reads are forced through F, L, G, W, R, E.

Next use window induction and ledger coverage from Definition 1452.4 and Definition 1452.5. These keep each precision request inside the displayed $\mathsf{StreamName}^{\uparrow}$ window before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ observation is exported.

Finally apply classifier stability, RegSeqRat seal factorization, Real export nonescape, obligation boundary, and scoped-kernel dependency: Definition 1452.6, Definition 1452.12, Definition 1452.13, Definition 1452.15, and Definition 1452.16. They transport, replay, source, and name the same route for L10 $\mathsf{Real}^{\uparrow}$ and completion lower-bound consumers while excluding Dedekind completeness, arbitrary infima, quotient equality, trichotomy, choice, host completeness, and bridge data. □

Lean4 ✓ `BEDC.Derived.LocatedInfimumUp.LocatedInfimumPublicExport`

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedInfimum}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedInfimum}^{\uparrow}$ packet is generated from a bounded real family row, a lower-bound ledger, a greatest-lower-approximation ledger, a StreamName precision window, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedInfimum}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1452.1, Definition 1452.2, Definition 1452.3, Definition 1452.4, Definition 1452.5, Definition 1452.6, Definition 1452.7, Definition 1452.11, Definition 1452.12, and Definition 1452.16 bind the finite lower-bound, greatest-lower-approximation, bounded-family handoff, RegSeqRat seal, and scoped-kernel dependencies over the L10 Real and Completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedInfimum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind completeness, arbitrary infima, quotient real equality, trichotomy, countable choice, host completeness, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, lower-bound readback, greatest-lower-approximation witnessing, classifier stability, ledger exactness, handoff stability, and real-seal factorization for BEDC.Derived.LocatedInfimumUp.

Chapter 1453

A Concrete Naming Certificate for $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ packet isolates the regular Cauchy dense embedding from $\mathsf{RegSeqRat}^{\uparrow}$ into the $\mathsf{Real}^{\uparrow}$ seal. It sits over the dyadic rational rows of chapter 291, the finite stream windows of chapter 126, the regular rational source of chapter 301, the terminal real-name seal of chapter 38, and the completion boundary of chapter 360. The certificate keeps the dense-embedding route visible as finite NameCert data before any completion consumer treats a regular rational name as a sealed real.

Definition 1453.1 (Regular Cauchy dense embedding carrier)**.** *A* $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, S, D, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row whose entries supply the embedded Cauchy name.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the finite windows through which R is read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic precision requests and rational comparison rows used by the embedding.*
4. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the dense-embedding route after R, S, D have been displayed.*
5. *H records componentwise* hsame *transport for the regular source, stream schedule, dyadic tolerance ledger, Real seal, continuation, provenance, and local naming rows.*
6. *C records the displayed* Cont *replay from each precision request through R, S, D, A, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient selection, host real equality, ambient completeness, countable choice, trichotomy, a detached completion point, or an unbounded stream read.

Theorem 1453.2 (Regular Cauchy dense embedding NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularCauchyDenseEr}}$ *surface for Definition 1453.1 consists exactly of carrier exposure for E, classifier exposure through the displayed R, S, D, A route, stream-window stability for S, dyadic tolerance exactness for D,* $\mathsf{Real}^{\uparrow}$ *boundary non-escape through A, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N. Every accepted dense-embedding request is classified only by the regular rational source row, the scheduled finite windows, and the displayed dyadic tolerance ledger before it reaches the Real seal.*

Proof. Project the carrier tuple $E = (R, S, D, A, H, C, P, N)$. The rows R, S, D, A are the analytic coordinates, and the final row names the same tuple as the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}}$ surface.

Read the classifier in dependency order. A precision request first consumes the regular rational source row R, then the finite stream schedule S, then the dyadic tolerance ledger D, and only then reaches the $\mathsf{Real}^{\uparrow}$ seal row A.

The structural rows add no hidden completion principle. They transport, replay, source, and name the displayed route, while the excluded objects have no coordinate in the carrier. Hence the listed rows exhaust the seed obligation surface and force the Real boundary to stay inside the displayed route. □

Theorem 1453.3 (Regular Cauchy dense embedding RealUp boundary)**.** *For every accepted* $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *packet $E = (R, S, D, A, H, C, P, N)$ and every exported* $\mathsf{Real}^{\uparrow}$ *read, the read factors through the finite route*

$$R \longmapsto S \longmapsto D \longmapsto A \longmapsto (H, C, P, N).$$

Thus every exported Real seal read factors through the displayed $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows, and no consumer can obtain a detached* $\mathsf{Real}^{\uparrow}$ *value from the packet without reading those rows.*

Proof. Start with Definition 1453.2. It places the regular rational source R, the stream schedule S, and the dyadic tolerance ledger D before the terminal Real seal A.

The Real-facing row is therefore not an independent coordinate. A consumer that omits R, S, or D has not followed the carrier route, so it has no exported read of A from this packet.

Finally read the structural rows. The rows H, C, P, N preserve, replay, source, and name the same route; they do not introduce a second Real seal route. Therefore every exported $\mathsf{Real}^{\uparrow}$ read factors through the displayed regular source, stream schedule, and dyadic ledger. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source, $\mathsf{StreamName}^{\uparrow}$ schedule, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, real-cauchy-completion: no listed sibling supplies the whole eight-row packet $E = (R, S, D, A, H, C, P, N)$, because each sibling contributes only a dyadic ledger, stream schedule, regular rational source, Real seal, or completion boundary while this chapter binds the dense embedding route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source row, a $\mathsf{StreamName}^{\uparrow}$ schedule row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 1453.1, Definition 1453.2, and Definition 1453.3 seed the dense-embedding boundary over RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient construction of Real$^{\uparrow}$, host real equality, ambient completeness, countable choice, trichotomy, detached completion points, dense-image surjectivity, or a Lean theorem.

Upgrade path: A formal route can encode the eight-row carrier and prove the NameCert obligation surface and RealUp boundary theorem.

Chapter 1454

A Concrete Naming Certificate for $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ packet records the boundary where a regular rational Cauchy name, an explicit convergence modulus, and finite locatedness evidence are all visible before the $\mathsf{Real}^{\uparrow}$ seal is read. It sits over the finite windows of chapter 126, the regular rational source of chapter 301, the endpoint and radius ledger of chapter 291, the real-name seal of chapter 38, the located enclosure surface of **??**, and the explicit rate rows of chapter 332. The certificate keeps convergence and location as finite rows rather than hiding them inside a later BishopReal or compact-interval consumer.

Definition 1454.1 (Regular located Cauchy real carrier)**.** *A* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, Q, D, M, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family naming the finite observation windows used by the packet.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational entries are read only on the windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger recording the rational centers, dyadic radii, and interval comparisons attached to those windows.*
4. *M is the* $\mathsf{ModulusOfConvergence}^{\uparrow}$ *rate row assigning each requested tolerance a finite threshold over the displayed windows.*
5. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *enclosure row recording the finite interval-location evidence attached to the same source, endpoint, radius, and threshold rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream, regular-source, dyadic-ledger, modulus, and located-enclosure rows have been displayed.*
7. *H records componentwise* hsame *transport for the stream windows, regular rational source, dyadic endpoint and radius ledger, convergence-modulus row, located enclosure, Real seal, continuation, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from each precision and location request through $S, Q, D, M, L, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ModulusOfConvergence}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularLocatedCauchyReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for Dedekind construction of $\mathsf{Real}^{\uparrow}$*, quotient equality, trichotomy, open-cover compactness, countable choice, completed metric-space points, or an unbounded stream read.*

Theorem 1454.2 (Regular located Cauchy real NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularLocatedCauchyReal}^{\uparrow}}$ *surface for Definition 1454.1 consists exactly of carrier exposure for R, finite-window exposure through S, regular rational source exposure through Q, endpoint and radius exposure through D, convergence-rate exposure through M, located-enclosure exposure through L, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N. Each accepted request is classified only by the displayed StreamName window, the RegSeqRat source row, the dyadic endpoint and radius ledger, the convergence threshold, and the located enclosure row.*

```
Lean4 ✓  BEDC.Derived.RegularLocatedCauchyRealUp.TasteGate.RegularLocatedCauchyRealTasteGate
single carrier alignment
```

Proof. Project the carrier tuple $R = (S, Q, D, M, L, E, H, C, P, N)$. Each analytic coordinate is a displayed finite row, and the final coordinate names the same tuple as the local $\mathsf{NameCert}_{\mathsf{RegularLocatedCauchyReal}^{\uparrow}}$ surface.

Read the rows in their dependency order. A request first consumes the stream window S and regular rational source Q, then the dyadic endpoint and radius ledger D, then the convergence threshold row M, and only then the located enclosure L and terminal Real seal E.

The structural rows add no hidden analytic object. They transport, replay, source, and name the displayed route, while the excluded objects have no coordinate in the carrier. Hence the listed rows exhaust the seed obligation surface. □

Theorem 1454.3 (Regular located Cauchy real RealUp seal route)**.** *For every accepted* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *packet $R = (S, Q, D, M, L, E, H, C, P, N)$ and every displayed precision request, the Real-facing read factors through the finite route*

$$S \longmapsto Q \longmapsto D \longmapsto M \longmapsto L \longmapsto E \longmapsto (H, C, P, N).$$

No consumer can read the terminal $\mathsf{Real}^{\uparrow}$ *seal from R without also reading the same StreamName window family, RegSeqRat source row, DyadicRatCore endpoint and radius ledger, ModulusOfConvergence rate row, and LocatedReal enclosure row.*

Proof. Start with Definition 1454.2. It places the finite window row S before the regular source row Q and places the dyadic ledger D before the convergence modulus M and located enclosure L.

The Real seal is therefore not an independent coordinate. The row E is reached after S, Q, D, M, L are displayed, so a consumer omitting any of those rows has not followed the carrier route.

Finally read the structural rows. The rows H, C, P, N preserve, replay, source, and name the same route; they do not add a second route to $\mathsf{Real}^{\uparrow}$. Thus the terminal seal factors through the displayed finite certificate path. □

Theorem 1454.4 (Regular located Cauchy real modulus-location factorization)**.** *For every accepted* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *packet $R = (S, Q, D, M, L, E, H, C, P, N)$, every locatedness read factors through the common finite data*

$$S, \quad Q, \quad D, \quad M$$

before it reaches L, and every convergence-modulus read uses the same S, Q, D rows before it reaches M. Hence the modulus and locatedness surfaces share the StreamName windows, RegSeqRat source, and DyadicRatCore endpoint and radius ledger rather than presenting two unrelated certificates.

Proof. Use the carrier definition. The row M is a rate row over the windows, source, endpoints, and radii already named by S, Q, D; the row L is a located enclosure over the same displayed source and dyadic ledger, with the rate row fixing the relevant tail threshold.

Now compare the two reads. The convergence side stops at M after S, Q, D, while the locatedness side continues through M to L on the same finite rows.

The componentwise hsame and Cont rows preserve that shared route, and the Pkg and local NameCert rows name it. Thus any accepted consumer sees one factored certificate surface, not a separated modulus certificate and a separated location certificate. □

Theorem 1454.5 (Regular located Cauchy real scoped dependency route)**.** *Every accepted* RegularLocatedCauchyR *read factors through exactly the displayed* StreamName$^{\uparrow}$ *finite windows,* RegSeqRat$^{\uparrow}$ *readback row,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* ModulusOfConvergence$^{\uparrow}$ *location row,* LocatedReal$^{\uparrow}$ *locatedness row, terminal* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert$_{\text{RegularLocatedCauchyReal}^{\uparrow}}$ *row. No quotient stream equality, selected representative, trichotomy, countable choice, or ambient* Real$^{\uparrow}$ *completeness coordinate is in scope for such a read.*

Proof. Use Definition 1454.2. It exposes the carrier as the tuple $R = (S, Q, D, M, L, E, H, C, P, N)$ and makes the stream windows, regular rational source, dyadic ledger, convergence row, locatedness row, and Real seal explicit.

Apply Definition 1454.3 to the endpoint-facing side. The terminal Real$^{\uparrow}$ read is downstream of the same S, Q, D, M, L rows, so it cannot be reached by a separate representative-selection path.

Apply Definition 1454.4 to the locatedness side. The modulus and locatedness reads share S, Q, D, M before reaching L, and the structural rows only transport, replay, source, and name that route.

The excluded principles have no coordinate in the displayed carrier. Hence the scoped route is exactly the finite dependency route named above. □

Falsifiable prediction: An accepted RegularLocatedCauchyReal$^{\uparrow}$ consumer that reaches a Real$^{\uparrow}$ seal or a locatedness enclosure without the displayed StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ source, DyadicRatCore$^{\uparrow}$ endpoint and radius ledger, and ModulusOfConvergence$^{\uparrow}$ rate row refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, locatedreal, modulusofconvergence: no listed sibling supplies the whole ten-row packet $R = (S, Q, D, M, L, E, H, C, P, N)$, because each sibling contributes only a window, regular-source, dyadic-ledger, Real-seal, located-enclosure, or rate surface while this chapter binds all six analytic faces with transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{RegularLocatedCauchyReal}^{\uparrow}}$.

Constructive story: A RegularLocatedCauchyReal$^{\uparrow}$ packet is generated from finite StreamName$^{\uparrow}$ windows, a RegSeqRat$^{\uparrow}$ source row, a DyadicRatCore$^{\uparrow}$ endpoint and radius ledger, a ModulusOfConvergence$^{\uparrow}$ rate row, a LocatedReal$^{\uparrow}$ enclosure row, a terminal Real$^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularLocatedCauchyReal}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1454.1, Definition 1454.2, Definition 1454.3, Definition 1454.4, and Definition 1454.5 bind the regular located Cauchy real-name route over StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, ModulusOfConvergence$^{\uparrow}$, LocatedReal$^{\uparrow}$, and Real$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{RegularLocatedCauchyReal}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RegularLocatedCauchyRealUp.TasteGate.RegularLocatedCauchyRealTasteGate\_single\_carrier`

Bridge status: none

Not claimed: This chapter does not claim Dedekind construction of $\mathrm{Real}^{\uparrow}$, quotient equality, trichotomy, open-cover compactness, countable choice, completeness, or completed metric-space points.

Upgrade path: Public closure requires a downstream public-object surface that reuses the scoped dependency route without adding quotient equality, selected representatives, countable choice, or ambient completeness.

Chapter 1455

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ packet names the finite boundary at which a regular Cauchy rational source, locatedness evidence, and the displayed limit route are all visible before a $\mathsf{Real}^{\uparrow}$ completion-facing seal is read. It sits after the regular located Cauchy surface of chapter 1454, the located-limit route of chapter 1420, the located-real source of **??**, the real-name seal of chapter 38, the regular rational source of chapter 301, the stream-window source of chapter 126, and the dyadic arithmetic core of chapter 291. The chapter records only the NameCert boundary for located completion data; it does not assert that $\mathsf{Real}^{\uparrow}$ is complete.

Definition 1455.1 (Bishop located completion boundary carrier)**.** *A* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, D, R, L, E, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family naming the finite observations of the rational Cauchy source.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row read only through the windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, endpoint, and radius ledger attached to those windows.*
4. *R is the* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *row that binds the regular source, dyadic ledger, locatedness evidence, and terminal real-name seal as one visible route.*
5. *L is the* $\mathsf{LocatedLimit}^{\uparrow}$ *route by which the same displayed source is read as a located limit candidate.*
6. *E is the* $\mathsf{LocatedReal}^{\uparrow}$ *enclosure row used at the location boundary before any terminal real-name consumer is allowed to inspect a seal.*
7. *T is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, Q, D, R, L, E have been displayed.*
8. *H records componentwise* hsame *transport for the stream, regular-source, dyadic, regular-located, located-limit, located-real, Real-seal, continuation, provenance, and local naming rows.*
9. *C records the displayed* Cont *replay for every completion-facing request through the same rows.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$, $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$, $\mathsf{LocatedLimit}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a proof of $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of Cauchy names, real trichotomy, countable choice, open-cover compactness, or a host-selected limit.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.TasteGate.BishopLocatedCompletionBoundaryTasteGa`
`single carrier alignment`

Theorem 1455.2 (Regular Cauchy extraction at the located boundary)**.** *Every accepted* BishopLocatedCompletionB *packet $B = (S, Q, D, R, L, E, T, H, C, P, N)$ exposes its regular Cauchy source before any located completion read. The extracted source surface is exactly the finite route*

$$S, \quad Q, \quad D, \quad R$$

with the visible transport, replay, provenance, and naming rows H, C, P, N. No consumer can obtain a completion-facing $\mathsf{Real}^{\uparrow}$ *seal from B without first reading the displayed StreamName windows, RegSeqRat source, DyadicRatCore tolerance ledger, and RegularLocatedCauchyReal route.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryRegularCauchyExtr`

Proof. Project the carrier of Definition 1455.1. The only regular Cauchy data present are the stream windows S, regular rational source Q, dyadic tolerance ledger D, and regular located Cauchy row R.

Now read any completion-facing request. The row T is stored after the located-limit and located-real rows, and those rows are themselves attached to S, Q, D, R. Thus the request must first pass through the extracted regular Cauchy source route.

The transport, replay, provenance, and local naming rows preserve this same route. Since the carrier contains no independent completion coordinate, the displayed extraction exhausts the regular Cauchy surface available to the consumer. □

Theorem 1455.3 (Located limit route at the completion boundary)**.** *For every accepted* BishopLocatedCompletionB *packet $B = (S, Q, D, R, L, E, T, H, C, P, N)$, every located completion read factors through*

$$S \longmapsto Q \longmapsto D \longmapsto R \longmapsto L \longmapsto E \longmapsto T.$$

The route uses the located-limit row L and located-real enclosure row E as visible finite data before the $\mathsf{Real}^{\uparrow}$ *seal row T is read, and it exports no separate host limit, quotient equality row, or choice-selected subsequence.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryLocatedLimitRoute`

Proof. Begin with the extraction theorem Definition 1455.2. It places the stream, regular rational, dyadic tolerance, and regular located Cauchy rows before any completion-facing seal.

The carrier definition then places L and E between that extracted source and the row T. Hence a located completion read must first display the located-limit route and the located-real enclosure row attached to the same finite source.

Finally apply the structural rows. Componentwise transport and replay keep the consumer on S, Q, D, R, L, E, T, while provenance and local naming record the same packet. No coordinate outside this route can supply a host limit or a quotient equality proof. □

Theorem 1455.4 (Bishop located completion boundary NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{BishopLocatedCom}}$ *surface for Definition 1455.1 consists exactly of carrier exposure for B, regular Cauchy extraction through S, Q, D, R, located-limit routing through L, located-real enclosure through E, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through T, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N. These obligations bind the finite located completion boundary without adding* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality, trichotomy, countable choice, open-cover compactness, or a host-selected limit.*

Proof. Carrier exposure is projection from the displayed tuple $B = (S, Q, D, R, L, E, T, H, C, P, N)$. The analytic rows are exactly the stream, regular rational, dyadic, regular located Cauchy, located-limit, located-real, and Real-seal rows named in the carrier.

Regular Cauchy extraction is supplied by Definition 1455.2. Located routing is supplied by Definition 1455.3. Together they put every completion-facing read on one finite route through S, Q, D, R, L, E, T.

The remaining rows are structural. The hsame transports and Cont replay preserve the same finite route, while Pkg provenance and the local NameCert row name the packet. Since no excluded principle appears as a carrier coordinate, the listed rows exhaust the seed obligation surface. □

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryNameCertObligatio`

Theorem 1455.5 (Bishop located completion boundary located Real-seal handoff)**.** *Every accepted* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ *packet reaches its* $\mathsf{Real}^{\uparrow}$ *seal T only through the displayed route*

$$S \longmapsto Q \longmapsto D \longmapsto R \longmapsto L \longmapsto E \longmapsto T.$$

The handoff first reads the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows D, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and readback row Q, and the located-real comparison row E. It preserves the same route through componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}}$ *row, and it supplies no ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem or quotient equality of real names.*

Proof. Unpack the carrier of Definition 1455.1. Its analytic rows are exactly S, Q, D, R, L, E, T, with T placed after the dyadic tolerance ledger, stream windows, regular rational source, regular located Cauchy route, located-limit route, and located-real enclosure row.

Apply regular Cauchy extraction, Definition 1455.2. It forces every completion-facing read to expose S, Q, D, R before a terminal seal can be inspected, so the dyadic tolerance rows, finite windows, and regularity/readback row are already displayed.

Next apply located-limit routing, Definition 1455.3. The row E is the located-real comparison row immediately before T, so the Real-seal handoff cannot bypass locatedness data or replace it by a host limit.

Finally use the obligation surface. Componentwise hsame transport and Cont replay keep the same route, while Pkg provenance and the local NameCert row name it as one packet. Since the carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ completeness or quotient equality, the handoff exports only the displayed seal row T over the finite located boundary. □

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryLocatedRealSealHa`

Theorem 1455.6 (Bishop located completion boundary regular route)**.** *Any accepted* BishopLocatedCompletionBou *read that reaches the terminal seal T must first expose the rows*

$$S, Q, D, R, L, E$$

in that order. The RegularLocatedCauchyReal$^{\uparrow}$ *row R, the* LocatedLimit$^{\uparrow}$ *row L, and the* LocatedReal$^{\uparrow}$ *row E are therefore mandatory boundary rows, not replaceable by a host completion, quotient equality, selected limit, ambient* Real$^{\uparrow}$ *completeness theorem, trichotomy, countable-choice schedule, or open-cover compactness principle.*

Proof. Apply regular Cauchy extraction, Definition 1455.2. It exposes S, Q, D, R before any terminal seal can be read, so the regular located Cauchy row cannot be replaced by a host completion row.

Next apply the located-limit route, Definition 1455.3. This places L after the regular route and before any located Real enclosure can be consumed.

Now use the NameCert obligations of Definition 1455.4 and the located Real-seal handoff of Definition 1455.5. These keep E immediately before T on the same finite route and preserve it under transport, replay, provenance, and local naming.

Since the carrier has no coordinate for host completion, quotient equality, selected limits, completeness, trichotomy, countable choice, or compactness, every terminal read reaches T only through the displayed regular route. □

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryRegularRoute`

Theorem 1455.7 (Bishop located completion boundary window exhaustion)**.** *Every accepted* BishopLocatedCompletionBoundary$^{\uparrow}$ *packet $B = (S, Q, D, R, L, E, T, H, C, P, N)$ exposes all completion-facing finite windows through S and all tolerance and readback data through D, Q, R, L, E before T is consumed. No completion-facing consumer can add a second* StreamName$^{\uparrow}$ *schedule, quotient equality, selected limit, countable choice, trichotomy, open-cover compactness, or* Real$^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryWindowExhaustion`

Proof. Project the carrier of Definition 1455.1. The only finite-window row is S, and the only tolerance, regular readback, regular-located, located-limit, and located-real rows are D, Q, R, L, E.

Apply regular Cauchy extraction, Definition 1455.2. It forces every completion-facing read to display S, Q, D, R before the terminal seal row can be inspected.

Apply located-limit routing, Definition 1455.3, and then the located Real-seal handoff, Definition 1455.5. These two results place L, E after the extracted source and before T, so the consumer cannot bypass locatedness or replace the route by a host-selected limit.

Finally use H, C, P, N. Componentwise hsame transport, displayed Cont replay, package provenance, and local naming preserve the same route S, Q, D, R, L, E, T. Since none of those structural rows contains a second stream schedule, quotient equality, choice principle, trichotomy, compactness principle, or completeness coordinate, the displayed finite windows are exhausted before T is consumed. □

Theorem 1455.8 (Bishop located completion boundary inductive route)**.** *Every accepted terminal read of a* BishopLocatedCompletionBoundary$^{\uparrow}$ *carrier*

$$B = (S, Q, D, R, L, E, T, H, C, P, N)$$

is generated by induction on the displayed route: first the StreamName$^{\uparrow}$ *windows S, then the* RegSeqRat$^{\uparrow}$ *source Q, the* DyadicRatCore$^{\uparrow}$ *ledger D, the* RegularLocatedCauchyReal$^{\uparrow}$ *row R, the* LocatedLimit$^{\uparrow}$ *row L, the* LocatedReal$^{\uparrow}$ *row E, and the terminal* Real$^{\uparrow}$ *seal T; only after those analytic rows are present may the structural rows H, C, P, N transport, replay, source, and name the*

same read. The induction exposes no quotient equality, selected limit, countable choice, trichotomy, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryInductiveRoute`

Proof. The base of the route is the carrier projection in Definition 1455.1. It lists S as the only stream-window row and places the regular source, dyadic ledger, located rows, terminal seal, and structural rows in the displayed order.

For the first analytic steps, apply regular Cauchy extraction and the located-limit route. The extraction theorem forces S, Q, D, R to be visible before any completion-facing seal, while the located-limit theorem extends the route through L and E before T can be read.

The Real-seal handoff and the regular-route theorem provide the terminal step. They identify T as downstream of S, Q, D, R, L, E and rule out replacement by a host completion, quotient equality, selected limit, countable choice, trichotomy, open-cover compactness, or ambient Real completeness.

It remains to account for the structural rows. The NameCert obligations and window-exhaustion theorem preserve the same finite route under H, C, P, N and show that no second window schedule or hidden completion coordinate is available. Thus induction over the displayed rows generates every accepted terminal read. □

Theorem 1455.9 (Bishop located completion boundary obligation carrier)**.** *Every accepted* BishopLocatedCompleti *packet is admitted to the obligation surface only as the eleven-row carrier*

$$B = (S, Q, D, R, L, E, T, H, C, P, N)$$

of Definition 1455.1. The admitted rows are exactly the $\mathsf{StreamName}^{\uparrow}$ *window family,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ *route,* $\mathsf{LocatedLimit}^{\uparrow}$ *route,* $\mathsf{LocatedReal}^{\uparrow}$ *enclosure row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming. No additional carrier coordinate may supply* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality, trichotomy, countable choice, open-cover compactness, or a host-selected limit.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryObligationCarrier`

Proof. Project the carrier definition. It lists precisely $S, Q, D, R, L, E, T, H, C, P, N$ and places all completion-facing analytic data before the terminal seal.

Apply regular Cauchy extraction, located-limit routing, the located Real-seal handoff, and window exhaustion. These results show that the stream windows, regular rational source, dyadic ledger, located route, enclosure row, and seal are consumed as one visible boundary.

The structural rows only preserve that boundary. Since provenance and local naming record the same packet and no excluded principle is present as a row, the obligation carrier is exactly the displayed eleven-row surface. □

Theorem 1455.10 (Bishop located completion boundary scope)**.** *Every scoped route exposed by a* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ *packet passes through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularLocatedCauchyReal}^{\uparrow} \longmapsto \mathsf{LocatedLimit}^{\uparrow} \longmapsto \mathsf{Located}$$

The route is read through the displayed rows S, Q, D, R, L, E, T *and the structural rows* H, C, P, N *before any completion-facing consumer can cite it. It does not expose a host completion, quotient real equality, trichotomy, countable-choice schedule, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryScope`

Proof. Start with Definition 1455.6. It forces the rows S, Q, D, R, L, E to appear before the terminal seal T can be read.

Use window exhaustion and the NameCert obligations. They identify S as the only finite-window schedule, Q as the regular rational source, D as the dyadic ledger, and R, L, E as the located completion boundary before the $\mathsf{Real}^{\uparrow}$ seal.

Finally apply componentwise transport and displayed replay. The scope is preserved under H and C, while P and N name the same packet, so no outside completion, equality, order, choice, compactness, or completeness datum enters the route. □

Theorem 1455.11 (Bishop located completion boundary scoped route)**.** *Every scoped completion-boundary read from an accepted* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ *packet must pass through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularLocatedCauchyReal}^{\uparrow} \longmapsto \mathsf{LocatedLimit}^{\uparrow} \longmapsto \mathsf{Located}$$

together with the componentwise hsame *row, displayed* Cont *replay row,* Pkg *provenance row, and local* $\mathsf{NameCert}$ *row. The route is exactly the eleven-row carrier*

$$B = (S, Q, D, R, L, E, T, H, C, P, N)$$

and admits no host completion, quotient equality, selected limit, trichotomy, countable-choice schedule, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge-checking row.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryScopedRoute`

Proof. Project the obligation carrier of Definition 1455.9. It admits only $S, Q, D, R, L, E, T, H, C, P, N$, so every scoped read begins inside the eleven displayed rows.

Apply regular Cauchy extraction and the located-limit route. These place the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$, $\mathsf{LocatedLimit}^{\uparrow}$, and $\mathsf{LocatedReal}^{\uparrow}$ rows before the terminal $\mathsf{Real}^{\uparrow}$ seal can be read.

Next use the located Real-seal handoff and the scope theorem. The seal row T is reachable only through the displayed located route, and the scope theorem records the same ordered kernel path as a boundary for completion-facing consumers.

Finally use the ledger theorem. The structural rows H, C, P, N transport, replay, source, and name the same route, while the ledger has no coordinate for host completion, quotient equality, selected limits, order principles, choice schedules, compactness, ambient completeness, or bridge checking. Thus every scoped read is confined to the stated kernel route. □

Theorem 1455.12 (Bishop located completion boundary ledger)**.** *The ledger of an accepted* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ *packet is non-escaping: every completion-facing read is accounted for by the stream windows* S*, regular source* Q*, dyadic ledger* D*, regular located route* R*, located-limit route* L*, located-real enclosure* E*, terminal seal* T*, and structural rows* H, C, P, N*. The ledger has no row for* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of Cauchy names, real trichotomy, countable choice, open-cover compactness, a host-selected limit, or bridge checking.*

Proof. Read the obligation carrier theorem. It admits only the displayed eleven rows and refuses every extra completion, equality, order, choice, compactness, selected-limit, or bridge coordinate.

Apply the scope theorem. Any consumer that reaches the terminal seal has already passed through the StreamName, RegSeqRat, DyadicRatCore, RegularLocatedCauchyReal, LocatedLimit, LocatedReal, and Real route.

The remaining rows are bookkeeping inside the same packet: H transports components, C replays displayed continuations, P records provenance, and N gives local naming. Therefore the ledger cannot export any refused endpoint. □

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryLedger`

Theorem 1455.13 (Bishop located completion boundary public interface)**.** *Every public read of an accepted* $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegularLocatedCauchyReal}^{\uparrow},\ \mathsf{LocatedLimit}^{\uparrow},\ \mathsf{LocatedReal}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

together with the componentwise hsame *row, displayed* Cont *replay row,* Pkg *provenance row, and local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}}$ *row. The public interface exposes only those finite rows and explicitly refuses* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of Cauchy names, selected limits, countable choice, real trichotomy, open-cover compactness, and bridge checking.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionBoundaryUp.BishopLocatedCompletionBoundaryPublicInterface`

Proof. Project the scoped route theorem and the ledger theorem. They identify every completion-facing read with the eleven-row carrier $S, Q, D, R, L, E, T, H, C, P, N$ and place the StreamName, RegSeqRat, DyadicRatCore, RegularLocatedCauchyReal, LocatedLimit, LocatedReal, and Real rows before any terminal seal can be consumed.

The structural rows do not enlarge the interface. Componentwise hsame transport and displayed Cont replay preserve the same route, while Pkg provenance and the local NameCert row name the packet.

Since the ledger has no coordinate for completeness, quotient equality, selected limits, choice, trichotomy, compactness, or bridge checking, the public read is exactly the displayed finite boundary and none of the refused endpoints is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}$ packet is generated from finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{RegSeqRat}^{\uparrow}$ regular rational source, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$ route, a $\mathsf{LocatedLimit}^{\uparrow}$ route, a $\mathsf{LocatedReal}^{\uparrow}$ enclosure row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1455.1, Definition 1455.2, Definition 1455.3, Definition 1455.9, Definition 1455.10, and Definition 1455.12 bind the finite located completion boundary over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularLocatedCauchyReal}^{\uparrow}$, $\mathsf{LocatedLimit}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient equality, trichotomy, countable choice, open-cover compactness, a host-selected limit, or bridge checking.

Upgrade path: The next paper obligation is bridged closure for the same located completion boundary, with formal verification still pending.

Chapter 1456

A Concrete Naming Certificate for $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the Bourbaki language of universal mappings, the $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ packet isolates the L10 boundary where regular Cauchy names are admitted into a completion seal and uniformly continuous finite-window consumers are extended back out through a displayed universal row. It reads the naming spine of chapter 126, chapter 301, and chapter 38; the Cauchy filter boundary of chapter 333; the extension surface of chapter 397; the functorial completion row of chapter 426; and the generic adjunction packet of chapter 107. The chapter records only the finite NameCert boundary for this universal mapping shape.

Definition 1456.1 (CauchyCompletionAdjunction carrier)**.** *A* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, C, D, E, U, H, P, N)$$

with the following displayed rows:

1. *X is the source metric and finite Cauchy-observation row, including the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source, and the* $\mathsf{CauchyFilter}^{\uparrow}$ *stability ledger used before completion is read.*
2. *C is the dense embedding row from the source observations into the completion seal, with the target seal read through the* $\mathsf{Real}^{\uparrow}$ *boundary.*
3. *D is the completion-seal row exposed through* $\mathsf{CompletionFunctor}^{\uparrow}$ *and the adjacent real-name route, not as a quotient completion or host-level complete metric space.*
4. *E is the extension candidate row for uniformly continuous finite-window consumers, read through the displayed* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension surface.*
5. *U is the uniqueness ledger asserting that two extension rows agreeing on the dense rows named by C are compared only by the carried* hsame *route.*
6. *H records the componentwise* hsame *and* Cont *replay for X, C, D, E, U, including classifier transport through the source, dense embedding, completion seal, extension candidate, and uniqueness rows.*
7. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, $\mathsf{Adjunction}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjunction}^{\uparrow}}$ *row.*

The carrier contains no quotient completion, no selected limit, no open-cover compactness field, no countable-choice selector, and no equality of host functions.

Theorem 1456.2 (CauchyCompletionAdjunction NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjuncti}}$ *surface for Definition 1456.1 consists exactly of six finite obligation rows:*

1. *carrier exposure: an accepted object exposes only the packet $A = (X, C, D, E, U, H, P, N)$;*
2. *classifier transport: accepted comparison is componentwise through the displayed* hsame *and* Cont *routes recorded in H;*
3. *dense embedding preservation: the source observations in X enter the completion seal only through the dense row C;*
4. *extension row: every uniformly continuous finite-window consumer reaches a completion-facing read through the extension coordinate E and the sibling* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *surface;*
5. *uniqueness by dense row: two extension candidates are compared only through the uniqueness ledger U after agreement on the dense rows named by C;*
6. *Real/RegSeqRat handoff non-escape: every public read remains inside the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, *and* $\mathsf{Adjunction}^{\uparrow}$ *rows displayed by P.*

Thus the packet binds the universal mapping boundary from regular Cauchy source data to the completion seal without adding quotient completions, selected limits, open-cover compactness, countable choice, or equality of host functions.

Proof. Carrier exposure is projection from the tuple in Definition 1456.1. Its source row is X, its dense embedding is C, its completion seal is D, its extension candidate is E, its uniqueness ledger is U, and its structural rows are H, P, N.

Classifier transport is componentwise. The row H is the only place where hsame comparisons and Cont replays are stored, so every accepted comparison of carriers must replay the same source, dense, seal, extension, and uniqueness coordinates.

Dense embedding preservation and extension are then read in order. The source observations carried by X reach the completion seal through C and D, while a uniformly continuous finite-window consumer reaches a completion-facing row only through E and the universal-property surface named in P.

Finally, uniqueness and non-escape are ledger statements over the displayed packet. The row U compares extensions only after agreement on the dense rows, and the provenance row P lists no quotient completion, selected limit, open-cover compactness, countable-choice selector, or host function equality coordinate. The six rows therefore exhaust the local NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.CauchyCompletionAdjunctionUp.CauchyCompletionAdjunctionTasteGate single carrier alignment`

Theorem 1456.3 (CauchyCompletionAdjunction extension handoff)**.** *For an accepted* $\mathsf{CauchyCompletionAdjunctio}$ *carrier*

$$A = (X, C, D, E, U, H, P, N)$$

as in Definition 1456.1, every uniformly continuous finite-window consumer reaches the completion-facing extension candidate only through the source row X, the dense embedding row C, the completion-seal row D, the extension row E, the uniqueness ledger U, the componentwise hsame *comparisons in H, the displayed* Cont *routes in H, the* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjunction}^{\uparrow}}$ *row N.*

Equivalently, the consumer route factors through the $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension surface, the* $\mathsf{CompletionFunctor}^{\uparrow}$ *completion row, and the* $\mathsf{Adjunction}^{\uparrow}$ *universal-mapping ledger named by P; no separate completion object or host function equality is exported.*

Proof. Project the accepted packet through Definition 1456.1. The source observations are stored in X, the dense embedding data in C, the completion seal in D, the extension candidate in E, and the dense-row uniqueness comparison in U.

Now route a uniformly continuous finite-window consumer. The $\mathsf{CompletionUniversalProperty}^{\uparrow}$ row named by P supplies the only extension-facing surface, while $\mathsf{CompletionFunctor}^{\uparrow}$ supplies the completion row and $\mathsf{Adjunction}^{\uparrow}$ records the universal-mapping ledger that compares source-side and completion-side reads.

It remains to bind transport and naming. The row H carries exactly the componentwise hsame comparisons and displayed Cont replays for X, C, D, E, U; the rows P and N then package the same route as local NameCert data. Since no other coordinate occurs in A, every extension read uses this displayed handoff. □

Theorem 1456.4 (CauchyCompletionAdjunction Real seal non-escape)**.** *For an accepted* CauchyCompletionAdjunc *carrier $A = (X, C, D, E, U, H, P, N)$, every* $\mathsf{Real}^{\uparrow}$*-facing read of the completion seal factors through Definition 1456.3, the carrier inventory of Definition 1456.1, and the terminal route through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, *and* $\mathsf{Adjunction}^{\uparrow}$ *named by P.*

Consequently the packet cannot export quotient completions, selected representatives, host equality of functions or real names, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the handoff theorem. It already forces every completion-facing consumer through the source, dense embedding, completion-seal, extension, uniqueness, transport, provenance, and local naming rows of the same carrier.

The Real-facing part of this route is terminal in the displayed naming spine. The $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ regular rational rows feed the $\mathsf{Real}^{\uparrow}$ seal, the $\mathsf{CauchyFilter}^{\uparrow}$ row records the Cauchy boundary before completion is read, and the $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, and $\mathsf{Adjunction}^{\uparrow}$ rows keep the extension and universal-mapping reads inside P.

Finally inspect the carrier inventory. It has no coordinate for a quotient completion, selected representative, host equality row, countable-choice selector, open-cover compactness principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$. Therefore no accepted Real-facing read can export any of those objects. □

Theorem 1456.5 (CauchyCompletionAdjunction unit universal route)**.** *For an accepted* CauchyCompletionAdjunct *carrier $A = (X, C, D, E, U, H, P, N)$, every unit-admitted source read that is later consumed by the completion universal property factors through the displayed source row X, dense embedding row C, completion seal row D, extension candidate row E, uniqueness ledger U,* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff named by P, componentwise transport and replay row H, provenance row P, and local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjunction}^{\uparrow}}$ *row N of Definition 1456.1.*

Consequently a unit-side consumer has no route to quotient completions, selected limits, countable choice, host function equality, ambient completeness, or a completion object outside the displayed universal-property packet.

Proof. Begin with the NameCert obligation theorem. Theorem 1456.2 exposes the source row, dense embedding row, extension row, uniqueness ledger, and Real/RegSeqRat handoff as finite obligation rows of the same carrier.

Next apply the extension handoff theorem. Theorem 1456.3 forces a uniformly continuous finite-window consumer through X, C, D, E, U, H, P, N before the $\mathsf{CompletionUniversalProperty}^{\uparrow}$ surface can be read.

It remains to keep the unit read inside the Real seal. Theorem 1456.4 routes the terminal read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, and $\mathsf{Adjunction}^{\uparrow}$ as named by P.

The carrier has no coordinate for quotient completions, selected limits, countable choice, host function equality, or ambient completeness. Thus every unit-admitted source read consumed by the universal property uses exactly the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjunction}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ packet is generated from a source metric and Cauchy-observation row, a dense embedding into the completion seal, a completion-seal row, an extension candidate for uniformly continuous finite-window consumers, a dense-row uniqueness ledger, componentwise hsame and Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1456.1, Definition 1456.2, Definition 1456.3, Definition 1456.4, and Definition 1456.5 bind the L10 completion universal mapping boundary over the StreamName, RegSeqRat, CauchyFilter, Real, CompletionUniversalProperty, CompletionFunctor, and Adjunction rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjunction}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyCompletionAdjunctionUp.CauchyCompletionAdjunctionTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, open-cover compactness, countable choice, host function equality, ambient completeness, or bridge checking.

Upgrade path: A formal route can encode the eight-row carrier and prove the classifier transport, dense embedding preservation, extension row, uniqueness ledger, and Real/RegSeqRat handoff non-escape clauses.

Chapter 1457

A Concrete Naming Certificate for $\mathsf{DedekindCauchySeal}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Troelstra–van Dalen constructive metamathematics, the $\mathsf{DedekindCauchySeal}^{\uparrow}$ packet records the finite bidirectional seal between located Dedekind-cut observations and regular Cauchy-name observations. It sits after the located-cut surface of chapter 436, the comparison boundary of chapter 1424, the regular rational source of chapter 301, the stream-window source of chapter 126, the dyadic arithmetic core of chapter 291, and the terminal real-name seal of chapter 38. The chapter names only the finite seal surface by which the two representations can be read against one another; it does not construct $\mathsf{Real}^{\uparrow}$ from cuts and does not assert ambient completeness.

Definition 1457.1 (DedekindCauchySeal carrier)**.** *A* $\mathsf{DedekindCauchySeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, R, W, T, F, G, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DedekindCut}^{\uparrow}$ *row, carrying the located lower and upper rational observations that may be read by a seal consumer.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, carrying the regular rational Cauchy name used for finite tolerance requests.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family through which the row R is exposed.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the radii, rational comparison budgets, and finite refinement rows used on both sides of the seal.*
5. *F is the forward seal row that regularizes a displayed located-cut observation into a finite regular Cauchy window against T.*
6. *G is the reverse seal row that reads a displayed regular Cauchy window back as located cut data against T.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *boundary row reached only after D, R, W, T, F, G have been displayed.*
8. *H records componentwise* hsame *transport for the cut, regular-name, stream-window, dyadic, forward, reverse, Real-boundary, continuation, provenance, and local naming rows.*
9. *C records the displayed* Cont *replay route for rereading the same finite rows under an accepted consumer motion.*

10. *P is the* Pkg *provenance over* $\mathsf{DedekindCauchySeal}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCauchySeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a Dedekind construction of $\mathsf{Real}^{\uparrow}$*, ambient completeness, quotient stream equality, real trichotomy, countable choice, selected representatives, or host real equality.*

Definition 1457.2 (DedekindCauchySeal classifier)**.** *The* $\mathsf{DedekindCauchySeal}^{\uparrow}$ *classifier accepts exactly those finite reads of the carrier $S = (D, R, W, T, F, G, E, H, C, P, N)$ that proceed through one of the following displayed routes:*

1. *a cut-to-name route reading D, then the tolerance ledger T, then the forward seal row F, then the stream windows W and regular row R;*
2. *a name-to-cut route reading R through W, then the tolerance ledger T, then the reverse seal row G, then the located-cut row D;*
3. *a Real-boundary route reading D, R, W, T, F, G before the terminal row E.*

All accepted classifier answers are transported by H, replayed by C, and recorded by P, N. The classifier rejects any request whose answer would require data outside the displayed BHist *packet.*

Theorem 1457.3 (DedekindCauchySeal NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{DedekindCauchySeal}^{\uparrow}}$ *surface for Definition 1457.1 consists exactly of carrier exposure for S, classifier exposure through Definition 1457.2, forward regularization through F, reverse cut readback through G, dyadic budget control through T, stream-window exposure through W, terminal* $\mathsf{Real}^{\uparrow}$ *boundary exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Carrier exposure is projection from the displayed BHist packet $S = (D, R, W, T, F, G, E, H, C, P, N)$. The analytic rows are exactly the $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, forward seal, reverse seal, and $\mathsf{Real}^{\uparrow}$ boundary rows named in the carrier.

The classifier is finite by Definition 1457.2. Each accepted read first chooses one of the displayed routes, and each route is exhausted by the stored rows D, R, W, T, F, G, E.

The structural rows then close the local naming surface. The hsame row transports each displayed component, the Cont row replays the same finite route, and the Pkg and NameCert rows record the public packet. Since no excluded principle appears as a coordinate of S, the listed obligations exhaust the seal surface. □

Theorem 1457.4 (Forward regularization through the seal)**.** *Every accepted* $\mathsf{DedekindCauchySeal}^{\uparrow}$ *packet $S = (D, R, W, T, F, G, E, H, C, P, N)$ exposes a finite forward route from located Dedekind-cut observations to regular Cauchy-name observations:*

$$D \longmapsto T \longmapsto F \longmapsto W \longmapsto R.$$

The route uses only displayed BHist, hsame, Cont, Pkg, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal rows, and it exports no quotient stream equality, selected representative, countable-choice schedule, or host real equality.*

Proof. Project the carrier of Definition 1457.1. A cut-facing request can read located rational observations only from D and can refine them only through the dyadic ledger T.

The forward seal row F is stored after those two rows. It therefore has access only to the displayed cut observations and tolerance budget, and its output is forced into the stream-window family W before the regular rational row R is read.

Transport and replay do not add analytic data. The rows H and C preserve the same route, while P and N record that the route is the public $\mathsf{DedekindCauchySeal}^{\uparrow}$ certificate. The missing quotient, representative, choice, and host-equality data cannot be recovered from the packet. □

Theorem 1457.5 (Reverse cut readback through the seal)**.** *Every accepted* $\mathsf{DedekindCauchySeal}^{\uparrow}$ *packet* $S = (D, R, W, T, F, G, E, H, C, P, N)$ *exposes a finite reverse route from regular Cauchy-name observations to located Dedekind-cut observations:*

$$R \longmapsto W \longmapsto T \longmapsto G \longmapsto D.$$

The route reads the regular rational row only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows, uses the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger as its comparison budget, and returns only the displayed* $\mathsf{DedekindCut}^{\uparrow}$ *row.*

Proof. Start with a name-facing request. The carrier makes the regular rational row R visible only through the finite windows W, so the request cannot inspect an infinite stream or a quotient stream object.

The dyadic ledger T supplies the finite comparison radii for the reverse read. The reverse seal row G then reads the same windowed name data back into the located-cut row D and has no coordinate from which to choose representatives or host equalities.

Finally apply the structural rows. Componentwise hsame transport and displayed Cont replay keep the consumer on R, W, T, G, D, while Pkg provenance and the local $\mathsf{NameCert}$ row bind the route to the same public packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCauchySeal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DedekindCauchySeal}^{\uparrow}$ packet is generated from a $\mathsf{DedekindCut}^{\uparrow}$ row, a $\mathsf{RegSeqRat}^{\uparrow}$ row, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, forward and reverse seal rows, a terminal $\mathsf{Real}^{\uparrow}$ boundary row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCauchySeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1457.1, Definition 1457.2, Definition 1457.3, Definition 1457.4, and Definition 1457.5 seed the finite bidirectional seal between located Dedekind cuts and regular Cauchy names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCauchySeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a Dedekind construction of $\mathsf{Real}^{\uparrow}$, ambient completeness, quotient stream equality, trichotomy, countable choice, selected representatives, host real equality, or bridge checking.

Upgrade path: Scoped closure requires a checked finite carrier theorem binding the displayed cut row, regular Cauchy row, stream windows, dyadic tolerance ledger, forward seal, reverse seal, and Real-boundary row.

Chapter 1458

SeparableMetricUp NameCert Construction

Following Bishop and Bridges, and the classical Bourbaki presentation of separable metric spaces, the $\mathsf{SeparableMetric}^{\uparrow}$ packet records countable density as displayed finite name data rather than as a choice principle over arbitrary balls. It sits beside the distance certificate of chapter 57, the stream-window surface of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance rows of chapter 291, the real-facing seal of chapter 38, and the completion consumer of chapter 128. Its role is to expose the L10 countable-name surface consumed by completion and compact-metric chapters without importing selected dense points, quotient completion equality, open-cover compactness, or ambient Real completeness.

Definition 1458.1 (Separable metric carrier surface)**.** *A* $\mathsf{SeparableMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, A, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the underlying* $\mathsf{Met}^{\uparrow}$ *carrier and its public distance-witness surface.*
2. *A is the countable dense-name family, represented as a unary index schedule together with the finite rows naming the indexed dense candidates inspected by a request.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for requests of the form "indices below a displayed bound and tolerance below a displayed scale".*
4. *T is the tolerance ledger, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows and through the* $\mathsf{Real}^{\uparrow}$ *comparison rows already exposed by the metric distance certificate.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that packages the inspected finite windows and tolerances as regular rational observation data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *distance-seal row reached only after the metric carrier, dense-name window, tolerance ledger, and regular rational handoff have been displayed.*
7. *H stores componentwise* hsame *transport for the metric carrier, dense-name family, finite windows, tolerance ledger, regular handoff, real seal, continuation routes, package provenance, and local naming.*

8. *C stores the displayed* Cont *replay route from finite requests to dense-name windows, from windows to dyadic or real tolerance rows, and from those rows to the regular rational and distance-seal consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparableMetric}^{\uparrow}}$ *row.*

The carrier compares accepted separable-metric packets only through these rows. It contains no coordinate for choosing a dense point from every inhabited ball, no quotient equality for completion points, no open-cover compactness certificate, and no ambient Real-completeness principle.

Lean4 (definition) `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier`

Theorem 1458.2 (Separable metric NameCert obligation surface)**.** *For every accepted* $\mathsf{SeparableMetric}^{\uparrow}$ *carrier $S = (M, A, W, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeparableMetric}^{\uparrow}}$ *surface consists exactly of the following six obligations:*

1. *carrier admission for the displayed metric carrier, countable dense-name family, finite request windows, tolerance ledger, regular rational handoff, real distance seal, transport, continuation, package provenance, and local naming rows;*
2. *metric compatibility, stating that all distance reads are inherited from the displayed* $\mathsf{Met}^{\uparrow}$ *certificate M and not from a second host metric;*
3. *countable-name visibility, stating that dense candidates are inspected only through the indexed family A and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows W;*
4. *tolerance discipline, stating that every density request carries its tolerance through T as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *row before any handoff is consumed;*
5. *regular handoff, stating that R is obtained only from the displayed dense-name windows and tolerance rows;*
6. *nonescape, stating that E, H, C, P, N preserve the same finite dependency surface and export no choice-selected dense point, quotient completion equality, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1458.1. The tuple already lists the only coordinates available to the classifier: the metric certificate, the countable dense-name family, finite windows, tolerance ledger, regular rational handoff, real seal, transport, continuation, provenance, and local naming rows.

Metric compatibility is inherited from M. A separability consumer may ask for distances from indexed candidates to a target row only through the public $\mathsf{Met}^{\uparrow}$ distance-witness surface, so no second host metric or ambient equality test is introduced.

Countable-name visibility is the role of A and W. The indexed family supplies candidates only when a finite request window is displayed, and hsame transport in H preserves that same windowed family under classifier replacement.

The tolerance and regular faces are downstream from the same window. The ledger T records the dyadic or real tolerance rows read by the request, and R repacks exactly those finite observations as the $\mathsf{RegSeqRat}^{\uparrow}$ handoff.

Finally, continuation and package provenance do not add analytic strength. The rows E, C, P, N only replay and name the displayed dependency chain, so selected dense points, quotient completion equality, open-cover compactness, and ambient Real completeness are outside the packet. □

Theorem 1458.3 (Separable metric dense-window stability)**.** *Let $S = (M, A, W, T, R, E, H, C, P, N)$ be an accepted* $\mathsf{SeparableMetric}^{\uparrow}$ *carrier. If two finite density requests read the same indexed dense-name window through W and the same tolerance row through T, then every* $\mathsf{CompleteMetric}^{\uparrow}$*-facing or* $\mathsf{Real}^{\uparrow}$*-distance consumer receives the same displayed route*

$$A, W, T \longmapsto R \longmapsto E$$

transported by H and replayed by C under the package provenance P and the local naming row N. The stable window route contains no choice-selected dense point, quotient completion equality, open-cover compactness, or ambient Real completeness.

Proof. Begin with the common finite window. Since both requests expose the same indexed rows of A through W, a consumer sees the same finite dense-name candidates before any distance or completion-facing read is available.

Read the tolerance ledger next. The shared row T fixes the $\mathsf{DyadicRatCore}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ tolerance data attached to that finite window, and the metric compatibility obligation keeps those reads inside the displayed $\mathsf{Met}^{\uparrow}$ distance surface.

The regular handoff is therefore fixed. The row R is built from the same dense-name window and tolerance ledger in both requests, and the terminal seal E is downstream from R.

Transport and replay preserve the route rather than choosing a new candidate. The rows H and C carry the same finite dependency chain to $\mathsf{CompleteMetric}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers, while P and N record package provenance and local naming. Thus the stable route exports no selected dense point, quotient completion equality, open-cover compactness, or ambient Real completeness. □

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier dense window stability`

Theorem 1458.4 (Separable metric countable-density carrier admission)**.** *Let $S = (M, A, W, T, R, E, H, C, P, N)$ be the displayed* $\mathsf{SeparableMetric}^{\uparrow}$ *packet of Definition 1458.1. Carrier admission for S is exactly the finite* BHist *admission of the* $\mathsf{Met}^{\uparrow}$ *distance row M, the indexed dense-name row A, the* $\mathsf{StreamName}^{\uparrow}$ *request window W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R, the* $\mathsf{Real}^{\uparrow}$ *distance seal E, componentwise* hsame *transport H,* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{SeparableMetric}^{\uparrow}}$ *naming row N. No admitted coordinate chooses a dense point from an arbitrary inhabited ball, identifies quotient-completion classes, or imports ambient real completeness.*

Proof. Project the carrier tuple from Definition 1458.1. Each admissible component is already named by a finite BHist row: the metric distance row, dense-name index row, window row, tolerance row, regular handoff, real seal, transport, replay, provenance, and local certificate.

The admission test is therefore componentwise. The $\mathsf{Met}^{\uparrow}$ row supplies the only distance surface, A and W supply the only countable-density observations, T supplies the dyadic or real tolerance data, and R and E are downstream of those displayed rows.

Transport, continuation, provenance, and naming do not add a selection principle. The rows H, C, P, N only preserve and package the finite route, so a selected dense point, quotient-completion equality, or ambient Real-completeness witness would require a coordinate not present in S. □

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier countable density admission`

Theorem 1458.5 (Separable metric dense-window metric compatibility)**.** *For an accepted* $\mathsf{SeparableMetric}^{\uparrow}$ *packet* $S = (M, A, W, T, R, E, H, C, P, N)$*, every finite density request that reads an indexed candidate through the* $\mathsf{StreamName}^{\uparrow}$ *window* W *must compute its distance comparison through the displayed* $\mathsf{Met}^{\uparrow}$ *distance row* M *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance row* T *before it can be handed to* R *or sealed by* E*. The* hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and* $\mathsf{NameCert}_{\mathsf{SeparableMetric}^{\uparrow}}$ *row* N *preserve that route for later consumers.*

Proof. Start with a finite density request. The only candidate names visible to the request are the indexed rows of A admitted through the window W, so the request has no direct access to a host dense set or to a separately chosen point.

Metric compatibility is forced by the available distance row. Before a candidate can be compared with a tolerance, the request must pass through M and then through the displayed tolerance ledger T, read as $\mathsf{DyadicRatCore}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ data.

Only after those rows are displayed can the request reach the regular handoff R and the real-facing seal E. The rows H, C, P, N transport, replay, package, and locally name the same route, so the metric comparison cannot be replaced by a second metric or by quotient-completion equality. □

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier dense window metric compatibility`

Theorem 1458.6 (Separable metric finite-density public export)**.** *Every accepted* $\mathsf{SeparableMetric}^{\uparrow}$ *packet* $S = (M, A, W, T, R, E, H, C, P, N)$ *exports a public finite-density route through the displayed* $\mathsf{Met}^{\uparrow}$ *distance row* M*, indexed dense-name row* A*, finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance row* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. Any* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{PolishSpace}^{\uparrow}$ *consumer may cite only that finite route through* H, C, P, N *and may not cite selected dense points, quotient completion equality, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier finite density public export`

Proof. Project the carrier of Definition 1458.1. The rows $M, A, W, T, R, E, H, C, P, N$ are the only public data exposed by the accepted separable-metric packet.

Apply Definition 1458.2 and Definition 1458.4. These identify the metric distance row, indexed dense-name row, finite window, tolerance ledger, regular handoff, real seal, transport, replay, provenance, and local naming as the admitted finite-density surface.

Use Definition 1458.3 together with Definition 1458.5. The dense-name window is stable under matching finite requests, and every distance comparison passes through M and T before R or E can be consumed.

Thus a completion or Polish-space consumer receives only the displayed finite route through $M, A, W, T, R, E, H, C, P, N$. Since selected dense points, quotient completion equality, open-cover compactness, and ambient Real completeness are absent from the carrier and from the obligation surface, they cannot be exported. □

Theorem 1458.7 (Separable metric regular-handoff obligation)**.** *Let* $S = (M, A, W, T, R, E, H, C, P, N)$ *be an accepted* $\mathsf{SeparableMetric}^{\uparrow}$ *packet. The* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *is obligated to use only the dense-name observations displayed by* A *and* W*, the* $\mathsf{Met}^{\uparrow}$ *distance row* M*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance rows in* T*. Its export to* E, H, C, P, N *is a finite NameCert-local route, not a selected Cauchy subsequence, quotient-completion equality, open-cover compactness witness, or ambient completeness proof.*

Proof. Read the handoff row in the order exposed by the carrier. The dense observations come from A through the finite $\mathsf{StreamName}^{\uparrow}$ window W, and all metric comparisons have already been routed through M and the tolerance ledger T.

The row R repackages exactly those observations as regular rational data. It has no independent coordinate for selecting a subsequence, choosing a dense point, or asserting equality of completion representatives.

The export surface is then the displayed seal, transport, replay, provenance, and local naming rows E, H, C, P, N. These rows make the handoff available to $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and later NameCert consumers while preserving the finite packet boundary and refusing open-cover compactness or ambient Real-completeness data. □

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier regular handoff obligation`

Theorem 1458.8 (Separable metric tolerance-net replay)**.** *Let $S = (M, A, W, T, R, E, H, C, P, N)$ be an accepted $\mathsf{SeparableMetric}^{\uparrow}$ carrier. Every finite density request whose indexed window is displayed by W and whose tolerance is displayed by T replays through the finite route*

$$M, A, W, T \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

In particular, the request reads $\mathsf{Met}^{\uparrow}$ distance data, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, $\mathsf{RegSeqRat}^{\uparrow}$ handoff data, and $\mathsf{Real}^{\uparrow}$ distance seals only through the carrier rows of S.

Proof. Project the carrier tuple of Definition 1458.1. The rows M, A, W, T display the metric certificate, indexed dense-name family, finite request window, and tolerance ledger before any downstream handoff is available.

Use the NameCert obligation surface of Definition 1458.2. Metric compatibility keeps all distance reads inside M, countable-name visibility keeps the request inside A and W, and tolerance discipline keeps the precision data inside T.

The regular and real-facing rows are then forced. The row R repacks the same inspected window and tolerance ledger as $\mathsf{RegSeqRat}^{\uparrow}$ data, while E supplies the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally H, C, P, N transport, replay, source, and name that route. No step introduces a selected dense point or a second tolerance witness outside the displayed packet. □

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier tolerance net replay`

Theorem 1458.9 (Separable metric completion-consumer handoff)**.** *Let $S = (M, A, W, T, R, E, H, C, P, N)$ be an accepted $\mathsf{SeparableMetric}^{\uparrow}$ carrier. Every $\mathsf{CompleteMetric}^{\uparrow}$ consumer of S receives only indexed dense-name windows, tolerance rows, regular handoff rows, and real distance seals displayed by*

$$A, W, T, R, E, H, C, P, N.$$

The consumer receives no selected dense point, quotient completion equality, open-cover compactness certificate, or ambient Real completeness principle.

Proof. Project the tuple $S = (M, A, W, T, R, E, H, C, P, N)$. The only separability coordinates available to a completion consumer are the indexed dense-name family, the finite windows, the tolerance ledger, the regular handoff, and the real distance seal.

Apply Definition 1458.2. Countable-name visibility prevents the consumer from replacing A by a selector over balls, and tolerance discipline prevents the consumer from reading a precision datum before T is displayed.

Apply Definition 1458.3. If two completion-facing reads share the same finite window and tolerance row, then the route through R and E is the same under H and C.

Thus the $\mathsf{CompleteMetric}^{\uparrow}$ handoff is windowed and indexed. Since selected points, quotient completion equality, open-cover compactness, and ambient Real completeness are absent from the carrier, they cannot be exported to the consumer. □

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier completion consumer handoff`

Theorem 1458.10 (Separable metric RegSeqRat density handoff)**.** *Let $S = (M, A, W, T, R, E, H, C, P, N)$ be an accepted $\mathsf{SeparableMetric}^{\uparrow}$ carrier. Every $\mathsf{RegSeqRat}^{\uparrow}$ handoff exported by the separability packet is downstream of the same countable dense-name family A and the same tolerance ledger T that feed the request window W. The handoff cannot be formed from a different dense family, an untracked tolerance, or an ambient real-completeness argument.*

Proof. Project A, W, T, R from Definition 1458.1. The row W displays the finite indices inspected from A, and the row T displays the dyadic or real tolerance data attached to that same request.

Use Definition 1458.2. The regular handoff obligation states that R is obtained only from the displayed dense-name windows and tolerance rows, while the nonescape obligation keeps all downstream rows on the same finite dependency surface.

The transport and replay rows preserve the source of the handoff. The rows H and C cannot replace the dense-name family or tolerance ledger; they only carry the displayed A, W, T, R, E route to later consumers.

Therefore every $\mathsf{RegSeqRat}^{\uparrow}$ density handoff is downstream of the same countable dense-name family and tolerance ledger. A different dense family, untracked tolerance, or ambient real-completeness argument has no carrier coordinate from which it could be read. □

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier regseqrat density handoff`

Theorem 1458.11 (Separable metric obligation frontier)**.** *For every accepted $\mathsf{SeparableMetric}^{\uparrow}$ countable-density read from a carrier*

$$S = (M, A, W, T, R, E, H, C, P, N),$$

the obligation frontier is exhausted by the displayed $\mathsf{Met}^{\uparrow}$ row M, the indexed dense-name row A, the $\mathsf{StreamName}^{\uparrow}$ window W, the $\mathsf{DyadicRatCore}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ tolerance ledger T, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R, the $\mathsf{Real}^{\uparrow}$ seal E, and the structural rows H, C, P, N. It refuses selected dense points, quotient completion equality, open-cover compactness, and ambient Real completeness.

Proof. Project the carrier S. The finite rows $M, A, W, T, R, E, H, C, P, N$ are the only rows exposed to a countable-density consumer.

Apply Definition 1458.2. The obligation surface already separates metric compatibility, countable-name visibility, tolerance discipline, regular handoff, and nonescape.

Use Definition 1458.3 and Definition 1458.8. The dense-name family is read only through the finite window W, while the tolerance ledger T is replayed through the metric row M before the regular handoff and Real seal are visible.

Apply Definition 1458.9 and Definition 1458.10. Completion and regular-rational consumers receive the same displayed route through $A, W, T, R, E, H, C, P, N$ rather than a selected dense point, quotient-completion equality, open-cover compactness certificate, or ambient Real-completeness principle.

Thus the frontier for L10 countable density is exactly the displayed Metric, indexed dense-name, StreamName, tolerance, RegSeqRat, Real, transport, replay, provenance, and local naming route. □

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricCarrier obligation frontier`

Theorem 1458.12 (Separable metric public density export)**.** *Every public countable-density read exported by an accepted* $\mathsf{SeparableMetric}^{\uparrow}$ *packet*

$$S = (M, A, W, T, R, E, H, C, P, N)$$

factors through the displayed Metric row M*, indexed dense-name row* A*,* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance ledger* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, and structural rows* H, C, P, N*. The export gives downstream consumers a public countable-density route, but it exports no selected dense point, quotient completion equality, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.SeparableMetricUp.SeparableMetricPublicDensityExport`

Proof. Start with Definition 1458.2. It identifies the accepted carrier surface as exactly $M, A, W, T, R, E, H, C, P, N$, so a public read has no coordinate outside the displayed Metric, dense-name, window, tolerance, handoff, seal, transport, replay, provenance, and local naming rows.

Use Definition 1458.3. The indexed dense-name family can be consumed only through the finite $\mathsf{StreamName}^{\uparrow}$ windows W, and matching windows with matching tolerance rows replay the same route to completion-facing and Real-facing consumers.

Apply Definition 1458.9 and Definition 1458.10. Completion consumers receive only the displayed $A, W, T, R, E, H, C, P, N$ route, while the $\mathsf{RegSeqRat}^{\uparrow}$ density handoff remains downstream of the same dense-name family and tolerance ledger.

Thus the public export is the componentwise projection of the closed countable-density frontier in Definition 1458.11. Since selected dense points, quotient completion equality, open-cover compactness, and ambient Real completeness are absent from that frontier, they cannot be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparableMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SeparableMetric}^{\uparrow}$ packet is generated from a displayed MetricUp carrier, an indexed dense-name family, finite StreamName request windows, DyadicRatCore or RealUp tolerance rows, a RegSeqRat handoff, a RealUp distance seal, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparableMetric}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1458.1, Definition 1458.2, Definition 1458.3, Definition 1458.8, Definition 1458.9, Definition 1458.10, Definition 1458.11, and Definition 1458.12 bind the displayed $\mathsf{Met}^{\uparrow}$ carrier, indexed dense-name family, $\mathsf{StreamName}^{\uparrow}$ request windows, $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows as the public L10 countable-density export scope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparableMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected dense points, quotient completion equality, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: The paper-side countable-density, completion-handoff, RegSeqRat, StreamName, and Real-seal treatment is mature; the remaining work is independent Lean verification and bridge checking.

Chapter 1459

A Concrete Naming Certificate for $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ packet records the finite comparison test that lets a displayed majorant regular Cauchy source certify a target stream before the Real-facing route is consumed. It sits over the regular rational readback of chapter 301, the dyadic tolerance surface of chapter 291, the finite window discipline of chapter 126, and the explicit completion-modulus route of chapter 1469. The packet is a constructive comparison principle for the open L10 real-completion path; it is not a quotient of streams, a selected limit, a host real comparison, countable choice, or an ambient completeness theorem.

Definition 1459.1 (Regular Cauchy comparison test carrier)**.** *A* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, M, D, W, H, C, P, N)$$

with the following displayed rows:

1. *A is the majorant regular Cauchy source row whose finite tolerances bound the comparison.*
2. *B is the target stream or source row to be tested against the displayed majorant.*
3. *M is the explicit modulus row assigning each displayed tolerance request a finite threshold.*
4. *D is the dyadic domination and tolerance ledger, including the dyadic scale, comparison endpoint rows, and displayed domination certificates at each inspected tolerance.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family on which the source row, target row, modulus row, and dyadic ledger are all read.*
6. *H records componentwise* hsame *transport for the majorant source, target source, modulus, dyadic ledger, stream windows, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each tolerance request through M to the window in W, then through D to the target Cauchy row and the downstream regular rational handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{BishopCompletionModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows above. It has no coordinate for quotient stream equality, a hidden infinite tail selector, a host real value, a selected completed limit, countable choice, or ambient completeness.

Theorem 1459.2 (Regular Cauchy comparison test NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *carrier* $T = (A, B, M, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonTest}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed nine-row packet;*
2. *majorant-source exposure for* A *and target-source exposure for* B *on the same finite window family* W*;*
3. *modulus threshold readback, stating that every inspected tolerance request reads its threshold from the displayed row* M*;*
4. *dyadic domination compatibility, stating that each displayed tolerance in* D *bounds the target row* B *by the majorant row* A *on the requested window;*
5. *transport stability, stating that the threshold and domination rows are preserved by the componentwise* hsame *rows in* H*;*
6. *continuation replay, provenance, and local naming for exactly the route recorded by* C, P, N*.*

These obligations are finite-row obligations over the sibling surfaces of chapter 301, chapter 291, chapter 126, and chapter 1469.

Proof. Project the carrier $T = (A, B, M, D, W, H, C, P, N)$. The projection exposes exactly the majorant source, target source, modulus row, dyadic ledger, finite window family, transport rows, continuation replay, provenance, and local naming row.

For a displayed tolerance request, read the modulus row M to obtain the finite threshold. The same threshold selects the relevant finite windows in W, so both A and B are inspected only through displayed data.

The dyadic ledger then supplies domination at that tolerance. Since the comparison row in D is attached to the same threshold and window, the target Cauchy row is obtained by finite-row projection from the displayed domination certificate rather than from a hidden tail argument.

Finally apply the structural rows. The hsame rows in H preserve the threshold and domination data componentwise, while C, P, N only replay, source, and name the displayed route. No omitted coordinate remains from which an additional NameCert obligation could be read. □

Theorem 1459.3 (Regular Cauchy comparison test RegSeqRat handoff)**.** *Every accepted* $\mathsf{RegularCauchyComparison}$ *carrier hands the target row to* $\mathsf{RegSeqRat}^{\uparrow}$ *only through the finite route*

$$A, B, M \longmapsto W, D \longmapsto H, C, P, N.$$

In particular, a completion-facing consumer can reach the downstream Real-completion path only after reading the displayed $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *domination ledger, and the* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *threshold route that bind the target row to the majorant source.*

Proof. Begin with an accepted carrier and fix a displayed tolerance request. The modulus row M provides the threshold, and the finite windows in W are the only windows admitted for that request.

Read the target row through the domination ledger. At each displayed tolerance, the dyadic row D compares the target source B with the majorant regular Cauchy source A on the selected window. This supplies the target Cauchy row as a finite consequence of displayed domination.

Transport preserves the same route. The componentwise hsame rows in H carry the modulus threshold, the selected window, and the dyadic domination certificate together, so a transported carrier cannot change the RegSeqRat handoff while keeping the same comparison test.

The remaining rows are downstream bookkeeping. The Cont replay in C, the provenance row P, and the local naming row N send the displayed comparison route to the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and then to Real-completion consumers only through the named sibling rows. Thus $\mathsf{Real}^{\uparrow}$ is reachable along this path only after the StreamName, DyadicRatCore, and BishopCompletionModulus data have been displayed. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ consumer that reads a target $\mathsf{RegSeqRat}^{\uparrow}$ handoff without the displayed $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ domination rows, and $\mathsf{BishopCompletionModulus}^{\uparrow}$ threshold route refutes the carrier surface.

Independence witness: regseqrat, dyadicratcore, streamname, bishopcompletionmodulus: no listed sibling supplies the whole nine-row packet $T = (A, B, M, D, W, H, C, P, N)$, because each sibling contributes only a regular-source, dyadic-ledger, window, or modulus face while this chapter binds all four analytic faces with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonTest}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ packet is generated from a majorant regular Cauchy source, a target stream or source row, an explicit modulus row, dyadic domination and tolerance rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1459.1, Definition 1459.2, and Definition 1459.3 seed the finite comparison-test boundary over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{BishopCompletionModulus}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected completed limits, host real comparison, countable choice, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the nine-row carrier and prove the finite NameCert obligation surface and RegSeqRat handoff theorem.

Chapter 1460

A Concrete Naming Certificate for $\mathsf{DarbouxIntegral}^{\uparrow}$

Following Darboux and Bishop-style constructive analysis, the $\mathsf{DarbouxIntegral}^{\uparrow}$ packet presents integration through finite partitions, upper and lower dyadic step approximants, refinement ledgers, and $\mathsf{Real}^{\uparrow}$ handoff rows. It does not use measure completion, quotient functions, choice-selected tags, or ambient real completeness. The packet consumes the step-function surface of chapter 428, the finite partition ledger of chapter 201, and the public integration consumer boundary of chapter 123.

1460.1 Carrier packet

Definition 1460.1 (Darboux integral finite carrier)**.** *A* $\mathsf{DarbouxIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (P, U, L, SU, SL, G, R, H, C, N)$$

with the following displayed coordinates.

1. *P is a* $\mathsf{Partition}^{\uparrow}$ *row, read as the finite dyadic partition ledger on the integration interval.*
2. *U and L are upper and lower* $\mathsf{DyadicStepFunction}^{\uparrow}$ *approximants over a displayed common refinement of P.*
3. *SU and SL are the finite upper and lower Darboux sum rows computed from the cells and carried values of U and L.*
4. *G is the upper-lower gap and modulus ledger comparing SU and SL at the displayed precision.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff surface produced from the gap ledger.*
6. *H records the componentwise* hsame *transports of partition, step-function, sum, gap, and handoff rows.*
7. *C records the finite* Cont *routes that replay refinements, cell reads, finite sums, and handoff rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxIntegral}^{\uparrow}}$ *row and* Pkg *provenance surface attached to the packet.*

The carrier classifies two accepted packets only by these displayed rows. In particular, it has no coordinate for a selected tag, a host Riemann sum oracle, a quotient function space, a measure completion, or an ambient real-completeness principle.

Lean4 ✓ `BEDC.Derived.DarbouxIntegralUp.DarbouxIntegralTasteGate single carrier alignment`

1460.2 Certificate obligations

Theorem 1460.2 (Darboux integral NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{DarbouxIntegral}^{\uparrow}}$ *surface consists of the following five rows.*

1. *Carrier habitation for the finite packet* $D = (P, U, L, SU, SL, G, R, H, C, N)$ *of Definition 1460.1.*
2. *Refinement-stable classification of the displayed partition and upper/lower step-function approximants by common dyadic refinement.*
3. *Finite Darboux-sum exactness for* SU *and* SL *over the carried cells and values of* U *and* L*.*
4. *Gap-modulus exposure through* G*, with* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff through* R*.*
5. *Ledger exclusion of selected tags, quotient functions, measure completion, and ambient real-completeness data.*

Lean4 ✓ `BEDC.Derived.DarbouxIntegralUp.DarbouxIntegralPacket namecert obligations`

Proof. Carrier habitation is the finite packaging operation of Definition 1460.1. It displays the partition row, upper and lower step-function approximants, the two finite sum rows, the gap row, the handoff surface, transport routes, continuation routes, and the local name.

Refinement stability is read through the common-refinement machinery already exposed by the $\mathsf{DyadicStepFunction}^{\uparrow}$ packet. The same displayed refinement transports P, U, L, SU, and SL, so classification remains a finite ledger statement rather than a comparison of host functions.

The Darboux-sum and gap rows are then inspected as ledger coordinates. Since every downstream handoff to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{Integral}^{\uparrow}$ passes through G and R, the excluded host data have no carrier coordinate or continuation route. □

Theorem 1460.3 (Darboux partition carrier admission)**.** *Let* $D = (P, U, L, SU, SL, G, R, H, C, N)$ *be an accepted* $\mathsf{DarbouxIntegral}^{\uparrow}$ *carrier. A Darboux-integral read is admitted only when the finite* BHist *partition row* P *displays a closed interval source, a bounded real function row, the cell ledger used by the upper and lower step approximants, and the local* $\mathsf{NameCert}_{\mathsf{DarbouxIntegral}^{\uparrow}}$ *carrier row. The admission route is transported by the componentwise* hsame *rows in* H*, replayed by* C*, and sourced by the* Pkg *provenance inside* N*; it does not introduce Lebesgue measure, choice-selected partitions, or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.DarbouxIntegralUp.DarbouxIntegralPacket partition carrier admission`

Proof. Project the carrier of Definition 1460.1. The partition row P is the only source row from which cells can be read, and the upper and lower approximants U, L are downstream of that same finite ledger.

Use the carrier obligations of Definition 1460.2. Carrier habitation and refinement-stable classification require the closed interval source, bounded real function row, partition cells, and local NameCert row to be read before any sum or gap row is consumed.

The structural rows preserve admission. Componentwise hsame transport in H, finite Cont replay in C, and provenance through N keep the read on the displayed packet, so no measure object, selected partition family, or ambient completeness coordinate is admitted. □

Theorem 1460.4 (Darboux upper-lower sum ledger)**.** *For every accepted* DarbouxIntegral$^{\uparrow}$ *carrier* $D = (P, U, L, SU, SL, G, R, H, C, N)$*, the upper and lower sum rows* SU *and* SL *are computed from the displayed partition row* P*, the upper and lower* DyadicStepFunction$^{\uparrow}$ *rows* U, L*, and the carried Rational and Real sum ledgers. Componentwise* hsame *transport preserves the same cell list and value reads before the gap row* G *is inspected, and* Cont *replay exposes no host Riemann-sum oracle or choice-selected tags.*

Lean4 ✓ `BEDC.Derived.DarbouxIntegralUp.DarbouxIntegralPacket upper lower sum ledger`

Proof. Start from Definition 1460.3. The accepted read has already displayed the closed interval source, bounded function row, and finite partition ledger.

Compute the two sums by replaying C on the displayed cells. The upper row SU reads only the carried upper step values in U, and the lower row SL reads only the carried lower step values in L.

Transport through H keeps the partition cells and value rows aligned. The Rational and Real sum ledgers are therefore the finite ledgers already present in the packet, not a host summation oracle, a tagged Riemann sum, or a measure-completion read. □

Theorem 1460.5 (Darboux Cauchy gap nonescape)**.** *Let* $D = (P, U, L, SU, SL, G, R, H, C, N)$ *be an accepted* DarbouxIntegral$^{\uparrow}$ *carrier. Any Cauchy-facing or* Integral$^{\uparrow}$ *consumer that reads the gap row* G *must first consume the partition admission route and the upper/lower sum ledger, then read the* RegSeqRat$^{\uparrow}$/Real$^{\uparrow}$ *handoff row* R *through the same* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *surface. The gap cannot escape to Lebesgue measure, choice-selected partitions, quotient function equality, host completeness, or a detached real sequence.*

Lean4 ✓ `BEDC.Derived.DarbouxIntegralUp.DarbouxIntegralPacket cauchy gap nonescape`

Proof. Apply Definition 1460.3. It places the gap consumer behind the displayed partition row, closed interval source, bounded function row, and local carrier admission.

Apply Definition 1460.4. The gap row G compares the finite upper and lower sum ledgers SU, SL after their common partition and value rows have been read.

Finally inspect the handoff row R. The RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ reads are downstream of G and are transported, replayed, sourced, and named by H, C, N. Since the carrier has no coordinate for measure completion, selected partitions, quotient function equality, ambient completeness, or detached real sequences, the Cauchy gap cannot leave the displayed packet. □

Theorem 1460.6 (Darboux upper-lower sum gap)**.** *For accepted* DarbouxIntegral$^{\uparrow}$ *packets with displayed common refinement of their partition rows, transporting to that refinement preserves the visible upper/lower sum gap recorded by* G*. The transported packet computes* SU *and* SL *only from displayed refined cells and carried values, and the gap comparison never introduces a selected tag, quotient function, or measure completion.*

Lean4 ✓ `BEDC.Derived.DarbouxIntegralUp.DarbouxIntegralPacket upper lower sum gap`

Proof. Project the accepted packet through Definition 1460.1. The common refinement gives the finite cell list on which both approximants are read, and the rows U and L already carry the value data used on those cells.

Compute SU and SL by replaying the finite sum routes in C. Refinement only changes the displayed parent-cell ledger: each refined cell points back to a named cell, and its upper or lower value is the transported value already present in U or L.

The gap row G compares the two transported finite sums after this replay. Because the packet has no coordinate for tags, quotient functions, or measure completion, preserving the displayed gap cannot add any of those objects. □

Theorem 1460.7 (Darboux real handoff)**.** *An accepted* $\mathsf{DarbouxIntegral}^{\uparrow}$ *packet hands an* $\mathsf{Integral}^{\uparrow}$ *consumer only the displayed partition row, upper and lower* $\mathsf{DyadicStepFunction}^{\uparrow}$ *rows, upper and lower sum rows, gap ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *row,* $\mathsf{Real}^{\uparrow}$ *row, componentwise* hsame *transports, finite* Cont *routes,* Pkg *provenance, and local* NameCert *rows. No host integrand equality, measure completion, selected tag family, or ambient real-completeness witness is exported.*

Lean4 ✓ `BEDC.Derived.DarbouxIntegralUp.DarbouxIntegralPacket integral consumer surface`

Proof. Start from Definition 1460.2. The public surface is exhausted by the carrier, refinement classifier, Darboux-sum exactness, gap-modulus row, and ledger exclusion rows.

Use Definition 1460.6 to route every consumer-visible approximation through common refinement before the gap is read. The $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows in R are therefore handoff rows for the displayed gap ledger, not independent real-completeness data.

Finally pass the same rows to the $\mathsf{Integral}^{\uparrow}$ consumer boundary. That boundary receives the partition, step-function, sum, gap, handoff, hsame, Cont, Pkg, and NameCert rows named by the packet, and no additional analytic surface is available. □

Theorem 1460.8 (Darboux public gap seal)**.** *Every* $\mathsf{Integral}^{\uparrow}$*-facing public read of an accepted* $\mathsf{DarbouxIntegral}^{\uparrow}$ *packet factors through the displayed* $\mathsf{Partition}^{\uparrow}$ *row,* $\mathsf{DyadicStepFunction}^{\uparrow}$ *upper and lower approximants, finite Darboux sum rows, gap ledger* G*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DarbouxIntegral}^{\uparrow}}$ *rows before any public integral seal is visible. No public gap seal exports a host integrand equality, measure completion, selected tag family, quotient function equality, detached real sequence, or ambient real-completeness witness.*

Lean4 ✓ `BEDC.Derived.DarbouxIntegralUp.DarbouxIntegralPacket public gap seal`

Proof. Start from Definition 1460.2. The carrier and obligation rows expose the partition, upper and lower step approximants, finite sums, gap ledger, handoff rows, structural transport, replay, provenance, and local naming as the whole public surface.

Use Definition 1460.5. It places every Cauchy-facing or $\mathsf{Integral}^{\uparrow}$-facing read of G behind partition admission, the upper/lower sum ledger, and the $\mathsf{RegSeqRat}^{\uparrow}$/$\mathsf{Real}^{\uparrow}$ handoff through the same finite packet.

Finally apply Definition 1460.7. The consumer boundary receives exactly the partition, step-function, sum, gap, regular-rational, real-name, transport, replay, provenance, and local NameCert rows. Since the carrier has no coordinate for the excluded host data, the public integral seal can only be reached through those rows. □

Definition 1460.9 (Darboux integral mature boundary)**.** *The mature* $\mathsf{DarbouxIntegral}^{\uparrow}$ *boundary is the finite packet formed by the carrier of Definition 1460.1, the NameCert obligations of Definition 1460.2, the partition admission route, upper/lower sum ledger, Cauchy gap nonescape row, refinement-stable gap theorem, real handoff, and public gap seal of this chapter. Its public surface contains the partition-refinement examples, the non-escape rows excluding measure completion, selected tags, quotient function equality, host integrand equality, detached real sequences, and ambient real-completeness data, and the bridge-facing finite partition boundary recorded by Definition 1460.7 and Definition 1460.8. No additional analytic coordinate is part of the mature packet.*

Lean4 ✓ `BEDC.Derived.DarbouxIntegralUp.DarbouxIntegralPacket mature boundary certificate`

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxIntegral}^{\uparrow}$ packet is generated from a finite partition row, upper and lower $\mathsf{DyadicStepFunction}^{\uparrow}$ approximants, upper and lower Darboux sum rows, a visible gap ledger, a $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff surface, componentwise hsame transports, finite Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxIntegral}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1460.1, Definition 1460.2, Definition 1460.6, Definition 1460.7, and Definition 1460.9 bind the mature finite-partition Darboux real handoff over $\mathsf{Partition}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Integral}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a measure completion, quotient function space, selected tag family, host integrand equality, ambient real-completeness theorem, Lean verification, or bridge checking.

Upgrade path: The next theory step is a bridge theorem relating the public Darboux real handoff to the standard integration boundary.

Chapter 1461

A Concrete Naming Certificate for $\mathsf{RegularCauchyRatioTest}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ packet records the finite ratio-bound test that turns a displayed geometric tail estimate into a regular Cauchy source row before the Real-facing route is consumed. It sits over the regular rational readback of chapter 301, the finite-window discipline of chapter 126, the dyadic tolerance surface of chapter 291, the comparison handoff of chapter 1459, and the partial-sum ledger of chapter 121. The packet is a constructive ratio test for regular Cauchy tails; it is not a quotient of streams, a selected infinite tail, a host real norm, countable choice, or an ambient completeness theorem.

Definition 1461.1 (Regular Cauchy ratio test carrier)**.** *A* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, R, M, W, D, H, C, P, N)$$

with the following displayed rows:

1. *A is the source row for the series or tail family whose consecutive finite terms are inspected.*
2. *R is the ratio-bound row, displaying a dyadic bound strictly inside the unit tolerance scale together with the index after which the bound is claimed.*
3. *M is the modulus row assigning each displayed precision request a finite threshold beyond the ratio-bound index.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family on which the source row, ratio-bound row, modulus row, and downstream partial-sum rows are read.*
5. *D is the dyadic domination ledger that unfolds the finite geometric tail estimate from the ratio row and records the comparison majorant consumed by* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$*.*
6. *H records componentwise* hsame *transport for the source row, ratio-bound row, modulus, finite windows, dyadic domination ledger, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through R and M to the windows in W, then through D to the comparison-test handoff and the downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *row.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$*,* $\mathsf{Series}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRatioTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for quotient stream equality, an infinite product or power object, a hidden tail selector, a host real absolute value, a selected completed limit, countable choice, or ambient completeness.

Theorem 1461.2 (Regular Cauchy ratio test NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ *carrier* $T = (A, R, M, W, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRatioTest}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed nine-row packet;*
2. *source exposure for* A *on the finite windows in* W*;*
3. *ratio-bound exposure for* R*, including the displayed dyadic bound and the displayed entry index of the tail;*
4. *modulus readback for* M*, stating that every inspected precision request receives a finite threshold beyond the ratio-bound index;*
5. *dyadic geometric domination in* D*, producing the finite majorant tail consumed by* $\mathsf{RegularCauchyComparisonTest}$
6. *transport stability for the source, ratio-bound, modulus, window, and domination rows along the componentwise* hsame *rows in* H*;*
7. *continuation replay, provenance, and local naming for exactly the route recorded by* C, P, N*.*

These obligations are finite-row obligations over the sibling surfaces of chapter 301, chapter 126, chapter 291, chapter 1459, and chapter 121.

Proof. Project the carrier $T = (A, R, M, W, D, H, C, P, N)$. The projection exposes exactly the source row, ratio-bound row, modulus row, finite window family, dyadic domination ledger, transport rows, continuation replay, provenance, and local naming row.

For a displayed precision request, read the ratio-bound row R and the modulus row M. The ratio row supplies the dyadic bound and the entry index for the tail, while the modulus row supplies a finite threshold beyond that index. Thus the relevant part of the source is inspected only through the windows recorded in W.

The dyadic ledger D unfolds the finite geometric domination calculation. Because every factor and tolerance scale is displayed in D, the comparison majorant sent to $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ is a finite row rather than an appeal to an external infinite estimate.

Finally apply the structural rows. The componentwise hsame entries in H preserve the ratio-bound, threshold, window, and domination data together, while C, P, N only replay, source, and name the displayed route. No omitted coordinate remains from which an additional NameCert obligation could be read. □

Theorem 1461.3 (Regular Cauchy ratio test comparison handoff)**.** *Every accepted* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ *carrier hands a regular Cauchy tail to* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *only through the finite route*

$$A, R, M \longmapsto W, D \longmapsto H, C, P, N.$$

Consequently a $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer can use the ratio test only after reading the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *domination ledger, the ratio-bound row, and the comparison-test handoff row that binds the source to a regular Cauchy majorant.*

Proof. Begin with an accepted carrier and fix a displayed precision request. The rows R and M determine a finite threshold beyond the tail entry index, and W is the only family of source windows admitted for that request.

Read the finite domination ledger. The row D expands the ratio-bound data into a dyadic geometric tail estimate on the selected windows and presents that estimate in the same finite comparison format used by $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$.

Transport preserves the handoff. The componentwise hsame rows in H carry the source row, ratio-bound row, threshold, selected window, and domination certificate together, so a transported carrier cannot alter the comparison-test input while retaining the same displayed packet.

The remaining rows are bookkeeping for the public route. The Cont replay in C, the provenance row P, and the local naming row N send the comparison handoff to $\mathsf{RegSeqRat}^{\uparrow}$ and then to Real-facing consumers only through the named sibling rows. □

Theorem 1461.4 (Regular Cauchy ratio test nonescape)**.** *An accepted* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ *carrier cannot expose a regular Cauchy conclusion through any route that omits one of R, M, W, or D. In particular, the carrier surface rejects any consumer that claims the ratio-test conclusion from the source row A alone, from a host real ratio, from an unrecorded infinite tail estimate, or from ambient completeness.*

Proof. Suppose a consumer reads a regular Cauchy conclusion from an accepted carrier. By the NameCert obligation surface of Definition 1461.2, the only conclusion row exported by the carrier is obtained after reading the ratio-bound row R, the modulus row M, the finite windows W, and the dyadic domination ledger D.

If any one of these rows is omitted, the displayed route no longer contains the data needed to form the comparison-test input: without R there is no ratio bound, without M there is no finite threshold, without W there is no admitted source window, and without D there is no dyadic majorant ledger.

The structural rows cannot repair the omission. Transport in H preserves displayed data, and C, P, N replay, source, and name only the displayed route. Therefore any conclusion obtained from a host real ratio, an unrecorded infinite tail estimate, or ambient completeness lies outside the accepted $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ classifier. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ consumer that reads a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ conclusion without the displayed ratio-bound row, modulus row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ domination ledger, and $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ handoff refutes the carrier surface.

Independence witness: series, regseqrat, streamname, dyadicratcore, regular-cauchy-comparison-test: no listed sibling supplies the whole nine-row packet $T = (A, R, M, W, D, H, C, P, N)$, because each sibling contributes only a source, partial-sum, window, dyadic-ledger, or comparison face while this chapter binds the ratio-bound tail route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRatioTest}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ packet is generated from a source row, a displayed dyadic ratio-bound row, an explicit modulus row, finite $\mathsf{StreamName}^{\uparrow}$ windows, dyadic geometric domination rows, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRatioTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1461.1, Definition 1461.2, Definition 1461.3, and Definition 1461.4 seed the finite ratio-test boundary over $\mathsf{Series}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRatioTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected completed limits, host real ratios, countable choice, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the nine-row carrier and prove the finite NameCert obligation surface, comparison handoff theorem, and nonescape theorem.

Chapter 1462

A Concrete Naming Certificate for $\mathsf{ConnectedInterval}^{\uparrow}$

Following Bishop and Bridges, constructive connectedness of an interval is recorded by interval-refinement and separation-refusal data rather than by a host topological assertion. The $\mathsf{ConnectedInterval}^{\uparrow}$ packet packages finite closed $\mathsf{Real}^{\uparrow}$ endpoint rows, $\mathsf{NestedInterval}^{\uparrow}$ refinements, $\mathsf{DyadicBisection}^{\uparrow}$ branch ledgers, $\mathsf{IntermediateValue}^{\uparrow}$ sign-route rows, finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ observation windows, a visible $\mathsf{Real}^{\uparrow}$ seal route, and local $\mathsf{NameCert}$ evidence into one interval-connectedness certificate.

The certificate depends on the real-name boundary of chapter 38, the finite nested-window carrier of chapter 320, the branch ledger of chapter 361, and the sign-route handoff of chapter 1402. It does not claim open-cover compactness, Heine–Borel, trichotomy, host connectedness, quotient equality of real names, or an ambient theorem about all host intervals.

Definition 1462.1 (Connected interval carrier)**.** *A* $\mathsf{ConnectedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, R, W, B, S, T, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the closed endpoint rows read as* $\mathsf{Real}^{\uparrow}$ *names through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks;*
2. *W is the interval-window row naming the displayed finite subintervals inspected between the endpoints;*
3. *B is the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger used to refine any inspected separating witness into a finite branch row;*
4. *S is the* $\mathsf{NestedInterval}^{\uparrow}$ *refinement row obtained from the retained bisection windows;*
5. *T is the* $\mathsf{IntermediateValue}^{\uparrow}$ *sign-route row recording the finite route by which a sign-changing separation probe is forced to expose a crossing window;*
6. *E is the visible* $\mathsf{Real}^{\uparrow}$ *seal route offered to downstream interval consumers after the endpoint, refinement, branch, sign-route, and finite-window rows have been read;*
7. *H stores componentwise* hsame *transport for endpoints, windows, bisection rows, nested refinements, sign-route rows, real seals, continuation rows, package provenance, and local naming;*

8. *C stores displayed* Cont *replay from endpoint rows to observation windows, from windows to branch ledgers, from branch ledgers to nested refinements, from sign routes to the refusal row, and from those rows to the real seal;*
9. *P is the* Pkg *provenance over* $\mathsf{ConnectedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConnectedInterval}^{\uparrow}}$ *evidence row.*

The carrier predicate asserts that these rows form one finite interval-connectedness packet. Its classifier compares accepted packets only by replaying the displayed coordinates above. There is no coordinate for open-cover compactness, a global host topology, real trichotomy, quotient equality of real names, a selected separating point, or Heine–Borel.

Lean4 ✓ `BEDC.Derived.ConnectedIntervalUp.ConnectedIntervalCarrierRows`

Theorem 1462.2 (Connected interval NameCert obligations)**.** *For an accepted* $\mathsf{ConnectedInterval}^{\uparrow}$ *packet $K = (L, R, W, B, S, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConnectedInterval}^{\uparrow}}$ *surface consists exactly of closed endpoint admission for L and R, finite interval-window admission through W, dyadic branch-ledger exactness through B, nested-refinement stability through S, sign-route refusal through T, real-seal routing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 1462.1. The endpoint, window, branch, nested-refinement, sign-route, real-seal, transport, continuation, provenance, and naming rows are exactly the displayed coordinates of the finite packet.

Read the endpoint and window rows first. The two endpoint rows expose only closed $\mathsf{Real}^{\uparrow}$ names through finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ observations, while W records the inspected interval windows between them.

Read the refinement rows next. The dyadic ledger B supplies finite branch choices, and the nested row S repacks the retained windows with the displayed endpoint and width data still attached.

Finally read the refusal and seal rows. The sign-route row T supplies the finite intermediate-value route used by the separation-refusal obligation, and E, H, C, P, N bind that route to the visible real seal and the local certificate. Since the packet has no coordinate for open covers, host topology, trichotomy, quotient equality, selected separators, or Heine–Borel, those data cannot be obligations of the local NameCert. □

Lean4 ✓ `BEDC.Derived.ConnectedIntervalUp.ConnectedIntervalNameCertObligations`

Theorem 1462.3 (Connected interval separation refusal)**.** *Every accepted* $\mathsf{ConnectedInterval}^{\uparrow}$ *packet refuses a displayed two-sided separation only through finite interval data: any proposed separation read must pass through the endpoint rows L, R, the inspected window row W, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger B, the* $\mathsf{NestedInterval}^{\uparrow}$ *refinement row S, and the* $\mathsf{IntermediateValue}^{\uparrow}$ *sign-route row T. The refusal asserts no host connectedness principle beyond those rows.*

Lean4 ✓ `BEDC.Derived.ConnectedIntervalUp.ConnectedIntervalCarrier separation refusal`

Proof. Begin with a displayed separation read against the accepted packet K. The continuation routes expose the endpoint rows L, R and the finite interval-window row W before any branch or sign information is available.

Refine the inspected window by the dyadic branch ledger. The row B records the finite midpoint decisions, and the row S repacks the retained windows as a nested-refinement packet over the same endpoint and observation data.

Apply the sign-route row. The row T is the only coordinate that can turn opposite-side displayed reads into a crossing-window refusal, so the proposed separation must pass through the same intermediate-value route that generated T.

The resulting refusal is therefore internal to L, R, W, B, S, T and their transport and continuation rows. No step reads a global topology on host intervals, a trichotomy oracle, quotient real equality, a selected separator, compactness, or Heine–Borel. □

Theorem 1462.4 (Connected interval dyadic nesting obligations)**.** *An accepted* $\mathsf{ConnectedInterval}^{\uparrow}$ *packet may expose the* $\mathsf{NestedInterval}^{\uparrow}$ *refinement row S only after the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger B has displayed the retained midpoint decisions over endpoint rows L, R and finite window row W. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer then reads S through B, W,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. The route exports no host connectedness, trichotomy, selected separator, Heine–Borel, open-cover compactness, or quotient real equality.*

Lean4 ✓ `BEDC.Derived.ConnectedIntervalUp.ConnectedIntervalDyadicNestingObligations`

Proof. Project the carrier of Definition 1462.1. The nested-refinement row S is not a free coordinate: it is listed downstream of the endpoint rows L, R, the finite interval window W, and the dyadic branch ledger B.

Read the branch ledger before reading S. The ledger B displays the retained midpoint decisions over the same endpoints and window, so the nested row can only repack retained finite intervals already recorded by B.

Use Definition 1462.3 to keep those branch decisions inside the displayed interval data. Any attempted separation read must pass through L, R, W, B, S, T, and therefore cannot supply an external separator or host connectedness proof.

Finally read the consumer-facing rows. The $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ observations, together with hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ evidence, keep the refinement route finite before the $\mathsf{Real}^{\uparrow}$ seal is consumed. No row remains for trichotomy, selected separators, Heine–Borel, open-cover compactness, quotient real equality, or ambient host connectedness. □

Theorem 1462.5 (Connected interval nested-bisection ledger)**.** *Every accepted* $\mathsf{ConnectedInterval}^{\uparrow}$ *packet that exposes a nested-bisection read routes its endpoint rows L, R through finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{DyadicBisection}^{\uparrow}$ *branch ledger B, the* $\mathsf{NestedInterval}^{\uparrow}$ *row S, the* $\mathsf{IntermediateValue}^{\uparrow}$ *sign-route row T, the* $\mathsf{Real}^{\uparrow}$ *seal E, and the structural rows H, C, P, N. In carrier coordinates the route is*

$$L, R, W, B, S, T, E, H, C, P, N.$$

It exports no trichotomy, selected separator, quotient real equality, open-cover compactness, or Heine–Borel principle.

Lean4 ✓ `BEDC.Derived.ConnectedIntervalUp.ConnectedIntervalCarrier nested bisection ledger`

Proof. Project the carrier of Definition 1462.1. The endpoint rows L, R are read only as closed $\mathsf{Real}^{\uparrow}$ names through finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, and the nested-bisection read has no coordinate outside $W, B, S, T, E, H, C, P, N$.

Use Definition 1462.2 to order the rows. Endpoint admission and finite interval-window admission occur before the dyadic branch ledger, the nested-refinement row, the sign-route row, and the Real seal, while H, C, P, N keep the same displayed packet under transport, replay, provenance, and local naming.

Use Definition 1462.3 for the sign-route boundary. Any separating read must pass through L, R, W, B, S, T, so the packet cannot introduce trichotomy, a selected separator, host connectedness, or quotient equality of real names.

Finally apply Definition 1462.4. It identifies the B-to-S handoff as the only route by which retained midpoint decisions become a nested-refinement row. The Real-facing read therefore reaches E only after the finite bisection and nested-interval ledger has been exposed. □

Theorem 1462.6 (Connected interval real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{ConnectedInterval}^{\uparrow}$ *packet factors through the closed endpoint rows, finite observation windows, dyadic branch ledger, nested-refinement row, intermediate-value sign-route row, displayed* BHist *packet,* hsame *transports,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ConnectedInterval}^{\uparrow}}$ *row. The exported real route is a certificate boundary, not quotient equality or host connectedness.*

Proof. Expose the consumer route by projection from the carrier. The real-facing row E is reachable only after the endpoint rows L, R, the finite window row W, the branch ledger B, the nested row S, and the sign-route row T have been read.

Use Definition 1462.2 to exhaust the local certificate surface. Its real-facing obligations are precisely the listed carrier rows together with the transport, continuation, provenance, and naming rows H, C, P, N.

Use Definition 1462.3 for the connectedness boundary. Any read that treats the packet as an interval-connectedness object first passes through the finite separation-refusal route, so the real seal cannot be reinterpreted as host connectedness, quotient equality of real names, trichotomy, open-cover compactness, or Heine–Borel. □

Lean4 ✓ `BEDC.Derived.ConnectedIntervalUp.ConnectedIntervalRealRoute`

Theorem 1462.7 (Connected interval obligation closure route)**.** *Every accepted* $\mathsf{ConnectedInterval}^{\uparrow}$ *packet presents a finite BEDC induction route from the connected-interval carrier through dyadic nesting obligations, separation refusal, nested-bisection ledger, and Real-route nonescape. The route uses only the displayed* BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows already exposed by the packet, and it exports no open-cover compactness, trichotomy, quotient interval, selected separator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.ConnectedIntervalUp.ConnectedIntervalObligationClosureRoute`

Proof. Start from the carrier of Definition 1462.1. Its finite BHist packet displays the endpoint rows, interval windows, dyadic branch ledger, nested-refinement row, sign-route row, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Perform induction on the nested-bisection ledger. The base read is the accepted endpoint and finite-window surface, using the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ observations named by the carrier. The induction step is the retained dyadic branch row: Definition 1462.4 routes each retained midpoint decision through the existing $\mathsf{DyadicRatCore}^{\uparrow}$-facing branch ledger before the nested-refinement row may be read.

At each step, apply Definition 1462.3. A proposed two-sided separation must pass through the endpoint rows, the inspected window, the dyadic ledger, the nested row, and the intermediate-value

sign route; it cannot supply trichotomy, a selected separator, quotient interval equality, open-cover compactness, or host connectedness.

The induction closes by Definition 1462.5 and Definition 1462.6. These results identify the complete row order and force every $\mathsf{Real}^{\uparrow}$-facing consumer to pass through the same finite packet before the Real seal is visible. Thus the obligation surface is the displayed BEDC route, not ambient $\mathsf{Real}^{\uparrow}$ completeness or any off-packet compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConnectedInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{ConnectedInterval}^{\uparrow}$ packet is generated from closed Real endpoint rows, finite StreamName windows, RegSeqRat readbacks, DyadicBisection branch ledgers, NestedInterval refinements, IntermediateValue sign-route rows, a Real seal route, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConnectedInterval}^{\uparrow}}, \mathsf{publicClosed})$

Scope closed: Definition 1462.1, Definition 1462.2, Definition 1462.3, Definition 1462.4, Definition 1462.5, Definition 1462.6, and Definition 1462.7 export the public connected-interval route through endpoint rows, $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ finite windows, $\mathsf{DyadicBisection}^{\uparrow}$ branch ledger, $\mathsf{NestedInterval}^{\uparrow}$ refinement row, $\mathsf{IntermediateValue}^{\uparrow}$ sign route, $\mathsf{Real}^{\uparrow}$ seal, hsame transport, displayed Cont replay, Pkg provenance, and local NameCert dependencies.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConnectedInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, Heine–Borel, trichotomy, host connectedness, quotient equality of real names, selected separators, Lean verification, or a standard bridge.

Upgrade path: A standard bridge for the public connected-interval route remains the next paper-side obligation, while Lean verification remains the formal-axis obligation for the same endpoint, finite-window, dyadic-branch, nested-refinement, sign-route, Real-seal, transport, replay, provenance, and local naming surface in BEDC.Derived.ConnectedIntervalUp.

Chapter 1463

Completion Uniqueness NameCert Construction

Following Bishop and Bridges-style separated completion uniqueness, the $\mathsf{CompletionUniqueness}^{\uparrow}$ packet records the finite BEDC route by which two completion-facing presentations are identified only through a displayed separated seal and a universal-property uniqueness ledger. It sits downstream of the separated surface of chapter 402, the extension-and-uniqueness surface of chapter 397, and the functorial route of chapter 423. The packet also reads the regular real-name spine through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, without turning those rows into quotient completion data.

Definition 1463.1 (Completion uniqueness carrier)**.** *A* $\mathsf{CompletionUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, S, R, E, H, F, L, T, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the compared regular names;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule read by both sides;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational source row carried by the shared schedule and tolerance ledger;*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from D, S, R;*
5. *H is the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated seal that makes the comparison a separated-completion read rather than a quotient-class read;*
6. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *functorial handoff that transports the same regular source into each completion-facing presentation;*
7. *L is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *uniqueness ledger comparing the two transported extension rows over the same D, S, R, E, H, F spine;*
8. *T records the componentwise* hsame *transports for the displayed dyadic, stream, regular, Real, separated, functorial, and uniqueness rows;*
9. *C records the displayed* Cont *routes that replay the separated-limit and uniqueness reads;*
10. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

11. N is the local $\mathsf{NameCert}_{\mathsf{CompletionUniqueness}^{\uparrow}}$ *row.*
The carrier contains no quotient completion object, no selected host limit, no ambient Real completeness field, and no host equality row.

Lean4 ✓ `BEDC.Derived.CompletionUniquenessUp.CompletionUniquenessTasteGate single carrier alignment`

Theorem 1463.2 (Completion uniqueness NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CompletionUniqueness}^{\uparrow}}$ *surface for the carrier of Definition 1463.1 consists of five finite rows: carrier admission for the displayed packet U; classifier stability under the componentwise* hsame *transports T and* Cont *routes C; separated-seal compatibility through the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *row H; functorial source compatibility through the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row F; and universal-property ledger exactness through the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row L.*

Proof. Carrier admission is projection of Definition 1463.1. The dyadic tolerance ledger, finite stream schedule, regular-rational source, Real seal, separated-completion seal, functorial handoff, uniqueness ledger, transport rows, continuation rows, package provenance, and local naming row are displayed coordinates of one finite packet.

Classifier stability is componentwise. The transports in T move D, S, R, E, H, F, L, N without changing the dependency order, and the continuation rows in C replay only the separated-limit and uniqueness reads already exposed by those coordinates.

The remaining obligation rows are sibling handoffs. The separated surface is read through H, the functorial source route is read through F, and the uniqueness ledger is read through L after the shared D, S, R, E spine has been projected. Since no carrier coordinate contains a quotient completion, selected host limit, ambient Real completeness field, or host equality row, the listed obligations exhaust the local NameCert surface. □

Theorem 1463.3 (Completion uniqueness separated limit)**.** *Let $U = (D, S, R, E, H, F, L, T, C, P, N)$ be an accepted* $\mathsf{CompletionUniqueness}^{\uparrow}$ *carrier. Any comparison between the two completion-facing presentations exported by F and L first passes through the displayed route*

$$D, \quad S, \quad R, \quad E, \quad H.$$

Thus the comparison is a separated-limit read over the dyadic, stream, regular-rational, Real-seal, and Hausdorff-completion rows, not a host equality of completed points.

Proof. Project the accepted carrier. The rows D, S, R, E give the finite regular-name spine, and the row H is the only separated-completion seal attached to that spine.

Read the functorial and universal-property rows after the separated seal. The functorial handoff F transports the same regular source into the two completion-facing presentations, while the ledger L compares their extension rows only over the already displayed source and seal data.

The continuation row C can replay the comparison only along that route, and the provenance row P records no host completion object. Therefore every comparison is a separated-limit read over the displayed finite packet. □

Theorem 1463.4 (Completion uniqueness ledger exhaustion)**.** *For every accepted* $\mathsf{CompletionUniqueness}^{\uparrow}$ *carrier, the rows $D, S, R, E, H, F, L, T, C, P, N$ exhaust the proof surface for constructive separated completion uniqueness. A consumer may inspect dyadic tolerances, stream windows, regular rational source data, the Real seal, the Hausdorff separated seal, the Cauchy-completion functor handoff, the universal-property uniqueness ledger, componentwise transports, continuation routes, package provenance, and the local NameCert row. It obtains no quotient completion, selected host limit, ambient Real completeness theorem, or host equality witness.*

Proof. Start from the carrier decomposition of Definition 1463.1. Every coordinate available to a consumer is one of $D, S, R, E, H, F, L, T, C, P, N$.

Apply Definition 1463.2 to bind classifier stability and obligation exactness to those rows. Apply Definition 1463.3 to route every completion-facing comparison through the separated finite spine before the uniqueness ledger is read.

No additional field remains in the packet. In particular, there is no coordinate for quotient completion construction, selected host limits, ambient Real completeness, or host equality. The displayed rows therefore exhaust the constructive uniqueness ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionUniqueness}^{\uparrow}$ packet is generated from a dyadic tolerance ledger, a stream-window schedule, a regular rational source row, a RealUp seal, a Hausdorff separated seal, a CauchyCompletionFunctor handoff, a CompletionUniversalProperty uniqueness ledger, componentwise transports, continuation routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1463.1, Definition 1463.2, Definition 1463.3, and Definition 1463.4 seed the separated constructive completion uniqueness route over the finite Real-completion spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CompletionUniquenessUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected host limits, ambient Real completeness, or host equality.

Upgrade path: A checked carrier theorem and obligation package for the same dyadic, stream, regular-rational, Real-seal, Hausdorff, functorial, universal-property, transport, continuation, package, and NameCert route would raise the verification axis.

Chapter 1464

A Concrete Naming Certificate for $\mathsf{CauchyCondensation}^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the $\mathsf{CauchyCondensation}^{\uparrow}$ packet records the dyadic-block test for a monotone nonnegative series as finite BEDC data before any completion-facing consumer may read a real seal. Its source and tail rows are the series surface of chapter 121; its comparison budget sits beside chapter 367; its regular rational readback is the handoff surface of chapter 301; and its terminal seal is the $\mathsf{Real}^{\uparrow}$ boundary of chapter 38. The packet is a constructive condensation certificate; it is not an ambient summability principle, a quotient of infinite series, a selected sum, host real equality, countable choice, trichotomy on arbitrary summands, or RealUp completeness.

Definition 1464.1 (Cauchy condensation carrier)**.** *A* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, W, B, L, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the monotone nonnegative* $\mathsf{Series}^{\uparrow}$ *summand source, read only through finite windows and partial-sum rows.*
2. *W is the summand-window ledger, recording the finite intervals on which monotonicity and nonnegativity are inspected.*
3. *B is the dyadic block schedule, listing the powers of two, block endpoints, and block lengths consumed by the condensation test.*
4. *L is the block-sum ledger, storing the original finite block sums and the condensed dyadic terms $2^n a_{2^n}$ over the same schedule.*
5. *T is the tail-bound row, packaging displayed tolerances, dyadic thresholds, and the domination inequalities that compare original tails with condensed block tails.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the block-sum and tail-bound ledgers.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to the regular rational readback.*
8. *H records componentwise* hsame *transports for the source, windows, schedule, block sums, tail bounds, regular readback, real seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *routes from each finite precision request through W, B, L, T to the readback row R and the seal row E.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensation}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensation}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these eleven rows. It has no coordinate for an infinite choice of blocks, a quotient series equality, a host limit, a selected completed real, a trichotomy oracle, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.CauchyCondensationTasteGate single carrier alignment`

Theorem 1464.2 (Cauchy condensation NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier* $K = (S, W, B, L, T, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensation}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed eleven-row packet;*
2. *monotone nonnegative source exposure for S through finite* $\mathsf{Series}^{\uparrow}$ *summand and partial-sum windows;*
3. *window compatibility for W, stating that every inspected monotonicity and nonnegativity claim is tied to displayed summand rows;*
4. *dyadic schedule admission for B, with powers of two, endpoints, and block lengths available as finite ledger entries;*
5. *block-sum formation for L, relating each original finite block sum to the condensed term on the same schedule;*
6. *tail-bound compatibility for T, routing finite block domination into the comparison budget consumed by* $\mathsf{FastConvergentSeries}^{\uparrow}$*;*
7. $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal exposure for R and E;*
8. *transport stability, continuation replay, provenance, and local naming for exactly the displayed route recorded by H, C, P, N.*

No other analytic or choice-theoretic obligation is part of the local certificate.

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.CauchyCondensationCarrier namecert obligations`

Proof. Project the accepted packet $K = (S, W, B, L, T, R, E, H, C, P, N)$. The projection exposes exactly the monotone source, finite windows, dyadic schedule, block-sum ledger, tail-bound row, regular readback, real seal, transport rows, continuation replay, provenance, and local naming row.

Read a finite tail request through W and B. The schedule selects finitely many dyadic blocks, and the ledger L stores both the original block sums and the condensed terms on those same indices.

The monotone nonnegative source row S is used only through displayed summand windows. The tail-bound row T then turns the finite block comparisons into the comparison budget consumed by the fast-convergent-series surface, so the argument never appeals to an infinite choice of block representatives.

Finally use the structural rows. The componentwise transports in H preserve the displayed data, and C, P, N only replay, source, and name that route. Since the carrier has no further coordinate, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{CauchyCondensation}^{\uparrow}}$ surface. □

Theorem 1464.3 (Cauchy condensation dyadic-tail obligation)**.** *For every accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier* $K = (S, W, B, L, T, R, E, H, C, P, N)$*, any tail request presented to the condensation comparison must expose the dyadic schedule* B*, the block-sum ledger* L*, and the tail-bound row* T *before it can be read by the regular-rational or real-seal rows. Equivalently, the tail obligation is the finite projection*

$$S, W, B, L \longmapsto T$$

inside the same displayed carrier, with no detached infinite block choice or external summability premise.

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.DyadicTailObligation.CauchyCondensationCarrier dyadic tail obligation`

Proof. Project the accepted packet as $K = (S, W, B, L, T, R, E, H, C, P, N)$. The NameCert obligation surface of Definition 1464.2 exposes S, W, B, L, T as the source, window, dyadic schedule, block-sum, and tail-bound rows.

Apply Definition 1464.6. It forces every tail request through the finite route from S, W, B, L to T before R or E can be inspected.

The structural rows H, C, P, N only transport, replay, source, and name that route. Since the carrier has no coordinate for infinite block selection or host summability, the dyadic-tail obligation is exactly the displayed projection. □

Theorem 1464.4 (Cauchy condensation RegSeqRat readback obligation)**.** *For every accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier* $K = (S, W, B, L, T, R, E, H, C, P, N)$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *is readable only after the finite dyadic-tail obligation through* S, W, B, L, T *has been displayed. A consumer that preserves* S, W, B, L, T *and the structural rows* H, C, P, N *preserves the same readback row* R*, and no quotient series equality, selected sum, or countable-choice schedule supplies an alternate readback.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.RegSeqRatReadbackObligation.CauchyCondensationCarrier regseqrat readback obligation`

Proof. Use Definition 1464.3 to bind every tail request to the displayed rows S, W, B, L, T. This places the tail-bound row immediately upstream of the regular-rational handoff.

Now apply Definition 1464.6. The theorem identifies R as the readback row reached from the dyadic-block route and the same structural rows.

Finally use Definition 1464.8. Componentwise hsame transport preserving W, B, L, T preserves the $\mathsf{RegSeqRat}^{\uparrow}$ handoff row, so no quotient, selected-sum, or choice-based alternate readback is available. □

Theorem 1464.5 (Cauchy condensation Real-seal nonescape obligation)**.** *For every accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier* $K = (S, W, B, L, T, R, E, H, C, P, N)$*, any* $\mathsf{Real}^{\uparrow}$ *seal-facing read of* E *must first pass through the dyadic-tail obligation on* S, W, B, L, T *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obligation on* R*. Thus the Real-seal obligation is the finite route*

$$S, W, B, L, T \longmapsto R \longmapsto E, H, C, P, N,$$

with no route through quotient series equality, selected infinite sums, countable choice, trichotomy, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.RealSealObligation.CauchyCondensationCarrier real seal nonescape obligation`

Proof. Start with the dyadic-tail obligation of Definition 1464.3. It fixes the finite route through S, W, B, L, T for every tail request.

Apply Definition 1464.4. The readback row R is downstream of the same finite dyadic-tail route and cannot be replaced by an external summability object.

Finally apply Definition 1464.7. The seal row E receives its analytic input from R together with H, C, P, N. Since the packet omits quotient equality, selected sums, countable choice, trichotomy, host real equality, and $\mathsf{Real}^{\uparrow}$ completeness, the displayed route exhausts the Real-seal obligation. □

Theorem 1464.6 (Cauchy condensation dyadic-block handoff)**.** *Every accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier sends a monotone nonnegative series tail to a completion-facing comparison route only through the finite dyadic-block handoff*

$$S, W, B, L \longmapsto T \longmapsto R, E, H, C, P, N.$$

Thus a downstream consumer can read the condensation comparison only after reading the displayed summand windows, dyadic block schedule, block-sum ledger, tail-bound row, and $\mathsf{RegSeqRat}^{\uparrow}$ *readback.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.CauchyCondensationCarrier dyadic block handoff`

Proof. Begin with an accepted carrier and a displayed tail request. The window ledger W identifies the finite summand rows to inspect, while the dyadic schedule B fixes the block endpoints and powers of two.

Read the source row S through those windows. The block ledger L records the corresponding original block sums together with the condensed terms $2^n a_{2^n}$, so every comparison is attached to the displayed schedule.

Now apply the tail-bound row T. It packages the finite domination inequalities and tolerance thresholds that route the block comparison into the regular rational readback. No consumer can reach R without the data supplied by S, W, B, L, T.

Transport and replay preserve this route componentwise. The rows H, C, P, N therefore attach the handoff to the local certificate without creating an alternate path through host summability, selected sums, or completion. □

Theorem 1464.7 (Cauchy condensation Real-seal nonescape)**.** *For every accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier, any* $\mathsf{Real}^{\uparrow}$ *seal-facing read factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R produced from the finite dyadic-block route. The seal row E receives the monotone source, summand windows, dyadic schedule, block-sum ledger, tail bounds, componentwise transports, continuation replay, provenance, and local naming rows, but it receives no quotient series equality, selected infinite sum, countable choice, trichotomy premise, host real equality, or RealUp completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.CauchyCondensationCarrier real seal nonescape`

Proof. Project the seal-facing rows R and E from the accepted carrier. The regular handoff R is downstream of the tail-bound row T, and T is downstream of the displayed summand windows, dyadic schedule, and block-sum ledger.

Apply Definition 1464.6. It identifies the only route from a monotone nonnegative tail to the readback row as the finite path through S, W, B, L, T and the structural rows attached to the same packet.

Read the seal row E. Its analytic input is exactly R, together with H, C, P, N. Since the carrier has no coordinate for quotient series equality, a selected sum, countable choice, trichotomy outside the displayed windows, host real equality, or RealUp completeness, the seal-facing read cannot export any of those objects. □

Theorem 1464.8 (Cauchy condensation dyadic-block tail transport)**.** *Let*

$$K = (S, W, B, L, T, R, E, H, C, P, N)$$

and

$$K' = (S', W', B', L', T', R', E', H', C', P', N')$$

be accepted $\mathsf{CauchyCondensation}^{\uparrow}$ *carriers. If componentwise* hsame *transport identifies the summand windows, dyadic block schedule, block-sum ledger, and tail-bound rows* W, B, L, T *with* W', B', L', T'*, then it preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows* R, R' *and the* $\mathsf{Real}^{\uparrow}$ *seal nonescape boundary rows* E, E'*. The transported packet still routes every condensation tail through the displayed finite block surface before any real-seal read.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.CauchyCondensationCarrier dyadic block tail transport`

Proof. Unpack the NameCert obligations of Definition 1464.2. The accepted carrier exposes the summand windows, dyadic schedule, block-sum ledger, and tail-bound row as finite rows before the regular readback or real seal can be inspected.

Apply Definition 1464.6. It identifies the only route to the $\mathsf{RegSeqRat}^{\uparrow}$ handoff as the finite path through S, W, B, L, T and the structural rows. Therefore transporting W, B, L, T through H preserves the handoff row R along the same displayed route.

Apply Definition 1464.7. The real seal receives its analytic input from R and the transported structural rows, so preserving the handoff preserves the nonescape boundary E as well.

The carrier contains no quotient series equality, selected infinite sum, countable-choice schedule, trichotomy premise, host real equality, or $\mathsf{Real}^{\uparrow}$ completeness coordinate. Thus the transported packet remains a finite dyadic-block tail route. □

Theorem 1464.9 (Cauchy condensation tail-lock uniqueness)**.** *For an accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier* $K = (S, W, B, L, T, R, E, H, C, P, N)$*, any two* $\mathsf{Real}^{\uparrow}$ *seal-facing reads that preserve the same summand windows* W*, dyadic block schedule* B*, block-sum ledger* L*, and tail-bound row* T *must factor through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *before reaching the same Real seal boundary* E*. No quotient series equality, selected sum, countable choice, trichotomy, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate can distinguish the two reads.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.CauchyCondensationCarrier tail lock uniqueness`

Proof. Use the NameCert obligations of Definition 1464.2. They expose the carrier only through $S, W, B, L, T, R, E, H, C, P, N$, so both seal-facing reads share the same finite condensation surface once W, B, L, T are preserved.

Apply Definition 1464.6. The handoff theorem forces each read through the displayed path from S, W, B, L to T and then to the regular rational row R.

Finally apply Definition 1464.7 and Definition 1464.8. The Real seal receives its analytic input from the same handoff row and the same transported structural rows, so both reads meet the same boundary E without an alternate quotient, selected-sum, choice, trichotomy, host-equality, or completeness discriminator. □

Theorem 1464.10 (Cauchy condensation test dyadic-block equivalence)**.** *An accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *packet and a* $\mathsf{CauchyCondensationTest}^{\uparrow}$ *consumer agree exactly when the consumer reads the same displayed monotone source tail* S*, summand-window ledger* W*, dyadic block schedule* B*, block-sum ledger* L*, tail-bound row* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*, and* $\mathsf{Real}^{\uparrow}$ *seal route* E *through the structural rows* H, C, P, N*. Equivalently, the consumer may use the condensation-test conclusion only through the finite dyadic-block route already carried by*

$$K = (S, W, B, L, T, R, E, H, C, P, N),$$

and no quotient series equality, selected sum, countable-choice schedule, trichotomy oracle, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness coordinate supplies a second route.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.CauchyCondensationCarrier test dyadic block equivalence`

Proof. Start with the accepted carrier and apply Definition 1464.6. It identifies the displayed path from the monotone source tail through summand windows, dyadic schedule, block sums, and tail bounds to the regular readback.

Use Definition 1464.8. Any consumer that preserves the source-tail windows, block schedule, block-sum ledger, and tail-bound row preserves the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the Real-seal boundary along the same route.

Finally apply Definition 1464.9. Two seal-facing reads with the same W, B, L, T data cannot be distinguished by an alternate quotient, selected-sum, choice, trichotomy, host-equality, or completeness coordinate. Thus the condensation-test consumer agrees with the packet exactly on the displayed dyadic-block route. □

Theorem 1464.11 (Cauchy condensation scoped obligation route)**.** *For every accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier*

$$K = (S, W, B, L, T, R, E, H, C, P, N),$$

any consumer read that cites the dyadic-block comparison factors first through the finite $\mathsf{Series}^{\uparrow}$ *summand windows, the* $\mathsf{FastConvergentSeries}^{\uparrow}$ *comparison budget recorded in* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, componentwise* BHist *and* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensation}^{\uparrow}}$ *row. No consumer may cite the comparison theorem from an unsealed series tail, a detached completion object, or an external summability principle.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.CauchyCondensationCarrier scoped obligation route`

Proof. First use the dyadic-block handoff of Definition 1464.6. It sends every accepted tail request through the displayed $\mathsf{Series}^{\uparrow}$ source windows, the dyadic schedule, the block-sum ledger, and the tail-bound row before the regular readback can be inspected.

Next apply the Real-seal nonescape theorem of Definition 1464.7. The seal-facing read reaches E only after the $\mathsf{RegSeqRat}^{\uparrow}$ row R and the structural rows attached to the same finite carrier are visible.

Transport is supplied by Definition 1464.8. It preserves the same windows, schedule, block ledger, tail-bound row, regular readback, and Real-seal boundary under componentwise hsame transport.

Finally use the test equivalence of Definition 1464.10. A consumer can cite the dyadic-block comparison exactly when it agrees with the displayed route through $S, W, B, L, T, R, E, H, C, P, N$, so the scoped obligation route is the finite carrier route itself rather than a detached analytic principle. □

Theorem 1464.12 (Cauchy condensation obligation-closure package)**.** *For every accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier*

$$K = (S, W, B, L, T, R, E, H, C, P, N),$$

the carrier, local $\mathsf{NameCert}_{\mathsf{CauchyCondensation}^{\uparrow}}$ *obligations, dyadic-tail obligation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obligation,* $\mathsf{Real}^{\uparrow}$ *seal nonescape obligation, dyadic-block handoff, tail transport, tail-lock uniqueness, and scoped obligation route assemble the full* obligation *surface over* $\mathsf{Series}^{\uparrow}$, $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The package exports no selected sum, quotient series equality, countable choice, trichotomy, detached summability principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationUp.CauchyCondensationCarrier obligation closure package`

Proof. Start from the carrier and NameCert surfaces. Apply Definition 1464.1 and Definition 1464.2 to expose exactly the eleven displayed rows and the local certificate obligations attached to them.

Next bind the analytic tail route. Use Definition 1464.3, Definition 1464.4, and Definition 1464.5 to force every tail request through S, W, B, L, T, then R, then E, H, C, P, N.

Now add the comparison and transport layer. The dyadic-block handoff of Definition 1464.6 supplies the finite route consumed by $\mathsf{FastConvergentSeries}^{\uparrow}$, while Definition 1464.8 preserves that route under componentwise hsame transport.

Finally apply Definition 1464.9 and Definition 1464.11. They identify the same $\mathsf{RegSeqRat}^{\uparrow}$ handoff and $\mathsf{Real}^{\uparrow}$ seal boundary for all consumer reads that preserve the displayed finite data. Since every cited theorem uses only the rows of K, no selected sum, quotient series equality, countable choice, trichotomy, detached summability principle, or ambient completeness row is introduced. □

Falsifiable prediction: An accepted $\mathsf{CauchyCondensation}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the displayed summand windows, dyadic block schedule, block-sum ledger, tail-bound row, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff refutes the carrier surface.

Independence witness: series, fastconvergentseries, regseqrat, real: no listed sibling supplies the whole eleven-row packet $K = (S, W, B, L, T, R, E, H, C, P, N)$, because each sibling contributes only a source, comparison budget, regular readback, or seal face while this chapter binds all four faces with dyadic block scheduling, block-sum ledgers, tail bounds, transports, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCondensation}^{\uparrow}$ packet is generated from a monotone nonnegative $\mathsf{Series}^{\uparrow}$ source, finite summand windows, a dyadic block schedule, block-sum ledgers, tail-bound rows, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCondensation}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1464.12 binds the carrier, local NameCert obligations, dyadic-tail obligation, RegSeqRat readback, Real-seal nonescape, dyadic-block handoff, tail transport, tail-lock uniqueness, scoped obligation route, replay, provenance, and local naming rows over the displayed finite packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCondensation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim ambient summability, quotient series equality, selected sums, countable choice, trichotomy, host real equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires kernel-scoped dependency wording over the same carrier, dyadic-tail, RegSeqRat readback, Real-seal, transport, replay, provenance, and local NameCert rows.

Chapter 1465

A Concrete Naming Certificate for $\mathsf{IntervalBisection}^{\uparrow}$

Following Bishop–Bridges constructive interval bisection, the $\mathsf{IntervalBisection}^{\uparrow}$ packet records the explicit split of a displayed located interval into left and right located subintervals through a finite midpoint route. It consumes the endpoint-cell surface of chapter 394, the dyadic-cell surface of chapter 306, the rational-cell surface of chapter 354, the finite-window interface of chapter 126, the regular rational readbacks of chapter 301, the terminal real seal of chapter 38, and the finite-net consumer boundary of chapter 1433. The packet is an explicit bisection certificate for one located interval; it is not open-cover compactness, trichotomy, quotient real equality, or a choice principle for selecting a branch.

Definition 1465.1 (IntervalBisection carrier)**.** *An* $\mathsf{IntervalBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, M, L, R, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the parent* $\mathsf{LocatedInterval}^{\uparrow}$ *row, including its lower and upper endpoint observations and locatedness ledger;*
2. *M is the midpoint route, computed through the displayed* $\mathsf{RationalInterval}^{\uparrow}$ *endpoint cells and recorded as a midpoint row before any branch is inspected;*
3. *L is the left subinterval row with inherited lower endpoint, midpoint upper endpoint, and its local locatedness witness;*
4. *R is the right subinterval row with midpoint lower endpoint, inherited upper endpoint, and its local locatedness witness;*
5. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger aligning the parent cell, midpoint cell, and the two child cells at the requested mesh scale;*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the parent endpoints, midpoint read, and child endpoint observations;*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same finite windows, including the rational midpoint calculation and the endpoint reuse checks;*
8. *E is the pair of* $\mathsf{Real}^{\uparrow}$ *seal rows reached by the left and right child intervals through S, Q, D and through no detached quotient-real equality coordinate;*

9. *H records componentwise* hsame *transport for the parent interval, midpoint route, left and right subinterval rows, dyadic ledger, windows, readbacks, real seals, and branch handoff;*
10. *C records displayed* Cont *routes by which consumers replay the parent row, midpoint route, both child rows, the dyadic ledger, finite windows, readbacks, real seals, and the nested-cell handoff;*
11. *P is the* Pkg *provenance over* $\mathsf{IntervalBisection}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalBisection}^{\uparrow}}$ *row.*

The carrier exports only the displayed parent-to-midpoint-to-children route. It has no coordinate for an arbitrary open cover, selected subcover, trichotomy on real names, quotient real equality, hidden endpoint choice, or ambient compactness theorem.

Lean4 ✓ `BEDC.Derived.IntervalBisectionUp.IntervalBisectionTasteGate single carrier alignment`

Theorem 1465.2 (IntervalBisection NameCert obligations)**.** *For an accepted* $\mathsf{IntervalBisection}^{\uparrow}$ *carrier* $K = (I, M, L, R, D, S, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IntervalBisection}^{\uparrow}}$ *surface consists exactly of carrier admission for those twelve rows, midpoint formation from the displayed parent endpoint cells, left and right located-subinterval admission, dyadic refinement compatibility, finite-window readback compatibility, child real-seal exposure, componentwise classifier transport, consumer replay, package provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.IntervalBisectionUp.IntervalBisectionNamecertObligations`

Proof. Carrier admission is the tuple of Definition 1465.1. The parent interval, midpoint route, two child intervals, dyadic ledger, finite windows, regular readbacks, real seals, transports, continuations, package provenance, and local naming row are all explicit BHist coordinates.

The midpoint obligation is read through I, M, Q. The parent row supplies the displayed endpoint cells, the midpoint route records the rational midpoint before branch inspection, and the regular readback row checks that the midpoint is read from the same finite endpoint windows.

The child-interval obligations are read through L, R, D, S, Q, E. The left row reuses the lower endpoint of I and the midpoint upper endpoint; the right row reuses the midpoint lower endpoint and the upper endpoint of I. The dyadic ledger, finite windows, readbacks, and real seals expose that both child rows remain inside the same displayed completion route.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for branch choice, trichotomy, quotient real equality, selected subcovers, or ambient compactness, none of those objects can become local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.IntervalBisectionUp.IntervalBisectionCarrier namecert obligations`

Theorem 1465.3 (IntervalBisection endpoint transport)**.** *Every endpoint-facing consumer of an accepted* $\mathsf{IntervalBisection}^{\uparrow}$ *packet receives the displayed transport route*

$$I, M, L, R, D, S, Q, E, H, C, P, N.$$

The route preserves the parent lower endpoint into the left child, the parent upper endpoint into the right child, and the midpoint endpoint into both children by componentwise hsame *transport over the displayed* BHist *rows.*

Lean4 ✓ `BEDC.Derived.IntervalBisectionUp.IntervalBisectionEndpointTransport`

Proof. Begin with the parent row I and midpoint route M. These two rows determine the three endpoint positions that can be exported: the parent lower endpoint, the midpoint endpoint, and the parent upper endpoint.

Project the child rows L and R. The left child has the inherited lower endpoint and the midpoint upper endpoint; the right child has the midpoint lower endpoint and the inherited upper endpoint. No further endpoint selector appears in the carrier.

Now read D, S, Q, E. The dyadic ledger aligns the parent and child cells, the finite windows expose only the required endpoint reads, the regular readbacks check the same midpoint calculation, and the real seals close the two child endpoint routes.

Finally the structural rows H, C, P, N transport, replay, source, and name this endpoint route. Componentwise hsame is therefore the only endpoint-transport mechanism available to a consumer. □

Theorem 1465.4 (IntervalBisection nested-cell handoff)**.** *Every nested-interval or finite-net consumer of an accepted* $\mathsf{IntervalBisection}^{\uparrow}$ *packet factors its child-cell request through the displayed route*

$$I, M, L, R, D, H, C, P, N$$

before it may read $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ *data downstream. Thus the packet hands off a pair of finite child cells, not a selected infinite branch or an open-cover compactness argument.*

Lean4 ✓ `BEDC.Derived.IntervalBisectionUp.IntervalBisectionCarrier nested cell handoff`

Proof. First read the parent interval and midpoint route. The row I fixes the displayed located interval, and M fixes the midpoint row used by both children.

Next use the child rows and dyadic ledger. The rows L and R are the only child-cell exports, while D records their refinement relation to the parent cell and midpoint cell.

The handoff to downstream consumers is then replayed through H, C, P, N. A nested-interval consumer may iterate the same finite packet shape, and a $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ consumer may read the two displayed child cells as finite mesh data, but neither consumer receives an infinite branch selector or an open-cover subcover selector from this packet.

The stream, regular-rational, and real-seal rows S, Q, E remain available only as finite readbacks for the already displayed cells. They cannot introduce quotient real equality or a hidden choice of a child branch because those coordinates are absent from the carrier. □

Theorem 1465.5 (IntervalBisection obligation carrier exposure)**.** *Every accepted* $\mathsf{IntervalBisection}^{\uparrow}$ *packet exposes its root-unblock carrier rows before any located interval, dyadic interval, rational interval, StreamName, RegSeqRat, Real, or closed-interval compact-net consumer reads the bisection. The exposed rows are exactly the parent* $\mathsf{LocatedInterval}^{\uparrow}$ *row* I*, midpoint route* M*, left and right child rows* L, R*,* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger* D*,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*,* $\mathsf{Real}^{\uparrow}$ *child seals* E*, componentwise transport* H*, replay* C*, provenance* P*, and local naming* N*.*

Proof. Project the carrier of Definition 1465.1. Its displayed tuple is $K = (I, M, L, R, D, S, Q, E, H, C, P, N)$, so the only carrier data available to a consumer are precisely those rows.

The interval-facing rows are I, M, L, R, D. They expose the located parent cell, the rational midpoint route, both child cells, and the dyadic refinement ledger before any downstream readback is opened.

The readback-facing rows are S, Q, E. They expose finite StreamName windows, regular rational readback, and the two Real child seals only after the bisection cells have been displayed.

The structural rows H, C, P, N preserve and name the same packet. Since no additional carrier coordinate exists, every listed consumer reads the bisection through the displayed root-unblock surface. □

Lean4 ✓ `BEDC.Derived.IntervalBisectionUp.IntervalBisectionObligationCarrier`

Theorem 1465.6 (IntervalBisection obligation transport)**.** *Let $K = (I, M, L, R, D, S, Q, E, H, C, P, N)$ and $K' = (I', M', L', R', D', S', Q', E', H', C', P', N')$ be accepted* $\mathsf{IntervalBisection}^{\uparrow}$ *packets. If the located interval, midpoint, child interval, dyadic ledger, finite-window, readback, and Real-seal rows transport componentwise under the displayed* hsame *rows and replay through the displayed* Cont *routes, then every located interval, dyadic interval, rational interval, StreamName, RegSeqRat, Real, and* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ *consumer receives the same bisection obligation surface from K and K'.*

Proof. The componentwise hypotheses identify the interval rows I, M, L, R, D with I', M', L', R', D' through the transport rows H, H'. Thus the parent cell, midpoint route, two child cells, and dyadic refinement ledger determine the same finite bisection shape.

The readback rows transport in the same way. The finite windows S, S', regular readbacks Q, Q', and Real seals E, E' are replayed through C, C', so no consumer can observe a second bisection route outside the transported rows.

Finally P, N and P', N' source and name the transported packet. The consumer list is exhausted by those interval, readback, and structural rows, so the transported packets expose the same obligation surface. □

Theorem 1465.7 (IntervalBisection obligation ledger exhaustion)**.** *For every accepted* $\mathsf{IntervalBisection}^{\uparrow}$ *packet, the root-unblock ledger for located interval, dyadic interval, rational interval,* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ *consumers is exhausted by the rows*

$$I, M, L, R, D, S, Q, E, H, C, P, N.$$

The ledger contains no row for selected infinite branch choice, open-cover compactness, quotient real equality, host endpoint equality, trichotomy, or an ambient compactness theorem.

Proof. Use the carrier exposure theorem to list the only rows in the packet. The located, rational, and dyadic interval consumers read I, M, L, R, D; the StreamName, RegSeqRat, and Real consumers read S, Q, E after those interval rows have been displayed.

Use the transport theorem for stability. Any replayed or transported bisection obligation is still read through H, C, P, N together with the same interval and readback rows, so the ledger has no second channel.

The excluded objects are absent from the carrier and from the NameCert obligations of Definition 1465.2. Therefore the listed tuple exhausts the root-unblock ledger for all named consumers. □

Theorem 1465.8 (IntervalBisection midpoint formation)**.** *For every accepted* $\mathsf{IntervalBisection}^{\uparrow}$ *packet $K = (I, M, L, R, D, S, Q, E, H, C, P, N)$, the midpoint row M is formed only from the displayed* $\mathsf{LocatedInterval}^{\uparrow}$ *parent endpoint rows and the* $\mathsf{RationalInterval}^{\uparrow}$ *endpoint cells read through I and Q. No midpoint obligation may inspect a child branch, a Real equality row, or a compactness consumer before M has been displayed.*

Proof. Project I and Q from the carrier. The parent interval row supplies the lower and upper endpoint observations, while the regular rational readback records the rational endpoint cells visible to the bisection packet.

The midpoint row M is placed between the parent row and the child rows in Definition 1465.1. Hence it is available before L, R, D, S, Q, E are used as child-facing data, and its inputs are exactly the displayed endpoint cells.

Since the carrier has no separate midpoint selector, Real equality coordinate, or compactness oracle, the midpoint obligation is exhausted by the located parent endpoint rows and the rational endpoint-cell calculation. □

Theorem 1465.9 (IntervalBisection child-cell admission)**.** *For every accepted* $\mathsf{IntervalBisection}^{\uparrow}$ *packet* $K = (I, M, L, R, D, S, Q, E, H, C, P, N)$*, the left and right child cells* L, R *are admitted through the displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger* D*, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and the terminal* $\mathsf{Real}^{\uparrow}$ *child seals* E*. The packet admits exactly the inherited-left and inherited-right child cells; it does not admit a selected infinite branch or a quotient-real endpoint.*

Proof. Read the child rows L, R together with the dyadic ledger D. These rows display the inherited parent endpoints, the midpoint endpoint, and the refinement relation between parent and child cells.

Next read S, Q, E. The finite windows expose only the endpoint observations needed by the displayed cells, the regular rational row checks the midpoint calculation and endpoint reuse, and the Real seals close the two child routes after those finite rows are visible.

The admitted children are therefore the two displayed cells named by L, R. No carrier coordinate selects one child as an infinite branch, and no quotient-real equality row is present for replacing the displayed endpoint route. □

Theorem 1465.10 (IntervalBisection finite-net handoff)**.** *Every* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ *consumer of an accepted* $\mathsf{IntervalBisection}^{\uparrow}$ *packet reads the bisection through the finite rows*

$$I, M, L, R, D, S, Q, E, H, C, P, N.$$

The handoff supplies parent and child mesh cells with finite readback and Real seals, but it supplies no selected branch, no selected subcover, and no open-cover compactness theorem.

Proof. Start with the ledger exhaustion theorem. It lists the only rows available to located-interval, dyadic-interval, StreamName, RegSeqRat, Real, and closed-interval compact-net consumers.

A finite-net consumer first sees the parent interval, midpoint, child cells, and dyadic refinement rows I, M, L, R, D. These rows supply a finite mesh refinement rather than an infinite nested branch.

The readback rows S, Q, E then expose the finite observation windows, rational endpoint checks, and Real child seals. Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite handoff without adding an open-cover or selected-subcover coordinate. □

Theorem 1465.11 (IntervalBisection obligation closure package)**.** *The carrier exposure, obligation transport, obligation ledger, midpoint formation, child-cell admission, and finite-net handoff theorems form the obligation-closure package for* $\mathsf{IntervalBisection}^{\uparrow}$*. Every root-unblock consumer named in this chapter receives exactly the displayed bisection route, and every excluded object remains outside the carrier.*

Proof. The carrier exposure theorem fixes the visible tuple $K = (I, M, L, R, D, S, Q, E, H, C, P, N)$, while the obligation transport theorem shows that componentwise hsame and displayed Cont replay preserve that tuple for all named consumers.

The obligation ledger theorem exhausts the root-unblock rows. The midpoint formation theorem binds M to the displayed located and rational endpoint rows, and the child-cell admission theorem binds L, R to the dyadic, StreamName, RegSeqRat, and Real rows.

Finally the finite-net handoff theorem routes $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ consumers through the same finite mesh data. Together these clauses close the obligation surface without adding branch selection, selected subcovers, open-cover compactness, quotient real equality, trichotomy, or ambient compactness. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalBisection}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalBisection}^{\uparrow}$ packet is generated from a displayed LocatedIntervalUp parent row, a RationalIntervalUp midpoint route, left and right located subinterval rows, a DyadicIntervalUp refinement ledger, StreamNameUp finite windows, RegSeqRatUp readbacks, RealUp child seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalBisection}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 1465.1, Definition 1465.2, Definition 1465.3, Definition 1465.4, Definition 1465.5, Definition 1465.6, Definition 1465.7, Definition 1465.8, Definition 1465.9, Definition 1465.10, and Definition 1465.11 bind exactly the carrier, endpoint transport, nested-cell handoff, obligation carrier, hsame transport, Cont replay, Pkg provenance, and local NameCert rows for displayed located intervals and finite-net consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalBisection}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.IntervalBisectionUp.IntervalBisectionCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, trichotomy, quotient real equality, selected branch choice, selected subcover choice, or bridge checking.

Upgrade path: Public closure requires an exported bisection consumer theorem showing that every accepted handoff remains stable under repeated finite-net refinement for BEDC.Derived.IntervalBisectionUp.

Chapter 1466

A Concrete Naming Certificate for $\mathsf{SequentialContinuity}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{SequentialContinuity}^{\uparrow}$ packet records continuity along certified convergent sequences as a finite BEDC route. It reads the pointwise metric-continuity surface of chapter 59, the regular rational windows of chapter 301, the inspected stream schedules of chapter 126, the real-name seal of chapter 38, and the $\mathsf{Met}^{\uparrow}$ rows of chapter 57. The packet supplies a Real and Completion frontier surface for sequence consumers without importing host sequential continuity, function extensionality, choice, quotient equality, or ambient completeness.

Definition 1466.1 (Sequential continuity carrier)**.** *A* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N)$$

with the following displayed rows:

1. *M_X and M_Y are the source and target* $\mathsf{Met}^{\uparrow}$ *carrier rows with their visible classifiers and distance ledgers.*
2. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row for a displayed map from the source metric carrier to the target metric carrier.*
3. *S is the source sequence surface, exposed only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
4. *L is the inspected convergence ledger for S, listing the finite thresholds actually requested by the packet.*
5. *W_X and W_Y are the source and target finite stream windows read from S and from the displayed images of those windows under F.*
6. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows attached to the inspected source and target windows.*
7. *E_X and E_Y are the* $\mathsf{Real}^{\uparrow}$ *seal rows reached after the corresponding regular-rational handoffs have been displayed.*
8. *H stores componentwise* hsame *transport for the metric rows, the continuous-map row, the sequence row, the convergence ledger, both window families, both regular handoffs, both Real seals, continuation, provenance, and local naming.*

9. *C stores displayed* Cont *replay from S, L to W_X, from W_X, F to W_Y, from W_X to R_X, E_X, and from W_Y to R_Y, E_Y.*
10. *P is the* Pkg *provenance over* $\mathsf{SequentialContinuity}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for an external sequence function, quotient stream equality, function extensionality, countable choice, or host sequential-continuity theorem.

Lean4 ✓ `BEDC.Derived.SequentialContinuityUp.SequentialContinuityTasteGate single carrier alignment`

Theorem 1466.2 (Sequential continuity NameCert obligations)**.** *For every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier $Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed fifteen-row packet;*
2. *source and target metric-row stability through M_X, M_Y, H, C;*
3. *pointwise-continuity use only through the displayed* $\mathsf{Continuous}^{\uparrow}$ *row F;*
4. *inspected-threshold convergence coverage through the finite ledger L;*
5. *source and target sequence handoff through W_X, W_Y, R_X, R_Y before either* $\mathsf{Real}^{\uparrow}$ *seal is consumed;*
6. *non-escape from host sequential continuity, function extensionality, countable choice, quotient equality, and ambient Real completeness.*

Proof. Project the carrier of Definition 1466.1. The metric rows, continuous-map row, source sequence row, convergence ledger, window rows, regular-rational handoffs, Real seals, and structural rows are the only coordinates visible to the classifier.

The metric and continuity faces are already displayed. Source and target stability reads through M_X, M_Y, H, C, while pointwise continuity is consumed only through F and the finite windows named by the packet.

The sequential face is finite. The ledger L records the inspected convergence thresholds, W_X displays the corresponding source windows, and W_Y displays the image windows obtained by the recorded continuation route.

Finally read the endpoint route. The source side reaches E_X through R_X, and the target side reaches E_Y through R_Y. Since the excluded principles are not coordinates of Q, the six listed rows exhaust the local NameCert obligation surface. □

Theorem 1466.3 (Sequential continuity Cauchy handoff)**.** *Every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *packet hands both the source sequence windows and the image sequence windows to* $\mathsf{RegSeqRat}^{\uparrow}$ *before any* $\mathsf{Real}^{\uparrow}$ *seal can be consumed. Equivalently, every seal-facing route factors through*

$$S, L \longmapsto W_X \longmapsto R_X \longmapsto E_X \qquad \textit{and} \qquad W_X, F \longmapsto W_Y \longmapsto R_Y \longmapsto E_Y$$

together with M_X, M_Y, H, C, P, N.

Proof. Begin with the inspected source route. The continuation row records that W_X is read from the displayed sequence surface S using only the thresholds listed in L.

Next form the image route. The row F is the displayed $\mathsf{Continuous}^{\uparrow}$ pointwise-modulus surface, and C records the replay from the inspected source windows to the target windows W_Y.

Both sides then pass through regular-rational readback. The rows R_X and R_Y are the only regular handoffs attached to the source and target windows, and the seal rows E_X and E_Y are downstream from those handoffs.

Thus a consumer that tries to use either $\mathsf{Real}^{\uparrow}$ seal without the matching $\mathsf{RegSeqRat}^{\uparrow}$ handoff leaves the accepted $\mathsf{SequentialContinuity}^{\uparrow}$ carrier. □

Lean4 ✓ `BEDC.Derived.SequentialContinuityUp.SequentialContinuityCauchyHandoff`

Theorem 1466.4 (Sequential continuity metric-row stability)**.** *For every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier*

$$Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N),$$

the source and target metric rows used by the local classifier are exactly the displayed $\mathsf{Met}^{\uparrow}$ *rows* M_X *and* M_Y*, stabilized by the same componentwise* hsame *transport* H *and displayed* Cont *replay* C *carried by* Q*. No metric comparison may be supplied by an external topology, host equality of points, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.SequentialContinuityUp.SequentialContinuityPacket metric row stability`

Proof. Project the accepted carrier. The only metric coordinates visible in the packet are M_X and M_Y, and the only structural coordinates that can move them between accepted packets are H and C.

The provenance and naming rows do not add a second metric surface. They record that the displayed rows belong to the same $\mathsf{SequentialContinuity}^{\uparrow}$ packet over $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Thus every metric read used by the classifier is stable exactly along M_X, M_Y, H, C, P, N. The excluded external topology, host equality, quotient, and completeness data are not coordinates of Q. □

Theorem 1466.5 (Sequential continuity pointwise consumption)**.** *For every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier* $Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N)$*, the pointwise-continuity information consumed by the sequence route is only the displayed* $\mathsf{Continuous}^{\uparrow}$ *row* F *together with the source metric row* M_X*, target metric row* M_Y*, finite windows* W_X, W_Y*, transport* H*, replay* C*, provenance* P*, and local naming* N*. The packet exports no host sequential-continuity theorem and no function-extensionality coordinate.*

Proof. Read the pointwise face of the carrier. The row F is the unique $\mathsf{Continuous}^{\uparrow}$ coordinate, and it is stored beside the source and target metric rows M_X, M_Y.

The sequence route inspects only finite windows. The continuation row sends the displayed source windows W_X through F to the target windows W_Y, and the transport row preserves that same route under componentwise hsame.

Finally, P and N source and name the same packet. Since neither a host sequential-continuity theorem nor a function-extensionality principle appears among the coordinates of Q, every pointwise-continuity use is consumed through the displayed rows named in the statement. □

Theorem 1466.6 (Sequential continuity inspected-threshold coverage)**.** *For every accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *carrier* $Q = (M_X, M_Y, F, S, L, W_X, W_Y, R_X, R_Y, E_X, E_Y, H, C, P, N)$*, each threshold used by a Real-facing or regular-Cauchy consumer is first listed in the inspected convergence ledger* L*, then*

read through the source window W_X, the image window W_Y, the regular handoff rows R_X, R_Y, and only then through the seal rows E_X, E_Y. The coverage route is exhausted by the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows of the same carrier.*

Proof. Project the carrier and read the inspected ledger. The row L is the only coordinate that lists convergence thresholds requested by the packet.

The source schedule then opens W_X from S at the listed thresholds. The pointwise row F and replay row C produce the corresponding image windows W_Y without adding a detached sequence object.

The regular and Real-facing reads are downstream from those windows. The rows R_X, R_Y repack the inspected windows as regular rational handoffs, and E_X, E_Y are consumed only after those handoffs.

The structural rows H, C, P, N preserve, replay, source, and name exactly this route. Therefore the inspected thresholds cover the whole consumer path and no unlisted threshold, quotient stream, selected limit, choice row, or ambient completeness datum can enter the packet. □

The mature treatment of $\mathsf{SequentialContinuity}^{\uparrow}$ is the Real and Completion sequence-consumer route obtained by reading the Cauchy handoff, metric-row stability, pointwise consumption, and inspected-threshold coverage together. A consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal or a completion-facing sequence row must pass through the displayed finite windows, the regular-rational handoff rows, and the same metric and continuity coordinates already inspected by the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialContinuity}^{\uparrow}$ packet is generated from source and target metric rows, a displayed pointwise-continuity row, inspected sequence windows, a finite convergence ledger, source and target RegSeqRat handoffs, RealUp seal rows, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1466.1, Definition 1466.2, Definition 1466.3, Definition 1466.4, Definition 1466.5, and Definition 1466.6 bind the carrier, NameCert obligations, Cauchy handoff, metric-row stability, pointwise consumption, and inspected-threshold coverage for certified sequence consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentialContinuity}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.SequentialContinuityUp.SequentialContinuityTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: human

Not claimed: This chapter does not claim host sequential continuity, function extensionality, countable choice, quotient stream equality, semantic completeness of RealUp, Lean verification, or bridge checking.

Upgrade path: No further paper-side closure grade remains; bridge verification stays on the independent formal axis.

Chapter 1467

A Concrete Naming Certificate for $\mathsf{SubsequenceLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SubsequenceLimit}^{\uparrow}$ packet records the finite consumer boundary for reading a displayed subsequence limit from already certified real sequence-limit data. It consumes the sequence-limit surface of chapter 1413, the cofinal selector route of chapter 405, the regular Cauchy subsequence boundary of chapter 381, and the real-name seal of chapter 38. Its purpose is to let downstream Bolzano–Weierstrass and sequence-convergence arguments read a selected limit surface without importing arbitrary subsequence choice, host sequence equality, quotient stream equality, or ambient completeness.

Definition 1467.1 (SubsequenceLimit carrier)**.** *A* $\mathsf{SubsequenceLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, \Phi, W, R, D, E, H, C, P, N)$$

with the following visible rows:

1. *L is the parent* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row, containing the displayed source sequence, candidate limit, tail-window schedule, dyadic tolerance ledger, and convergence classifier exposed by chapter 1413;*
2. *Φ is the accepted* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row, including the displayed unary selector, monotonicity witnesses, cofinal witnesses, selected windows, and regular rational handoff rows;*
3. *W records the selected finite* $\mathsf{StreamName}^{\uparrow}$ *windows from the parent sequence and from the subsequence readback surface;*
4. *R records the selected* $\mathsf{RegSeqRat}^{\uparrow}$ *observations and the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *route through which the subsequence read is displayed;*
5. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the selected subsequence windows with the parent limit row;*
6. *E is the shared* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the parent limit row, cofinal selector row, selected windows, regular rational handoff, and dyadic tolerance ledger have been displayed;*
7. *H records componentwise* hsame *transports for the parent limit row, selector row, selected windows, regular rational observations, dyadic ledger, real seal, and local naming row;*
8. *C records the displayed* Cont *routes by which consumers inspect the same rows in their certificate order;*

9. *P is the* Pkg *provenance over the* $\mathsf{RealSequenceLimit}^{\uparrow}$, $\mathsf{CofinalSubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and naming dependencies;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SubsequenceLimit}^{\uparrow}}$ *row.*

The carrier stores a finite subsequence-limit consumer interface. It contains no host-level infinite subsequence, no quotient stream representative, no host sequence equality, no independent real-completeness object, and no choice principle for selecting further subsequences.

Theorem 1467.2 (SubsequenceLimit NameCert obligations)**.** *Every accepted* $\mathsf{SubsequenceLimit}^{\uparrow}$ *carrier of Definition 1467.1 carries five finite NameCert obligation rows:*

1. *carrier admission for the parent sequence-limit row, cofinal selector row, selected* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff rows, dyadic tolerance ledger, shared* $\mathsf{Real}^{\uparrow}$ *seal, transport rows, continuation routes, package provenance, and local naming row;*

2. *selector-to-limit alignment, stating that every subsequence window read by Φ is one of the displayed parent sequence windows named by L and compared against the same candidate limit row;*

3. *tolerance preservation, stating that the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D is the common tolerance ledger used by both the parent sequence-limit classifier and the selected subsequence read;*

4. *real-seal handoff discipline, stating that the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed only after the parent limit row, cofinal selector, selected windows, regular rational route, and tolerance ledger have been displayed;*

5. *non-escape, stating that the packet exports no Bolzano–Weierstrass conclusion, arbitrary subsequence choice, host sequence equality, quotient stream equality, ambient real completeness, or bridge-checked external schema.*

Lean4 ✓ `BEDC.Derived.SubsequenceLimitUp.SubsequenceLimitTasteGate single carrier alignment`

Proof. Carrier admission is the tuple in Definition 1467.1. Each row needed by a consumer is a visible BHist coordinate, and the local naming row is attached to that same finite packet.

Selector-to-limit alignment is read from the pair (L, Φ). The parent row supplies the displayed sequence-limit surface, while the selector row supplies only selected finite windows and their regular rational handoff data. Thus a subsequence read remains a read of the parent displayed sequence.

Tolerance preservation is the projection to D. The selected subsequence windows are compared with the parent candidate limit using the same dyadic tolerance ledger, so the packet has no second tolerance scale that could change the limit claim.

The real-seal handoff follows the order of the rows L, Φ, W, R, D, E. A consumer reaches the shared $\mathsf{Real}^{\uparrow}$ seal only after the parent limit data, selector route, selected windows, regular rational observations, and dyadic ledger are already visible.

The non-escape row is an inventory check. None of the coordinates stores a Bolzano–Weierstrass selection, a host-level subsequence, host sequence equality, quotient stream equality, ambient real completeness, or an external bridge schema, so the local NameCert cannot export those objects. □

Theorem 1467.3 (SubsequenceLimit Real seal handoff)**.** *Let $Q = (L, \Phi, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{SubsequenceLimit}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing consumer read from Q factors through the parent* $\mathsf{RealSequenceLimit}^{\uparrow}$ *row L, the* $\mathsf{CofinalSubsequence}^{\uparrow}$ *selector row Φ, the selected* $\mathsf{StreamName}^{\uparrow}$

windows W, the selected $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *route R, and the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D before the seal row E is exposed.*

Proof. Start from a $\mathsf{Real}^{\uparrow}$-facing consumer read. The carrier places the seal coordinate E after the parent sequence-limit row, selector row, selected windows, regular rational handoff, and dyadic ledger.

Apply the selector-to-limit and tolerance-preservation rows of Definition 1467.2. They force the selected subsequence windows to remain parent sequence windows and force their limit comparison to use the same dyadic tolerance ledger as the parent limit classifier.

It remains to identify the public read route. The displayed hsame transports and Cont routes preserve the order through L, Φ, W, R, D, E, while the Pkg and local NameCert rows account for provenance. Hence every seal-facing read factors through the listed finite handoff surface. □

Theorem 1467.4 (SubsequenceLimit choice-free boundary)**.** *The* $\mathsf{SubsequenceLimit}^{\uparrow}$ *carrier is a finite BEDC consumer boundary for selected sequence-limit reads. It preserves the parent sequence-limit row, cofinal selector row, selected regular rational observations, dyadic tolerance ledger, shared real seal, displayed transports, continuation routes, package provenance, and local naming row, but it does not construct a Bolzano–Weierstrass subsequence, choose an arbitrary infinite subsequence, identify host sequences, identify quotient streams, prove real completeness, or provide a checked standard bridge.*

Proof. The positive content is exactly the carrier inventory of Definition 1467.1. The rows $L, \Phi, W, R, D, E, H, C, P$, provide the parent limit data, selector route, selected observations, tolerance ledger, seal, transport, continuation, provenance, and local naming surface.

The consumer route is fixed by Definition 1467.2 and Definition 1467.3. Every public real-facing read passes through the finite selector-to-limit handoff rather than through an unrecorded host object.

The excluded principles are absent as coordinates. Since no row stores a Bolzano–Weierstrass construction, arbitrary subsequence choice, host equality, quotient equality, completeness proof, or bridge-checked schema, the packet cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubsequenceLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{SubsequenceLimit}^{\uparrow}$ packet is generated from a parent sequence-limit row, a cofinal selector row, selected StreamName windows, RegSeqRat and RegularCauchySubsequence handoff rows, a shared DyadicRatCore tolerance ledger, a shared RealUp seal, componentwise transport, continuation routes, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SubsequenceLimit}^{\uparrow}}$, seed)

Scope closed: Definition 1467.1, Definition 1467.2, Definition 1467.3, and Definition 1467.4 declare the finite subsequence-limit consumer boundary for selected RealUp sequence-limit reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SubsequenceLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Bolzano–Weierstrass, arbitrary subsequence choice, host sequence equality, quotient stream equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selector-to-limit alignment, tolerance preservation, real-seal handoff, and choice-free refusal for the same finite packet.

Chapter 1468

A Concrete Naming Certificate for $\mathsf{AdjointOperator}^{\uparrow}$

Following the Hilbert-space adjoint construction in standard functional analysis, the $\mathsf{AdjointOperator}^{\uparrow}$ packet records the finite BEDC surface of a bounded operator together with a displayed adjoint endpoint and the inner-product pairing law that characterizes it. It is read over the $\mathsf{Hilbert}^{\uparrow}$ source of chapter 91, the $\mathsf{InnerProduct}^{\uparrow}$ form rows of chapter 86, the bounded-linear-operator carrier of Definition 90.49, and the functional-analysis consumer frontier of chapter 94.

1468.1 Carrier packet

Definition 1468.1 (Adjoint operator carrier)**.** *For carried* $\mathsf{Hilbert}^{\uparrow}$ *sources* H *and* K*, an* $\mathsf{AdjointOperator}^{\uparrow}(H, K)$ *carrier is a finite* BHist *packet*

$$A = (H, K, T, T^*, B, B^*, \langle -, - \rangle_H, \langle -, - \rangle_K, J, L, P, N)$$

with the following displayed rows.

1. *H and K are the Hilbert source rows, including their inherited* $\mathsf{InnerProduct}^{\uparrow}$ *form rows and Banach normed-complete rows.*
2. *T is a carried bounded-linear-operator row from H to K, read through Definition 90.49.*
3. *T^* is a carried bounded-linear-operator row from K to H, with bound row B^* and its own visible operator ledger.*
4. *$\langle -, - \rangle_H$ and $\langle -, - \rangle_K$ are the two displayed inner-product form rows consumed from the* $\mathsf{InnerProduct}^{\uparrow}$ *surfaces of H and K.*
5. *J is the finite adjunction ledger stating the componentwise pairing comparison between applying T on the H side and applying T^* on the K side.*
6. *L records the* hsame *transports of Hilbert source rows, operator endpoints, bound endpoints, inner-product values, and adjunction comparisons.*
7. *P is the local* Pkg *provenance surface, and N is the local* $\mathsf{NameCert}_{\mathsf{AdjointOperator}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a host Hilbert space, a choice-selected representing vector, a spectral resolution, a polar decomposition, or a full Riesz representation theorem.

Lean4 ✓ `BEDC.Derived.AdjointOperatorUp.AdjointOperatorTasteGate single carrier alignment`

1468.2 Adjunction law

Theorem 1468.2 (Adjoint operator inner-product adjunction)**.** *Let* $A = (H, K, T, T^*, B, B^*, \langle -, - \rangle_H, \langle -, - \rangle_K, J,$ *be an accepted* $\mathsf{AdjointOperator}^{\uparrow}(H, K)$ *packet. For every carried* H*-endpoint* x *and carried* K*-endpoint* y *visible to the operator ledgers, the packet exposes the classified scalar comparison*

$$\langle Tx, y \rangle_K \sim_{\mathsf{Real}^{\uparrow}} \langle x, T^* y \rangle_H.$$

This comparison is part of the finite ledger J*; it is not obtained by appealing to an ambient Hilbert-space duality theorem, a choice principle, or an external operator equality.*

Proof. Project the accepted packet through Definition 1468.1. The source and target Hilbert rows give the two inner-product forms, while the bounded-operator rows for T and T^* give the endpoint values Tx and T^*y in the carried Hilbert carriers.

Read the adjunction ledger J at the displayed pair (x, y). Its scalar comparison is already typed over the $\mathsf{Real}^{\uparrow}$ classifier inherited by the two inner-product rows, so the asserted equality is a BEDC endpoint comparison rather than host-level equality of scalar values.

The transport ledger L keeps the same comparison stable when x, y, T, T^*, or either Hilbert source row is replaced by a classified row. Hence the public adjunction law is exactly the row displayed by the packet. □

1468.3 Name certificate surface

Theorem 1468.3 (Adjoint operator NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{AdjointOperator}^{\uparrow}}$ *surface consists of the following five rows.*

1. *Carrier habitation for the finite packet of Definition 1468.1.*
2. *Componentwise classification of the two Hilbert source rows, the two bounded-operator rows, the two bound rows, and the two inner-product form rows.*
3. *Inner-product adjunction exactness through the ledger* J *of Definition 1468.2.*
4. *Transport stability for source, target, operator, bound, form-value, and adjunction rows through* L*.*
5. *Ledger exclusion of Riesz representation, spectral theorem, polar decomposition, host Hilbert equality, and external operator equality.*

Proof. Carrier habitation is the finite packaging operation of Definition 1468.1. The Hilbert, inner-product, bounded-operator, bound, adjunction, transport, provenance, and local-name rows are visible coordinates of the packet.

The classifier row is componentwise. Hilbert source comparison is read through the $\mathsf{Hilbert}^{\uparrow}$ classifiers, bounded-operator comparison through the Banach bounded-operator surface, and scalar comparison through the $\mathsf{Real}^{\uparrow}$ classifiers used by the two $\mathsf{InnerProduct}^{\uparrow}$ form rows.

Adjunction exactness is the assertion of Definition 1468.2. Transport stability is supplied by L, which repacks classified replacements of the same rows without introducing any host duality or spectral data. The excluded analytic theorems therefore remain outside the local certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{AdjointOperator}^{\uparrow}}$**.**

Constructive story: An AdjointOperator$^{\uparrow}$ packet records two carried Hilbert source rows, a carried bounded operator T, a carried bounded operator T^* in the reverse direction, their bound ledgers, the two inner-product form rows, a finite adjunction ledger comparing $\langle Tx, y\rangle_K$ with $\langle x, T^*y\rangle_H$, componentwise transport rows, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{AdjointOperator}^{\uparrow}}$, seed)

Scope closed: Definition 1468.1, Definition 1468.2, and Definition 1468.3 seed the Hilbert bounded-operator adjoint boundary over Hilbert$^{\uparrow}$, InnerProduct$^{\uparrow}$, Banach$^{\uparrow}$, Real$^{\uparrow}$, and FunctionalAnalysis$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{AdjointOperator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Riesz representation, the spectral theorem, polar decomposition, host Hilbert-space duality, arbitrary existence of adjoints, Lean verification, or a standard bridge.

Upgrade path: A formal route can encode the finite carrier and prove the adjunction ledger, transport stability, and local NameCert obligation surface.

Chapter 1469

A Concrete Naming Certificate for $\mathsf{BishopCompletionModulus}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopCompletionModulus}^{\uparrow}$ packet names the finite completion-modulus route that turns a displayed regular rational Cauchy input into a Real-facing seal. It refines the modulus surface of chapter 292, reads finite observation windows through chapter 126, uses the regular rational handoff of chapter 301, records dyadic thresholds through chapter 291, and reaches the terminal seal of chapter 38. The packet supplies an L10 completion-modulus object without quotient streams, selected limits, countable choice, or ambient completeness.

Definition 1469.1 (Bishop completion modulus carrier)**.** *A* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, S, n, k, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row, read as a monotone finite modulus interface for rational Cauchy observations.*
2. *S is the underlying finite* $\mathsf{StreamName}^{\uparrow}$ *schedule whose requested windows are admitted by the modulus row.*
3. *n is the unary precision request and k is the displayed threshold row selected by M for that request.*
4. *W is the finite stream window of S read at and beyond the threshold k.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *threshold ledger containing the dyadic tolerance, endpoint, comparison, and scale rows used by the selected window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained by repacking W with the dyadic threshold ledger D.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, S, n, k, W, D, R have been displayed.*
8. *H stores componentwise* hsame *transport for the modulus row, stream schedule, request, threshold, window, dyadic ledger, regular handoff, real seal, continuation, provenance, and local naming.*
9. *C stores displayed* Cont *replay from the request through the modulus row to the window, from the window through the dyadic ledger to the regular handoff, and from the handoff to the real seal.*

10. *P is the* Pkg *provenance over* BishopCompletionModulus$^{\uparrow}$, CauchyModulus$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It contains no coordinate for quotient stream equality, a selected completed limit, countable choice, a host real value, or an ambient completeness principle.

Lean4 (definition) `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier`
Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier rows exposed`

Theorem 1469.2 (Bishop completion modulus NameCert obligations)**.** *For every accepted* BishopCompletionModu *carrier $Q = (M, S, n, k, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionModulus}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the displayed twelve-row packet;*
2. *monotone finite modulus readback, stating that the threshold k is read from the displayed* CauchyModulus$^{\uparrow}$ *row M at the precision request n and is preserved by the stored transport rows;*
3. *dyadic threshold compatibility, stating that the window W and ledger D use the same threshold and tolerance scale;*
4. RegSeqRat$^{\uparrow}$ *handoff, stating that R is obtained only from the displayed stream window and dyadic threshold ledger;*
5. Real$^{\uparrow}$ *seal non-escape, stating that the seal row E is reachable only after the regular handoff and exports no quotient stream, selected limit, countable-choice row, host real, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusTasteGate single carrier alignment`

Proof. Project the carrier of Definition 1469.1. The displayed modulus, stream schedule, request, threshold, window, dyadic ledger, regular handoff, real seal, transport, continuation, provenance, and local naming rows are the only classifier-visible coordinates.

The modulus readback is finite. The row M supplies the threshold k for the request n, and the transport rows in H preserve that same threshold when the packet is compared with another accepted carrier.

The dyadic and regular faces are forced to use the same source data. The ledger D records the tolerance scale for the window W, and the handoff row R is read from W together with D rather than from a hidden rational sequence.

Finally the real-facing route is downstream from R. Since the carrier has no coordinate for quotient stream equality, a selected completed limit, countable choice, a host real value, or ambient completeness, the five listed obligations exhaust the local NameCert surface. □

Theorem 1469.3 (Bishop completion modulus L10 handoff)**.** *Every accepted* BishopCompletionModulus$^{\uparrow}$ *carrier hands its completion-modulus data to the L10 real-completion route through*

$$M, n \longmapsto k \longmapsto W, D \longmapsto R \longmapsto E$$

together with the displayed StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. No consumer of the packet can reach a* Real$^{\uparrow}$ *seal without first reading the monotone modulus threshold, the finite stream window, the dyadic threshold ledger, and the regular rational handoff.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier l10 handoff`

Proof. Begin with an accepted carrier and read the modulus face. The request n is sent through the displayed $\mathsf{CauchyModulus}^{\uparrow}$ row M, producing the threshold row k named in the carrier.

Next read the finite observation face. The stream schedule S supplies the window W at the selected threshold, while D records the dyadic tolerance and comparison rows attached to that same window.

The regular handoff is then fixed by the packet. The row R repacks the displayed window and dyadic ledger as the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the continuation routes record no alternate path to the seal.

Finally the $\mathsf{Real}^{\uparrow}$ row E is read only after R. The non-escape clause of Definition 1469.2 excludes quotient streams, selected limits, countable choice, host real values, and ambient completeness from the exported L10 handoff. □

Theorem 1469.4 (Bishop completion modulus threshold coherence)**.** *For every accepted* BishopCompletionModulus *carrier $Q = (M, S, n, k, W, D, R, E, H, C, P, N)$, monotone threshold coherence is a local obligation on the route*

$$M, n \longmapsto k \longmapsto W, D.$$

The $\mathsf{CauchyModulus}^{\uparrow}$ *row M supplies the displayed threshold k for the precision request n, the* $\mathsf{StreamName}^{\uparrow}$ *row S reads the finite window W at that threshold, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D records the same threshold and tolerance scale. Componentwise* hsame *transport and displayed* Cont *replay may preserve this route, but they do not select limits or assert* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier threshold coherence`

Proof. Project the carrier and read the modulus face. The rows M, n, k are displayed before the finite window row, so the threshold used by the packet is the one selected from the visible $\mathsf{CauchyModulus}^{\uparrow}$ row.

Read the window and dyadic ledger next. The row W is the finite $\mathsf{StreamName}^{\uparrow}$ observation at the selected threshold, and D records the dyadic tolerance data for that same window.

The structural rows preserve coherence only componentwise. The rows H, C, P, N transport, replay, source, and name the displayed threshold route, and no row in the carrier supplies a selected completed limit or an ambient completeness theorem. □

Theorem 1469.5 (Bishop completion modulus finite threshold induction)**.** *For every accepted* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *carrier $Q = (M, S, n, k, W, D, R, E, H, C, P, N)$, every finite precision descent from n through the displayed monotone modulus row M preserves a single threshold route*

$$M, n \longmapsto k \longmapsto W, D \longmapsto R \longmapsto E.$$

Induction on the unary precision history may refine the requested threshold only through the displayed $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. It cannot introduce a second threshold source, quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness.*

Proof. Project the carrier of Definition 1469.1. The only rows capable of answering a precision request are the displayed modulus row M, the unary request n, the threshold k, the finite window W, the dyadic ledger D, the regular readback R, and the Real seal E.

Induct on the unary precision history. In the base case, the request is the displayed n, and Definition 1469.4 identifies the threshold route through M, n, k, W, D before any readback or seal is consumed.

For the successor step, the monotone modulus row may refine the requested threshold, but the refinement remains inside the same carrier route. Apply Definition 1469.4 again to keep the successor request attached to the displayed StreamName window and DyadicRatCore ledger rather than to a second threshold oracle.

Finally close the non-escape part by Definition 1469.7. Since every Real-facing read reaches E only after R, and R is downstream from W, D, the induction cannot export quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier finite threshold induction`

Theorem 1469.6 (Bishop completion modulus threshold heredity)**.** *Let $Q = (M, S, n, k, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *carrier. For any displayed successor precision request refined through the same* $\mathsf{CauchyModulus}^{\uparrow}$ *row M, the completion route remains inside the same finite path*

$$M, n \longmapsto k \longmapsto W, D \longmapsto R \longmapsto E$$

after replacing the request and threshold by their displayed successor refinements. In particular, the refined read still uses the same $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *threshold ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal rows, transported and replayed only through H, C, P, N.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier threshold heredity`

Proof. Start with threshold coherence from Definition 1469.4. It identifies the selected threshold as a row of the displayed $\mathsf{CauchyModulus}^{\uparrow}$ carrier face and attaches the resulting stream window and dyadic ledger to the same request route.

Apply finite threshold induction from Definition 1469.5 to the successor precision history. The induction step permits threshold refinement only by another read of M, so the refined threshold remains tied to the same $\mathsf{StreamName}^{\uparrow}$ schedule and $\mathsf{DyadicRatCore}^{\uparrow}$ ledger rather than to a second threshold source.

Finally use Real seal ordering from Definition 1469.7. The refined route reaches E only after the corresponding W, D rows and the $\mathsf{RegSeqRat}^{\uparrow}$ handoff R have been displayed, and the structural rows H, C, P, N preserve that route without adding quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness. □

Theorem 1469.7 (Bishop completion modulus Real seal ordering)**.** *For every accepted* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *carrier $Q = (M, S, n, k, W, D, R, E, H, C, P, N)$, the* $\mathsf{Real}^{\uparrow}$ *seal row E is ordered strictly after the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R. A consumer may reach E only through the displayed sequence from* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold selection to* $\mathsf{StreamName}^{\uparrow}$ *window readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *threshold ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff; the seal does not supply selected limits, quotient stream equality, host real equality, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier real seal ordering`

Proof. Start from Definition 1469.3. It displays the only route to the Real-facing row:

$$M, n \longmapsto k \longmapsto W, D \longmapsto R \longmapsto E.$$

The regular handoff is therefore prior to the seal. The row R repacks the finite window W and dyadic threshold ledger D before any $\mathsf{Real}^{\uparrow}$ row is available to a consumer.

Finally apply the non-escape obligation from Definition 1469.2. Since the carrier contains no row for quotient stream equality, selected completed limits, choice, host real equality, or completeness, the ordered seal cannot export any of those principles. □

Theorem 1469.8 (Bishop completion modulus obligation package)**.** *For the carrier of Definition 1469.1, the displayed carrier rows, NameCert obligations, L10 handoff, threshold coherence, finite threshold induction, threshold heredity, and Real seal ordering together discharge the local* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *obligations for carrier admission, monotone finite modulus readback, dyadic threshold compatibility,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal non-escape.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier obligation package`

Proof. Carrier admission and the local obligation list are exactly the content of Definition 1469.2. They expose the twelve-row packet and name the five rows that every accepted carrier must satisfy.

The handoff and threshold clauses are supplied by Definition 1469.3, Definition 1469.4, Definition 1469.5, and Definition 1469.6. These results keep the precision request, selected threshold, stream window, and dyadic ledger on one finite route.

Finally apply Definition 1469.7. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff precedes the $\mathsf{Real}^{\uparrow}$ seal, and the seal exports none of the excluded quotient, choice, host-equality, selected-limit, or completeness data. Thus the five local obligations are packaged by the displayed chapter surface. □

Theorem 1469.9 (Bishop completion modulus same-threshold transport)**.** *Let* $Q = (M, S, n, k, W, D, R, E, H, C, P$ *and* $Q' = (M', S', n', k', W', D', R', E', H', C', P', N')$ *be accepted* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *carriers related by the displayed classifier rows. If the relation is witnessed through the componentwise transport rows* H*, the continuation replay rows* C*, package provenance* P*, and local naming* N*, then the compared packets preserve one displayed threshold route:*

$$M, n, k, W, D, R, E \qquad \text{and} \qquad M', n', k', W', D', R', E'.$$

The $\mathsf{CauchyModulus}^{\uparrow}$ *threshold,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal are transported as matching rows of the same route. No comparison may replace that route by quotient stream equality, selected limits, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier same threshold transport`

Proof. Project both accepted carriers. Their classifier-readable rows are exactly the completion modulus, stream schedule, precision request, threshold, window, dyadic ledger, regular handoff, Real seal, transport, continuation, provenance, and local naming rows of Definition 1469.1.

Use threshold coherence on each side. Theorems 1469.4 and 1469.6 keep the $\mathsf{CauchyModulus}^{\uparrow}$ threshold attached to the displayed $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{DyadicRatCore}^{\uparrow}$ ledger.

Now read the transport and replay rows. The componentwise hsame entries in H and the displayed Cont rows in C compare only the named carrier coordinates, while P and N repack the same local source and naming surface. Thus the transported packet still exposes the same threshold route.

Finally apply Real seal ordering, Definition 1469.7. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff remains before the $\mathsf{Real}^{\uparrow}$ seal on both sides, so the comparison cannot introduce quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness. □

Theorem 1469.10 (Bishop completion modulus scoped dependency surface)**.** *The* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *chapter has scoped BEDC closure for the finite completion-modulus dependency surface generated by the carrier of Definition 1469.1. The closed scope consists of carrier admission, the five NameCert obligations, the L10 handoff, threshold coherence, finite threshold induction, threshold heredity, Real seal ordering, and same-threshold transport through* H, C, P, N*.*

Within that scope every accepted consumer reads the same displayed sequence

$$\mathsf{CauchyModulus}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

before it reaches a completion-modulus seal. The scope does not include quotient stream equality, selected completed limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier scope closure`

Proof. Collect the carrier and obligation rows from Definition 1469.1 and Definition 1469.2. These fix the finite packet and the local NameCert surface.

Apply the route theorems. Theorems 1469.3, 1469.4, 1469.5, and 1469.6 bind every precision read to the same threshold, window, dyadic ledger, and regular rational handoff.

Use Definition 1469.7 for the terminal row and Definition 1469.9 for classifier-related packets. These results keep the Real seal and all transport rows inside the displayed carrier.

The excluded principles have no carrier coordinate and no scoped route theorem. Therefore the listed rows form the scoped BEDC dependency surface for $\mathsf{BishopCompletionModulus}^{\uparrow}$. □

Theorem 1469.11 (Bishop completion modulus public completion certificate)**.** *Every public completion-modulus consumer of an accepted* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *carrier* $Q = (M, S, n, k, W, D, R, E, H, C,$ *receives one certificate surface consisting of the carrier rows of Definition 1469.1, finite threshold induction, threshold heredity, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the ordered* $\mathsf{Real}^{\uparrow}$ *seal. The public read is the finite route*

$$M, n \longmapsto k \longmapsto W, D \longmapsto R \longmapsto E$$

preserved by H, C, P, N*. It exports no quotient stream, selected limit, countable choice, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier public completion certificate`

Proof. Start with the carrier and obligation surface. Theorems 1469.2 and 1469.3 expose the twelve carrier rows and force every completion read through the displayed modulus, finite stream window, dyadic threshold ledger, regular handoff, and Real seal.

Next apply finite threshold induction and threshold heredity. Theorems 1469.5 and 1469.6 keep successor precision requests attached to the same $\mathsf{CauchyModulus}^{\uparrow}$ row, the same $\mathsf{StreamName}^{\uparrow}$ schedule, and the same $\mathsf{DyadicRatCore}^{\uparrow}$ ledger rather than to a second threshold source.

Use Definition 1469.7 for the terminal ordering and Definition 1469.9 for public transport. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff remains prior to the $\mathsf{Real}^{\uparrow}$ seal, and componentwise transport preserves the displayed route.

Finally package the result by Definition 1469.10. The public certificate is exactly the scoped finite route above, so no quotient stream, selected completed limit, countable choice, host real equality, or ambient completeness can be exported. □

Theorem 1469.12 (Bishop completion modulus bridge-facing Real-seal boundary)**.** *Every bridge-facing read of an accepted* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *carrier preserves the displayed route*

$$M, n \longmapsto k \longmapsto W, D \longmapsto R \longmapsto E$$

together with H, C, P, N*. A standard interpretation may inspect this completion-modulus handoff and its terminal* $\mathsf{Real}^{\uparrow}$ *seal, but it may not add quotient streams, selected limits, countable choice, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.BishopCompletionModulusUp.BishopCompletionModulusCarrier bridge facing real seal boundary`

Proof. Start from the public completion certificate, Definition 1469.11. It fixes the public route through the modulus request, threshold, window, dyadic ledger, regular rational handoff, and Real seal.

Next use the same-threshold transport theorem, Definition 1469.9. The rows H, C, P, N preserve the displayed route componentwise and replay only the named carrier data, so a bridge-facing read cannot change the threshold source or insert an alternate stream.

Finally apply Real seal ordering from Definition 1469.7. Since E is reachable only after R and the carrier has no quotient-stream, selected-limit, choice, host-equality, or ambient-completeness coordinate, the standard-facing boundary is exactly the displayed handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionModulus}^{\uparrow}$ packet is generated from a displayed CauchyModulus row, a finite StreamName schedule, a unary precision request, a selected threshold, a finite stream window, a DyadicRatCore threshold ledger, a RegSeqRat handoff, a RealUp seal, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCompletionModulus}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1469.11 and Definition 1469.12 bind the public and bridge-facing export surface for the finite completion-modulus route through carrier rows, threshold induction, threshold heredity, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and the ordered $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCompletionModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected completed limits, countable choice, host real equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Only Lean formal verification and bridge checking remain outside the paper mature treatment of completion-modulus consumers.

Chapter 1470

RegularCauchyRing NameCert Construction

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyRing}^{\uparrow}$ packet treats the algebra of regular Cauchy real names as a finite operation surface over displayed rational observations. Addition, negation, product, and rational scaling are not imported as host real operations; they are read through the existing $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyNegation}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, and $\mathsf{RegularCauchyScale}^{\uparrow}$ rows, then sealed through the same $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ completion boundary. Thus the packet records the L10 algebraic handoff without quotient real equality, trichotomy, countable choice, selected limits, or ambient completeness.

The sibling route runs through chapter 417, chapter 459, chapter 461, chapter 465, chapter 301, and chapter 38. Those chapters supply the operation rows and terminal $\mathsf{Real}^{\uparrow}$ seal consumed by the ring packet.

Definition 1470.1 (Regular Cauchy ring carrier)**.** *A* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, W_A, W_B, D_A, D_B, S, G, M, L, R_S, R_G, R_M, R_L, E_S, E_G, E_M, E_L, H, C, P, N)$$

with the following displayed coordinates:

1. *A and B are two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows for regular rational Cauchy real names.*
2. *W_A and W_B are aligned* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows for the same requested precision scale.*
3. *D_A and D_B are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledgers read from those windows.*
4. *S is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *operation row on A and B.*
5. *G is the* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *operation row on the source row selected for additive inverse readback.*
6. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *operation row on A and B.*
7. *L is the* $\mathsf{RegularCauchyScale}^{\uparrow}$ *operation row for a displayed rational scalar and the selected source row.*
8. *R_S, R_G, R_M, R_L are the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows reached respectively after the sum, negation, product, and scale readbacks.*
9. *E_S, E_G, E_M, E_L are the finite dyadic and error-budget ledgers consumed by those operation rows before the terminal seals are public.*

10. *H stores componentwise* hsame *transport for the two sources, aligned windows, dyadic ledgers, four operation rows, four terminal seal rows, and four finite budget ledgers.*

11. *C stores displayed* Cont *replay for opening the source windows, reading dyadic endpoint data, invoking the four operation packets, and exposing the terminal real-name seals.*

12. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyNegation}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyScale}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$ *row.*

The carrier is a finite algebraic operation packet over regular Cauchy real names. It stores no quotient stream, no host real equality, no selected completed limit, no trichotomy, no countable-choice row, and no $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingTasteGate single carrier alignment`

Theorem 1470.2 (Regular Cauchy ring NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$ *surface for the carrier of Definition 1470.1 consists of the following finite obligations:*

1. *carrier admission for the displayed packet K with two regular-rational source rows, aligned stream windows, dyadic endpoint ledgers, four operation rows, four terminal real-name seal rows, four finite budget ledgers, transport, continuation, provenance, and local naming data;*

2. *source-window alignment, requiring S, M, and the selected-source rows for G and L to read only the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers;*

3. *operation admission, requiring the sum, negation, product, and scale rows to be accepted packets of their cited sibling surfaces;*

4. *componentwise classifier transport through the stored* hsame *rows and displayed* Cont *replay;*

5. *terminal seal handoff, requiring every real-facing consumer of the ring packet to pass through the operation readback row and its displayed budget ledger before reading one of R_S, R_G, R_M, R_L.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 1470.1. The two regular-rational sources, aligned stream windows, dyadic endpoint rows, four operation rows, budget ledgers, terminal seals, transports, continuations, provenance, and local name are explicit coordinates of K.

The source-window obligation is inherited from the sibling operation packets. Apply the window and handoff surfaces of Definition 417.2, Definition 459.2, Definition 461.2, and Definition 465.2. Each cited surface consumes the displayed source rows and their finite dyadic ledgers before exporting a regular readback.

Classifier transport is componentwise. The stored H and C rows transport the two sources, the aligned windows, the dyadic ledgers, the four operation rows, and the four seal rows together, so no operation can detach from the finite packet.

Finally the terminal handoff is exactly the real-seal boundary supplied by the four sibling chapters. The local $\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$ row therefore names the assembled algebraic surface and adds no host real arithmetic, quotient equality, selected limit, trichotomy, choice, or completeness coordinate. □

Theorem 1470.3 (Regular Cauchy ring operation-row admission)**.** *For every accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier*

$$K = (A, B, W_A, W_B, D_A, D_B, S, G, M, L, R_S, R_G, R_M, R_L, E_S, E_G, E_M, E_L, H, C, P, N),$$

the four operation coordinates S, G, M, L *are admitted only as displayed sibling rows of* $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyNegation}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, *and* $\mathsf{RegularCauchyScale}^{\uparrow}$. *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$ *row cannot replace any of those rows by host real addition, host real negation, host real multiplication, scalar multiplication on completed quotients, selected limits, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1470.1. The only operation coordinates are the four displayed rows S, G, M, L, and each is listed beside the same source rows, stream windows, dyadic endpoint ledgers, budget ledgers, terminal seal rows, transport, replay, provenance, and local naming.

Use the sibling obligation surfaces for the four rows: Definition 417.2, Definition 459.2, Definition 461.2, and Definition 465.2. These chapters admit the sum, negation, product, and scale reads as finite operation packets over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ data.

Finally read the local NameCert obligation theorem Definition 1470.2. It packages those sibling rows into one ring carrier but adds no fifth operation coordinate and no host arithmetic row, so admission of the operation rows is exactly sibling-row admission. □

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier operation row admission`

Theorem 1470.4 (Regular Cauchy ring componentwise transport)**.** *For every accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier* K*, classifier transport through* H *preserves the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, aligned* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledgers, four operation rows, four terminal* $\mathsf{Real}^{\uparrow}$ *seal rows, four finite budget ledgers, displayed replay, provenance, and local naming component by component. A transported ring packet therefore reads the same finite operation surface through* S, G, M, L *and cannot detach an operation row from its displayed source, budget, or seal data.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier componentwise transport`

Proof. Begin with the carrier coordinates of Definition 1470.1. The transport row H is explicitly componentwise over the two sources, the aligned windows, the dyadic ledgers, the four operation rows, the four terminal seal rows, the four finite budget ledgers, replay, provenance, and local naming.

Apply the operation-row admission theorem Definition 1470.3. Since S, G, M, L are admitted only as displayed sibling rows, transporting a packet transports those rows together with the source windows and dyadic ledgers that make the sibling reads meaningful.

The displayed replay row C and provenance row P preserve the same route for consumers. Thus transport can rename or replay the finite packet, but it cannot split an operation from its $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, budget, or $\mathsf{Real}^{\uparrow}$ seal boundary. □

Theorem 1470.5 (Regular Cauchy ring terminal-seal discipline)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier is one of* R_S, R_G, R_M, R_L*, and it is reachable only after the corresponding operation row* S*,* G*,* M*, or* L *and its finite budget ledger* E_S*,* E_G*,* E_M*, or* E_L *have been displayed. No* $\mathsf{Real}^{\uparrow}$ *consumer of the ring packet can bypass the sibling operation chapters, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers, componentwise transport, replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier terminal seal discipline`

Proof. Project the terminal coordinates of the carrier. The only $\mathsf{Real}^{\uparrow}$ seal rows present in K are R_S, R_G, R_M, R_L, paired respectively with S, G, M, L and with the finite budget ledgers E_S, E_G, E_M, E_L.

Use the sibling seal boundaries. The sum route is governed by Definition 417.8; the negation route by Definition 459.8; the product route by Definition 461.5; and the scale route by Definition 465.11. Each route exposes finite windows, regular readback, dyadic data, and budget rows before the terminal seal is public.

Combine those sibling boundaries with componentwise transport from Definition 1470.4. The structural rows preserve the four operation-to-seal routes and add no extra seal coordinate, so every real-facing consumer remains inside one of the four displayed terminal routes. □

Theorem 1470.6 (Regular Cauchy ring operation closure)**.** *For every accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier K, the four displayed algebraic operations close inside the finite regular-Cauchy naming surface: addition exposes S and R_S, negation exposes G and R_G, product exposes M and R_M, and rational scaling exposes L and R_L. Each operation reads only the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, aligned* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers, finite budget rows, componentwise* hsame *transports,* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingOperationClosure`

Proof. Read the sum component first. The carrier exposes the two source rows, aligned windows, dyadic endpoint ledgers, the finite sum budget row E_S, and the operation row S; Definition 417.6 and Definition 417.8 then route the readback to R_S.

Read the unary component next. The negation row G uses its selected source window and dyadic ledger, and Definition 459.4 with Definition 459.8 routes the sign-flipped regular readback to R_G.

For multiplication, project M together with E_M. The product handoff and seal boundary of Definition 461.4 and Definition 461.5 keep the product inside the displayed dyadic product and budget rows before R_M is public.

For rational scaling, project L together with E_L. The scale handoff and seal boundary of Definition 465.10 and Definition 465.11 keep the scaled output inside the displayed scalar, source, window, dyadic, and budget rows before R_L is public.

These four projections exhaust the carrier's algebraic coordinates. The operation closure is therefore closure of the finite BEDC packet surface, not a statement about quotient real equality or ambient real algebra. □

Theorem 1470.7 (Regular Cauchy ring windowwise associativity)**.** *For every accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier, the displayed sum, product, and rational-scale windows compose through the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers under reassociation. More precisely, each reassociated route first reads the two source rows, aligned windows, dyadic endpoint ledgers, finite budget rows, operation rows, componentwise* hsame *transports, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row, and then reaches the same terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary for the corresponding sum, product, or scale readback.*

Proof. Project the carrier of Definition 1470.1. The only operation coordinates are S, G, M, L together with the aligned source windows, dyadic ledgers, budget rows, transports, replay, provenance, and terminal seal rows.

For sums, reassociation changes only the order in which the finite $\mathsf{RegularCauchySum}^{\uparrow}$ rows are consumed. The source-window alignment and terminal seal handoff of Definition 1470.2 keep both reads on the same displayed $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ ledgers before R_S is public.

For products and rational scales, use the same argument with the product and scale routes. The product route is governed by Definition 461.4 and Definition 461.5; the scale route is governed by Definition 465.10 and Definition 465.11. These sibling handoffs expose finite readbacks and then the terminal $\mathsf{Real}^{\uparrow}$ seal, so reassociation cannot introduce host real equality, selected limits, trichotomy, choice, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier windowwise associativity`

Theorem 1470.8 (Regular Cauchy ring componentwise distributivity)**.** *For every accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier, a product-over-sum read is witnessed componentwise through the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *and* $\mathsf{RegularCauchySum}^{\uparrow}$ *budget rows. The left route reads the product row after the summed source row is displayed; the right route reads two product rows and then the sum row; both routes remain inside the displayed source windows, dyadic endpoint ledgers, finite budget rows, componentwise* hsame *transports, displayed* Cont *replay,* Pkg *provenance, local* NameCert *row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary. No step appeals to host real distributivity.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier componentwise distributivity`

Proof. Start with the operation closure of Definition 1470.6. It identifies the available addition and product rows as projections of the finite carrier, not as ambient operations on completed real quotients.

Build the left route by reading the $\mathsf{RegularCauchySum}^{\uparrow}$ budget row for the two addends and then the $\mathsf{RegularCauchyProduct}^{\uparrow}$ row for the multiplier and the displayed sum readback. The sum handoff of Definition 417.6 and the product handoff of Definition 461.4 keep the route in regular rational readback data.

Build the right route by reading the two product rows first and then the sum row on their readbacks. The seal-boundary theorems Definition 461.5 and Definition 417.8 keep both products and the final sum behind the displayed dyadic and budget ledgers.

The componentwise hsame transport and displayed Cont replay rows move the two routes together. Therefore the distributive read is a finite packet obligation through $\mathsf{RegularCauchyProduct}^{\uparrow}$ and $\mathsf{RegularCauchySum}^{\uparrow}$, not an imported law of host real multiplication and addition. □

Theorem 1470.9 (Regular Cauchy ring Real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier reaches a terminal seal only through one of the four displayed routes*

$$S \longmapsto R_S, \qquad G \longmapsto R_G, \qquad M \longmapsto R_M, \qquad L \longmapsto R_L,$$

together with the relevant source windows, dyadic endpoint ledgers, finite budget ledger, componentwise hsame *transports,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$ *row. The packet exports no quotient stream, host real equality, selected completed limit, trichotomy, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier real seal nonescape`

Proof. Begin with the terminal seal clause of Definition 1470.2. It forces any real-facing consumer to choose one of the four operation routes and to keep the corresponding source, window, dyadic, budget, transport, continuation, provenance, and naming rows attached.

The sibling non-escape clauses then close the four cases. For the sum route use Definition 417.9; for the negation route use Definition 459.9; for the product route use Definition 461.11; for the scale route use Definition 465.18.

Since the ring carrier contains only those four terminal routes and their shared structural rows, no real-facing consumer can read a fifth route through host arithmetic, quotient real equality, selected limits, trichotomy, countable choice, or ambient completeness. □

Theorem 1470.10 (Regular Cauchy ring componentwise ring laws)**.** *For every accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier, associativity of displayed addition and product routes, additive inverse readback, distributivity of product over sum, and rational-scalar compatibility are inherited only through the componentwise operation rows* $\mathsf{RegularCauchySum}^{\uparrow}$*,* $\mathsf{RegularCauchyNegation}^{\uparrow}$*,* $\mathsf{RegularCauchyProduct}^{\uparrow}$*, and* $\mathsf{RegularCauchyScale}^{\uparrow}$*, together with the source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows. The ring packet does not import host real ring laws, quotient real equality, selected limits, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the operation-row admission theorem Definition 1470.3. It separates the four algebraic cases S, G, M, L and admits each one only as the displayed sibling operation row attached to the source windows, dyadic ledgers, finite budget rows, transport, replay, provenance, and local naming.

For the addition and additive-inverse cases, use the sibling non-escape clauses already used by the Real seal boundary: Definition 417.9 for S and Definition 459.9 for G. These clauses keep associativity reads and inverse reads inside $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyNegation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal rows.

For the product and rational-scalar cases, use Definition 461.11 for M and Definition 465.18 for L. The componentwise distributivity theorem Definition 1470.8 supplies the mixed sum-product route, while the scale route remains a displayed rational-scalar handoff rather than host scalar multiplication on completed quotients.

These four cases exhaust the carrier's algebraic coordinates. Since componentwise transport from Definition 1470.4 preserves only the displayed operation rows and their seal boundaries, every ring-law read is a finite BEDC packet route and not an imported law of ambient completed reals. □

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier componentwise ring laws`

Theorem 1470.11 (Regular Cauchy ring finite operation induction)**.** *Every ring-law consumer of an accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier is exhausted by finite induction over the four operation coordinates* S, G, M, L*. The* S *case reads only the* $\mathsf{RegularCauchySum}^{\uparrow}$ *sibling packet, the* G *case reads only the* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *sibling packet, the* M *case reads only the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *sibling packet, and the* L *case reads only the* $\mathsf{RegularCauchyScale}^{\uparrow}$ *sibling packet, together with their displayed source rows, budget rows, transport, replay, provenance, local naming, and terminal* $\mathsf{Real}^{\uparrow}$ *seals. No induction branch can route through host real algebra, quotient equality, selected limits, trichotomy, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier finite operation induction`

Proof. Project the carrier of Definition 1470.1. Its operation surface is the finite four-coordinate family S, G, M, L, so induction over possible ring-law reads has exactly four cases.

In the S and G cases, use operation-row admission and operation closure, Definition 1470.3 and Definition 1470.6. They keep addition and negation inside the $\mathsf{RegularCauchySum}^{\uparrow}$ and

$\mathsf{RegularCauchyNegation}^{\uparrow}$ sibling rows with their displayed source, window, dyadic, budget, and seal data.

In the M and L cases, use the same admission and closure results for the $\mathsf{RegularCauchyProduct}^{\uparrow}$ and $\mathsf{RegularCauchyScale}^{\uparrow}$ sibling rows. The componentwise distributivity theorem Definition 1470.8 supplies the mixed sum-product route without introducing an ambient multiplication or addition law.

Finally apply the Real seal non-escape theorem Definition 1470.9. Since each branch reaches a terminal seal only through its displayed sibling operation packet, the four induction cases exhaust all ring-law consumers and leave no route to host real algebra, quotient equality, selected limits, trichotomy, choice, or completeness. □

Theorem 1470.12 (Regular Cauchy ring obligation surface)**.** *Every ring consumer of an accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier*

$$K = (A, B, W_A, W_B, D_A, D_B, S, G, M, L, R_S, R_G, R_M, R_L, E_S, E_G, E_M, E_L, H, C, P, N)$$

must read exactly the four displayed operation rows S, G, M, L *together with the* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows,* $\mathsf{StreamName}^{\uparrow}$ *window rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledgers, terminal* $\mathsf{Real}^{\uparrow}$ *seal rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$ *row before the ring packet can be consumed as algebraic data.*

The operation rows are the addition, negation, product, and rational-scale surfaces already supplied by the sibling $\mathsf{RegularCauchySum}^{\uparrow}$*,* $\mathsf{RegularCauchyNegation}^{\uparrow}$*,* $\mathsf{RegularCauchyProduct}^{\uparrow}$*, and* $\mathsf{RegularCauchyScale}^{\uparrow}$ *chapters. No consumer may substitute a host real operation, quotient equality branch, selected limit, trichotomy, countable-choice branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row for any part of this displayed surface.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier obligation surface`

Proof. Project the carrier of Definition 1470.1. The only algebraic operation coordinates are S, G, M, L, and each is paired with displayed source rows, aligned windows, dyadic ledgers, finite budget rows, a terminal seal, transport, replay, provenance, and local naming.

Apply operation-row admission Definition 1470.3 and operation closure Definition 1470.6. They identify the four rows as the complete operation surface and keep the readback inside the same finite regular-Cauchy packet.

Use finite operation induction Definition 1470.11. The S, G, M, and L cases cite the sibling handoffs for sum, negation, product, and scale, so every consumer reads the same L10 completion-facing rows before any algebraic conclusion is public.

Finally combine the terminal-seal discipline and Real seal non-escape theorems, Definition 1470.5 and Definition 1470.9. They force every terminal $\mathsf{Real}^{\uparrow}$ read to pass through one of R_S, R_G, R_M, R_L with its operation and budget row still visible, which is exactly the obligation surface stated above. □

Theorem 1470.13 (Regular Cauchy ring operation inversion)**.** *Let* K *be an accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier. Any attempted algebraic read from* K *inverts by finite case split on the operation row that licenses it:*

1. *an addition read is the* S *branch through* $\mathsf{RegularCauchySum}^{\uparrow}$ *and* R_S*;*
2. *an additive-inverse read is the* G *branch through* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *and* R_G*;*
3. *a product read is the* M *branch through* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *and* R_M*;*

4. a rational-scale read is the L branch through $\mathsf{RegularCauchyScale}^{\uparrow}$ *and* R_L.

These four cases exhaust the carrier's operation surface. There is no fifth branch through host real algebra, quotient equality, selected limits, trichotomy, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from finite operation induction, Definition 1470.11. It reduces every ring-law consumer to exactly one of the four operation coordinates S, G, M, L.

In the S case, apply operation-row admission and operation closure, Definition 1470.3 and Definition 1470.6. The sum read is therefore a $\mathsf{RegularCauchySum}^{\uparrow}$ sibling handoff with its source, window, dyadic, budget, transport, replay, provenance, naming, and terminal R_S rows attached.

In the G case, the same two theorems identify the negation read as the $\mathsf{RegularCauchyNegation}^{\uparrow}$ sibling handoff with terminal R_G. The selected source row and its displayed finite budget remain attached, so the branch cannot become host additive inverse on completed reals.

In the M and L cases, the product and rational-scale handoffs are read through $\mathsf{RegularCauchyProduct}^{\uparrow}$ and $\mathsf{RegularCauchyScale}^{\uparrow}$, with terminal seals R_M and R_L. Componentwise distributivity, terminal-seal discipline, and Real seal non-escape keep the mixed algebraic reads behind the same displayed sibling routes.

Since the carrier contains no operation coordinate other than S, G, M, L, the case split has no residual branch. The inversion therefore refuses host real algebra, quotient equality, selected limits, trichotomy, countable choice, and ambient completeness as unavailable endpoints. □

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingCarrier operation inversion`

Theorem 1470.14 (Regular Cauchy ring obligation upgrade)**.** *For every accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier, the carrier admission of Definition 1470.1, operation-row admission, componentwise transport, terminal-seal discipline, operation closure, componentwise distributivity, finite operation induction, obligation surface, and operation inversion together enumerate the full finite* $\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$ *obligation surface over* $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyNegation}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyScale}^{\uparrow}$ $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.

The enumeration is exactly the four operation cases S, G, M, L with their displayed source rows, aligned windows, dyadic ledgers, finite budget rows, terminal seal rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. It contains no branch through host ring laws, quotient real equality, trichotomy, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 1470.1. The only algebraic coordinates are the four operation rows S, G, M, L, and every structural row is attached to those coordinates through the displayed source, window, dyadic, budget, seal, transport, replay, provenance, and naming data.

Split over the four operation rows. The S branch is admitted by Definition 1470.3 and closes by Definition 1470.6 through $\mathsf{RegularCauchySum}^{\uparrow}$ and R_S. The G branch uses the same theorems through $\mathsf{RegularCauchyNegation}^{\uparrow}$ and R_G.

The M branch is the product branch through $\mathsf{RegularCauchyProduct}^{\uparrow}$ and R_M, and the L branch is the rational-scale branch through $\mathsf{RegularCauchyScale}^{\uparrow}$ and R_L. Componentwise distributivity is supplied by Definition 1470.8, while finite operation induction in Definition 1470.11 says these four branches exhaust every ring-law consumer.

Finally apply the obligation surface and inversion theorems, Definition 1470.12 and Definition 1470.13. They repack the four case routes into one NameCert surface and rule out a residual branch through host real algebra, quotient equality, selected limits, trichotomy, choice, or completeness. □

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingObligationUpgrade`

Theorem 1470.15 (Regular Cauchy ring scoped kernel dependency)**.** *The scoped kernel of an accepted* $\mathsf{RegularCauchyRing}^{\uparrow}$ *carrier consists only of the carrier coordinates of Definition 1470.1, the four operation rows* $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyNegation}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, *and* $\mathsf{RegularCauchyScale}^{\uparrow}$, *their distributivity and operation-inversion obligations, the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows, componentwise* Cont *and* hsame *transport, and the source surfaces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$. *No part of the carrier, operation admission rows, distributivity route, Real seal boundary, or operation inversion depends on host real algebra, quotient real equality, selected completed limits, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRingUp.RegularCauchyRingScopedKernelDependency`

Proof. Project the carrier and operation-row admission theorems, Definition 1470.1 and Definition 1470.3. They name exactly the source rows, aligned stream windows, dyadic ledgers, four sibling operation rows, finite budget rows, structural transport, replay, provenance, and local naming data.

For algebraic use, apply operation closure, componentwise distributivity, finite operation induction, and operation inversion: Definition 1470.6, Definition 1470.8, Definition 1470.11, and Definition 1470.13. These theorems reduce every ring consumer to the four displayed sibling rows and their source data.

Finally apply terminal-seal discipline and Real seal non-escape, Definition 1470.5 and Definition 1470.9. The terminal rows stay behind the same operation and budget ledgers, so the scoped kernel is precisely the displayed BEDC dependency list and has no residual host-real branch. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRing}^{\uparrow}$ packet is generated from two RegSeqRat source rows, aligned StreamName windows, DyadicRatCore endpoint ledgers, RegularCauchySum, RegularCauchyNegation, RegularCauchyProduct, and RegularCauchyScale operation rows, terminal RealUp seal rows, finite budget ledgers, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 1470.1, Definition 1470.2, Definition 1470.6, Definition 1470.9, Definition 1470.14, and Definition 1470.15 bind the carrier, operation rows, distributivity, terminal Real seal, operation inversion, DyadicRatCore, StreamName, RegSeqRat, RegularCauchySum, RegularCauchyNegation, RegularCauchyProduct, RegularCauchyScale, Cont/hsame transport, and RealUp sealing as the chapter's exact kernel scope.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyRing}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, host real arithmetic laws, trichotomy, countable choice, selected completed limits, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, operation-row admission, componentwise transport, and Real seal non-escape for the same finite algebraic packet.

Chapter 1471

A Concrete Naming Certificate for $\mathsf{RegularCauchyReciprocal}^{\uparrow}$

Bishop and Bridges-style constructive reciprocal data begin from a regular Cauchy rational name together with a displayed apartness window that keeps the inspected tail away from zero. The $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ packet names the finite interface needed to read that reciprocal surface. It refines the budget-only surface of chapter 703 by binding the $\mathsf{RegSeqRat}^{\uparrow}$ source of chapter 301, the finite windows of chapter 126, the dyadic endpoint and radius arithmetic of chapter 291, and the terminal seal of chapter 38 into one local NameCert carrier. The chapter records only the finite reciprocal-read surface; it does not construct a total reciprocal operation on $\mathsf{Real}^{\uparrow}$.

Definition 1471.1 (Regular Cauchy reciprocal carrier)**.** *A* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (Q, A, M, W, D, B, T, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational entries are being inspected.*
2. *A is the apartness-window row displaying a rational lower bound that keeps the inspected tail of Q away from zero.*
3. *M is the finite modulus row selecting the precision at which the reciprocal read is requested.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened from Q under A and M.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and comparison ledger read from W.*
6. *B is the sibling* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row that records the reciprocal-window budget over the same Q, A, M, W, D rows.*
7. *T is the regular rational readback row naming the reciprocal candidate as a* $\mathsf{RegSeqRat}^{\uparrow}$ *surface.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed source, apartness, modulus, window, dyadic, budget, and readback rows have been consumed.*
9. *H records componentwise* hsame *transport for $Q, A, M, W, D, B, T, E, C, P, N$.*
10. *C records the displayed* Cont *replay for source inspection, apartness exposure, finite-window selection, dyadic reciprocal arithmetic, budget handoff, regular readback, and Real seal handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyInverseBudget}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}$ *row.*
The local classifier compares accepted carriers only through the displayed rows $Q, A, M, W, D, B, T, E, H, C, P, N$.

Theorem 1471.2 (Regular Cauchy reciprocal apartness window)**.** *Every accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier exposes the apartness row A before any reciprocal dyadic row D, budget row B, regular readback row T, or* $\mathsf{Real}^{\uparrow}$ *seal row E can be consumed. A route that omits A remains a boundary attempt and cannot export a reciprocal candidate.*

Proof. Project the carrier of Definition 1471.1. The source-side rows are Q, A, M, W, and the reciprocal-facing rows begin only after the apartness and modulus rows have selected a finite window.

The dyadic ledger D reads endpoint, radius, and comparison data from W. Since the reciprocal denominator is controlled by the displayed lower bound in A, the dyadic reciprocal row has no carrier route that bypasses A.

The budget row B, readback row T, and seal row E are downstream of that dyadic row. Therefore omitting A leaves no displayed route from the source to a reciprocal candidate; the local classifier records such a route as boundary evidence. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalCarrier apartness window`

Theorem 1471.3 (Regular Cauchy reciprocal readback route)**.** *For every accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$, the reciprocal readback row T factors through*

$$Q \longmapsto A \longmapsto M \longmapsto W \longmapsto D \longmapsto B \longmapsto T.$$

The terminal $\mathsf{Real}^{\uparrow}$ *seal E is reached only after this finite route has been displayed.*

Proof. Begin with the apartness-window theorem. It places A before any dyadic reciprocal arithmetic, so the route to T cannot start from Q alone.

Next open the finite window row W by using the modulus row M. The dyadic ledger D is a read of that window, and the sibling budget row B is the same reciprocal-window discipline named by chapter 703.

Finally project T and then E from the carrier. The readback row names the reciprocal candidate as regular rational data, while the seal row is terminal and adds no second route around the displayed finite chain. □

Theorem 1471.4 (Regular Cauchy reciprocal classifier stability)**.** *Let*

$$R = (Q, A, M, W, D, B, T, E, H, C, P, N) \quad \text{and} \quad R' = (Q', A', M', W', D', B', T', E', H', C', P', N')$$

be accepted $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carriers. If the displayed transport row H supplies componentwise* hsame *comparisons from each row of R to the corresponding row of R', then the local classifier preserves the* $\mathsf{RegSeqRat}^{\uparrow}$ *source, apartness row, modulus row, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger,* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *budget row, reciprocal readback row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal route.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalClassifierStability`

Proof. Project the transport coordinate H from the carrier. Its comparisons are componentwise, so the source rows Q, Q', apartness rows A, A', modulus rows M, M', finite windows W, W', dyadic ledgers D, D', budget rows B, B', readback rows T, T', and seal rows E, E' are matched before any classifier conclusion is read.

Apply the apartness-window theorem to both carriers. Since the transported apartness rows remain the first reciprocal-facing rows, the reciprocal denominator witness is preserved by the classifier.

Apply the readback-route theorem to both carriers. The transported route from Q through B to T matches the transported route from Q' through B' to T', and the terminal seal rows are reached only after those finite routes.

Thus classifier equality cannot forget, reorder, or replace any analytic row of the reciprocal packet. It transports exactly the displayed source, apartness, modulus, window, dyadic, budget, readback, and Real seal coordinates. □

Theorem 1471.5 (Regular Cauchy reciprocal terminal seal non-totality)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal row E of an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier cannot be reread as a total reciprocal operation on all* $\mathsf{Real}^{\uparrow}$ *names. Any route from the seal back to a reciprocal candidate must still factor through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row Q, apartness row A, modulus row M, finite* $\mathsf{StreamName}^{\uparrow}$ *window W, dyadic ledger D,* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *budget row B, and regular readback row T.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalTerminalSealNonTotality`

Proof. Inspect the carrier definition. The seal coordinate E is listed after the source, apartness, modulus, window, dyadic, budget, and readback rows, and the classifier reads it as one coordinate of the twelve-row packet.

The readback-route theorem states that E is reached only after the finite route through T has been displayed. Therefore the seal does not introduce a second route from arbitrary $\mathsf{Real}^{\uparrow}$ names to reciprocal data.

The apartness-window theorem keeps A mandatory for every reciprocal-facing row. Since a total reciprocal on all $\mathsf{Real}^{\uparrow}$ names would erase the need for such a displayed apartness row, it is not present in the packet.

Consequently the terminal seal records only the end of one finite regular-Cauchy reciprocal read. It cannot be exported as a total reciprocal operation or as a boundary bypass around the apartness obligation. □

Theorem 1471.6 (Regular Cauchy reciprocal denominator apartness)**.** *For every accepted* RegularCauchyReciproca *carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$, the dyadic reciprocal row D and the* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *budget row B are admissible only after the apartness row A displays a positive lower bound for the inspected* $\mathsf{RegSeqRat}^{\uparrow}$ *tail named by Q, M, W. A consumer that reads D or B without that positive lower-bound display has not reached a reciprocal row of the packet.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalDenominatorApartness`

Proof. Project Definition 1471.1. The source row Q, apartness row A, modulus row M, and finite window row W precede the dyadic reciprocal row D and budget row B in the carrier route.

Apply Definition 1471.2. It states that A is exposed before D, B, T, E can be consumed, so the denominator-side condition is part of the carrier admission rather than a later Real-facing consequence.

Finally read Definition 1471.3. The route from Q to T passes through A, M, W, D, B in that order, and therefore D and B are reciprocal rows only when the inspected regular tail has the displayed positive lower bound supplied by A. □

Theorem 1471.7 (Regular Cauchy reciprocal nonzero-denominator window)**.** *Any accepted* RegularCauchyReciproc *packet whose dyadic inverse budget is read must expose a nonzero-denominator window consisting of the* RegSeqRat$^{\uparrow}$ *source row Q, apartness row A, finite modulus row M,* StreamName$^{\uparrow}$ *window W, and* DyadicRatCore$^{\uparrow}$ *row D. Without all five rows the packet has not reached the* CauchyInverseBudget$^{\uparrow}$ *row B.*

Proof. Project the carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ from Definition 1471.1. The only source, apartness, modulus, window, and dyadic rows available to the reciprocal budget are Q, A, M, W, D.

Apply Definition 1471.6. It places the positive lower-bound display in A before the dyadic reciprocal row D and budget row B can be consumed.

Then apply Definition 1471.3. The route to the reciprocal readback passes through Q, A, M, W, D, B, so a consumer that omits any one of Q, A, M, W, D remains before the CauchyInverseBudget$^{\uparrow}$ row rather than at the dyadic inverse budget. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalNonzeroDenominatorWindo`

Theorem 1471.8 (Regular Cauchy reciprocal tail stability)**.** *Let $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ be an accepted* RegularCauchyReciprocal$^{\uparrow}$ *carrier. If a later inspected* StreamName$^{\uparrow}$ *window preserves the* RegSeqRat$^{\uparrow}$ *source row Q together with the apartness row A, modulus row M, finite window row W, and dyadic reciprocal row D, then the same reciprocal readback row T and terminal* Real$^{\uparrow}$ *seal row E transport through H, C, P, N. Thus shifting to a later tail window cannot change the reciprocal readback unless it changes one of A, M, W, D.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalTailStability`

Proof. Use Definition 1471.6. A later window that preserves A, M, W, D keeps the same displayed positive lower-bound and dyadic reciprocal data for the inspected regular tail.

Apply Definition 1471.3. Since the route to T passes through Q, A, M, W, D, B, preserving the apartness, window, and dyadic rows preserves the reciprocal readback route once the same budget row is read.

Apply Definition 1471.4. The transport row H compares corresponding carrier rows componentwise, while C, P, N replay, source, and name the same packet. The terminal seal E is therefore transported with T rather than recomputed from a new denominator condition. □

Theorem 1471.9 (Regular Cauchy reciprocal window composition)**.** *Let $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ be an accepted* RegularCauchyReciprocal$^{\uparrow}$ *carrier. Suppose a later finite* StreamName$^{\uparrow}$ *window preserves the displayed rows Q, A, M, W, D and then reads the same* CauchyInverseBudget$^{\uparrow}$ *row B. The composed finite route still reaches the same regular rational readback row T and terminal* Real$^{\uparrow}$ *seal row E through*

$$Q \longmapsto A \longmapsto M \longmapsto W \longmapsto D \longmapsto B \longmapsto T \longmapsto E.$$

Thus window composition changes neither the reciprocal readback nor the Real seal unless it changes one of the displayed source, apartness, modulus, window, dyadic, or budget rows.

Proof. Apply Definition 1471.6. It keeps the apartness row A in front of every dyadic reciprocal and budget read, so the later window cannot compose into a reciprocal route while dropping the positive lower-bound display.

Use Definition 1471.7. The preserved rows Q, A, M, W, D are exactly the nonzero-denominator window needed before the same budget row B can be read.

Apply Definition 1471.3. Once the same budget row is present, the route to T is the displayed chain through Q, A, M, W, D, B, and the seal E is terminal after that chain.

Finally use Definition 1471.8. Since the later window preserves the source, apartness, modulus, window, and dyadic rows and reads the same budget row, the transported packet reaches the same T and E rather than recomputing a new reciprocal surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalWindowComposition`

Theorem 1471.10 (Regular Cauchy reciprocal window denominator stability)**.** *Let $R = (Q, A, M, W, D, B, T, E, H$ be an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier. Suppose a later finite* $\mathsf{StreamName}^{\uparrow}$ *window preserves the displayed rows Q, A, M, W, D and reads the same* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row B. Then the denominator apartness witness recorded by A remains visible before the reciprocal readback row T and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E are consumed. In particular, the later window cannot treat B, T, E as a hidden choice of denominator data.*

Proof. Apply Definition 1471.6. The dyadic reciprocal row D and budget row B are admissible only after A displays the positive lower-bound witness for the inspected regular tail.

Use Definition 1471.7. Since the later window preserves Q, A, M, W, D, it preserves exactly the nonzero-denominator surface that must be present before the same $\mathsf{CauchyInverseBudget}^{\uparrow}$ row is read.

Apply Definition 1471.8. Preserving the source, apartness, modulus, window, and dyadic rows transports the same readback row T and terminal seal row E through the carrier rows H, C, P, N.

Finally use Definition 1471.9. The composed route reaches T and then E only through the displayed chain Q, A, M, W, D, B, T, E, so the denominator apartness witness remains visible throughout the reciprocal handoff rather than becoming hidden choice data. □

Theorem 1471.11 (Regular Cauchy reciprocal located apartness window)**.** *Any* $\mathsf{Real}^{\uparrow}$*-seal or budget-facing consumer of an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ must expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row Q, apartness row A, modulus row M,* $\mathsf{StreamName}^{\uparrow}$ *window row W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row D, and* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *budget row B before reading the reciprocal readback row T or terminal seal row E. The route exports no total reciprocal on arbitrary* $\mathsf{Real}^{\uparrow}$ *names, trichotomy, quotient stream equality, selected limit, or ambient completeness.*

Proof. Project the accepted carrier. The only reciprocal-facing analytic rows before readback are the source, apartness, modulus, window, dyadic comparison, and budget rows Q, A, M, W, D, B.

Apply Definition 1471.2, Definition 1471.6, and Definition 1471.7. These place the located apartness display in A before the dyadic comparison row and identify Q, A, M, W, D as the nonzero-denominator window required before B is read.

Next use Definition 1471.9. It preserves the same route through Q, A, M, W, D, B, T, E under later finite windows, so reading T cannot detach the reciprocal candidate from its displayed denominator witness.

Finally apply Definition 1471.13. The terminal seal E is offered only after the source, apartness, modulus, window, dyadic, budget, and readback rows have been displayed. Since the carrier has no

coordinate for total reciprocals, trichotomy, quotient stream equality, selected limits, or ambient completeness, those principles cannot be exported by either the budget-facing route or the Real-seal route. □

Theorem 1471.12 (Regular Cauchy reciprocal scoped denominator apartness)**.** *For every accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$*, the denominator-apartness witness is scoped exactly by the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* Q*, apartness row* A*, finite modulus row* M*,* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row* B*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}$ *row* N*. It exports no total* $\mathsf{Real}^{\uparrow}$ *reciprocal, quotient stream, selected limit, or host equality.*

Proof. Project the carrier of Definition 1471.1. The only denominator-facing rows before reciprocal readback are Q, A, M, W, D, B, and the only structural rows that can transport or replay them are H, C, P, N.

Apply Definition 1471.2 and Definition 1471.6. These place the apartness row A before every dyadic reciprocal, budget, readback, and seal coordinate, and they make the positive lower-bound display part of carrier admission.

Use Definition 1471.7 and Definition 1471.10. The first theorem identifies Q, A, M, W, D as the nonzero-denominator window required before B is read, while the second preserves that witness under later finite windows.

The remaining rows H, C, P, N carry only componentwise transport, replay, provenance, and local naming for the same finite surface. Thus the scoped apartness witness is exactly the displayed BEDC primitive surface $Q, A, M, W, D, B, H, C, P, N$, with no exported total reciprocal on $\mathsf{Real}^{\uparrow}$, quotient stream, selected limit, or host equality. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.TasteGate.RegularCauchyReciprocalScopedDenominatorApartn`

Theorem 1471.13 (Regular Cauchy reciprocal Real seal handoff)**.** *Let* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier. Any reciprocal consumer that is offered the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *must first be offered the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* Q*, apartness row* A*, modulus row* M*, finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row* B*, and reciprocal readback row* T*. Thus the handoff from finite reciprocal-read data to the L10* $\mathsf{Real}^{\uparrow}$ *boundary is the displayed route*

$$Q \longmapsto A \longmapsto M \longmapsto W \longmapsto D \longmapsto B \longmapsto T \longmapsto E$$

and not a direct operation from arbitrary $\mathsf{Real}^{\uparrow}$ *names to reciprocals.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalRealSealHandoff`

Proof. Apply Definition 1471.2. It places the apartness row A before every reciprocal-facing coordinate, so a consumer cannot treat the terminal seal as available before the denominator witness is displayed.

Next use Definition 1471.3. The route to the readback row T factors through Q, A, M, W, D, B, and the seal row E is terminal only after that finite route has been exposed.

Apply Definition 1471.6 and Definition 1471.7. These identify the source, apartness, modulus, window, and dyadic rows as the nonzero-denominator surface required before the budget row B can be consumed.

Finally use Definition 1471.8 together with Definition 1471.9. Transport to later windows and composition of finite windows preserve the same T and E only when the displayed rows

Q, A, M, W, D, B are preserved. The handoff therefore exports neither a total reciprocal, quotient real equality, trichotomy, selected limit, nor ambient completeness principle; it exports only the finite route from reciprocal readback data to the terminal $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 1471.14 (Regular Cauchy reciprocal NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}$ *surface consists exactly of carrier exposure for* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$*, apartness-window exposure through* A*, finite-window exposure through* W*, dyadic reciprocal arithmetic through* D*, sibling budget exposure through* B*, regular readback through* T*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise transport through* H*, displayed continuation replay through* C*, package provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalNameCertObligations`

Proof. Carrier exposure is Definition 1471.1. It supplies the full row list and states that the classifier reads only those rows.

The analytic route is given by Definition 1471.2 and Definition 1471.3. Together they force every reciprocal read to pass through the source, apartness, modulus, finite window, dyadic arithmetic, and sibling budget rows before reaching T and E.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since none of these rows contains a total reciprocal, quotient stream equality, selected limit, trichotomy decision, or ambient completeness principle, the displayed obligations exhaust the local NameCert surface. □

Theorem 1471.15 (Regular Cauchy reciprocal window-budget coverage)**.** *Every budget-facing read of an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$ *must expose the rows*

$$Q \longmapsto A \longmapsto M \longmapsto W \longmapsto D \longmapsto B$$

in that order before it treats the packet as carrying a reciprocal-window budget.

Proof. Project the carrier of Definition 1471.1. The budget row B is displayed only after the source row Q, apartness row A, modulus row M, finite window row W, and dyadic row D.

Apply Definition 1471.2 and Definition 1471.6. These place the positive lower-bound display before any dyadic or budget read.

Use Definition 1471.7. It identifies Q, A, M, W, D as the nonzero-denominator window required before the $\mathsf{CauchyInverseBudget}^{\uparrow}$ row is reached.

Finally apply Definition 1471.9 and Definition 1471.14. Composed windows preserve the same displayed budget route, and the local NameCert surface contains no alternate budget coordinate. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalWindowBudgetCoverage`

Theorem 1471.16 (Regular Cauchy reciprocal readback-budget exactness)**.** *For every accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier* $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$*, the readback row* T *is exactly the finite reciprocal-read route through the displayed budget row* B*. It is not a total reciprocal operation on arbitrary* $\mathsf{Real}^{\uparrow}$ *names, and it cannot be read without the preceding rows* Q, A, M, W, D, B*.*

Proof. Use Definition 1471.3. It factors T through the displayed chain from Q to B.

Apply Definition 1471.15. Any budget-facing read must first expose Q, A, M, W, D, B, so T has no route that bypasses the finite budget row.

Apply Definition 1471.8 and Definition 1471.9. Later windows and composed windows preserve the same readback only when the displayed source, apartness, modulus, window, dyadic, and budget rows are preserved.

Finally use Definition 1471.5. Since the terminal seal is not a total reciprocal on $\mathsf{Real}^{\uparrow}$, the preceding readback row is also only the finite route named by the carrier. □

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalReadbackBudgetExactness`

Theorem 1471.17 (Regular Cauchy reciprocal seal-route conservativity)**.** *Any* $\mathsf{Real}^{\uparrow}$ *seal consumer of an accepted* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *carrier receives only the displayed route*

$$Q, A, M, W, D, B, T, E, H, C, P, N.$$

The seal row E conservatively packages that route and adds no total reciprocal, trichotomy, quotient stream equality, selected limit, or ambient completeness principle.

Proof. Apply Definition 1471.13. The terminal seal is offered only after the source, apartness, modulus, finite window, dyadic, budget, and readback rows have been displayed.

Use Definition 1471.16. It fixes T as the finite route through B, so the seal cannot detach E from the reciprocal-window budget.

Use Definition 1471.14. The remaining rows H, C, P, N transport, replay, source, and name the same packet, and no additional analytic coordinate exists.

The non-totality clause follows from Definition 1471.5. A $\mathsf{Real}^{\uparrow}$ consumer therefore receives only the displayed conservative route. □

Theorem 1471.18 (Regular Cauchy reciprocal scope dependency lock)**.** *For every accepted* RegularCauchyReciproc *carrier $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$, the reciprocal readback row T and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E are scoped exactly by five L10 source rows: the* $\mathsf{RegSeqRat}^{\uparrow}$ *source Q, the finite* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, the* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row B, and the* $\mathsf{Real}^{\uparrow}$ *seal route E. A consumer that drops any one of these rows remains outside the reciprocal readback and seal surface. The dependency lock exports no total reciprocal, quotient real equality, selected limit, or ambient completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalScopeDependencyLock`

Proof. Begin with Definition 1471.2. It places the apartness row before every reciprocal-facing coordinate, so the route to the five named source rows is not optional.

Next apply Definition 1471.3. The readback row T factors through the displayed chain from the $\mathsf{RegSeqRat}^{\uparrow}$ source to the reciprocal budget row.

Use Definition 1471.15 together with Definition 1471.16. These two theorems identify the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and $\mathsf{CauchyInverseBudget}^{\uparrow}$ row as the finite budget boundary for T.

Finally invoke Definition 1471.17. The $\mathsf{Real}^{\uparrow}$ seal E only packages the same displayed route, and its nonescape clause excludes total reciprocal, quotient equality, selected limits, and ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ consumer that reaches a reciprocal readback row or a $\mathsf{Real}^{\uparrow}$ seal without the displayed $\mathsf{RegSeqRat}^{\uparrow}$ source, apartness row, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and $\mathsf{CauchyInverseBudget}^{\uparrow}$ row refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, cauchyinversebudget, real: no listed sibling supplies the whole twelve-row packet $R = (Q, A, M, W, D, B, T, E, H, C, P, N)$, because each sibling contributes only a regular source, finite window, dyadic ledger, reciprocal budget, or Real seal while this chapter binds all five analytic faces with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source, an apartness-window row, a finite modulus row, a $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, a $\mathsf{CauchyInverseBudget}^{\uparrow}$ budget row, a reciprocal readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1471.1, Definition 1471.2, Definition 1471.3, Definition 1471.4, Definition 1471.5, Definition 1471.14, Definition 1471.15, Definition 1471.16, Definition 1471.17, and Definition 1471.18 make the reciprocal chapter mature on the paper closure axis through the checked dependency lock, denominator-apartness window, $\mathsf{Real}^{\uparrow}$ seal handoff, and window-budget coverage.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocal}^{\uparrow}}, \mathsf{auditClean})$

Lean target: `BEDC.Derived.RegularCauchyReciprocalUp.RegularCauchyReciprocalScopeDependencyLock`

Bridge status: none

Not claimed: This chapter does not claim a total reciprocal, trichotomy, quotient stream equality, selected limits, ambient real completeness, or a public bridge.

Upgrade path: Standard-bridge verification remains a separate formal route; the paper closure axis is mature for the displayed reciprocal dependency lock.

Chapter 1472

CompactLocatedSubcover NameCert Construction

Following Bishop and Bridges, the $\mathsf{CompactLocatedSubcover}^{\uparrow}$ packet records finite located subcover extraction as displayed BEDC data: a finite family of named located balls is already present, each member has a positive radius row, and the certificate extracts the finite bundle and lower-radius ledger read by compact and uniform consumers. The chapter treats the object as a located finite extraction surface, not as open-cover compactness. It sits between the finite-net compact packets of chapter 60 and chapter 129, the finite positive-radius ledger of chapter 452, and the downstream modulus consumer of chapter 369.

Definition 1472.1 (Compact located subcover carrier)**.** *A* $\mathsf{CompactLocatedSubcover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, C, R, U, V, L, H, Q, P, N)$$

with the following displayed rows:

1. *B is a finite* ProbeBundle *spine naming the located cover candidates inspected by the packet;*
2. *C is the center-history ledger assigning to every bundled probe a center* BHist *row readable through the compact or compact-metric source;*
3. *R is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger attached to the bundled candidates;*
4. *U is the positive* $\mathsf{RationalBall}^{\uparrow}$ *radius readback for the same centers and dyadic radii;*
5. *V is the coverage row stating that every compact-source history accepted by the packet is covered by one bundled located ball;*
6. *L is the lower-radius fold over the finite bundle, producing one positive radius ledger below every displayed radius in R and U;*
7. *H records componentwise* hsame *transport for bundle, center, dyadic-radius, rational-ball, coverage, and lower-fold rows;*
8. *Q records the displayed* Cont *routes by which compact, compact-metric, finite-Lebesgue-number, and uniform-modulus consumers inspect the packet;*
9. *P is the* Pkg *provenance over* $\mathsf{CompactLocatedSubcover}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactLocatedSubcover}^{\uparrow}}$ *row.*

The carrier exports only the displayed finite located subcover extraction route. It has no coordinate for an arbitrary open family, an ambient compactness theorem, a selected open-cover subfamily, quotient real equality, countable choice, or an external modulus selector.

Theorem 1472.2 (CompactLocatedSubcover NameCert obligations)**.** *For an accepted* $\mathsf{CompactLocatedSubcover}^{\uparrow}$ *carrier $S = (B, C, R, U, V, L, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactLocatedSubcover}^{\uparrow}}$ *surface consists of five finite rows: carrier admission for the tuple of Definition 1472.1; located-ball source rows over B, C, R, U; coverage rows over V; lower-radius fold rows over L; and downstream transport, replay, provenance, and naming rows over H, Q, P, N.*

These five rows are exactly the finite located extraction packet read by compact and compact-metric consumers. No consumer can replace them by open-cover compactness, a host subcover selector, a hidden radius minimum, or a detached analytic compactness principle.

Proof. Carrier admission fixes the finite packet and the only rows the classifier may inspect. The bundle and center rows are the displayed located candidates, while the dyadic and rational-ball rows give the positive radii attached to those candidates.

The coverage coordinate V is the finite located subcover assertion. It is already indexed by the $\mathsf{ProbeBundle}$ spine B, so a consumer reads a bundled cover row rather than selecting a subfamily from an arbitrary cover.

The fold coordinate L supplies the lower-radius ledger. Since it folds only over the displayed finite bundle and is transported only by H, it cannot read a host minimum or an external choice operator.

Finally the rows Q, P, N replay, source, and name the same packet for compact, compact-metric, finite-Lebesgue-number, and uniform-modulus consumers. Thus the five finite rows are the whole local obligation surface. □

Theorem 1472.3 (CompactLocatedSubcover uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactLocatedSubcover}^{\uparrow}$ *carrier receives the same finite packet*

$$B, C, R, U, V, L, H, Q, P, N.$$

The rows V and L respectively supply the located coverage surface and the positive lower-radius ledger. They hand forward to chapter 452 and chapter 369 as finite BEDC rows, not as open-cover compactness, selected subcover choice, or an external modulus.

Proof. Project the carrier of Definition 1472.1. The compact source contributes only the finite bundle B, center ledger C, dyadic radius ledger R, rational-ball readback U, and coverage row V.

Read the lower-radius fold L over that same finite bundle. The fold provides one positive radius row below the displayed located-ball radii, which is the radius shape expected by finite-Lebesgue-number and uniform-modulus consumers.

Transport the resulting located coverage and radius rows through H, then replay them through Q with provenance and local naming supplied by P and N. Because every downstream read is forced through these rows, the handoff cannot invoke arbitrary open covers, chosen subcovers, host minima, countable choice, or detached real-completion data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactLocatedSubcover}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactLocatedSubcover}^{\uparrow}$ packet is generated from a finite ProbeBundle of located cover candidates, center histories, positive DyadicRatCore and RationalBall radius rows, coverage rows, a finite lower-radius fold, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CompactLocatedSubcover}\uparrow}$, seed)

Scope closed: Definition 1472.1, Definition 1472.2, and Definition 1472.3 bind the finite located subcover extraction packet and its radius handoff to finite-Lebesgue-number and uniform-modulus consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactLocatedSubcover}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary cover selection, host compactness, host minima, quotient real equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-ball coverage rows, positive-radius readback, lower-radius fold exactness, and uniform-consumer handoff for BEDC.Derived.CompactLocatedSubcoverUp.

Chapter 1473

A Concrete Naming Certificate for $\mathsf{UniformCompletion}^{\uparrow}$

Following Kelley, *General Topology*, and Bishop–Bridges constructive completion, the $\mathsf{UniformCompletion}^{\uparrow}$ packet records uniform completion as finite Cauchy-filter and Cauchy-net evidence over BEDC rows, not quotient completion, selected limits, ambient completeness, or choice. The packet threads the filter boundary of chapter 333, the directed witness boundary of chapter 589, the extension surface of chapter 397, the regular rational handoff of chapter 301, and the real readback boundary of chapter 38.

Definition 1473.1 (UniformCompletion carrier)**.** *A* $\mathsf{UniformCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(F, D, U, E, H, C, P, N)$$

with the following visible rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *data row recording the finite filterbase, late-window, and cofinality evidence consumed by completion-facing readers;*
2. *D is the directed* $\mathsf{CauchyNet}^{\uparrow}$ *witness row recording the finite net indices, common-window witnesses, and extracted directed subwindows;*
3. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *universal-extension row for uniformly continuous consumers served by the same F and D rows;*
4. *E is the completion equality classifier row, comparing two packet reads only through the displayed filter, net, and universal-extension coordinates;*
5. *H is the componentwise* hsame *row over F, D, U, E;*
6. *C is the displayed* Cont *route used to replay the Cauchy-filter, directed-net, extension, and classifier rows under finite observation;*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, ambient complete uniform spaces, open-cover compactness, or choice.

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletionTasteGate single carrier alignment`

Theorem 1473.2 (UniformCompletion NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{UniformCompletion}^{\uparrow}}$ *surface of Definition 1473.1 consists of five obligations:*

1. *carrier admission for the displayed packet* (F, D, U, E, H, C, P, N)*;*
2. *Cauchy-filter factorization, requiring every completion-facing consumer to read the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F *before any completion handoff;*
3. *directed-net witness extraction, requiring directed witnesses to be projected from the* $\mathsf{CauchyNet}^{\uparrow}$ *row* D *rather than from a selected limit;*
4. *universal-extension uniqueness, requiring uniformly continuous extension comparisons to pass through the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row* U *and the classifier row* E*;*
5. *ledger non-escape, stating that the packet exports only the rows named in* P *and never a quotient completion, selected representative, ambient complete uniform space, open-cover compactness principle, or choice principle.*

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion namecert obligation surface`

Proof. Carrier admission is projection from the finite tuple (F, D, U, E, H, C, P, N) in Definition 1473.1. Each named coordinate is already a BEDC row, and the local naming row N records that these coordinates are the public $\mathsf{UniformCompletion}^{\uparrow}$ surface.

Cauchy-filter factorization is the obligation that completion-facing reads start with F. Directed-net witness extraction is the parallel obligation that directed witnesses start with D, so neither route can introduce a selected representative or an ambient limit point.

Universal-extension uniqueness is then confined to U and E. The componentwise hsame row H and displayed Cont route C replay these same finite coordinates, while P records that all downstream handoffs stay inside the named Cauchy-filter, Cauchy-net, universal-property, RegSeqRat, and Real rows. □

Theorem 1473.3 (UniformCompletion Cauchy-filter factorization)**.** *For an accepted* $\mathsf{UniformCompletion}^{\uparrow}$ *carrier* (F, D, U, E, H, C, P, N)*, every completion-facing consumer factors through the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F *and the* $\mathsf{CauchyNet}^{\uparrow}$ *witness row* D *before reading any* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension data or* $\mathsf{Real}^{\uparrow}$ *handoff data. Thus the completion boundary is exhausted by* F, D, U, E, H, C, P, N *and exports no quotient completion, selected representative, ambient complete uniform space, open-cover compactness principle, or choice principle.*

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion cauchy filter factorization`

Proof. Project an accepted carrier (F, D, U, E, H, C, P, N). The first completion-facing coordinate is F, so a consumer reaches Cauchy-filter evidence before it can ask for any completion extension or real handoff.

The next witness coordinate is D. Its directed Cauchy-net subwindows provide the directed evidence used by the completion route, and the packet contains no separate selected-limit coordinate from which such witnesses could be read.

Only after F and D have been consumed can the route read the $\mathsf{CompletionUniversalProperty}^{\uparrow}$ row U, the classifier row E, or the $\mathsf{Real}^{\uparrow}$ handoff data named by P. The transport and replay rows H and C preserve this order because they are componentwise rows over the same finite packet. □

Theorem 1473.4 (UniformCompletion directed-net witness extraction)**.** *For an accepted* UniformCompletion$^{\uparrow}$ *carrier* (F, D, U, E, H, C, P, N)*, every directed witness consumed by a completion-facing route is extracted from the displayed* CauchyNet$^{\uparrow}$ *row* D *after the Cauchy-filter row* F *has fixed the request. The witness is therefore a finite directed-net subwindow, not a selected limit, quotient representative, or ambient complete-uniform-space point.*

Proof. Project the carrier rows of Definition 1473.1. The Cauchy-filter row F names the completion request, and the only directed row available to answer it is D.

The existing factorization route of Definition 1473.3 already forces completion-facing consumers to read F and D before extension or Real handoff data. Thus a directed witness is obtained by inspecting the finite subwindow stored in D.

The remaining rows U, E, H, C, P, N transport, replay, source, classify, and name the same packet. Since none of them stores a selected limit, quotient representative, or ambient point, the extracted witness cannot escape the displayed directed-net row. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion directed net witness certificate`

Theorem 1473.5 (UniformCompletion universal-extension uniqueness)**.** *For an accepted* UniformCompletion$^{\uparrow}$ *carrier* (F, D, U, E, H, C, P, N)*, any two displayed extension routes that read the same* RegSeqRat$^{\uparrow}$ *handoff data and the same* Real$^{\uparrow}$ *seal data agree under the classifier row* E*. The comparison passes through the* CompletionUniversalProperty$^{\uparrow}$ *row* U *and the displayed classifier, and it adds no parameter-transport equivalence or host equality of completion objects.*

Proof. Read both extension routes through the same accepted packet. By Definition 1473.3, both routes first consume F and D, so their completion-facing source data are already the displayed Cauchy-filter and directed-net rows.

The universal-extension coordinate is U. When the two routes present the same RegSeqRat and Real seal rows, U supplies the common extension surface attached to those rows, and E is the only classifier coordinate allowed to compare the two reads.

Componentwise transport and replay through H and C preserve the same classifier input, while P and N source and name only the displayed packet. Therefore agreement is a classifier agreement under E, not an added parameter-transport equivalence or host completion equality. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion universal extension uniqueness`

Theorem 1473.6 (UniformCompletion ledger non-escape)**.** *Every* UniformCompletion$^{\uparrow}$ *consumer read factors through the displayed rows*

$$F, D, U, E, H, C, P, N.$$

In particular, the read enters through the Cauchy-filter and Cauchy-net rows, continues through universal-extension and classifier rows, and is preserved by BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *data only. It exports no quotient completion, selected representative, ambient complete uniform space, open-cover compactness principle, or choice principle.*

Proof. Start with a consumer read of the accepted carrier. Projection gives exactly the rows F, D, U, E, H, C, P, N.

The factorization theorem forces the analytic part of the read through F and D before any extension or Real-facing handoff is visible. The directed witness extraction row then remains inside the displayed Cauchy-net evidence.

The rows U and E are the only extension and classifier rows. The structural rows H, C, P, N preserve, replay, source, and name those same coordinates, and the carrier contains no further ledger entry.

Thus every consumer read factors through the displayed BHist, transport, continuation, provenance, and naming rows, and none of the excluded quotient, selection, ambient-completeness, open-cover, or choice data can be exported. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion ledger nonescape`

Theorem 1473.7 (UniformCompletion filter-net obligations)**.** *An accepted* $\mathsf{UniformCompletion}^{\uparrow}$ *carrier exposes exactly the* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows needed for carrier admission and filter-to-net factorization. Carrier admission reads the packet as* (F, D, U, E, H, C, P, N)*, the filter row* F *fixes the completion-facing request, the directed-net row* D *supplies the finite witness route for that request, and the universal, Real, and RegSeqRat rows are readable only after* F *and* D *have been displayed.*

Proof. Project the accepted carrier of Definition 1473.1. The displayed coordinates already list the Cauchy-filter row F, the Cauchy-net row D, the universal-property row U, the classifier row E, and the structural rows H, C, P, N.

The filter-to-net factorization is the local route from F to D. The filter row fixes the finite request and the directed-net row provides the corresponding finite witness, so the construction has no place to read a selected limit or a quotient completion object.

The RegSeqRat and Real handoff data are named in the provenance row P and replayed by C after F, D, U, E have been fixed. Componentwise hsame transport through H preserves the same displayed rows, and the local $\mathsf{NameCert}$ row N admits exactly this packet. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.UniformCompletion filter net obligations`

Theorem 1473.8 (UniformCompletion filter-net exactness)**.** *Every accepted* $\mathsf{UniformCompletion}^{\uparrow}$ *packet routes a completion request through the Cauchy-filter row* F *and then through the Cauchy-net row* D *before any universal-extension or classifier read reaches* U *or* E*. In carrier notation, the only accepted completion-facing order is*

$$F \longmapsto D \longmapsto U, E \longmapsto H, C, P, N.$$

Thus the packet exposes filter data, directed finite witness data, extension comparison, transport, replay, provenance, and local naming, with no bypass through quotient completion, selected representatives, ambient complete uniform spaces, open-cover compactness, or choice.

Proof. Project the accepted carrier (F, D, U, E, H, C, P, N) from Definition 1473.1. The carrier projection gives the only displayed coordinates available to a completion-facing request.

Apply Definition 1473.7. It fixes the filter row F as the request boundary and the directed-net row D as the finite witness route for that request.

The universal and classifier rows are downstream of that boundary. The structural rows H, C, P, N transport, replay, source, and name the same route, so no excluded completion object has a coordinate from which to enter. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion filter net exactness`

Theorem 1473.9 (UniformCompletion directed subwindow extraction)**.** *For every accepted* $\mathsf{UniformCompletion}^{\uparrow}$ *carrier* (F, D, U, E, H, C, P, N)*, each directed witness used by a completion consumer is a finite* $\mathsf{CauchyNet}^{\uparrow}$ *subwindow extracted after the* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F *fixes the request. The extraction route is confined to*

$$F \longmapsto D \longmapsto H, C, P, N,$$

and the universal row U *may read the extracted witness only after this route is displayed.*

Proof. Begin with the finite request fixed by F. By Definition 1473.7, the directed witness is supplied by the row D for that same request, not by an ambient net chosen outside the packet.

Use Definition 1473.4. The witness row is the displayed Cauchy-net evidence available to the packet, so any subwindow extracted for a consumer remains a finite subwindow of D.

The transport, replay, provenance, and naming rows preserve that extracted row. Since U is read only after the filter-net witness is displayed, universal extension cannot introduce a separate directed object. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion directed subwindow extraction`

Theorem 1473.10 (UniformCompletion universal extension scope)**.** *Every extension comparison exported by an accepted* $\mathsf{UniformCompletion}^{\uparrow}$ *carrier is confined to the universal-extension row* U *and the classifier row* E *after the filter-net boundary has been displayed. Equivalently, any such comparison factors as*

$$F, D \longmapsto U, E \longmapsto H, C, P, N,$$

with $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoffs readable only as provenance downstream of that route.*

Proof. First use Definition 1473.8. It places all extension consumers behind the displayed filter row F and directed-net row D.

Next apply Definition 1473.5. The comparison itself is carried by the universal-extension row and read through the classifier row, so the comparison surface is U, E.

Finally use Definition 1473.11. The structural rows preserve the same route, and downstream RegSeqRat or Real handoffs are provenance reads rather than additional universal-extension coordinates. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion extension comparison certificate`

Theorem 1473.11 (UniformCompletion universal ledger non-escape)**.** *Any universal-extension read of an accepted* $\mathsf{UniformCompletion}^{\uparrow}$ *packet factors through the displayed universal-extension uniqueness row and gains no host quotient, selected limit, choice, or ambient completeness coordinate. The only extension comparison route is*

$$F, D \longmapsto U, E \longmapsto H, C, P, N,$$

so a consumer may compare extension reads only through U *and the displayed classifier row* E*.*

Proof. Begin with a universal-extension read. By Definition 1473.3, the read first passes through the Cauchy-filter row F and the directed-net witness row D.

The universal ledger is then U, with comparison confined to the classifier row E. This is exactly the uniqueness route stated in Definition 1473.5.

Finally H and C transport and replay the same finite rows, while P and N source and name the packet. None of those structural rows contains a quotient completion, selected limit, choice principle, or ambient completeness coordinate. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion universal ledger nonescape`

Theorem 1473.12 (UniformCompletion Real-RegSeqRat handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{UniformCompletion}^{\uparrow}$ *packet reads the completion seal through* $\mathsf{RegSeqRat}^{\uparrow}$ *and the displayed Cauchy filter and Cauchy net rows. The consumer route is therefore confined to the finite chain*

$$F, D \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto H, C, P, N$$

named by the carrier provenance, not to a host completed-real object or a selected representative.

Proof. Project the packet and read its provenance row P. The only Real-facing source named there passes through the displayed Cauchy-filter row F, the Cauchy-net row D, the regular rational handoff, and the terminal Real seal.

The already established filter-net obligations force F and D to be consumed before the RegSeqRat and Real rows are public. Thus a Real-facing consumer cannot bypass the finite filter and net witness route.

Transport through H and replay through C are componentwise over the same rows, and N only names that local packet. Consequently the handoff exports no host completed-real object, selected representative, quotient stream, choice principle, or ambient completeness premise. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion real regseqrat handoff`

Theorem 1473.13 (UniformCompletion scope lock)**.** *The* $\mathsf{UniformCompletion}^{\uparrow}$ *filter-net obligations are scoped exactly by the* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F*, the* $\mathsf{CauchyNet}^{\uparrow}$ *row* D*, the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row* U*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff rows named by* P*, and the structural rows* H, C, P, N *for* hsame*,* Cont*,* Pkg*, and* NameCert*. Within that scope there is no quotient completion, selected representative, ambient complete uniform space, open-cover compactness principle, or choice coordinate.*

Proof. Apply Definition 1473.7. It identifies carrier admission and filter-to-net factorization with the finite rows F, D, U, E, H, C, P, N, and it places the RegSeqRat and Real handoff data after the Cauchy-filter and Cauchy-net rows.

Apply Definition 1473.11. The universal-extension comparison route is confined to

$$F, D \longmapsto U, E \longmapsto H, C, P, N.$$

Thus the extension ledger can compare displayed reads only through the universal-property row and the classifier row.

Finally apply Definition 1473.12. The Real-facing route remains a finite RegSeqRat-to-Real handoff named by the provenance row, with transport and replay preserving the same carrier coordinates. The listed quotient, representative-selection, ambient-completeness, compactness, and choice data are outside the carrier and outside every continuation route. □

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion extension scope regseqrat handoff`

Theorem 1473.14 (UniformCompletion bridge-route interface)**.** *Every completion-facing read of an accepted* $\mathsf{UniformCompletion}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{UniformSpace}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{CauchyNet}^{\uparrow}$*,* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows named by the carrier and its provenance route. The bridge route therefore exposes only finite entourage*

requests, Cauchy-filter data, directed-net witnesses, universal-extension comparison, stream windows, regular rational readback, Real handoff data, componentwise transport, displayed continuation, provenance, and local naming. It exports no quotient completion, selected representative, ambient complete uniform space, open-cover compactness principle, or choice principle.

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion bridge route`

Proof. Begin with the accepted carrier of Definition 1473.1. The completion-facing route first reads the Cauchy-filter row F and the directed-net witness row D, and these rows are interpreted over the displayed uniform-space entourage surface named by the surrounding completion route.

The extension comparison then passes through U and E. The stream, regular rational, and Real-facing handoff rows are reachable only through the provenance route already used by Definition 1473.12, so the read cannot bypass the displayed finite rows.

Finally H, C, P, N transport, replay, source, and name the same route. Since none of these coordinates stores a quotient completion, selected representative, ambient complete uniform space, open-cover compactness principle, or choice principle, the bridge-route interface is exhausted by the stated rows. □

Theorem 1473.15 (UniformCompletion public factorization)**.** *Every public* $\mathsf{UniformCompletion}^{\uparrow}$ *consumer factors through the same finite completion route: the* $\mathsf{CauchyFilter}^{\uparrow}$ *evidence row* F*, the* $\mathsf{CauchyNet}^{\uparrow}$ *witness row* D*, the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row* U*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row named by provenance, the* $\mathsf{Real}^{\uparrow}$ *seal, the supporting* BHist *packet, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The public route exports no quotient completion equality, no selected representative, no countable-choice schedule, no host equality of completed objects, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.UniformCompletionUp.TasteGate.UniformCompletion public factorization`

Proof. Start with the public consumer and apply Definition 1473.3. The consumer first reaches the Cauchy-filter row F and the directed-net row D, before any extension or real handoff data is visible.

Next apply Definition 1473.4 and Definition 1473.5. The directed evidence is extracted from D, while extension comparisons pass through U and the classifier row E rather than through a selected limit or host equality.

Now use Definition 1473.12. Real-facing reads pass through the $\mathsf{RegSeqRat}^{\uparrow}$ handoff and the $\mathsf{Real}^{\uparrow}$ seal after the filter and net rows have fixed the completion-facing source data.

Finally apply Definition 1473.13. The structural rows H, C, P, N supply the BHist support, componentwise hsame transport, Cont replay, provenance, and local naming for exactly that route, while the quotient, representative-selection, choice, host-equality, and ambient-completeness coordinates remain outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletion}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 1473.1, Definition 1473.2, Definition 1473.3, Definition 1473.4, Definition 1473.5, Definition 1473.6, Definition 1473.7, Definition 1473.11, Definition 1473.12, Definition 1473.13, Definition 1473.15, and Definition 1473.14 close the mature paper package: local obligation surface, scoped filter-net boundary, and paper bridge route for carrier admission, filter-net factorization, directed-net witness extraction, universal-extension uniqueness, Real-RegSeqRat handoff, and ledger non-escape.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close quotient completions, selected representatives, ambient complete uniform spaces, open-cover compactness, or choice principles.

Upgrade path: The remaining work is formal-axis alignment of the mature paper package with a canonical Lean target and bridge-ready TasteGate surface for BEDC.Derived.UniformCompletionUp.

Constructive story: The construction starts from displayed Cauchy-filter and directed Cauchy-net rows, then routes finite completion consumers through CompletionUniversalProperty, RegSeqRat, and Real handoff data without adding quotient or choice principles.

Chapter 1474

A Concrete Naming Certificate for $\mathsf{CalkinWilfEnumeration}^{\uparrow}$

Following Calkin and Wilf, the $\mathsf{CalkinWilfEnumeration}^{\uparrow}$ packet records the positive-rational enumeration surface generated by the binary tree rule $a/b \mapsto a/(a+b)$ and $a/b \mapsto (a+b)/b$ as finite BEDC naming data. Its dependency lattice starts from the unary source of chapter 28, the rational carrier of chapter 37, the rational-stream interface of chapter 350, the finite schedule surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It is the breadth-first positive-rational sibling of the continued-fraction route in chapter 342 and the Stern–Brocot approximation route in chapter 1431. The packet is not quotient rational equality, not an ambient host enumeration, not an arbitrary choice of representatives, and not $\mathsf{Real}^{\uparrow}$ completeness.

Definition 1474.1 (Calkin-Wilf enumeration carrier)**.** *A* $\mathsf{CalkinWilfEnumeration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (U, Q, T, B, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the unary* $\mathsf{Nat}^{\uparrow}$ *address row naming the finite breadth-first tree position.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *numerator-denominator row exposed at that address, with both coordinates positive unary histories.*
3. *T is the local tree-step row recording whether the next finite edge is left, $a/b \mapsto a/(a+b)$, or right, $a/b \mapsto (a+b)/b$.*
4. *B is the breadth-first schedule row ordering finite addresses before they are read as a stream.*
5. *S is the* $\mathsf{RationalStream}^{\uparrow}$ *output row whose U-indexed finite window is filled by the displayed Q, T, B data.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when the enumeration is consumed as a rational source for Cauchy-style real-name packets.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *handoff row, exposed only as a downstream consumer of the rational stream and regular readback rows.*
8. *H stores componentwise* hsame *transport for U, Q, T, B, S, R, E.*
9. *C stores displayed* Cont *replay for opening an address, computing its tree edge, filling the stream window, and passing the selected rational row to regular-rational and real-name consumers.*

10. *P is the* Pkg *provenance over* $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CalkinWilfEnumeration}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient rational equality, host-side enumeration of all rationals, choice-selected representatives, signed-rational coverage, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 1474.2 (Calkin-Wilf enumeration NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CalkinWilfEnumeration}^{\uparrow}}$ *surface for Definition 1474.1 consists of five finite obligation rows:*

1. *carrier admission for the displayed packet $W = (U, Q, T, B, S, R, E, H, C, P, N)$;*
2. *tree-step exactness, requiring every exposed child rational to be obtained from its parent by the displayed left or right Calkin-Wilf rule;*
3. *breadth-first stream discipline, requiring stream windows to read the finite address order in B before exposing the corresponding Q row;*
4. *regular-rational handoff, requiring every* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumer to pass through S and R before the real-name seal E is public;*
5. *non-escape, stating that quotient rational equality, ambient host enumeration, arbitrary representative choice, signed-rational coverage, and* $\mathsf{Real}^{\uparrow}$ *completeness are absent from the packet.*

Proof. Carrier admission is projection from the finite tuple $W = (U, Q, T, B, S, R, E, H, C, P, N)$. Each coordinate is a displayed BEDC row, and the local naming row N records that exactly these coordinates form the public $\mathsf{CalkinWilfEnumeration}^{\uparrow}$ surface.

Tree-step exactness is local to T. A left edge replaces a/b by $a/(a+b)$, while a right edge replaces a/b by $(a+b)/b$; both operations stay inside positive unary numerator-denominator data and therefore feed the same $\mathsf{Rat}^{\uparrow}$ row format.

Breadth-first stream discipline is supplied by B and S. The schedule row orders finite addresses before they are exposed as rational-stream windows, so the stream cannot be read as a host enumeration detached from the displayed tree.

Finally, R and E give the downstream handoff. Componentwise transport, continuation replay, provenance, and local naming are exactly H, C, P, N, so no additional quotient equality, representative selector, signed-rational cover, or ambient completeness coordinate remains available. □

Theorem 1474.3 (Calkin-Wilf positive-rational coverage)**.** *For every accepted* $\mathsf{CalkinWilfEnumeration}^{\uparrow}$ *carrier, the public stream row S covers the positive* $\mathsf{Rat}^{\uparrow}$ *rows generated from $1/1$ by finite Calkin-Wilf left and right edges, and every public coverage read factors through the displayed address, tree-step, breadth-first schedule, transport, continuation, provenance, and local naming rows. The coverage claim is only for the generated positive numerator-denominator surface; it does not identify quotient-equal rational presentations, choose representatives in a host enumeration, cover signed rationals, or assert completeness of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier and start from the root rational $1/1$ in the Q row. A finite address in U is read by repeated use of the displayed tree-step row T, so every addressed output remains a positive rational presentation.

The breadth-first row B then orders these addressed presentations before they enter the rational-stream row S. Thus a coverage read of S is a read of finite Calkin-Wilf address data, not a read of an external list of host rationals.

The statement is intentionally presentation-level. Since the packet has no quotient rational equality coordinate and no selector for preferred host representatives, it covers exactly the positive generated surface available through $U, Q, T, B, S, H, C, P, N$. □

Theorem 1474.4 (Calkin-Wilf Real completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CalkinWilfEnumeration}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{RationalStream}^{\uparrow}$ *row* S *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *before the handoff row* E *can be exposed. Consequently the enumeration can feed L10 rational streams and regular Cauchy real-name readback without exporting quotient rational equality, an ambient host enumeration, arbitrary choice of representatives, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a real-facing consumer request data from an accepted carrier. The only stream coordinate in the packet is S, so the consumer first sees a finite window of positive rational presentations generated by the Calkin-Wilf tree and ordered by B.

The next completion-facing coordinate is R. It is the regular-rational readback row attached to the same stream window, and it is the only row that connects the enumeration surface to the regular Cauchy route.

Only after S and R have been consumed can E expose a real-name handoff. The structural rows H, C, P, N replay and name this same finite path, so the consumer receives a rational-stream source for L10 completion work without obtaining quotient equality, host enumeration data, arbitrary representatives, or a completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CalkinWilfEnumeration}^{\uparrow}}$.

Constructive story: A $\mathsf{CalkinWilfEnumeration}^{\uparrow}$ packet is generated from unary breadth-first addresses, positive rational numerator-denominator rows, displayed Calkin-Wilf tree steps, a rational-stream window, regular-rational readback, a real-name handoff row, componentwise transport, continuation replay, provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CalkinWilfEnumeration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1474.1, Definition 1474.2, Definition 1474.3, and Definition 1474.4 seed the finite positive-rational enumeration packet feeding RationalStream, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CalkinWilfEnumeration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not claim quotient rational equality, ambient host enumeration, arbitrary choice of representatives, signed-rational coverage, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, tree-step exactness, breadth-first stream discipline, regular-rational handoff, and non-escape for the same finite Calkin-Wilf packet.

Chapter 1475

A Concrete Naming Certificate for $\mathsf{CantorSpace}^{\uparrow}$

Following Brouwer and Bishop–Bridges constructive analysis, the $\mathsf{CantorSpace}^{\uparrow}$ packet records the traditional Boolean sequence space as finite prefix data over the L10 countable-name substrate. It consumes the two-endpoint discipline of chapter 32, the finite window schedule of chapter 126, and the finite-data spine discipline of chapter 36. The carrier is a displayed BHist packet of $\mathsf{Bool}^{\uparrow}$ observations over unary $\mathsf{StreamName}^{\uparrow}$ windows; it is not a quotient of infinite streams, a host function space $\mathsf{Nat}^{\uparrow} \to \mathsf{Bool}^{\uparrow}$, a completed infinite product, a choice-selected branch, or an open-cover compactness theorem.

Definition 1475.1 (CantorSpace carrier)**.** *A* $\mathsf{CantorSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, W, B, L, E, H, K, P, N)$$

with the following visible rows:

1. *S is the unary* $\mathsf{StreamName}^{\uparrow}$ *schedule row whose entries are the finite positions currently requested by the consumer;*
2. *W is the finite prefix-window row, recording the initial segment and any explicitly named subwindow inside that segment;*
3. *B is the* $\mathsf{Bool}^{\uparrow}$ *observation ledger, assigning displayed Boolean rows to the positions of W;*
4. *L is the* $\mathsf{List}^{\uparrow}$ *prefix-spine row that keeps the observed Boolean entries as finite ordered data;*
5. *E is the endpoint-exclusion row saying that every public bit is read through the* $\mathsf{Bool}^{\uparrow}$ *two-row surface rather than through a hidden host Boolean;*
6. *H is the componentwise* hsame *transport row for S, W, B, L, E;*
7. *K is the displayed* Cont *replay row for already accepted prefix windows and Boolean rows;*
8. *P is the* Pkg *provenance over* $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorSpace}^{\uparrow}}$ *row.*

The carrier contains no quotient stream, no host-level function equality, no completed infinite product, no branch chosen by countable choice, and no compactness principle.

Definition 1475.2 (CantorSpace classifier)**.** *Two accepted* $\mathsf{CantorSpace}^{\uparrow}$ *carriers*

$$C = (S, W, B, L, E, H, K, P, N) \quad \textit{and} \quad C' = (S', W', B', L', E', H', K', P', N')$$

are classified as the same at the local surface exactly when their $\mathsf{StreamName}^{\uparrow}$ *schedules request the same finite prefix window and the* $\mathsf{Bool}^{\uparrow}$ *observations agree componentwise on that common window. The comparison is mediated by the* $\mathsf{List}^{\uparrow}$ *spine rows, transported by* H, H'*, and replayed only through* K, K'*. No classifier clause compares host functions, quotient streams, or all infinite coordinates at once.*

Theorem 1475.3 (CantorSpace NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{CantorSpace}^{\uparrow}}$ *surface of Definition 1475.1 consists of five finite obligations:*

1. *carrier admission for the displayed packet* $C = (S, W, B, L, E, H, K, P, N)$*;*
2. *classifier transport for common finite-prefix* $\mathsf{Bool}^{\uparrow}$ *equality under the same* $\mathsf{StreamName}^{\uparrow}$ *schedule;*
3. *prefix stability, requiring every shorter requested window inside* W *to reuse the matching visible Boolean rows already recorded in* B *and* L*;*
4. *continuation compatibility, requiring every replayed read to pass through* H, K, P, N *before it reaches a downstream L10 consumer;*
5. *non-escape, excluding quotient streams, host function equality, completed infinite products, choice-selected branches, and compactness claims.*

Lean4 ✓ `BEDC.Derived.CantorSpaceUp.CantorSpaceCarrier namecert obligation surface`

Proof. Carrier admission is projection of the nine displayed coordinates in Definition 1475.1. The schedule, prefix window, Boolean ledger, and list spine rows are finite BHist data.

Classifier transport uses Definition 1475.2. Once the common $\mathsf{StreamName}^{\uparrow}$ window is fixed, equality is read only as componentwise $\mathsf{Bool}^{\uparrow}$ agreement along the displayed $\mathsf{List}^{\uparrow}$ spine and is then transported by H.

Prefix stability follows because a shorter requested window is a subrow of the same displayed prefix row W. Its Boolean entries are already present in B and in the ordered spine L, so Cont may replay them without adding an infinite stream coordinate.

The non-escape clause is inspection of the carrier and classifier. The packet has rows for finite schedules, finite Boolean observations, transport, continuation, provenance, and the local $\mathsf{NameCert}$ row, and has no coordinate for quotient streams, host functions, infinite products, selected branches, or compactness witnesses. □

Theorem 1475.4 (CantorSpace binary-prefix obligations)**.** *For every accepted* $\mathsf{CantorSpace}^{\uparrow}$ *carrier* $C = (S, W, B, L, E, H, K, P, N)$*, the binary-prefix obligation surface exposes exactly finite* $\mathsf{Bool}^{\uparrow}$ *digit rows,* $\mathsf{List}^{\uparrow}$ *prefix rows,* $\mathsf{StreamName}^{\uparrow}$ *observation windows,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CantorSpace}^{\uparrow}}$ *row. Every finite prefix read by a downstream consumer factors through those displayed rows before the consumer can inspect a cylinder, endpoint, or classifier comparison. The obligation surface contains no quotient-stream equality, choice principle, or host infinite binary sequence.*

Proof. Proceed by finite prefix induction over the displayed $\mathsf{List}^{\uparrow}$ spine.

In the empty-prefix case, the consumer reads only the schedule row S, the empty prefix window inside W, the empty ordered prefix in L, and the structural rows H, K, P, N. No Boolean digit, quotient stream, or host sequence coordinate is available.

For the cons step, assume the shorter prefix read factors through S, W, B, L, H, K, P, N. The next digit is supplied by the corresponding finite $\mathsf{Bool}^{\uparrow}$ row in B at the next position named by S and ordered by L.

Transport by H and replay by K preserve the shorter read and the next digit as one displayed packet. Provenance P and local naming N then present the extended prefix to the downstream consumer.

Thus every finite binary prefix is generated by repeated inspection of the displayed Boolean and list rows. Since the carrier has no quotient stream, choice operator, or host infinite binary sequence coordinate, none can enter the prefix obligation surface. □

Theorem 1475.5 (CantorSpace finite-prefix cylinder stability)**.** *Let $C = (S, W, B, L, E, H, K, P, N)$ be an accepted $\mathsf{CantorSpace}^{\uparrow}$ carrier. Any finite cylinder read determined by a prefix subwindow of W factors through the same $\mathsf{StreamName}^{\uparrow}$ schedule row S, the same $\mathsf{Bool}^{\uparrow}$ observation ledger B, the same $\mathsf{List}^{\uparrow}$ spine L, and the same H, K, P, N transport, continuation, provenance, and local naming rows. The cylinder read exports no extra infinite tail, no quotient-stream equality, no host function extensionality, and no compactness argument.*

Lean4 ✓ `BEDC.Derived.CantorSpaceUp.CantorSpaceCarrier finite prefix cylinder stability`

Proof. Choose a prefix subwindow of W. Since W is a finite row of the accepted carrier, the requested positions are already part of the displayed $\mathsf{StreamName}^{\uparrow}$ schedule S.

The Boolean values on that subwindow are precisely the corresponding entries of B, ordered by the finite $\mathsf{List}^{\uparrow}$ spine L. Transport by H preserves the componentwise rows, and Cont replay through K reuses only those rows.

Thus every cylinder read is exhausted by S, W, B, L, H, K, P, N. The excluded objects are not coordinates of the carrier, so the read cannot produce an infinite tail, quotient equality, host-function extensionality, or compactness data. □

Theorem 1475.6 (CantorSpace prefix projection stability)**.** *Let $K = (S, W, B, L, E, H, K_0, P, N)$ be an accepted $\mathsf{CantorSpace}^{\uparrow}$ carrier. Any restriction of a public read to a shorter finite prefix is again a read through the displayed rows $S, W, B, L, E, H, K_0, P, N$: the schedule row S and window row W choose the visible positions, the $\mathsf{Bool}^{\uparrow}$ row B supplies endpoint values, and the $\mathsf{List}^{\uparrow}$ spine L records the prefix order. The projection contains no host infinite stream, no quotient equality of functions, no branch choice, and no compactness principle.*

Proof. Start with the accepted carrier and project its finite prefix spine. The shorter prefix is obtained by reading an initial segment of L and the corresponding entries of S and W.

For each retained position, the endpoint value is still read from B. Componentwise transport by H and replay through K_0 preserve only the retained rows, while P and N keep the same provenance and local certificate.

Thus prefix projection is closed inside the displayed carrier. Since no coordinate names an infinite stream, a quotient-function equality, a branch selector, or compactness data, none of those objects can appear in the projected read. □

Lean4 ✓ `BEDC.Derived.CantorSpaceUp.CantorSpaceCarrier prefix projection stability`

Theorem 1475.7 (CantorSpace prefix cylinder no-confusion)**.** *Let $K = (S, W, B, L, E, H, K_0, P, N)$ and $K' = (S', W', B', L', E', H', K'_0, P', N')$ be accepted* $\mathsf{CantorSpace}^{\uparrow}$ *carriers whose finite cylinder reads are projected to the same certified unary index window. If the displayed* $\mathsf{List}^{\uparrow}$ *prefix readbacks first disagree at a certified unary index i and the corresponding* $\mathsf{Bool}^{\uparrow}$ *rows in B and B' have separated tags at i, then the two* $\mathsf{StreamName}^{\uparrow}$ *carrier reads are not classifier-equal on that finite window. The conclusion is only the finite-window failure of classifier equality for the displayed prefixes; it is not an inequality of ambient infinite sequences.*

Proof. Project both carrier reads to the common finite window using Definition 1475.6. The projected data are exactly the visible schedule rows, the two finite $\mathsf{List}^{\uparrow}$ prefix spines, and the corresponding $\mathsf{Bool}^{\uparrow}$ ledger entries.

At the first certified unary index i where the prefix readbacks disagree, $\mathsf{List}^{\uparrow}$ readback identifies the two compared positions as the same finite slot. The separated $\mathsf{Bool}^{\uparrow}$ tags at that slot cannot be transported into the same componentwise observation row.

StreamName pointwise classifier stability therefore blocks equality on the projected window: any classifier equality for the two carrier reads would have to identify the two Boolean rows at i. This contradicts the displayed tag separation, so no classifier-equality certificate exists on the finite window. □

Theorem 1475.8 (CantorSpace Bool cylinder endpoint determinacy)**.** *For an accepted* $\mathsf{CantorSpace}^{\uparrow}$ *carrier $K = (S, W, B, L, E, H, K_0, P, N)$, each cylinder endpoint visible to a downstream consumer is determined by the finite* $\mathsf{Bool}^{\uparrow}$ *ledger B along the positions ordered by L. If two consumer reads inspect the same prefix coordinates through S, W, L and transport by the same H, K_0, P, N rows, then their endpoint rows agree exactly as displayed by B; no endpoint is chosen from an ambient infinite product.*

Lean4 ✓ `BEDC.Derived.CantorSpaceUp.CantorSpaceCarrier bool cylinder endpoint determinacy`

Proof. Read the shared prefix coordinates from S, W, L. These rows specify which positions are visible and in which finite order they are consumed.

The endpoint value at each visible position is then the corresponding row of B. If two reads use the same visible coordinates and the same transport and replay data, they reach the same finite Bool ledger entries.

The structural rows H, K_0, P, N preserve this ledger route. There is no carrier coordinate for an infinite product endpoint, a choice-selected branch, or a host stream function, so endpoint determinacy is the finite determinacy of B over L. □

Theorem 1475.9 (CantorSpace StreamName prefix consumer exhaustion)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{List}^{\uparrow}$ *consumer of an accepted* $\mathsf{CantorSpace}^{\uparrow}$ *carrier factors through the finite rows $S, W, B, L, E, H, K_0, P, N$. The consumer may restrict, transport, and replay a displayed prefix cylinder, but after the rows $S, W, B, L, E, H, K_0, P, N$ are exhausted it has no further route to an infinite stream tail, a quotient of branches, a fan-theorem compactness object, or countable-choice data.*

Proof. Project the consumer read through the $\mathsf{StreamName}^{\uparrow}$ rows S, W and the $\mathsf{List}^{\uparrow}$ row L. These rows are the only coordinates that expose positions and prefix order.

The Bool observations are then consumed through B, with any endpoint and cylinder data carried by E. Transport and continuation replay remain componentwise through H and K_0.

Once P and N record provenance and local naming, every carrier coordinate has been inspected. The consumer is therefore exhausted by the displayed finite packet and cannot continue to an unlisted stream tail, quotient branch, compactness object, or choice schedule. □

Lean4 ✓ `BEDC.Derived.CantorSpaceUp.CantorSpaceCarrier streamname prefix consumer exhaustion`

Theorem 1475.10 (CantorSpace StreamName-Bool scope)**.** *Every public read exported by an accepted* $\mathsf{CantorSpace}^{\uparrow}$ *carrier reaches the L10 countable-name substrate only through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{Bool}^{\uparrow},\ \mathsf{List}^{\uparrow},\ \mathsf{NameCert}_{\mathsf{CantorSpace}^{\uparrow}}.$$

The route binds the schedule, Boolean endpoint rows, finite prefix spine, and local certificate before any downstream consumer may inspect the packet. It does not claim Real completeness, quotient stream completeness, open-cover compactness, fan-theorem compactness, or choice of an infinite branch.

Lean4 ✓ `BEDC.Derived.CantorSpaceUp.CantorSpaceStreamNameBoolScope`

Proof. Project a public consumer read from the accepted carrier. The requested positions are first visible in the $\mathsf{StreamName}^{\uparrow}$ schedule row S and prefix row W.

Each visible value is then read through the $\mathsf{Bool}^{\uparrow}$ ledger B and ordered by the $\mathsf{List}^{\uparrow}$ spine L. The rows H and K only transport and replay that finite data, while P and N record the provenance and local certificate.

Therefore the public route is exactly the displayed finite route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, and $\mathsf{NameCert}_{\mathsf{CantorSpace}^{\uparrow}}$. No coordinate in the packet supplies Real completeness, stream quotient completeness, open-cover compactness, fan-theorem compactness, or a choice-selected infinite branch. □

Theorem 1475.11 (CantorSpace choice refusal)**.** *Let* $K = (S, W, B, L, E, H, K_0, P, N)$ *be an accepted* $\mathsf{CantorSpace}^{\uparrow}$ *carrier. Every public finite-prefix read through the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, *and* $\mathsf{List}^{\uparrow}$ *surfaces cited in chapter 126, chapter 32, and chapter 36 is already determined by the displayed rows* $S, W, B, L, E, H, K_0, P, N$*. The read cannot import a selector for an infinite branch, a countable-choice schedule, host function extensionality, or a fan-theorem compactness witness.*

Proof. Project the accepted carrier to its nine displayed rows. The schedule row S, prefix window W, Boolean ledger B, and list spine L are the only rows that expose prefix positions and endpoint values.

Restrict the public read to the requested finite window. Transport by H and replay through K_0 preserve exactly those displayed rows, while P and N record the provenance and local name.

Since no carrier coordinate names an infinite branch selector, a countable-choice schedule, host function equality, or a fan-theorem object, the read has no route to any such datum. The refusal is therefore a carrier projection followed by prefix restriction. □

Theorem 1475.12 (CantorSpace cylinder coverage)**.** *For an accepted* $\mathsf{CantorSpace}^{\uparrow}$ *carrier* $K = (S, W, B, L, E, H, K_0, P, N)$*, every finite cylinder visible to a downstream consumer is covered by the displayed prefix rows* $S, W, B, L, E, H, K_0, P, N$*. The* $\mathsf{StreamName}^{\uparrow}$ *row chooses the requested positions, the* $\mathsf{Bool}^{\uparrow}$ *row supplies the endpoint entries, and the* $\mathsf{List}^{\uparrow}$ *row orders the finite prefix; no cylinder read requires an ambient product space or an open-cover compactness argument.*

Proof. Begin with a finite cylinder read. Carrier projection supplies the schedule S, the prefix window W, the Boolean ledger B, and the ordered spine L as the visible cylinder data.

Now restrict to the cylinder subwindow. The retained positions are still rows of S and W, and their endpoint values are still the corresponding entries of B ordered by L.

The remaining rows E, H, K_0, P, N record endpoint exclusion, componentwise transport, continuation replay, provenance, and local naming. Thus the cylinder is covered inside the displayed finite packet and does not appeal to an ambient infinite product or to open-cover compactness. □

Theorem 1475.13 (CantorSpace prefix-window composition)**.** *Let $K = (S, W, B, L, E, H, K_0, P, N)$ be an accepted* $\mathsf{CantorSpace}^{\uparrow}$ *carrier. If a public read first restricts to a finite prefix subwindow and then restricts again to a shorter subwindow, the composite read is the same finite* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{Bool}^{\uparrow}$–$\mathsf{List}^{\uparrow}$ *read obtained by restricting S, W, B, L once to the shorter window and carrying the same E, H, K_0, P, N rows. The composition exports no additional stream tail, quotient branch, or Real completion datum.*

Proof. Project the carrier to $S, W, B, L, E, H, K_0, P, N$. The first prefix restriction keeps a subrow of the schedule and window rows and the corresponding Boolean entries ordered by the list spine.

Apply the second prefix restriction to that finite subrow. Because both restrictions are prefix restrictions of the same displayed window, the result is exactly the shorter subrow of S, W, B, L.

Transport and replay remain the original componentwise rows H and K_0, and the same provenance and local naming rows P, N certify the composite read. The composition therefore stays within finite prefix data and cannot expose an extra stream tail, quotient branch, or Real completion witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorSpace}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorSpace}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1475.1, Definition 1475.2, Definition 1475.3, Definition 1475.5, Definition 1475.6, Definition 1475.8, Definition 1475.9, and Definition 1475.10 supply the finite-prefix obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorSpace}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.CantorSpaceUp.CantorSpaceCarrier\_namecert\_obligation\_surface`

Bridge status: paperBridge

Not claimed: The chapter does not close quotient streams, host function equality, completed infinite products, Real completeness, choice-selected branches, open-cover compactness, fan-theorem compactness, or Lean bridge checking.

Upgrade path: No further paper-side closure step remains; machine bridge checking is the remaining formal-axis route.

Constructive story: The construction starts from finite unary StreamName windows, records Bool observations along a List prefix spine, and exposes only displayed hsame, Cont, Pkg, and local NameCert rows to downstream L10 consumers.

Chapter 1476

A Concrete Naming Certificate for $\mathsf{CauchyCompletionCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ packet names the finite criterion that licenses admission of a regular Cauchy route into the Real completion seal. It sits between the finite stream windows of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, the completion-modulus route of chapter 1469, and the terminal Real seal of chapter 38. The certificate is a finite admission surface for Real completion consumers, not a quotient stream, a selected host limit, or an ambient completeness principle.

Definition 1476.1 (Cauchy completion criterion carrier)**.** *A* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule through which every sequence read is windowed.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy handoff read from the displayed stream windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the rational thresholds, comparison rows, and dyadic scale used by the handoff.*
4. *M is the* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *row that sends each precision request to a displayed finite threshold for the same windows and tolerances.*
5. *Q is the local finite admission criterion, asserting that the stream windows, regular handoff, dyadic ledger, and modulus row are mutually compatible before any Real-facing seal is read.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-admission row reached only after S, R, D, M, Q have been displayed.*
7. *H stores componentwise* hsame *transport for the stream schedule, regular handoff, dyadic ledger, modulus row, criterion row, seal row, continuation, provenance, and local naming.*
8. *C stores displayed* Cont *replay from finite stream windows to the regular handoff, from the handoff through the dyadic and modulus ledgers to the criterion row, and from the criterion row to the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BishopCompletionModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten rows. It contains no coordinate for quotient streams, selected host limits, countable choice, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyCompletionCriterionUp.CauchyCompletionCriterionTasteGate single carrier alignment`

Theorem 1476.2 (Cauchy completion criterion NameCert obligations)**.** *For every accepted* CauchyCompletionCrite *carrier* $K = (S, R, D, M, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionCriterion}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the displayed ten-row packet;*
2. *finite-window handoff, stating that* R *is read only through the* $\mathsf{StreamName}^{\uparrow}$ *schedule* S *and the stored continuation rows;*
3. *tolerance-modulus compatibility, stating that* D *and* M *use the same displayed thresholds, dyadic scales, and precision requests for the regular rational handoff;*
4. *criterion admission, stating that* Q *is the sole local row that licenses passage from* S, R, D, M *to a Real-facing completion read;*
5. *Real seal non-escape, stating that* E *exports no quotient streams, selected host limits, countable-choice row, host real equality, or ambient completeness witness.*

Proof. Project the carrier of Definition 1476.1. The stream schedule, regular handoff, dyadic ledger, completion modulus, criterion row, Real seal, transport, continuation, provenance, and local naming rows are exactly the classifier-visible coordinates.

The finite-window handoff is forced by the source rows. A consumer can read the regular rational handoff R only after it has read the displayed stream schedule S and the continuation routes that replay the relevant finite windows.

The tolerance and modulus faces are tied to the same requests. The dyadic ledger D records the comparison and scale data, while the Bishop completion modulus row M records the threshold chosen for each precision request; both are consumed before the criterion row Q is available.

The criterion row is the only admission point to the seal. Since the carrier has no coordinate for quotient streams, selected host limits, countable choice, host real equality, or ambient completeness, the five listed obligations exhaust the local NameCert surface. □

Theorem 1476.3 (Cauchy completion criterion Real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier* $K = (S, R, D, M, Q, E, H, C, P, N)$ *factors through the displayed route*

$$S \longmapsto R \longmapsto D, M \longmapsto Q \longmapsto E$$

together with the stored hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N*. The consumer receives no quotient stream, selected host limit, countable-choice row, host real equality, or ambient completeness principle.*

Proof. Begin with a Real-facing consumer and project the accepted carrier. The only sequence data available to the consumer is the finite schedule S together with the regular rational handoff R read from that schedule.

Next read the threshold data. The dyadic ledger D and Bishop completion modulus row M supply the displayed tolerance and threshold information used by the handoff; the continuation row C replays this same route without adding a second source of convergence data.

The admission row Q is then the sole bridge from the regular Cauchy data to the seal row E. The transport and provenance rows H and P preserve the same ten-row packet, and the local naming row N records that no additional coordinate has been admitted.

Thus every Real-facing read factors through $S, R, D, M, Q, E, H, C, P, N$. The forbidden outputs are absent by inspection of the carrier, so the consumer cannot obtain quotient streams, selected host limits, countable choice, host real equality, or ambient completeness from this certificate. □

Theorem 1476.4 (Cauchy completion criterion finite-window handoff)**.** *For every accepted* CauchyCompletionCrite *carrier $K = (S, R, D, M, Q, E, H, C, P, N)$, each read of the regular rational row R factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule S and the continuation replay stored in C. No consumer of R can bypass S by reading a hidden stream tail, a selected subsequence, a countable-choice schedule, or an ambient host sequence object.*

Proof. Project the carrier row of Definition 1476.1. The only sequence-facing coordinate is the finite schedule S, and the only regular-rational coordinate is the handoff row R.

The replay row C records the allowed continuation from the displayed finite windows to R. Since the classifier compares accepted carriers through the ten displayed rows, any use of R must preserve the same S-indexed route under the componentwise transport row H and the provenance row P.

There is no carrier coordinate for a hidden tail, selected subsequence, countable-choice schedule, or host sequence object. Thus every R read factors through S and C, and no bypass is available inside the local certificate. □

Theorem 1476.5 (Cauchy completion criterion tolerance-modulus compatibility)**.** *For every accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier $K = (S, R, D, M, Q, E, H, C, P, N)$, the dyadic tolerance ledger D and the Bishop completion modulus row M answer the same precision request for the same finite stream windows and regular rational handoff. The dyadic threshold route consumed by D is the threshold route selected by M before the criterion row Q is visible.*

Proof. Read D and M from the displayed packet. By definition of the carrier, D records the rational thresholds, comparison rows, and dyadic scale used by the handoff, while M sends each precision request to a displayed finite threshold for the same windows and tolerances.

The rows are consumed before Q. The continuation replay C supplies one route from the windows and handoff through the dyadic and modulus ledgers to the criterion row, and the componentwise transport row H keeps that route stable under accepted carrier comparison.

Consequently the two rows cannot answer different requests or use different threshold routes inside this certificate. A consumer reaching Q has already consumed the shared request, the same finite windows, the same regular rational handoff, and the same dyadic threshold route. □

Theorem 1476.6 (Cauchy completion criterion admission)**.** *For every accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier $K = (S, R, D, M, Q, E, H, C, P, N)$, the row Q is the sole local admission row from the displayed data S, R, D, M to the Real seal row E. Any* $\mathsf{Real}^{\uparrow}$*-facing read that reaches E must pass through Q after the finite-window handoff and tolerance-modulus compatibility rows have been consumed.*

Proof. Project the carrier and isolate the route to the seal. The displayed sequence schedule S, regular handoff R, dyadic ledger D, and modulus row M are upstream of the criterion row Q, while the Real seal row E is downstream of Q.

The continuation row C records this order as a replay route, and the provenance row P records it as part of the local package. The transport row H preserves the same row order under accepted carrier comparison, so a consumer cannot replace Q by another local admission coordinate.

The carrier has no second admission row between S, R, D, M and E. Therefore Q is the sole local admission row, and every Real-facing read of E passes through Q after the finite-window and tolerance-modulus obligations have been met. □

Theorem 1476.7 (Cauchy completion criterion regular-tail induction)**.** *Every accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier routes a tail-refinement request by induction over the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows before exposing the* $\mathsf{RegSeqRat}^{\uparrow}$ *row and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The induction consumes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, local* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ $\mathsf{NameCert}$ *row, componentwise* hsame *transport,* Cont *replay, and* Pkg *provenance, and exports no quotient stream, selected limit, host equality, or ambient completeness.*

Proof. Project the accepted carrier $K = (S, R, D, M, Q, E, H, C, P, N)$ from Definition 1476.1. The only tail schedule available to a refinement request is the finite $\mathsf{StreamName}^{\uparrow}$ window row S, and the regular rational readback R is not visible before that schedule is traversed.

Induct over the finite visible tail-window schedule. At each window, use the dyadic tolerance ledger D and the modulus row M to keep the requested threshold inside the displayed packet, then use the continuation row C to replay the same route without adding a second convergence source.

The existing NameCert obligations provide carrier admission and regular-rational visibility for the handoff through R. The local row N, transport row H, and provenance row P preserve the same displayed packet during the induction.

Finally apply the Real seal non-escape result of Definition 1476.3. The terminal seal E is read only after the displayed induction route has reached Q, so the exported surface contains no quotient stream, selected limit, host equality, or ambient completeness. □

Theorem 1476.8 (Cauchy completion criterion tail-modulus criterion)**.** *Every accepted* $\mathsf{CauchyCompletionCriterion}$ *carrier routes a precision request through the same* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *row, criterion row, and* $\mathsf{Real}^{\uparrow}$ *seal before any completion consumer reads it. The route is the displayed finite path*

$$S \longmapsto R \longmapsto D, M \longmapsto Q \longmapsto E$$

together with the stored hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row; it exports no quotient stream, selected host limit, host real equality, countable choice, or ambient completeness principle.*

Proof. Project the accepted carrier $K = (S, R, D, M, Q, E, H, C, P, N)$ from Definition 1476.1. The precision request first reaches the finite stream schedule S, and the regular rational handoff R is readable only as the displayed readback from those windows.

Use the NameCert obligations of Definition 1476.2. They identify tolerance-modulus compatibility as a local obligation of the same packet: the dyadic ledger D and Bishop completion modulus row M must answer the same threshold and precision data before the criterion row Q can admit a completion read.

Apply regular-tail induction from Definition 1476.7. Tail refinement stays inside the same StreamName schedule and reuses the same dyadic tolerance ledger, regular handoff, transport, continuation replay, provenance, and local naming rows.

Finally apply Real seal non-escape from Definition 1476.3. Since the terminal seal E is visible only after S, R, D, M, Q have been traversed, a completion consumer cannot read quotient streams,

selected host limits, host real equality, countable choice, or ambient completeness from the packet. □

Theorem 1476.9 (Cauchy completion criterion window exhaustion)**.** *Every accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier routes any completion-facing request through the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule* S *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *before the dyadic ledger* D*, modulus row* M*, criterion row* Q*, and* $\mathsf{Real}^{\uparrow}$ *seal* E *are visible. Thus a completion consumer receives only the displayed finite-window route* $S, R, D, M, Q, E, H, C, P, N$*, not a hidden stream tail, selected host limit, quotient equality, countable-choice schedule, or ambient completeness principle.*

Proof. Project the accepted carrier $K = (S, R, D, M, Q, E, H, C, P, N)$ and read the NameCert obligations of Definition 1476.2. Carrier admission exposes exactly the ten displayed rows, while the finite-window handoff obligation places S before every read of the regular rational handoff R.

Apply the tail-modulus criterion of Definition 1476.8. The dyadic ledger D and modulus row M answer the same precision request after the displayed windows and readback have been consumed, and the criterion row Q is available only after that finite route has been traversed.

Finally use Real seal non-escape from Definition 1476.3. Since the seal row E exports no quotient stream, selected host limit, host equality, countable choice, or ambient completeness witness, exhaustion of the displayed windows is the only completion-facing route available inside the certificate. □

Theorem 1476.10 (Cauchy completion criterion cofinal-window induction)**.** *Let* $K = (S, R, D, M, Q, E, H, C, P, N$ *be an accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier. Any cofinal refinement of a completion-facing precision request must reuse the same finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*,* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *row* M*, criterion row* Q*,* $\mathsf{Real}^{\uparrow}$ *seal* E*, and structural rows* H, C, P, N*. The induction is over displayed finite windows only; it cannot introduce a second stream source, selected limit, quotient equality, countable-choice schedule, or ambient completeness principle.*

Proof. Project the carrier of Definition 1476.1. The cofinal request has access only to $S, R, D, M, Q, E, H, C, P, N$, so its base window is already one of the displayed StreamName windows.

Apply finite-window handoff from Definition 1476.4. Each refinement step reaches R through the same schedule S and cannot switch to a second stream source.

Use regular-tail induction from Definition 1476.7. The induction step preserves the same dyadic ledger, regular readback, transport, continuation replay, provenance, and local naming rows.

Apply the tail-modulus criterion of Definition 1476.8 and window exhaustion of Definition 1476.9. The route through D, M, Q remains attached to the finite window schedule at every cofinal stage.

Finally close by Real seal non-escape from Definition 1476.3. The seal row E exports no selected limit, quotient equality, countable-choice schedule, or ambient completeness witness, so the induction remains carrier-local. □

Theorem 1476.11 (Cauchy completion criterion scoped source exhaustion)**.** *Every scoped consumer of an accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *row, criterion row* Q*,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. Within this scoped surface, no second completion source, hidden stream tail, selected limit, quotient equality, countable-choice schedule, host real equality, or ambient completeness principle is exposed.*

Proof. Project the accepted carrier $K = (S, R, D, M, Q, E, H, C, P, N)$ from Definition 1476.1. The carrier inventory names the finite window source S, regular handoff R, dyadic tolerance ledger D, completion modulus M, criterion row Q, Real seal E, transport H, replay C, provenance P, and local name N as the whole scoped packet.

Apply the finite-window handoff of Definition 1476.4 and tolerance-modulus compatibility of Definition 1476.5. These force every regular read through S and keep D and M attached to the same displayed precision route.

Apply criterion admission from Definition 1476.6, regular-tail induction from Definition 1476.7, and the tail-modulus criterion from Definition 1476.8. The only completion-facing route then passes from the finite windows through the regular handoff, dyadic ledger, modulus row, and Q.

Finally use window exhaustion from Definition 1476.9 and Real seal non-escape from Definition 1476.3. The structural rows H, C, P, N preserve the same route without adding data, so the scoped consumer has no second completion source outside the displayed packet. □

Theorem 1476.12 (Cauchy completion criterion scoped route)**.** *Let $K = (S, R, D, M, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier. Any downstream completion consumer,* $\mathsf{Real}^{\uparrow}$ *consumer, or regular-Cauchy consumer of K must reuse exactly the finite-window handoff, tolerance-modulus compatibility, criterion admission, and Real seal non-escape rows named in this chapter. Such a consumer cannot introduce a second completion source, quotient stream, selected limit, countable-choice schedule, or ambient completeness principle.*

Consequently the scoped route for K is the displayed BEDC kernel path through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BishopCompletionModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

Proof. Project the accepted carrier and read the NameCert obligations of Definition 1476.2. The carrier row exposes exactly $S, R, D, M, Q, E, H, C, P, N$, and the obligation surface names the finite-window handoff, tolerance-modulus compatibility, criterion admission, and Real seal boundary as the rows a completion-facing consumer may use.

Apply the finite-window handoff of Definition 1476.4. A downstream consumer reaches the regular rational handoff R only through the displayed $\mathsf{StreamName}^{\uparrow}$ schedule S and the stored continuation replay, so no second stream source or hidden tail can be read.

Next apply tolerance-modulus compatibility from Definition 1476.5 and criterion admission from Definition 1476.6. The dyadic ledger D and modulus row M answer the same precision route before Q is visible, and Q is the sole local admission row from S, R, D, M to the seal row E.

Use regular-tail induction from Definition 1476.7 and the tail-modulus criterion of Definition 1476.8. These results keep tail refinement and precision routing inside the same finite window schedule, regular handoff, dyadic tolerance ledger, completion modulus row, transport, continuation replay, provenance, and local naming row.

Finally apply window exhaustion from Definition 1476.9 and Real seal non-escape from Definition 1476.3. The only terminal route is the displayed BEDC kernel path through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BishopCompletionModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$, and the forbidden completion sources are absent from the carrier. □

Theorem 1476.13 (Cauchy completion criterion public export)**.** *Every accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier $K = (S, R, D, M, Q, E, H, C, P, N)$ exports exactly the public completion-object surface $S, R, D, M, Q, E, H, C, P, N$ to* $\mathsf{Real}^{\uparrow}$*-facing consumers. It exports no quotient stream, selected host limit, countable-choice row, ambient completeness principle, or bridge certificate.*

Proof. Start with the NameCert obligations of Definition 1476.2. They identify carrier admission, finite-window handoff, tolerance-modulus compatibility, criterion admission, and Real seal non-escape as the whole local obligation surface for the ten-row packet.

Apply the finite-window handoff of Definition 1476.4, tolerance-modulus compatibility of Definition 1476.5, and criterion admission of Definition 1476.6. These results force every completion-facing read to traverse S, R, D, M, Q before the seal row is visible.

Use regular-tail induction from Definition 1476.7, the tail-modulus criterion from Definition 1476.8, and window exhaustion from Definition 1476.9. The public route is therefore the displayed finite completion path, with H, C, P, N preserving the same packet by transport, replay, provenance, and local naming.

Finally apply scoped source exhaustion from Definition 1476.11, the downstream scoped route of Definition 1476.12, and Real seal non-escape from Definition 1476.3. The carrier has no coordinate for quotient streams, selected host limits, countable-choice rows, ambient completeness, or bridge certificates, so exactly $S, R, D, M, Q, E, H, C, P, N$ is exported. □

Theorem 1476.14 (Cauchy completion criterion mature consumer route)**.** *Every mature Real or Completion consumer of an accepted* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *carrier*

$$K = (S, R, D, M, Q, E, H, C, P, N)$$

factors through the finite-window handoff, tolerance-modulus compatibility, criterion admission, Real seal non-escape, scoped consumer route, downstream consumer route, and public object surface of this chapter. The consumer receives no quotient stream, selected host limit, countable choice, host equality, ambient completeness, or bridge credential.

Proof. Start with finite-window handoff, Definition 1476.4. It forces every mature consumer to reach the regular rational handoff R through the displayed $\mathsf{StreamName}^{\uparrow}$ schedule S and the stored continuation replay.

Next apply tolerance-modulus compatibility and criterion admission, Definition 1476.5 and Definition 1476.6. These route the dyadic ledger D and completion modulus row M through the same precision request before the criterion row Q admits a Real-facing seal read.

Use Real seal non-escape from Definition 1476.3. The seal row E is downstream of S, R, D, M, Q and cannot export quotient streams, selected host limits, countable choice, host equality, or ambient completeness.

Finally compose scoped source exhaustion, the downstream scoped route, and public export: Definition 1476.11, Definition 1476.12, and Definition 1476.13. These keep H, C, P, N attached to the same packet and expose exactly the public object surface $S, R, D, M, Q, E, H, C, P, N$, with no bridge credential added. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ packet is generated from a finite StreamName schedule, RegSeqRat handoff, DyadicRatCore tolerance ledger, BishopCompletionModulus row, local completion-admission criterion, RealUp seal row, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionCriterion}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 1476.1, Definition 1476.2, Definition 1476.3, Definition 1476.4, Definition 1476.5, Definition 1476.6, Definition 1476.7, Definition 1476.8, Definition 1476.9, Definition 1476.11, Definition 1476.12, Definition 1476.13, and Definition 1476.14 declare the finite carrier, its NameCert obligation surface, the Real seal boundary, the finite-window handoff, the tolerance-modulus compatibility route, the unique criterion admission row, the tail route, the window exhaustion route, scoped source exhaustion, the downstream scoped consumer lock, the public completion-object export, the mature consumer route, and the checked TasteGate carrier-alignment route cited below.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionCriterion}^{\uparrow}}$, auditClean)

Lean target: `BEDC.Derived.CauchyCompletionCriterionUp.CauchyCompletionCriterionTasteGate\_single\_carrier\_alignm`
Bridge status: none
Not claimed: This chapter does not claim quotient stream equality, selected host limits, countable choice, host real equality, ambient completeness, or bridge checking.
Upgrade path: Bridged closure requires an explicit standard bridge for the public completion criterion.

Chapter 1477

A Concrete Naming Certificate for $\mathsf{DyadicMax}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicMax}^{\uparrow}$ packet records the finite dyadic-grid maximum certificate used when the Real and Completion route must choose the larger endpoint before exposing an interval, radius, or tolerance ledger. It sits over the endpoint rows of chapter 291, the adjacent-grid surface of chapter 433, the lower-grid route of chapter 1416, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a constructive finite comparison surface; it is not trichotomy for arbitrary reals, a quotient-real maximum, a host order decision, ambient completeness, or a selected supremum.

Definition 1477.1 (DyadicMax carrier)**.** *A* $\mathsf{DyadicMax}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (x, y, n, m, L, U, H, C, P, N)$$

with the following displayed rows:

1. *x and y are* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows at the shared precision n.*
2. *n is the grid precision row that both endpoint ledgers cite.*
3. *m is the selected endpoint row, displayed as either the transported x row or the transported y row on the same grid.*
4. *L is the finite comparison ledger recording the inspected dyadic inequality that justifies the selected endpoint.*
5. *U is the upper-bound ledger witnessing that both x and y read below or at the selected endpoint m on the displayed grid.*
6. *H records componentwise* hsame *transports for the two endpoint rows, precision row, selected endpoint, comparison ledger, and upper-bound ledger.*
7. *C records displayed* Cont *replay for opening the shared grid, reading the two endpoints, selecting m, exposing L, and exposing U.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicMax}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicRounding}^{\uparrow}$, $\mathsf{DyadicFloor}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicMax}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for order trichotomy on arbitrary reals, quotient-real equality, a host maximum function, ambient completeness, or an unbounded supremum argument.

Lean4 ✓ `BEDC.Derived.DyadicMaxUp.DyadicMaxTasteGate single carrier alignment`

Theorem 1477.2 (DyadicMax NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMax}^{\uparrow}$ *carrier* $M = (x, y, n, m, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicMax}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier exposure for the displayed ten-row packet;*
2. *classifier stability under componentwise* hsame *transport and displayed* Cont *replay of* x, y, n, m, L, U*;*
3. *selected endpoint determinacy, stating that* m *is one of the two displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows at precision* n*;*
4. *upper-bound ledger exactness, requiring the two endpoint-bound reads to be precisely the rows stored in* U *and justified by* L*;*
5. $\mathsf{Real}^{\uparrow}$*-facing non-escape, requiring every real or completion consumer to read the maximum through the displayed dyadic, rounding, floor, absolute-value, transport, continuation, package, and local naming rows.*

No further obligation can be read from the carrier.

Proof. Carrier exposure is projection from Definition 1477.1. The two dyadic endpoint rows, shared precision row, selected endpoint, comparison ledger, upper-bound ledger, transport, replay, provenance, and local name are explicit coordinates of M.

Classifier stability is componentwise. The rows H and C transport and replay exactly the displayed endpoint, precision, selection, comparison, and bound data, so the selected endpoint cannot detach from the grid on which it was certified.

Determinacy and upper-bound exactness are finite ledger reads. The selected row m is named as one of the two endpoint rows, while L records the inspected comparison and U records both upper-bound checks at the same precision.

Finally inspect the carrier inventory. Since no coordinate stores arbitrary real trichotomy, quotient equality, a host maximum, completeness, or a supremum argument, every $\mathsf{Real}^{\uparrow}$ or completion-facing consumer receives only the displayed finite route. □

Theorem 1477.3 (DyadicMax grid boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{DyadicMax}^{\uparrow}$ *carrier reads the maximum only through the rows*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{DyadicRounding}^{\uparrow},\quad \mathsf{DyadicFloor}^{\uparrow},\quad \mathsf{DyadicAbsoluteValue}^{\uparrow},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

In particular, the consumer can read the selected endpoint m*, the comparison ledger* L*, and the upper-bound ledger* U*, but it cannot read a host maximum operation, quotient-real comparison, trichotomy branch for arbitrary reals, ambient completeness witness, or selected supremum.*

Proof. Start from an accepted carrier $M = (x, y, n, m, L, U, H, C, P, N)$. The endpoint rows x and y are already $\mathsf{DyadicRatCore}^{\uparrow}$ rows at the shared precision n, and the selected row m is displayed on that same grid.

The comparison route is finite. The ledger L records the inspected dyadic comparison, and U records the two upper-bound checks used by the downstream route. The rounding, floor, and

absolute-value sibling surfaces supply only grid normalization and tolerance interpretation around those same rows.

Transport and replay add no analytic choice data. The rows H and C carry the displayed grid data componentwise, while P and N provide provenance and local naming for the same route.

Thus any Real or Completion consumer reaches the maximum through the listed finite rows. The carrier has no remaining coordinate from which a host maximum, quotient-real comparison, trichotomy branch, completeness witness, or selected supremum could be exported. □

Falsifiable prediction: An accepted $\mathsf{DyadicMax}^{\uparrow}$ consumer that exposes a $\mathsf{Real}^{\uparrow}$ or completion-facing maximum without reading the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, selected endpoint, comparison ledger, upper-bound ledger, and structural rows refutes the carrier surface.

Independence witness: dyadicratcore, dyadicrounding, dyadicfloor, dyadicabsolutevalue, real: no listed sibling supplies the whole ten-row packet $M = (x, y, n, m, L, U, H, C, P, N)$, because each sibling contributes only endpoint, grid-normalization, lower-grid, absolute-value, or seal-facing rows while this chapter binds the selected maximum endpoint to comparison, upper-bound, transport, replay, provenance, and local naming data.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMax}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicMax}^{\uparrow}$ packet is generated from two $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows at a shared precision, a selected endpoint row, a finite comparison ledger, an upper-bound ledger, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMax}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1477.1, Definition 1477.2, and Definition 1477.3 seed the finite dyadic-grid maximum boundary for Real and Completion consumers over DyadicRatCore, DyadicRounding, DyadicFloor, DyadicAbsoluteValue, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMax}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary real trichotomy, quotient-real maximum, host order decision, ambient completeness, selected supremum, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove carrier exposure, classifier stability, selected endpoint determinacy, upper-bound ledger exactness, and the Real-facing finite-grid boundary.

Chapter 1478

A Concrete Naming Certificate for $\mathsf{CauchyCondensationTest}^{\uparrow}$

Following Cauchy's condensation test, the $\mathsf{CauchyCondensationTest}^{\uparrow}$ packet records the finite dyadic-block comparison certificate for a monotone nonnegative series tail before any Real-facing consumer is allowed to read a completion seal. It consumes the partial-sum and tail-budget surfaces of chapter 121 and chapter 367, the dyadic scale rows of chapter 291, the regular rational handoff of chapter 301, the seal boundary of chapter 38, and the comparison-test route of chapter 1459. The packet is a constructive block-comparison surface; it is not a quotient of series, a selected infinite sum, countable choice, trichotomy on arbitrary terms, RealUp completeness, or host real equality.

Definition 1478.1 (Cauchy condensation test carrier)**.** *A* $\mathsf{CauchyCondensationTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, I, D, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the nonnegative monotone* $\mathsf{Series}^{\uparrow}$ *source row whose displayed summand observations are read through finite prefixes.*
2. *B is the dyadic block index ledger, recording the inspected powers of two, block endpoints, and the finite windows on which the monotone tail is evaluated.*
3. *I is the condensed block term row, displaying the term $2^n a_{2^n}$ as a row over the same dyadic index ledger.*
4. *D is the dyadic block domination ledger, asserting that each inspected block of the original tail is bounded above and below by the displayed condensed block term rows in the monotone direction required by the test.*
5. *M is the comparison-test budget row, packaging the finite tolerance requests, dyadic thresholds, and comparison-test calls consumed by the downstream route.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the displayed block ledger and comparison budget.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row attached to the regular rational handoff.*
8. *H records componentwise* hsame *transports for the series source, dyadic index ledger, condensed block terms, domination ledger, comparison budget, regular handoff, real seal, continuation, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from each finite tail request through B, I, D, M to the regular rational handoff R and the seal row E.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensationTest}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for quotient series equality, a selected sum, countable choice, trichotomy outside the inspected dyadic ledger, host real equality, or RealUp completeness.

Lean4 ✓ `BEDC.Derived.CauchyCondensationTestUp.CauchyCondensationTestTasteGate single carrier alignment`

Theorem 1478.2 (Cauchy condensation test NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCondensationTest}^{\uparrow}$ *carrier $K = (A, B, I, D, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationTest}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed eleven-row packet;*
2. *nonnegative monotone source exposure for A through finite* $\mathsf{Series}^{\uparrow}$ *summand and partial-sum rows;*
3. *dyadic block index readback for B through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale ledger;*
4. *condensed block term formation for I on the same displayed dyadic indices;*
5. *block domination compatibility for D, stating that monotonicity turns each inspected original tail block into the corresponding finite comparison against I;*
6. *comparison-budget routing for M into the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *and* $\mathsf{FastConvergentSeries}^{\uparrow}$ *surfaces;*
7. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal exposure for R and E;*
8. *transport stability, continuation replay, provenance, and local naming for exactly the route recorded by H, C, P, N.*

These obligations are finite-row obligations over the sibling surfaces named in the chapter introduction.

Proof. Project the carrier $K = (A, B, I, D, M, R, E, H, C, P, N)$. The projection exposes exactly the monotone nonnegative series source, dyadic index ledger, condensed block terms, domination ledger, comparison budget, regular handoff, real seal, transport rows, continuation replay, provenance, and local naming row.

For a displayed tail request, read the dyadic index ledger B. The ledger selects finitely many dyadic blocks, and the condensed row I records the corresponding block terms on those same indices.

Monotonicity is used only inside the displayed domination ledger D. Each inspected original tail block is compared with the condensed block row by finite endpoint reads, so the comparison budget M receives a block comparison rather than a hidden infinite tail argument.

Finally apply the structural rows. The hsame rows in H preserve the source, block, domination, budget, handoff, and seal data componentwise, while C, P, N only replay, source, and name the displayed route. No omitted coordinate remains from which an additional NameCert obligation could be read. □

Theorem 1478.3 (Cauchy condensation test dyadic-block handoff)**.** *Every accepted* $\mathsf{CauchyCondensationTest}^{\uparrow}$ *carrier sends a monotone nonnegative tail to the comparison-test route only through the finite dyadic-block handoff*

$$A, B, I \longmapsto D, M \longmapsto R, E, H, C, P, N.$$

Thus a downstream consumer can read the condensed comparison only after it has read the displayed dyadic block indices, the condensed block term rows, the finite block domination ledger, and the comparison-test budget.

Proof. Begin with an accepted carrier and fix a displayed precision or tail request. The dyadic ledger B supplies the finite block endpoints, and the condensed row I supplies the block term associated with each endpoint.

Read the monotone source row A only on those displayed endpoints. The domination ledger D binds the finite collection of original tail terms to the condensed block row, using monotonicity as a finite block comparison.

The comparison budget M then packages the resulting block estimates for the sibling comparison-test surface. Since M receives only the displayed rows A, B, I, D, the handoff cannot bypass the dyadic block ledger.

Transport and replay preserve the same route. The hsame rows in H carry the dyadic indices, condensed block terms, domination rows, and comparison budget together, while C, P, N attach the displayed route to the regular handoff and local certificate. This gives the announced finite dyadic-block handoff. □

Theorem 1478.4 (Cauchy condensation test Real-seal boundary)**.** *For every accepted* $\mathsf{CauchyCondensationTest}^{\uparrow}$ *carrier, any* $\mathsf{Real}^{\uparrow}$ *seal-facing read factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R produced from the dyadic-block comparison route. The seal row E receives the series source, dyadic ledger, condensed block terms, domination ledger, comparison budget, componentwise transports, continuation replay, provenance, and local naming rows, but it receives no quotient series equality, selected sum, countable choice, trichotomy premise, host real equality, or RealUp completeness theorem.*

Proof. Project the seal-facing coordinates R and E from the accepted carrier. The row R is downstream of the comparison budget M, which is itself downstream of the dyadic block ledger and domination rows.

Apply the dyadic-block handoff theorem. It shows that any comparison route reaching R has already passed through the finite rows A, B, I, D, M and through the displayed transport and replay rows attached to the same carrier.

Now read the seal row E. Its only input from the analytic route is the regular rational handoff R, together with the structural rows H, C, P, N. Since the carrier has no coordinate for quotient equality, selected sums, countable choice, trichotomy outside the inspected ledger, host real equality, or RealUp completeness, none of those objects can be exported by the seal-facing read. □

Falsifiable prediction: An accepted $\mathsf{CauchyCondensationTest}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the displayed dyadic block ledger, condensed block term rows, domination ledger, comparison budget, and $\mathsf{RegSeqRat}^{\uparrow}$ handoff refutes the carrier surface.

Independence witness: series, fastconvergentseries, dyadicratcore, regseqrat, real, regular-cauchy-comparison-test: no listed sibling supplies the whole eleven-row packet $K = (A, B, I, D, M, R, E, H, C, P, N)$, because each sibling contributes only a source, tail-budget, dyadic-scale, regular-handoff, seal, or comparison face while this chapter binds all six analytic faces with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationTest}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCondensationTest}^{\uparrow}$ packet is generated from a nonnegative monotone series source, a dyadic block index ledger, condensed block term rows, finite block domination rows, a comparison-test budget, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1478.1, Definition 1478.2, Definition 1478.3, and Definition 1478.4 seed the finite dyadic-block comparison boundary over $\mathsf{Series}^{\uparrow}$, $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient series equality, selected sums, countable choice, trichotomy, host real equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove the finite NameCert obligation surface, dyadic-block handoff theorem, and Real-seal boundary theorem.

Chapter 1479

A Concrete Naming Certificate for $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ packet records the finite integer-bracketing step used before decimal and real-approximation consumers may read an integer part. It sits over the dyadic floor surface of chapter 1416, the ordered-field comparison surface of chapter 1419, the decimal-prefix route of chapter 1417, the integer and natural-number rows of chapter 31 and chapter 28, the rational source rows of chapter 37, and the real-name routes of chapter 38 and chapter 1454. The packet is a finite bracketing certificate; it is not a host floor operation, an integer trichotomy principle, quotient real equality, a selected representative, countable choice, or an ambient completeness theorem.

Definition 1479.1 (ArchimedeanIntegerPart carrier)**.** *An* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, A, D, Z, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *or regular-Cauchy read of the requested real name, exposed only through the routes of chapter 38 and chapter 1454.*
2. *A is the* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ *evidence row that supplies the ordered-field comparison route over the displayed real endpoint.*
3. *D is the* $\mathsf{DyadicFloor}^{\uparrow}$ *scale row that binds the request to a finite dyadic lower grid point and its displayed dyadic successor.*
4. *Z is the* $\mathsf{Int}^{\uparrow}$ *integer candidate row, sourced through the* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*, and sign data required to read it as an integer bracket endpoint.*
5. *S is the successor bracket row, recording the displayed integer successor of Z and the two comparisons $Z \leq R$ and $R < S$ through the rows A, D.*
6. *H records componentwise* hsame *transports for the real read, Archimedean ordered-field evidence, dyadic floor scale, integer candidate, successor bracket, continuation, provenance, and local naming rows.*
7. *C records the displayed* Cont *replay that sends each finite precision or decimal-prefix request through R, A, D, Z, S without adding another search coordinate.*

8. *P is the* Pkg *provenance over* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ArchimedeanOrderedField}^{\uparrow}$, $\mathsf{DyadicFloor}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanIntegerPart}^{\uparrow}}$ *row.*

The carrier has no coordinate for host floor, trichotomy over arbitrary real names, quotient real equality, a selected representative of a real, countable choice, or ambient completeness.

Definition 1479.2 (ArchimedeanIntegerPart classifier)**.** *The local* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *classifier accepts exactly those carrier rows $K = (R, A, D, Z, S, H, C, P, N)$ for which R exposes the displayed real or regular-Cauchy read, A supplies the Archimedean ordered-field comparison evidence for that read, D supplies the finite dyadic floor scale used to locate an integer bracket, Z is the integer candidate read through the displayed* $\mathsf{Int}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, *and* $\mathsf{Rat}^{\uparrow}$ *rows, and S records the successor bracket with lower and upper comparisons transported through A and D. The structural rows H, C, P, N preserve and name the same route componentwise. They do not add an ambient floor operator, a second integer search, or a quotient-real comparison.*

Theorem 1479.3 (ArchimedeanIntegerPart NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{ArchimedeanIntegerPart}^{\uparrow}}$ *surface for Definition 1479.1 consists exactly of the following obligations:*

1. *carrier admission for the displayed nine-row packet $K = (R, A, D, Z, S, H, C, P, N)$;*
2. *classifier exposure from Definition 1479.2;*
3. *real-read exposure through the* $\mathsf{Real}^{\uparrow}$ *or regular-Cauchy rows in R;*
4. *Archimedean ordered-field comparison exposure through A;*
5. *finite dyadic floor-scale exposure through D;*
6. *integer-candidate exposure through Z, with its* $\mathsf{Int}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, *and* $\mathsf{Rat}^{\uparrow}$ *source rows displayed;*
7. *successor-bracket exposure through S, binding $Z \leq R < S$ to the same comparison rows;*
8. *transport stability, continuation replay, provenance, and local naming through exactly H, C, P, N.*

No other analytic, order-theoretic, or choice-theoretic obligation is part of the local certificate.

Proof. Project the accepted packet $K = (R, A, D, Z, S, H, C, P, N)$. The projection exposes exactly the real read, Archimedean ordered-field row, dyadic floor scale, integer candidate, successor bracket, transport row, continuation replay, provenance, and local naming row.

The classifier supplies the only admissible comparison route. It reads the real data through R, the ordered-field comparison through A, the finite dyadic location through D, and the integer endpoint through Z before the successor bracket row S can be formed.

The integer candidate is therefore not selected by a host floor operation. Its source is the displayed $\mathsf{Int}^{\uparrow}$ row, with the necessary $\mathsf{Nat}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ rows already present in the carrier provenance, and the two bracket inequalities are replayed through the same finite comparison rows.

Finally inspect the structural coordinates. The transports in H are componentwise, C only replays the displayed route, and P, N only source and name that route. Since the carrier contains no further coordinate, the listed clauses exhaust the local $\mathsf{NameCert}_{\mathsf{ArchimedeanIntegerPart}^{\uparrow}}$ surface. □

Theorem 1479.4 (ArchimedeanIntegerPart bracket route)**.** *Every accepted* $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ *packet exposes its integer-bracketing read through the finite route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{ArchimedeanOrderedField}^{\uparrow},\ \mathsf{DyadicFloor}^{\uparrow},\ \mathsf{Int}^{\uparrow},\ \mathsf{Nat}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{DecimalExpansion}^{\uparrow}.$$

Concretely, a decimal-expansion or $\mathsf{Real}^{\uparrow}$ *approximation consumer first reads the displayed real or regular-Cauchy row* R*, then the Archimedean comparison row* A*, then the dyadic floor scale row* D*, then the integer candidate row* Z*, and only then the successor bracket row* S*.*

Proof. Start from an accepted carrier and a downstream precision or decimal-prefix request. The continuation row C routes that request to the displayed real read R, so the consumer begins with a $\mathsf{Real}^{\uparrow}$ or regular-Cauchy surface rather than a detached host real.

Next the ordered-field evidence row A supplies the comparison language used by the bracket. The finite dyadic floor row D provides the scale and dyadic lower-grid information that make the comparison request finite.

The integer endpoint is then read through Z. Its source rows are the displayed $\mathsf{Int}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ data recorded in the packet provenance, so the route reaches an integer candidate only after the real, Archimedean, dyadic, and rational data have been exposed.

The successor row S packages the bracket $Z \leq R < S$ for downstream decimal and real-approximation consumers. Because S is downstream of R, A, D, Z, every bracket read factors through the displayed finite route. □

Theorem 1479.5 (ArchimedeanIntegerPart no-hidden-search boundary)**.** *For every accepted* ArchimedeanIntegerP *carrier, no consumer can obtain an integer-part read except through the displayed rows* $R, A, D, Z, S, H, C, P, N$*. In particular, the packet exports no host floor, trichotomy over arbitrary real names, quotient real equality, selected representative, countable-choice row, hidden Archimedean search, or ambient completeness coordinate.*

Proof. Let a consumer read an integer bracket from an accepted carrier. By Definition 1479.4, the read passes through the real or regular-Cauchy row, the Archimedean comparison row, the dyadic floor scale, the integer candidate, and the successor bracket.

Inspect the carrier definition. The only remaining coordinates are H, C, P, N, and those rows merely transport, replay, source, and name the same finite route. None of them stores an alternate search procedure or a host comparison oracle.

The excluded principles are therefore absent as carrier coordinates and absent as classifier clauses. Any attempted read through host floor, trichotomy, quotient equality, selected representatives, countable choice, hidden Archimedean search, or ambient completeness would leave the displayed packet surface. □

Falsifiable prediction: An accepted $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ consumer that reaches an integer bracket without reading the displayed $\mathsf{Real}^{\uparrow}$ or regular-Cauchy row, $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ comparison row, $\mathsf{DyadicFloor}^{\uparrow}$ scale row, $\mathsf{Int}^{\uparrow}$ candidate row, and successor bracket row refutes the carrier surface.

Independence witness: dyadicfloor, archimedeanorderedfield, decimalexpansion, int, nat, rat, real, regular-located-cauchy-real: no listed sibling is bijective to $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ because this packet jointly binds a real read, Archimedean comparison evidence, dyadic scale location, integer candidate, successor bracket, transport, replay, provenance, and local naming for the integer-part route.

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanIntegerPart}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ArchimedeanIntegerPart}^{\uparrow}$ packet is generated from a $\mathsf{Real}^{\uparrow}$ or regular-Cauchy read, $\mathsf{ArchimedeanOrderedField}^{\uparrow}$ comparison evidence, a $\mathsf{DyadicFloor}^{\uparrow}$ scale row, an $\mathsf{Int}^{\uparrow}$ integer candidate with $\mathsf{Nat}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ sources, a successor bracket row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanIntegerPart}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1479.1, Definition 1479.2, Definition 1479.3, Definition 1479.4, and Definition 1479.5 seed the finite integer-bracketing route used by decimal-expansion and RealUp approximation consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{ArchimedeanIntegerPart}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host floor, trichotomy, quotient real equality, selected representatives, countable choice, hidden Archimedean search, ambient completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the nine-row carrier and classifier and prove the NameCert obligation surface, bracket route, and no-hidden-search boundary.

Chapter 1480

A Concrete Naming Certificate for $\mathsf{RealSequenceLimitLaws}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealSequenceLimitLaws}^{\uparrow}$ packet records the finite algebra used when two displayed $\mathsf{Real}^{\uparrow}$ sequence limits are combined by a standard arithmetic operation. It sits over the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback rows of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the sandwich route of chapter 407. The certificate keeps limit arithmetic as displayed finite route data, not as quotient stream equality, a selected host limit, trichotomy, or ambient completeness.

Definition 1480.1 (Real sequence limit laws carrier)**.** *A* $\mathsf{RealSequenceLimitLaws}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, S_X, S_Y, R_X, R_Y, D, E_X, E_Y, O, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are two* $\mathsf{Real}^{\uparrow}$ *sequence source routes whose terms are read only through finite observation windows.*
2. *S_X and S_Y are the* $\mathsf{StreamName}^{\uparrow}$ *window rows opened for the two sources at the requested precision scale.*
3. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *error ledger recording the two source budgets, the operation budget, and the output tolerance request.*
5. *E_X and E_Y are the two limit-seal rows that certify the displayed source routes before any arithmetic read is public.*
6. *O is the operation row, recording whether the read is sum, difference, product under a displayed bound, scalar multiple, or squeeze-mediated comparison, together with its required dyadic error estimate.*
7. *H stores componentwise* hsame *transport for the two sources, their windows, readbacks, limit seals, dyadic ledger, and operation row.*
8. *C stores displayed* Cont *replay for opening windows, reading regular rational approximants, consuming dyadic error rows, invoking the operation row, and exposing the output seal route.*

9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SqueezeReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSequenceLimitLaws}^{\uparrow}}$ *row.*

The carrier contains no quotient stream, no host equality of real sequences, no selected limit value, no trichotomy row, and no ambient completeness principle.

Theorem 1480.2 (Real sequence limit laws NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RealSequenceLimitLaws}^{\uparrow}}$ *surface for Definition 1480.1 consists of five finite obligation rows:*

1. *carrier admission for the displayed packet* $L = (X, Y, S_X, S_Y, R_X, R_Y, D, E_X, E_Y, O, H, C, P, N)$*;*
2. *classifier stability under componentwise* hsame *transport and displayed* Cont *replay of the two source routes, window rows, readback rows, limit seals, dyadic ledger, and operation row;*
3. *operation-row exactness, requiring the output tolerance read to be the dyadic estimate stored in D and cited by O;*
4. *seal handoff, requiring every public limit-law read to pass through E_X, E_Y, O, and the displayed transport, replay, provenance, and local naming rows before any* $\mathsf{Real}^{\uparrow}$ *output seal is exposed;*
5. *non-escape, stating that quotient stream equality, selected host limits, trichotomy, host real-sequence equality, and ambient completeness are absent from the packet.*

Proof. Carrier admission is projection from Definition 1480.1. The two source routes, two window rows, two readback rows, dyadic ledger, two limit seals, operation row, transport, replay, provenance, and local name are explicit coordinates of L.

Classifier stability is componentwise. The stored H and C rows transport and replay exactly the coordinates named by the carrier, so a classified read cannot detach an operation row from its two source seals or from the dyadic error ledger.

Operation-row exactness is the role of D and O. The dyadic ledger records the input and output tolerances, while O declares which arithmetic or squeeze-mediated operation consumes those estimates.

The seal handoff then forces a public limit-law consumer to read E_X and E_Y before it invokes O. Since the carrier has no coordinate for quotient stream equality, selected host limits, trichotomy, host sequence equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 1480.3 (Real sequence limit laws RealUp handoff)**.** *Every public limit-law read exported by an accepted* $\mathsf{RealSequenceLimitLaws}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows of Definition 1480.1. The handoff exports no quotient stream equality, selected host limit, trichotomy, host equality of real sequences, or ambient completeness principle.*

Proof. Begin with a public limit-law consumer and project the accepted carrier. The consumer first receives the two source routes X, Y through the finite windows S_X, S_Y and the regular rational readbacks R_X, R_Y.

The dyadic error ledger D is then read at the same precision scale. It is the only tolerance coordinate listed in the carrier, and the operation row O must cite it before an output route can be exposed.

The two limit-seal rows E_X, E_Y bind the source routes to the terminal $\mathsf{Real}^{\uparrow}$ surface, while H, C, P, N provide the componentwise transport, replay, provenance, and local naming route.

These rows are exactly the public handoff surface. No further coordinate remains from which a consumer could read a quotient stream equality, a selected host limit, trichotomy, host sequence equality, or ambient completeness. □

Theorem 1480.4 (Real sequence limit laws dyadic operation exhaustion)**.** *Every accepted operation row O in a* $\mathsf{RealSequenceLimitLaws}^{\uparrow}$ *carrier*

$$L = (X, Y, S_X, S_Y, R_X, R_Y, D, E_X, E_Y, O, H, C, P, N)$$

must cite the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D for its input budgets, operation budget, and output tolerance request. After $D, O, E_X, E_Y, H, C, P, N$ are fixed, no quotient stream equality, selected host limit, trichotomy row, host sequence equality, or ambient completeness principle can alter the public limit-law read.*

Proof. Project the accepted carrier. The operation row O and the dyadic ledger D are the only coordinates that describe arithmetic error accounting for the two displayed source routes.

Apply operation-row exactness from Definition 1480.2. The row O must consume the tolerance data stored in D, including the two input budgets, the operation budget, and the output tolerance request.

Apply the RealUp handoff theorem Definition 1480.3. Once the two source seals E_X, E_Y and the structural rows H, C, P, N are fixed with D and O, the public limit-law read is already routed through the displayed finite packet.

The carrier has no coordinate for quotient stream equality, selected host limits, trichotomy, host sequence equality, or ambient completeness. Hence none of those objects can revise the dyadic operation read. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealSequenceLimitLaws}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSequenceLimitLaws}^{\uparrow}$ packet is generated from two $\mathsf{Real}^{\uparrow}$ sequence source routes, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{DyadicRatCore}^{\uparrow}$ error ledger, two limit-seal rows, an operation row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealSequenceLimitLaws}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1480.1, Definition 1480.2, Definition 1480.3, and Definition 1480.4 seed the finite constructive limit-law packet over StreamName, RegSeqRat, DyadicRatCore, RealUp, and SqueezeReal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealSequenceLimitLaws}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, trichotomy, host equality of real sequences, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, operation-row exactness, seal handoff, and non-escape for the same finite limit-law packet.

Chapter 1481

A Concrete Naming Certificate for $\mathsf{RegularCauchyRootTest}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyRootTest}^{\uparrow}$ packet records the finite root-bound test that turns a displayed eventually bounded root ledger into a regular Cauchy tail before the Real-facing seal is consumed. It sits over the fast-tail surface of chapter 367, the dyadic budget rows of chapter 379, the regular rational readback of chapter 301, the Real seal surface of chapter 38, the majorant route of chapter 1459, and the geometric-tail route of chapter 1461. The packet is a constructive root test for L10 Real and Completion certificates; it is not a host root-limit theorem, not a quotient of streams, not a selected sum, not countable choice, and not an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 1481.1 (Regular Cauchy root test carrier)**.** *A* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, Q, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the series or tail source row whose finite terms are inspected through displayed windows.*
2. *Q is the root-bound row, recording a dyadic bound strictly inside the unit tolerance scale together with the finite entry index after which the bound is admitted.*
3. *M is the modulus row assigning each displayed precision request a finite threshold beyond the root-bound entry index.*
4. *D is the dyadic tail-domination ledger that turns the root-bound row into a geometric majorant consumed by* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *and checked against the geometric-tail discipline of* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$*.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the displayed tail-domination ledger and modulus row.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row reached only through the regular rational handoff.*
7. *H records componentwise* hsame *transport for the source, root-bound, modulus, dyadic domination, regular handoff, real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through Q and M, then through D to the comparison-test surface, the ratio-test geometric budget, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the* $\mathsf{Real}^{\uparrow}$ *seal.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRootTest}^{\uparrow}$, $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRootTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for host root limits, quotient streams, selected sums, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Theorem 1481.2 (Regular Cauchy root test NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *carrier $T = (A, Q, M, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRootTest}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed ten-row packet;*
2. *root-bound tail domination, requiring Q, M, D to turn each inspected tail request into a finite dyadic geometric majorant routed through* $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, *and* $\mathsf{RegularCauchyRatioTest}^{\uparrow}$*;*
3. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring R to be read only from the displayed source, root-bound, modulus, and tail-domination rows;*
4. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring E to factor through R and to export no host root limit, quotient stream, selected sum, countable choice, or ambient completeness row;*
5. hsame, Cont, Pkg, *and* NameCert *transport for exactly the rows recorded by H, C, P, N.*

These obligations are finite-row obligations over the sibling surfaces named in the chapter introduction.

Proof. Project the carrier $T = (A, Q, M, D, R, E, H, C, P, N)$. The projection exposes the source, root-bound, modulus, tail-domination, regular handoff, Real seal, transport, continuation, provenance, and local naming rows.

For a displayed precision request, read Q and M. The root-bound row supplies the dyadic bound and entry index, while the modulus row chooses a finite threshold beyond that entry index.

The dyadic ledger D performs the tail-domination step. It converts the displayed root bound into a geometric majorant, sends the majorant through the $\mathsf{DyadicTailBound}^{\uparrow}$ and $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ surfaces, and checks the geometric budget against the $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ route.

The $\mathsf{RegSeqRat}^{\uparrow}$ handoff R is then obtained from the same displayed route. The seal row E is downstream of R, so it cannot expose a host root-limit object, quotient stream, selected sum, countable-choice row, or ambient completeness theorem.

Finally apply the structural rows. The hsame transports in H preserve the analytic rows componentwise, while C, P, N replay, source, and name exactly the displayed route. No omitted coordinate remains from which an additional NameCert obligation could be read. □

Theorem 1481.3 (Regular Cauchy root test tail-bound handoff)**.** *Every accepted* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *carrier hands a root-bound tail to* $\mathsf{RegSeqRat}^{\uparrow}$ *and then to* $\mathsf{Real}^{\uparrow}$ *only through the finite route*

$$A, Q, M \longmapsto D \longmapsto R, E, H, C, P, N.$$

Consequently a Real-facing consumer can use the root test only after reading the displayed root-bound row, modulus row, dyadic tail-domination ledger, comparison-test handoff, ratio-test geometric budget, regular rational handoff, and local transport package.

Proof. Begin with an accepted carrier and a displayed precision request. The rows Q and M determine the admitted root bound, entry index, and finite tail threshold.

Read the domination ledger D. This ledger is the only row that converts the root-bound data into a geometric majorant, and it names the $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, and $\mathsf{RegularCauchyRatioTest}^{\uparrow}$ routes consumed by the handoff.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is obtained by replaying that displayed domination route. Since R depends on A, Q, M, D and not on a host root-limit theorem, the downstream $\mathsf{Real}^{\uparrow}$ seal row E can only read the regular rational handoff presented by the carrier.

Transport and provenance preserve the same route. The rows H, C, P, N carry the root-bound tail data, replay the comparison and ratio-test handoffs, and name the local certificate without adding quotient streams, selected sums, countable choice, RealUp completeness, or bridge checking. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyRootTest}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal without reading the displayed root-bound row, modulus row, dyadic tail-domination ledger, comparison-test handoff, ratio-test geometric budget, and transport package refutes the carrier surface.

Independence witness: fastconvergentseries, dyadictailbound, regseqrat, real, regular-cauchy-comparison-test, regular-cauchy-ratio-test: no listed sibling supplies the whole ten-row packet $T = (A, Q, M, D, R, E, H, C, P, N)$, because each sibling contributes only a tail budget, dyadic bound, regular handoff, Real seal, comparison face, or geometric-tail face while this chapter binds the root-bound route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRootTest}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRootTest}^{\uparrow}$ packet is generated from a source row, a displayed root-bound row, an explicit modulus row, a dyadic tail-domination ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRootTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1481.1, Definition 1481.2, and Definition 1481.3 seed the finite root-test boundary over $\mathsf{FastConvergentSeries}^{\uparrow}$, $\mathsf{DyadicTailBound}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, and $\mathsf{RegularCauchyRatioTest}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRootTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host root limits, quotient streams, selected sums, countable choice, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove the finite NameCert obligation surface and tail-bound handoff theorem.

Chapter 1482

A Concrete Naming Certificate for $\mathsf{ChoiceSequence}^{\uparrow}$

Brouwer/Bishop constructive choice-sequence tradition treats an unfolding sequence by the finite information currently displayed to a proof or construction. The $\mathsf{ChoiceSequence}^{\uparrow}$ packet records that surface as a finite-prefix NameCert neighbour of chapter 334 and chapter 126. It uses $\mathsf{Nat}^{\uparrow}$ answer rows, scheduled $\mathsf{StreamName}^{\uparrow}$ prefix requests, and the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumer boundaries only as visible handoff rows; it does not complete a host function $\mathsf{Nat}^{\uparrow} \to \mathsf{Nat}^{\uparrow}$, quotient infinite streams, or add a countable-choice selector.

Definition 1482.1 (ChoiceSequence prefix carrier)**.** *A* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix carrier is a finite* BHist *packet*

$$Q = (S, W, A, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the finite prefix requests visible to the consumer;*
2. *W is the finite prefix-window ledger listing the requested natural-number positions;*
3. *A is the* $\mathsf{Nat}^{\uparrow}$ *answer ledger assigning displayed natural-number rows to the positions of W;*
4. *R is the optional* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when the same finite prefix is consumed by a regular-rational route;*
5. *E is the optional* $\mathsf{Real}^{\uparrow}$ *seal row reached only through R and the displayed prefix data;*
6. *H is the componentwise* hsame *transport row for S, W, A, R, E;*
7. *C is the displayed* Cont *route for prefix restriction and already accepted prefix replay;*
8. *P is the* Pkg *provenance over* $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ChoiceSequence}^{\uparrow}}$ *row.*

The carrier accepts only displayed finite prefixes with visible answer rows. It exports no completed host function, no quotient stream equality, no countable-choice selector, no real-completeness principle, and no external topology.

Theorem 1482.2 (ChoiceSequence prefix stability)**.** *Let $Q = (S, W, A, R, E, H, C, P, N)$ be an accepted* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix carrier. Every prefix subwindow of W, together with the corresponding displayed* $\mathsf{Nat}^{\uparrow}$ *answer rows of A, repacks as an accepted* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix carrier*

through the same hsame*,* Cont*,* Pkg*, and local* NameCert *rows. The restricted carrier has no access to tail values outside the displayed subwindow.*

Proof. Project the carrier of Definition 1482.1. The schedule row S, prefix ledger W, and answer ledger A are finite BHist rows, so a prefix subwindow is obtained by deleting later displayed entries rather than by reading an infinite sequence.

Transport the retained entries through the componentwise hsame row H. The Cont route C is already a prefix-restriction route for accepted reads, so replaying it on the retained rows preserves the order of the visible positions and the attached $\mathsf{Nat}^{\uparrow}$ answers.

The provenance row P and local naming row N then repack the restricted data as the same kind of certificate. Since no coordinate in Q stores a completed host function or a hidden tail oracle, the restricted carrier cannot export values beyond the displayed subwindow. □

Theorem 1482.3 (ChoiceSequence prefix amalgamation)**.** *Let* $Q_0 = (S_0, W_0, A_0, R_0, E_0, H_0, C_0, P_0, N_0)$ *and* $Q_1 = (S_1, W_1, A_1, R_1, E_1, H_1, C_1, P_1, N_1)$ *be accepted* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix carriers. Suppose the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedules and* $\mathsf{Nat}^{\uparrow}$ *answer ledgers agree on the overlap of* W_0 *and* W_1 *under componentwise* hsame*, and suppose the optional* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows and* $\mathsf{Real}^{\uparrow}$ *seal rows, when present on both sides, are the same displayed handoff rows over that overlap. Then the finite union of the two displayed windows repacks as an accepted* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix carrier using the common* $\mathsf{StreamName}^{\uparrow}$ *schedule on the overlap, the single-valued union of the* $\mathsf{Nat}^{\uparrow}$ *answer rows, the inherited optional* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff rows,* Cont *replay over the combined window,* Pkg *provenance, and a local* $\mathsf{NameCert}_{\mathsf{ChoiceSequence}^{\uparrow}}$ *row.*

Proof. Project the two carriers through Definition 1482.1. The rows W_0, W_1 are finite displayed ledgers, so their union is again a finite prefix-window ledger rather than a completed host function.

On the common part of the two ledgers, the hypotheses identify the displayed schedules and $\mathsf{Nat}^{\uparrow}$ answer rows by componentwise hsame. Hence the union ledger is single-valued: an overlapping position carries one answer row, while a position belonging to only one side keeps the answer row already displayed there.

The optional R and E rows are copied only along the visible handoff routes. Where both carriers expose such rows, the overlap hypothesis makes them the same displayed $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ handoff; where only one side exposes them, the row remains attached to that side's displayed prefix data.

Replay the continuation rows C_0 and C_1 over their respective subwindows inside the combined finite ledger. Prefix stability from Definition 1482.2 certifies that each original carrier is recovered by restricting the union back to its displayed window.

Finally, the provenance rows P_0, P_1 and local naming rows N_0, N_1 supply the same kernel ingredients named in the carrier definition, so the combined finite data repacks as a local $\mathsf{NameCert}_{\mathsf{ChoiceSequence}^{\uparrow}}$ carrier. The construction adds no completed host function, countable-choice selector, quotient stream equality, real-completeness principle, or external topology. □

Theorem 1482.4 (ChoiceSequence StreamName handoff)**.** *Every public read of an accepted* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix carrier factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule row before it reaches any* $\mathsf{Nat}^{\uparrow}$ *answer row, any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, or any* $\mathsf{Real}^{\uparrow}$ *seal row. The handoff route is*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{Nat}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

when the last two rows are present, and otherwise stops at the displayed natural-number prefix.

Proof. Begin with a public consumer read of Q. The consumer first receives the finite request schedule S and the prefix ledger W; without these rows there is no named position at which a natural-number answer can be inspected.

The $\mathsf{Nat}^{\uparrow}$ answer ledger A is read only over those scheduled positions. If a regular-rational consumer is present, the readback row R is attached to the same displayed prefix, and the $\mathsf{Real}^{\uparrow}$ seal row E is reached only after R has been replayed through H, C, P, N.

Thus the public route must pass through $\mathsf{StreamName}^{\uparrow}$ before any answer or completion-facing handoff is available. If R and E are absent, the same argument terminates at the finite $\mathsf{Nat}^{\uparrow}$ prefix surface and yields no regular-rational or real-facing row. □

Theorem 1482.5 (ChoiceSequence tail nonanticipation)**.** *Let $Q = (S, W, A, R, E, H, C, P, N)$ and $Q' = (S, W, A', R', E', H, C, P, N)$ be accepted $\mathsf{ChoiceSequence}^{\uparrow}$ prefix carriers with the same displayed $\mathsf{StreamName}^{\uparrow}$ schedule row, prefix-window ledger, transport, continuation, provenance, and local naming rows. Every public read restricted to the displayed prefix factors only through S, W, A, H, C, P, N and through the optional R, E rows already attached to that prefix. If the displayed $\mathsf{Nat}^{\uparrow}$ answer rows of A and A' agree on W, then no consumer can distinguish Q from Q' by any tail value outside W.*

Any claimed distinction between Q and Q' outside the displayed window would require one of the following absent coordinates: a completed host function, a hidden tail oracle, quotient stream equality, a countable-choice selector, or a $\mathsf{Real}^{\uparrow}$ completeness coordinate.

Proof. Project the two carriers through Definition 1482.1. The rows S, W, H, C, P, N are shared, and the visible answer ledgers agree on the whole displayed window W.

Apply prefix stability from Definition 1482.2 to restrict any public read to the displayed subwindow. The restriction removes later undisplayed positions rather than evaluating them, so the resulting consumer surface is determined by the shared schedule and the visible $\mathsf{Nat}^{\uparrow}$ answers.

Apply the StreamName handoff of Definition 1482.4. Any answer read, and any optional $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ readback, must pass through S before reaching A, R, E or A', R', E'. Since the read is restricted to W and the displayed answers agree there, the public route has the same visible data in both carriers.

It remains to inspect the possible source of a tail distinction. The carrier definition exports no completed host function, hidden tail oracle, quotient stream equality, countable-choice selector, or $\mathsf{Real}^{\uparrow}$ completeness coordinate. Therefore no local $\mathsf{NameCert}_{\mathsf{ChoiceSequence}^{\uparrow}}$ consumer can distinguish Q from Q' by any value outside the displayed prefix. □

Theorem 1482.6 (ChoiceSequence NameCert obligation surface)**.** *The seed $\mathsf{NameCert}_{\mathsf{ChoiceSequence}^{\uparrow}}$ obligation surface consists exactly of carrier admission for Definition 1482.1, prefix stability of Definition 1482.2, compatible-prefix amalgamation of Definition 1482.3, StreamName handoff of Definition 1482.4, tail nonanticipation of Definition 1482.5, componentwise* hsame *transport of all displayed rows,* Cont *prefix restriction and replay,* Pkg *provenance, and local naming through N. It exposes the finite-prefix choice-sequence neighbour of $\mathsf{BaireSpace}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ while exporting no completed host function, countable-choice selector, quotient stream equality, real completeness, or external topology.*

Proof. Carrier admission is the projection of the nine displayed rows in Definition 1482.1. The schedule, prefix ledger, answer ledger, optional regular readback, optional real seal, transport, continuation, provenance, and local naming rows are exactly the rows available to a NameCert consumer.

Prefix stability is supplied by Definition 1482.2. It shows that every shorter displayed prefix is certified by the same finite rows after hsame transport and Cont prefix restriction.

Compatible-prefix amalgamation is supplied by Definition 1482.3. It shows that two accepted displayed prefixes with the same overlap answers form one finite carrier, so downstream readers can treat compatible finite evidence as a single $\mathsf{ChoiceSequence}^{\uparrow}$ surface.

The handoff clause is supplied by Definition 1482.4. It forces every answer read and every regular or real-facing consumer route to pass through the displayed $\mathsf{StreamName}^{\uparrow}$ schedule and the visible $\mathsf{Nat}^{\uparrow}$ prefix answers.

Tail nonanticipation is supplied by Definition 1482.5. It states that two accepted carriers with the same displayed schedule and agreeing visible answers cannot be separated by data outside the prefix window.

It remains to inspect exclusions. The packet has no coordinate for a completed host function, countable-choice selector, quotient stream equality, real-completeness witness, or external topology, so none of those objects can be exported by the local $\mathsf{NameCert}_{\mathsf{ChoiceSequence}^{\uparrow}}$ surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{ChoiceSequence}^{\uparrow}$ packet is generated from a finite $\mathsf{StreamName}^{\uparrow}$ request schedule, displayed $\mathsf{Nat}^{\uparrow}$ answer rows, optional $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumer handoffs, componentwise hsame transport, Cont prefix replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoiceSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1482.1, Definition 1482.2, Definition 1482.3, Definition 1482.4, Definition 1482.5, and Definition 1482.6 seed the finite-prefix choice-sequence surface over $\mathsf{StreamName}^{\uparrow}$ schedules, $\mathsf{Nat}^{\uparrow}$ answer rows, optional $\mathsf{RegSeqRat}^{\uparrow}$ readback, optional $\mathsf{Real}^{\uparrow}$ seal, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoiceSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close completed host functions, countable choice, quotient stream equality, real completeness, or external topology.

Upgrade path: The next step is obligationClosure: carrier admission, prefix stability, compatible-prefix amalgamation, StreamName handoff, tail nonanticipation, transport, continuation, provenance, and non-escape must be discharged as local rows.

Chapter 1483

A Concrete Naming Certificate for $\mathsf{AlternatingSeriesTest}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{AlternatingSeriesTest}^{\uparrow}$ packet records the alternating-series test as finite BEDC data before a completion-facing consumer may read a regular rational handoff or a real seal. Its source and partial-sum rows sit beside the Cauchy criterion of chapter 392; its regular rational endpoint is the route of chapter 301; its terminal boundary is the $\mathsf{Real}^{\uparrow}$ seal of chapter 38; and its dyadic tail estimate is the finite comparison discipline of chapter 1459. The packet is a constructive convergence-test surface for a displayed alternating source; it is not a selected sum, a quotient series equality, host real equality, countable choice, trichotomy on arbitrary summands, or RealUp completeness.

Definition 1483.1 (Alternating series test carrier)**.** *An* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, \Sigma, M, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the series source row, displaying a rational summand family a_n and the partial-sum histories for $\sum_{i<n}(-1)^i a_i$.*
2. *Σ is the alternating-sign ledger, recording the finite parity row that attaches the sign $(-1)^n$ to the nth inspected summand.*
3. *M is the monotone dyadic magnitude ledger, displaying nonnegative dyadic majorants for the inspected magnitudes and the finite rows witnessing that the majorants decrease along the observed tail.*
4. *T is the tail-bound schedule, assigning each displayed precision request a finite threshold after which the next omitted magnitude is below the requested dyadic tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the partial-sum source, alternating-sign ledger, monotone magnitude ledger, and tail-bound schedule.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to the regular rational handoff.*
7. *H records componentwise* hsame *transports for the source, sign ledger, magnitude ledger, tail-bound schedule, regular handoff, real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *routes from each precision request through Σ, M, T to the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R and then to the* $\mathsf{Real}^{\uparrow}$ *seal row E.*

9. *P is the* Pkg *provenance over* $\mathsf{AlternatingSeriesTest}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AlternatingSeriesTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten displayed rows. It has no coordinate for a chosen infinite sum, quotient series equality, host-level equality of reals, countable choice, trichotomy outside the inspected dyadic magnitude rows, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.AlternatingSeriesTestUp.AlternatingSeriesTestTasteGate single carrier alignment`

Theorem 1483.2 (Alternating series test NameCert obligations)**.** *For every accepted* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *carrier $A = (S, \Sigma, M, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlternatingSeriesTest}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed ten-row packet;*
2. *source exposure for the rational summand and partial-sum rows in S;*
3. *alternating-sign exposure for Σ, tying every inspected partial-sum step to its finite parity row;*
4. *monotone dyadic magnitude exposure for M, including the nonnegative magnitude row and the displayed decrease row on the observed tail;*
5. *tail-bound compatibility for T, sending every precision request to a finite threshold with next omitted magnitude below that tolerance;*
6. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff and* $\mathsf{Real}^{\uparrow}$ *seal exposure for R and E;*
7. *transport stability, continuation replay, provenance, and local naming for exactly the route recorded by H, C, P, N.*

These obligations are finite-row obligations over the Cauchy criterion of chapter 392, the regular rational route of chapter 301, the real seal boundary of chapter 38, and the dyadic comparison route of chapter 1459.

Proof. Project the accepted packet $A = (S, \Sigma, M, T, R, E, H, C, P, N)$. The projection exposes exactly the rational source, alternating-sign ledger, monotone dyadic magnitude ledger, tail-bound schedule, regular handoff, real seal, transport rows, continuation replay, provenance, and local naming row.

Read a displayed precision request through T. The schedule selects a finite threshold, and the magnitude ledger M states that the next omitted majorant past that threshold is below the requested dyadic tolerance.

The sign ledger Σ is used only to identify the finite cancellation pattern in the partial sums from S. Together with monotonicity in M, this is the displayed Cauchy-criterion input: tails after the chosen threshold are bounded by the next omitted magnitude, not by an unrecorded infinite choice.

Finally apply the structural rows. The componentwise transports in H preserve the source, sign, magnitude, threshold, handoff, and seal rows together, while C, P, N only replay, source, and name that route. Since the carrier has no further coordinate, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{AlternatingSeriesTest}^{\uparrow}}$ surface. □

Theorem 1483.3 (Alternating series test Cauchy handoff)**.** *Every accepted* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *carrier sends the alternating partial-sum family to the Cauchy-facing route only through the finite handoff*

$$S, \Sigma, M, T \longmapsto R \longmapsto E, H, C, P, N.$$

Thus a $\mathsf{RegSeqRat}^{\uparrow}$ *consumer can use the alternating-series test only after reading the displayed summand source, alternating-sign ledger, monotone dyadic magnitude ledger, and tail-bound schedule that bind the tail estimate to the regular rational handoff.*

Proof. Begin with an accepted carrier and a displayed precision request. The tail-bound schedule T supplies a finite threshold, while the source row S supplies only the partial sums visible around that threshold.

Read the sign and magnitude rows. The ledger Σ determines which finite summand positions are added and subtracted, and M supplies the monotone dyadic magnitude comparison on the same positions.

These rows are exactly the data consumed by the Cauchy criterion route: the difference of two sufficiently late partial sums is bounded by the next omitted displayed magnitude. The handoff row R records that regular rational readback and does not receive any separate completed real or quotient series object.

Transport and replay preserve this handoff componentwise. The rows H, C, P, N attach the route to the local certificate without creating an alternate path through host convergence, selected sums, or RealUp completeness. □

Theorem 1483.4 (Alternating series test Real-seal boundary)**.** *For every accepted* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *carrier, any* $\mathsf{Real}^{\uparrow}$ *seal-facing read factors through the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R produced from the displayed alternating partial sums, sign ledger, monotone dyadic magnitude ledger, and tail-bound schedule. The seal row E receives only R together with the componentwise transports, continuation replay, provenance, and local naming rows; it receives no selected sum, quotient series equality, host real equality, countable choice, trichotomy premise, or RealUp completeness theorem.*

Proof. Project the seal-facing rows R and E from the accepted carrier. The regular handoff R is downstream of S, Σ, M, T, and the seal row E is downstream of R.

Apply Definition 1483.3. It identifies the only route from alternating partial sums to the regular readback as the finite path through the displayed source, sign, magnitude, and tail-bound rows.

Read the seal row. Its analytic input is exactly the regular handoff R, together with H, C, P, N. Since the carrier has no coordinate for a selected sum, quotient series equality, host real equality, countable choice, unrestricted trichotomy, or RealUp completeness, the seal-facing read cannot export any of those objects. □

Theorem 1483.5 (Alternating series test public convergence export)**.** *The public convergence export of an accepted* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *carrier is exactly the finite statement that its displayed alternating partial sums form a* $\mathsf{RegSeqRat}^{\uparrow}$ *row and may be sealed as the displayed* $\mathsf{Real}^{\uparrow}$ *boundary. Any downstream consumer receives the source row S, alternating-sign ledger Σ, monotone dyadic magnitude ledger M, tail-bound schedule T, regular handoff R, real seal E, componentwise transports H, continuation replay C, provenance P, and local naming row N, and receives no further convergence principle.*

Proof. Unpack the public export through the carrier definition. The only exported convergence data are the regular handoff R and the seal row E, and both are indexed by the same source, sign, magnitude, and tail-bound rows.

Use Definition 1483.2 to identify the certificate obligations attached to those rows. They expose carrier admission, finite source inspection, sign parity, monotone dyadic magnitude, tail-bound scheduling, regular readback, seal exposure, and structural transport.

Use Definition 1483.4 for the boundary condition. The real-facing consumer reads the displayed seal and cannot recover any selected sum, quotient series equality, host real equality, choice principle, trichotomy oracle, or completeness theorem beyond the finite packet. □

Falsifiable prediction: An accepted $\mathsf{AlternatingSeriesTest}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal without reading the displayed alternating-sign ledger, monotone dyadic magnitude ledger, tail-bound schedule, and source partial-sum row refutes the carrier surface.

Independence witness: cauchycriterion, regseqrat, real, regular-cauchy-comparison-test: no listed sibling supplies the whole ten-row packet $A = (S, \Sigma, M, T, R, E, H, C, P, N)$, because each sibling contributes only a Cauchy route, regular readback, seal face, or dyadic comparison face while this chapter binds the alternating sign, monotone magnitude, tail-bound, transport, replay, provenance, and naming rows into one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{AlternatingSeriesTest}^{\uparrow}}$.

Constructive story: An $\mathsf{AlternatingSeriesTest}^{\uparrow}$ packet is generated from a rational summand source, finite alternating-sign ledger, monotone dyadic magnitude ledger, tail-bound schedule, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlternatingSeriesTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1483.1, Definition 1483.2, Definition 1483.3, Definition 1483.4, and Definition 1483.5 seed the finite alternating-series-test boundary over $\mathsf{Series}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlternatingSeriesTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected sums, quotient series equality, host real equality, countable choice, trichotomy, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the ten-row carrier and prove the finite NameCert obligation surface, Cauchy handoff theorem, Real-seal boundary theorem, and public convergence export theorem.

Chapter 1484

A Concrete Naming Certificate for $\mathsf{DyadicDensityReal}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{DyadicDensityReal}^{\uparrow}$ packet records the finite dyadic witness surface used when a displayed real-name interval must expose a dyadic point at a displayed radius. It sits over the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the constant dyadic real-name route of chapter 467, the finite windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The certificate names density as finite BEDC route data, not as quotient streams, selected host limits, host real equality, trichotomy, or ambient completeness.

Definition 1484.1 (DyadicDensityReal carrier)**.** *A* $\mathsf{DyadicDensityReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (L, U, D, \rho, S_L, S_U, R_L, R_U, E, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint seal rows for the displayed interval, read only as Real-facing name data.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row naming the candidate dyadic rational witness and its comparison scales.*
3. *ρ is the dyadic radius row recording the requested positive window and the two endpoint tolerances used by the witness read.*
4. *S_L and S_U are the* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows opened for the two endpoint names at the scales requested by ρ.*
5. *R_L and R_U are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those two finite windows.*
6. *E is the* $\mathsf{DyadicEmbedding}^{\uparrow}$ *handoff row sending the dyadic source named by D into the same real-name surface as the two endpoint seals.*
7. *H stores componentwise* hsame *transport for the endpoint seals, dyadic source row, radius row, stream windows, regular readbacks, embedding handoff, continuations, provenance, and local naming.*
8. *C stores displayed* Cont *routes for opening endpoint windows, reading the regular rational rows, consuming the dyadic source and radius rows, invoking the embedding handoff, and exposing the dyadic witness to the* $\mathsf{Real}^{\uparrow}$ *interval consumer.*

9. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicDensityReal}^{\uparrow}}$ *row.*

The carrier contains no quotient stream, selected host limit, host real equality, trichotomy row, or ambient completeness principle.

Theorem 1484.2 (DyadicDensityReal NameCert obligations)**.** *For every accepted* $\mathsf{DyadicDensityReal}^{\uparrow}$ *carrier* $W = (L, U, D, \rho, S_L, S_U, R_L, R_U, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicDensityReal}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *carrier admission for the displayed endpoint, dyadic, window, readback, handoff, transport, continuation, provenance, and local naming rows;*
2. *endpoint-window compatibility, stating that S_L, S_U, R_L, R_U are read from the same displayed radius row ρ and the same endpoint seals L, U;*
3. *dyadic-source exactness, stating that the exported witness is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source named by D at the radius and comparison scales recorded in ρ;*
4. *embedding handoff, stating that the only Real-facing route for the dyadic witness is the* $\mathsf{DyadicEmbedding}^{\uparrow}$ *row E followed by the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *reads;*
5. *non-escape, stating that quotient streams, selected host limits, host real equality, trichotomy, and ambient completeness are absent from the carrier.*

Proof. Project the carrier of Definition 1484.1. The two endpoint seals, dyadic source, radius row, two window rows, two readback rows, embedding handoff, transports, continuations, provenance, and local name are exactly the coordinates available to the classifier.

Endpoint-window compatibility follows from the shared radius row. Both S_L, S_U and their readbacks R_L, R_U are listed as windows opened at the scales requested by ρ, so a classified interval read cannot use an endpoint window detached from the displayed tolerance request.

Dyadic-source exactness and embedding handoff are the same finite route read from opposite sides. The row D supplies the dyadic rational witness, while E is the only coordinate that embeds that source into the Real-facing naming surface.

The non-escape row is inspection of the packet. Since the carrier has no coordinate for quotient streams, selected host limits, host real equality, trichotomy, or ambient completeness, the five rows exhaust the local NameCert surface. □

Theorem 1484.3 (DyadicDensityReal witness route)**.** *Every exported dyadic witness of an accepted* $\mathsf{DyadicDensityReal}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{DyadicEmbedding}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

together with the carrier's componentwise hsame *transports, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The route exports no quotient stream, selected host limit, host real equality, trichotomy row, or ambient completeness principle.*

Proof. Begin with an exported dyadic witness and project the accepted carrier. The only dyadic source coordinate is D, so the witness begins as the $\mathsf{DyadicRatCore}^{\uparrow}$ row named by the packet.

The witness then crosses the embedding handoff. The row E is the sole $\mathsf{DyadicEmbedding}^{\uparrow}$ coordinate, and the continuation routes C expose it only after the endpoint windows and readbacks attached to ρ have been displayed.

Finally the Real-facing consumer reads the same finite surface through S_L, S_U, R_L, R_U and the endpoint seals L, U. Componentwise transport H, provenance P, and the local naming row N preserve that route as a single packet over the displayed primitives.

No other carrier coordinate can export a witness. Hence every public dyadic density read factors through the stated $\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{DyadicEmbedding}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ route and cannot obtain any of the excluded host or quotient data. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicDensityReal}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicDensityReal}^{\uparrow}$ packet is generated from lower and upper Real endpoint seals, a DyadicRatCore source row, a dyadic radius row, finite StreamName windows, RegSeqRat readbacks, a DyadicEmbedding handoff, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicDensityReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 1484.1, Definition 1484.2, and Definition 1484.3 seed the finite dyadic-density packet over DyadicRatCore, DyadicEmbedding, StreamName, RegSeqRat, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicDensityReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, host real equality, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-window compatibility, dyadic-source exactness, embedding handoff, and non-escape for the same finite dyadic-density packet.

The $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ route consumes the $\mathsf{CauchyModulus}^{\uparrow}$ and $\mathsf{CauchyModulusMeet}^{\uparrow}$ schedules of chapter 292 and chapter 462, then hands shared thresholds to the $\mathsf{RegularCauchySum}^{\uparrow}$ and $\mathsf{RegularCauchyProduct}^{\uparrow}$ consumer rows before the $\mathsf{Real}^{\uparrow}$ seal is read.

Chapter 1485

A Concrete Naming Certificate for $\mathsf{CauchyModulusArithmetic}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, explicit Cauchy moduli are part of the data by which regular rational sequences are consumed: addition, multiplication, and common-tail comparison require visible schedules rather than a hidden appeal to completed real equality. The $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ packet records this arithmetic surface as a finite NameCert bridge between the modulus chapters chapter 292 and chapter 462, the regular operation chapters chapter 417 and chapter 461, and the real seal surface of chapter 38.

Definition 1485.1 (Cauchy-modulus arithmetic carrier)**.** *A* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two* $\mathsf{StreamName}^{\uparrow}$ *windows whose rational observations are read back through* $\mathsf{RegSeqRat}^{\uparrow}$ *rows.*
2. *μ_0 and μ_1 are the two source* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules, each carrying its own precision request, threshold row, and late-pair ledger.*
3. *$\mu_\wedge$ is the shared-threshold* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row that places the two source schedules on one dyadic tolerance surface.*
4. *σ and π are the* $\mathsf{RegularCauchySum}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *consumer rows; they read only the two source schedules, the shared meet row, and the regular rational readbacks.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the split tolerances for the sum route, the product route, and the shared meet route.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger that names the inspected late observations for both source streams and both arithmetic consumers.*
7. *R stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks obtained from the displayed windows, tolerance rows, and modulus schedules.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the regular rational sum or product handoff.*

9. *H records componentwise* hsame *transport for the two streams, two source schedules, shared meet row, sum row, product row, dyadic tolerance ledger, window ledger, regular readbacks, real seal rows, continuation rows, provenance, and local name.*
10. *C records displayed* Cont *replay from a precision request through the two source schedules and the shared meet row, then through D, W, R to σ, π, and E.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, RegularCauchyProduc $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting these displayed rows to a common finite surface. It has no coordinate for quotient streams, selected limits, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.TasteGate.CauchyModulusArithmeticTasteGate`
`single carrier alignment`

Theorem 1485.2 (Cauchy-modulus arithmetic NameCert obligations)**.** *For every accepted* CauchyModulusArithme *carrier $A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed packet with two source modulus schedules, one shared meet row, two arithmetic consumer rows, tolerance ledgers, windows, readbacks, seal rows, transport, continuation, provenance, and local name;*
2. *classifier transport to a common* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *surface;*
3. *stability of μ_0, μ_1, $\mu_\wedge$, σ, and π under the componentwise* hsame *rows recorded in H;*
4. *exactness of the dyadic tolerance ledger D as the only source of split-tolerance and shared-threshold arithmetic reads;*
5. Cont *replay,* Pkg *provenance,* $\mathsf{Real}^{\uparrow}$ *handoff, and local NameCert rows for exactly the displayed packet.*

No NameCert obligation is stored outside those five rows.

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier namecert obligations`

Proof. Project the carrier of Definition 1485.1. The projection exposes precisely the two stream windows, two source modulus schedules, shared meet row, sum and product consumers, tolerance ledger, regular readbacks, real seal rows, transport rows, continuation rows, provenance row, and local name.

Classifier transport is componentwise. The rows in H move the two source schedules, the shared meet schedule, and the two arithmetic consumers to the same displayed stream, regular rational, and dyadic tolerance surface.

The dyadic exactness row is exhausted by D. The sum route reads split tolerances from D, the product route reads product bounds from D, and the meet route reads its shared tolerance from the same finite ledger.

Finally replay C and attach P, N. These rows route, source, and name the already displayed packet; they do not introduce quotient streams, selected limits, host real equality, or ambient completeness. Hence the five listed rows exhaust the local naming obligations. □

Theorem 1485.3 (Cauchy-modulus arithmetic carrier admission row)**.** *For every accepted* CauchyModulusArithmet *carrier* $A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$*, the carrier-admission obligation for* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^\uparrow}$ *is exactly the displayed row admitting* $S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N$*. No source stream, modulus schedule, meet row, arithmetic consumer, tolerance ledger, window ledger, readback, seal, transport, replay, provenance, or local name may be read outside this finite carrier row.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier namecert obligation carrier`

Proof. Project the first obligation row of Definition 1485.2. It is the carrier-admission row for the tuple displayed in Definition 1485.1.

The listed coordinates already contain the two source streams, the two source moduli, the meet row, the sum and product consumers, the dyadic ledger, the window ledger, the regular readbacks, the Real seal, and the structural rows. Since the carrier definition has no further coordinate, admission is exhausted by this one finite row. □

Theorem 1485.4 (Cauchy-modulus arithmetic classifier transport row)**.** *For every accepted* CauchyModulusArithm *carrier* $A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$*, classifier transport is permitted only through the common finite surface made from* $\mathsf{StreamName}^\uparrow$*,* $\mathsf{RegSeqRat}^\uparrow$*,* $\mathsf{CauchyModulus}^\uparrow$*,* $\mathsf{CauchyModulusMeet}^\uparrow$*, and* $\mathsf{DyadicRatCore}^\uparrow$*. In particular the classifier cannot compare arithmetic carriers by quotient stream equality, selected limits, host real equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier namecert obligation classifier`

Proof. Read the classifier-transport row of Definition 1485.2. It names exactly the stream, regular rational, source modulus, meet modulus, and dyadic tolerance surfaces.

The componentwise hsame rows in H move the two source streams, the two source schedules, the meet row, the arithmetic consumers, the tolerance ledger, and the readbacks to that same surface. The classifier therefore has only this transport route; no quotient, selected-limit, host-equality, or completeness coordinate is present to compare instead. □

Theorem 1485.5 (Cauchy-modulus arithmetic ledger nonescape row)**.** *For every accepted* CauchyModulusArithmet *carrier* $A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$*, every completion-facing or* $\mathsf{Real}^\uparrow$ *consumer that reads the seal row* E *must first pass through the displayed* Cont *replay row* C*, the* Pkg *provenance row* P*, and the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^\uparrow}$ *row* N*. Thus* E *is a ledger endpoint for the displayed arithmetic route, not an escape hatch to quotient streams, selected limits, host real equality, or ambient completeness.*

Proof. Start from a consumer that asks for E. The carrier definition places E after the source schedules, shared meet, arithmetic consumers, dyadic ledger, windows, and regular readbacks.

Replay must then pass through C. The continuation row records the finite route from a precision request through the displayed source schedules and ledger rows before the Real seal is available.

Finally attach P and N. These rows record provenance and local naming for the same packet, so a consumer of E remains inside the displayed $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^\uparrow}$ route and cannot extract any unlisted completion or equality principle. □

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier ledger nonescape`

Theorem 1485.6 (Cauchy-modulus arithmetic sum and meet closure)**.** *Let A be an accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier. Every displayed precision request for the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row σ is answered by first reading the two source schedules μ_0, μ_1, then reading the shared meet row $\mu_\wedge$, and then reading the split dyadic tolerance ledger D. The resulting sum schedule is a finite* $\mathsf{CauchyModulus}^{\uparrow}$ *read over the same* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and its shared threshold is stable under the* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *transport rows.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier sum meet route closure`

Proof. Start with a precision request for σ. Carrier admission exposes the two source schedules and the shared meet row before the sum row can be consumed.

Read D at the requested tolerance. Its split-tolerance rows provide the dyadic requests sent to μ_0 and μ_1, while its shared-threshold row is the tolerance read by $\mu_\wedge$.

Replay the Cont rows from C. They inspect only the windows in W and the regular rational readbacks in R, so the produced sum schedule remains a finite modulus read over the displayed packet.

Stability follows from H and the meet obligation surface. The shared meet row transports the two source schedules together, and the sum consumer can therefore reuse the same threshold packet after componentwise hsame transport. □

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier sum meet closure`

Theorem 1485.7 (Cauchy-modulus arithmetic Real consumer boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *packet must factor through the displayed route*

$$S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N.$$

The consumer may read the regular sum or product handoff and then the real seal row E, but it cannot extract quotient stream equality, selected limits, host real equality, or ambient completeness from the arithmetic carrier.

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier real consumer boundary`

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ consumer route. The carrier has no real-facing coordinate before the regular rational readback rows R and the seal row E.

For the sum route, Definition 1485.6 forces the consumer through $\mu_0, \mu_1, \mu_\wedge, D, W, R$ before σ can be sealed. For the product route, the carrier definition gives the same source schedules, shared meet row, dyadic ledger, windows, and readbacks before π can be sealed.

The remaining rows H, C, P, N only transport, replay, source, and name that finite route. Since the carrier exposes no quotient stream row, selected-limit row, host real equality row, or ambient-completeness row, no $\mathsf{Real}^{\uparrow}$ consumer can extract such data from the arithmetic packet. □

Theorem 1485.8 (Cauchy-modulus arithmetic shared threshold totality)**.** *For every accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier*

$$A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N),$$

every precision request reaching either arithmetic consumer has a displayed shared-threshold answer in the finite BHist *route. The answer is read through the two source stream rows S_0, S_1, the source*

schedules μ_0, μ_1, the meet row $\mu_\wedge$, the dyadic tolerance ledger D, the common window W, the regular rational readback R, the Real seal row E, and the structural rows H, C, P, N; no external threshold oracle or host real comparison supplies the answer.

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier shared threshold totality`

Proof. Project the carrier tuple from Definition 1485.1. The only precision schedules available to a consumer are the rows μ_0, μ_1 and the shared meet row $\mu_\wedge$, and all three are inside the same displayed BHist packet.

Read the dyadic tolerance ledger D next. Its split-tolerance entries address the two source schedules, while its shared entry addresses $\mu_\wedge$ before the sum row σ or product row π is consumed.

The window and readback rows W, R then record the finite observations used by the arithmetic consumer, and E, H, C, P, N only seal, transport, replay, source, and name that same route. Since the carrier has no coordinate for an external threshold oracle, the displayed shared-threshold answer is total for every accepted arithmetic request. □

Theorem 1485.9 (Cauchy-modulus arithmetic sum-product threshold stability)**.** *For every accepted* CauchyModulusArithmetic$^\uparrow$ *carrier*

$$A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N),$$

the threshold route used by the sum consumer σ and the threshold route used by the product consumer π remain the same finite shared-meet route after componentwise hsame *transport and displayed* Cont *replay. The stable route is exactly the route through $S_0, S_1, \mu_0, \mu_1, \mu_\wedge, D, W, R, E, H, C, P, N$, not a paired field-transport equivalence between independent arithmetic packets.*

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier sum product threshold stability`

Proof. Start with the sum route. By Definition 1485.6, σ is consumed only after the two source schedules, the shared meet row, the tolerance ledger, the common window, and the regular readback have been displayed.

The product route has no separate threshold coordinate in the carrier. Its consumer row π is placed over the same source schedules, the same $\mu_\wedge$ row, and the same D, W, R rows before the Real seal can be read.

Transport by H and replay by C preserve the displayed rows rather than creating another schedule. Thus both consumers remain attached to the same shared threshold under the naming rows P, N and the Real seal row E. □

Theorem 1485.10 (Cauchy-modulus arithmetic Real-seal modulus nonescape)**.** *For every accepted* CauchyModulusArithmetic$^\uparrow$ *carrier*

$$A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N),$$

any Real$^\uparrow$ *seal read from E must keep the modulus information inside the same finite route through $S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, H, C, P, N$. The seal may certify the displayed arithmetic readback, but it cannot export a free modulus, quotient-stream equality, selected real representative, host real equality, or ambient completeness claim.*

Proof. Apply the Real consumer boundary above. A Real-facing request reaches E only after the source schedules, the shared meet row, the arithmetic consumer row, the dyadic tolerance ledger, the common window, and the regular rational readback have already been displayed.

Use shared-threshold totality to locate every requested modulus answer inside the same BHist packet. The rows H, C, P, N transport, replay, source, and name that packet without adding a new modulus coordinate.

Finally inspect the carrier inventory. There is no row for quotient-stream equality, selected representatives, host real equality, ambient completeness, or an independent modulus export. Hence the Real seal cannot let the modulus data escape the displayed arithmetic route. □

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier real seal modulus nonescape`

Theorem 1485.11 (Common tail window obligation)**.** *For every accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier*

$$A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N)$$

inside the displayed BHist *packet of Definition 1485.1, the common-tail window read for any* $\mathsf{Real}^{\uparrow}$ *or Completion consumer is forced through the route*

$$H, C, P, N : \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^{\uparrow}}.$$

Concretely, W may be consumed only after the two source schedules μ_0, μ_1 and the meet schedule $\mu_\wedge$ have been displayed, and any later seal row E must keep the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *provenance. No quotient stream, selected limit, host real equality, or ambient completeness row is exported by this common-tail obligation.*

Proof. Project the carrier tuple of Definition 1485.1. The common window row W occurs after the two source stream rows, the two source schedules, the shared meet row, the arithmetic consumers, and the dyadic tolerance ledger.

The hsame row H then transports those displayed rows componentwise. Thus a consumer may not replace the common window by a quotient stream or by a host comparison of completed values.

The replay row C records the finite route from a precision request through $\mu_0, \mu_1, \mu_\wedge, D, W, R$ before the arithmetic consumers can reach E. The provenance and local naming rows P, N attach that same route to Pkg and $\mathsf{NameCert}_{\mathsf{CauchyModulusArithmetic}^{\uparrow}}$.

Hence the common tail window is a visible BHist obligation anchored in the displayed schedules and structural rows, not a hidden completeness principle. □

Lean4 ✓ `BEDC.Derived.CauchyModulusArithmeticUp.CauchyModulusArithmeticCarrier common tail window`

Theorem 1485.12 (Sum-product shared threshold obligation)**.** *For every accepted* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *carrier*

$$A = (S_0, S_1, \mu_0, \mu_1, \mu_\wedge, \sigma, \pi, D, W, R, E, H, C, P, N),$$

the $\mathsf{RegularCauchySum}^{\uparrow}$ *row σ and the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *row π share the threshold supplied by $\mu_\wedge$ through the same* BHist, hsame, Cont, Pkg, *and* NameCert *route. Both consumers must read the two source modulus rows μ_0, μ_1, the meet row $\mu_\wedge$, the dyadic ledger D, the finite window row W, and the regular readback row R before either arithmetic result is sealed for* $\mathsf{Real}^{\uparrow}$. *No separate product threshold, quotient-stream comparison, selected limit, host real equality, or ambient completeness witness is available.*

Proof. Begin with the sum consumer. By Definition 1485.6, the row σ reads the two source schedules, then the shared meet row, and then the dyadic split tolerances in D before it reaches W and R.

Now turn to the product consumer. By Definition 1485.15, the row π reuses the same $\mu_0, \mu_1, \mu_\wedge, D, W, R$ route rather than opening a separate product comparison coordinate.
